GAME BIRDS *TO* GUITTONE

GAME BIRDS. In North America the term game birds includes the so-called upland game birds (native gallinaceous or chickenlike birds) such as quail, pheasant, grouse and partridge; aquatic game birds such as ducks, geese and swans; and the shore birds—woodcock, snipe and plover. In Great Britain the term applies only to grouse. pheasant and partridge.

This article deals with game bird farming, or the production of game birds under artificial conditions for restocking areas for shooting purposes and for the sale of game birds for food For description, classification, food habits, breeding. etc., of the various species of game birds see the separate articles QUAIL; PHEASANT, etc.

The propagation of these birds involves two distinct phases. The first, raising game birds in captivity, began with the desire to assist in the restoration of game in depleted areas to produce birds for hunting. Some still believe that this method of stocking game is necessary to insure good hunting Although research has indicated that in North America it is far too costly, and thus impractical, it is still an important undertaking in areas in which hunters are willing to pay the cost Specialists in game production and management agree that suitable cover and food in the wild is of first importance in supporting a natural abundance of game birds; and with intelligent supervision and frugal cropping. this situation should maintain a reasonable supply. This was the concept of game management in the second half of the 20th century (*See* also WILDLIFE CONSERVATION) The second phase, a later development that rapidly gained in magnitude, was the raising of game birds for meat It was thought that eventually pen-raised game birds nould become as common in the diet of ordinary citizens as turkey and duck

In both North America and Great Britain game farming is a long established practice, but there is a difference in the purpose of it. In North America, where it is illegal to sell wild birds the major purpose is to supply the food market nith artificially reared birds. In Great Britain the object is to restock ground where shooting takes place. The reasons for this difference are both social and climatic.

In North America the right to hunt is in theory, and largely in practice, free to all. Hunters do not expect to kill particularly large numbers of birds and conservation measures are aimed at enabling each hunting licence holder to take a fair share (say, four to ten birds) in a day. In Great Britain game birds are the property of the owner of the land on which they exist and as such they form. part of the crop. Since game-bearing land carries an extra revenue assessment which the landlord must pay, it follows that he must make this crop as large as possible. The British climate militates against this to a greater extent than the American climate does. since in Britain the nesting and hatching period of the year is likely to be afflicted by storms which. if the whole process of game reproduction were left to nature. might decimate the stock in any particular year. Therefore. while America relies on carefully fostered natural reproduction for all purposes, except to supply the food trade, Britain relies to a great extent on artificial rearing in order to make the game crop pay its way.

Game farming was a 20th-century introduction both in North America and Great Britain, though in Britain its roots went farther back. probably to the mid-19th century when the substitution of the breech-loading for the muzzle-loading shotgun and the improvement of the cartridge made it possible to kill large numbers of birds and thus supply a poultry market. Probably the first game farmers were keepers (wardens) who set up on their own account to supply fertile eggs, chicks and grown young birds to estates in the vicinity. Changes in farming practice in the early years of the 20th century induced them to specialize in game farming as opposed to gamekeeping. and 22 established game farms in Great Britain were in business on a very considerable scale at the end of the 1950s.

The farming change which had the greatest effect was the introduction of fall plowing on arable land. The effect of this was to bury the stubbles on which game birds used to feed throughout the winter months and to replace it with equivalent areas of plowed land which contained no grain or seed for the birds to live on. Thus there was a marked change in the game-carrying capacity of a good area of land before and after plowing. A heavy stock had to be heavily shot to save it from starvation and then artificially replenished the following summer when food again became available.

Species Raised.—Quail and pheasant are raised in every section of the United States and in parts of Canada. The bobwhite quail is the most numerous, most popular and best kno n of the upland game birds. In the northern United States it is called "quail," but in the south it is commonly referred to as "partridge." California and valley quail are also produced in captivity. In addition, there are gambel, mountain and scaled quail and the Texas, Mexican, masked and mearns bobwhite quail.

More ring-necked pheasants are raised in pens than any other species of game bird The true pheasant has no white ring around the neck, a common characteristic of the Chinese and Mongolian species which have been mixed considerably in breeding. The ordinary wild pheasant, so abundant in the United States, is in reality a hybrid. There are also golden, amherst and silver pheasants. Other upland game birds raised successfully include the partridge. The chukar (Alectoris graeca) from India and the Hungarian or European partridge (Perdix *perdix*) are the more important species. Some attempts have been made to raise grouse and the prairie chicken. or pinnated grouse. but with little success.

Aquatic game bird production (wild ducks and geese) was a small but growing industry in the second half of the 20th century. The market for mallard ducks and the Canadian goose as food was increasing. Other species were produced only in small numbers.

Licences and Permits. — In the United States a state licence is required to raise game birds in captivity. Such a licence and copies of laws pertaining to game bird production may be obtained from the state game or conservation commission. In most states, usually under certain restrictions, game birds raised in pens may be sold for food. Over 30 states allowed the sales of all kinds of pen-raised game birds for meat; three states restricted sales to pheasant exclusively, and one state limited sales to exotic species.

The canning of pheasant was carried on in several states and quick-freezing was used in others. To buy or sell migratory waterfowl, including wild ducks, geese or swans raised in captivity, a federal permit is required from the U.S. department of the interior's fish and wildlife service.

Developments. — Raising game birds often has been a profitable undertaking, if operated as a business. In the suburbs, persons sometimes have raised birds in back yards and on adjacent land, rented for the purpose. In this manner, the overhead was kept at a minimum and the cost of experience was low. Poultry dealers in the United States and Canada showed more interest in raising and selling game birds and the public was developing a taste for game bird meat.

In the United States, pheasants were raised more extensively in the east, north central, middle Atlantic and Pacific coast states. Bob hites were produced more extensively in the south Atlantic and east north central states. California quail were confined to the Pacific coast. In the second half of the 20th century 1 game bird was raised for every 38 domestic turkeys produced; 1 for every 16 ducks; 1 for every 2 pigeons; 1 for every 1.5 geese and 1 for every 1.3 guineas.

Most of the British game farms were established in their present form in the first decade of the 20th century. They received a considerable stimulus after the end of World War I when many estates, from which the keepers had gone to war, needed to re-establish a breeding stock on short notice. From that date on the idea of replenishing breeding stock from game farms spread to other countries outside Great Britain, of which Denmark and Hungary perhaps deserve special mention.

A considerable export trade had been built up and this, though sometimes limited by restrictions imposed by agricultural departments, was increasing in the second half of the 20th century. British game farms were exporting great numbers of birds to the countries of western Europe and Scandinavia and to some countries in South America, where high-density game production was becoming better understood and appreciated. Before World War II a considerable export trade had been carried on with countries in eastern Europe and with some of the Arab countries in the middle east.

Techniques. — In North America, feeding, breeding, management and marketing are similar to those of poultry production. The problems involved in game bird farming were greatly simplified, because of research conducted by federal and state experiment stations and by commercial feed companies.

Those raising game birds found that the completely mixed and balanced rations developed by the feed companies were quite satisfactory.

The cost of producing game birds in the second half of the 20th century was largely a labour cost. Practically all the equipment required to raise upland game birds could be built at home. Metal equipment (purchased from manufacturers and dealers) proved to be more durable than that made of wood and wire netting; it was also easier to clean and disinfect.

Birds adapted to small-scale production are quail, chukar and Hungarian partridge. It makes little difference whether a beginner starts with the bird or the egg. Eggs may be purchased for incubation by a hen or in an incubator. A small number of day-old chicks is also an inexpensive way to start raising game birds. Quite a few new game breeders begin operations with mature birds. The best location for pens is on high ground, sloping toward the east, nith no net places nearby where mosquitoes might breed. It was found that game birds should not be raised on ground previously occupied by poultry or other domesticated birds because of the danger of contracting their diseases; that the area about the pens should be kept free of manure piles, garbage heaps and other sources of contamination; and that the bird area should be enclosed nith a 6-ft. chicken wire fence to keep out stray dogs, cats and other animals.

Marketing. — Game birds may be sold alive as breeders, for restocking purposes and for meat. Those for food purposes are sold in feather or oven-dressed. The meat may be marketed fresh. quick-frozen or canned. In the second half of the 20th century clubs. restaurants and hotels offering game birds on their menus were increasing in the United States and Canada. Some larger and older game farms developed a lucrative business especially featuring game bird gift packages. The leading food magazines carried advertisements offering birds in feather or oven-dressed, attractively wrapped and boxed.

In addition to marketing native game birds, several of the larger farms imported and sold birds such as Scotch grouse and English red-leg partridge.

GAMELIN, MAURICE GUSTAVE (1872–1958), French army officer. was born in Paris on Sept. 20, 1872. Commissioned from St. Cyr in 1893. he served in World War I, first on Gen. Joseph Joffre's staff, then as division commander. After that war he headed a military mission to Brazil until 192j, when he assumed command of French forces in the Levant. He became army chief of staff in 1931, vice-president of the Conseil Supérieur de la Guerre and army inspector general in 1935, and finally chief of staff of national defense in 1938.

In World War II Gamelin commanded the Allied forces on the western front until May 1940, when his armies fell before the German offensive.

Relieved of his command, he was subsequently arrested, placed on trial to answer for the defeat and then, in 1943, interned in Germany, where he remained until May 1945. He died in Paris on April 18, 1958.

Gamelin's memoirs were published under the title *Servir*, 3 vol. (1946–47). (M. V.)

GAMELINE (? –1271), lord chancellor of Scotland and bishop of St. Andrews, was named lord chancellor in 1250 and was made one of Pope Innocent IV's chaplains in 1254. In the following year he was elected bishop of St. Andrews by the prior and canons, and the selection was subsequently confirmed by the king and council.

On St. Stephen's day of the same year he was consecrated by the bishop of Glasgow, upon a warrant from the pope. During the course of a political upheaval Gameline fell into disfavour at court and was forced to leave the country. His enemies accused him on several charges, but when he submitted his case to the pope in Rome he was acquitted and later returned to his see in Scotiand.

In 1267 he was again involved in a controversy with the court. He died on April 29, 1271, and was buried in his cathedral at St. Andrews.

GAMELYN, THE TALE OF, a verse romance written about the middle of the 14th century and once ascribed to Geoffrey Chaucer because the only existing version was found in the manuscript of his *Canterbury Tales.* It is generally believed that Chaucer planned to develop it as one of the *Tales.*

The tale, about 900 lines in length, concerns the youngest of three brothers who is robbed of his inheritance and persecuted by the eldest brother and finally triumphs with the aid of a band of outlaws. The story was used by Thomas Lodge in his novel *Rosalynde* which was later to provide the basis for Shakespeare's comedy *As You Like It.* The original story has no "love interest" as embodied in the Rosalind and Celia of Shakespeare's version, but is simply an account of the young brother's adventures and his eventual return to property and respectability after the defeat of his enemy.

GAMES, CLASSICAL. Public Games.—The public games of Greece (ἀγῶνες) and Rome *(ludi)* consisted in athletic contests and spectacles of various kinds, generally connected with and forming a part of a religious observance. Probably no institution exercised a greater influence in moulding the national character and producing that unique type of physical and intellectual beauty which is seen reflected in Greek art and literature than the public contests of Greece *(see* ATHLETE; ATHLETIC SPORTS; GLADIATORS).

For them each youth was trained in the gymnasium; they were the central mart where poet, artist and merchant each brought his wares and the common ground of union for every member of the Hellenic race. It is in Greece, therefore, that the earliest form and the fullest development of ancient games is to be found. The shows of the Roman circus and amphitheatre were at best a shadow, and in the later days of the empire a travesty, of the Olympia and Pythia, and require only a cursory notice.

The earliest games of which there is any record are those at the funeral of Patroclus, which form the subject of the 23rd *Iliad.* They are noteworthy as shouing that Greek games were in their origin clearly connected with religion; either, as here, a part of the funeral rites, or else instituted in honour of a god, or as a thank offering for a victory gained or a calamity averted, or in expiation of some crime. Each of the great contests was held near some shrine or sacred place and each is associated with some deity or mythical hero It was not before the 4th century B.C. that this honour was paid to a living man *(see* Plutarch, *Lysander,* 18).

The games of the *Iliad* and those of the *Odyssey* at the court of Alcinous show at what an early date the distinctive forms of Greek athletics—boxing, wrestling. putting the weight, the foot and the chariot race—were determined.

The Olympian games were the earliest, and to the last they remained the most celebrated, of the four national festivals. Olympia was a naturally enclosed spot in the plain of Elis. It was bounded on the north by the rocky heights of Cronion and on the south and west by the Alpheus and its tributary, the Cladeus. There was the grove of Altis, in which were ranged the statues of the victorious athletes, and the temple of Olympian Zeus with the chryselephantine statue of the god. the masterpiece of Pheidias. There Heracles (so ran the legend which Pindar has introduced in one of his finest odes), when he had conquered Elis and slain its king Augeas, consecrated a temenos and instituted games in honour of his victory. A later legend, which probably embodies historical fact, tells how, when Greece was torn by dissensions and ravaged by pestilence, Iphitus inquired of the oracle for help and was bidden restore the games which had fallen into desuetude; and there was, in the time of Pausanias, suspended in the temple of Hera at Olympia, a bronze disk whereon were inscribed, with the regulations of the games, the names of Iphitus and Lycurgus. From this it may be safely inferred that the games were a primitive observance of the Eleians and Pisans, and first acquired their celebrity from the powerful concurrence of Sparta. The sacred armistice, or cessation of all hostilities during the month in which the games were to be held, is also credited to Iphitus.

In 776 B.C. the Eleians engraved the name of their countryman, Coroebus, as victor in the foot race, and thenceforward there is an almost unbroken list of the victors in each succeeding Olympiad or fourth recurrent year.

For the next 50 years no names occur but those of Eleians or their next neighbours. After 720 B.C. Corinthians and Megareans are found, and later still, Athenians and extra-Peloponnesians. Thus what at first was nothing more than a village feast became a bond of union for all the branches of the Doric race, and grew in time to be the high festival to which every Greek gathered, from the mountain fastnesses of Thessaly to the remotest colonies of Cyrene and Marseilles. It survived even the extinction of Greek liberty, and had nearly completed 12 centuries when it was abolished by the decree of the Christian emperor, Theodosius, in the tenth year of his reign.

Let us attempt to call up the scene which Olympia in its prosperous days must have presented as the great festival approached. Heralds had proclaimed throughout Greece the "truce of God." So religiously was this observed that the Spartans chose to risk the liberties of Greece, when the Persians were at the gates of Pylae, rather than march during the holy days. Those white tents belong to the Hellanodicae, or ten judges of the games, chosen one for each tribe of the Eleians. They have been already here ten months, receiving instruction in their duties. All. too, or most of the athletes must have arrived, for they have been undergoing the indispensable training in the gymnasium of the Altis. But along the "holy road" from the town of Elis a motley throng is crowding. Conspicuous in the long train are the θεωροί or sacred deputies, clad in their robes of office and bearing with them, in their carriages of state, offerings to the shrine of the god.

There is no lack of noted visitors. It may be Alcibiades, who, they say, has entered no less than seven chariots; or Gorgias, who has written a famous ἐπίδειξις for the occasion; or the sophist Hippias, who boasts that all he bears about him, from the sandals on his feet to the dithyrambs he carries in his hand, are his own manufacture; or Aetion, who will exhibit his picture of the marriage of Alexander and Roxana—the picture which gained him no less a prize than the daughter of the Hellanodices Praxonides; or, in an earlier age, the poet laureate of the Olympians, Pindar himself.

A feature of the mediaeval tournament and the modern racecourse, however, is wanting. Women might indeed compete and win prizes as the owners of teams, but all except the priestesses of Demeter were forbidden, matrons on pain of death, to enter the enclosure.

At daybreak the athletes presented themselves in the bouleuterion, where the judges were sitting, and proved by witnesses that they were of pure Hellenic descent and had no stain, religious or civil, on their character. Laying their hands on the bleeding victim, they swore that they had duly qualified themselves by ten months' continuous training in the gymnasium, and that they would use no fraud or guile in the sacred contests. Thence they proceeded to the stadium, where they stripped to the skin and anointed themselves. A herald proclaimed, "Let the runners put their feet to the line," and called on the spectators to challenge any disqualified by blood or character. If no objection was made, they were started by the note of the trumpet, running in heats of four, ranged in places assigned by lot. The presidents seated near the goal adjudged the victory.

The foot race was only one of 24 Olympian contests which Pausanias enumerates, though it must not be supposed that these were all exhibited at any one festival. Till the 77th Olympiad all was concluded in one day, but afterward the feast was extended to **five.**

The order of the games is for the most part a matter of conjecture, but, roughly speaking, the historical order of their institution was followed. The most important are described below in this order.

1. The Foot Race.—For the first 13 Olympiads the δρόμος, or single lap of the stadium, which was 200 yd. long, was the only contest. The δίαυλος, in which the course was traversed twice, was added in the 14th Olympiad, and in the 15th the δόλιχος, or long race, of 7, 12 or, according to the highest computation, 24 laps, about 2 5 mi. in length. It is said that the Spartan Ladas, after winning this race, dropped down dead at the goal. There was also, for a short time, a race in heavy armour, which Plato highly commends as a preparation for active service.

2. Wrestling was introduced in the 18th Olympiad. The importance attached to this exercise is shown by the very word "palaestra," and Plutarch calls it the most artistic and cunning of athletic games. The practice differed little from that of modem times, save that the wrestler's limbs were anointed with oil and sprinkled with sand. The third throw, which decided the victory, passed into a proverb, and struggling on the ground was not allowed in the upright wrestling of the Olympic pentathlon, though it was permitted in the *pancratium* (see below).

3. In the same year was introduced the πένταθλον (pentathlon), a combination of the five games enumerated in the well-known pentameter ascribed to Simonides: ἅλμα, ποδωκείην, δίσκον, ἄκοντα, πάλην. Only the first of these calls for any comment. The only leap practised seems to have been the long jump. The leapers increased their momentum by means of ἁλτῆρες or dumbbells. which they swung in the act of leaping. The take-off may have been slightly raised, and some commentators with very little warrant have stated that springboards were used. The record jump with which Phayllus of Croton is credited, 55 ft, is incredible with or without a springboard. It is disputed whether a victory in all five contests, or in three at least, was required to win the πένταθλον.

4. The rules for boxing (q v.) did not differ greatly from those of the modern ring, and the chief difference was in the use of the caestus. This device. in Greek times, consisted of leather thongs bound round the boxer's fists and wrists The weighting with lead or iron or metal studs, which made the caestus more like a "knuckle duster" than a modern boxing glove, mas a later Roman development. The killing of an antagonist, unless it was proved to be accidental, not only disqualified for a prize, but was severely punished. The use of earguards and the comic allusions to broken ears rather than noses suggest that the Greek boxer did not hit out straight from the shoulder, but fought windmill fashion. In the *pancratium*, in which the only recognized fouls were biting and gouging. hitting uith the fists and wrestling were combined.

5. The chariot race had its origin in the 23rd Olympiad. Of the hippodrome, or racecourse, no traces remain, but from the description of Pausanias it may be inferred that the dimensions were approximately 1,600 ft. by 400 ft. Down the centre there ran a bank of earth, and at each end of this bank was a turning post around which the chariots had to pass. "To shun the goal with rapid nheels" required both nerve and skill, and the charioteer played a more important part in the race than even the modern jockey. Pausanias says that horses would shy as they passed the fatal spots. The places of the chariots were determined by lot, and there were elaborate arrangements for giving the drivers a fair start. The number of chariots that might appear on the course at once is uncertain. Pindar (Pyth. v, 46) praises Arcesilaus of Cyrene for having brought off his chariot uninjured in a contest where no fewer than 40 took part. The large outlay involved excluded all but rich competitors, and even kings and tyrants eagerly contested for the victory. Thus in the list of victors is found the names of Cylon. the would-be tyrant of Athens, Pausanias the Spartan king, Archelaus of Macedon, Gelon and Hiero of Syracuse and Theron of Agrigentum.

Chariot races with mules, with mares and with two horses in place of four were successively introduced. Races on horseback date from the 33rd Olympiad.

Lastly, there were athletic contests of a similar kind for boys, and a competition of heralds and trumpeters, introduced in the 93rd Olympiad.

The prizes were at first, as in the Homeric times, of some intrinsic value, but after the 6th Olympiad the only prize for each contest was a garland of wild olive, which was cut with a golden sickle from the *kallistephanos,* the sacred tree brought by Hercules "from the dark fountains of Ister in the land of the Hyperborean~to be shelter common to all men and a crown of noble deeds" (Pindar. 01. iii. 18).

Greek writers from Herodotus to Plutarch dwell with complacency on the magnanimity of a people who cared for nothing but honour and were content to struggle for a corruptible crown. But though the Greek games present in this respect a favourable contrast to the greed and gambling of the modern racecourse, yet to represent men like Milon and Damoxenus as actuated by pure love of glory is a pleasing fiction of the moralists. The successful athlete received, in addition to the honours, very substantial rewards. A herald proclaimed his name, his parentage and his country; the Hellanodicae took from a table of ivory and gold the olive crown and placed it on his head, and in his hand a branch of palm; as he marched in the sacred revel to the temple of Zeus, his friends and admirers showered in his path flowers and costly gifts, singing the old song of Archilochus, τήνελλα καλλίνικε, and his name was canonized in the Greek calendar. Fresh honours and rewards awaited him on his return home. If he was an Athenian he received, according to the law of Solon, 500 drachmas and free rations for life in the Prytaneum; if a Spartan, he had as his prerogative the post of honour in battle. Poets like Pindar. Simonides and Euripides sang his praises, and sculptors like Pheidias and Praxiteles were engaged by the state to carve his statue. And there were well-attested instances of altars being built and sacrifices offered to a successful athlete. An Olympian prize was regarded as the crown of human happiness. Cicero, with a Roman's contempt for Greek frivolity, observes with a sneer that an Olympian victor receives more honours than a triumphant general at Rome, and tells the story of the Rhodian Diagoras who, having himself won the prize at Olympia and seen his two sons crowned on the same day. was addressed by a Laconian in these words: "Die. Diagoras, for thou hast nothing short of divinity to desire."

Alcibiades, when setting forth his services to the state, puts first his victory at Olympia and the prestige he had won for Athens by his magnificent display. But perhaps the most remarkable evidence of the exaggerated value which the Greeks attached to athletic prowess is a casual expression which Thucydides employs when describing the enthusiastic reception of Brasidas at Scione. The state. he says, voted him a crown of gold. and the multitude flocked around him and decked him with garlands, as though he were an athlete.

The Pythian games originated in a local festival held at Delphi, anciently called Pytho in honour of the Pythian Apollo, and were especially devoted to musical competitions. The date at which they became a Panhellenic ἀγών (so Demosthenes calls them) cannot be determined, but the Pythiads as a chronological era date from 527 B.C., by which time music had been added to all the Panhellenic contests. Now, too, these were held at the end of every fourth year; previously there had been an interval of eight years. The prize was a chaplet of laurel.

The Nemean games uere biennial and date from 516 B.C. They were by origin an Argive festival in honour of Nemean Zeus, but in historical times were open to all Greece and provided the established round of contests, except that no mention is made of a chariot race. A wreath of wild celery was the prize.

The Isthmian games, which were held on the Isthmus of Corinth in the first and third years of each Olympiad, date, according to Eusebius, from 523 B.C. They are variously reported to have been founded by Poseidon or Sisyphus in honour of hlelicertes. or by Theseus to celebrate his victory over the robbers Sinis and Sciron. Their early importance is attested by the law of Solon which bestowed a reward of 100 drachmas on every Athenian who gained a victory. The festival was managed by the Corinthians; and after the city was destroyed by Mummius (146 B.C.) the presidency passed to the Sicyonians until Julius Caesar rebuilt Corinth

(46 B.C.). They probably continued to exist till Christianity became the religion of the Roman empire. The Athenians were closely connected with the festival, and had the privilege of *proedria,* the foremost seats at the games, while the Eleians were absolutely excluded from participation. The games included gymnastic, equestrian and musical contests. The prize was a crown, at one time of parsley (or wild celery) and later of pine. The importance of the Isthmian games in later times is shown by the fact that Flamininus chose the occasion for proclaiming the liberation of Greece. 196 B.C. That at a later anniversary (A.D. 67) Nero repeated the proclamation of Flamininus, and coupled with it the announcement of his own infamous victory at Olympia, shows alike the hollowness of the first gift and the degradation which had befallen the Greek games, the last faint relic of Greek nationality.

The *ludi publici* of the Romans included feasts and theatrical exhibitions as well as the public games with which alone this article is concerned. As in Greece, they were intimately connected with religion. At the beginning of each civil year it was the duty of the consuls to vow to the gods games for the safety of the commonwealth, and the expenses were defrayed by the treasury. Thus, at no cost to themselves. the Roman public were enabled to indulge at the same time their religious feelings and their love of amusement. Their taste for games naturally grew till it became a passion, and under the empire games were looked upon by the mob as one of the two necessaries of life. The aediles who succeeded to this duty of the consuls were expected to supplement the state allowance from their private purse. Political adventurers were not slow to discover so ready a road to popularity, and what at first had been exclusively a state charge was taken up by men of wealth and ambition. A victory over some barbarian horde or the death of a relation served as the pretext for a magnificent display.

The worst extravagance of private citizens was eclipsed by the reckless prodigality of the Caesars, who squandered the revenues of whole provinces in catering to the mob of idle sightseers on whose favour their throne depended.

Though public games played as important a part in Roman as in Greek history, and must be studied by the Roman historian as an integral factor in social and political life. yet. regarded solely as exhibitions, they are comparatively devoid of interest, and one might well sympathize with Pliny. who asks his friend how any man of sense can go day after day to view the same dreary round of fights and races.

It is easy to explain the different feelings which the games of Greece and of Rome excite. The Greeks, at their best; were actors; the Romans, from first to last. were spectators. It is true that even in Greek games the professional element played a large and ever-increasing part. As early as the 6th century B.C. Xenophanes complains that the wrestler's strength is preferred to the wisdom of the philosopher, and Euripides, in a well-known fragment, holds up to scorn the brawny, swaggering athlete. But, what in Greece was a perversion and acknowledged to be such, the Romans not only practised but held up as their ideal. No Greek, however high in birth. was ashamed to compete in person for the Olympic crown. The Roman, though little inferior in gymnastic exercises, kept strictly to the privacy of the palaestra; and for a patrician to appear in public as a charioteer is stigmatized by the satirist as a mark of shameless effrontery.

Roman games are generally classified as fixed: extraordinary and votive; but they may be more conveniently grouped according to the place where they were held, viz., the circus or the amphitheatre.

For the Roman world, the circus was at once a political club, a fashionable lounge. a rendezvous of gallantry, a betting ring and a playground for the million. Juvenal, speaking loosely, says that in his day it held the whole of Rome: but there is no reason to doubt the precise statement of P. Victor, that in the Circus Maximus there were seats for 350,000 spectators.

Of the various *ludi circenses* it may be enough here to give a short account of the most important, the *Ludi Magni* or *Maximi*.

Initiated, according to legend, by Tarquinius Priscus, the **Ludi** *Magni* were originally a votive feast to Capitoline Jupiter, promised by the general when he took the field and performed on his return from the annual campaign. They thus presented the appearance of a military spectacle, or rather a review of the whole burgess force, which marched in solemn procession from the capitol to the forum and thence to the circus, which lay between the Palatine and Aventine. First came the sons of patricians, mounted on horseback, next the rest of the burghers ranged according to their military classes, after them the athletes. naked save for the girdle round their loins, then the company of dancers with the harp and flute players, next the priestly colleges bearing censers and other sacred instruments and lastly the simulacra of the gods, carried aloft or drawn in cars.

The games themselves were fourfold: (1) the chariot race; (2) the *ludus Troiae;* (3) the military review; and (4) the various gymnastic contests. Of these only the first two call for any comment.

1. The chariot employed in the circus was the two-wheeled war car, at first drawn by two, afterward by four and more rarely by three horses. Originally only two chariots started for the prize, but under Caligula reference is made to as many as 24 heats run in the day, each of four chariots. The distance traversed was 14 times the length of the circus or nearly 5 mi. The charioteers were apparently from the first professionals, though the stigma under which the gladiator lay never attached to their calling. Indeed a successful driver may compare in popularity and fortune with a modern jockey. The drivers were divided into companies, distinguished by colours, whence arose the factions of the circus which assumed such importance under the later emperors. In republican times there were two factions, the white and the red; two more, the green and the blue, were added under the empire, and for a short time in Domitian's reign there were also the gold and the purple. Even in Juvenal's day party spirit ran so high that a defeat of the green was looked upon as a second Cannae. After the seat of empire had been transferred to Constantinople these factions of the circus were made the basis of political cabals, which frequently resulted in sanguinary tumults, such as the famous Nika revolt (A.D. 532), in which 30.000 citizens lost their lives.

2. The *ludus Troiae* was a sham fight on horseback, in which the actors were patrician youths. A description of it will be found in the fifth *Aeneid*. *(See* also CIRCUS.)

The two exhibitions which are next considered, though occasionally given in the circus, belong more properly to the amphitheatre. *Venatio* was the baiting of wild animals, who were pitted against one another or against men—captives, criminals or trained hunters called *bestiarii*. The first certain instance on record of this amusement is in 186 B.c., when M. Fulvius exhibited lions and tigers in the arena. The taste for these brutalizing spectacles grew apace, and the most distant provinces were ransacked by generals and proconsuls to supply the arena with rare animals—giraffes, tigers and crocodiles. Sulla provided for a single show 100 lions. and Pompey 600 lions. besides elephants, which were matched with Gaetulian hunters. Julius Caesar enjoys the doubtful honour of inventing the bullfight. At the inauguration of the Colosseum 5,000 wild and 4,000 tame beasts were killed, and to commemorate Trajan's Dacian victories there was a butchery of 11,000 beasts.

The *naumachia,* was a sea fight, either in the arena, which was flooded for the occasion by a system of pipes and sluices, or on an artificial lake. The rival fleets were manned by prisoners of war or criminals, who often fought till one side was exterminated. In the sea fight on Lake Fucinus, arranged by the emperor Claudius, 100 ships and 19,000 men were engaged.

But the special exhibition of the amphitheatre was the *munus gladiatorium*, which dates from the funeral games of Marcus and Decimus Brutus, given in honour of their father. 264 B.C. It was probably borrowed from Etruria. and was a refinement on the common savage custom of slaughtering slaves or captives on the grave of a warrior or chieftain. Nothing so clearly demonstrates the vein of coarseness and inhumanity running through the character of the Roman as his passion for gladiatorial shows. One can imagine how Pericles, or even Alcibiades, would have loathed a spectacle that Augustus tolerated and Trajan patronized. Only after the conquest of Greece is there evidence of their introduction into Athens, and they were then admitted rather out of compliment to the conquerors than from any love of the sport. In spite of numerous prohibitions from Constantine downward, they continued to flourish even as late as St. Augustine. To a Christian martyr, if the story told by Theodoret and Cassiodorus may be credited. belongs the honour of their final abolition. In the year 404 Telemachus. a monk who had travelled from the east on this sacred mission, rushed into the arena and endeavoured to separate the combatants but he was instantly dispatched by the praetor's orders.

The emperor Honorius. on hearing the report. however, issued an edict abolishing the games, which were never afterward revived. *(See* GLADIATORS.)

Of the other Roman games the briefest description must suffice. The *Ludi Apollinares* were established in *212* B.c.. and were annual after *211* B.c., consisting mainly of theatrical performances.

The *Megalenses* were in honour of the great goddess, Cybele, instituted 204 B.C., and from 191 B.C. celebrated annually. A procession of Galli, or priests of Cybele, was a leading feature. Under the empire the festival assumed a more orgiastic character. Four of Terence's plays were produced at these games. The *Ludi Saeculares* were celebrated at the beginning or end of each *saeculum,* a period variously interpreted by the Romans themselves as 100 or 110 years.

The celebration by Augustus in 17 B.C. is famous by reason of the ode composed by Horace for the occasion. They were solemnized by the emperor Philip A.D. *248* to commemorate the millennium of the city.

Private Games.—These may be classified as outdoor and indoor games. There is quite naturally a much closer resemblance between the pursuits and amusements of children than of adults. Homer's children built castles in the sand, and Greek and Roman children alike had their dolls, their hoops. their skipping ropes, their hobbyhorses, their kites and their knucklebones and played at hopscotch, tug of war. pitch and toss, blindman's buff. hide-and-seek and kiss in the ring, or at closely analogous games. Games of ball were popular in Greece from the days of Nausicaa, and at Rome there were five distinct kinds of ball, and more ways of playing with them. For particulars the dictionary of antiquities must be consulted. It is strange that there is found in classical literature no analogy to cricket, tennis, golf or polo. and though the *follis* resembled modern football. it was played with the hand and arm, not with the leg. Cockfighting was popular both at Athens and Rome, and quails were kept and put to various tests to prove their pluck.

Under indoor games may be distinguished games of chance and games of skill, though in some of them the two elements were combined.

Tesserne, marked with pips like modern dice, were evolved from the *tali,* knucklebones with only four flat sides. The old Roman threw a hazard and called a main, just as did Charles Fox. The vice of gambling was lashed by Juvenal no less vigorously than by Pope. The Latin name for a dicebox survived in the fritillary butterfly and flower.

The primitive game of guessing the number of fingers simultaneously held up by the player and his opponent was still popular in modern times in Italy, where it became known as *morra.* The proverbial phrase for an honest man was *quicum* in *tenebris mices,* one you would trust to play at *morra* in the dark.

Athena found the suitors of Penelope seated upon cowhides and playing at *πεσσοί,* which was a form of draughts, an invention ascribed to Palamedes. In its earliest form it was played on a board with five lines and with five pieces. Later there were 11 lines: and a further development was the division of the board into squares. In the Roman *latrunculi* (soldiers), the men were distinguished as common soldiers and "rovers," the equivalent of crowned pieces.

Duodecim scripta, as the name implies, was played on a board with 12 double lines and approximated very closely to modern backgammon. There were 15 pieces on each side, and the moves were determined by a throw of the dice; 'iblots" might be taken, and the object of the player was to clear off all his own men. Lastly must be mentioned the *cottabus,* a game peculiar to the Greeks, and with them the usual accompaniment of a wine party. In its simplest form each guest threw what was left in his cup into a metal basin, and the success of the throw, determined partly by the sound of the wine in falling, was reckoned a divination of love.

For the various elaborations of the game, Athenaeus and Pollux must be consulted.

GAMES, THEORY OF, is a branch of mathematics that aims to analyze various problems of conflict by abstracting common strategic features for study in theoretical "models"—termed "games" because they are patterned on actual games such as bridge and poker. By stressing strategic aspects *(i.e.,* aspects controlled by the participants). it goes beyond the classical theory of probability. in which the treatment of games is limited to aspects of pure chance. A theory of games of strategy. broached in 1921 by Emile Borel. was established in 1928 by John von Neumann. who went on. with Oskar Morgenstern, to develop it as a means of dealing with competitive economic behaviour. Their joint work (published in 1944) stemmed from the presence, both in actual games and in economic situations. of several common factors. such as conflicting interests. incomplete information and the interplay of free rational decision and chance. Although most actual games elude full-scale analysis because of the amount of intricate cataloguing and computing that would be required, many can be analyzed in miniature or simplified form. Of greater consequence. perhaps. is the opening to mathematical attack of a wide range of gamelike problems, not only in economics but also in sociology, psychology, politics and war.

CLASSIFICATION OF GAMES

The theory identifies a game, for analysis, as: (1) singular. dual or plural; *(2)* extensive or normalized: (3) finite or infinite. This three-way classification highlights strategic likenesses and differences in games, reflecting results of the theory and divisions within it.

Singular, Dual and Plural Games.—In classifying games by the number of players, the significant figure is not the number of individuals involved but rather the number of parties with distinct interests actively represented in the play. It is assumed specifically that these interests are measured in terms of money or some other numerical scale of utility. The presence of only one such interest, though there may be more than one participant, characterizes a game as singular. Typical are solitaire card games, many types of puzzles and problems of an isolated economic unit with a single goal *(e.g.,* Robinson Crusoej. Such games are distinguished by the absence of conflict; with no opponent to thwart his plans, the single player need only, in theory. list all his possible courses of action and then select the best, as measured on his scale of utility. Conflict enters with dual games (called zero-sum two-person games by von Neumann and Morgenstern), played by two parties in diametric opposition—what one wins, the other loses. Each party, in seeking an optimal course of action. must reckon with the possible actions of an opponent with contrary aims. This direct conflict of interests is exemplified by two-person board games such as chess, two-handed card games such as cribbage and two-team card games such as bridge. In contrast, the presence of active interests that are not diametrically opposed stamps a game as plural. All games having more than two active interests fall in this class; so do two-party bargaining situations in which the parties stand to gain by reaching an agreement.

Extensive and Normalized Forms.—From the rules of any game. two abstract forms can be obtained. The extensive form of a game eliminates all features which refer specifically to the means of playing it—all those features which characterize it as a card game, a dice game or an economic conflict. Thus the extensive form amounts to a literal translation of the rules into the technical terms of a formal system designed to describe all games. The normalized form is a more condensed version of the game, stripped of all features but the choice of over-all strategies.

The raw material for the extensive form comes from the common elements of strategic games, such as the interrelations between the players' choices, the variety and character of information available to them and the effect of chance on the play. The object of a systematic description of these features is to isolate those junctures at which a player is called upon to make a choice and the states of information on which his choices are based. From this analysis emerges a precise definition of the first key concept on uhich the theory of games has been built. This is the notion of a pure strategy for a player; namely, a complete set of advance instructions that specifies a definite choice for every conceivable situation in which the player may be required to act. Such a set of instructions represents a total plan that covers all contingencies the player may face during any playing of the game, whether these are attributable to choices of other players or to events governed by chance: its execution could be delegated perfectly well to an agent without discretionary power. The complexity imposed on a single pure strategy by its completeness. and the enormous number of pure strategies that may need cataloguing. explain the failure of the theory to analyze most common parlour games. However, the practical difficulties do not prevent the enumeration in theory of all the pure strategies of a game.

While the extensive form of a game may have a large number of moves. or junctures at which a player must make a choice, in the normalized form each player makes only one move, which consists of a single choice irom his set of pure strategies. As a result, the game is replaced by the following prototype: Each player chooses a pure strategy. making his choice in absolute ignorance of the choices of the other players. After all strategies have been chosen, they are submitted to an umpire who charts the course of the play, making chance moves in accordance with the probabilities dictated by the rules and otherwise using the choices given by the players' pure strategies. In this way there is determined for each player a set of outcomes with associated probabilities, the "expected" value of which constitutes the player's payoff.

Finite and Infinite Games.—In most games the number of pure strategies available to the players is finite because the rules ordinarily make the game terminate after a finite number of occasions for choice by the players, and because, at each occasion, a player is usually confronted by a finite number of alternatives.

Games with an infinite number of strategies often arise as idealizations of situations that are too complicated to handle in their original form (such as replacing the full, but finite, range of poker hands by a continuum of numbers). It has proved possible in this way to treat problems of many sorts as normalized dual games in which the pure strategies for each player are represented by the real numbers from zero to one (called games on a square). Infinite games have also provided a fertile source of pathological examples that offer a contrast to the regular properties found in the finite case. In a different direction, Abraham Wald's theory of statistical decision has shown that the general problem of statistical inference may be regarded as an infinite dual game in which the statistician is pitted against nature.

NORMALIZED DUAL GAMES

Matrix Games; **Saddlepoints.**—A finite dual game, when normalized, has a very simple conceptual scheme. Each of the players. A and B, chooses a pure strategy irom a finite list, without knowing the other's choice. The outcome thus determined can be specified by a single number P, the payoff *A* stands to receive: positive, negative or zero according as A wins from B, loses or draws. By the diametric opposition characteristic of a dual game, B then stands to win —P. In this way the game is described by a rectangular array of numbers, in which each horizontal row corresponds to a pure strategy for A and each vertical column to a pure strategy for B; the entry P common to the row and column is the payoff *to* A from B that these pure strategies produce. The array of numbers is called the payoff matrix; normalized finite dual games presented in such form are called matrix games. (Examples appear in Tables I and II; in each case the payoff matrix is the central box of arabic numbers.) Since the matrix entries represent gains to A and losses to B, A's aim is to maximize and B's to minimize the result that comes out of the matrix.

As A weighs the consequences of various courses of action open to him in a dual game, the theory of games counsels him to gauge each by the gain it assures him, regardless of what B does. In effect, this is equivalent to the pessimistic assumption by A that B knows his plan and will counter it to limit his gain to a bare minimum. So. to maximize his assured gain, A is led to seek a maximum of minima, abbreviated "max-min"; he should act so as to make as great as possible the least gain to which B can limit him. The antithetical aim of B is to choose a course of action that will hold to a minimum the greatest loss *A* may inflict. Thus, B's goal is a minimum of maxima, abbreviated "min-max." The clear fact that A cannot establish a floor under his possible gains that is higher than the ceiling B succeeds in placing over his possible losses is expressed by the formula:

$$A\text{'s gain-floor} = \text{max-min} \leqq \text{min-max} = \text{B's loss-ceiling.}$$

With evaluation limited to pure strategies only, this is the most precise statement that can be made for the entire class of dual games. (The effect of further restrictions is considered below under Extensive Games—A Poker Example.) The highest gain-floor for *A*, using a single pure strategy, is obtained by choosing the strategy row in which the least entry is greatest: the lowest loss-ceiling for B, using a single pure strategy, is obtained by choosing the strategy column in which the greatest entry is least. These two values are equal only when there is an entry in the payoff matrix which is, at the same time, the least in its row and the greatest in its column. Such an entry is called a saddlepoint; *e.g.*, see Table I. case (3), where the entry 3 is a saddlepoint.

Mixed Strategies; Minimax Theorem.—To close the gap between max-min and min-max in the general case in which the payoff matrix contains no saddlepoint. it is necessary to broaden the concept of strategy. Von Neumann (as well as Borel and R. A. Fisher) took the decisive step of introducing weighted averages of pure strategies. In the broadened concept the frequencies with which a player uses his pure strategies in the long run are specified by weights (some but not all of which may be zero). Operationally, the selection of the pure strategy to be used in a particular playing of the game is left to a suitable chance mechanism, which selects in a random manner from among the pure strategies in accordance with the weights the player has chosen (*e.g.*, in matching pennies. as ordinarily played, the pure strategy of showing "heads" uniformly and that of showing "tails" uniformly are randomized with equal weights by tossing the coin before showing it). This randomization by a chance mechanism avoids a mixture pattern from which the opponent might profit in the long run (*e.g.*, to alternate uniformly between heads and tails in matching pennies would weight them equally but be quite unwise in repeated play). Such a mixture of pure strategies, randomized in fixed proportions, is called a mixed strategy It is clear that neither player's position is worsened by using mixed strategies since any pure strategy is still tenable as a mixed strategy by assigning nonzero weight only to it.

When A's gain-floor and B's loss-ceiling are re-evaluated in terms of mixed strategies, it turns out that in any matrix game

$$\text{max-min} = \text{min-max.}$$

This minimax theorem of von Neumann (1928) is the main theorem of normalized finite dual games and the keystone of the whole theory. It shows that any such game has a solution consisting of (1) a "minimax" value (the common max-min and min-max), (2) an "optimal" mixed strategy for A that assures him a gain of at least the minimax value on the average and (3) an "optimal" mixed strategy for B that insures him against a loss on the average of more than the minimax value.

Examples of Matrix Games.—A and B choose whole numbers independently; A wins if the sum is odd. B wins if the sum is even. Roman numerals are used throughout to denote the numbers from which A and B make their choices. The first case shown in Table I is a very rudimentary dual game; it is the same as matching pennies. with B winning if head (I) matches head (I) or tail (II) matches tail (II), and A winning otherwise. The other four cases are variants which suggest the range of possibilities that arise even in small-scale dual games. Directly to the right of an A choice and below a B choice there appears the resulting payoff, positive if A wins (and B loses), negative if A loses (and B wins). In the rudimentary first case the amount of the payoff is simply one unit, but throughout the other four cases in Table I the amount of the payoff is the sum of the numbers chosen by A and B; *e.g.,* if A chooses I while B chooses III, as in cases (3), (4) and (j), the payoff entry is -4 because $1+3=4$, an even number, lost by A, won by B. The vertical column of weights listed for A in each case combines with a parallel column of payoffs to form the weighted payoff sum shown at the foot of that column; *e.g.,* in case (j), column I, $0(-2)+15(-4)+13(5)=5$ is the weighted payoff sum. The horizontal row of weights listed for B combines with a parallel row of payoffs to form the weighted payoff sum shown at the right end of that row. These weighted

(5) minimax $= -\frac{3}{28}$

sums become weighted averages when divided by the sum of the weights, written (with ÷) at the lower right. By randomizing their choices with the particular weights listed, A and B achieve "optimal" strategies; on the average, *A* is assured of winning at least the "minimax value" shown and B against losing more than this value. To verify the solution in each case shown in Table I, observe that the minimax value is both the minimum of the *A*-weighted average payoffs and the maximum of the B-weighted average payoffs. Note that in case (3) the payoff matrix has a saddlepoint; viz., the entry 3.

Symmetric Games.—A and B each show one or two fingers and at the same time call "two," "three" or "four," attempting to guess the total number of fingers shown; a right call wins from a wrong call—otherwise it is a draw. This is a two-finger form of an ancient game known as morra (see GAMES, CLASSICAL). In the rudimentary first version shown in Table II, the amount of the payoff is simply one unit for a win and zero for a draw; in the somewhat more sophisticated second version the amount of a winning payoff equals the total number of fingers shown by *A* and B (*e.g.,* if *A* shows I and calls II while B shows II and calls III, the payoff entry in the second version is -3, because the total number of fingers shown by A and B is $1+2=3$ and hence A's call is wrong and B's right). In either version the game is fully symmetric: both players face identical choices and rewards. This is partly disguised by the tabulation, which presents the payoffs from the viewpoint of A. To interchange *A* with B, not only must horizontal payoff rows be transposed into vertical columns. but also the sign of each payoff must be changed (to B's viewpoint). The net result of such a twofold shift leaves the payoff arrays in Table II just as they are—which is the characteristic property of

TABLE 11.—Two Games of Morra

A			0	0	0	7	÷35

the tabulation of a fully symmetric dual game. As a result of the symmetry, any optimal strategy for one player must also be optimal for the other and the minimax value must be zero. Consequently. in each of the above versions of morra, the listings of weights for *A* and B which achieve the zero minimax could be reversed and this shows that both players have more than one optimal strategy. Actually, in the first version any weights *p*, q, q, *p* yield an optimal strategy; and in the second version any weights o, *p*, q, o yield an optimal strategy, provided $p/(p+q)$ is a fraction between 20/3j and 21/35.

Computation of Solutions.—The solution of a matrix game with m columns and *n* rows of payoff entries amounts to the solution of a system of linear inequalities in $m+n+1$ unknowns, A's *m* weights, *B*'s *n* weights and the minimax value. The system comprises *n* inequalities which express the A-weighted average payoffs as equal to or greater than the minimax value and *m* inequalities which express the B-weighted average payoffs as equal to or less than the minimax value; in addition, the m+n weights must be non-negative, reduced usually to fractional form with unit sum for each set, so that the weighted payoff sums become weighted averages without division. L. S. Shapley and R. N. Snow have shown that any basic solution of such a system is characterized as the unique solution of a suitably chosen subsystem of linear equations. As a result, the solution (if unique) or the full set of solutions (if more than one exist) can be determined by at most a finite number of arithmetic operations, but this number increases so rapidly, as the numbers *m* and *n* of rows and columns increase, that the solution of a large-scale matrix game by this method is formidable or impracticable.

The solution of a pair of dual linear programs, which call for maximizing and minimizing linear functions of several variables subject to constraints given by linear inequalities or equations, is equivalent to the solution of a matrix game, and vice versa, as was shown by George B. Dantzig and by David Gale, H. W. Kuhn and A. W. Tucker (see T. C. Koopmans and others [eds.], Activity Analysis of Production.and Allocation). Hence, the "simplex" method devised by Dantzig for linear programming can be applied to solve reasonably sized matrix games. Iterative procedures for approximating game solutions were formulated by George W. Brown and John von Neumann to exploit high-speed automatic electronic computers.

Games on a Square.—Imagine the finite array of payoffs of a matrix game replaced by an infinite array of payoffs, one for each point of a square *OMLN* (see fig. *1*). Let *A* choose a point X in the edge *OM* and, independently, B a point Y in the edge ON; then have A get from B the payoff attached to the point of intersection of the lines XX' and YY' perpendicular to *OM* and *ON*. This is an infinite dual game "on a square." Fig. 2 presents an example: A and B divide the area *OMJLKN*, formed by the square *OMLN* and two isosceles right triangles *MJL* and *LKN*, by means of the lines XX" and YY" based on independent choices by *A* and B of X in *OM* and Y in *ON;* A gets the unshaded area, B the shaded area. By direct calculation, taking OM $=ON=$ one unit and OX $=x$, OY $=$ y, the net payoff (A's area minus B's area) is found to be

$$P=4x+2y+y^2-x^2-4xy-2.$$

A wishes to maximize P, B to minimize P (*i.e.*, to maximize $-P$).

By analogy with a matrix game. a saddlepoint for a game on a square is at the intersection of a line XX' and a line YY', for which the payoff at the point of intersection is equal to or less than every other payoff on XX', and is equal to or greater than every other payoff on YY' (see fig 1) (A saddlepoint is so called because it appears as an actual surface-saddlepoint in the three-dimensional graph of the payoff over the square.) In the area-division game (fig. 2) $x=0.8$, y $=0.6$ give a saddlepoint having payoff 0.2, since the net payoff can be rearranged as:

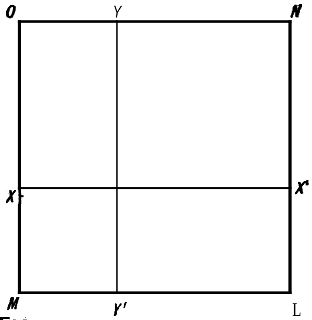

FIG 1.—GAME ON A SQUARE (see TEXT FOR FURTHER EXPLANATION)

$$P=0.2+(y-0.6)^2 \text{ if } x=0.8 \text{ and } P=0.2-(x-0.8)^2 \text{ if } y=0.6.$$

By choosing $x=0.8$, A assures himself at least 0.2, since $(y-0.6)^2$ is never less than zero; while, by choosing y $=0.6$, B guards against losing more than 0.2, since $-(x-0.8)^2$ is never greater than zero. The claim that this point is a saddlepoint can also be verified by geometric reasoning. based on the fact that it is the critical position at which XX" and YY'' bisect one another (in fig. 2).

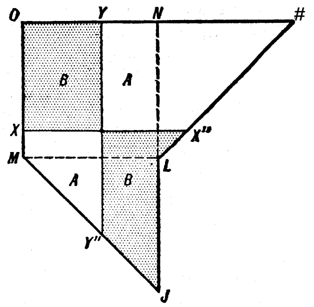

FIG. 2.—AREA-DIVISION GAME. SHOWING SADDLEPOINT DIVISION (see TEXT FOR FURTHER EXPLANATION)

The solution in pure strategies possessed by the area-division game is exceptional. because games on a square. like matrix games. do not usually possess saddlepoints. In general. each player must "weight" the points in his interval. OM or ON, if he is to do the best he can for himself. Such distributions of weights over an interval are known as probability distributions; they play a role analogous to that of mixed strategies in matrix games. Yet, even when both players employ probability distributions. the minimax theorem does not hold without some mild restriction on how the payoffs vary over the square. For the continuous case of payoffs without abrupt jumps, the equality of max-min and min-max was established by Jean Ville in 1938.

EXTENSIVE GAMES—A POKER EXAMPLE

Pure Strategies.—The primary objective of the study of a game in extensive form is the analysis of the combinatorial structure defined by the rules and its influence on the subsequent definition of strategies. This structure can be presented in the form of a branching diagram (of the sort exhibited in Table III) in which the junctures represent occasions at which a player or a chance mechanism (specified by the rules, such as cards. dice, etc.) is called upon to decide upon one of the several branches that continue the course of the play. These branches contain the state of information of the next player to act. If the branching ceases at any stage, the play is over and the payments specified by the rules are listed.

Several junctures in the diagram may be prefixed with the same information for a single player (e g., in a card game. these may be situations that differ only in the unrevealed cards held by his opponents). For strategical purposes, a player must consider such junctures to be the same. since he cannot distinguish between two such junctures and hence cannot decide in advance to make distinct choices should one or the other occur in the course of play. This means that the problem of formulating a pure strategy for a player is solved by listing all his junctures with distinct states of information and making a definite choice of a branch for each. Such a plan fulfils the requirements for a pure strategy set forth previously.

Historically, the first result on games in extensive form was stated (for the game of chess) by E. Zermelo and given a complete proof by von Neumann. It applies to games with perfect information; that is, games in which a player is always informed of the complete previous history of the play. The theorem asserts that finite dual games with perfect information can always be solved by pure strategies without randomization. In other n-ords, there is always a saddlepoint in the payoff matrix of such games. As regards chess, in particular, this means that exactly one of the following three alternatives is valid: (1) White has a pure strategy that wins, no matter what Black does; (2) both players have pure strategies that ensure at least a draw, no matter what the other does; (3) Black has a pure strategy that wins, no matter what White does. However, the theory gives no practical method for deciding which assertion is true.

Behaviour Strategies.—The lack of a solution in pure strategies for a general finite dual game means that a player must randomize his actions in some manner to obtain the amount due him (as measured by the minimax value) In the extensive form of a game, it is possible to introduce a method. alternative to that of mixed strategies, for varying his choices from contest to contest of the game in an undecipherable pattern. This method specifies by weights the long-run frequencies with which a player chooses the various alternatives presented to him in a given state of information. Rather than using a chance mechanism to select a complete plan prior to the playing of a game. a player employs such a device throughout the play, at each occasion for choice, to select an alternative in accordance with weights he has chosen. Such a decentralized system of play, randomizing the choices for each distinct state of information in fixed proportions, is called a behaviour strategy, since these weights are the statistics of a player's behaviour that an external observer could gather from a long series of contests.

Since the number of weights needed to specify a behaviour strategy is. in general. much smaller than the number of weights in a mixed strategy, it is useful to know when they produce the same results. H. W. Kuhn showed that a player can use either with equal success in any game with perfect recall; *i.e.*, any game in which a player's state of information always includes everything he has done or known previously. Poker is a game with perfect recall and hence can be played effectively with behaviour strategies. Bridge, on the other hand, does not have perfect recall since each player is a pair of persons, neither of whom is informed of the other's hand. Since there can be no correlation between the selections made by the chance devices for different states of information when a player employs a behaviour strategy. it is possible that bridge players must use mixed strategies to achieve the minimax value.

Simplified Poker.—A simplified version of poker is played by A and B with a deck containing a large number of cards marked "high" (H) and "low" (L). First. each player "antes" four chips and is dealt a single card; the four possible deals are assumed to be equally likely. Then A has two options: to "see," or to "raise" by adding two chips to the pot. If A decides to see. the higher hand wins the pot and equal hands split the pot equally. If A decides to raise. B has three options: to "fold," to see by adding two chips to the pot or to raise by adding three chips to the pot. If B folds, A wins the pot (with no hands revealed). If B sees, the higher hand wins the pot and equal hands split the pot equally. If B raises, A has two options: to fold, or to see by adding one chip to the pot. If A folds, B wins the pot (with no hands revealed). If A' sees, the higher hand wins the pot and equal hands split the pot equally. (This simplified poker adds the possibility of a raise by B to the tno-handed case [S=2] of a simplified poker treated in von Neumann and Morgenstern, Theory of Games and Economic Behavior, pp. 211–219.)

The possible sequences of choices by the players, independent

						*L*7*L*7	→ 0

Equally likely

of the actual cards held. are shown at the top of Table III. The player to act precedes, and his alternatives follow. each juncture. The possible payoffs (listed as *A*'s gain, since this is a dual game) are given when the play is over. The precise payoff that occurs is determined by the cards held. In the body of Table III appears the complete branching diagram. taking account of the deal. Four-place symbols present the states of information. The first two symbols give the hand and current bet of A, the last two symbols give the hand and current bet of *B*. All are given as known to the player who is next to act; *e.g.*, the symbol ?6*L*4 preceding *B* means that *B* is to act, not knowing *A*'s card, but knowing that A has bet six chips. and B holds a low card and has bet four chips. For ready reference, the actual card held is listed below each question mark. Whenever the play ends, the payoff to A is listed; if either player has folded. the symbol X is used to indicate that neither hand need be revealed.

Certain terminal situations (starred in the table) will never occur in rational play; *e.g.*, player *A* mill never see in the second stage while holding a high card since he stands to win at least as much (and sometimes more) by raising. Similar arguments advise both players to bet the limit at every juncture where they hold a high card. Reduced in this manner. a pure strategy for either player consists merely of how high he should carry his bet on a low card. These pure strategies are listed as two-place symbols to the left and above the payoff matrix in the left half of Table IV. The first number (7) gives the limit a player will bet on a high card, the second (4. 6 or 7) gives the limit on a low card. To compute the payoff to **A** when two of these strategies are

TABLE IV.—*Simplified* Poker

(Optimal mixed strategies and optimal behaviour strategies)

wt.		9	1	2	*B*

		see	4
B	?6*L*4	fold	9
		see	1
		raise	2

played. an average is taken over the four terminal situations that can follow the four possible deals; *e.g.*, when A plays 76 against 74 for B, the play ends in *H*7*H*7, *X*6*X*4, *X*6*X*7 or *X*6*X*4 and the corresponding entry is $\frac{1}{4}(0)+\frac{1}{4}(4)+\$(-6)+\frac{1}{4}(4)=\frac{2}{4}$. (The unreduced payoff matrix would consist of nine rows and nine columns, labelled 44, 46, 47, 64, 66, 67, 74, 76. 77.)

The weights listed are the only weights that achieve the minimax value. Player A must play "bluffing strategies" (either 76 or 77) one-half of the time, while B must decide to bluff one-fourth of the time.

The average behaviour imposed by these optimal mixed strategies upon a player with a given state of information constitutes an optimal behaviour strategy. The optimal weights, so defined, are given in the right half of Table IV (*e.g.*, with information L4?4, player *A* assigns the "seeing" pure strategy 74 the, weight 6 and assigns the "raising" pure strategies 76 and 77 the weights 2+4= 6; in common parlance this means that, in the long run, A sees as often as he raises upon being dealt a low card).

PLURAL GAMES

Economic Example: Non-Co-operative Solutions.—Two basically different approaches to the behaviour of parties to plural games have been proposed. The solutions that they suggest are contrasted in the following (highly simplified) problem from economics: Two sellers. A and B, in competition with each other. are contemplating a price cut of the same amount. Each knows that if they both sell at the same price they will divide the market evenly. while if one cuts his price and the other does not, then the former will capture the entire market. If the total profits at the higher and lower prices are known. this situation gives rise to a symmetric two-party plural game. The top part of Table V lists the payoffs for four of these games; in all cases, six units of profit are available at the higher price, while the lower price, in the four cases, yields four, two, zero and minus two units of profit respectively (negative profit is positive loss). The profits of *A* and *B* in each of the four games are shown to the right of each pair of prices (*i.e.*, pure strategies).

As a solution to the sellers' problem, the non-co-operative theory of John Nash suggests and proves the existence of a pattern of independent action in which there is no incentive for deviation by any player alone. As such, it is an extension of the minimax theory for dual games. A price cut by each seller is a Nash equilibrium point in each of the first three games, and if both keep the higher price, the result is an equilibrium point in the last three

TABLE V.—*Price* Cut *Example*

Prices		Profits (1)		(2)		(3)		(4)	
A	B	*A*	*B*	A	*B*	A	*B*	A	*B*
	high	3	3	3*	3*	3*	3*	3*	3*
	low	0	4	0	2	0	0	0	−2
low	high	4	0	2	0	0	0	−2	0
low	low	2*	2*	1*	1*	0*	0*	−1	−1
Coalition		Maximum assured profit							
A with *B*		6		6		6		6	
A alone		2		1		0		0	
B alone		2		1		0		0	

games. These solutions (starred in the top part of Table V) can be checked by verifying that unilateral changes in strategy are not rewarded. In the first game. the stability of the solution derives from the fact that a lone decision by either party to sell high would decrease his profit from two units to nothing. Although it is clear in this case that both sellers would benefit from an agreement binding each other to the higher price. this pattern is considered unstable since either seller could increase his profit by unilateral action. In like manner, a cut by a single seller can be considered a (fictitious) coalition between that seller and the buyers of the market, but can be upset by lone action by the other seller to his advantage. Indeed, the dilemma posed by the first game consists of the instability. with respect to unilateral defections. of each of the three possible two-party coalitions that may form among the two sellers and the market.

Co-operative Solutions.—The co-operative theory of von Neumann and Morgenstern for plural games (their general n-person games) is built upon these coalitions and introduces the possibility that the parties to an agreement may distribute their payments so as to maintain the coalition. The bottom part of Table V continues the analysis of the sellers' problem from this point of view. It lists for each of the four games the maximum assured profit for A and B acting together, for *A* alone and for B alone (*e.g.*, the greatest profit *A* can assure himself in the fourth game is zero; to do this he holds to the higher price). The co-operative theory suggests, for all four games, that (1) the sellers agree to hold to the higher price; (2) that each receive at least as much from the coalition as by independent action; (3) that the remainder be distributed in some manner between them (*e.g.*, in the second game, each seller surely receives one unit and the four additional units are divided in an unspecified manner). No mode of distribution is singled out, because even though one seller may prefer one division to another, he cannot enforce it by a unilateral change of his strategy or his allegiance. On the other hand. every other distribution of the profits is less advantageous to the collective interest of the two active parties, the sellers. In general. the stability of a co-operative solution derives from these two sources: internal consistency and external domination.

In 1953 D. B. Gillies showed that a sizable swath of plural games possess co-operative solutions.

Simple Games; A Power Index.—The co-operative theory has a political aspect when the only prospects of a coalition are to win or lose; this is the case in voting systems, such as legislatures, committees and voting stockholders. Such games are called simple, and the only tao possible outcomes, win or lose, for the coalitions are indicated numerically by one and zero. L. S. Shapley proposed an a *priori* numerical indicator of the relative equities of the players of any co-operative game, which is easily calculated for such a situation. This power index measures the average contribution of a player to the coalitions to which he might belong. taking account of the order in which the members join the coalition; *e.g.*, a participant in a simple game contributes to a coalition only if his entrance changes it from a losing to a winning coalition

As representative of this class, consider a four-man committee composed of a chairman, with three votes, and three other members, with one vote each. A simple majority of votes wins, while ties are considered as a loss for both sides. The 24 possible sequences in which the members might vote are listed in Table VI; the chairman is denoted by *A* and the three ordinary members by b, c and d. The pivotal player, the first to complete a majority in each voting order, is starred in each column. Since the chairman is pivotal three-fourths of the time, his power index is 75%. The ordinary members share the remaining fourth equally and have as indices $8\frac{1}{3}$%. Thus the voting ratio of 3:1 results in a power ratio of 9:1 in this simple game.

Table VI.—*Committee Voting Example*

GAMETE, in biology the name given to the special cells set apart in most plants and animals for sexual reproductive purposes. (See Sex.)

They are usually of two kinds: (1) the ovum, which is large, stationary and heavily laden with food materials (yolk); and (2) the spermatozoon or (in plants) spermatozoid, which is small, actively motile and, in all animals except the Arthropoda (insects, spiders, crabs, etc.) and nematode worms, consisting of a head of nuclear material (see Cytology) and a long vibratile tail. In the higher plants (conifers and flowering plants) and in many fungi this element is much modified (see Plants and Plant Science), but in most of the lower plants the spermatozoid closely resembles the animal spermatozoon.

In some Algae (*q.v.*), both gametes are spermatozoonlike; and in certain Algae and Protozoa the whole organism acts as a gamete. The two gametes, in all the above cases, fuse to form a zygote, which develops into the adult organism.

An organism producing ova is said to be female; one producing spermatozoa, male; one producing both. hermaphrodite. (See Sex; Heredity; Cytology; Hermaphrodite; Embryology).

GAMETOGENESIS, in embryology the name given to an abnormal form of egg fertilization caused by the entrance of a number of spermatozoa into the ovum instead of one as in normal fertilization. A corresponding number of male pronuclei are formed, and the subsequent development, if it takes place at all, is abnormal.

The spermatozoa and ova are called the gametes. In the Arthropoda, selachians. amphibians and mammals the reproductive organs can admit of several spermatozoa normally entering the ovum. but of these only one forms a male pronucleus, the rest being absorbed.

(See Embryology; Heredity; Sex.)

GAMING AND WAGERING: see Gambling and Betting; Horse Racing and Breeding.

GAMMA-RAYS (written γ-rays) are electromagnetic radiations of very high frequency emitted by radioactive bodies (see Radioactivity. Artificial; Radioactivity. Natural). These radiations have wave lengths from 3Å to 0.005 Å (1 Å = 1 angstrom unit = 1×10^{-8} cm.). They are the shortest waves of the electromagnetic wave spectrum. They are similar to and have the same general properties as X-rays, except that they are of higher frequency and more penetrating (see X-rays, Nature of).

(J. D. Sn.)

See Eastman Kodak Co., *Radiography of Materials* (1943).

GAMUT, a term in music used to mean generally the whole compass or range of notes possessed by an instrument or voice (from the Greek letter *gamma,* used as a musical symbol, and ut, the first syllable of the mediaeval hymn. *Sanctus* Johannes). Historically, however, the sense has developed from its stricter musical meaning of a scale (the recognized musical scale of any period), originating in the mediaeval "great scale," of which the invention has usually been ascribed to Guido of Arezzo (*q.v.*) in the 11th century. The whole question is somewhat obscure, but, in the evolution of musical notation out of the classical alphabetical system, the invention of the mediaeval gamut is more properly assigned to Hucbald (d. 930). In his system of scales the semitone was always between the and and 3rd of a tetrachord, as G, A, ♭B, C, so the ♮ B and ♯ F of the second octave were in false relation to the ♭ B and the ♮ F of the first two tetrachords. To this scale of four notes G. A, ♭ B, C were subsequently added a note below and a note above which made the hexachord with the semitone between the 3rd and 4th both up and down, as F, G, A. ♭ B, C, D. It was at a much later date that the 7th, the leading note in modern music, was admitted into a key, and for this the first two letters of the last line of the above-named hymn. *Sanctus Johannes,* would have been used, save for the notion that as the note Mi was a semitone below Fa, the same vowel should be heard at a semitone below the upper Ut, and the syllable Si was substituted for Sa. Long afterward the syllable Ut was replaced by Do in Italy. but it was retained in France; and in these two countries, with whatever others employ their nomenclature, the original Ut and the substituted Do stand for the sound defined by the letter C in English and German terminology. The literal musical alphabet thus accords with the syllabic:

A	B	C	D	E	F	G
La,	Si,	Ut or Do,	Re,	Mi,	Fa,	Sol.

In Germany a remnant of Greek use survives. A was originally followed in the scale by the semitone above, as the classical Mesē was followed by Paramesē, and this note. namely ♭ B, is still called B in German. English ♮ B (French and Italian Si) being represented by the letter H. The gamut which, whenever instituted, did not pass out of use until the 19th century, regarded the hexachord and not the octachord, employed both letters and syllables. made the former invariable while changing the latter according to key relationship and acknowledged only the three keys of G, C and F.

(*See* also MUSICAL NOTATION.)

GANDA, a Bantu tribe of east equatorial Africa. The Hamitic invaders. while remaining the light-skinned aristocracy. were much more absorbed by the local Bantu who form the peasantry. Apart from this distinction of skin colour there is not much to distinguish the aristocracy from the peasantry (*bakopi*) in physical appearance. though there is in speech, and class distinction is no longer an ethnic one.

The hair of the Ganda people is thick and woolly and is kept short. and the Ganda alone among the surrounding Bantu tribes do not mutilate their persons in any way. Bracelets of iron, copper and ivory are worn but otherwise the people are not addicted to personal adornment. They cover the whole body from chest to ankles with robes of bark cloth, the manufacture of which is an important industry.

They live in large circular huts, divided by many partitions and thatched with unusual care and skill. The walls and partitions are covered with a characteristic reed work. and every home of importance has attached to it a series of neatly kept courtyards surrounded by high fences of reed work. A number of these residences surrounded by luxuriant gardens go to form a loose settlement. of which the market place is the conspicuous feature. The houses of the peasantry are simpler. of smaller dimensions and of ruder structure. Broad roads. carried over swamps by solid causeways. radiate from the capital to the villages of chiefs.

The Ganda are skilled watermen and maintain a large flotilla of war canoes. Their canoes are in remarkable contrast to the dugouts of most of their neighbours. their keel, false prow and sewn boards suggesting an Indonesian origin.

Their weapons consist of thrusting spears. a club which is used for war and executions, an oval shield of wickerwork with a central boss of wood or iron. Children use bows and arrows. They manufacture good pottery and artistic mats. and have a variety of musical instruments including the xylophone, flutes. harps, horns and drums. The drums of the *kabaka* or king are a tribal property and each is individually named. special drummers being detailed by chiefs for monthly duty.

Though they keep the usual domestic animals (their cattle being mostly of the short-horned. humped variety), they are essentially agriculturalists. the banana and sweet potato being the staple crop though a few cereals are also raised. All land except the clan burial grounds is the property of the *knbaka,* and individual holdings which are cultivated by a man's wife are granted him by his chief or directly by the *kabaka.*

The clans are totemic and exogamous, have each certain social and political functions and are graduated in social status and prestige by various factors which are not constant. Certain clans are debarred from presenting a prince as candidate to the throne. Clans and their subdivisions have their separate estates (*butaka*) which are the clan burial grounds in charge of clan functionaries called *bataka*, who among other duties have to select the male and female life servants of the *kabaka.*

Inheritance is patrilineal and the heir is one of the sons of the deceased. who is selected after the funeral by his brothers and sisters. Wives are not inherited but live as widows (with considerable licence) in separate huts built for them by the heir. Polygyny is usual. and blood brotherhood is a widely practised institution.

Society is elaborately organized on a feudal system. at the centre of which is the *kabaka* who exercises direct and absolute rule. He is assisted by three ministers, the *katikiro* or chief executive, the *mulamuzi* or chief justice and *muwanika* or treasurer, and a variety of lesser officials including his naval and military commanders in chief. These ministers are also members of the *lukiko* or council, which consists of the chiefs of the 20 *saza* or counties into which the country is divided. together with three notables for each county and six additional men of importance for the kingdom—all nominated by the *kabaka.* The functions of the *lukiko* are judicial. administrative and advisory. Each county is in charge of a chief appointed by the *kabaka* who assigns him estates on appointment, but neither these nor the chieftainship are hereditable and are held solely at the *kabaka's* pleasure. The counties are subdivided into approximately ten districts each called *gombolola* under district chiefs subordinate to the county chiefs. and these district chiefs have a varying number of petty headmen or *miruka* under them. The peasants are tenants at will of the landholders, to whom they owe allegiance and service, including the maintenance of roads, personal labour, taxes and military obligations.

Through all the hierarchy of chieftainship the same state and similar functionaries are maintained as at the royal court. and judicial procedure prescribes that with certain exceptions trials shall start at the lowest court and reach the *lukiko* by a series of appeals or commitments.

The *kabaka's* mother has a very important position in the constitution.

Their religion combines ancestor worship with the worship of a number of natural phenomena. such as Kiwanuka the lightning, Musisi the earthquake. Kazoba the firmament was the nearest approach to a high god, but such a conception is probably subsequent to Mohammedan and Christian influence and is not earlier than the comparatively modern deity Katonda. There is a caste of priests and diviners called *Bamandwa,* and virgins were dedicated as brides to the nature deities.

See E. Hornell, "Indonesian Culture in East Africa," *Man,* i (1928); Sir H. H. Johnston, *The Uganda Protectorate* (1902); J. Roscoe, *The* Baganda (1911). (J. H. D.)

GANDAK, a river of northern India. It is formed in the Nepal Himalayas by the union of the waters of the Kali Gandak, Buria Gandak, Trisuli, etc. The united stream, at first called Trisulganga. flows southwest until it reaches Indian territory, where it turns southeast across the Gorakhpur district of Uttar Pradesh, and then between the Champaran and Saran districts of Bihar. It falls into the Ganges opposite Patna, after a 475-mi. course. It is a snow-fed stream, its floods endangering the surrounding plains.

The LITTLE GANDAK rises in the Nepal hills, enters Gorakhpur district about 8 mi. W. of the Gandak and joins the Gogra just within the Saran district of Bihar.

The BURHI (or old) GANDAK also rises in the Nepal hills, and runs roughly parallel to and east of the Gandak, of which it represents an old channel, passing Muzaffarpur and joining the Ganges nearly opposite to Monghyr. Its principal tributary, the Baghmati, rises in the hills north of Kathmandu, flows southward through Tirhut and joins the Burhi Gandak close to Rusera.

GANDAMAK, a village of Afghanistan, west-southwest of Jalalabad. on the road to Kabul.

On the retreat from Kabul of Gen. William Elphinstone's army in 1842, a hill near Gandamak was the scene of the massacre of the last survivors of the British force by the Afghans.

A treaty was signed there in 1879 with Yakub Khan, recognized by the people of Kabul as amir. He ceded to Great Britain the Kurram valley and the Pishin and Sibi areas, and the control of the Khyber and Michni passes was also assumed by the British.

(See AFGHANISTAN: *History.)*

GANDHARA, a region of ancient India. now in northwestern Pakistan. corresponding to the vale of Peshawar, with extensions into the lower valleys of the Kabul and Swat rivers, and the eastern plain of the Indus northwest of Taxila.

Gandhara appears in the inscriptions of the Achaemenid rulers of Persia. The region probably came under their influence during the reign of Cyrus the Great (559–530 B.C.), although records only exist from the time of Darius I (522–486 B.C.). Herodotus confirms the inscriptions and mentions the presence of Gandharans in the army of Xerxes.

In Indian sources references to Gandhara and its inhabitants go back to the Rigveda and Brahmana literature; the early Buddhist texts also contain many references. Taxila is mentioned as the capital and as a great centre of learning. Pushkalavati (modern Charsadda) is also sometimes mentioned as the capital. The ruler of Taxila submitted (327 B.C.) to Alexander the Great. Later Gandhara became a province of the Mauryas and thereafter was ruled successively by Indo-Greeks. Sakas and Parthians. The monuments of Gandhara have been famous for more than a century; excavations were carried out by the archaeological survey of India at Taxila and in the vale of Peshawar.

From the 1st century A.D. Gandhara became the centre of a flourishing school of sculpture and architecture. The origins of this school have been much disputed, but it contained both Indian and Hellenistic (or Roman) elements. The former were largely associated with the spread of Mahayana Buddhism. while the latter owed their introduction to the extensive trade of the Parthians with the Mediterranean: and their development to the Kushans. The earlier view that the art style arose from the Greek dynasties in Bactria and northwest India appears to be incorrect. The Gandhara school lasted, at least locally, until the Muslim invasions in the 7th and 8th centuries. The architecture is mainly of stone, frequently adorned with sculpture in either schist or stucco. The monuments take the form of Buddhist stupas and monasteries, often of locally developed varieties. The sculptures are almost entirely Buddhist: many of the details and motifs find close parallels in the contemporary art of Rome. See INDIAN ART: *Gandhara (Greco-Buddhist) Sculpture.*

GANDHARVA, (1) in Vedic Hindu mythology a celestial spirit of the highest sky. though in the Avesta he was a dragonlike monster. Gandarewa, dwelling in the sea. the abode of the white Haoma *(see* SOMA). But he was soon multiplied into a class of minor deities with various collective functions. Gandharva's union with the Apsaras *(q.v.)* typifies marriage. and they are parents of the first men. He is also a herbalist. Later, the Gandharvas preside over battles, the most popular being Tumburu, the "tambour" who leads them to watch those of men.

Gandharvas have their own breed of horses, their own land, located on both sides of the Indus, suggesting Gandhara. while Takshila and Pushkalavata were in Gandharva-desa and Gandhara-desa respectively. But Gandharva-nagara— "town"–is sometimes spoken of as a real city and sometimes as only a mirage. (2) In Hindu law a *gandharva* marriage is informal, based on mutual consent.

See A. A. Macdonell, *Vedic Mythology* (Strasbourg, 1897); E. W. Hopkins, *Epic Mythology* (Strashourg. 1915).

GANDHI, MOHANDAS KARAMCHAND (1869–1948), Hindu nationalist leader, was born on Oct. 2. 1869. at Porbandar in western India of a Hindu family with official traditions. His father was chief minister of one of the Gujarat states. When 18 years old Mohan was sent by his family to study law in London. and there he remained for more than three years, being called to the bar in 1891.

It is significant that on the voyage to England he nearly starved himself, having promised his mother that he would eat no meat. Though refusing to break his promise in spite of the inconvenience. he was not then a convinced vegetarian: but he read vegetarian writings in London and became an active member of the Vegetarian society. This led to a lifelong study of diet and personal hygiene, on which he wrote books. There can be no doubt that his careful personal regimen was largely responsible for the vigour of mind and body which he retained! in spite of a poor physique, to the end of his life.

When he returned to India, although professionally qualified) he was self-distrustful and made little headway as a lawyer until he was called to South Africa in 1893 by an Indian firm in that country.

In South Africa he became aware at once of the disabilities under which the Indians were suffering. Within a few years he was drawn so completely into the struggle far political rights that he gave up what had become a lucrative legal practice and undertook a drastic course in *brahmacharya,* or self-discipline. in order to devote his whole energies to public work. From the time of the formation of the Natal Indian congress in 1894 the agitation grew stronger year by year. At one stage in the struggle Gandhi and his friends. including several non-Indians. started a self-supporting colony. called Tolstoy farm, in order to free themselves for disciplined public activity without dependence on the ordinary life of the community.

In the forming of his social convictions Gandhi mas powerfully influenced by the writings of John Ruskin and Leo Tolstoy and also by an Indian poet. Raychandbhai. though the deepest influences of all were from the *Bhagavadgita* and the New Testament. He became convinced that the good life was life lived near the soil. with a minimum of dependence on machines. He himself learned the arts of farming. cooking, nursing. sanitation and teaching. He taught his own four sons.

In the course of the fight with the South African government, he and his wife and companions suffered arrest and imprisonment, and he was assaulted on one occasion by Europeans upon landing after a visit to India and on another by Indians. some of whom could not understand his insistence on always thinking the best of the "enemy." Once. at least. he refused to proceed with the movement of resistance to the government. when he saw that it had other peculiar difficulties to face. Moreover. both during the South African War of 1899–1902 and the so-called Zulu rebellion of 1906 he organized ambulance corps; for at that time he believed that the British empire was essentially beneficent, and he considered it his duty to assist to the utmost in times of stress.

The climax of the South African struggle came in 1913. A series of repressive measures. culminating in a demand that every Indian seeking to live in the Transvaal register himself. was met by repeated crossings of the Transvaal border by groups of Indians. Finally. a body of more than 2.000 Indians. many of them unlettered coolie labourers. followed Gandhi over the frontier. The unfailing forbearance, courtesy and restraint of leaders and followers was too much for public opinion. and a commission was appointed which reported in favour of the repeal of most of the obnoxious acts.

Gandhi also won the respect of Gen. Jan Smuts. who at the beginning had done his utmost to crush the movement. In 1914, feeling that he was no longer needed by the Indian community in South Africa. he returned to India.

Gandhi was already convinced that India was ripe for home rule. or *Swaraj* (self-rule) as it was usually called at that time. As soon as he had allowed himself a year's probation. enjoined by his mentor, the Indian statesman G. K. Gokhale. Gandhi threw himself actively into the work of the Indian National Congress party.

In South Africa he had organized nonviolent resistance to the government and had formed the conviction that war or revolution is always wrong and that when changes cannot be achieved by persuasion and constitutional agitation alone, nonviolent forms of direct action must be attempted. So. too. during the first few years of his residence in India, he and his friends organized corporate *Satyagraha,* or soul force, as a remedy for social and political injustices in various parts of the country. Finally. after the promulgation of the Rowlatt acts in the spring of 1919. which gave the government extraordinary powers to suppress the unrest that at the time nas widespread in the Punjab, he called on his followers to withdraw from all government appointments and institutions. even from schools and colleges. and to undertake mass civil disobedience against the government.

Not all his followers. however. understood his insistence on nonviolence; and when outbreaks of violence occurred he called off the movement and underwent personal penances. When hundreds of people who had gathered in Amritsar to attend a prohibited political demonstration were shot down in April 1919. Gandhi called the government "satanic"; but he confessed that he himself had committed a "Himalayan blunder" in failing to perceive that the people were not yet sufficiently disciplined to remain nonviolent in the face of severe provocations a-hen the policy of nonviolence was once launched. On three separate occasions the movement broke into violence and each time he called it off. to the exasperation of many of his associates. Finally. in 1922. he was arrested and sentenced to six years' imprisonment. The bearing of both judge and prisoner at the trial created a profound impression.

At the beginning of 1924, following an operation for appendicitis. he was released.

Between 1918 and 1922 Gandhi had done his utmost to produce an accord between the Hindu and Moslem communities; in furtherance of this purpose he actively supported the Moslem agitation for preserving the Turkish *Khilafut*, as the symbol of the unity of Islam. While he was in prison, relations between the two communities deteriorated and there were communal riots in a number of towns.

Accordingly, in Sept. 1924, he undertook a three weeks' fast at Delhi, hoping thereby to induce Hindus and Moslems to come to a better understanding. For a time the fast seemed to have achieved its object but before long conflict broke out again.

In 1925, being out of sympathy with the desire of most Congress leaders to enter the new legislatures set up under the Montagu-Chelmsford reforms of 1919, Gandhi retired from active politics and announced his intention of observing a year's political silence. In fact he did not return to full political leadership for three or four years. During this period he was constantly at work in the villages of India urging the people to take up hand-spinning in order to break free from their dire poverty and dependence on shoddy. town-made goods. and also urging them to abolish the evil of untouchability. At every village meeting that he addressed, if he found that the organizers had divided it into two sections, one for caste people, the other for untouchables, he would always sit among the untouchables to speak; and he had welcomed untouchables to his *ashram* or settlement at Sabarmati soon after his return to India.

He also fought against the drink and drug-taking habits of the people; he urged them to tend their cattle properly; he constantly taught good will between the religious communities and in other ways sought to promote the well-being of the myriad villages in which 90% of the people of India live. Throughout his public life in India. whenever he saw a barrier in the way of immediate political action, he turned to what he called "the constructive program" in faith that he was thereby preparing the country better for the next struggle for freedom.

In 1927 the British government appointed a parliamentary commission to consider whether India was ready for another instalment of self-government. This commission, led by Sir John Simon, was met in India by a widespread boycott, and an attempt was made to organize an all-parties reply to the commission in the form of an Indian-drafted dominion constitution. But the younger generation, led by Jawaharlal Nehru (*q.v.*) and Subhas Chandra Bose. had made up their minds for full independence. One section, impatient with the slow progress of the government and with the frustrations and persecutions arising from alien rule, broke loose from the Congress methods of action and started a campaign of violence. This brought Gandhi back into political activity. The Congress resolved that, as the government would make no promise of immediate dominion status; a new campaign of civil disobedience must be launched, and Gandhi was put in charge. He resolved to defy the government's salt monopoly. Accordingly, in April 1930, he walked all the way from his *ashram* near Ahmedabad to the sea at Dandi. and there he and his followers made salt from the sea. This salt march had an extraordinary effect in the country and before long many thousands of his followers were in jail for breaking various laws; finally Gandhi was himself imprisoned again.

During this imprisonment the government called a round-table conference in London, which was attended by a number of Indian moderates. It took such long strides toward self-government that, on their return to India. the chief delegates persuaded Gandhi, who had been set free, to meet the viceroy, Lord Irwin; and after prolonged talks between Gandhi and Irwin the Delhi pact was signed on March 5, 1931.

A few months later Gandhi attended the second round-table conference. but the British government had changed and this conference achieved nothing. On Gandhi's return to India he and his followers were arrested. During 1932 once again all the Congress leaders were behind prison bars.

Before the end of that year, when the MacDonald communal award was published, giving the untouchables or depressed classes separate political representation, Gandhi, in jail, started a fast unto death. He could not tolerate the idea of the perpetual separation of the untouchables from the rest of the people. Hindu and depressed-class leaders gathered round his bedside, and in a few days a compromise was accepted which for a period of years reserved many places for the depressed classes in the legislatures, but voting was to be in joint constituencies.

The next year Gandhi was released and he gave his main energies to work for the untouchables, for whom he coined the new name of *Harijans* or children of God. His weekly paper was published under this name for the rest of his life. During the next few years he undertook several more fasts in the interests of communal tolerance and the rights of the depressed classes. For Gandhi a fast signified his willingness to suffer for the cause that was close to his heart and at the same time was undertaken as an act of self-purification.

When World War II broke out, Gandhi was prepared to offer moral support to Great Britain. but he fell into line with his Congress colleagues in insisting that there could only be full co-operation from India if they were assured that one of the fruits of a British victory would be full freedom for India; and no such promise was forthcoming.

By 1940 the Congress had become completely estranged, and Gandhi started an individual civil disobedience movement, asserting the right of Indians to declare themselves in opposition to the war. He declared, however, that he did not wish to embarrass the British in their struggle. In 1942 Sir Stafford Cripps, on behalf of the government, made an effort to break the deadlock; but his proposals, although they assured freedom when the war was over, no longer met the Congress demand and Gandhi described them as a "postdated cheaue."

In Aug. 1942 the Congress leaders endorsed a demand made in July for an immediate transfer of responsibility and were thereupon arrested uith thousands of their followers. Gandhi held the British government responsible for the turmoil that followed in the early autumn of 1942 and. being unable to induce the government to change its policy, he fasted for three weeks while he was being held in detention in the spring of 1943. The government, however. was unmoved. In Feb. 1944 Mrs. Gandhi died in detention and Gandhi, after a serious illness, was released a few months later.

After his release Gandhi's first effort was to come to an understanding with Mohammed Ali Jinnah. the leader of the Moslem league, who was demanding, in the name of the 90.000 000 Moslems of India, the establishment of an independent Moslem state, to be called Pakistan. But the Gandhi-Jinnah talks proved unfruitful. When the Congress leaders were released, after the conclusion of the war, Congress and the Moslem league continued to drift apart.

With the advent of the Labour government in Britain. Indian nationalism entered its last phase. After a cautious beginning the new government indicated its willingness to transfer power in India completely, and three cabinet ministers visited India to negotiate a final settlement.

The question still remained: was it to be one free India or two? Gandhi withstood division to the end, insisting that Hindus and Moslems were one people. But the tide at the moment was flowing the other way. In the summer of 1946 terrible killings between the communities broke out in Calcutta and quickly spread to East Bengal, then to Bihar and later to other areas. especially the Punjab. Gandhi spent months during the winter of 1946–47, at the age of 77, tramping barefoot from village to village in Bengal, and later visiting the affected districts of Bihar and the Punjab, reminding the people that the God whom they worshipped under various names was the same God, that their real interests were identical. and urging the minority community to cast out its fears and the majority to win back the minority by rebuilding their ruined homes. He and his helpers had a large measure of success but a section of the political leaders of both the Hindu and Moslem communities opposed them.

In the spring of 1947 the Congress leaders agreed to the division of India. though Gandhi himself still disapproved. The date for independence and for the division was fixed for Aug. 15. Two days before that date Gandhi. having reached Calcutta. entered into a pact with H. S. Suhrawardy, who was the prime minister of Bengal until its partition. an active member of the Moslem league and one of Gandhi's most outspoken critics a few months previous. He was deeply distrusted by the Hindus of Bengal: but the determination of the two men to act together for the peace of Calcutta and Bengal had an almost miraculous effect. Instead of bringing fresh massacres to Calcutta. as had been widely anticipated. Aug. 1 j was a day of general rejoicing and fraternization all over the city. throughout eastern India and also in Delhi and elsewhere.

A few disappointed Hindus tried to break the peace a fortnight later: Gandhi immediately began a fast and within five days all parties in Calcutta promised to work together for peace.

As soon as he had recovered from his fast. Gandhi hurried to Delhi. for in the northwest the division of the Punjab had caused fresh outbreaks of violence. Unspeakable horrors were committed against the minority communities on both sides of the new frontier. and millions of people were fleeing in terror to the safety they hoped to find beyond the frontier. Delhi itself was swept into the flames of hatred and terror.

For four months Gandhi, living in Delhi and sometimes visiting the adjacent districts of the Punjab, did his utmost to fight against the violence and fury that surrounded him. Many Hindus and Sikhs. who had lost their relatives and their property in the western Punjab, were bent on revenge and resolved to turn all Moslems out of India.

Gandhi confessed that his lifelong teaching of nonviolence had not affected the people as he had believed; but he fought on dauntlessly. still insisting that, whatever might be happening in Pakistan. in India all communities must have equal rights—it must be a land for all.

In the middle of Jan. 1938. seeing that even the capital city of Delhi nas still unsafe for Moslems, he once again undertook a fast, and within a fen. days all the Delhi leaders had entered into a solemn agreement that they would welcome their Moslem neighbours back to their homes. But a small fringe of Hindus was not to be convinced. They saw that. so long as Gandhi lived. India could never become a Hindu-dominated state. Accordingly. on Jan. 30, 1948, ten days after his fast. as he was walking to his daily prayer meeting in the garden of Birla house. Delhi. he was fatally shot by a Hindu extremist.

Gandhi's Teaching.— Gandhi may be remembered, first and foremost, as a prophet of nonviolence in an age that saw two world wars: as a man who identified himself at all times with the poor and the disinherited. never abandoning his exacting standards of personal self-discipline even when he was the acknonledged leader of the nation and the idol of millions; or perhaps most of all as a man who asserted the validity of moral principles (especially the principle of truth) and their application to public life in all circumstances. even when the application of principle was manifestly against the immediate interest of his party or nation. He would not allow that any plea of expediency could justify a deviation from truth.

It is significant that he called his own autobiography *The* Story of *My Experiments With Truth;* and. indeed. it is no ordinary biography at ail, for it omits many important incidents and concentrates on those experiences which had led him to some fresh insight into truth.

It was often said that Gandhi was a religious man. a saint who had strayed into politics. But he himself said that he was a politician who was trying to become a saint. Yet it is true that he was fundamentally a religious man. Nothing would induce him to abandon his two regular times of open prayer, held about 3:30 A.M. and 5 or 6 P.M. He might add to them but he would not excuse himself from them. In addition. whenever he was alone (except during sleep the amount of such times was very small) he spent much time in meditation and prayer. Although to the end of his life he used certain Hindu forms of prayer and had great faith in the efficacy of repeating certain set forms. yet the essence of his religion was universal. God, he declared in *Harijan* (from which the quotations here and below are taken with the permission of the Navajivan trust). was to him identical with truth. "God is. even though the World deny him. Truth stands. even though there be no public support. It is self-sustained. Truth is perhaps the most important name of God. In fact it is more correct to say that Truth is God than to say that God is truth." "Let then our first act every morning be to make the following resolve for the day: 'I shall not fear anyone on earth. I shall fear only God. I shall not bear ill-will towards anyone. I shall not submit to injustice from anyone. I shall conquer untruth by truth and in resisting untruth I shall put up with all suffering.' "

This last quotation suggests the link in his mind between truth and nonviolence. two principles which, in later life especially, he constantly linked together. Every resort to violence. he believed, showed a failure to hold on to the matchless weapon of truth. A man n-ho resorts to angry argument against an opponent does so because he has no faith that truth alone will convict or convert. Sometimes. indeed. it is necessary to appeal not only to the head but to the heart. That means that a man must be prepared not only to be tireless in seeking to persuade his opponent by patient argument but also to undergo suffering for the truth that he declares. Such suffering, cheerfully undergone. may induce those who have not yielded to persuasion to re-examine their fundamental motives. It may lead to a change of heart. Here can be seen the mainspring to Gandhi's fasts.

Nonviolence, though negative in form. was to Gandhi a positive principle. It is a literal translation of the word *ahimsa*. But Gandhi himself coined a special word. *Satyagraha,* meaning soul force or truth force. in order to show that the man who renounces violent weapons. and even violent speech and thought. is still a fighter. He need not be. he must not be. passive when faced with evil. His weapons are to be truth and love or good will. "*Ahimsa,*" he wrote. "is not merely a negative state of harmlessness but it is a positive state of love. of doing good even to the evil-doer. But it does not mean helping the evil-doer to continue to wrong or tolerating it by passive acquiescence. On the contrary. love. the active state of *Ahimsa,* requires you to resist the wrongdoer by dissociating yourself from him even though it may offend him or injure him physically." "Complete non-violence is complete absence of ill-will against all that lives. It therefore embraces even subhuman life, not excluding noxious insects or beasts. They have not been created to feed our destructive propensities. If we only knew the mind of the Creator we should find their proper place in his creation. Non-violence is therefore in its active form good-will towards all life. It is pure Love. I read it in the Hindu scriptures. in the Bible. in the Koran." "When a person claims to be non-violent. he is expected not to be angry with one who has injured him. He will not wish him harm; he will wish him well."

Gandhi achieved this ideal to an extraordinary degree. He was often attacked and vilified; yet it may be doubted whether even his intimate friends ever heard him speak angrily or contemptuously of his critics. On the contrary, he was constantly contriving means for repaying evil with good. He nas the most charitable of men. and the most tolerant. If he thought a man were doing evil, he would say so: but he would welcome opportunities for meeting such a man and inducing him to do good.

Gandhi's determination to revive hand-spinning and weaving and other village crafts has been interpreted as a complete rejection of machinery. This is a misapprehension. Primarily, he urged these things as the first and simplest steps in the fight against the abysmal poverty of the Indian villages. "The spinning-wheel itself." he pointed out. "is a machine. What I object to is the craze for machinery, not machinery as such. The craze is for what they call labour-saving machinery. Men go on saving labour till thousands are without work and thrown on the open streets to die of starvation." "Scientific truths and discoveries should first of all cease to be the mere instruments of greed. Then labourers will not be over-worked and machinery, instead of being a hindrance, will be a help." "The supreme consideration is man. The machine should not tend to make atrophied the limbs of men." "Replace greed by love and everything will be right."

Similarly, his strong criticisms of medical science have suggested that he rejected all scientific treatment of disease. Again, it is largely a matter of emphasis. He believed that strict adherence to the rules of hygiene and the laws of health ("overworking the body is a form of violence," he once said) would lead to the avoidance of nearly all illness. When they did occur, he believed that most illnesses could be best treated by "nature cure" rather than by drugs.

In politics he called himself a democrat and a socialist. but he had his own explanation of these terms. "The truest test of democracy is in the ability of anyone to act as he likes, so long as he does not injure the life or property of anyone else." "If the whole of India were to say that even peaceful public meetings may not be held without permission, that peaceful volunteer associations may not be formed without permission and that newspapers cannot be published without permission, that prohibition cannot be accepted. For a man may not be expected to ask for another's leave to breathe or eat or drink. The three things I have mentioned are the breath. the food and the drink of public life." "Liberty of speech means that it is unassailed, even when it hurts."

His socialism certainly was not state socialism. for he wanted the state to wither away. nor was it connected with the teachings of Karl Marx or other western socialists. It was a deduction from his principle of nonstealing. Anyone who took for his own use more than he needed was, in Gandhi's view, robbing the poor. He did not object to employers of labour or to capitalists or landowners as such: but he called on them to abandon their riches, to share their wealth with the community, to be trustees for those who were dependent on them. He was less concerned with changing the social structure than with changing human motives. By these principles he himself lived. He was constantly trying to get rid of his dependence on possessions, even the possession of any home of his own, or dependence on secretarial help. He strove to make himself dependent on God alone.

Thousands of men were his friends; the circle was ever-widening. But none was his intimate; or rather, all were. With all his friends and visitors he was courteous, patient. tolerant. sometimes playful and ever ready to be merry, even when his lifework was threatened with destruction. His spirit was unconquerable.

GANDÍA, a seaport of eastern Spain in the province of Valencia; on the Gandía-Alcoy and Alcira-Denia railways. Pop. (1950) 20.205 (mun.). The town is on the left bank of the Alcoy or Serpis river, which drains a rich and densely populated plain. The river enters the Mediterranean sea at the small harbour of Gandia (El Grao). 3 mi. N.E.

Among the ancient buildings are the Gothic church, the college founded by the director-general of the Jesuits (1510–1572) and the palace of the dukes of Gandia. The town manufactures leather. silk, velvet and ribbons, and exports fruit and imports coal, timber and flour.

GANDO, a former amirate of west Africa, in the northwest part of the Federation of Nigeria, and west of the Niger river. The state was established, about 1819, on the death of Othman Dan Fodio, the founder of the Fula empire. and its area and importance varied considerably during the 19th century. several of the Fula amirates being regarded as tributaries. while Gando itself was more or less dependent on Sokoto. Gando in the middle of the century included both banks of the Niger at least as far northwest as Say.

The districts outside the British protectorate now belong to France. Treaty relations with the British were entered into in 1884 and in 1903 the part assigned to the British sphere by agreement with France came definitely under the control of the administration in Nigeria.

Gando is included in the province of Sokoto. The chief town is Gando, on the Sokoto. the first considerable affluent of the Niger from the east, about 60 mi. S.W. of the town of Sokoto.

GANESHA or GANESH, in the post-Epic Hindu mythology. eldest son of Siva and Parvati. His name means leader of (Siva's) attendants; he is a creator of obstacles and as such came to be placated for their removal.

Depicted with an elephant's head, to symbolize his sagacity, he is the god of worldly wisdom; and is invoked on the first page of every book, especially in ledgers, as he bestows prosperity in trade.

He is worshipped all over India, especially in the south. and is affected by six sects, under his six titles. Maha-Ganapati, etc. These hold him, not Siva, to be the real first cause and the Hairamba Ganapatiyas are taxed with unedifying rites.

See "Ganapatiyas" in J. Hastings, *Encyclopaedia of Religion and Ethics*, vol. vi (Edinburgh, 1913).

GANESH DATTA SHASTRI, SHRI JAGADGURU (1861–1940), Indian philosopher who published several works on Sanskrit. was born on July 12, 1861, son of Pandit Upendra Datta Shastri. astronomer and Sanskritist. He was educated at the Oriental college, Lahore, and Punjab university, and in 1882 became a teacher. He held professorships of Sanskrit at Forman Christian college (1886- go;), Government college and of Vedanta philosophy at Oriental college (1908–17). In 1917 he was appointed senior professor of Sanskrit and theology at Sanatan Dharam college, Lahore. In 1926 he was invested by the government of India with the highest Sanskrit title of *Mahāmahopādhyāya;* he was the first Punjabi on whom this title was conferred. He died at Lahore in 1940. He trained a large band of scholars who made considerable contributions to Sanskrit scholarship. Shastri's works are still used.

His publications include: *The Students' Practical Sanskrit-English-Hindi Dictionary* (Lahore, 1905); *The Etymological Sanskrit-Hindi Dictionary*, called *Padmachandrakosh* (1898); *Shāstriyasiddhānta* (Lahore, 1909); and a commentary on the *Bhagavadgita* (1926).

GANGES (Hindi GANGA), a great river of northern India, formed by the drainage of the southern Himalayas. Its lower reaches focus the river system of Bengal and it falls into the Bay of Bengal after a course of 1.540 mi. The greater of its two main headstreams, the Xlaknanda, rises in the neighbourhood of the Garhwal-Tibet border. about 30 mi. N. of Nanda Devi; the lesser, the Bhagirathi, issues from an ice cave at the foot of a Himalayan snow bed near Gangotri. in Tehri-Garhwal district. Uttar Pradesh, 10,300 ft. above sea level. Devaprayag, the point of junction of the Alaknanda and Bhagirathi streams, is a celebrated place of pilgrimage, as is also Gangotri. At Sukhi it pierces the Himalayas and turns southwest to Hardwar. also a place of great sanctity. It proceeds by a tortuous course along the eastern boundaries of Dehra Dun. Saharanpur, Muzaffarnagar. Meerut, Bulandshahr. Aligarh and Etah districts. and into Farrukhabad. in which last district it receives the Ramganga. Thus far the Ganges has been little more than a series of broad shoals, long deep pools and rapids, except during the melting of the snows and throughout the rainy season. At Xllahabad. however, it receives the Jumna. a large river. which also rises in the Himalayas farther west. The combined river winds east by southeast through Uttar Pradesh. receiving the Gumti and the Gogra at consecrated spots. But the tongue of land at Allahabad (*q.v.*), where the Jumna and the Ganges join, is the true Prayag, or place of pilgrimage. to which hundreds of thousands of devout Hindus repair to wash away their sins in the sacred river. The great festival called the Magh Mela is held there.

Shortly after passing the holy city of Benares the Ganges enters Bihar and. after receiving the Sone from the south, passes Patna and is joined by the Gandak, which rises in Nepal. Farther east it receives the Kosi. and then. skirting the Rajmahal hills. turns sharply southward, passing near the ruined city of Gaur. Between Murshidabad and Rajshahi districts, down to where the Matabhanga branches off, the Ganges is the frontier between India and East Pakistan. The delta begins 220 mi. in a straight line. or 300 mi. by the windings of the river. from the Bay of Bengal. The main channel, which is in Pakistan, takes the name of the Padma or Padda. and proceeds in a southeasterly direction past Pabna to Goalanda. above which it is joined by the Jamuna or main stream of the Brahmaputra. The vast confluence receives further additions from the hill country to the east, and forms a broad estuary known as the Meghna. which enters the Bay of Bengal near Noakhali. This estuary. however, is only the largest and most easterly of a great number of mouths or channels. The most westerly is the Hooghly. which receives the waters of a number of distributary channels that start from the parent Ganges above Murshidabad.

Between the Hooghly on the west (in India) and the Meghna on the east (in Pakistan) lies the delta. Its northern angle consists of rich and fertile districts. such as Murshidabad and Twenty-four Parganas, Nadia in India and Jessore in Pakistan. But toward its southern base. resting on the sea. the country sinks into a series of swamps, intersected by a network of channels. This waste is known as the Sundarbans. from the sundari tree, which grows in abundance in the seaboard tracts.

The most important channel of the Ganges for commerce is the Hooghly (*q.v.*), on which stands Calcutta, about go mi. from the mouth. Above this city navigation is undertaken by native craft and is practicable as far as Garhmuktesar. 100 mi. below Hardwar. Below Calcutta important boat routes through the delta connect the Hooghly with the eastern branches of the river.

The catchment basin of the Ganges is bounded north by a length of about 700 mi. of the Himalayan range, south by the Vindhya mountains and east by the ranges which separate East Bengal from Burma; its area is nearly 450,000 sq.mi. and it forms one of the most densely populated river plains in Asia. The average fall from Allahabad to Benares is six inches per mile; from Benares to Calcutta. between four and five inches: from Calcutta to the sea, one to two inches.

Great changes take place from time to time in the river bed. Extensive islands are thrown up and attach themselves to the mainland, while the river deserts its old bed and seeks a new channel. perhaps many miles away. Many decayed or ruined cities attest such changes in ancient times.

The Ganges is crossed by six railway bridges on its course as far as Benares; by another at Mokameh. 60 mi. E. of Patna; and another at Sara in East Bengal. The Cpper Ganges canal and the Lower Ganges canal. with headworks at Hardwar, are the two principal systems of perennial irrigation in Uttar Pradesh.

GANGOTRI, a celebrated place of Hindu pilgrimage in the Himalayas. It is in Tehri-Garhwal district in Uttar Pradesh, India, on the Bhagirathi, one of the two chief headstreams of the Ganges. Gangotri contains a small temple about 20 ft. high, in which there are images representing Ganga, Bhagirathi and various other figures of mythology.

The bed of the river adjoining the temple is divided off by the Brahmans into three basins, where the pilgrims bathe. One of these basins is dedicated to Brahma. another to Vishnu and the third to Siva. The pilgrimage to Gangotri is considered efficacious in washing away sin and ensuring eternal happiness. The water taken from this sacred spot is exported by pilgrims to other parts of India. The temple is 10,319 ft. above sea level.

GANGPUR, a former feudatory state, geographically within Orissa, but administered under British paramountcy through the Eastern States agency.

The state had an area of 2,477 sq.mi. and a population (1941) of 398,171. Its capital was Suadi. After India became independent Gangpur was merged into Sundergarh district, Orissa (Jan. 1, 1948). and made into two subdivisions.

GANGRENE, a synonym in medicine for mortification or death of tissues of varying extent. There may be gangrene of an appendix, an extremity or of the whole body after death. It may result from injury. infection as in gas gangrene and from diseases of the blood vessels. There are various diseases in which it is prone to occur such as diabetes and arteriosclerosis. It is likely to occur after severe burns and freezing. Treatment varies with the cause but the recovery depends largely upon factors which prevent continuation or extension of the cause and the re-establishment of circulation. *See* also NECROSIS. (*F.* L. A.)

GANIVET, ANGEL (1865–1898), Spanish essayist and novelist, was born at Granada. He entered the diplomatic profession and was appointed consul at Antwerp, Helsingfors (where he published in 1896 his first book *Granada la bella)* and Riga. Ganivet shows a brilliant power of evocation in the novels *La Conquista del reino de Maya . . .* (1897) and *Los Trabajos del infatigable creador Pio Cid* (1898).

His best work lies, however: in the field of the essay—in the *Idearium español* (189; ; Eng. trans., *Spain: an Interpretation,* 1946), where, as in the *Epistolario* (1904), his original thought on Spanish problems has free play.

GANJA (KIROVABAD), a town in the Azerbaijan A.S.S.R., in 40° 43' N. and 46° 20' E., altitude 1,446 ft., on a northern spur of the Armenian plateau above the valley of the Kura river. Pop. (1956 est.) 111,000, mainly Tatars and Armenians.

The position of Ganja on the railway facilitated the production of wine and liquorice and textile manufactures, including wool. cotton and silk. It became the outlet for the copper mines of Kedabek and the sulphur pyrites of Chigari-dzor. Manganese is found in this district, where cotton plantations, vineyards, fruit gardens and a silkworm-breeding industry were also established. Beekeeping is profitable.

The town is very old, and changed hands between Persians, Khazars and Arabs even in the 7th century. Later it was captured by Mongols, Persians, Georgians and Turks. In 1904 it became Russian and was known as Elisavetpol until the formation of the Azerbaijan S.S.R., when it resumed its original name. In 1935 it was renamed Kirovabad.

In 1926 the Russians under Ivan Paskevich defeated a Persian attack on the town. Amid the ruins of old Ganja, 4 mi. distant, is the Green mosque, and the beautiful mosque of the Persian Shah Abbas (1620) is in the modern town. The Persian poet. Shah Nizam (Nizami), was probably born there about 1141 and his grave is said to be in the vicinity.

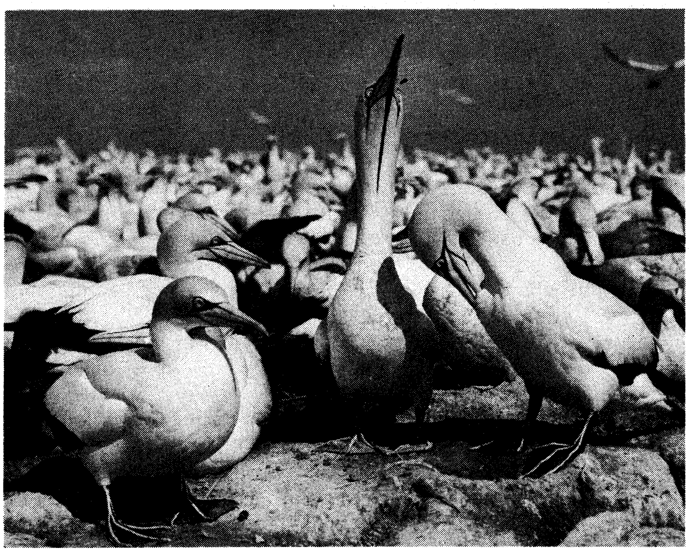
There is a marked contrast between the newer quarters and the winding, narrow! unhealthy ancient streets with their low-roofed, windowless huts.

GANJAM, a district of Orissa state, India; before 1936 in Madras. Area 4.828 sq.mi.; pop. (1951) 1,624,829. It is largely mountainous. rocky and afforested. The Maliahs. a chain of the Eastern Ghats. have an average height of about 2,000 ft. The chief rivers are the Rushikulya, the Vamsadhara and the Nagavali.

Ganjam formed part of the ancient kingdom of Kalinga. The inaccessible country long kept the rising Mohammedan power at hay; and it was not till nearly a century after the first invasion of Orissa that a Mohammedan governor was sent to govern the Chicacole Circar. including the present district of Ganjam. In 1753 the Northern Circars, including Chicacole. were made over to the French. In 1759 Masulipatam was taken by an English force, and the French had to abandon Ganjam and their other factories in the north. In 1765 the Northern Circars were granted to the English by imperial firman. and in Aug. 1768 an English factory was founded at Ganjam. protected by a fort. In 1816 Ganjam was overrun by the Pindaris; and in 1836 occurred the Gumsur campaign. when the British first came into contact with the aboriginal Kondhs and suppressed their practice of human sacrifice.

The district's principal crops are rice, other food grains, pulses and oilseeds; half the cultivated land is under irrigation. Many people are occupied with river and sea fishing and curing. Salt is evaporated. as a government monopoly, along the coast. Sugar is refined at Aska. The busy ports of Gopalpur and Calingapatam are only open roadsteads. The district is traversed throughout by the east coast line of the Eastern railway. The district headquarters are at Berhampur.

GANNET, any of several large gull-like sea birds which with the boobies constitute the family Sulidae, order Pelicaniformes, particularly three larger species (Morus) inhabiting cooler temperate seas. The North Atlantic gannet or solan goose (M. *bassana*) is 36 in. long, white tinged with pale yellowish straw on head and neck, and has a cigar-shaped body with stout pointed beak, pointed tail and long slender black-tipped wings. It breeds locally in large colonies on steep island cliffs and offshore rocks, principally about the British Isles but also at the Faeroes, Iceland, Labrador and islands in the Gulf of St. Lawrence, ranging south in winter to northwest Africa and the Gulf of Mexico. The most famous gannetry is located on Bass Rock, off the coast of Scotland.



AUTHENTICATED NEWS

SOUTH AFRICAN GANNET (MORUS CAPENSIS)

When in full plumage, at three years of age, the birds breed once a year after mutual courtship performances. A crude nest of seaweed and grasses is built on a ledge; one egg, rarely t o, of pale blue, hidden by thick chalk and nest stained, is incubated by both birds in turn for about 44 days. The young are hatched naked and blind, but soon become covered by white down, which is replaced by brown feathers speckled with white. The bird waddles on land, but is an expert flyer, moving in single file 30 to 40 ft. up over the sea, alternating rapid wing beats with gliding. With half-closed wings it plunges into the sea for fish, which it swallows whole.

While diving, the gannet is cushioned by subcutaneous air spaces connected with the lungs; the nostrils are closed. The bird floats high while sitting on the water. Young at the nest take regurgitated food from the wide-opened mouth of the parent.

There are two slightly smaller southern species: the South African or cape gannet (*M.* capensis), breeding on islands off the Cape of Good Hope; and the Australian gannet (M. serrator), middle tail feathers dark, breeding on islands about Tasmania and North Island, New Zealand.

The six smaller species, the booby gannets or boobies (Sula), so called because of their stupid appearance and reaction to man, breed on tropical and subtropical islands, ranging far over the sea. Three are cosmopolitan: the white-bellied brown booby (*S.* leucogaster); and two white species, the red-faced or red-footed booby (S. Sula), which usually nests in low trees, and the masked or blue-faced booby (S. dactylatra).

Two are important guano birds along the northwest coast of South America; the blue-footed booby or camanay (S. nebouxii), brown and white streaked in colour, found from western Mexico to northern Peru and the Galapagos Islands; and the Peruvian booby or piquero (S. variegata) of islands off the coast of Peru and northern Chile. It fishes in the cold Humboldt current offshore, has a white head and body and variegated brown and white back, wings and tail. S. *abbotti* breeds on Assumption and Christmas Islands in the Indian ocean. Boobies usually lay two eggs, in a slight depression in the sand or rock, with the exception of the red-footed booby which builds a nest of twigs in low bushes. They are preyed on by the frigate bird (*q.v.*). (G. F. Ss.)

GANODONTA, or TAENIODONTA, an extinct group of clawed mammals of the North American Palaeocene and Eocene. Seven genera are known, distributed in two subfamilies of the family Stylinodontidae. The more primitive Conoryctinae, confined to the Palaeocene, are rather generalized and insectivorelike. The Stylinodontinae, forming a progressive series throughout the Palaeocene and Eocene, culminate in large animals with high-crowned, rootless, columnar teeth, superficially slothlike. The skull is short faced. deep jawed and small brained. The tail is massive and the limbs are strong and heavy, of digging type, with large, compressed claws. Some students have maintained that the taeniodonts were edentates, related to the ground sloths, but more recent studies suggest that the resemblance is probably due to similar habits and not to common ancestry. The taeniodonts probably represent an independent and isolated offshoot of the earliest Insectivora. (G. G. Si.)

GANOID, any fish having ganoid scales, rhombic bony scales covered on the outer surface with a layer of ganoin, an enamellike shiny substance. It is now known that ganoid scales differ considerably in structure, and that the ganoids are not a natural taxonomic group. Most fish with ganoid scales are extinct. but the gar (Lepisosteus), sturgeon, paddlefish or spoonbill and bowfin survive in the fresh waters of North America and elsewhere, and the Polypteridae in the rivers of Africa. See FISHES.

GANYMEDE, son of Tros (or Laomedon), king of Troy. Because of his surpassing beauty, he was carried off by the gods, or Zeus or, according to a later myth, the eagle of Zeus or the god himself in eagle shape, to serve as cupbearer. In compensation, Zeus gave his father a stud of immortal horses (or a golden vine). From fairly early times (Theognis. 6th century B.C.), and perhaps especially among Dorians, his kidnapper was supposed to have a homosexual passion for him, hence the connotation which Catamitus, the popular Latin form of his name, had and has. A Cretan variant of the legend makes Minos, the island's primitive ruler, Ganymede's ravisher. He was later identified with the constellation Aquarius.

GAON, a Hebrew word (plural Geonim) meaning "excellency," describing the head of a talmudic academy. The Geonim were the spiritual leaders of post-talmudic and early medieval Jewry, and they functioned, with occasional lengthy interruptions, from the middle of the 7th century to the end of the 13th. Gaon is the fourth of a series of titles—Sofer, Tanna, Amora and Gaon—of Jewish postbiblical teachers. The geonic academies—which were engaged in the interpretation and development of the talmudic law, and thus served also as high courts adjudicating controversies over the law—arose first in Babylonia, and later appeared also in Palestine. The teaching of the Geonim, like that of their predecessors. safeguarded tradition, and their advice or decisions on points in the law (responsa) were often invoked far beyond the limits of their schools or communities. The responsa are of special importance for Jewish history and theology.

Among the great Geonim may be mentioned Sherira ben Hanina (d. 1000) of the academy at Pumbeditha, author of the famous letter addressed to Jacob ben Nissim of Kairwan in which the history of the talmudic and geonic periods is set forth; Amram ben Sheshna of the Sura academy, the first authority to arrange a complete domestic and synagogal liturgy; Saadia ben Joseph (*q.v.*) of Sura. who fought Karaism, translated the Scriptures into Arabic, compiled a dictionary and was a pioneer in the fields of theology and philosophy; and his contemporary and adversary, Aaron ben Meir of Jerusalem. The last great Geonim were Samuel ben Hofni (d. 1034), Hai ben Sherira (*q.v.*) and Samuel ben Ali, Gaon of Baghdad, contemporary and adversary of Maimonides (*q.v.*).

Jewish scholars usually differentiate between the Babylonian and Palestinian Geonim. There existed a constant rivalry between the two Gaonates, a rivalry which broke out in open struggle at the time of Saadia. Ben Meir lost the battle for supremacy, and thereafter the superior authority of the Babylonian Gaonate was rarely questioned.

The spread of talmudic studies during the geonic period to many Jewish communities in other countries brought about the establishment of talmudic academies outside Babylonia. There thus occurred a gradual weakening of the Babylonian Gaonate, which by the end of the 13th century had disappeared altogether. The age of codifiers succeeded, and their codes exercised great unifying influence over scattered world Jewry. The codes, especially Joseph Qaro's (*q.v.*) *Shulhan Arukh,* became the halakic authority in Jewry, and later activity in the field of Halakah centred in them.

After the end of the geonic period the word "Gaon" was used in Jewry merely as a title of honour, to describe excellence in learning. In later centuries one outstanding halakic authority, Elijah ben Solomon (*q.v.*), was called the Vilna Gaon or the Gaon. *See* also TALMUD.

GAP, the capital of an *arrondissement* in the French *département* of Hautes-Alpes, 122 mi. by rail from Marseille. Pop. (1954) 13,338. It is the *Vapincum* of the Romans founded by Augustus about 14 B.C. In 1232 most of the region passed from Provence by marriage to the dauphins of Viennois. The town itself, however, remained under the rule of the bishops until 1512, when it was annexed to the crown of France. The town was sacked by the Huguenots in 1567 and 1577, and by the duke of Savoy in 1692. It was the birthplace of the reformer Guillaume Farel (1489–1565), who first preached his doctrines there about 1561–62.

Gap is built at a height of 2,418 ft. on the right bank of the Luye (an affluent of the Durance). The 17th-century cathedral was entirely reconstructed (1866–1905). The prefecture contains scientific and archaeological collections, as well as the archives. which include many manuscripts from the monastery of Durbon. etc. The episcopal see of Gap, in the ecclesiastical province of Aix-en-Provence, first mentioned in the 6th century, was in 1791 enlarged by the annexation of that of Embrun.

GARAMOND (GARAMONT), **CLAUDE** (c. 1480–1561), French type designer and publisher, one of the first punch cutters to work independently of printers, who perfected the design of roman type faces and so assisted the roman letter to oust the gothic from European typography outside Germany, was born in Paris about 1480. He mas apprenticed about 1510 to A. Augerau and by 1520 was working with Geoffroy Tory. His first romans, and his *grecs du roi,* were cut for the great firm of Estienne. In 1545 he began to publish books, with P. Gaultier as his printer. He died in poverty in Paris in 1561. His roman fonts, cut from 1531 onward. surpassed the best Aldine romans in grace and clarity. and influenced European punch cutters for 150 years. His Greek set the pattern for Greek printing until the early 19th century; cut for Francis I in the 1540s, the *grecs du roi* displayed larger and more emphatic capitals than the Aldine Greek, but retained a larger number of ligatures and contractions. Garamond may have cut no italics until 1545, and then perhaps only two fonts; these followed the Aldine style in general, with a reduced number of ligatures, but were the most influential early italics to be designed with sloped and flourished capitals. Eighty years after his death. his types were copied and adapted by J. Jannon; revived forms of these copies bear Garamond's name today, but do not bear witness to his skill. (H. A. F. W.)

GARASHANIN, ILIYA (1812–1874), Serbian statesman. was born on Jan. 28. 1812. at Garasha (Kragujewac). In 1836 Prince Milosh appointed him a colonel and commander of the then just organized regular army of Serbia. In 1842 he was called to the position of assistant to the home minister, and from that time until his retirement from public life in 1867 he was repeatedly minister of home affairs. He rendered great services to his country as minister for foreign affairs. He sought to replace the Russian protectorate over Serbia by the joint protectorate of all the great powers of Europe. In 1853 he opposed co-operation with Russia against Turkey and the western powers. His anti-Russian views led Prince Menshikov, while on his mission in Constantinople, 1853, peremptorily to demand his dismissal. Nevertheless his personal influence in the country secured the neutrality of Serbia during the Crimean War. It was due to Garashanin that France proposed to the peace conference of Paris (1856) that the old constitution. granted to Serbia by Turkey as suzerain and Russia as protector in 1839. should be replaced by a more modern and liberal constitution, framed by a European international commission. But the agreement of the powers was not secured. Garashanin induced Prince Alexander Karageorgevich to convoke a national assembly. which had not been called to meet for ten years. The assembly was convoked for St. Andrew's Day 1858. but its first act was to dethrone Prince Alexander and to recall the old prince Milosh Obrenovich.

When after the death of his father Milosh (in 1860) Prince Michael ascended the throne, he entrusted the premiership and foreign affairs to Iliya Garashanin. The result of their policy was that Serbia was given a new, although somewhat conservative, constitution, and that she obtained, without mar, the evacuation of all the fortresses garrisoned by the Turkish troops on the Serbian territory, including the fortress of Belgrade (1867). Garashanin was preparing a general rising of the Balkan nations against the Turkish rule, and had entered into confidential arrangements with the Rumanians, Bosnians, Albanians. Bulgarians and Greeks, and more especially with Montenegro. But the execution of his plans was frustrated by his sudden resignation (at the end of 1867), and by the assassination of Prince Michael a few months later (June 10, 1868).

Although he was a Conservative in politics, and as such often in conflict with the leader of the Liberal movement. Yovan Ristich. Garashanin certainly was one of the ablest statesmen whom Serbia had in the 19th century.

His son, NILUTIN GARASHANIN (1843–1898), entered parliament in 1874. He was minister of the interior (1880–83), and prime minister (1884–87). In 1894 he became ambassador in Paris, where he died on March 7, 1898.

GARAT, DOMINIQUE JOSEPH (1749–1833), French writer who played a prominent part in political life between 1789 and 181j, was born at Bayonne (Basses-Pyrénées), Sept. 8. 1749. He was a deputy to the states-general and achieved notoriety for his accounts of its proceedings published in the *Journal de Paris.* Garat's assiduity in following the fluctuations of public opinion, however, made his role in politics undignified and ridiculous. He had the duty, as minister of justice, of informing Louis XVI of his death sentence and, after March 1793 when he became minister of the interior, of maintaining public order. Having failed conspicuously in this latter task, he resigned (Aug. 1j) and was arrested on Oct. 2, 1793. Although he owed his prompt release and freedom from interference during the Terror to friendship with Robespierre, this debt did not prevent his turning against the dictator on 9th Thermidor. After the revolution of 18th Brumaire, he quickly became a supporter of Napoleon who rewarded Garat's adulation with the titles of senator (1800) and count (1808), while from 1803 he was also a member of the Institute of France. Garat was unsuccessful in his attempt to change sides yet again in 1814 and 1815, and during the Bourbon restoration he went into retirement. He was, horn-ever, recalled to his place in the Institute in 1832.

Garat died near Ustaritz (Basses-Pyrénées), Dec. 9, 1833.

GARAT, PIERRE-JEAN (1764–1823), French singer, nephew of Dominique Joseph Garat, was born in Bordeaux on April 25, 1764. Gifted with a voice of exceptional timbre and compass he was the favourite singer of Marie Antoinette. to whom he gave lessons. At the beginning of the Revolution he accompanied Rode to England, where the two musicians appeared together in concerts. He returned to Paris in 1794 but fell under suspicion, was imprisoned for a short time, and then left Paris for Hamburg. He gained a great reputation in all the capitals of Europe, and retained his voice for a long period. He was a keen partisan of Gluck in opposition to Handel. On the institution of the Paris conservatory he became its first professor of singing and had many famous pupils.

See Bernard Miall, *Pierre Garat* (1913).

GARBORG, ARNE EVENSEN (1851–1924), Norwegian writer, was born on Jan. 25, 1851, at Thime. He joined the movement for the creation of a Norwegian literary language based on the *landsmaal* or peasant dialect derived from old Norsk, in place of the Dano-Norwegian literary medium. He wrote a series of novels deeply penetrated by religious feeling. In 189j he wrote a cycle of lyric poems in the *landsmaal, Haugtussa* (1895), which describe a young girl's belief in the supernatural. He also translated the *Odyssey* (1918) and a selection from the *Mahabharata* (1921), and, for representation at the *landsmaal* theatre, which he and his wife had founded, Holberg's classical comedy, *Jeppe paa Berget* (1921). His collected works, *Skrifter i samling,* began to appear in 1908. Garborg died on Jan. 14, 1924, at Asker.

GARÇÃO, PEDRO ANTÓNIO CORREIA (1724–1772), one of the principal neoclassical Portuguese poets. Born in Lisbon on April 29, 1724, he was the son of a foreign office official; his mother was of French descent. He studied law at Coimbra but does not appear to have taken his degree. In 1751 his marriage brought him a rich dowry and he had a moderately lucrative post in the *Casa da Índia,* but later a lawsuit reduced him to poverty. From 1760 to 1762 he edited the *Lisbon Gazette.* In 1756 he became a member of the *Arcádia Lusitana,* a literary society founded to rid Portuguese poetry of the still-persisting 17th-century liking for conceits, windy words and rhetorical phrases. For reasons which are still obscure Garção was arrested in April 1771 and imprisoned, but he was never brought to trial. He died in Lisbon on the day of his release, Nov. 10, 1772.

Taking Horace as his model, and aided by sound judgment, scholarship and wide reading, Garção adopted a classical simplicity of form and expression. His sonnets and epistles reveal him as a man of good taste and good sense, devoted to his friends and possessing high ideals of conduct and of art. His verse comedies, the *Teatro Novo* (1766) and the *Assemble'ia ou Partida* satirize respectively the theatre and the social life of Lisbon. In the "Cantata de Dido," included in the latter play, he combined the spirit of classical art with perfection of form to produce one of the most celebrated 18th-century Portuguese poems.

BIBLIOGRAPHY.—Garção's works were published posthumously (1778). The most complete edition is by J. A. de Azevedo Castro, *Obras poéticas* e *oratórias* (1888). *See* also T. Braga, *A Arcádia Lusitana* (1918); F. de Figueiredo, *História da Literatura Clássica,* 2nd. ed. (1924); H. Cidade, *Lições de cultura e literatura portuguesas,* vol. 2 (1940). (N. J. L.)

GARCÍA (DEL POPOLO VICENTE), MANUEL (1775–1832), Spanish tenor singer and composer, was born in Seville on Jan. 22, 177j. At 17 he made his début on the stage at Cádiz, in an operetta which included songs of his own composition. He had already a considerable reputation as a composer of light operas and as an operatic singer when he appeared in Paris in 1808, in Paer's opera *Griselda.* At Naples later he created some famous rôles in Rossini's operas, and sang them until 1816 when he visited London and Paris. Between 1819 and 1823 he lived in Paris, singing in *Il Barbière, Otello, Don Giovanni,* etc., and producing some operas of his own—he wrote about 100 in all—of mhich *La Morte* di *Tasso* mas the most important. But his greatest work was done as a teacher of singing in London and Paris. Of his principles and method he left an account in his *Metado di Canto,* the substance of which was subsequently incorporated by his son Manuel in his admirable *Traité complet de l'art du chant* (1847). He died in Paris on June 2, 1832.

His son, MANUEL GARCÍA (1805–1906), who celebrated his hundredth birthday in London on March 17, 1905, was born at Madrid, and as a teacher became no less famous than his father. He was a professor at the Paris Conservatoire (1830–48), at the Royal Academy of Music, London (1848–95), and will be remembered, it is safe to say, so long as the art of singing is studied, as the inventor of the laryngoscope.

See M. Sterling Mackinlay, *Garcia the Centenarian and his Times* (1908).

GARCÍA DE LA HUERTA Y MUÑOZ, VICENTE ANTONIO (1734–1787), Spanish playwright, poet and critic, achieved success with *Raquel* (1778), a drama of national history, but of modern outlook, and the only actable Spanish tragedy of his era. He was born at Zafra, March g, 1734, and died at Madrid on March 12, 1787. His translations from Sophocles and Voltaire and his affection for the traditional Spanish stage indicate a breadth of interest which sometimes confused his critical judgment; *e.g.,* in his eccentric collection *Teatro Hespañol* (1785–86). As a polemist, defending Spanish literature, he was inefficient, but as a poet he had lyrical moments which are unjustly forgotten.

(I. L. Mc C.)

GARCÍA LORCA, FEDERICO: *see* LORCA, FEDERICO GARCÍA.

GARD, a department in the south of France, part of the old province of Languedoc. Pop. (1954) 396,742. Area 2,271 sq.mi. It is bounded N. by the departments of Lozbre and Ardbche, E. by the Rhône, which separates it from Vaucluse and Bouches-du-Rhône, S. by the Mediterranean, S.W. by Hérault and W. by Aveyron. Gard is divided into three sharply-defined regions. The tree-clad Cévennes, with their deep and fruitful valleys, occupy the northwest, reaching a height of 5,120 ft. on the frontier of Lozbre. The Garrigues, a dry, hilly limestone region stretches south from the Cévennes over about half the department, and grows cereals, grapes and olives. The southern coastal plain is unhealthful because it has numerous lagoons and marshes, but it comprises the best arable land and vineyards in Gard.

Besides the Rhône and the Ardkche, the principal rivers are the Ckze. Gard, Vidourle and Hérault. They all rise in the Cévennes, and the Ckze and the Gard feed the Rhône, the lower Vidourle forming the southwest boundary of the department. The Hérault rises, and flows for a short part of its course, in the west of Gard. The upper course of the river Gard is in mountain gorges, and melting snows often cause disastrous floods. Near Remoulins it is crossed by a celebrated Roman aqueduct — the Pont du Gard. The canal de Beaucaire extends from the Rhône at Beaucaire to Aigues-Mortes. which communicates with the Mediterranean at Grau-du-Roi by means of the Grand-Roubine canal.

The climate is narm in the southeast. colder in the northwest; it is rather changeable, and rain storms are common. The cold and violent northwest wind known as the mistral is its worst drawback. Les Fumades (near Allkgre) and Euzet have mineral springs. The chief grain crops are wheat and oats. Rye, barley and potatoes are also grown. Gard is famed for its cattle. its breed of small horses and its sheep, which yield very fine wool. In the rearing of silkworms it ranks first among French departments. The principal fruit trees are olive, mulberry and chestnut. The vine is extensively cultivated and yields excellent red and white wines. The department is rich in minerals namely coal, iron, lime, lignite, asphalt. zinc, lead and copper, for the most part situated in the neighbourhoods of Alès and La Grand' Combe and Le Vigan. Much salt is obtained from the coastal marshes. The fisheries are productive. Manufactures include silk, of which Alès is the chief centre, cotton and woolen fabrics, hosiery, carpets, ironware, hats (Anduze), gloves, paper, leather, earthenware and glass. There are important metallurgical works, the chief of which are those of Besskges. The exports of Gard include coal, lignite, coke, asphalt, building stone, iron, steel. silk. hosiery, mine, olives. grapes and truffles.

The department is served by the P.L.M. railway. It is divided into the three arrondissements of Nîmes, Alks and Le Vigan, with 40 cantons and 353 communes. The chief town is Nimes, the seat of a bishopric of the province of Avignon and of a court of appeal. Gard belongs to the 15th military region (Marseilles), and to the académie (educational division) of Montpellier. Nîmes, Alks, Uzès, Aigues-Mortes, Beaucaire, Saint-Gilles, Bessèges, La Grand' Combe and Villeneuve-lès-Avignon are the principal towns. Opposite the manufacturing town of Pont-St.-Esprit the Rhône is crossed by a fine medieval bridge more than 1,000 yd. long built by the Pontiff brethren. Le Vigan, an ancient town with several old houses, carries on silk spinning.

GARDA, LAKE OF, Italy, the most easterly and the most extensive of the Lombard lakes (the *Lacus Benacus* of the Romans), surpassed in the Alpine region only by those of Geneva and Constance. The lake is now divided between the provinces of Verona, Brescia and Trento. Its broad basin orographically represents the southern portion of the valley of the Adige, though that river now flows through a narrow trench which is separated from the lake by the long narrow ridge of the Monte Baldo (7,277 ft.). The lake is fed by the Sarca at its north end, while at the southern extremity of the lake the Mincio flows out, on its way to join the Po. The area is 143 sq.mi., length $32\frac{1}{4}$ mi., greatest breadth about 10 mi., height of surface above sea-level 213 ft. and the greatest depth 1,135 ft. Its upper northern end is narrow, but between Garda (east) and Salo (west) the lake expands gradually into a nearly circular basin. Because of this conformation the lake is much exposed to sudden and violent winds. The steep grey limestone crags of Monte Baldo, on the eastern side of the lake, contrast strongly with the rich vegetation on the western and southern shores. The portion of the western shore that extends from Gargnano to Salo is the most sheltered and warmest part of the region, so that not merely does it resemble one continuous garden (producing lemons, figs, mulberries and olives) but is frequented in winter. The lovely promontory of Sermione (anc. Sirmio) at the southern end of the lake, has also an extremely luxuriant vegetation. It was a favourite residence of Catullus; but the large ruins of a Roman villa on the promontory belong to the imperial period, while there are also remains of the Lombard period, and a fine castle of the Scaligers.

At the south end of the lake are the towns of Peschiera ($14\frac{1}{4}$ mi. by rail from Verona on the east) and of Desenzano ($17\frac{1}{2}$ mi. by rail from Brescia on the west), which are $8\frac{3}{4}$ mi. distant from each other. There is a regular steamer service from these two towns. On the west shore of the lake are Salò, Maderno, Toscolano (a place important in the early history of the printing press), Gargnano and Limone, while the rugged east shore can boast only of Bardolino and Garda. At the northern end of the lake is Riva.

GARDELEGEN, a town in the district of Magdeburg, Germany, on the main Berlin-Hanover railway. Pop. (1950) 13,385. Gardelegen was founded in the 10th century, and on the neighbouring heath Margrave Louis I of Brandenburg gained, in 1343, a victory over Otto of Brunswick. It has a Romanesque church, and a hospital founded in 1285. There are considerable manufactures, notably agricultural machinery and buttons, and its beer has a great repute.

GARDEN, MARY (1877–), U.S. operatic singer, was born at Aberdeen, Scot., on Feb. 20, 1877. At the age of six she was taken to the United States. In 1888 her family settled in Chicago, where her early musical training was received. She went to Paris in 1896, and studied under Trabadello, Chevallier and Fougère. She made her debut at the Opéra Comique, Paris, April 3, 1900, in the title rôle of *Louise.*

Miss Garden's first appearance in the United States was in New York city in the title role of *Thais,* Nov. 25, 1907. In 1910 she became a member of the Chicago Civic Opera company, assuming, among others, the parts of Salomé, Thai's, Mélisande and Louise. She was general director of the Chicago Opera Association in 1921–22. In 1927 she sang in *Pelléas et Mélisande* in Geneva, Switzerland; also in Paris in the opera *Resurrection.*

She retired in 1934.

GARDEN: *see* HORTICULTURE; LANDSCAPE ARCHITECTURE.

GARDENA, a city of California, U.S., on the southern plain of Los Angeles county, 9 mi. S. of Los Angeles. Founded in 1883 as a farming community, it was known as a garden spot in a semi-arid region. Its growth was very slow for more than 25 years. In 1909, the town moved farther west to avoid being included in the "shoestring strip" connecting Los Angeles with San Pedro harbour. It was incorporated in 1930 with less than 3,000 residents.

Following World War II, Gardena changed rapidly into a commercial and residential city. Its citizens include a broad cross section of economic, cultural and religious groups. Manufacturing and oil production in neighbouring areas provide the principal means of employment. Local schools have been a part of the Los Angeles school district since 1907.

For comparative population figures *see* table in CALIFORNIA: *Population.* (R. C. GM.)

GARDEN CITIES. This term, first used in 1869 by A. T. Stewart in connection with the development of an estate on Long Island, N.Y., was adopted by Ebenezer Howard in writing *To-morrow: A Peaceful Path to Real Reform* (London, 1898), in which he outlined a scheme for building a new model town to be called "Garden City." Apart from the name and the fact that Howard's proposal included the idea of houses with gardens in a planned area there was nothing in common between Stewart's scheme and his. In fact Howard owed much to Edward Gibbon Wakefield's A *View of the Art of Colonization* (London, 1849). The publication of Howard's book led to the formation of the Garden Cities association in 1899 and to the establishment of Letchworth, the first garden city, in 1903, and Welwyn, the second, in 1920. The main features of Howard's scheme were (1) purchase of a large area of agricultural land within a ring fence; (2) planning of a compact town surrounded by a wide rural belt; (3) accommodation of residents, industry and agriculture; (4) limitation of the extent of the town and prevention of encroachment upon the rural belt; (5) the rise in land values to be secured for the town itself.

Howard based his scheme upon the urgent need for remedying the congestion of towns and the depopulation of the countryside. He suggested that, since towns grew because people were attracted to them from country districts which they did not like, the country must be made attractive by establishing there the qualities of town life. The new town could be limited in extent because it is possible, he considered, to get everything that is required in a town of about 30,000, while a group of such towns would between them provide all the advantages of a big city; and because the inhabitants of the rural belt would be kept in close touch with town life and rural interests would form part of the town's economy. Such towns scattered over the country would, he believed, check rural depopulation and the overgrowth of the great towns.

The garden city was to be created by a private corporation and would raise money on loan, lay out the town, construct the roads, drainage, public services, etc., and let the land on revisable leases, rents increasing with the growth of population. How-ard showed that reasonable rents would be amply sufficient to pay a return on the expenditure, leaving a considerable surplus. The rents, moreover, were to be "rate-rents," that is to sap they were to include such charges on property as were normally required to meet the expenditure of the local authority. Howard contended that his scheme was practicable for two main reasons: (1) if land were purchased at agricultural value and a large population brought to it, the increment in land value would be sufficient to provide a substantial economic foundation; (2) as manufacturers were establishing works on the outskirts of towns and in country villages because they found the costs and conditions of working in the cities too onerous, a concerted movement of industry could be organized from the over-burdened cities to the garden cities.

Howard's proposals attracted many people interested in the question of industrial housing: in the garden cities good houses could be cheaply provided ior the working classes. When Howard put forward his scheme there was no public interest in England in town planning, but the advantages of planning a town before building it were appreciated and gave additional point to his contentions. The housing and town-planning movements of the 20th century were thus profoundly influenced by the garden city movement, but the specific proposals for garden cities and the general ideas on which they were based were by no means expressed in the housing and town-planning activities that reached their heights in England in the years immediately after World War I. In particular the development of "garden suburbs" was contrary to Howard's idea, which was concerned with a town as a whole.

Letchworth.—In 1903 the first garden city was established on Howard's plan. An area of 3,822 ac. (afterward increased to 4,552) was purchased, 35 mi. from London and within $2\frac{1}{2}$ mi. of the old market town of Hitchin in Hertfordshire. A joint stock company, First Garden City Ltd., was formed to carry out the enterprise, with an authorized capital of £300,000, the dividend limited to 5% per annum. A plan was prepared for a town of 32,000 inhabitants (afterward increased to 35,000), with areas for houses, schools, etc., shops and factories and a rural belt. Development started in 1904. The company constructed the roads, drainage system, water, gas and electricity supplies. By 1951 the town had a population of 20,322, occupied with engineering, corset making, printing and bookbinding. Industrial growth continued. London county council proposed building houses ior London's overspill, which would virtually complete the scheme. In 1956 the company surrendered the limited-dividend principle.

Welwyn Garden City.—The second garden city was started in

1920 by a joint stock company (an authorized share capital £250,000, dividends not to exceed 7%). Welwyn, 20 mi. from London, north of Hatfield, consisted of 2,383 ac. (afterward increased to 5,071), on which a town of 50,000 with a rural belt was planned. The estate purchased was completely rural, and the company constructed roads, drainage, water, electricity and other supplies. By 1951 the town had a population of 18,314 with engineering, breakfast food and radio iactories, printing and other industries.

Although the Welwyn scheme at its inception aroused great interest the company experienced difficulties owing to shortness of capital and underwent two financial reconstructions, at the end oi which it abandoned the limited-dividend principle. The scheme made slower progress than was expected; but it demonstrated the economic advantages of a town site held in a single hand. The features of Welwyn are its consistent architectural development, site planning, public gardens, and large central departmental stores owned by the company, with other individual shops. As at Letchworth, land was let on building lease (but for 999 years).

Planning After World War 11.—World War II had a very adverse effect on the two garden cities: virtually no houses, factories or other buildings could be erected except for war purposes; both towns became overcrowded as evacuation areas; and there was some change in industry and population. Furthermore, the effect of the Town and Country Planning act, 1947, was to remove for nearly five years the economic basis upon which the garden cities were established, for the unearned increment (or improved value) of land was appropriated by the state in "development charges" (abolished in Nov. 1952). Moreover, although Sir Patrick Abercrombie's *Greater London Plan* (1944) showed the value of the two garden cities' contribution, the minister of town and country planning reduced the ultimate population of Letchworth to 32,000 and that of Welwyn Garden City to 36,500.

Under the New Towns act, 1946, however, Welwyn Garden City was expropriated, its building and development organization scrapped and the completion of the town entrusted to a new development corporation financed by the British treasury. The Garden City company was thus forced into liquidation. But even though the basis of compensation did not permit recognition of the full value of the property, total compensation of £3,550,000 in cash was paid for the land and building expropriated, a sum far in excess oi all that the company had spent. If the town had been completed as projected so that the economic results could have been fully realized and preserved for the town, Howard's idea of rate-rents might well have been proved right, at least in part. At Letchworth the minister was content to lay down conditions for development and to put a representative on the board of directors; otherwise the company was allowed to continue, but as mentioned above it has departed from its basic principle.

Letchworth and Welwyn Garden City were the only garden cities in Great Britain, or indeed in the world, but now exist as such only in name. While the new towns sponsored by the British government, as well as building development schemes in the U.S. and on the continent of Europe, borrowed certain characteristic and important features of the garden city idea, their economic structure was not the same, and in particular the principle of the rural belt as an integral part of town structure was not observed.

BIBLIOGRAPHY.—Ebenezer Howard, *Garden Cities of Tomorrow* (1902); Sir Patrick Abercrombie, *Greater London Plan* (1944); C. B. Purdom, *The Building of Satellite Towns,* rev. ed., (1949). (C. B. P.)

United States.—In the U.S., there was a long tradition in the development of industrial communities by private corporations, sometimes well-planned but more often lacking in spaciousness or attractiveness. The stigma of the "company town" frequently detracted from those which were built to high standards of design and construction, and no attempt was made in the early years of the 20th century to follow the conception of the garden city developed in the writings of Ebenezer Howard. Among better examples of well-planned industrial communities were Chicopee, Ga.; Kingsport, Tenn.; Kohler, Wis.; and Longview, Wash.

Planning of new communities in the United States along lines similar to those of the English garden cities of Letchworth and Welwyn came during World War I. New housing communities were designed for the United States Shipping board by teams of town planners, architects and engineers, some of the best of them having many oi the features of the English garden city. The plans for these-communities were also influenced by the examples of Forest Hills Gardens, N.Y., planned in 1911 by Frederick Law Olmsted, Jr., in collaboration with Grosvenor Atterbury as architect, and of Kingsport, Tenn., designed by John Nolen in 1915.

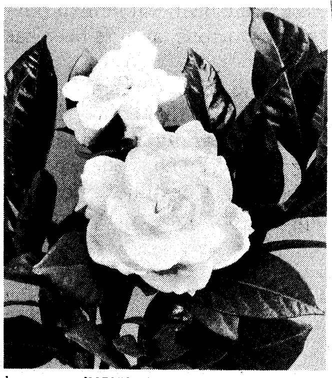
However, the nearest approach to the development in the United States of garden cities which followed the principles laid down by Ebenezer Howard was exemplified by Radburn, N.J.—the "Town for the Motor Age," designed by Clarence Stein and Henry Wright ior the City Housing corporation in 1928—and the various Greenbelt towns built by the Suburban Resettlement Division of the U.S. Resettlement administration during the late 1930s. While these communities had many of the features of the garden city such as comprehensive planning, low residential densities and controls over the extent and type of future development, none was self-sufficient industrially or was surrounded by a permanent belt of rural land. While the Greenbelt towns were originally owned by the federal government, they were later sold in whole or in part to private individuals or co-operatives.

During World War II a number of new communities were built by agencies of the federal government, such as Oak Ridge, Tenn., constructed by the Atomic Energy commission. The privately sponsored "new town" of Park Forest, Ill., in suburban Chicago, designed by Elbert Peets for American Community Builders, Inc.. was an excellent example of a well-planned residential community. It lacked diversity in its social structure and was dependent on the larger city ior its economic base, but it provided a low density residential development surrounded largely by publicly owned reservations giving the community many of the advantages of the English garden city. Another postwar example of a large-scale residential community which was planned and completed in its entirety by private interests was Levittown, Pa. It mas developed primarily to serve the needs of employees of a new steel plant built at a considerable distance from established population centres. (F. J. A.)

GARDEN CITY, a village of Nassau county, on west Long Island, 18 mi. E. of New York city, in southeastern New York, U.S., is one of the few communities in the United States that was planned as a model town from its beginning. In 1869 Alexander T. Stewart, one of New York's leading merchants, bought a tract of over 7,000 ac. of the Hempstead plain with the idea of creating a "garden city," a term adopted later by the pioneer English city planner Sir Ebenezer Howard. (See GARDEN CITIES) Stewart envisioned parks and tree-lined avenues not less than 80 ft. wide. His heirs founded The Garden City company, which guided the affairs of the community until its incorporation as an independent village in 1919.

Garden City is distinguished for its handsome residential areas and for the beautiful Cathedral of the Incarnation, the see of the Episcopal diocese of Long Island. Industries include publishing and printing. Points of interest are Adelphi college, founded in Brooklyn in 1896 (moved to Garden City in 1929) as the first degree-granting liberal arts college on Long Island, and Roosevelt field, named for Theodore Roosevelt's son Quentin, a World War I aviator, and noted as the airport where Charles A. Lindbergh began his transatlantic flight in 1927. (The field was closed to flying in 1951 and became the site of a large shopping centre, dedicated as the Roosevelt Field Development International Flight mall in 1956.) For comparative population figures see table in NEW YORK: Population. (WI. M. D.)

GARDENIA, a genus of evergreen shrubs and trees of the madder family (Rubiaceae; *q.v.*), containing about 60 species, natives of subtropical parts of the old world. Several are grown in greenhouses for their handsome, sweet-scented white flowers, which are developed singly at the end of a branch or in the leaf axils and are funnel- or salver-shaped, with a long tube.



J. HORACE MCFARLAND CO

GARDENIA (G JASMINOIDES)

The double forms of Gardenia *jasminoides* (China), the Cape jasmine, or gardenia of the florists are among the most beautiful and highly perfumed of any in cultivation. Gardenias are readily propagated by cuttings.

The outdoor culture of a more hardy form than the gardenia of the florists is common in the warmer parts of the United States. The shrub, usually called *Gardenia* jasminoides fortuniana (or G. veitchii), is 6–8 ft. high and produces its very fragrant white flowers in midsummer.

This particular gardenia mill not stand severe frosts and requires a rich, acid soil. No other plant of outdoor culture is so spicily fragrant.

A form of it, known as G. radicans, is perhaps only a low, more or less prostrate variety of the Cape jasmine and is widely grown along the Gulf coast and in California. (N. TR.)

GARDENING: see HORTICULTURE.

GARDINER, SAMUEL RAWSON (1829–1902), English historian, son of Rawson Boddam Gardiner, was born near Alresford, Hants. He was educated at Winchester and Christ Church, Oxford, where he took a first class in *literae humaniores,* and became a fellow of All Souls (1884) and Merton (1892). For some years he was professor of modern history at King's college, London. Gardiner, who was himself a descendant of Cromwell and Ireton, is the historian of the Puritan revolution, and has written its history in a *History of England from the Accession of James I to the Outbreak of the Civil War, 1603–1642*, 10 vol. (1863–82); *History of the Great Civil War, 1642–1649*, 4 vol. (1886); and *History of the Commonwealth and Protectorate, 1649–1660*, 3 vol. (1894–1903). His researches in public and private collections of manuscripts at home, and in the archives of Simancas, Venice, Rome, Brussels and Paris, were indefatigable. In his judgments of men and their actions he is unbiassed, and his appreciations of character exhibit a remarkable fineness of perception and a broad sympathy. Throughout his work he gives a prominent place to everything which illustrates human progress in moral and religious as well as political conceptions, and specially to the rise and development of the idea of religious toleration, finding his authorities not only in the words and actions of men of mark, but in the writings of obscure pamphleteers, whose essays indicate currents in the tide of public opinion.

Gardiner's style is clear and unadorned; he appeals constantly to the intellect rather than to the emotions, and is seldom picturesque, though in describing a few famous scenes, such as the execution of Charles I., he writes with pathos and dignity. Among the most noteworthy of his separate works are: *Prince Charles and the Spanish Marriage* (2 vols., 1869); *Outline of English History* (1st. ed. 1887, later ed. 1919); *Constitutional Documents of the Puritan Revolution, 1625–1660* (1st ed., 1889; 3rd ed., 1906); *Student's History of England* (2 vols., 1st ed. 1890–91; later ed. 1920); *What Gunpowder Plot Was* (1897); *Oliver Cromwell* (1901). He edited collections of papers for the Camden Society, and from 1891 was editor of the *English Historical Review.*

See H. B. Learned, *Samuel Rawson Gardiner* (1902); R. G. Usher, "Critical study of the historical method of S. R. Gardiner," in *Washington University Studies,* vol. iii., part ii., no. i. (1915).

GARDINER, STEPHEN (1493?–1555), English bishop and lord chancellor, was born at Bury St. Edmunds, the son of a cloth merchant. He was educated at Trinity Hall, Cambridge, and became doctor of civil law in 1520, and of canon law in the following year. About 1525 he was made secretary to Cardinal Wolsey whom he accompanied on his important diplomatic mission to France in 1527. Next year Gardiner was sent by Wolsey to Italy with Edward Fox, provost of King's college, Cambridge, to promote the business of Henry's divorce from Catherine of Aragon. Though he failed to procure the desired decretal commission, Gardiner by his great intrepidity, won from Clement his consent to a general commission for Campeggio and Wolsey to try the cause in England. This, as Wolsey saw, was quite inadequate and he again instructed Gardiner to press the pope to send the desired decretal on, even if the latter was only to be shown to the king and himself and then destroyed. At last the pope gave what was desired on the express conditions that Campeggio was to show it to the king and Wolsey and no one else, and then destroy it, the two legates holding their court under the general commission. In 1529 Gardiner was sent again to Italy, but this time the pope would make no further concessions, or promise not to revoke the cause to Rome.

Gardiner's services, however, were fully appreciated. He was appointed the king's secretary. He had been already some years archdeacon of Taunton, and the archdeaconry of Norfolk was added to it in March 1529, which two years later he resigned for that of Leicester. In 1530 he was sent to Cambridge to procure the decision of the university as to the unlawfulness of marriage with a deceased brother's wife, in accordance with the new plan for settling the question without the pope's intervention. In this he succeeded, though not without a good deal of artifice. In Nov. 1531 the king rewarded him with the bishopric of Winchester, vacant by Wolsey's death. In 1532, nevertheless, he displeased the king by the part he took in the preparation of the famous "Answer of the Ordinaries" to the complaints brought against them in the House of Commons.

His next important action was not so creditable; for he was "assistant" to Cranmer as counsel for the king, when the archbishop, in the absence of Catherine, pronounced her marriage with Henry null and void on May 23, 1533. Immediately afterwards he was sent to Marseilles, where an interview between the pope and Francis I. took place in September, of which event Henry stood in great suspicion, as Francis had hitherto maintained the justice of his cause. At this interview Bonner intimated the appeal of Henry VIII. to a general council in case the pope should proceed to sentence against him. This appeal, and also one on behalf of Cranmer presented with it, were drawn up by Gardiner. In 1535 he and other bishops were called upon to vindicate the king's new title of "Supreme Head of the Church of England." The result was his celebrated *De vera obedientia,* the ablest of all the vindications of royal supremacy, reprinted in 1537 by the Swiss reformers. In the same year he had a dispute with Cranmer about the visitation of his diocese. He was also employed to answer the pope's brief threatening to deprive Henry of his kingdom. During the next few years he was engaged in various embassies in France and Germany until 1538 when, owing to Cromwell's mistrust, he was replaced as ambassador in Paris by Bonner. In 1539 he took part in the enactment of the severe statute of the Six Articles, which led to the resignation of bishops Latimer and Shaxton and the persecution of the Protestant party. In 1540, on the death of Cromwell he was elected chancellor of the University of Cambridge. A few years later he attempted to fasten a charge of heresy upon Archbishop Cranmer in connection with the Act of the Six Articles; and but for the intervention of the king would probably have succeeded. Though he had supported the royal supremacy, Gardiner objected to the religious doctrines of the Reformation. He had to contend with frequent storms of royal indignation; but the king had need of him quite as much as he had of Cranmer; for Gardiner, even under royal supremacy, was anxious to prove that England had not fallen away from the faith, while Cranmer's authority as primate was necessary to upholding that supremacy. Thus Gardiner and the archbishop maintained opposite sides of the king's church policy; and though Gardiner was encouraged by the king to put up articles against the archbishop for heresy, the archbishop could always rely on the king's protection.

Under Eduard VI. Gardiner was completely opposed to the policy of the dominant party both in ecclesiastical and in civil matters. The religious changes he objected to both on principle and on the ground of their being moved during the king's minority, and he resisted Cranmer's project of a general visitation. His remonstrances, however, were met by his committal to the Fleet, and the visitation of his diocese was held during his imprisonment. Though soon released, it was not long before he was called before the council, and, refusing to give them satisfaction, was thrown into the Tower, where he remained for over five years. His bishopric was given to Poynet, a chaplain of Cranmer's and bishop of Rochester. On Mary's accession, Gardiner was restored to his bishopric, and as lord chancellor, set the crown on the queen's head at her coronation. He also opened her first parliament and for some time was her leading councillor.

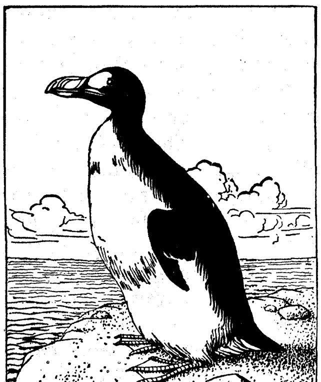
He was now called upon, in advanced life, to undo not a little of his early work—to vindicate the legitimacy of the queen's birth and the lawfulness of her mother's marriage, to restore the old religion, and to recant what he had written touching the royal supremacy. It is said that he wrote a formal retraction of his *De vera obedientia* which is no longer extant. As chancellor he negotiated the queen's marriage treaty with Philip, to which he shared the general repugnance, though he could not oppose her will. In executing it, however, he provided that the Spaniards should in nowise interfere in the government of the country. After the coming of Cardinal Pole, and the reconciliation of the realm to the see of Rome, he still remained in high favour. He no doubt approved of the act, which passed the House of Lords while he presided there as chancellor, for the revival of the heresy laws. Neither is there any doubt that he sat in judgment on Bishop Hooper, and on several other preachers whom he condemned to be degraded from the priesthood. But he endeavoured to save the lives of Cranmer and Northumberland, and much as he was maligned by opponents, there are strong evidences that his natural disposition was humane and generous. In May 1553 he went to Calais as one of the English commissioners to promote peace with France; but their efforts were ineffectual. In Oct. 1555 he again opened parliament as lord chancellor, but soon fell ill and died at Whitehall on Nov. 12. He was buried in Winchester cathedral.

Besides his conspicuous statesmanship and legal ability, Gardiner possessed a learning in divinity far from commonplace. His part in the drawing up of doctrinal formularies in Henry VIII.'s time is not clear; but at a later date he wrote tracts in defence of the Real Presence against Cranmer, some of which, being written in prison, were published abroad under a feigned name. Controversial writings also passed between him and Bucer, with whom he had several interviews in Germany. when he was there as Henry VIII.'s ambassador. A friend of learning he took great interest in promoting the study of Greek at Cambridge. He was, however, opposed to the new method of pronouncing the language introduced by Sir John Cheke, and wrote letters to him and Sir Thomas Smith upon the subject, in which, according to Ascham, his opponents showed themselves the better critics, but he the superior genius. His house was spoken of by Leland as the seat of eloquence and the special abode of the muses.

GARDNER, PERCY (1846–1937), English classical archaeologist, was born in London, and was educated at the City of London school and Christ's college, Cambridge (fellow, 1872). He was Disney professor of archaeology at Cambridge (1880–87), and professor of classicdl archaeology at Oxford (1887–1925). Gardner was a fellow of the British Academy and of other learned societies in many foreign countries. Among his works are: *Types of Greek Coins* (1883); *A Numismatic Commentary on Pausanias* (with F. Imhoof-Blumer, 1887); *New Chapters in Greek History* (1892), an account of excavations in Greece and Asia Minor; *Manual of Greek Antiquities* (with F. B. Jevons, 2nd ed. 1898); *Grammar of Greek Art* (1905); *Principles of Greek Art* (1913); *New Chapters in Greek Art* (1926); and a number of works on theological and ecclesiastical subjects.

His brother, ERNEST ARTHUR GARDNER (1862–1939), educated at the City of London school and Caius college, Cambridge (fellow, 1885), was director (1887–95) of the British School at Athens, and later became professor of archaeology at University college, London, and dean of the university. His publications include: *Introduction to Greek Epigraphy* (1887); *Catalogue of the Vases in the Fitzwilliam Museum, Cambridge* (1897); *Ancient Athens* (1902); *Handbook of Greek Sculpture* (1905); new and enlarged ed. (1915); *The Art of Greece* (1925), etc.

GARDNER, a city among the hills of northern Worcester county in north-central Massachusetts, U.S., 59 mi. N.W. of Boston, was organized as a town on June 27, 1785, on the petition of John Glazer of Westminster and was incorporated as a city on March 15, 1921. It was named after Col. Thomas Gardner, who was killed in the battle of Bunker Hill. Gardner has been called the chair city of the world; the first chair factory was started there by James M. Comee in 1805. Major products include baby carriages and walkers, fabricated structural products, furniture, office machinery, sporting and athletic goods, and toys. A wooden chair near the Boston and Maine railroad station is a landmark that is reputed to be the largest chair ever constructed. For comparative population figures *see* table in MASSACHUSETTS: *Population.* (J. F. Z.)



GREAT AUK (PINGUINUS IMPENNIS), KNOWN ALSO IN THE HEBRIDES, WHICH IT FREQUENTED, AS THE GAREFOWL

GAREFOWL, also known as great auk (*Pinguinus impennis*), a large flightless sea bird, now extinct. Slightly smaller than a tame goose, it resembled its relative the razorbill (*Alca torda*) in appearance, but a large patch of white occupied nearly all the space between the bill and the eye, while the bill itself bore eight or more transverse grooves. Because of the small size of the wings the bird was unable to fly. The great auk was 30 in. long, with a wing less than 6 in.; the razor-billed auk (*q.v*), 17 in. long, has an 8-in. wing. It bred at St. Kilda, the Faeroes, Iceland and Funk Island off Newfoundland, where the French fishermen used both the bird and its eggs for food. Enormous numbers were killed, the birds being driven up a plank into the hold of the vessel (*see* Ritchie, *Animal Life in Scotland*). It became extinct about 1844, when the last pair, with an egg, was killed at Eldey, Iceland, in June. The egg resembled that of the razorbill in shape and colour, but was larger, measuring nearly 5 by 3 in. (*See* AUKS.) (G. F. Ss.)

GARFIELD, JAMES ABRAM (1831–1881), 20th president of the United States, was born on Nov. 19, 1831, in a log cabin in the little frontier town of Orange, Cuyahoga county, Ohio. His early years were spent in the performance of such labour as fell to the lot of every farmer's son in the new states, and in the acquisition of such education as could be had in the district schools held for a few weeks each winter. But life on a farm was not to his liking, and at 16 he left home and tramping across the country to Cleveland, Ohio, sought employment from the captain of a lake schooner. But the captain drove him from the deck, and, wandering on in search of work, he fell in with a canal boatman who engaged him. During some months young Garfield served as bowsman, deck-hand and driver of a canal boat. An attack of the ague sent him home, and on recovery, having resolved to attend a high school and fit himself to become a teacher, he passed the next four years in a hard struggle with poverty and in an earnest effort to acquire an education; worked as a teacher, a carpenter and a farmer; studied for a time at the Western Reserve Eclectic Institute at Hiram, Ohio, and finally entered Williams College. On graduation, in 1856, Garfield became professor of ancient languages and literature in the Eclectic Institute at Hiram, and within a year rose to be its principal.

Soon afterwards he entered political life. In the early days of the Republican party, when the shameful scenes of the Kansas struggle were exciting the whole country, and during the campaigns of 1857 and 1858, he became known as an effective speaker and ardent anti-slavery man. His reward for his services was election in 1859 to the Ohio senate as the member from Portage and Summit counties. When the "cotton States" seceded, Garfield appeared as a warm supporter of vigorous measures, and when the call came for 75,000 troops, at once offered his services to the governor, and became lieutenant-colonel and then colonel of the 42nd Ohio Volunteers, recruited largely from among his former students He served in Kentucky, was promoted to the rank of brigadier-general of volunteers early in 1862; took part in the second day's fighting at the battle of Shiloh, served as chief of staff under Rosecrans in the Army of the Cumberland in 1863, fought at Chickamauga, and was made a major-general of volunteers for gallantry in that battle. In 1862 he was elected a member of Congress from the Ashtabula district of Ohio, and, resigning his military commission, took his seat in the House of Representatives in Dec. 1863. In Congress he 'joined the radical wing of the Republican party, advocated the confiscation of Confederate property, approved and defended the Wade-Davis manifesto, and was soon recognized as a hard worker and ready speaker. Capacity for work brought him places on important committees and his ability as a speaker enabled him to achieve distinction on the floor of the House and to rise to leadership. The year 1874 was one of disaster to the Republican party. The greenback issue, the troubles growing out of reconstruction in the South, the Crédit Mobilier and the "Salary Grab," disgusted thousands of independent voters and sent a wave of democracy over the country. Garfield himself was accused of corruption in connection with the Crédit Mobilier scandal, but the charge was never proved. A Republican convention in his district demanded his resignation, and re-election seemed impossible; but he defended himself in two pamphlets, "Increase of Salaries" and "Review of the Transactions of the Crédit Mobilier Company," made a village-to-village canvass, and was victorious. In 1876 Garfield for the eighth time was chosen to represent his district; and afterwards as one of the two representatives of the Republicans in the House, he was a member of the Electoral Commission which decided the dispute regarding the presidential election of 1876. When, in 1877, James G. Blaine was made a senator from Maine, the leadership of the House of Representatives passed to Garfield. and he became the Republican candidate for speaker. But the Democrats had a majority in the House, and he was defeated. Hayes, the new president, having chosen John Sherman to be his secretary of the treasury, an effort was made to send Garfield to the United States Senate in Sherman's place. But the President needed his services in the House, and he was not elected to the Senate until 1880.

The time had now come (1880) when the Republican party must nominate a candidate for the presidency. Gen. U. S. Grant had served two terms (1869–77) and the unwritten law of custom condemned his being given another. But the "bosses" of the Republican party in three great states — New York, Pennsylvania and Illinois — were determined that he should be renominated. These men and their followers were known as the "stalwarts." Opposed to them were two other factions, one supporting James G. Blaine, of Maine, and the other John Sherman, of Ohio. When the convention met and the balloting began, the contest along these factional lines started in earnest. For 28 ballots no change of any consequence was noticeable. Though votes were often cast for ten names, there were but two real candidates before the convention, Grant and Blaine. That the partisans of neither would yield in favour of the other was certain. That the choice therefore rested with the supporters of the minor candidates was manifest, and with the cry "Anything to beat Grant!" an effort was made to find some man on whom the opposition could unite. Such a man was Garfield. His long term of service in the House, his leadership of his party on its floor, his candidacy for the speakership and his recent election to the United States Senate marked him as the available man. Between the casting of the 1st and the 33rd ballot, Garfield, who was the leader of Sherman's adherents in the convention, had sometimes received one or two votes and at other times none. On the 34th he received 17, on the next 50 and on the next almost the entire vote hitherto cast for Blaine and Sherman, and was declared nominated. During the campaign Garfield was subject to violent personal abuse; the fact that he was alleged to have received $329 from the Crédit Mobilier as a dividend on stock led his opponents to raise the campaign cry of "329," and this number was placarded in the streets of the cities and printed in flaring type in partisan newspapers. The forged "Morey letter," in which he was made to appear as opposed to the exclusion of the Chinese, was widely circulated and injured his candidacy in the west. That the charges against Garfield were not generally credited, however, is shown by the fact that he received 214 electoral votes to his opponent's 155. He was inaugurated on March 4, 1881.

On July 2, while on his way to attend the commencement exercises at Williams college, Williamstown, Mass., the new president was shot in a Washington railway station by a disappointed office seeker named Charles J. Guiteau, and on Sept. 19, 1881, he died at Elberon, N.J., where he had been moved on Sept. 6. He was buried in Cleveland, O., where in 1890 a monument was erected by popular subscription to his memory.

President Garfield's writings, edited by Burke A. Hinsdale, were published in 1882. *See* also Theodore Clarke Smith, *The Life* and *Letters* of *James A. Garfield (1925).*

GARFIELD, a city of Bergen county, in northeastern New Jersey, U.S., at the juncture of the Passaic and Saddle rivers, is 12 mi. W. of New York city and 10 mi. N.W. of Newark. Founded in 1679 by the Dutch after purchase of the land from the Hackensack clan of the Delaware tribe of the Algonkin Indians of the Lenni Lenape nation, the city was originally known as Cadmus Melon Patch and later as East Passaic. It was renamed Garfield in 1881 after Pres. James Garfield and incorporated as a borough in 1898 and as a city in 1917. Garfield is an industrial city, whose chief industries include the manufacture of textiles, chemicals, aircraft parts, nonferrous metals, paperboard, machinery and rubber products. For comparative population figures see table in NEW JERSEY: Population. (D. N. A.; M. P. M.)

GARFIELD HEIGHTS, a suburban city of Cuyahoga county, in northern Ohio, U.S., is immediately southeast of Cleveland. Named for Pres. James Garfield, whose parents had once lived nearby, Garfield Heights did not receive village status until 1919. The area was part of the original township of Newburgh, organized in 1814, and underwent a gradual process of contraction as sections were annexed to Cleveland. The village of South Newburgh uas established in 1904 and 15 years later became Garfield Heights. By 1932 the village qualified for designation as a city. In a rapidly expanding residential area, the city encouraged limited industrial activity, including the manufacture of women's apparel, tools and dies, abrasives and metal products.

After World War II, Garfield Heights experienced a sharp increase in population; for comparative population figures see table in OHIO: Population. (W. G. K.)

GARFISH, a family of fishes (Belonidae) found in most temperate and tropical seas, also called needlefish, and recognized by their long, slender, compressed and silvery bodies, and by their jaws being produced into long, pointed, bony and sharply toothed beaks. About 50 species are known, some attaining a length of four or five feet. One species is common on the British coasts, and is well known by the name of "long-nose." The green bones deter many people from eating this wholesome food.

The skipper (Scomberesox) and halfbeak (*Hemirhamphus*), in which the lower jaw only is prolonged, are akin to the garfishes.

GARGANEY, or SUMMER TEAL, *Anas* querquedula, is one of the smallest of the ducks and is a summer visitant to England, where it breeds in the east Norfolk Broads. Slightly larger than the common teal (A. crecca), the male has a nutmeg-brown beard and a uhite line behind the eyes. The female resembles the hen teal, but possesses no wing spot. In Ireland and Scotland the garganey is rare. It has not a high northern range, and its appearance in Norway and Sweden is casual. It is nowhere common in Europe, but ranges far to the eastward in Asia and yearly visits India in winter in enormous numbers. It nests very frequently in reed beds. It is related to the blue-winged teal or summer teal (A. discors) of Canada and the United States.

GARGANO, MONTE (anc. Garganus *Mons*), a massive mountainous peninsula projecting eastward from the north coast of Apulia, Italy, and belonging geologically to the opposite Dalmatian coast; it was indeed separated from the rest of Italy by an arm of the sea as late as the Tertiary period. It is of the same character as the Carso, being composed of fractured calcareous rock, and has numerous superficial and subterranean cavities. The highest point (Monte Calvo) is 3,465 ft. above sea level. The oak forests for which it was renowned in Roman times have entirely disappeared except in three sections, and have left the soil dry and stony. Monte Sant' Angelo (*q.v.*) is the principal town.

GARGOYLE, in architecture, a decorated waterspout. Although technically speaking the term applies to the carved lions of classic cornices, or to the terra-cotta spout, such as those found frequently in Pompeii, in general usage the word has become restricted to the grotesque, carved spouts of the middle ages, and is even, incorrectly, applied to other grotesque beasts, such as the *chimères* that decorate the parapets of Notre Dame at Paris. The gargoyle of the developed Gothic period is usually a grotesque bird or beast sitting on its haunches on the back of a cornice molding and, in order to throw the water far from the building, projecting for several feet.

GARHWAL is a mountainous district in the Kumaon division of Uttar Pradesh, India. Pop. (1951) 639,625; area 5,631 sq.mi. Administrative headquarters are at Pauri (pop., 1951, 5,250). The celebrated temple of Badrinath, set high among the mountains, is a favourite resort for pilgrims. The district consists almost entirely of rugged mountain ranges separated by narrow valleys which in some cases become deep gorges or ravines. The only level portion of the district is a narrow strip of waterless forest between the southern slopes of the hills and the fertile plains of Rohilkhand. The Alaknanda, the source of the Ganges, receives with its affluents the whole drainage of the district. At Devaprayag it unites with the Bhagirathi to become the Ganges. Cultivation is principally confined to the immediate vicinity of the rivers.

Main exports are grain and coarse cloth; imports are salt, borax, livestock and wool.

GARIBALDI, GIUSEPPE (1807–1882). Italian patriot, was born at Nice on July 4, 1807. He entered the Sardinian naw, and, with companions on board the frigate "Euridice," plotted to seize the vessel and occupy the arsenal of Genoa at the moment when Mazzini's Savoy expedition entered Piedmont. The plot being discovered, Garibaldi fled, but was condemned to death by default on June 3, 1834. Escaping to South America in 1836, he was given letters of marque by the state of Rio Grande do Sul, which had revolted against Brazil, and after a series of victorious engagements passed into the service of Uruguay. In Montevideo, he formed the Italian legion, with which he won the battles of Cerro and Sant' Antonio in 1846 and assured the freedom of Uruguay. He returned to Italy upon receiving news of the incipient revolutionary movement, and landing at Nice on June 24, 1848, placed his sword at the disposal of Charles Albert. He formed a volunteer army 3,000 strong, but shortly after the defeat of Custozza had to flee to Switzerland. Proceeding thence to Rome, he was entrusted by the Roman republic with the defense of San Pancrazio against the French. where he gained the victory of April 30, 1849. During May he dispersed the Bourbon troops at Palestrina, Velletri and elsewhere, and after the fall of Rome started on his wonderful retreat through central Italy pursued by the armies of France, Austria, Spain and Naples. He escaped to Ravenna, then to Piedmont and ultimately to America, from whence he returned to Italy in 1854 and purchased the island of Caprera. on which he built his home. On the outbreak of war in 1859 he was in command of the Alpine infantry, defeating the Austrians at Casale on May 8, crossing the Ticino on May 23, and, after a series of victorious fights: liberating Alpine territory as far as the frontier of Tirol.

Returning to Como to wed the Countess Raimondi, by whom he had been aided during the campaign, he was apprised, immediately after the wedding, of circumstances which caused him to abandon his wife and start for central Italy. Forbidden to invade the Romagna, he returned to Caprera, where with Crispi and Bertani he planned the invasion of Sicily. Assured by Sir James Hudson of English sympathy, he began preparations for the process which ended in the making of Italy. He reached Marsala on May 11, 1860, landed under the protection of the British vessels "Intrepid" and "Argus," and on the following day his dictatorship was proclaimed at Salemi. On May 1j the Keapolitan troops were routed at Calatafimi, on May 25 Palermo was taken, on June 6, 20.000 Keapolitan regulars capitulated, on July 20 Messina fell and on Aug. 21 the battle of Reggio was won. On Sept. 7 Garibaldi entered Naples. and a month later routed the remnant of the Bourbon army on the Yolturno. On Nov. 7 he accompanied Yictor Emmanuel during his entry into Naples, and next day returned to Caprera.

Indignant at the cession of Nice to France and at the neglect of his followers by the government, he returned to political life. Elected deputy in 1861, his anger against Cavour found violent expression, until Cavour's successor. Ricasoli. enrolled the Garibaldians in the regular army. Marching on Rome in the following year, he was taken prisoner at Aspromonte on Aug. 27. Liberated by an amnesty, Garibaldi returned once more to Caprera amid general sympathy, and in 1864 was enthusiastically received in London. On the outbreak of war in 1866 he assumed command of a volunteer army! and on July 3 he defeated the Austrians at Monte Saello. on the ;th at Lodrone. on the 10th at Darso, on the 16th at Condino, on the 19th at Ampola, on the 21st at Bezzecca; when on the point of attacking Trent, he was ordered by General Lamarmora to retire. His famous reply, *"Obbedisco"* ("I obey"), has often been cited as a classical example of military obedience to a command destructive of a successful leader's hopes, but documents later published (cf. *Corriere della sera,* Aug. 9, 1906) prove that Garibaldi had for several days known that the order to evacuate the Trentino would shortly reach him. As early as July 16 Crispi had been sent to warn Garibaldi that. because of Prussian opposition. Austria would not cede the Trentino to Italy and that the evacuation was inevitable. He returned to Caprera to mature his designs against Rome, which had been evacuated by the French in pursuance of the Franco-Italian convention of Sept. 1864. In 1867 he prepared to enter papal territory. but was arrested at Sinalunga by the government and conducted to Caprera. He escaped to Florence and, with the complicity of the second Rattazzi cabinet, entered Roman territory at Passo Corese on Oct. 23. Two days later he took Monterotondo, but on Kov. 2 his forces were dispersed at Mentana by French and papal troops. Recrossing the Italian frontier, he was arrested at Figline and taken back to Caprera. In 1870 he formed a fresh volunteer corps and went to the aid of France. defeating the German troops at Chatillon, Autun and Dijon. Elected a member of the Versailles assembly, he resigned his mandate in anger at French insults and withdrew to Caprera until, in 1874, he was elected deputy for Rome. Popular enthusiasm induced the Conservative Minghetti cabinet to propose that £40,000 with an annual pension of £2,000 be conferred upon him, but the proposal was refused by Garibaldi. Upon the advent of the left to power. however, he accepted both gift and pension. He died at Caprera on June 2, 1882, one of the greatest masters of revolutionary war.

GARLAND, HAMLIN (1860–1940), U.S. author, perhaps best remembered for his autobiographical "Middle Border" series, was born at West Salem! Wis., on Sept. 14, 1860. As his family moved progressively westward. Garland rebelled against the vicissitudes of pioneering and turned to Boston for a literary career. A follower of William Dean Howells, Garland far exceeded his mentor in the bitterness of his realism as he resentfully recorded the frustrations of rural life. The short stories of *Main-Travelled Roads* (1891), *Prairie Folks* (1893) and *Wayside Courtships* (1897), and the novel *Rose of Dutcher's Cooley* (1895) raised a storm of protest.

Garland's critical theories of "veritism," set out in *Crumbling Idols* (1894), were largely derivative but well in advance of contemporary popular acceptance. Garland next turned to the "high country" of the American west and to the occult for materials, producing a series of mediocre novels which were serialized in the burgeoning "slick magazines." His Indian stories, however. written during this period (though uncollected until 1923 in *The Rook of the American Indian),* remain one of the earliest accurate and sympathetic appraisals of this minority group. Garland grew increasingly critical of the "excesses" of the naturalists. and in 1917 in mellow autobiographical mood wrote *A Son of the Middle Border*, apostrophizing the vanishing frontier. The book won immediate and deserved acclaim. A somewhat unsuccessful sequel, *A Daughter of the Middle Border* (1921), was the Pulitzer choice for biography. *Trail-Makers of the Middle Border* (1926) nostalgically described the epic sweep of migrations which settled the American continent. In his later years Garland compiled from his journals *Roadside Meetings of a Literary Nomad* (1930) and successive reminiscent volumes.

An indefatigable lecturer and promoter of literary organizations as well as a fecund writer, Garland in his lifetime was a force in literary affairs. In youth the spokesman of the "local color school" of realists, he came in time to be the *bête noire* of the naturalistic critics. Later critical opinion was sharply divided as to the extent of his influence upon American letters.

GARLAND, JOHN (JOHANNES DE GARLANDIA) (*c.* 1195–*c.* 1272), English grammarian and poet, whose works were important in the development of medieval Latin, was born in England of a noble family. He studied at Oxford under a certain John of London, and about 1202 went to Paris where Alain de Lille was his teacher. Garland taught at Paris until 1229 when he went to the new University of Toulouse. In 1232 or 1233 he had to flee Toulouse because of religious troubles with the Albigensians. Among his grammatical works were *Compendium grammatice* and *Liber de constructionibus*. His *Dictionarius*, a Latin vocabulary, was edited in 1857 by T. Wright, who also published fragments of the *Poetria* (1841), since edited in full by G. Mari (1892 and 1902).

The best known of Garland's poems are *De triumphis ecclesiae* (ed, by Wright, 1856), books iv–vi giving a detailed account of the Albigensian crusade in the south, and *Epithalamium beatae Mariae Virginum*. *De mysteriis ecclesiae* was edited by B. W. Otto (1812) and the *Morale scolarium*, which covers such topics as general behaviour. table manners, virtue and the defense of the pope against simony, by L. J. Paetow (1927) who in his introduction gives an account of the life and works of Garland.

GARLAND, a city of Dallas county, in northeastern Texas, U.S., is 14 mi. N.E. of Dallas. Known in the 1880s as Duck Creek and later as Embree, it was named in honour of A. H. Garland, U.S. attorney general under Pres. Grover Cleveland. It was long an agrarian town, with a population of only 2,233 as late as 1940. After World War II industrial expansion increased the population. (For comparative population figures *see* table in TEXAS: *Population.*) More than 50 industrial firms were established in Garland between 1940 and 1960.

In 1951 Garland adopted the council-manager form of government. (E. C. BE.)

GARLIC (*Allium sativum*), a bulbous perennial plant of the family Liliaceae (lily family), used for flavouring. It is native to middle Asia west of the Himalayas. The membranous skin of the bulb encloses up to 20 small edible bulbils called cloves. which are quite unrelated to the spice of that name. These bulbils are borne in the axils of the inner leaves of the bulb. The 15 to 20 leaves are long, flat and solid with a ridge on the under side of each. Flower stalks sometimes arise to one foot or more. bearing tiny bulblets and sterile flowers but no seeds. Garlic is propagated by planting either cloves or top bulblets and is grown as an annual crop by methods similar to those used in the growing of onions. It is little grown in the United States except in California.

(V. R. B.)

GARLIC MUSTARD (*Alliaria officinalis*), a plant of hedgebanks, low woods and waste grounds, called also hedge garlic, Jack-by-the-hedge and sauce-alone. It is an erect: somewhat branching. biennial or perennial herb, 2 ft. to 3 ft. high, of the mustard family (Cruciferae), native to Europe and temperate Asia and naturalized in North America from Quebec and Ontario to Virginia. The long-stalked, coarsely toothed leaves emit, when crushed. a garliclike odour. The plant bears white flowers.

GARMISCH-PARTENKIRCHEN, a resort town in Bavaria, Ger., on the edge of the Bavarian Alps and under the shadow of the Zugspitze, the highest mountain in Germany. It lies southwest of Munich in one of the valley highways leading to the Brenner pass to Italy and is on the railway from Augsburg to Innsbruck. Pop. (1950) 25,142.

GARNEAU, FRANÇOIS XAVIER (1809–1866), Canadian historian, whose *Histoire du Canada* established scientific method there, was born June 15, 1809, in Quebec, the son of a carriage maker. Leaving school at 14, he entered the court clerk's office and two years later a notary's firm, becoming himself a notary in 1830. He was in London from 1831 to 1833 as secretary to D. B. Viger, a Canadian political delegate. Back in Quebec, he wrote poetry, started a short-lived paper and dabbled in history. In 1837 he turned bank cashier and became somewhat active in politics He was appointed translator to the legislative assembly (1843) and was Quebec city clerk (1844–64). His *Histoire du Canada* (1845–48) met with great success and was translated into English. *Voyage en Angleterre et en France* appeared in 1855. Scarcely touching economics. he concentrates on war and politics, being invariably impartial. His inspiration is based on the conservation of Quebec's religion, language and laws. Revitalizing ethnic pride and aspirations, he ranks as the national historian of French-Canada. He died at Quebec, Feb. 3, 1866.

(G. LT.)

GARNER, JOHN NANCE (1868–). U.S. vice-president during Pres Franklin D. Roosevelt's first two terms was born in a log cabin in Red River county, Tex., Nov. 22, 1868. After limited schooling, he studied law and was admitted to the Texas bar in 1890. He served two terms in the Texas legislature. 1898–1902. He was elected a Democratic representative in the U.S. congress in 1902 and continued as such for 30 years. After being successively Democratic whip and leader in the house, he was elected speaker in 1931. In 1932 he was a candidate for the Democratic nomination for president, but released his delegates in favour of Roosevelt. Garner was then nominated for rice-president and was elected; four years later he was re-elected with Roosevelt. Garner opposed a number of New Deal measures during his second term. He retired in Uvalde, Tex.

GARNET (GARNETT), **HENRY** (1555–1606), English Jesuit. was born at Heanor, Derbyshire, educated at Winchester and afterwards studied law in London. Having become a Roman Catholic. he joined the Jesuits in Italy in 1575, and in 1587 was made superior of the English province. Fearless and indefatigable in carrying on his propaganda and in ministering to the scattered Catholics, even in their prisons, Garnet is remembered for his connection with the Gunpowder plot, for which he suffered death. On June 9, 1605, Garnet was asked by Robert Catesby whether any undertaking which should involve the destruction of the innocent together with the guilty was lawful. Garnet answered in the affirmative, giving as an illustration the fate of persons besieged in time of war. Afterwards, however, he admonished Catesby against intending the death of "not only innocents but friends and necessary persons for a commonwealth," and showed him a letter from the pope forbidding rebellion. According to Sir Everard Digby, Garnet. when asked the meaning of the brief, replied "that they (meaning the priests) mere not to undertake or procure stirs, but yet they would not hinder any, neither was it the pope's mind they should. that should be undertaken for Catholic good. . . . This answer, with Mr. Catesby's proceedings with him and me, gave me absolute belief that the matter in general was approved, though every particular was not known." A few days later, according to Garnet, the Jesuit. Oswald Tesimond, known as Greenway, informed him of the whole plot "by way of confession," but he urged Greenway to do his utmost to prevent its execution. Garnet's conduct in keeping the plot a secret has been a matter of considerable controversy not only between Roman Catholics and Protestants, but among Roman Catholic writers. He appears to have taken no decisive steps to prevent the crime, and his movements immediately prior to the attempt were certainly suspicious. In

September, shortly before the expected meeting of parliament on Oct. 3, Garnet organized a pilgrimage to St. Winifred's Well in Flintshire, which included Sir Everard Digby, Ambrose Rokewood, John Grant and Robert Winter. During the pilgrimage Garnet asked for prayers "for some good success for the Catholic cause at the beginning of parliament." After his return he went to Coughton where it had been settled the conspirators were to assemble after the explosion. On Nov. 6, Bates, Catesby's servant and one of the conspirators, brought him a letter with the news of the failure of the plot. On the 30th Garnet addressed a letter to the government in which he protested his innocence. On Dec. 4, Garnet and Greenway were, by the confession of Bates, implicated in the plot. In company with another priest, Oldcorne, alias Hall. Garnet hid himself, but at last on Jan. 30, 1606, surrendered and was taken up to London. Examined by the council on Feb. 13, he refused to incriminate himself. Subsequently, Garnet and Oldcorne having been placed in adjoining rooms and enabled to communicate with one another, their conversations were overheard on several separate occasions and considerable information obtained. Garnet at first denied all speech with Oldcorne, but later on March 8, confessed his connection with the plot. He was tried at the Guildhall on the 28th.

His trial, like many others, was influenced by the political situation. the case against him being supported by general political accusations against the Jesuits as a body, and with evidence of their complicity in former plots. The prisoner himself prejudiced his cause by his numerous false statements, and by adhering to the doctrine of equivocation. He was declared guilty. and executed on May 3, 1606. He acknowledged himself justly condemned for his concealment of the plot, but maintained to the last that he had never approved it. Garnet was the author of a letter on the martyrdom of Godfrey Maurice, alias John Jones, in Diego Yepres's *Historia particular de la persecucion de Inglaterra* (1599); a *Treatise of Schism;* a translation of Canisius' *Summa of Christian Doctrine* (1622); a treatise on the Rosary; a Treatise of Christian Renovation (1616).

The original documents are preserved in the *Gunpowder Plot Book* at the Record Office. *See* also GUNPOWDER PLOT.

GARNET is a general name applied to a group of specific silicate minerals having similar crystal structures. The name is from Lat. *granatum,* "pomegranate." and alludes to the resemblance of some red varieties to the seeds of this fruit. Garnets typically occur in metamorphic rocks, but also in certain types of igneous rocks and, usually in minor amounts! in clastic sediments as detrital grains. Excepting bluish tints, garnets show great diversity of colour, including colourless and black, in addition to various shades of red. Garnets are frequently employed commercially in the form of semiprecious gems, jewel bearings in watches and abrasive materials.

Gem Uses.—Use of garnets as gems began with the ancient Egyptians, if not earlier. During the latter part of the 19th century, preparation of garnets for jewelry employed many persons in Czechoslovakia, and garnet jewelry in the form of bracelets and brooches was popular. Tastes in jewelry change according to whims, however, and Bohemian jewelry declined in popularity with an apparent decline in the use of dark-coloured stones that took place during the 20th century. Most familiar during the peak of popularity were varieties of pyrope, cut both *en cabochon* and in faceted forms. Because of the dark colour, larger stones cut *en cabochon* frequently were cut concave on the reverse. Many varietal names have been applied, some of the commonest of which are mentioned below under the specific names. As is true of other gem minerals, garnet varieties have become known by misleading names. frequently consisting of a locality name used as an adjective before the name of another mineral variety, such as emerald or ruby. Although possibly the most attractive in appearance, uvarovite occurs in such small crystals as to be unusable as a gem; otherwise it might rival the emerald in popularity. Except for some of the darker varieties, the hardness of garnets is somewhat less than what would be desirable for mounting in finger rings. Garnet is considered the birthstone for those persons born during January according to an American association of jewelers. As is true of many other gems. mystical significance was attached to the wearing of garnets; they were supposed to ward off accidents during travel. In diabolical apposition is their use as bullets in ancient firearms. *See* also GEM; JEWELLERY.

Industrial Uses.—The hardness of garnets and their sharp fracture make them suitable as abrasives for wood, leather and plastics, and for lens grinding and metal and glass polishing. For discussion of these uses *see* ABRASIVES.

Heating to about 800° C.. followed by quenching, improves the toughness and fracture characteristics of iron-bearing garnets, and such a process is used by several manufacturers of garnet-coated abrasive papers and cloths. Fracture is also dependent to a considerable extent on the impurities within the crystals. At Gore mountain, in Warren county. N.Y., garnet crystals averaging five inches. but reaching a maximum of a few feet in size, are produced from a complex metamorphic rock which consists principally of hornblende and garnet. Other commercial deposits are in Benewah county. Idaho. In New Hampshire, almandite has been produced from schistose rocks. Production, sometimes as a by-product of other mining operations, has occurred in Florida, North Carolina and California. Intermittently, notable quantities of garnet have been produced for abrasive use in Canada, Czechoslovakia, India. Madagascar, Spain and South Africa.

Crystallography and Physical Characters.—In their crystallization. garnets are cubic, or apparently pseudocubic for some compositions, and commonly exhibit either dodecahedra1 or trapezohedral forms or both. The hexoctahedron, trisoctahedrbn, octahedron and cube are rare. Crystals commonly attain an inch or more in size as isolated individuals, but massive examples, consisting essentially of granular textures of very small crystals. occur also. Within a garnet crystal may be included many small grains of other mineral species.

The smallest symmetrical unit of the crystal structure contains 96 oxygen atoms arranged in tetrahedral co-ordination about 24 silicon atoms. Combined with the silicon and oxygen, garnets contain calcium, magnesium, iron and aluminum. Interstitially divalent and trivalent atoms occur in the proportions 3 to 2, leading to a general formula $R''_3R'''_2(SiO_4)_3$, where the bivalent element, R''. may be calcium, magnesium, ferrous iron or manganese, and the trivalent element, R''', may be aluminum, ferric iron, chromium or manganese. On analysis. garnets may be found to contain other metallic atoms in minor amounts as well as nonmetallic constituents other than silicon. (For discussion of type formulas and the replacement of one element by another *see* MINERALOGY: *Chemical Characters.)*

Garnetoids are essentially isostructural substances which contain a nonmetallic atom in isomorphous substitution for silicon. Both an arsenate and a phosphate mineral, berzeliite and griphite, fall in this group, as well as hydrogrossularite. The synthetic laboratory analogue of the last is tricalcium aluminate hexahydrate $(Ca_3Al_2[O_4H_4]_3)$. In this compound the structure appears to be essentially similar to that of the garnets except for the absence of the silicon atoms and the occurrence of four hydrogen atoms for each silicon atom. Expectably such a hydrated compound decomposes at a considerably lower temperature than does the analogous silicate, the garnet grossularite, $Ca_3Al_2(SiO_4)_3$.

Without taking into account such isomorphous substitutions as sodium for calcium, it is possible to account for the equivalence of the number of structural positions by the formula $X_3Y_2(ZO_4)_{3-m}(OH)_{4m}$. Z is a pentavalent atom for berzeliite and thus requires commensurate substitutions for either X or Y in order to preserve the electrical neutrality of the structure.

The common, silicate species denoted by garnet can be written as pure compounds, although the natural substances are isomorphous intermediates consisting of combinations of two or more end members, thus:

Grossularite	$Ca_3Al_2(SiO_4)_3$
Pyrope	$Mg_3Al_2(SiO_4)_3$
Almandite	$Fe_3Al_2(SiO_4)_3$
Spessartite	$Mn_3Al_2(SiO_4)_3$
Andradite	$Ca_3Fe_2(SiO_4)_3$
Uvarovite	$Ca_3Cr_2(SiO_4)_3$

Other combinations, such as ferrous-ferric and manganous-manganic end members, have been suggested and named (skiagite and blythite, respectively) but the mere introduction of additional names does not contribute toward a better understanding of the crystal chemistry involved. Varieties containing titanium (T) and the rare-earth yttrium (Y) also occur. Indeed, inasmuch as some otherwise normal garnets contain small amounts of phosphorus pentoxide, the supposed failure of some garnets to yield precise stoichiometric proportions may be attributable to the inadequacy of the analyses rather than inherent structural imperfections of the crystals. This is emphasized by the possible occurrence of aluminum atoms in tetrahedral co-ordination instead of silicon, as is true of the synthetic garnetoid $Y_3Al_2(AlO_4)_3$.

The physical properties of the garnets are variable, depending upon the composition. Grossularite has a hardness of about 6.5, whereas other varieties may be as high as 7.5 or 8 (in the case of a New Hampshire almandite). The specific gravity ranges from slightly above 3.5 (pyrope) to 4.3 (almandite). For a nearly pure end member, the lowest refractive index has been measured for grossularite (1.735) and the greatest for andradite (above 1.88). Depending upon the titanium content, the refractive index may be appreciably higher. A schorlomite variety from Kuusamo, Fin., has a refractive index above 2. Although the refractive index of pyrope has been calculated to be 1.705, specimens containing more than 60% of this end member are extremely rare.

Garnets of some compositions, particularly grossularite, andradite, spessartite and uvarovite, are not strictly isotropic at ordinary temperatures, but are composed of anisotropic sectors. On heating the anisotropism is said to disappear, suggesting that passage through an inversion temperature has brought the crystal to a truly cubic condition which is not stable at lower temperatures. Many observations on the anisotropism indicate that the individual sectors commonly have orthorhombic or lower symmetry. An anisotropic garnet from Nevada displays spectacular iridescence

The thermal behaviour and synthesis of garnets have been studied extensively. Most garnets melt incongruently, *i.e.*, decompose on or before melting and form pyroxenes, anorthite, spinels and other minerals on solidification. Grossularite. spessartite and almandite fuse at far lower temperatures than uvarovite. Utilizing high pressures and water vapour, garnets of various coinpositions can be synthesized, but only uvarovite, spessartite and possibly melanite have been produced at atmospheric pressure and possibly only the first two from a dry melt. On fusion most garnets form melts having appreciably lower specific gravities. Ferriferous varieties yield a magnetic material on cooling.

Varieties.— *Almandzte* or so-called precious garnet is usually deep red and slightly purple in colour. It occurs typically in schistose rocks formed by regional or dynamic metamorphism of argillaceous sediments, in gneisses and in granulites. Its presence is used as a criterion to indicate the grade of metamorphism by dynamic processes. Well-known localities include Gore mountain, N.P.; Salida, Colo.; Minas Gerais. Braz.; Fort Wrangell, Alsk.; Nordland, Nor.; southern Greenland; Ceylon and India. Gem quality garnet is produced mostly in Brazil, Ceylon and India. Almandite may display asterism in the form of a four-rayed cross but this phenomenon is nearly always less spectacular than that of the star ruby or sapphire.

Pyrope also is frequently deep red, owing its colour to the presence of the almandite end member with which it occurs isomorphously combined, but there is reason to believe that pure pyrope would be very nearly colourless. A rose red variety found at Macon county, N.C., is called rhodolite. The common garnet of the jewelry trade, variously called Cape ruby or Bohemian garnet, contains appreciable quantities of pyrope. Pyrope of gem quality occurs in alluvial deposits near Prague. The characteristic occurrences of pyrope are basic igneous rock, such as peridotites, and the serpentinites derived from their alteration.

Grossularite, called the gooseberry garnet because its rounded shape and greenish colour may produce a close resemblance to the fruit, when pure is completely colourless, or white because of numerous internal fractures. White, dodecahedra1 crystals from Mexico are well known, as is a pink variety called rosolite. Reddish-brown varieties include so-called cinnamon stone and hessonite (or essonite) that are occasionally seen in jewelry. A massive variety is called South African or Transvaal jade from the locality and its jadelike colour. Grossularite occurs typically in impure limestones that have been thermally metamorphosed in proximity to an intrusive igneous rock. A typical mineralogical assemblage in addition to grossularite would include several or all of these: coarsely crystalline calcite, wollastonite, idocrase, diopside and scapolite. Many such contact metamorphic zones are known throughout the world so that grossularite is a common garnet, particularly when isomorphously combined with andradite.

Andradite is similar in its occurrence to grossularite, except that availability of ferric iron is essential, and related thermally metamorphosed rocks are more likely to contain ore deposits. Andradite also occurs in igneous rocks that have assimilated other rock fragments during emplacement. Titaniferous varieties may be black by reflected light but appear dark brown by light transmitted through thin slices. Schorlomite, a highly titaniferous variety, is found in nepheline syenite at Magnet Cove, Ark. Melanites, so called because of their dark colour, are varieties containing titanium that likewise occur in association with alkaline igneous rocks, particularly in Norway, the Kola peninsula, U.S.S.R., Tasmania and the Kaiserstuhl, Ger.

The crystal chemistry of the titanium-bearing garnets has not been thoroughly investigated. but it has been supposed that schorlomite contains Ti_2O_3 in addition to the TiO_2 contained in the melanites. Green gem varieties of andradite are called demantoid because of the high index of refraction and dispersion. The deceptive name Uralian emerald has sometimes been applied to such gems inasmuch as this material occurs in the Ural mountains, as well as Saxony and Hungary. Pure andradite is probably yellow, but the colour is influenced by the presence of other isomorphous constituents. Topazolite, resembling topaz in colour, is a variety from the Piedmont region of Italy.

Spessartite, the manganese-aluminum garnet, is yellow when pure but red or orange when combined with almandite. It occurs in granites, their associated pegmatite veins, in acidic lavas and in thermal metamorphic rocks if manganese is available. Garnet predominantly of spessartite composition is found in association with metamorphic manganese ores in central India. It is found in cavities in rhyolite with topaz at Silver Cliff, Colo., and near Nathrop, Utah. In the Spessart district of Bavaria, whence the name, it occurs in granite. Other noteworthy localities include the Piedmont of Italy, Alba, It., and Madagascar.

Uvarovite, the chromium-containing garnet, is comparatively rare. It is emerald green in colour and typically occurs as small, brilliant, euhedral crystals in veins in chromite. Also it is reported from metamorphosed limestones in Tasmania and from serpentinites. First reported from the northern Urals, it is found also in California, Canada, Finland and Silesia.

GARNETT, RICHARD (1835–1906), English librarian and author, son of the learned philologist the Rev. Richard Garnett (1789–1850), priest-vicar of Lichfield cathedral and afterward keeper of printed books at the British Museum, was born at Lichfield. He was educated at home and at a private school, and in 1851, just after his father's death, entered the British Museum as an assistant in the library. In 1875 he rose to be superintendent of the reading room, and from 1890 to 1899, when he retired, he was keeper of the printed books. In 1895 he was made a C.B. In the history of the British Museum library his place is second only to that of Panizzi. Besides introducing the "sliding press" in 1887 he was responsible for reviving the publication of the general catalogue, the printing of which, interrupted in 1841, was resumed under him in 1880, and gradually completed. He married (1863) an Irish wife, Olivia Narney Singleton (d. 1903); his son Edward (1868–1937), a well-known author, married Constance Black, known under her married name as the translator of the works of Turgenev, Tolstoy and other Russian authors.

Garnett's chief publications in book form were: in verse, *Primula* (1858), *Io in Egypt* (1859), *Idylls and Epigrams* (1869, republished in 1892 as *A Chaplet From the Greek Anthology*), *The Queen and Other Poems* (1902), *Collected Poems* (1893); in prose, biographies of Carlyle (1887), Emerson (1887), Milton (1890), Edward Gibbon Wakefield (1898); a volume of remarkably original and fanciful tales, *The Twilight of the Gods* (1888); a tragedy, *Iphigenia in Delphi* (1890); *A Short History of Italian Literature* (1898); *Essays in Librarianship and Bibliophily* (1899); *Essays of an Ex-librarian* (1901).

GARNIER, (JEAN LOUIS) CHARLES (1825–1898), French architect, creator of the Paris Opera house, was born in Paris on Nov. 6, 1825, and died there on Aug. 3, 1898. The son of a wheelwright, he studied at the Petite École de Dessin and entered the atelier of L. H. Lebas in preparation for the École des Beaux Arts. Admitted in 1842, he won the Grand Prix de Rome in 1848 and went to the Villa Medici. He entered and won the competition for the new Opéra de Paris, in 1860. One of the most famous buildings of the century, the Opera house followed an eclectic style with lavish ornamentation which was intended as a foil to the pageantry of a glittering court and a suitable palace of the arts of the second empire. Started in 1861, this vast undertaking, interrupted by the war of 1870, was completed in 1875. Garnier's other works included the small theatre for the casino of Monte Carlo, the casino and baths at Vittel. the observatory at Nice, an apartment house and the Hôtel du Cercle de la Librairie in Paris, as well as villas in Bordighera. For the Paris exposition of 1889 he conceived the Exposition des Habitations Humaines, which became the subject of his book *L'Habitation Humaine* (with A. Ammann, 1892). He also published, in 1871, *Le Théâtre*, and in 1878–81, *Le Nouvel Opéra de Paris*, a monumental description and defense of the work with which his name is irrevocably linked. (Jn. P. C.)

GARNIER, MARIE JOSEPH FRANÇOIS [Francis] (1839–1873), French officer and explorer, was born at St. Étienne on July 25, 1839. He entered the navy, and after voyaging in Brazilian waters and the Pacific he obtained a post on the staff of Admiral Charner, who from 1860 to 1862 was campaigning in Cochin-China. After some time spent in France he returned to the East, and in 1862 he was appointed inspector of the natives in Cochin-China, and entrusted with the administration of Cholon, a suburb of Saigon. At his suggestion the marquis de Chasseloup-Laubat sent a mission to explore the valley of the Mekong. Garnier accompanied Captain Doudart de Lagrée on this expedition. From Kratie in Cambodia to Shanghai 5,392 mi. were traversed, and of these 3,625 mi. were of country largely unknown to European geography. The area was surveyed with care and positions fixed by astronomical methods. most of the observations being taken by Garnier himself. Volunteering to lead a detachment to Talifu, the capital of Sultan Suleiman. the sovereign of the Mohammedan rebels in Yunnan, he successfully carried out the dangerous enterprise. When shortly afterwards Lagrée died. Garnier conducted the expedition in safety to the Tang-tsze-Kiang, and thus to the Chinese coast The preparation of his narrative, after his return to France. was interrupted by the Franco-German War, and during the siege of Paris he served as principal staff officer to the admiral in command of the eighth "sector." Returning to Cochin-China he found the political circumstances of the country unfavourable to further exploration, turned to China, and in 1873 followed the upper course of the Yang-tsze-Kiang to the waterfalls. He was next commissioned by Admiral Dupré, governor of Cochin-China, to found a French protectorate or a new colony in Tongking. On Nov. 20, 1873 he took Hanoi the capital of Tongking. and on the 21st of December he was slain in fight with the Black Flags. His chief fame rests on the fact that he originated the idea of exploring the Mekong, and carried out the larger portion of the work.

The narrative of the principal expedition appeared in 1873, as *Voyage d'exploration en Indo-Chine effectué pendant les années 1866, 1867 et 1868, publié sous la direction de M. Francis Garnier, avec le concours de M. Delaporte et de M. M. Joubert et Thorel* (2 vols). An account of the Yang-tsze-Kiang from Garnier's pen is given in the *Bulletin de la Soc. de Géog.* (1877) His *Chronique royale du Cambodje*, was reprinted from the *Journal Asiatique* in 1872 See *Ocean Highways* (1874) for a memoir by Colonel Yule; Petit. *Francis Garnier* (1885) and Hugh Clifford, *Further India*, in the Story of Exploration series (1904).

GARNIER, ROBERT (c. 1545–c. 1600), French tragic poet, was born at Ferté Bernard (Le Maine). He published his first work while still a law-student at Toulouse, where he won a prize (1565) in the *jeux floraux*. It was a collection of lyrical pieces, now lost, entitled *Plaintes amoureuses de Robert Garnier* (1565). After some practice at the Parisian bar, he became *conseiller du roi* in his native district, and later *lieutenant-général criminel*.

In his early plays Garnier was a close follower of the Senecan school. His pieces in this rhetorical manner are *Porcie* (published 1568, acted at the hôtel de Bourgogne in 1573), *Cornélie* and *Hippolyte* (both acted in 1573 and printed in 1574). His next group of tragedies—*Marc-Antoine* (1578), *La Troade* (1579), *Antigone* (acted and printed 1580)—shows an advance on the theatre of Etienne Jodelle and Jacques Grévin, and on his own early plays, since the rhetoric is accompanied by some action.

In 1582 and 1583 he produced his two masterpieces *Bradamante* and *Les Juives*. In *Bradamante*, which alone of his plays has no chorus, he cut himself adrift from Senecan models, and sought his subject in Ariosto, the result being what came to be known later as a tragi-comedy. The dramatic and romantic story becomes a real drama in Garnier's hands, though even there the lovers. Bradamante and Roger, never meet on the stage. The contest in the mind of Roger supplies a genuine dramatic interest. *Les Juives* has for its theme the story of the barbarous vengeance of Nebuchadrezzar on the Jewish king Zedekiah and his children. This tragedy, although almost entirely elegiac in conception, gains unity by the personality of the prophet. Emile Faguet says that of all French tragedies of the 16th and 17th centuries it is, with *Athalie*, the best constructed with regard to the requirements of the stage. Actual representation is continually in the mind of the author; his drama is, in fact, visually conceived.

The best edition of his works is by Wendelin Foerster, 4 vol. (Heilbronn, 1882–83). A detailed criticism of his works is to be found in Emile Faguet, *La Tragédie française au XVI^e siècle*, pp. 183–307 (1883).

GARNIER, TONY (1869–), a precursor, with August Perret, of 20th-century French architecture, was born at Lyon in 1869. Both Garnier and Perret explored the means of expression inherent in the new material, reinforced concrete. Most of the works of Garnier were executed in Lyon, under the aegis of the mayor, Édouard Herriot. The large complex of the stockyards (1909), the stadium (1915), the Granges-Blanches hospital with its 22 pavilions (started in 1915), as well as his planned housing schemes (*see* T. Garnier, *Grands travaux de la ville de Lyon*, 1919), developed out of the farsighted planning of his *Cite' In-*

dustrielle ("industrial city"), which secured Garnier's place in the history of architecture. On his Grand Prix de Rome grant he developed (beginning in 1898, exhibited in 1904 and published in 1917) plans for an entire city, embracing new concepts of city planning far more advanced than the garden city idea: long narrow lots running east-west, buildings separated by wide open spaces, separate levels provided for pedestrians and houses with roof gardens. The detailed ground plans for the houses were decades in advance of their time. The plasticity and strength of Garnier's chief material, concrete reinforced with steel, was employed to reach unexpected solutions for his schools, railway stations and sanatoriums. (S. GN.)

GARNIER-PAGÈS, LOUIS ANTOINE (1803–1878), French republican leader, was born at Marseilles on Feb. 16. His brother Étienne (1801–1841) was active as a republican leader under the restored Bourbons, supported the revolution of 1830 and after 1831 sat in the chamber of deputies as a leader of the republican opposition. Louis Antoine likewise supported the revolution of 1830 and after his brother's death was elected to the chamber. He took a leading part in the revolution of 1848, became a member of the provisional government in that year and was acclaimed mayor of Paris. In March he was made minister of finance and incurred great unpopularity by his imposition of additional taxes. He was a member of the constituent assembly and the executive commission. Under the second empire he became a leader of the republican opposition and opposed the war with Prussia. After the fall of Napoleon III he served as a member of the government of national defense. Failing to secure election to the national assembly of 1871, he retired into private life and died in Paris on Oct. 31, 1878. His writings include *Histoire de la révolution de 1848,* 10 vol. (1861–72), and *L'Opposition et l'Empire,* 2 vol. (1873). (D. TN.)

GARNISH: *see* ATTACHMENT; PRACTICE AND PROCEDURE; BANKRUPTCY.

GAROFALO, BENVENUTO DA (BENVENUTO TISI or TISIO) (1481–1559). Italian painter, was the most prolific 16th-century painter of the Ferrarese school. Modern knowledge of his early life and training is due entirely to Giorgio Vasari, who records Garofalo's apprenticeship with Domenico Panetti, his association with the Cremonese Boccaccio Boccaccino and his two visits to Rome in the first and second decades of the century. The style of his early works confirms Vasari's account but shows in addition the strong influence of Dosso Dossi, especially in the treatment of landscape backgrounds. This is clearest in several pictures of the Nativity painted before 1520; it is also apparent in the fine "Sacrifice to Ceres" (1526) in the National gallery, London. North Italian influences, particularly from Andrea Mantegna's "Camera degli Sposi," also dominate the ceiling paintings in the Seminario at Ferrara (1519).

The influence of Raphael and Michelangelo made itself increasingly felt from about 1520 onward, however, and Garofalo, though he seems never to have left Ferrara at this time, kept pace with the developments of Michelangelesque mannerism in Florence and Rome, for example, in the "Baptist Taking Leave of His Father" (1542) in S. Salvatore, Bologna. Garofalo died in his native Ferrara on Sept. 6, 1559. The history of his development well illustrates the derivative status of the Ferrarese school after its great period in the second half of the 15th century.

See E. G. Gardner, *The Painters of the School of Ferrara* (1911). (*M. W. L.* K.)

GARO HILLS, a district in the Assam Valley division of Assam, India. Area 3,149 sq.mi. Pop. (1951) 242,075. It takes its name from the Garos, a tribe of Tibeto-Burmese origin, by whom it is almost entirely inhabited. The Garos are probably a section of the great Bodo tribe, which at one time occupied a large part of Assam. In the 18th century they were a terror to the inhabitants of the plains below their hills. The early period of British rule is a record mainly of raids by the Garos, followed by blockades of the hills. At last in 1866 a British officer was posted among the hills with a small police force. This step was effective in putting a stop to raids till 1871–72, when further outrages were committed by some independent Garos. It was decided to annex their territory. A police force marched through the hills and there were no further disturbances.

The district consists of the westernmost spurs of the Assam hills, which run down almost to the bank of the Brahmaputra where it emerges upon the plain of Bengal and takes its great sweep to the south. The district headquarters are at Tura. Coal in large quantities and petroleum are known to exist in the hills. Nomadic cultivation is practised; *i.e.,* patches of forest are burnt and cleared with the axe and crops are grown among the ashes. These patches are cultivated for a few years and then left, fresh areas being cleared in the same way. Nearly half of the cotton grown in Assam is raised by the Garos; it is remarkable for a short staple and wooly fibre, which has led to its being mixed with wool for carpet making.

The Garos are an Assam tribe of the Bodo group which seems to have migrated from the direction of Bhutan, but probably absorbed some pre-existing local stock (wavy and even curly hair is frequent); the existing culture suggests Indonesian affinities. A Tibeto-Burmese language is spoken; the tribe is related to the Rabhas, Kacharis and Tipperas.

Villages are built on river banks, the houses raised on piles; land is communal and cultivation shifting, rice and cotton being grown. Garos are good fishermen but indifferent hunters. Distension of the ear is practised. There are a dozen subtribes with varying customs and dialects, but all are divided into matrilineal clans. Marriage is exogamous and polygamous and the proposal comes from the woman, who, if accepted, lives for a time in the bridegroom's house on probation, but this system is subject to compulsory cross-cousin marriage coupled with a rule by which a man must marry his wife's father's widow, who is in such cases the husband's father's sister, actual or classificatory. Such a wife takes precedence of her daughter married before her. A man's sister's son, called his *nokrom,* stands therefore in intimate relationship to him, as the husband of one of the daughters and ultimately of his widow and the vehicle through which his family's interest in the property of his wife is secured for the next generation, for no male can inherit property.

The dead are buried, followed by various forms of secondary disposal including urn burial, burial by water and sometimes by special treatment of the frontal bone. Head-hunting (*q.v.*) used to be practised, enemy skulls being kept in the latrines, and there are faint traces of cannibalism and human sacrifice in the past. Religion is generally animistic, but provides a benevolent creator and a sort of vague ancestor worship with soul figures of wood or stone, probably phallic, and a fertility cult which involves the sacrifice of an imitation horse. They believe in the reincarnation of the soul. *See* also HEAD-HUNTING; LYCANTHROPY; METEMPSYCHOSIS.

See A. Playfair, *The Garos* (1909).

GARONNE (Lat. *Garumna*), a river of southwestern France, rising in the Maladetta group of the Pyrenees and flowing in a wide curve to the Atlantic ocean. It is formed by two torrents, one of which has a subterranean course of $2\frac{1}{2}$ mi., disappearing in the sink known as the Trou du Taureau ("bull's hole") and reappearing at the Goueil de Jouéou. After a course of 30 mi. in Spanish territory, during which it flows through a fine gorge, the Vallée d'Aran, the Garonne enters France in the *département* of Haute-Garonne through the narrow defile of the Pont du Roi, and at once becomes navigable for rafts. At Montréjeau it receives on the left the Neste, and encountering at this point the vast plateau of Lannemezan, turns abruptly east, flowing in a wide curve to Toulouse. At Saint Martory it gives off the irrigation canal of that name. At that point the Garonne enters a fertile plain and supplies the motive power to several mills. It is joined on the right by various streams fed by the snows of the Pyrenees. Such are the Salat, at whose confluence river navigation begins, and the Arize and the Ariège (both names signifying "river").

From Toulouse the Garonne flows to the northwest, skirting the northern border of the plateau of Lannemezan which there drains into it by the Save, Gers and Baïse. On its right the Garonne receives its two chief tributaries, the Tarn, near Moissac, and the Lot, below Agen; afterward it is joined by the Drot (or

Dropt) and on the left by the Ciron. Between Toulouse and Castets, 333 mi. above Bordeaux, the river is accompanied at a distance of from $\frac{1}{2}$ mi. to 3 mi. by the so-called "lateral canal" of the Garonne, constructed in 1838–56. This canal is about 120 mi. long. From Toulouse to Agen the main canal follows the right bank of the Garonne, crossing the Tarn on an aqueduct at Moissac, while another aqueduct carries it across the Garonne at Agen. It has a fall of 420 ft. and more than 50 locks. The carrying trade upon it is chiefly in agricultural produce and provisions, building materials, wood and industrial products. At Toulouse the canal connects with the Canal du Midi, which runs to the Mediterranean.

After passing Castets the Garonne begins to widen out considerably to about 650 yd. at Bordeaux, its great commercial port. From there it flows between two flat shores to the Bec d'Ambès ($15\frac{1}{2}$ mi.), where, after a course of 357 mi., it unites with the Dordogne to form the vast estuary known as the Gironde. The peninsula lying between these two great tidal rivers, the Entre-deux-Mers ("between two seas"), is famous for its wines. The drainage area of the Garonne is 22,079 sq.mi. Floods are of common occurrence and descend very suddenly. The most disastrous occurred in 1875, 1856 and in 1770, when the flood level at Castets was the record height of $42\frac{1}{2}$ ft. above low-water mark.

GAR PIKE (Lepisosteus), a genus of fishes with four, or perhaps more, species in the rivers of North and Central America, with elongate body covered with hard rhombic scales, with the jaws produced and with strong conical teeth. Fishes with ganoid scales of the same structure were abundant in Mesozoic times, but Lepisosteus is not known before the Eocene. In the billfish or long-nosed gar (L. osseus) the jaws are exceedingly long and slender, in other species shorter and broader. The alligator gar of Cuba, Mexico and the southern United States, reaches a length of 10 ft. These are piscivorous fishes, of sluggish habits, but very voracious. The name gar or garfish is also given to the Belonidae, fishes of warm seas, slender and with long jaws, but with thin cycloid scales, and not related to the gar pikes.

GARRET, properly a small lookout tower built on a wall, and hence the name given to a room on the top story of a building, the sloping ceiling of which is formed by the roof.

GARRETT, JOÃO BAPTISTA DA SILVA LEITÃO DE ALMEIDA, VISCONDE DE ALMEIDA GARRETT (1799–1854), one of Portugal's finest prose writers, the most important playwright since Gil Vicente and chief of the romantic poets. He was born on Feb. 4, 1799, in Oporto, but the French invasion of Portugal drove the family to the Azores where he lived for a time. In 1816 he went to the University of Coimbra where he soon earned notoriety by the precocity of his talents and his fervent liberalism. His tragedy *Lucrécia* was played at Coimbra in Feb. 1819, and there also he wrote *Mérope* and a great part of *Catão*. All these plays, which are of little merit, belong to the so-called classical school. After taking a degree in law, he went to Lisbon, and on Nov. 11, 1822, married Dona Luisa Midosi, but the marriage proved unhappy, and a formal separation was granted in 1839.

The reactionary movement against the liberal revolution of 1820 reached its height in 1823, and Garrett, forced to leave Portugal by order of the absolutist ministry, went to England where he read and was impressed by the work of the English romantics. Imbued with the spirit of patriotism, he published in 1825 the poem, *Camões,* which, together with his Dona Branca of 1826, undermined the influence of the worn-out classical and Arcadian poets. He was permitted to return to Portugal in 1826, and thereupon devoted himself to journalism. His defense of liberal principles led to three months' imprisonment and when Dom Miguel was proclaimed king on May 3. 1828, Garrett again had to leave the country. He spent the next three years in and about Birmingham, Warwick and London. Returning in Feb. 1832, he disembarked at the island of Terceira, whence he proceeded to São Miguel, then the seat of the liberal government. There he co-operated with the statesman Mousinho da Silveira, assisting him in drafting the laws which were to revolutionize the framework of Portuguese society. In his spare time he wrote some of the lyrics later collected in *Flores* sem Fruto (1845). He took part in the expedition that landed on the Portuguese mainland at Mindelo on July 8, 1832, and in the subsequent occupation of Oporto by the liberal forces. In Oporto, influenced by the works of Walter Scott, he sketched out his historical romance *O* Arco de *Sant'Ana,* the first part of which was published much later, in 1845.

During 1834–35 Garrett served as consul general and chargé d'affaires in Brussels. Entering parliament in 1837, he soon made his mark as an orator, and was asked by the government to draw up proposals for the formation of a national theatre. Thus a school of actors and playwrights arose under his influence. To give them models he wrote a series of prose dramas, choosing his subjects from Portuguese history. He began in 1838 with the Auto de Gil Vicente and followed this with Dona *Filipa* de Vilhena (1840), *O* Alfngeme de *Santarém* (1841) and Frei *Luís* de Sousa (1843), one of the greatest of 19th-century Portuguese plays.

An excursion to Santarém in July 1843 resulted in a prose masterpiece describing his journey. *Viagens na* minha terra (1846). He took no part in the intermittent civil war which raged in Portugal about this time. He spent much of 1850 in completing his Romanceiro, a collection of traditional poems; he was the first to perceive the value of this type of poetry. In June 1851 he was created a viscount, and in 1852 was for a short time minister of foreign affairs. In 1853 he brought out Folhas *Caídas,* a collection of short love poems exquisite in form—the best Portuguese lyric poems of the romantic period. He died in Lisbon on Dec. 9, 1854. Poet, dramatist, novelist, journalist and orator, he deserves the comment of Rebelo da Silva: "Garrett was not a man of letters only but an entire literature in himself."

Garrett was endowed with a deep sensibility, a creative imagination and a fine control of language. He was first and always an artist. His artistic temperament is revealed in his many-sided activity, his expansive kindliness, his seductive charm, especially for women, his ardent patriotism, his aristocratic pretensions, his vanity and dandyism and the ingenuousness that made forgivable the many faults of his irregular life. His sincere, sensual and melancholy lyrics, his eloquence, the truth of his comedy and the elegance of his lighter compositions are all expressions of his richly endowed personality.

BIBLIOGRAPHY.—Garrett's complete works were edited by T. Braga in 28 vol. (1904–05). *See* also Gomes de Amorim, *Garrett, memórias biográficas,* 3 vol. (1881–84); T. Simões, *Garrett* (1954).

(E. P.; A. B.; N. J. L.)

GARRICK, DAVID (1717–1779), perhaps the greatest English actor and theatrical manager, was of French Huguenot descent. His grandparents. probably surnamed Garrigues, escaped to England from Bordeaux on the revocation of the Edict of Nantes, anglicized their name and, in due course, purchased a commission in the English army for their elder son, Peter. After Peter had married Arabella Clough, the daughter of a lay singer of Lichfield cathedral, he made Lichfield his home, bringing up a large family on modest means. His famous second son was born, however, at Hereford on Feb. 19, 1717, during a recruiting campaign. David, like Samuel Johnson before him, was educated at Lichfield grammar school under that stern disciplinarian John Hunter. In 1731 Captain Garrick, after some years on half pay, rejoined his regiment at Gibraltar, relying on "Davy" as the eldest son at home to send him regular reports on the doings at Lichfield during his absence. On his return in 1736 he sent David to be coached at Samuel Johnson's newly opened academy at Edial. But the seminary closed down six months later, and master and pupil decided to seek their fortunes in London. On March 2, 1737, Johnson, aged 27, and Garrick, aged 20, left Lichfield together on horseback for London—Johnson, as he later recalled, "with twopence halfpenny in his pocket" and Garrick "with three-halfpence in his." Intended by his father for the bar, David dutifully betook himself to Rochester to read law under the tutelage of John Colson, but Captain Garrick's death and a legacy of £1,000 from an uncle released him from studies profoundly uncongenial to him. In 1738 he and his elder brother, Peter, who had abandoned his career in the navy, set up in partnership as vintners in Lichfield and London, David managing the London branch.

Garrick had been stagestruck since childhood, and on the pretext of seeking custom, frequented the coffee houses of Covent Garden, where he made many theatrical friends, including Charles Macklin, whose theories on the reform of acting he assimilated, and Charles Fleetwood, manager of Drury Lane. Henceforth Garrick haunted the theatres, studying every branch of the art from tragedy to pantomime. On April 15, 1740, Fleetwood presented Garrick's first comic sketch, *Lethe,* which entered on a long period of popularity. In March 1741 Garrick appeared incognito as Harlequin in Henry Giffard's small unlicensed theatre at Goodman's Fields. In the summer Giffard's company opened at Ipswich, and there, under the name of Lyddal, Garrick made his first appearance as an actor as Aboan in T. Southerne's tragedy, *Oroonoko.* On Oct. 19, 1741, he appeared anonymously as Richard III at Goodman's Fields with resounding success. His daringly naturalistic style discredited forever the singsong elocution and formalized movements of the older tragedians—a style introduced into England from France after the Restoration. Among those who applauded him was Macklin, whose novel interpretation of Shylock earlier that year had prepared the way for Garrick's greater break with tradition. Londoners flocked to Goodman's Fields. Alexander Pope saw him three times and declared "that young man never had his equal and he never will have a rival." Having made his name as a tragedian, Garrick turned to comedy and after the hunchback king came a coxcomb, an aged madman, a tragic young lover, a foolish old husband and many more in a dazzling display of versatility, until it became an open question whether he excelled in comedy or tragedy. On Dec. 2, 1741, he used his own name for the first time as Lothario in N. Rowe's *The Fair Penitent.* Within the first seven months of his career he acted 18 characters.

Garrick's decision to go on the stage deeply offended his family, and they were slow to forgive him. On the day after his initial triumph in 1741, he wrote to Peter proposing to break their partnership. He had, he said, already lost £400 of his capital, whereas as an actor his future was assured. Neither his arguments nor the success of his farce, *The Lying Valet,* mollified his brother. Nevertheless, Garrick's fortune was indeed made, and Fleetwood engaged him for Drury Lane for the nine month season opening in Sept. 1742 at the record salary of 500 guineas. In preparation for his debut, Garrick acted at Drury Lane on three benefit nights in May. In June he went to Dublin and played opposite the fascinating Irish actress Peg Woffington at Smock Alley theatre. Their liaison, which lasted three years, began that summer. From Sept. 1742 to April 1745 he played at Drury Lane. After this he went again to Dublin and, jointly with Thomas Sheridan, managed Smock Alley theatre for the whole of the ensuing winter season. On his return in 1747 he accepted a short engagement with John Rich at Covent Garden and gave his last performances under a management not his own. At the close of the 1746–47 season, Fleetwood's patent for the management of Drury Lane expired, and Garrick, in partnership with James Lacy, purchased its renewal. Garrick contributed two-thirds of the money; *i.e.,* £8,000. The partners agreed to draw £500 a year each as managers, and Garrick, in addition, his actor's salary of 500 guineas with a clear benefit. On April 8, 1747, the agreement was signed, and in the autumn Garrick began his career as a manager.

The theatre reopened on Sept. 15, 1747, with Macklin's Shylock. Johnson's famous prologue was spoken by Garrick, whose policy as a manager it may be taken to express, while the latter's epilogue was spoken by Mrs. Woffington. The company included, besides Garrick himself, Mrs. Cibber, Mrs. Pritchard, Mrs. Clive, Mrs. Woffington, Spranger Barry, Macklin, Richard Yates and Edward Shuter. Henry Woodward joined them a year later. Fulfilling most of the functions of a modern producer, Garrick brought discipline to a slipshod stage and with judicious casting and strict rehearsing achieved a unity of style and an all-round excellence of performance new to its history. His own acting continued to astonish and delight. He chose his parts wisely, preferring those with energetic action and rapid changes of mood to suit his flamboyant style. Although his short stature made failure in such parts as Othello and Hotspur inevitable, his supremacy was never challenged. In tragedy, Barry most nearly approached him; in comedy, Woodward.

As a manager, Garrick's aim was to restore Shakespeare to favour and to discredit the Restoration plays, whose obscenity and false sentiment had, he thought, vitiated taste. Every season he presented at least ten plays popularly accepted as Shakespeare's, although most of them were in fact adaptations. He gave Nahum Tate's *King Lear,* without the Fool and with a happy ending; Colley Cibber's *Richard 111,* in which only half the lines were Shakespeare's; and John Dryden's *The Tempest,* in which Miranda has a sister and the love interest is doubled. Among his own versions are *Catherine and Petruchio, Florizel and Perdita* and *Cymbeline.* No copy of his ridiculed *Hamlet,* omitting the gravediggers and with a sentimentalized ending, survives, and the manuscript is said to have been buried with him. Like his audiences, he valued Shakespeare's dramatic situations rather than his poetry, but by popularizing certain roles he aroused fresh interest in Shakespeare's then unfamiliar text.

In considering new plays Garrick was ready to encourage talent and during his 29 years' management presented 75 new plays, exclusive of afterpieces. Nevertheless, disappointed authors accused him of malice and self-interest and involved him in many paper wars. Even Johnson, whose turgid play, *Irene,* he presented in 1749 with painstaking care, showed little gratitude. Among his few sins of omission are his refusals of R. Dodsley's *Cleone* and J. Home's *Douglas.* More reprehensibly, he failed to recognize Oliver Goldsmith's dramatic gifts and missed the opportunity of presenting *She Stoops to Conquer.* He did little to bring greater historical'accuracy to stage costume, excelling rather in spectacle, thus preparing the way for melodrama. In Philippe de Loutherbourg, he discovered a stage designer of genius.

Garrick had married in 1749 Eva Maria Veigel, a Viennese dancer professionally known as Mlle. Violette, the ward of Lord and Lady Burlington. Little is known of her prior to her arrival in England in 1746, and her adoption by the Burlingtons has inspired many legends as to her parentage. The Garricks' marriage, though childless, was ideally happy. When in London they lived in Southampton street until 1772, when they removed to Adelphi terrace. Their real home was, however, by the Thames at Hampton, where in 1754 Garrick bought a villa. In 1763 fatigue suggested the need for a holiday. Leaving his younger brother, George, in charge of his personal interests, he and Mrs. Garrick went abroad for 18 months. In Naples they basked in the flattering attentions of the English aristocracy; elsewhere in Italy they were also cordially received. In Munich, Garrick suffered a serious abdominal illness, which left him with a weakness he never wholly overcame. In Paris, where they broke their outward and homeward journeys, Garrick made many friends among the actors and among the *Philosophes,* to whom as Shakespeare's champion he was especially interesting. His private performances of Shakespearean scenes in dumbshow started a vogue for naturalism in the English manner, and Denis Diderot's *Paradoxe sur le comédien* was the outcome of their meeting.

In Nov. 1765 Garrick reappeared at Drury Lane as Benedick in *Much Ado About Nothing.* Henceforth he acted less frequently and never again in a new role. His refusal to play Lord Ogleby in his own and G. Colman's *The Ctandestine Marriage* led to a quarrel between them, but Thomas King's brilliant rendering of the part contributed to the comedy's success in Feb. 1766. In 1769 Garrick organized the Shakespeare jubilee at Stratford-on-Avon, thus bringing that town into prominence as the poet's birthplace. In 1773 he was elected to the Literary club and, as a member of the Johnson circle, makes many appearances in the pages of James Boswell's *Life of Johnson.* In 1776 he sold his share of the Drury Lane patent for £35,000 and gave a series of last performances in his favourite roles. They included Hamlet, Lear, Richard III and Benedick, Lusignan in A. Hill's *Zara,* Drugger in Ben Jonson's *The Alchemist,* Sir John Brute in Sir John Vanbrugh's *The Provoked Wife,* Archer in Thomas Farquhar's *The Beaux' Stratagem,* Leon in John Fletcher's *Rule a Wife and Have a Wife* and Ranger in John Hoadly's *The Suspicious Husband.* Finally, on June 10, he bade farewell to the stage as the youthful Don Felix in Mrs. Centlivre's *The Wonder!* In the course of his career he had played 96 roles. He died in London on Jan. 20, 1779, and was buried in the Poets' corner of Westminster abbey. He left a fortune of over £100,000. Mrs. Garrick survived him until 1822.

Garrick was under medium height and in later years inclined to stoutness. His large, well-marked features and compelling black eyes served him as an actor in a theatre lit by candlelight better than conventional good looks. The extraordinary mobility of his whole person, which enabled him to transform himself, as it were, at will, are attested by many anecdotes. His charm and culture gained him many friends among the aristocracy, but his vanity, touchiness and snobbishness alienated his fellow actors. His reputation for meanness was ill-deserved. According to Johnson, Garrick had given away more money than any man in England. Goldsmith's poem *Retaliation* is a portrait of penetrating truth. Garrick's own work has proved ephemeral. "A fellow-feeling makes one wond'rous kind" is one of the few lines remembered from his 80 prologues and epilogues. Of his songs, the best-known is "Heart of Oak."

Portraits and engravings of Garrick are numerous. Sir Joshua Reynolds painted him many times. Hogarth, Zoffany and Sir Nathaniel Dance-Holland depicted him in character. Mrs. Garrick's favourite likeness of him by Gainsborough perished in the fire at Stratford in 1946. L. Roubillac's statue of Shakespeare, for which Garrick sat, is in the British museum.

BIBLIOGRAPHY.—Garrick's dramatic works, nearly all of which are adaptations, have never been collected. A selection was published in 3 vol. in 1768. *The Poetical Works of David Garrick* in 2 vol. appeared in 1785. Chief authorities for his life are his own letters, ed. by James Boaden, from manuscripts in the Victoria and Albert museum, *The Private Correspondence of David Garrick* (1831), and Tom Davies' *Memoirs of the Life of Garrick* (1780). Subsequent studies: Percy Fitzgerald, *The Life of David Garrick* (1868; rev. ed., 1899); Joseph Knight, *David Garrick* (1894); and Margaret Barton, *Garrick* (1947). References occur in the memoirs of Fanny Burney, Richard Cumberland, Mrs. Thrale (Mrs. Hester Piozzi), Hannah More and Tate Wilkinson. (MT. BN.)

GARRISON, LINDLEY MILLER (1864–1932), U.S. lawyer and secretary of war, was born at Camden, N.J., on Nov. 28, 1864. He attended Phillips Exeter academy, Harvard (for one year) and graduated from the University of Pennsylvania law school in 1886. In the same year he was admitted to the Pennsylvania bar and began law practice in Philadelphia. In 1888 he was admitted to the New Jersey bar and practised law in Camden until 1898 when he founded a law firm in Jersey City. He was appointed to the office of vice-chancellor of the state in June 1904, and, at the end of his first term in 1911, was reappointed and remained in office until 1913 when President Wilson named him for a post in his cabinet as secretary of war.

During his term of office, Garrison initiated a system of summer training camps to provide for a reserve of commissioned army officers. Originally designed for college students, the plan was extended in 1915, after the beginning of World War I, to include camps for business men. He instituted reforms in the administration of the insular possessions and was credited with writing a bill which, among other things, established a legislature for the Philippines. At the president's request, Garrison, aided by the general staff, developed a plan for increasing the military forces of the country but resigned on Feb. 10, 1916, when the president did not support his proposals as fully as he had expected. He resumed the practice of law, and died at Sea Bright, N.J., Oct. 19, 1932.

GARRISON, WILLIAM LLOYD (1805–1879), the American antislavery leader, was born in Newburyport, Mass., on Dec. 10, 1805. His parents were from the British province of New Brunswick. The father, Abijah, a sea captain, drank heavily and deserted his home when William was a child, and it is not known whether he died at sea or on land. The mother, whose maiden name was Lloyd, is said to have been a woman of high character, charming in person and eminent for piety. She died in 1823. William had little education but made the most of his opportunities. He was set to learn the trade of a shoemaker, first at Newburyport, and then, after 1815, at Baltimore, Md. Then he was apprenticed to a cabinet-maker at Haverhill, Mass., but ran away. In Oct. 1818, when he was 14, he was indentured to Ephraim W. Allen, proprietor of the Newburyport *Herald*, to learn the trade of a printer. He soon became an expert compositor, and after a time began to write anonymously for the *Herald*. His communications won the commendation of the editor, who had not at first the slightest suspicion that he was the author. He also wrote for other papers with equal success. His skill as a printer won for him the position of foreman, while his ability as a writer was so marked that the editor of the *Herald*, when temporarily called away from his post, left the paper in his charge.

The printing office afforded him an opportunity to increase his meagre education. He was enthusiastic about liberty; the struggle of the Greeks to throw off the Turkish yoke enlisted his sympathy; and at one time he seriously thought of entering the West Point academy and fitting himself for a soldier's career. His apprenticeship ended in 1826, when he beqan the publication of a new paper (actually the old one under a new name), the *Free Press*, in his native place. The paper, whose motto was "Our Country, our Whole Country, and nothing but our Country," was an intellectual force, but was too radical for Newburyport, and the enterprise failed.

Garrison then went to Boston, where, after working for a time as a journeyman printer, he became the editor of the *National Philanthropist*, the first journal established in America to promote the cause of total abstinence from intoxicating liquors; but a change in the proprietorship led to his withdrawal before the end of the year. In 1828 he established the *Journal of the Times* at Bennington, Vt., to support the re-election of John Quincy Adams to the presidency of the United States. This paper also died within a year. In Boston he had met Benjamin Lundy (*q.v.*), who had for years been preaching the abolition of slavery. Garrison had been deeply moved by Lundy's appeals, and after going to Vermont he showed the deepest interest in the slavery question. Lundy was then publishing in Baltimore a small monthly paper, *The Genius of Universal Emancipation*, and he went to Bennington and invited Garrison to join him in the editorship. His mission was successful.

Garrison first accepted Lundy's views of gradual emancipation, but soon changed to total and immediate freedom for slaves when he joined Lundy in Baltimore in 1829. Lundy believed that the Negroes, on being emancipated, must be colonized somewhere beyond the limits of the United States; Garrison held that they should be emancipated on the soil of the country, with all the rights of freemen. Garrison saw that it would be idle to expose and denounce the evils of slavery, while responsibility for the system was placed upon former generations, and the duty of abolishing it transferred to an indefinite future. His demand for immediate emancipation fell like a tocsin upon the ears of slaveholders. The *Genius*, when it became a vehicle for this dangerous doctrine, was feared and hated. Baltimore was then one of the centres of the domestic slave trade, and upon this trafficGarrison heaped the strongest denunciations. He was prosecuted for libel by the owner of a slave-carrying vessel, was fined $50, and, in default of payment, committed to jail.

John G. Whittier interceded with Henry Clay to pay Garrison's fine and thus release him from prison. Clay responded favourably, but before he could act Arthur Tappan, a philanthropic merchant of New York, contributed the necessary sum and set the prisoner free after an incarceration of seven weeks. The partnership between Garrison and Lundy was then dissolved by mutual consent, and Garrison resolved to establish a paper of his own, in which he could advocate the doctrine of immediate emancipation and oppose the scheme of African colonization. He first proposed to establish his paper at Washington, in the midst of slavery, but on returning to New England and observing the state of public opinion there, he came to the conclusion that little could be done in the south while the non-slaveholding north was lending her influence for the sustenance of slavery. He determined, therefore, to publish his paper in Boston, and set himself to the task of awakening an interest in the subject by lectures in some of the principal cities and towns of the north. In Boston, then a great cotton mart, he tried in vain to procure a church or vestry for the delivery of his lectures, until a body of infidels under the leadership of Abner Kneeland (1774–1844), proffered him the use of their small hall. He accepted it gratefully, and delivered in Oct. 1830 three lectures, in which he unfolded his principles and plans.

On Jan. 1, 1831, without capital and without a subscriber, he and his partner, Isaac Knapp (1804–43), issued the first number of the *Liberator,* avowing their "determination to print it as long as they could subsist on bread and water, or their hands obtain employment." Its motto "Our country is the world—our countrymen are mankind," shows his changed viewpoint. The paper in addition to favouring abolition, attacked war, alcoholic liquors and tobacco, and assailed freemasonry, capital punishment, and imprisonment for debt. The editor, in his address to the public, uttered the words which have become memorable as embodying the whole purpose and spirit of his life: "I am in earnest—I will not equivocate—I will not excuse—I will not retreat a single inch—and I will be heard." For many months Garrison and his partner made their bed on the floor of the room in which they printed their paper, and where Mayor Harrison Gray Otis of Boston, in compliance with the request of Governor Robert Y. Hayne of South Carolina, "ferreted them out." Otis decided, however, that the paper could not be suspended. In the same year (1831), $5,000 reward was offered for Garrison's arrest and conviction under the laws of Georgia. The *Liberator,* though in constant financial difficulties, exerted a mighty influence, and lived to record not only President Lincoln's proclamation of emancipation, but the adoption of an amendment to the constitution of the United States forever prohibiting slavery.

Garrison was a pacifist, and sought the abolition of slavery by moral means alone. He knew that the national government had no power over the system in any state, though he thought it should bring its moral influence to bear in favour of abolition. His idea was to combine the moral influence of the north, and pour it through every open channel upon the south. To this end he made his appeal to the northern churches and pulpits, beseeching them to bring the power of Christianity to bear against the slave system, and to advocate the rights of the slaves to immediate and unconditional freedom. When they did not respond, he denounced them, and by 1840 had become very unorthodox. The first society organized under Garrison's auspices, and in accordance with his principles, was the New England antislavery society in Jan. 1832. The same spring Garrison issued his *Thoughts on African Colonization,* in which he showed from official documents that the American colonization society was organized in the interest of slavery, and that in offering itself as a practical remedy for that system it was guilty of deception. Garrison was deputed by the New England antislavery society to visit England for the purpose of counteracting the influence there of agents of the colonization society. He went in the spring of 1833, and was received with great cordiality by British abolitionists. He took home with him a "protest" against the American colonization society signed by Wilberforce, Zachary Macaulay, Samuel Gurney, William Evans, S. Lushington, T. Fowell Buxton, James Cropper, Daniel O'Connell and others.

Garrison's visit to England enraged the pro-slavery people, and when he returned in September with the "protest" against the colonization society, and announced that he had engaged the services of George Thompson as a lecturer against American slavery, there were fresh outbursts. The American antislavery society was organized in December of that year (1833), the declaration of its principles coming from Garrison's pen. The activities of this society and Thompson's lectures aroused such fury that, in the autumn of 1835, Thompson was compelled to return secretly to England. He had announced that he would address the women's antislavery society in Boston, and a mob gathered. Not finding him, it seized Garrison and dragged him through the streets until he was rescued, and protected in the jail until he could leave the city in safety.

The abolitionists of the United States were a united body until 1839–40 when division occurred. Garrison countenanced the activity of women in the cause, even appointing them as lecturing agents; moreover, he believed in the political equality of the sexes, to which a strong party was opposed upon social and religious grounds. His attack on the churches caused dissent. Many believed that Garrison injured abolitionism by causing it to be associated in men's minds with these unpopular views on other subjects. These differences led to the organization of a new national antislavery society in 1840, and to the formation of the "Liberty Party" (*q.v.*) in politics (*see* BIRNEY, JAMES *G.*). The two societies sent their delegates to the world's antislavery convention in London in 1840, and Garrison refused to take his seat in that body, because the women delegates from the United States were excluded. The discussions of the next few years served to make clearer than before that the constitution of the United States supported slavery; and Garrison came to the conclusion that its pro-slavery clauses were immoral, and that it was therefore wrong to take an oath for its support. Because of this, Garrison burned the constitution, denouncing it as "a covenant with death and an agreement with hell." He chose as his motto, "No union with slaveholders," and thereafter worked for peaceful disunion. When in 1861 the southern states seceded from the union and took up arms against it, he saw clearly that slavery would perish in the struggle and that the constitution would be purged of its pro-slavery clauses. He therefore ceased to advocate disunion, and devoted himself to hastening the inevitable event. His services at this period were recognized and honoured by President Lincoln and others in authority, and the whole country knew that the agitation which resulted in the abolition of slavery was largely due to his uncompromising spirit and indomitable courage.

In 1865 at the close of the war, he declared that, slavery being abolished, his career as an abolitionist was ended. He counselled a dissolution of the American antislavery society, insisting that it had become *functus officiis,* and that whatever needed to be done for the protection of the freedmen could best be accomplished by new associations formed for that purpose. The *Liberator* was discontinued at the end of the same year, after an existence of 35 years. He visited England for the second time in 1846, and again in 1867, when he was received with distinguished honours, public as well as private. In 1869 he became president of the Free Trade league, advocating the abolition of custom houses throughout the world. In 1877, he again visited England, and declined every form of public recognition. He died in New York on May 24, 1879, at the age of 74, and was buried in Boston, after a most impressive funeral service, four days later. In 1843 a small volume of his *Sonnets and other Poems* was published, and in 1852 appeared a volume of *Selections from his Writings and Speeches.*

Garrison's son, WILLIAM LLOYD GARRISON (1838–1909), was a prominent advocate of the single tax, free trade, woman's suffrage, and of the repeal of the Chinese Exclusion act, and an opponent of imperialism. Another son, WENDELL PHILLIPS GARRISON (1840–1907), was literary editor of the New York *Nation* from 1865 to 1906.

BIBLIOGRAPHY.—The great authority on the life of Garrison is the thorough and candid work of his sons, W. P. and F. J. Garrison, *William Lloyd Garrison, 1805–1879; The Story of his Life told by his Children* (4 vols., 1885–89). See *Garrison: an Outline of his Life* (1879), and *William Lloyd Garrison and his Times* (1880) by Oliver Johnson, a prominent abolitionist and intimate friend of Garrison. Goldwin Smith's *The Moral Crusader; a Biographical Essay on William Lloyd Garrison* (1892) is a brilliant sketch. J. J. Chapman's *Garrison* (1913) is valuable for its picture of the abolition movement; Lindsay Swift, *William Lloyd Garrison* (1911), is a reliable biography though it is too eulogistic; Edward Channing, *A History of the United States* (vol. v and vi, 1905–25), and Ellis Paxson Oberholtzer, *A History of the United States since the Civil War* (1917–26) give the relation of Garrison to the history of his time.

GARROTTE (Spanish for "cudgel"), an appliance used in Spain and Portugal for the execution of condemned criminals (*see* CAPITAL PUNISHMENT). The execution was performed originally by twisting a cord or bandage on the criminal's neck until strangulation occurred but later a mechanically operated metal collar was adopted. "Garrotting" is the name given in England to a form of robbery with violence which became rather common in the winter of 1862–63. An act of 1863, imposing the penalty of flogging in addition to penal servitude for this offense, had the effect of stopping it almost entirely.

GARRYA, the single genus of attractive, broad-leaved, evergreen, treelike shrubs of the family Garryaceae consisting of several Californian, Mexican and Central American species closely related to the dogwood family, Cornaceae. Their male and female flower-bearing catkins occur on separate plants, are pendulous, several inches long and somewhat woolly—hence the common name "Silk Tassel Bush." Hypogynous, pulpy berries develop in the female catkins.

The leaves of different species vary from light to dark green on top. are hairy or downy on the lower surface, and have smooth to wavy margins. Two California species, *Garrya elliptica* and *G. fremontii,* have been horticulturally adapted.

GARSHIN, VSEVOLOD MIKHAILOVICH (1855–1888), Russian author. was born in the government of Ekaterinoslav (Dnepropetrovsk) in Feb. 1855, the son of a retired army officer. From his childhood he had a nervous temperament, and in 1872 he was put under restraint for a year. In 1874 he entered the High School of Mines at St. Petersburg (now Leningrad), but on the outbreak of the Russo-Turkish War (1877) he enlisted as a private in an infantry regiment. Wounded in hug. 1878 he was invalided home; from that time he suffered from frequent attacks of melancholia. He died on March 24, 1888. Many of his best known stories, *The Signal* (1912); *The Coward, Mad Love,* or *An Artist's Dream* (1889); *The Red Flower* (1883); *Attalea Princeps* and *That which was Not* have been translated into English. His *Four Days,* written while he was lying wounded at Kharkov. created a great sensation.

GARSTANG, JOHN (1876–1956), British archaeologist whose unusually wide experience of sites in the middle east culminated in his work at Mersin, Turkey, during 1937–47, was born in Blackburn. Lancashire, May 5, 1876. In 1897, while a mathematical scholar at Jesus college, Oxford, he began the excavation of Roman sites in England and in 1902 was made honorary reader in Egyptian archaeology at Liverpool university. He became professor of archaeological methods and practice there in 1907, and retained this position until his retirement in 1941. During 1900–08 he excavated sites in Egypt, Nubia and Asia Minor, becoming an authority on the Hittite civilization, on which he published a standard work, *The Land of the Hittites* (1910), revised as *The Hittite Empire* in 1929. His excavations of the ancient Ethiopian capital, Meroë, 1909–14, revealed evidence of its occupation by Roman troops.

During World War I Garstang served with the Red Cross in France. In 1919 he was made director of the British School of Archaeology in Jerusalem and in 1920 was also made first director of the Palestine department of antiquities. He retired from both posts in 1926 In 1930 he began work at Jericho, where important discoveries were made about the city's history in the Bronze Age. His work at hfersin began in 1937; he published his conclusions in 1953 (*Prehistoric Mersin)*; and although some features of his method and presentation were criticized, its importance was recognized by his appointment as first director of the British Institute of Archaeology at Ankara. 1947–48, and president from 1949 until his death at Beirut, Lebanon, Sept. 12, 1956. His books included *The Foundations of Bible History: Joshua, Judges* (1931).

GARSTIN, SIR WILLIAM EDMUND (1849–1925), British engineer, was born in India on Jan. 29, 1849. He was educated at Cheltenham and King's college, London, and in 1872 entered the Indian public works department. In 1885 he was transferred to Egypt, and in 1892 became inspector general of irrigation and under secretary of state for public works. He proved himself an indefatigable worker, and by his efforts extensive areas were reclaimed in Egypt and the Sudan. Among his greatest works were the Asyut barrage and the Aswan reservoir. In addition, it was due to him that the White Nile was cleared of sudd, thus rendering possible free navigation between Khartoum and Gondokoro. In 1907 he was appointed British government director of the Suez Canal company. During World War I he devoted himself to Red Cross work in England, being created G.B.E. in 1918.

He died in London on Jan. 8, 1925.

GARTH, SIR SAMUEL (1661–1719), English physician and poet, entered Peterhouse, Cambridge, in 1676, graduating B.A. In 1679, and M.A. in 1684. He took his M.D. and became a member of the College of Physicians in 1691. In 1699 he published a mock-heroic poem, *The Dispensary,* in six cantos, which had an instant success, passing through three editions within a year. The poem is a record of the first attempt to establish the outpatient rooms which later became common in England, and ridicules the apothecaries and their allies among the physicians. Garth was a member of the Kit-Kat club, and became the leading physician of the Whigs, as Radcliffe was of the Tories. In 1714 he was knighted by George I and was made physician-in-ordinary to the king and physician-general to the army. He died on Jan. 18. 1719.

GARTOK (GARYARSA) is the capital of Ngari (Ari) district in the western Tibetan highland. Ngari was the birthplace of the native pre-Buddhic Tibetan religion, Bon Po, a mixture of exorcism and primitive worship, and was also the scene of the Buddhist renaissance in the 11th century. Gartok, on the upstream of the Indus, is the western gateway to Tibet. A caravan route leading to Leh and Simla in India through the Shipki pass has existed for centuries. Gartok is joined to Ngachuka via Zhikatse, and to Polur and Khotan in Sinkiang by modern highways. The Taklakot or Taklakhar highway, 157 mi. long, links Gartok with Pulanchung (Puran Tzong), a rich agricultural region on the south.

Gartok, once a desolate town in winter, was considerably built up after the Chinese Communist occupation of Tibet. A large garrison force is stationed in the region. New banks, post offices, schools, general stores and hospitals have been constructed along the Gar river.

During the warm season, a brisk barter trade is carried on between the nomads from the northern plain, the Zhikatse merchants and the traders from India and Nepal. Regular fairs are held throughout the summer, attracting as many as 2,000 people daily, with hundreds of tents littering the bare plain and hillside during the night. (T.-L. S.)

GARUT, a regency in Java, Indonesia. It has a population of 847,758, and is the centre of a well-cultivated region, noted for its tea, rubber and cinchona plantations, but is better known as one of the most beautiful health resorts of Java. Situated at a height of 2,300 ft. above sea level, the town (pop. 55,850) is very charmingly laid out. The regency forms a plateau, around which are grouped magnificent mountains, some volcanoes, with mountain lakes, hot springs and other wonders of nature. Among the most interesting excursions are the crater of the Papandayan, a volcano still active, which blew out the greater part of one side of a mountain in 1772, killing thousands of people and destroying much of the surrounding countryside; the Kawah Kamodyan, a most interesting collection of pools of boiling mud, geysers and fumaroles; the Telega Bodas, or White lake, situated amid charming forest scenery; the Kawah Manut, or Bird's Crater; the lakes of Bagendit and Leles, and the hot springs of Chipanas; the lake of Pendjalu; and Mount Chikorai. The regency was occupied by the Japanese from March 1942 to the end of World War II.

GARY, ELBERT HENRY (1846–1927), U.S. jurist and chief organizer of the United States Steel corporation, was born on Oct. 8, 1846, near Wheaton, Ill. He studied law first in the office of his uncle, Col. Henry Vallette, and then at the Union College of Law in Chicago, from which he was graduated in 1867. In 1869 he began his law practice in Chicago. He was elected judge of Du Page county in 1882 and again in 1886. During this period he also frequently held court in Chicago and Cook county and occasionally presided over important cases in other counties throughout the state of Illinois. He was three times elected president of the town of Wheaton and, on its becoming a city in 1890, served as mayor for two terms.

A leader and authority in corporation law and insurance matters, he became general counsel and a director in a number of large railroads, banks and industrial corporations, including steel and wire companies. In 1891 he was one of the organizers of the Consolidated Steel and Wire company. In 1898. upon the organization of the Federal Steel company, with the financial backing of J. P. Morgan and Company, he became its first president and retired from legal practice. This company was merged in 1901 with the U.S. Steel corporation, which was then organized with a capital stock exceeding $1,000,000,000, then by far the largest industrial corporation in the world. Gary was elected chairman of the executive committee and later chairman of the board of directors and of the finance committee, and continued to be chief executive officer during 26 years of remarkable development of the steel industry and growth of the corporation.

The steel mills and town of Gary, Ind., were laid out in 1906 by the U.S. Steel corporation and later named in his honour. By the time of Gary's death, the town had grown to be a city of more than 100,000, with enormous and varied mills for the manufacture of iron and steel products. As chairman of U.S. Steel, he advocated and established many measures for the welfare of the employees of industrial corporations, including stock ownership by them and participation in profits, high wages and safe, sanitary and pleasing surroundings. He was always a strong advocate and a firm upholder of the open shop. During his chairmanship the 7-day week and the 12-hour day for labour in the steel mills were abolished. He died in New York city, Aug. 15, 1927.

(J. A. FA.; X.)

GARY, one of the largest cities in Indiana. is located at the southern end of Lake Michigan. The city's history began in 1906 with the construction of the huge steel mills and various subsidiary plants of the United States Steel corporation. Since the building of the municipality was included in the plans of the steel company, Gary was a "city by decree." Gary was incorporated as a town in 1906 and became a city in 1909. It was named for Judge Elbert H. Gary, chairman of the board of directors of United States Steel.

In 1905 and 1906 the steel company purchased 9,000 ac. of sand ridges and swamps which included a frontage of more than seven miles on Lake Michigan. The location was selected because of its position midway between the iron ore beds of the north, accessible by water, and the coal region of the south. The steel works were constructed along the lake shore and the city was located to the south. The Gary Land company, a subsidiary of the steel corporation. platted and laid out its part of the city, constructed the streets and sidenalks, installed the sewage system and built the water works and electric plant. In Dec. 1908 the first blast furnace was fired, and the production of steel began early the following year. Subsidiary plants of the United States Steel corporation, American Bridge, American Sheet and Tin Plate and National Tube mills were located in the vicinity, and a large manufactory of portland cement was established. Manufacturers of screws and bolts, steel springs, automobile bodies and chemicals also established plants in the course of the years. However, Gary is essentially a one industry city; it has periodically suffered economic hardship when steel production has declined and when the huge mills have been shut down by strikes, as during the 116-day strike in the fall of 1959, which was finally settled in Jan. 1960.

Culturally, Gary was the scene of the establishment by William A. Wirt of the work-study-play school, more popularly known as the platoon school, a significant development in the history of public-school education. The city is served by an extension centre of Indiana university. The park system includes a public beach on Lake Michigan. The population soared, reaching 178,320 in 1960; for comparative population figures *see* table in ISDIANA: *Population.* In the 1950 census Gary was treated as a part of the Chicago metropolitan area; in 1960 it was designated a central city of the Gary-Hammond-East Chicago standard metropolitan statistical area, comprising Lake and Porter counties, pop. 573,548, a part of the Chicago standard consolidated area. *See* CHICAGO: *Population: Metropolitan Area.* (P. ME.)

GAS, a general term for one of the three states of aggregation of matter; also more specifically applied to coal gas. *See* ANESTHESIA AND ANESTHETICS; CHEMISTRY: *Physical Chemistry*; GAS INDUSTRY; CHEMICAL WARFARE.

GAS CHAMBER, a method of execution used in the United States, introduced in an effort to provide a more humane way of killing condemned criminals; it was first used in Nevada in 1924. It consists of a sealed chamber into which poisonous fumes are injected. The condemned man is strapped in a chair in the lethal chamber and is killed by inhaling the fumes. If the prisoner breathes deeply, his death is almost instantaneous and painless, but many resist by holding their breath or by taking short, slow breaths, and some observers claim that these prisoners suffer very much By the second half of the 20th century nearly one-fourth of the states prescribed the gas chamber as the method of execution

(R. G. CL.)

GASCOIGNE, GEORGE (c. 1530–1577), English poet: was one of the most talented of the writers who flourished during the early Elizabethan period, before Edmund Spenser's *Shepheardes Calender* (1579) gave a new direction and impetus to English poetry. The son of Sir John Gascoigne of Cardington, Bedfordshire, he attended Trinity college, Cambridge, began the study of law at Gray's Inn in 1555, and thereafter pursued careers as a politician, country gentleman, courtier, soldier of fortane and man of letters, achieving moderate distinction in each. He was M.P. for Bedford in the parliaments of 1557–58 and 1558–59. In 1561 he married Elizabeth Breton, a widow, and thus became stepfather to the poet Nicholas Breton. On his paternal estate be became involved in litigation, mainly because of his extravagance and debts. was once imprisoned in Bedford jail and gained a reputation for disorderly living. From 1572 to 1574 he served with English troops in the Low Countries and obtained a captain's commission, ending his military career as a repatriated prisoner of war. In 1575 he helped to arrange the celebrated entertainments provided for Queen Elizabeth I at Kenilworth and Woodstock, and in 1576 went to Holland as an agent in the royal service. Gascoigne died at Bernack, near Stamford; on Oct. 7, 1577, and was buried at Stamford. Among his personal friends were many of the leading poets, courtiers and court ladies of his day, notably the poets George Whetstone, George Turberville and Edmund Spenser and the literary patron Lord Grey of Wilton.

Gascoigne was a skilled literary craftsman, and his work is memorable for its versatility and vividness of expression and for his treatment of events based on his own experience; but his chief importance is as a pioneer of the English Renaissance, with a remarkable aptitude for domesticating ioreign literary genres. He foreshadowed the English sonnet sequences with groups of linked sonnets in his first published work, *A Hundreth Sundrie Flowres* (1573), a collection of verse and prose. In *The Posies* (1575), an authorized revision of the earlier work which had been published anonymously, he included also "Certain Notes of Instruction," the first treatise on prosody in English. In *The Steel Glass* (1576), one of the earliest formal satires in English, he wrote the first original nondramatic English blank verse. In subject, however, *The Steel Glass* is traditional; it is an attack, in the spirit of *Piers Plowman,* on the worldliness, corruption and Italianate manners of the aristocracy, and a defense of native feudal virtues. In two amatory poems, the autobiographical "Dan Bartholomeu of Bath" (published in *A Hundreth Sundrie Flowres)* and *The Complaint of Pkilomene* (1576), Gascoigne developed Ovidian verse narrative, the form used by Shakespeare in *Venus and Adonis* and *Lucrece.*

"The Adventures of Master F. J.", published in *A Hundreth Sundrie Flowres,* was the first original prose narrative of the English Renaissance. Probably because of embarrassment caused by the factual elements in this tale of love intrigue in an English country house, Gascoigne revised the work; and it appeared in *The Posies* as "The Pleasant Fable of Ferdinando Jeronimi and Leonora de Valasco," purportedly a translation from the Italian with the more libidinous passages removed. Another prose work. *The Spoil of Antwerp* (1576), is an early example of war journalism, characterized by objective and graphic reporting.

Gascoigne's *Jocasta* (performed in 1566) was the first Greek tragedy to be presented on the English stage. Translated into blank verse, with the collaboration of Francis Kinwelmersh, from Lodovico Dolce's *Giocasta,* it derives ultimately from Euripides' *Phoenissae.* In comedy, Gascoigne's *Supposes* (1566?), a prose translation and adaptation of Ariosto's *I Suppositi,* was the first prose comedy to be translated from Italian into English. A dramatically effective work, it provided the subplot for Shakespeare's *The Taming of the Shrew.* A third play, *The Glass of Government* (1575), is a didactic drama on the prodigal son theme. Together with several moralistic works in traditional forms of verse and prose on such commonplace themes as the vanity of human life, the sinfulness of man and the evils of drunkenness, it rounds out the picture of Gascoigne as a typical literary man of the early Renaissance, who never lost contact with native tradition as he made his periodic excursions into foreign literature to bring back new forms and themes.

The standard edition is *The Complete Works of George Gascoigae,* edited by J. W. Cunliffe, published in two volumes (1907–10). The original version of his first published work was reprinted in *George Gascoigne's "A Hundreth Sundrie Flowres,"* edited by C. T. Prouty (1942).

See C. T. Prouty, *George Gascoigne, Elizabethan Courtier, Soldier, and Poet* (1942); S. A. Tannenbaum, *George Gascoigne, a Concise Bibliography* (1942). (L. A. SK.)

GASCOIGNE, SIR WILLIAM (c. 1350–1419), chief justice of England in the reign of Henry IV. Gascoigne practised as an advocate in the reigns of Edward III and Richard II. On the banishment of Henry of Lancaster, Gascoigne was appointed one of his attorneys, and soon after Henry's accession to the throne was made chief justice of the court of king's bench. After the suppression of the rising in the north in 1405, Henry eagerly pressed the chief justice to pronounce sentence upon Scrope, the archbishop of York, and the earl marshal Thomas Mowbray, who had been implicated in the revolt. This he absolutely refused to do, asserting the right of the prisoners to be tried by their peers. Although both were afterward executed, the chief justice had no part in the transaction. The oft-told tale of his committing the prince of Wales to prison is unauthentic, though it is characteristic of Gascoigne's independence. Gascoigne appears to have been removed from his post or to have resigned soon after the accession of Henry V. He died in 1419, and was buried in the parish church of Harewood in Yorkshire.

GASCONY (WASCONIA; Fr. *Gascogne),* an old province in southwest France. It takes its name from the Vascones, people of Iberian origin settled in the north of Spain who, between 561 and 602, crossed the Pyrenees and invaded the district known to the Romans as Novempopulana or Aquitania Tertia. Basque, the national language of the Vascones, took root only in a few of the high valleys of the Pyrenees, such as Soule and Labourd; in the plains Latin dialects prevailed, Gascon being a Romance language. In the 7th century the name of Vasconia was substituted for that of Novempopulana. The Vascones readily recognized the sovereignty of the Merovingian kings, but in reality they remained independent. They even appointed national dukes, against whom Charlemagne had to fight at the beginning of his reign. Finally, during the second half of the 9th century, the Carolingians were able to establish Frankish dukes in the country. But it must be admitted that, at that time and in the 10th century, the history of Gascony falls into the profoundest obscurity. In the feudal period Gascony comprised a great number of countships (including Armagnac, Bigorre, Fezensac, Gaure and Pardiac), viscountships (including Béarn, Lomagne, Dax, Juliac, Soule, Marsan, Tartas, Labourd and Maremne) and seigneuries (Albret, etc.).

During the Hundred Years' War Gascony was a battlefield for the forces of England and of France. The French seized the duchy, but, aided by the rivalry between the powerful houses of Foix and Armagnac, Edward III was able to recover it; and by the treaty of Brétigny in 1360 John II recognized the absolute sovereignty of England therein. Handed over as a principality by Edward to his son, the Black Prince, it was used by its new ruler as a base during his expedition into Spain, in which he received substantial help from the Gascon nobles. The renewal of the war between England and France, which took place in 1369, was due in part to a dispute over the sovereignty of Gascony, and during its course the whole of the duchy save a few towns and fortresses was lost; but the victories of Henry V in northern France postponed for a time the total expulsion of the foreigner. This was reserved for the final stage of the war and was one result of the efforts of Joan of Arc, the year 1451 witnessing the capture of Bayonne and the year 1453 the final retreat of the English troops from southwestern France.

The French kings, especially Louis XI, managed to restore the royal authority in the duchy, although this was not really accomplished until the close of the 15th century when the house of Armagnac was overthrown. It was by means of administrative measures that these kings attained their object. Gascony was governed on the same lines as other parts of France; and from the time of Henry IV, who was prince of Béarn and who united his hereditary lands with the crown, its history differs only slightly from that of the rest of the country. The Renaissance inspired the foundation of educational institutions and the Reformation was largely accepted in BCarn, but not in other parts of Gascony. The wars of religion swept over the land, which was the scene of some of the military exploits of Henry IV; and Louis XIV made some slight changes in its government. As may be surmised, the boundaries of Gascony varied from time to time, but just before the outbreak of the Revolution they were the Atlantic ocean, Guienne, Languedoc and the Pyrenees; and from east to west the duchy at its greatest extent measured 170 mi.

At the end of the *ancien régime* Gascony was united with Guienne to form a great military government. After the division of France into *de'partements,* Gascony, together with Béarn, French Navarre and the Basque country, formed the *de'partements* of Basses-Pyrénées, Landes, Hautes-Pyrénées and Gers. Parts of Gascony also now form *arrondissements* and cantons of the *départements* of Lot-et-Garonne, Haute-Garonne, Ariège and Tarn-et-Garonne.

GAS ENGINE: *see* INTERNAL-COMBUSTION ENGINE.

GASHOLDERS. Since the manufacture of gas must be maintained at an approximately even rate throughout the 24 hrs., while the rate of consumption varies considerably at the different hours of the day, it is necessary to provide storage for the gas produced during the periods of minimum demand, and also to provide against any temporary breakdown in the manufacturing plant. In the early days of the gas industry the vessel in which the gas was stored was known as a "gasometer," since this vessel had to serve the dual purpose of storing and measuring the amount of gas made. With the advent of the station meter in the year 1820 for measuring the volume of gas, the name of "gasholder" was adopted, but even now in Great Britain journalists and others invariably use the technically obsolete word "gasometer."

The capacity of the gasholder should be equal to at least 75% of the maximum daily output. There are now four distinctive types of gasholders: (1) frame guided; (2) spirally guided; (3) dry or tankless; (4) spherical. The frame guided and spirally guided holders may have one or more lifts, the one lift type being known as a single lift holder, and the other as a telescopic gasholder, the latter type being generally adopted for economic reasons. The movable vessel in which the gas is stored is known as the floating gasholder. The steel structure which guides the floating holder as it ascends or descends is termed the guide framing, and is erected round the circumference of the steel or brick tank which contains the water for sealing the sides of the floating gasholder, thus preventing the escape of gas. Gas is admitted into the holder by means of an inlet pipe which passes through the bottom of the tank, and extends to a height of about 6 in. above the water level; another similar pipe is provided as an outlet for the gas to the district mains; both pipes being controlled by slide valves.

The telescopic form of holder (fig. 1) consists of two or more lifts, which work or slide inside one another, much in the same way as an ordinary telescope. The inner or first lift is constructed to a certain diameter, according to the capacity required, and the diameter of each succeeding lift is increased by about 2 ft., whilst the depth of each lift would be constant, and equal to about one-fifth the diameter. In order to secure a gas-tight joint between

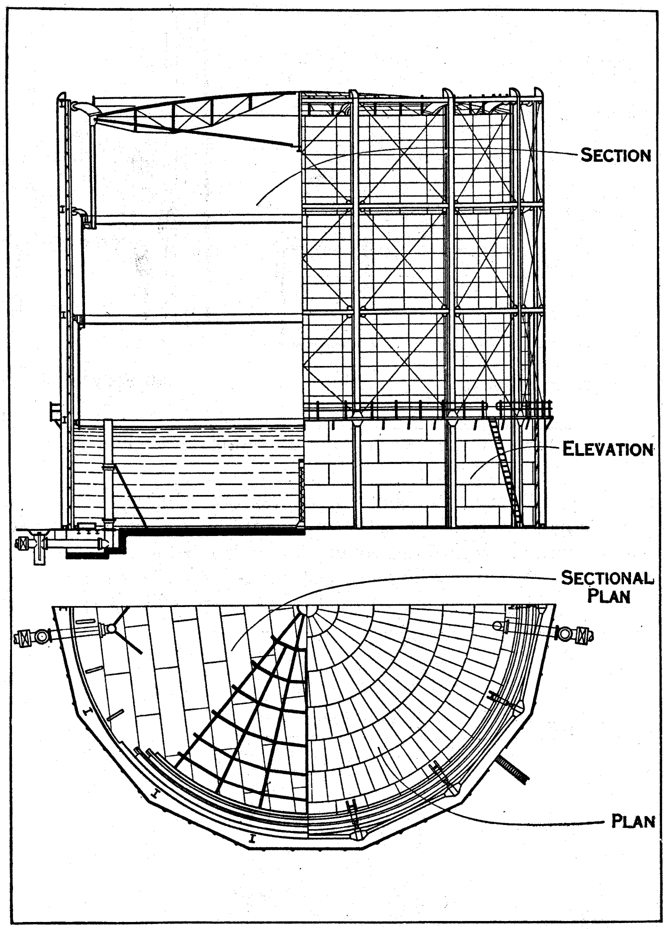

FIG. 1.—ELEVATION AND SECTIONAL PLAN OF TELESCOPIC GASHOLDERS
This type consists of two or more lifts working into each other on the telescopic principle. The diameters of the lifts decrease by 2 ft., the depths remaining constant

the lifts as they leave the tank, the bottom row of sheeting of the inner lift is prepared with a channel cup about 18 in. deep, whilst the top row of sheeting of the adjoining lift is fitted with an inverted channel cup, usually termed the "dip" (fig. 2). As the inner lift rises out of the water in the tank, the channel cup engages with the dip, thus making a gas-tight water-sealed joint between the lifts. Each succeeding lift is fitted with a dip at the top, and a cup at the bottom, with the exception of the final or outer lift, which is provided with a dip at the top only, and a strong angle steel curb at the bottom. The crown of the holder is dome-shaped, and when at rest in the tank, is either supported by a trussed steel roof forming part of the inner lift, or upon a permanent steel or timber framing erected in the tank. The sheeting of the sides and crown of the holder is about $\frac{1}{8}$ in. thick, with the exception of the rows of sheets adjoining the cup and dip, and also the junction between the crown and sides of the inner lift, which are much thicker, in order to allow for extra wear and strain at these points. The tank may be constructed in brick, concrete or steel. Brick and concrete tanks are usually constructed by excavating the ground and building up the sides of the tank, so that the top of same finishes about 6 in. above the ordinary ground level Water-tightness is obtained by encasing the bottom and side walls of the tank in a layer of clay puddle, or by coating the inside surface of the tank walls with cement. Steel tanks are usually erected on a flat bed of concrete, laid at a foot or so below the normal ground level, the sides being formed of a number of tiers of steel plates varying in thickness to suit the pressure due to the depth of water. in the tank. Steel tanks are much less costly than either brick or concrete tanks, and can be much more quickly erected.

Frame Guided **Gasholders.**—These consist of a series of columns or standards fixed at equal distances round the circumference of the tank, which are connected together by one or more tiers of horizontal girders or struts, and a series of diagonal bracing rods, thus forming a continuous tie all round. The guide framing may be carried up to the full height of the holder when fully inflated, or to the top of the second lift only, thus allowing the inner lift to run clear of the guide framing, which is then known as a "flying lift." Channel guide runs are fixed to the inner face of the standards, to form a pathway for the guide rollers—which are attached to the crown and the dip of each lift—to work up and down for the purpose of guiding the gasholder and enabling it to withstand the overturning force of the wind. The underside of each cup is fitted with a corresponding number of radial rollers, which run in channel guides fixed to the inside of the next adjoining lift; the bottom curb of the outer lift is also fitted with similar rollers working in channel guides fixed to the sides of the tank.

Spirally Guided **Gasholders.**—The floating lifts of a spirally guided gasholder (fig. 3) are practically the same in construction

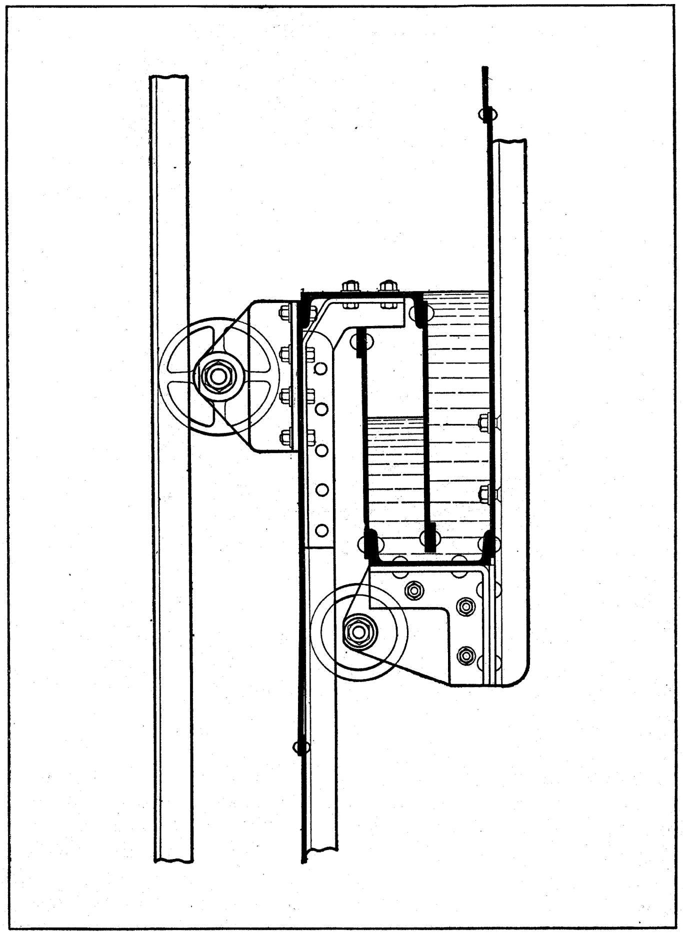

FIG. 2.—CROSS-SECTION OF THE "CUP AND DIP." WHICH MAKES THE CONNECTION BETWEEN THE TWO LIFTS AND FORMS THE HYDRAULIC SEAL

as the frame guided holder, with the exception that a number of double flanged rails, inclined at an angle of 45° are secured to the side sheeting of each lift at equal distances round the circumference. The spiral guides run between a corresponding number of sets of rollers (fig. 4) mounted in adjustable carriages, secured to the dips of the holder and top curb of the tank. The action of the holder in rising or falling is comparable with the action of a coarse-threaded screw, and the spiral motion thereby imparted to the floating vessel is sufficient to maintain the holder in a level condition, and enables it to resist the overturning force produced by the wind. This form of holder costs from 10% to 15% less than the frame guided holder.

Dry **Gasholders.**—In this type of holder (fig. 5) the tank with its water content is dispensed with, thereby greatly reducing the cost of foundations. The tankless gasholder consists of a cylindrical steel plate tower, within which a horizontal disk or piston moves up or down, receiving or expelling the gas. The piston is guided in its vertical movement by a system of rollers, travelling up or down the inner sides of the steel cylinder. The periphery or outer edge of the piston is lubricated and maintained gastight by means of several layers of moulded rubber packing rings, which

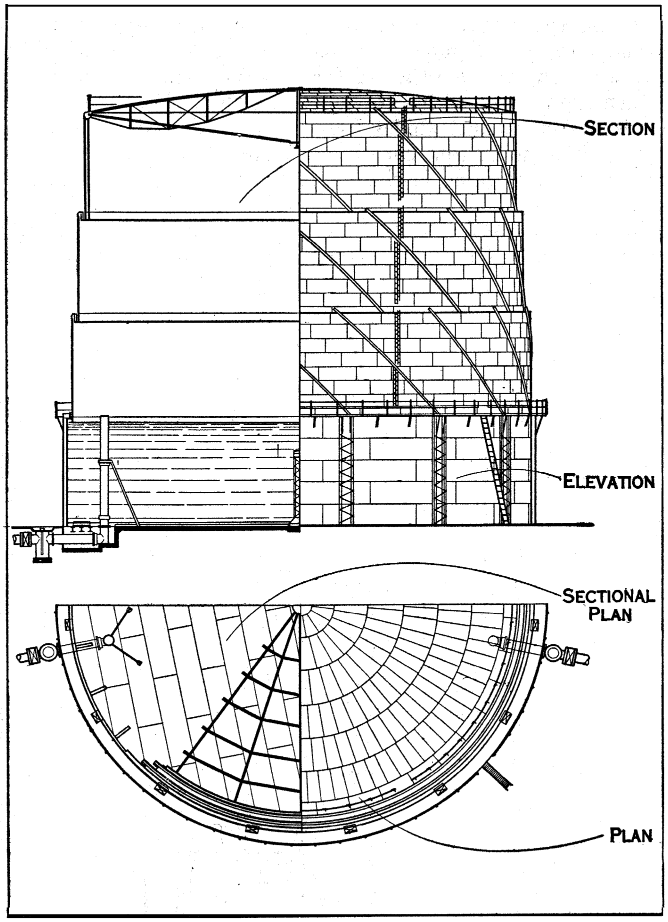

FIG. 3.—THE ELEVATION AND PLAN OF SPIRALLY GUIDED GASHOLDER

The construction differs from the telescopic type in having a number of double-flanged rails, inclined at 45°, secured to the side sheeting of each lift

effectively confine the gas to the underside of the piston. The interior of the tower above the piston is freely accessible, well ventilated and lighted by openings provided in the sides of the tower above the highest gas level. The packing seal, guide rollers and lubricators can, therefore, be readily inspected at any time, without interfering with the normal working of the gasholder. The roof of the dry gasholder does not enclose the gas—this being the function of the moving piston—and is only required to perform the duty of sheltering the moving piston from rain, snow and dust.

Another type of dry gasholder consists of a polygonal steel tower, with movable piston, similar in construction to that previously described, but in this design the periphery of the piston is maintained gastight by means of a light gas tar of moderate viscosity, contained in an annulus formed on the outer edge of the piston. As this seal is not absolutely tartight, a small quantity of tar escapes and flows to the bottom of the cylinder, where it is collected in a series of chambers and is pumped up again by a number of automatically controlled electric pumps to the top of the tower.

Spherical **Gasholders.**—This type (fig. 6) is principally used for storing gas under pressure. It is a plain sphere of simple construction, usually about 50 ft. in diameter, formed of steel plates about $\frac{9}{16}$ in. thick. The gas to be stored is forced by a com-

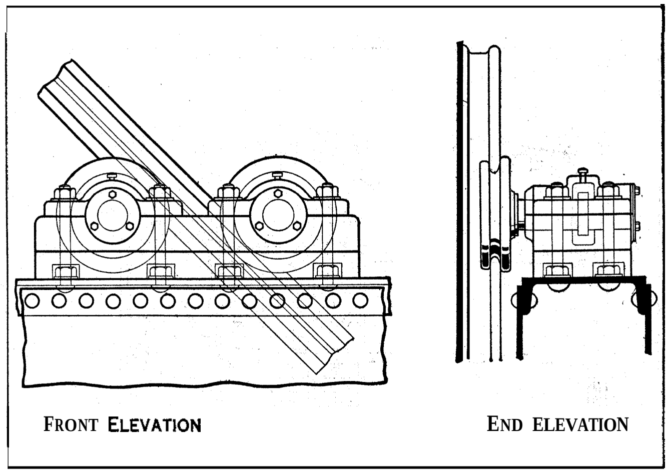

FIG. 4.— FRONT AND END ELEVATIONS OF SPIRAL GUIDE RUN BETWEEN SET OF ROLLERS

pressing plant into the sphere at a pressure of about 50 lb. per sq.in. When the gas leaves the outlet of the sphere, it is passed through suitable controlling governors, which reduces the pressure to such an extent as will meet the needs of the consumers. A sphere filled at a pressure of 50 lb. per sq.in. will store and de-

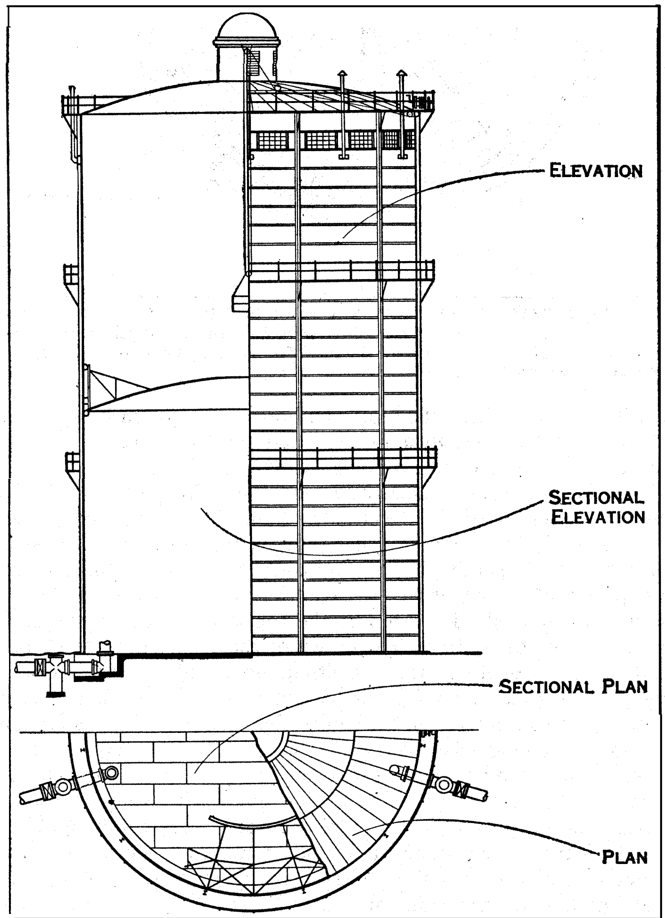

FIG. 5.— DRY GASHOLDER IN WHICH WATER TANK IS ELIMINATED

In this type of holder a great reduction in foundation costs is effected. The holder consists of a cylindrical steel tower in which a horizontal piston moves up and down, receiving or expelling the gas liver about 33 times its cubical content at the lower pressure required in the distributing mains.

GAS INDUSTRY. Despite the increasing use of oil, coal remained, in the middle of the 20th century, the main source of heat and energy for the industries and homes of Great Britain, supplying about 90% of the country's energy requirements in 1953. Coal production was about 220,000,000 tons a year; of this more than 40,000,000 tons were processed annually to produce secondary or derived fuels, mainly coke and gas. Gaseous fuels are of various types, dependent upon the particular process employed and whether the source is coal itself or coke. Coal heated in the absence of air yields a solid residue. known as coke, together with volatile matter, most of which is the gas known as coal gas. This process. termed carbonization. was in the 1950s still by far the most important method for producing derived fuels from coal, but other gaseous fuels were being manufactured by methods known as gasification; *i.e.*, water gas made by the action of steam upon red-hot coke; and producer gas made by blowing air, usually niixed with some steam. through a deep bed of hot coke or coal. Coal gas has the highest heating value, averaging about 500 B.T.C. per cubic foot; water gas averages about 300 B.T.U., but may be enriched with oil vapours (carburetting; Table I) up to or above the value for coal gas. The heating value of producer gases is much lower (120–160 B.T.U. per cubic foot) because about one-half or as much as two-thirds of their volume is mdde up from nitrogen contained in the air used for gasification. The familiar "gas," or town gas, distributed for public supply after purification. is coal gas itself, or coal gas mixed with straight or enriched water gas. In some cases, coke-oven gas may also be added; this is essentially similar to coal gas in that it is produced by carbonizing coal. but the process is different because it is directed more to the production of coke than of gas. Producer gas is used mainly for large-scale industrial furnaces. including in particular the retorts used for the manufacture of coal gas. A broad comparison of the properties of these gases is given in Table I.

Structure and Development of the Gas Industry.— The first use of coal gas was as an illuminant which burned with a characteristic yellowish luminous flame. The earliest demonstration of this property has been variously ascribed to Jean Pierre Minckelers of Belgium. to Philippe Lebon of France and to Lord Dundonald and William Murdock of Great Britain; but William Murdock is usually given entire credit for being the first to apply coal gas on any considerable scale. Murdock set up a small experimental plant in 1795, lighted a Soho (Birmingham) factory by gas a few years later and in Feb. 1808 was awarded the Rumford medal of the Royal society of London for his invention as described in a paper read before the society.

The year 1813 saw the foundation of the London and Westminster Gas company, soon to become the famous Gas Light and Coke company. It possessed three manufacturing stations with 15 mi, of mains, and Westminster bridge was lit by its gas. Gas lighting was introduced in Bristol in 1823, by which time the Gas Light and Coke company in London was producing nearly 250,000,000 cu.ft. of gas annually for distribution through 122 mi. of street mains. Rapid expansion followed. so much so that the gas companies which had sprung up in the metropolis and in the provinces are recorded as "innumerable" in 1860. Public supply was governed by many local and general acts of parliament. With the advent of electric lighting in 1882 the industry encountered serious competition, which appeared to threaten its very existence. In fact, however, the severe shock that it experienced was a stimulus to the industry to look elsewhere than to lighting for the disposal of its products, and the great potential market available to gas in its capacity of a heating medium was soon recognized. The year 1920 stands out as epoch-making in the history of the industry. Then the Gas Regulation act was introduced. the main provision of which was to make it obligatory to charge for gas on the basis of its declared and attested heating value; furthermore, gas had to be supplied at a minimum pressure of 2 in. water gauge in mains or services of 2 in. or more in diameter. These and earlier regulations, including the requirement that gas should be entirely free from the very poisonous and objectionable hydrogen sulphide, fully protected the interests of the consumer. At that time the annual production of gas in Great Britain had risen to 250,000,000,000 cu.ft.; and there were 7,000,000 consumers (4,250,000 supplied through prepayment or "slot" meters) receiving gas through some 40,000 mi. of mains.

On May 1, 1949, the gas industry passed into national ownership in accordance with the provisions of the Gas act, 1948. Many of the provisions of the acts which previously had nationalized the coal and electricity industries were repeated, but there was one significant difference: the larger measure of decentralization and regional responsibility accorded to the gas industry.

Twelve area boards were constituted to assume the ownership of 1,037 undertakings for the nation. The area boards were separate, corporate bodies, each charged with the prime duty of developing and maintaining an efficient, co-ordinated and economical system for the supply of gas and coke and to develop and maintain efficient methods of recovering the by-products of gas manufacture.

TABLE I.—Properties of Coal, Water and Producer Gases

Properties	Coal gas	Water gas		Producer gas	
		Straight (blue)	Carburetted	From coal	From coke
Composition					
Oxygen	0.4%	—	0.4%	—	—
Carbon dioxide	2%–4%	4.7%	5.6%	4%	5%
Cnsaturated hydrocarbons	2%–4%	—	7.0%	0.4%	—
Carbon monoxide	8%–18%	41%	30.5%	29%	29%
Hydrogen	50%–54%	49%	37%	12%	11%
Methane	20%–30%	0.8%	14%	2.6%	0.5%
Nitrogen	4%–6%	4.5%	5.5%	52%	54.5%
Heating value B.T.U. per cubic foot	475–560	295	500	163	132
Density (relative to air=1)	0.4–0.48	0.55	0.63	0.87	0.90

At the same time parliament decided that a central body, the Gas council, was needed to represent the industry as a whole and to be responsible for such matters as capital finance, labour relations, research and others calling for central action. The Gas council was to consist of a chairman. a deputy chairman and the 12 chairmen of the area boards; its duty was to advise the minister of fuel and power on questions affecting the industry and generally to assist the area boards to exercise their statutory functions. Thus, after about 140 years of progressive expansion, the gas industry was unified under its central council but at the same time possessed a regional structure that was acknowledged to be well suited to its particular requirements and conducive of the best service to its consumers. Research was specified to be one of the council's responsibilities, and its obligation in this respect was interpreted as being the search for fundamental knowledge and the development of new ideas up to and including the pilot-plant stage. Large-scale plant development and the normal improvement of appliances was entrusted to the area boards and to the plant manufacturers. A permanent committee, including scientists from outside the industry, was set up to advise the council on methods of research. Research stations were established in London and Birmingham; in addition, the council contributed to a number of research associations engaged on work of interest to the industry. It also maintained the industry's close association with the University of Leeds and with the British Ceramic Research association. Statistics for the year from April 1, 1953, to March 31, 1954, showed that the area boards during that period controlled fixed and current assets amounting to £489,345,518; had a revenue of £170,138,530 from selling 2,451,000,000 therms of gas (1 therm= 100,000 B.T.U.) to 12,474,818 consumers; used 27,091,000 tons of coal in gasmaking; kept 83,427 mi of mains in use (there were thus 150 consumers per mile of main); and employed 145,031 people, comprising 109,098 operatives and an administrative and clerical staff of 35,933. The average selling price of gas per therm rose from 12.55*d.* in 1949–50 to 16.25*d.* in 1953–54, mainly because of rising coal costs and national increases in wage scales.

TABLE 11. —Composition of Coal Gas

Gases	High temperature			Low temperature
	Horizontal retort	Vertical retorts		
		Without steam	With steam	
Carbon dioxide .	2.0%	2.2%	3.4%	4.5%
Unsaturated hydrocarbon;	3.1%	2.3%	1.8%	3.8%

Carbon monoxide . .	8.0%	10.3%	15.1%	8.3%
Hydrogen	50.6%	49.5%	49.3%	29.1%
Methane	28.1%	28.5%	21.2%	49.1%
Nitrogen	7.7%	6.8%	8.5%	5.0%

MANUFACTURING METHODS

In Murdock's apparatus coal was contained in an inclined iron retort heated by a fire burning on a grate below. Cast-iron retorts were used for a long time in the early days of manufacture. Charged with the coal to be carbonized, the retorts were heated by small coal to temperatures of about 600°–700° C., much lower than those used in modern practice. At this point it is convenient to consider the principles involved in the carbonization process.

Coal is the term applied to those rocks in the earth's crust produced by the decay of plant remains and accumulated many millions of years ago. Coal is thus a complex mixture of organic substances which so far cannot be recognized except in broad terms. The essential elementary constituents are carbon, hydrogen and oxygen, with small quantities of nitrogen and sulphur and some incombustible matter — the ash. When heated out of contact with air, the coal more or less fuses and partially decomposes. Gaseous products of decomposition force their way through the plastic mass and give it a honeycombed structure. As the temperature of the mass increases, the coal becomes less fusible and is transformed into a porous solid known as coke. Further heating drives off more gas and results in shrinking and hardening of the-coke. The volatile matter evolved in the lower-temperature stages is rich in easily condensible tarry matter and gaseous hydrocarbons. At temperatures above 800° C. the volatile matter is principally hydrogen, with some carbon monoxide.

The manufacturing process thus consists essentially in driving off the volatile products by heat, leaving the solid residue of coke in the retort for subsequent extraction. The volatile matter, or crude gas, leaves the retorts at a temperature usually between 700°–800° C., heavily charged with steam (derived from hydrogen and oxygen in the coal as well as from actual moisture) and with condensible tarry vapours, hydrocarbons, some sulphur-containing gases, some hydrogen cyanide and ammonia. These constituents must be removed before the gas is distributed to consumers.

When the gases enter the collecting main they are cooled so that condensation takes place; and this is further assisted by washing with water. Water from condensation or from washing dissolves part of the ammonia and other constituents, forming "ammonia liquor." As a consequence of the condensation process, the volatile matter is divided into three portions; two, the tar and the ammonia liquor, are liquid. but they do not mix; the third is the gas itself, which, after further purification from tar fog, residual ammonia and hydrogen sulphide. is ready for distribution.

The proportions of gas. coke, tar and liquor vary according to the particular method used for carbonization and to the nature of the coals carbonized. In broad terms, however, the yield of these products per ton of coal processed in horizontal retorts is about 14 cwt. of coke, 10 gal. of tar and 30 gal. of liquor, the last representing a recovery of approximately 25 Ib. of ammonia as sulphate. Table II shows the composition of coal gas according to the method of carbonization employed. The tar is composed of pitch (61 3%), creosote oil (13%), carbolic oil (12.1%), light oils (9.4%), crude naphtha (2.6%) and water (1.6%). The liquor, when horizontal retorts are used, yields for every 100 c c. of its volume, 1.5 g. of fixed ammonia; 0 5 g. of free ammonia; 0.25 g. of sulphide as H_2S; 0.01 g. of cyanide as HCN; 0.1 g. of thiosulphide as S; 0.2 g. of thiocyanate as CNS; and 0.2 j g. of phenols as C_6H_5OH.

Of the various circumstances that determine the quantities and compositions of the tar, liquor and gas, the temperature at which the coal is carbonized is particularly important. The low-temperature products are those resulting from the first processes of breakdown in the coal. The high-temperature products contain many of the substances formed by the secondary decomposition of the primary products, brought about by subjecting them to a higher temperature. The difference shows itself very plainly both in the gas yield, which is much higher for high-temperature working, and in the nature of the gas, which contains much more hydrogen and less of the easily decomposable compounds of carbon and hydrogen. The tar is usually smaller in amount for high-temperature working. when it is characterized by the presence of the so-called aromatic hydrocarbons of the benzene type, which are products of secondary decomposition and are absent from low-temperature tars. The increased yield of gas in high-temperature working is partly due to the secondary decomposition of some of the more decomposable tar constituents, although it is mainly accounted for by an extensive formation of hydrogen peculiar to high-temperature working.

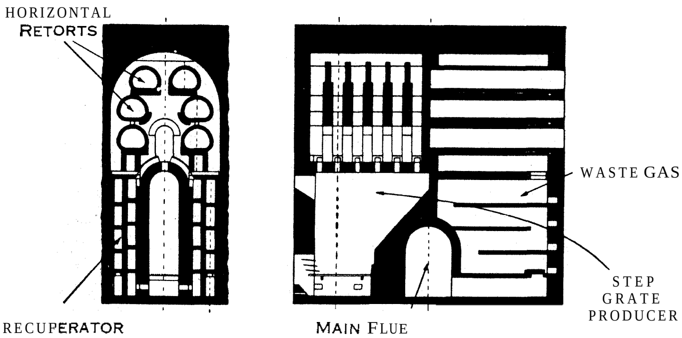

FIG. 1.—CROSS SECTION AND LONGITUDINAL SECTIONS OF A SETTING OF 6 HORIZONTAL RETORTS

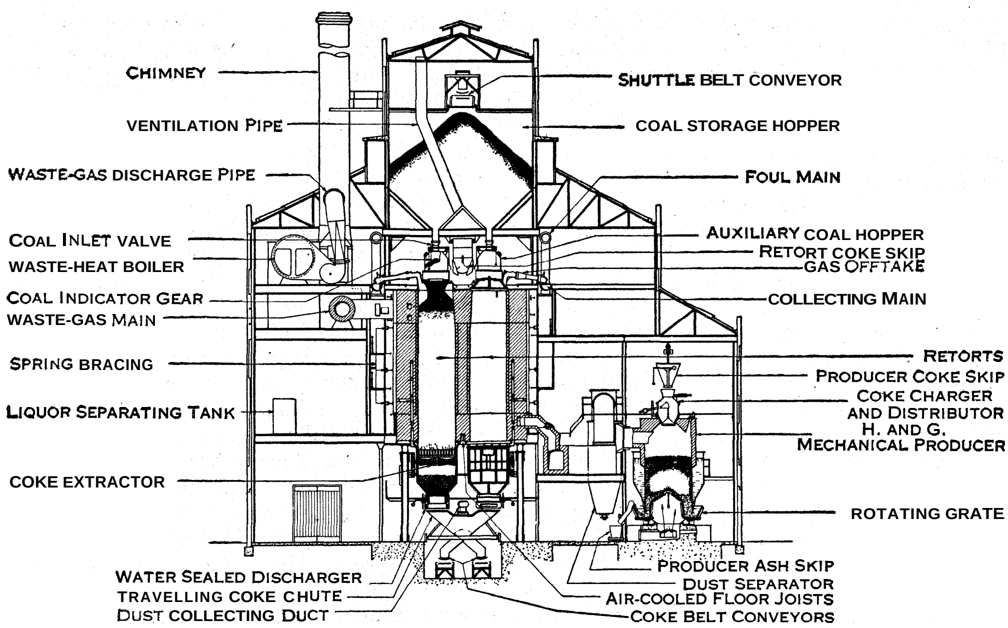
Retorts.—The volume of gas obtainable by working in iron retorts was limited by the properties of this material. An important advance was made when fire clay was substituted for iron, as a higher temperature was permissible. Further improvements of a radical character followed when. in the heating of these retorts, gas firing and the recuperative principle could be employed.



BY COURTESY OF WOODALL DUCKHAM CONSTRUCTION COMPANY LTD.

FIG. 2.— CROSS SECTION OF A CONTINUOUS VERTICAL RETORT INSTALLATION

Recuperative.—The principle of the recuperative retort will be understood from fig. 1, which shows a setting of  -shaped horizontal fire-clay retorts. They are heated by producer gas made by passing air through a deep layer of red-hot coke. This gas, meeting hot air immediately under the retorts, burns around them and carbonizes the coal contained therein. The waste gases, after heating the retorts do not. hen-ever pass away directly to a chimney, as in older methods of "direct" firing, but are turned downward into the recuperator, where they pass along channels in which they are only separated by a thin fire-clay partition from air travelling upward to meet the gas. In this way some of the heat is abstracted from the waste gases and restored to the setting in the air used for combustion. Consequently, less heat leaves the setting and a higher temperature can be attained together with economy in fuel. This system of carbonization in horizontal recuperative fire-clay retorts rapidly became standard practice and remains so to some extent, although horizontal retorts are now obsolescent. It enabled an average gas yield of 10,000 cu.ft. of gas per ton of coal to be obtained; and it lowered the proportion of fuel required for heating the setting from 25%–30% of the weight of coal carbonized to 15–20%.

Although excellent in many mays. the horizontal retort setting as so far described had the disadvantage of requiring heavy labour for hand charging. This drawback has been to some extent neutralized by the use of mechanical charging machines. Other methods were hen-ever, coming forward by which the aid of gravity could be invoked for the moving of the coal and coke during carbonization and some other advantages secured. In the second half of the 20th century new installations were invariably of the vertical retort type.

Vertical.—The simplest form of the vertical retort was one in which the retorts were all set vertically (instead of horizontally, as in the past). and, being filled with coal, were heated until the whole of the charge had been carbonized, after which it was withdrawn. This so-called intermittent vertical system was patented in England by J. Bueb in 1904, after previous trial at the Dessau gasworks. It had the advantage, as compared with the hand-charged horizontal retort setting, of reducing labour and requiring less ground space for a given output. Another novel advantage was that the retort could be fully charged, thereby lessening that contact of the volatile matter with red-hot coke and the walls of the retort which gives rise to secondary decomposition. A further advance was made almost at once by the introduction of continuous working into the vertical retort system by which, instead of completing the carbonization of the whole charge before withdrawing any portion of the coke residue, a continuous feed of coal was made to the top of the retort and coke was continuously withdrawn from the bottom by an extraction mechanism.

The principal firms associated with this system are Woodall-Duckham, Glover-West and Robert Dempster and Sons. and it has been widely adopted. The idea had been applied with limited success previously by Settle and Padfield. Fig. 2 illustrates a typical setting of retorts. The heating gas from the producer passes through apertures, which can be regulated, into heating channels surrounding the retorts. The upper sections are heated by waste gases alone.

The heating quality of the gas being now of paramount importance, the heating value of a gas per cubic foot superseded its illuminating power in "standard candles" as the statutory method of defining its quality. The British Gas Regulation act of 1920 introduced the sale of gas by the therm, a therm being 100,000 B.T.U., and allowed gas companies and authorities to specify the standard quality in B.T.U. per cubic foot of the gas that they would supply (insistence, however, being rightly made upon the maintenance of that standard as all-important). These changes in the conditions of manufacture and of use, together with the new legislation, permitted and encouraged such developments in gas manufacture as make for more complete gasification of coal; *i.e.*, for obtaining a larger proportion of its potential heat in the gas made.

Steaming.--One method of achieving this aim. to which reference has already been made, was to work at a higher temperature. This, in turn, called for special attention to the quality of the refractory materials used in the construction of the retorts and their settings and led to an increase in the use of silica instead of fire clay in vital parts subject to the higher temperatures. In modern practice silica refractories are preferred for the walls of retorts

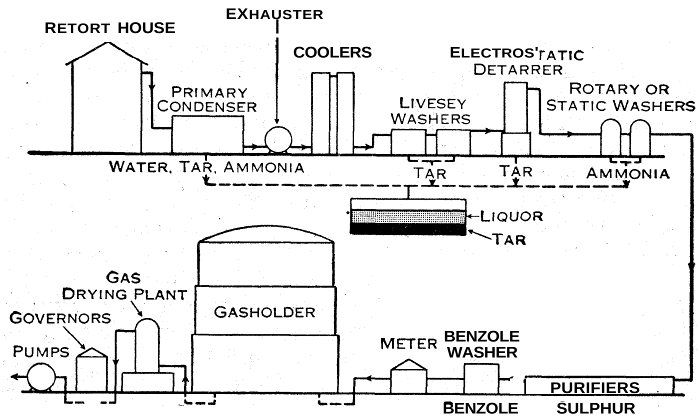


FIG. 3.— DIAGRAMMATICLAYOUT OF A GASWORKS PURIFICATION SYSTEM

(except for a few feet at the top and the bottom) because of their higher stability, strength and general durability. By such means, higher yields of gas per ton (13,000 cu.ft. per ton) have become common. The gas so made is rich in hydrogen and poorer in illuminating constituents than what mas usually supplied for lighting purposes and is lower in calorific value (say 500 as compared with 600 B.T.U. per cubic foot). Another widely used method of increasing the yield in volume and thermal units is known as the "steaming" of vertical gas retorts which is carried out by introducing steam at the base of the continuous vertical retort where it can react with the red-hot coke. By this means an addition is made to the volume of gas by the interaction of carbon and steam which generates water gas, as already mentioned.

An investigation by the joint research committee of the University of Leeds and the Institution of Gas Engineers, carried out on a Glover-West setting of continuous vertical retorts, showed that a lean coal gave 10,400 cu.ft. of gas per ton of a calorific value of 544 B.T.U. per cubic foot (gross), when steaming was not used. This corresponds to 56.j therms in the gas per ton of coal carbonized. When steaming was employed, to the extent of 26.4% of steam on the weight of the coal used, the yield increased to 16,900 cu.ft. of gas with a calorific value of 447 B.T.U. per cubic foot representing 75.7 therms in the gas made per ton of coal.

Thermal Efficiency.—The development.of gas practice, as traced above, has resulted not only in a greater yield of gas but in an increased thermal efficiency for the whole process of carbonization. In other words, the total number of heat units obtainable by the combustion of gas, coke and tar has become more and more a higher proportion of the heat units originally contained in the coal carbonized. This has been effected by improved design of the setting and the use of the recuperative principle, resulting in a lowered consumption of coke for the heating of the retorts. Moreover, by the use of higher temperatures and steaming, the proportion of the heating value of the coal obtained in the gas has been increased, as compared with that left in the coke. This is of primary importance, because in the consideration of a carbonization process it is necessary to bear in mind that, because of the efficiency of gas in use as compared with a solid fuel, the thermal value of a heat unit carried by gas is usually greater than that of a heat unit in coal or coke, and the comparative monetary value is correspondingly increased. The need for economy in fuel has encouraged the development of more efficient appliances for burning solid fuel. and the margin between the utilization efficiency of gas and solid fuels has narrowed considerably. There are, however, still many cases where gas can be utilized as a heating medium with twice or more the efficiency of solid fuels.

In normal horizontal-retort practice it may be taken that, for every 100 heat units contained in the coal carbonized. 24 will appear in the gas, 42 in the coke available for sale after the heating of the retorts has been provided for and 5.6 in tar, which means that 71.6 of the original 100 heat units have been obtained in the available useful products of carbonization. Otherwise expressed, the thermal efficiency of the carbonization process so conducted is 71.6%, 28.4% having been used and lost in the manufacture. In modern large installations of vertical retorts, higher values would usually be attained. The report of the Gas council for 1953–54 gave the average figure of production efficiency (as expressed on the basis given above) as 75.2% for the whole of the industry. The figure in 1948 had been 71.0%; the increase was due to improved methods of working, to the replacement of obsolete with modern plant and to concentrating manufacture in larger and more economic units.

Purification.— As already indicated, the crude gas leaving the retorts contains constituents which have to be removed in order to purify the gas before distribution and to recover by-products of commercial value. Many of these constituents are more or less easily condensed or washed out, and the appropriate plant consists of a train of vessels that vary widely in detail from one works to another but are essentially the same in principle. Fig. 3 shows diagrammatically the individual plant units in a typical gasworks and the sequence of steps in the manufacturing process.

Gases travel from the retorts through an "ascension" pipe, which then bends over and dips below the liquid seal in the so-called hydraulic main, the seal being used to prevent access of air to the main when the retort is opened for charging and discharging. Some cooling and consequent condensation of tarry matter occurs in ascension pipes. It is usual for the gas from a number of retorts to be collected in a common hydraulic main. Easily condensible constituents gather there and in the foul main which leads to the condensers. The condensers consist of nests of pipes cooled externally by air or water; the temperature of the gas within them is thus lowered resulting in further condensation of both tar and water, which collect at the base of the pipes.

The next stage is the washing or scrubbing of the gas, in which further cooling and removal of constituents by solution in water are secured. There are many designs of washers and scrubbers but all act on the principle of obtaining the greatest possible contact between gas and liquid. In the Livesey washer, for example, the gas stream is repeatedly broken up and forced through mater. In modern practice there may follow an electrostatic detarrer, for the complete removal of tar. Next in sequence are rotary or static washers, in which the gas is brought into intimate contact with water or weak liquor. Ammonia is completely removed from the gas at this stage, although a trace may be allowed to pass forward to preserve alkalinity in the purifiers used later for extracting hydrogen sulphide. Additional scrubbing, using suitable oil solvents, is needed if it is intended to remove volatile tar constituents such as benzene and toluene. The tar and liquor condensed at different points in the system are usually led away to a common well, but there is good reason to suppose that some separation of the various liquors is desirable because some may be more potent than others, so that the question of disposal is not equally easy for all.

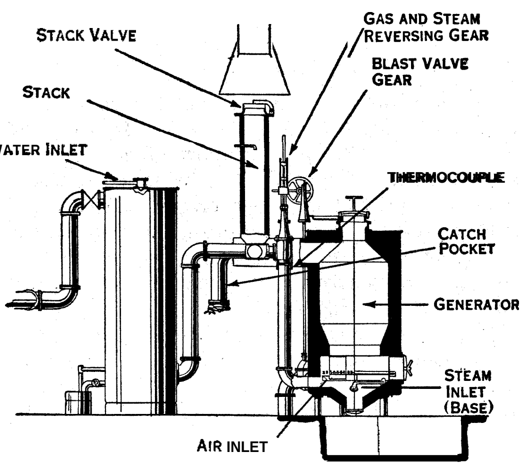
It has already been mentioned that one constituent of coal gas which by law has to be completely eliminated if the gas is to be used for public supply is hydrogen sulphide. The final process of purification in ordinary practice is to pass the gas through iron oxide purifiers and thence to gasholders (*q.v.*). The purifiers contain hydrated oxide of iron spread on grids. The oxide absorbs hydrogen sulphide rapidly, becoming converted into iron sulphide. The formation of iron sulphide tends to render the material inactive for absorbing hydrogen sulphide but it can be reactivated by removal and exposure to air, or by admitting a little air into the gas stream, when regeneration takes place in ***situ.*** In both cases the sulphided material is reoxidized with the formation of free sulphur. When the sulphur content has risen to about 50%, the so-called spent oxide is removed and sold for sulphuric acid manufacture. Most of the sulphur in crude coal gas is present as hydrogen sulphide (about 1%) and is completely removed by this process. Smaller quantities of sulphur are present, however, in the form of organic sulphur compounds which are not extracted to any extent by iron oxide but which may be reduced considerably in amount by special additional processes. In 1942 a special committee set up by the industry recommended that the organic sulphur should be reduced to 10 grains per 100 cu.ft. (about 0.01%) as a first step and that processes should be introduced to obtain lower figures as they became available. The recovery of benzol by oil washing simultaneously removes much of the organic sulphur so that additional processing is more the exception than the rule in general practice. Satisfactory methods for reducing the organic sulphur, to, say 5–6 grains per 100 cu.ft., are available, however, and are applied when gas of exceptionally low sulphur content is needed. Such processes are frequently used to purify the gas after distribution to the consumer's works.

Ammonia and Tar.—Liquor containing the ammonia washed out of the gas is either sold as such or used at gasworks for the production of ammonium sulphate. Distillation of the liquor with lime drives off ammonia which may be absorbed in sulphuric acid to form the sulphate, which constitutes a valuable fertilizer. The quantity obtained at gasworks usually lies between 20 and 30 lb. of ammonium sulphate per ton of coal carbonized. The ammonia yield can be increased by steaming the retorts, but the liquor obtained is usually weaker because of the passage of undecomposed steam from the top of the gas retort into the gas. A weaker liquor has a lower commercial value if it has to be sent away for treatment and has the further disadvantage that after distillation for ammonia the residual liquor is greater in amount.

The direct method of recovering ammonia, in which the gas is passed through sulphuric acid for the absorption of ammonia, instead of effecting a separation of the ammonia liquor and distilling it, has found little application in gasworks.

The disposal of the residual liquor after distillation for ammonia. or sometimes of the crude undistilled liquor itself, presents the gas industry with a problem all the more serious because of the stringent regulations designed to minimize the pollution of rivers and streams. Although liquor is relatively weak, it is nonetheless a strong trade effluent and its direct disposal into streams is prohibited. The usual method is to feed it into the local sewer for eventual decomposition in bacteria beds. It has, however, long been known that the constituents of liquor throw an increased load on the sewage-purification process, so that the rate at which liquor may be discharged into sewers has to be carefully controlled. Normally the maximum permissible discharge of spent liquor is about 0.5% of the dry-weather flow of the sewage. Much attention has been given both to re-examining the amount of liquor that can properly be discharged into sewers and also to developing alternative methods of disposal, the latter being particularly directed to meet the needs of those gas (and coke-oven) works whose situation is remote from suitable sewage-disposal plant.

The tar made at gasworks is subjected to a complicated process of distillation which resolves it into fractions boiling over in different temperature ranges, the fractions being afterward refined. These operations are usually carried out at separate tar distilleries.



BY COURTESY OF THE INSTITUTION OF GAS ENGINEERS

FIG. 4.— BLUE WATER-GAS PLANT. SHOWING PARTS

Among the many products from tar may be mentioned toluol, cresol, naphthalene and anthracene, which find application in the production of dyes, medicines, perfumes, disinfectants, solvents, plastics and paints. Tar oil is used for fuel and also for road construction, whereas distilled tar and pitch is used for many purposes; *i.e.,* in connection with building materials, roofing felts, briquettes. etc.

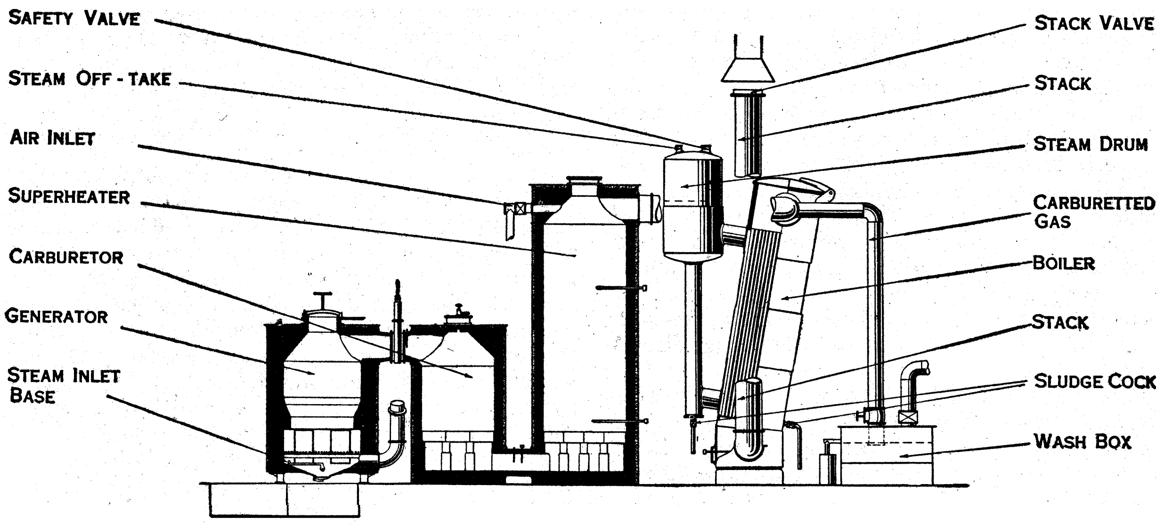
The average yield of tar by the ordinary gasworks process can be taken as 5% of the weight of coal carbonized. At lower temperatures, more tar is produced and the light oil fraction coming over on distillation is usually greater in volume.

Costs of Manufacture.— The relative costs of the different processes used in gas manufacture depend on the size of the production unit as well as on many other factors, but the over-all picture for works of reasonably large size may be taken as follows: net cost of coal carbonized. 60%; carbonization process, 10%; purification, 1.0%; power and sundry processes. 8.5%; maintenance and repairs, 11.5%; and general charges, 9%.

The actual average price at which gas was sold to the consumer in 1953–54 was 16.2 jd. per therm, made up as follows: surplus, 0.2*d.*; rates, 0.39*d.*; administration, 0.58*d.*; employees' welfare, 0.62*d.*; interest. 1.13*d* : depreciation and amounts written off. 1.56*d.*; distribution and consumer service, 1.86*d.*; and cost of gas produced and purchased, 9.91*d*.

Water Gas.—Limited gasification of coke in steam can be effected in the continuous vertical retort as already described, but complete gasification of carbon in coke is carried out in an entirely different type of apparatus known as a water-gas plant. At high temperatures, carbon decomposes steam into hydrogen and carbon monoxide, but with an absorption of heat according to the equation $C+H_2O \rightarrow CO+H_2-56{,}145$ B.T.U. When the temperature of the carbon has been brought down. by this absorption of heat, the reaction is altered with the production of carbon dioxide. An equilibrium tends to be established by the catalytic action of the solid carbon (and inorganic ash constituents) so that a ratio $\frac{CO \times H_2O}{CO_2 \times H_2}$ may be set up between the gas constituents, the ratio being constant for any one temperature but falling as the temperature becomes less. The reversible reaction occurring ($CO+H_2O \rightleftarrows CO_2+H_2$) results in a higher carbon-dioxide content of the gas as the temperature is lowered; and, moreover, since the velocity of gasification is rapidly lowered with falling temperature, the gas made with the same rate of steam supply comes to contain more undecomposed steam. Carbon dioxide lowers the calorific value of the gas and the steam requires condensation. The high temperature of the carbon can, however, be restored by stopping the steam and blowing with air, thus raising the temperature of the fuel bed and generating a producer gas. The industrial process based upon this principle of alternately blowing a bed of coke with steam and air was developed by Gaillard (1849), Tessié du Motay and T. S. C. Lowe (1873) and called the water-gas process. The plant as illustrated in fig. 4, is that of Humphreys and Glasgow. The coke bed is enclosed in a steel casing, lined with firebrick, and may be blown through the grate below by either air or steam. An arrangement of valves also enables the steam to be introduced above the coke for a "down run." The exact arrangement and time in the up run with steam, down run with steam and blowing with air is varied to suit the fuel and other conditions and constitutes a cycle of operations which is carried out systematically and automatically in modern plant. The coke is blown with steam until, as the temperature falls. the carbon dioxide produced in the water gas is reducing its quality too far. During the steam blow, the water gas made is carried forward to a scrubber down which water is running and then goes fonvard to join the main gas stream of the works for purification from hydrogen sulphide. This water gas should have a calcrific value of 300 B.T.U. per cubic foot. When the steam blast is replaced by air, in order to restore the high temperature in the fuel bed, the producer gas generated, being heavily charged with nitrogen, is not allowed to go forward to the scrubber but is turned up the stack as waste. That continues until a satisfactory high temperature has been re-established in the fuel bed, when steam is again employed. The heaviest thermal loss in the process is that of the potential and thermal heat in the producer gas, but this is lessened in modern plants by the installation of a waste-heat boiler.

Carburetted Water Gas.—It has been noted that the water gas made by the process as described above has a calorific value approximating to 300 B.T.U. per cubic foot. It is known as "blue" water gas because of the characteristic colour of its flame and is definitely lower in grade than the coal gas made from retorts. The calorific value can be increased, however, by using some of the heat in the gases leaving the generator to crack oil (*i.e.,* to convert it into permanent gas rich in hydrocarbons), so obtaining a "carburetted" water gas of enhanced calorific value. Fig. 5 illustrates a Humphreys and Glasgow plant used for the process. The gas from the generator passes through two chambers, a carburettor and a superheater packed with brickwork, which are raised to redness, some air being admitted for the combustion of the "blow" gas therein. The oil is run in from the top of the carburettor and should be such as can be efficiently cracked under the conditions of the process. (In early stages of the development of the plant the oil was run directly upon the coke in the generator, but this was unsatisfactory for various reasons.) In this plant, blue water gas leaves the generator with a calorific value of 300 B.T.U. per cubic foot, but leaves the superheater enriched by the carburetting to an extent determined by the amount of oil used. The thermal efficiency of the oil cracking in the plant is high, amounting to something like 90%; consequently the thermal efficiency of the carburetted water-gas process is higher than that of the blue water-gas process and increases with the amount of oil used. The extent of carburetting employed is influenced by this factor, by the price of oil and by the quality of the gas desired. In Great Britain, carburetting is



BY COURTESY OF THE INSTITUTION OF GAS ENGINEERS

FIG. 5.— CARBURETTED WATER-GAS PLANT AND WASTE-HEAT BOILER

usually carried out so far as to bring the carburetted water gas up to something like the same calorific value as the coal gas made at the same works, say 500 B.T.U.; but in the U.S. it has in the past been usually carried much farther. It is plain, too, that blue water gas, enriched by carburetting to the extent desired, can be used as a means of modifying the calorific value of the mixture of coal gas and water gas supplied from a works. The extent to which the coke made in a gasworks may be economically gasified and water gas supplied depends on relative capital and operating costs and the prices of coal. coke and oil.

The main advantages of water-gas plant are that it can be put rapidly into full operation. to meet maximum demands and that the yield of gas per ton of fuel is high; for example, modern plants may give about 50,000 cu.ft. of 300-B.T.U. water gas or 70,000 cu.ft. of 500-B.T.U. carburetted water gas per ton of coke (the compositions of these gases have already been indicated).

Modern carburetted water-gas plants are entirely automatic, with an annular boiler around the generator and self-clinkering grates. A regular quantity of coke is fed to the generator during each gas-making cycle without interruption to the gasification process. Large-capacity plants are now virtually self-supporting in their requirements of steam.

Modern Trends in Gas-Making Processes.—The processes so far described represent what by the middle of the 20th century had long been established as standard practice; but much attention had meanwhile been paid, especially in the later years of the period, to methods of completing the gasification of coal in one process instead of carbonizing it first and then gasifying the coke residue, so far as may be desired, in a separate generator.

Alternative methods for making gas, particularly from coals of poorer quality than had been used hitherto, then came to assume great importance to the industry because of the increasing scarcity of the special coals needed for the manufacture of gas and coke by orthodox methods. Furthermore, oil fuels became so plentiful and cheap as to demand attention as raw materials for gas-making on a greater scale. The pattern of the future industry could be seen as a system of interlinked large stations of high efficiency, preferably situated at or near the coal fields and operating processes best suited to the coal available. However, the object of complete-gasification methods is to process the coal solely into gas with no solid residue other than ash; so that the extent to which such processes could be effectively introduced depended upon the balance needed between the supply of gas and of coke (it should be pointed out in this connection that the new emphasis on minimizing atmospheric pollution was bound to result in a greater demand for smokeless fuels, such as coke). But complete gasification methods, being efficient and flexible, seemed certain to find extensive application in the gas industry.

Most of these processes depend upon a combination of carbonization and generation of water gas. In the modern plant of Humphreys and Glasgow, the blow takes place in the lower part of the generator, the blow gases being led to the carburettor via an annulus surrounding the generator. Available heat in the blow gases is stored in the carburettor and superheater and used to assist carbonization of the coal by transference back to the generator. Part of it may also be used for carburetting. A back-run produced by admitting steam to the top of the superheater and then to the base of the generator gives water gas; the heat in this gas then carbonizes coal in the upper part of the generator. In another part of the run steam admitted to the generator base, this time without superheat, generates hot water gas which again passes through the coal in the upper part of the generator. This gas also can be fed to the carburettor if desired. The yield may be from 175 to 190 therms of 345-B.T.U. gas per ton. The plant is designed to gasify coal, coke or any mixture, with subsequent enrichment by oil as may be desirable.

Considerable importance was attached to finding a means of developing these processes and applying them on a large scale. The availability of low-cost oxygen stimulated the development of methods in which the gasification of solid fuels is carried out in oxygen and steam. In the U.S., where the reserves of natural gas and oil, great as they are, were seen to be quite small when related to the reserves of coal, a large section of opinion held that it would eventually become necessary to augment natural gas with gas of comparable heating value from coal. This, together with an unprecedented industrial and domestic demand for natural gas, oil gas and oil, was the prime reason for the U.S. concentration upon complete gasification in the 1950s. In Germany and elsewhere, from *c.* 1945, the Lurgi process of gasification in steam and oxygen under pressure was successfully applied on a large scale to lignites (young coals unsuitable for carbonization by orthodox means). This process came to be accepted as having many attractive features for the manufacture of town gas: it can make use of small coal of high ash-content and of weakly caking coals unsuitable for carbonization; the plant operates at very high output; and the gas can be readily freed from sulphur and is available at pressure for long-distance transmission. For Great Britain, the search for new gasification processes was given first place in the research program of the Gas council (the former Gas Research board); and exhaustive studies of the Lurgi process applied to British coals were being conducted (on the pilot-plant scale) by 1954. An important achievement of the British work was the demonstration that the considerable proportion of methane characteristic of Lurgi gas was not due to the synthesis under pressure from carbon monoxide and hydrogen produced on gasification but resulted directly from the hydrogenation of coal, a reaction which proceeds vigorously under pressure. As a consequence, the possibility of manufacturing gas comparable in quality with town gas by gasification methods adapted to favour hydrogenation appeared to be most promising, although many technical problems would have to be solved before large-scale application could follow.

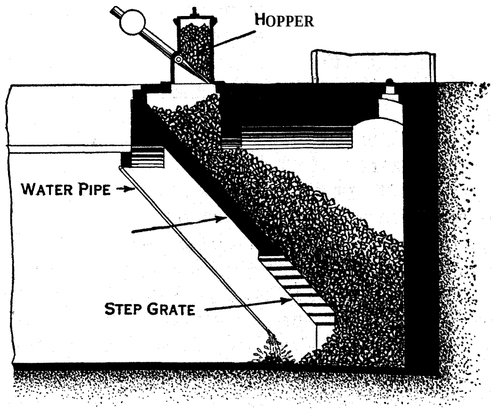
Complete-gasification methods were therefore expected to play an important part in the gas manufacture of the immediate future. Full details of contemporary trends and practice may be found in the *Proceedings* of the International Conference on Complete Gasification, held at Liège in 1954 (Organisation Européenne de Coöpération Économique, Paris).

New processes for the direct gasification of oil, without recourse to water-gas production, were adopted by certain area boards in Great Britain. The plant developed by the North Thames Gas board and installed at their Southend works produces a rich gas by the partial combustion of oil. Another process, devised by the South Eastern Gas board and installed in its own area and also within the North Eastern board's area, generates gas by the catalytic decomposition of oil. Other methods include the Onia-Gegi, giving an oil gas (from 300 to 1,000 B.T.U.) by the cyclic catalytic cracking of heavy oil; and the Geim process for the continuous production of gas (from 370 to 470 B.T.U.) by the thermal cracking of gas oil. The synthesis of gases rich in methane by hydrogenating coal under pressure was an important objective of the search for new gas-making processes.

In addition, a country-wide search for new sources of natural gas was sponsored by the Gas council, and by 1954 experimental supplies of methane drained from coal mines were being taken by some area boards in Great Britain.

Producer Gas.—The gas manufactured for public supply, as opposed to producer gas, finds extensive and increasing applications for industrial heating. Being thoroughly cooled and cleansed it can be well controlled through taps and valves, which make for convenience, cleanliness and efficiency in use. It is a smokeless fuel, and its use saves ground space and obviates expenditure on *ad hoc* gas-making apparatus. Since, too, such gas is of high calorific value and does not carry into its Aame any large proportion of nitrogen or other inert constituents, it can be used for high-temperature processes in simple apparatus without that preheating of the air or of the gas or of both which is necessary for such processes when the leaner producer gas is employed. On the other hand, producer gas is simple to manufacture and is the usual means adopted for the beating of steelmaking and other large industrial furnaces.

When air is passed through a deep bed of carbon maintained at a high temperature, above 1,000° C., such that complete contact



FROM RAMBUSH'S "MODERN GAS PRODUCERS" (BENN BROS.)

FIG. 6.— OLD-TYPE PRODUCER WORKING WITH MATERIAL DRAUGHT AND NO BLAST UNDER PRESSURE

with the carbon is ensured and equilibrium obtained, almost the whole of the carbon is obtained as carbon monoxide, according to the equation

$$C+\frac{1}{2}\{O_2+4N_2\}\rightarrow CO+2N_2+29{,}000 \text{ cal.}$$

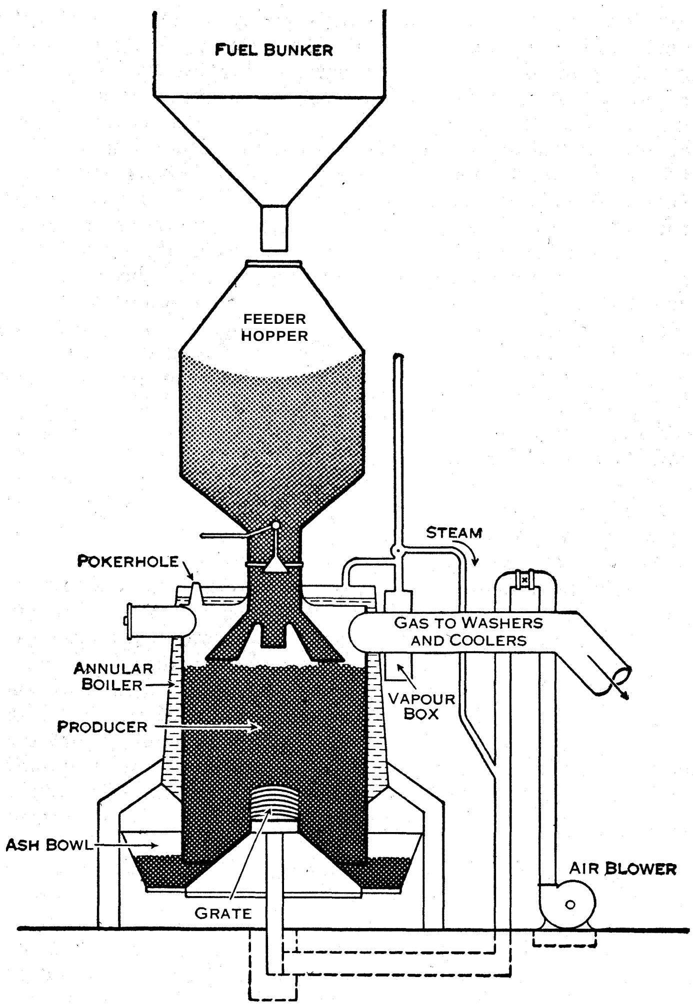


FIG. 7.— DIAGRAM OF A GAS PRODUCER

If the temperature is lower, even although the contact is complete and equilibrium is still attained, some carbon will be burned to CO_2 according to the equation

$$C+O_2+4N_2\rightarrow CO_2+4N_2+97{,}000 \text{ cal.}$$

If, however, the high temperature has been maintained and the carbon entirely converted to CO, it is plain that the gas will consist of one-third carbon monoxide and two-thirds nitrogen, and the equation representing its formation may be called the ideal producer gas equation. If this producer gas is collected and burned with air, it will generate heat according to the equation

$$CO+2N_2+\frac{1}{2}\{O_2+4N_2\}\rightarrow CO_2+4N_2+68{,}000 \text{ cal.}$$

It will be seen that even if the whole of the heat generated in making the producer gas by converting the carbon to CO were lost, some 70% (actually $\frac{68}{97}$ths) of the total heat of combustion of carbon to CO_2 would still remain available for use by its combustion of the gas. This large proportion of heat available for the second stage of the combustion of the carbon in burning carbon monoxide to carbon dioxide is the basis of producer-gas practice. There are various factors which cause divergence in the composition of producer gas from that of the ideal producer-gas equation. In the first place, when coal is used as a fuel and is fed down on the fuel bed. it is at once subjected to a process of distillation or carbonization in the current of producer gas ascending from below, made by the action of the blast upon the carbonized fuel. Producer gas is in this way enriched to some extent with hydrogen and hydrocarbons, particularly methane, and the percentage of nitrogen is correspondingly diminished. More important, however, is the modification in composition brought about by the steam consequent upon a lowering of the temperature of the fuel bed and the formation of water gas by interaction with carbon. The more steam is used, the lower the temperature and the more carbon dioxide and hydrogen at the expense of carbon monoxide is formed. The percentage of nitrogen is further lowered by the admixture with water gas. Moreover, as the quantity of steam is increased and the temperature decreases, the rate of steam decomposition by the carbon lessens and steam passes through the fuel bed undecomposed. The quantity of steam supplied is best controlled by the temperature of the mixed blast at a point well beyond the introduction of the steam, so as to allow a thorough mixing. The temperature of the blast rises with the proportion of steam. It will be understood that undecomposed steam, which begins to occur in quantity as soon as the saturation temperature of 60° C. has been exceeded, is an objectionable constituent in the producer gas, since it is thermally useless and would tend to prevent the attainment of high temperatures on combustion because of its high specific heat. W. A. Bone and R. V. Wheeler followed changes brought about in the composition and yield of producer gas, by gradually increasing the proportion of steam, with results shown in Table III. The coal used was washed nut screened over a 1 in. mesh.

As the saturation temperature was raised by more steam, the gas composition shows a rise in carbon dioxide from 5% to 13% and a change-over from a carbon monoxide producer gas, in which that constituent is dominant to a hydrogen producer gas is explained. The nitrogen has fallen and the percentage of total combustibles has also fallen on account of the increase of carbon dioxide, resulting from the lower temperature of the fuel bed. The calorific value of the gas has slightly diminished, but the volumetric yield increased. so that the yield in therms contained in the gas per ton of coal gasified shows little change. The weight of steam undecomposed per lb. of coal has run up from 0.09 to 0.9 lb. per ton of coal.

Producer Construction.—The development of the apparatus in which the manufacture of producer gas is carried out can now be traced. It would appear that the earliest gas producers were deep shafts of brickwork, but the name most closely identified with the successful establishment of the gas producer is that of K. W. (Sir William) Siemens, and a diagram of his producer (1861) is given in fig. 6. It illustrates how the coal falls from

TABLE III.—*Producer* Gas as *Modified by Steam*

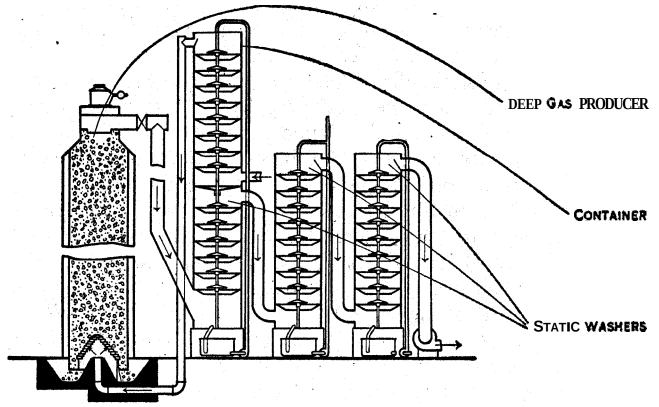
the hopper and lies in the producer above the step grate. The producer was connected to a furnace, and the air for gasification was drawn through the fuel bed by natural chimney draft, operative on the furnace. but supplemented at times by a syphon effect induced by the disposition of the main between producer and furnace.

Pressure Producers.—Although producers based essentially on Siemens' simple design were in widespread use, the demands of industry for higher outputs per unit of space and grate area led to the development of producers working under a positive blast of air and steam. Today the gas producer is essentially of the design shown diagsammatically in fig. 7. The generator is a cylindrical body provided with a grate or tuyère through which



BY COURTESY OF THE POWER GAS CORP.

FIG. 8.—DEEP GAS PRODUCER FROM WHICH GAS PASSES THROUGH STATIC WASHERS FOR WASHING. AMMONIA ABSORPTION AND COOLING

the air-steam blast is admitted at the bottom and with an outlet for gas at the top. The generator is water-jacketed, with the object of preventing adhesion of clinker and at the same time raising the steam needed to saturate the blast. Fuel for a run of about six hours on full load is contained in a feed hopper from which it falls into the producer through several chutes arranged so as to ensure uniform distribution and to prevent segregation. The Koller grate is a series of superposed cast-iron rings, the space between which forms horizontal ports through which the blast is distributed evenly. The grate is secured to a revolving ashpan, designed to continuously shear the bottom from the column of ash, break up lumps of clinker and discharge both over a plow bolted to the sealing ring. Steam from the annular boiler passes into a vapour box and thence to the air-blast pipe. Blast is supplied by a blower and is measured by a Venturi meter; it is then saturated with steam at any desired temperature and admitted to the producer from beneath the grate. Satisfactory operation of a gas producer depends upon keeping the distribution of blast and ascending gas current as uniform as possible across the section of the fuel bed, so as to give proper contact in all parts with the descending fuel. For this purpose the producer may be provided with holes through which pokers may be inserted to keep the fuel bed level and free from channels which would tend to short-circuit the gas stream. Some designs incorporate mechanical revolving pokers.

In many cases the producer gas can be used hot and direct from the generator, without further cleaning; the advantage gained is that the sensible heat in the hot gases is retained. When a clean gas is required (as for example, in a gas engine) the gas must be cleaned and cooled. This is usually effected by means of a washer cooler containing water sprays, in which dust and some tar are removed. Next, a centrifugal washer takes out most of the remaining dust and tar; the gas then passes through a moisture eliminator and then ta a dry scrubber in which the final removal of dust is accomplished. This scrubber may consist of an oxide box to remove hydrogen sulphide.

In the past by-product recovery from producer gas was practised on a considerable scale, and modified designs and processes were developed to obtain larger yields of ammonia and tar than were normally obtainable. The essential feature was the use of a very deep fuel bed of coal (12 to 14 ft.) working at a lower temperature which favoured high yields of tar and ammonia. The recovery process called for a rather elaborate plant, the main features of which are indicated in fig. 8. The gas is washed; freed from ammonia and cooled by passing in turn through three Lymm static washers, the ammonia being absorbed in weak ammonium-sulphate solution maintained slightly acid. Gas leaving such a plant was ready for furnace use but needed more thorough cleansing by tar extractors and scrubbers before its use in engines. With such plants, coal could be gasified to yield an average of 122,000 cu.ft. of 178-B.T.U. gas per ton, with a recovery of 90 lb. of ammonium sulphate and 21 gal. of tar per ton of dry fuel gasified. A few such plants still remained in use in the 1950s, though the type was by then obsolete.

Blast-Furnace Gas. — Blast-furnace gas is a low-grade gas with a calorific value of about 95 B.T.U. produced on a large scale as the inevitable by-product of the smelting of iron. The blast furnaces used for the production of pig iron may be regarded as very deep, air-blown gas producers giving a gas containing some 27% of carbon monoxide and 11% of carbon dioxide, with 60% of nitrogen. The cleaned gas is used for steam raising and power production; but for furnace firing it usually needs to be mixed with a richer gas.

BIBLIOGRAPHY.—For gas manufacture *see* Alwyne Meade, *The New Modern Gasworks Practice* (London, 1934); and Walter King, Ltd., *Manual of Gas Manufacture* (London, 1948; rev. ed., 10 sections, 1951–53). Producer gas is covered by N. E. Rambush, *Modern Gas Producers* (London, 1923); J. E. Dowson and A. T. Larter, *Producer Gas* (London, 1920); and the National Federation of Gas Coke Associations, *Producer Gas Plant for Industrial Purposes* (London, 1942). More general are W. A. Bone, *Coal and its Scientific Uses* (London, 1918); R. T. Haslam and R. P. Russell, *Fuels and Their Combustion* (New York, 1926); and G. W. Himus, *Elements of Fuel Technology* (London, 1947). The *Transactions* of the Institution of Gas Engineers (London) and the *Proceedings* of the American Gas association (New York), the *Gas Journal* (London), the *Gas World* (London) and the *Gas Tinzes* (Leighton Buzzard) are periodicals dealing specially with gas manufacture. Full details of the working of the nationalized gas industry are available in the annual reports of the Gas council (1950–54) and of the area boards (H.M.S.O., London).

GAS SUPPLY IN THE UNITED STATES

The First Gas Plants. — Following the discovery of gas making from coal and the unparalleled success of gaslighting in one or two European cities, gaslighting got its start in the United States in Baltimore. Although there were a few isolated instances of gas being used by individuals in other cities previously, introduction of gaslights in Rembrandt Peale's museum in Baltimore in 1816 proved to be such a success that the city council passed an ordinance on June 17, 1816, permitting Peale and others to manufacture gas, lay pipes in the streets and contract with the city for street lighting. The first recorded demonstration of gas in the United States was in Philadelphia in Aug. 1796. The gas was manufactured by M. Ambroise and Co., Italian fireworkers and artists. A few years later, in 1812, David Melville of Newport, R.I., lighted his home and the street in front with gas which he manufactured. He also lighted a factory at Pawtucket and induced the government to use gas at Beaver Tail lighthouse.

Baltimore, however, was the first city to use gas commercially, and other cities followed its lead.

Growth and Changes in the Industry. — By the second half of the 20th century the gas industry had grown into one of the key industries, showing remarkable ability to adapt itself to meet severe competition, changing raw materials, and drastic economic and labour conditions, while constantly maintaining and expanding its service. Initiated and long maintained as a lighting service, when this market was taken by the invention of electric lighting, the gas service emerged as a heat producing one; when the severe labour and raw material inflations and dislocations caused by World War II threatened the manufactured gas service and solvency, the industry maintained and expanded its markets by drawing more natural gas from transcontinental pipelines.

Changing Processes and Raw Material. — Public utility gas first was manufactured gas made by heating a high-volatile coal in a metal retort and subjecting the resulting gas to cooling and purification. A water gas process was introduced later. This injected steam over the coal which was heated externally. The work of Thaddeus Lowe, a Union balloon officer in the Civil War, made possible the economic manufacture of water gas in internally fired machines. This became the basis of the modern carburetted and blue water-gas processes. By-product coke-oven gas supplemented and often supplanted utility coal gas and water gas. Internally fired oil-gas processes were invented and developed. Prior to World War II these were used very little in the United States except on the west coast. Even there prior to World War II, oil gas was declining as natural gas became available.

All these changes, important, and, in some respects even revolutionary as they were, were dwarfed by the change from manufactured gas to natural gas. This tremendous exploitation of natural gas followed the discovery and proof of large reserves of natural gas in the midcontinental and southwestern areas in the 1920s, areas that were later expanded. In 1925 seamless electrically welded steel pipe made the transportation of oil and gas long distances economically feasible. The change was particularly striking after World War II freed transcontinental pipelines from petroleum transportation to gas transmission and the economic inflation and short labour supply made public utility gas manufacture based on solid fuels generally uneconomic.

By the mid-1950s intra- and interstate transportation of natural gas by major pipelines had become so far-flung that, except in six states, Maine, Vermont, Idaho, Nevada, Oregon and Washington, there was practically no major city in the United States beyond the reach of natural gas supplies and plans had been made to bring major supplies of natural gas to the Pacific northwest.

Long distance transmission of natural gas changed the engineering and economic problems of a gas industry. It involved heavy investments in long pipelines and, in many cases, the substitution of high thermal value natural gas for medium thermal value manufactured gas. These changes led to major new developments in gas manufacturing processes, storage and sales. The investments in long pipelines favour the use of these lines at high load factors; thus natural gas becomes the base gas or the base material for gas manufacture. Off-peak sales of natural gas at attractive rates to industry is favoured with shutoff agreements at peak public demands. Potential major or total interruptions to supplies from distant sources, requiring quick start-ups, coupled with labour and material problems, reduced reliance on the gas manufacturing processes based on solid fuels, and led to striking developments in quick-starting, flexible liquid-fuel processes.

A number of oil-gas processes have been designed and developed to utilize the cheaper grades of heavy oils. In many situations component parts of abandoned water-gas equipment have been built in the new heavy oil-gas machines. Other studies have developed new equipment as well as new processes for the purpose. Characteristic of these heavy oil developments has been the ability to manufacture high heat content gases with combustion characteristics such that they may be distributed for use in mixture with or as substitutes for natural gas. In general, such heavy oil-gas making machines use oil and air internally to create the heat they require; then inject oil and steam into the heated zone to make the gas. Partial combustion with air is sometimes simultaneously employed to increase the volume of the gas made. The cycle is then continued by returning to the heating phase, followed by another gas making phase. Good heat economy and good heat distribution within the machine are obtained in the same phase by heating alternately in a forward and a reverse direction, followed by making gas in the forward and reverse directions. The incoming oil, air and steam are preheated regeneratively by waste heat from the outgoing products, thereby securing good thermal efficiencies.

Where mixed gases of a total thermal content less than that of natural gas are distributed, or where liquefied petroleum gases are used for enrichment, natural gas, liquefied petroleum gases, gasolines and petroleum oils may be reformed in machines of the water-gas or oil-gas type to greater volume, lower thermal content and controlled combustion characteristics and gravity to meet production and mixing needs. The reforming processes may involve partial combustion, pyrolysis or reaction with steam or some combination of these. Reforming, with enrichment of the reformed gas with liquefied petroleum gases or refinery oil gases may also be used to meet peak loads on natural gas systems.

Unique in post-World War II gas-making processes was the development of catalytic reforming. The feed stock may be natural gas, propane, butane. refinery oil gases or natural gasoline. The reforming is carried on in chrome-nickel alloy tubes externally heated, usually with light fuel oil. The tubes are filled with a nickel oxide catalyst, and the reforming gas zone is maintained at a temperature of about 1,800° F. The type of reformed gas depends upon the relative proportions of air and steam in the feed mixture. Pyrolysis of the feed mixture is not attempted. The ultimate capacity depends upon the rate of deposition of carbon, excessive carbon being objectionable. The unit is very flexible. The reformed gas, usually of 180 to 350 B.T.U. per cubic foot (at 60° F. and 30 in. mercury barometer saturated with water), with a specific gravity from 0.52 to 0.65 referred to air, is then enriched with undecomposed feed stock. The unit can produce a perfectly matched gas that can be used as 100% replacement of the regular utility sendout. A continuous process, its automatic controls and flexibility permit feeding directly into the distribution system. A minimum of labour is required, capital investment is low, purification of the gas is not necessary and there are no tars and no waste disposal problems. As the plant produces no smoke or dust it can be tolerated in highly residential locations. Its flexibility and ability to match regular send-out gas permit it to be located in distant areas to relieve low pressure during peak loads and to feed back into the supply main from the primary plant or city gates, thereby affecting large increases in main capacities.

Natural Gas.—Although natural gas had been noted in the United States before manufactured gas was introduced, it was not used commercially until long after manufactured gas was distributed. There is a record of a "Burning Spring" in 1775 near Charleston. W.Va., on land which George Washington dedicated as a public park.

In 1821 near another "burning spring" at Fredonia, N.Y., the first natural gas well in the United States was drilled to a depth of 27 ft. In 1854 the first deep gas well, some 1,200 ft., was sunk at Erie, Pa. In 1859 Edwin L. Drake began the petroleum industry at Titusville, Pa. Natural gas is frequently associated with petroleum in the earth's crust and its pressure serves to drive the oil to the surface. Oil men in early days ignored natural gas. The gas liberated from the oil at the surface was piped to a flare and burned as a gigantic torch. Wells that gave gas only were flared and allowed to burn themselves out over the years.

The first natural gas corporation in the United States was the Fredonia Gas Light and Water Works Co., organized in 1858. In 1873, Titusville, Pa., was supplied with natural gas through a 2-in. iron pipe, five miles long. In 1870 a burning well at Bloomfield, N.Y.. was extinguished and connected to a 25-mi. pipeline of white pine logs bored with an 8-in. hole. In 1872, this gas was turned into the mains of the Rochester Gas Co., but the venture soon failed.

By the mid-1950s there were about 70,000 gas wells in the United States; these with gas producing oil wells, accounted for a total of about 8,500,000,000,000 cu.ft. of marketed production annually. Gas wells had been drilled to great depths, down as much as two or three miles. Recoverable reserves in the U.S. were estimated to total more than 200,000,000,000,000 cu.ft.; for a number of years more natural gas had been found than was consumed.

Estimates of recoverable reserves have run as much as 500,000,000,000,000 cu.ft.

Long distance high pressure transmission of natural gas through seamless steel pipes welded into a unitary metallic pipeline made available to cities and industries at a reasonable price, tremendous supplies of energy in the form of an ideal fuel. The marketed production of natural gas in the mid-1950s totalled 8,500,000,000,000 B.T.U. This was more than $5\frac{1}{2}$ times the electrical energy generated in all public and private plants in the United States in the same time (442,000,000,000 kw.hr. equivalent to 1,508,000,000,000,000 B.T.U.). Manufactured gas contributed 90,000,000,000,000 B.T.U. and liquefied petroleum gas for fuel 326,000,000,000,000 B.T.U.

Liquefied Petroleum Gases.—The liquefied petroleum gases, propane and butane, have been obtained from natural gas condensates at wellheads, in compression operations, or low temperature points in "wet" gas transmission systems. A very important source has been the crude natural gas gasoline extracted from natural gas by oil absorption. The enriched gasoline-oil mixture is stripped with steam and the vapours from the crude gasoline are then fractionally distilled. These hydrocarbons are also recovered in petroleum refining and petroleum cracking operations.

Propane alone has sufficiently high vapour pressure at the customary temperatures prevailing over the United States to permit it to be distributed as a gas without admixture. Butane, however, requires a carrier gas. For single consumer installations beyond gas mains a mixture of propane-butane compressed into steel cylinders is sold as bottled gas. Where a number of consumers are to be supplied, propane alone may be distributed by small mains. Larger communities, too small to warrant a gas plant, may be served with a butane-air mixture in which the content of air must be sufficiently high to avoid condensation of butane from the mixture, but the air must also be always very much less than 91.59% and the butane must be more than 8.41% by volume under ordinary atmospheric pressure. The proportions stated are required to form a high limit explosive mixture. Maximum air content usually does not exceed 67%.

Butane-air gas may be mixed with natural gas under some peak load conditions to assist in meeting consumer demands. A butane-air plant can be instrumented so that it is operated, controlled and safeguarded completely by automatic devices, consequently its small demands for labour and supervision make it very suitable for service to isolated small communities.

Storage of Gas.—The generation and transmission of gas for variable demand loads as in public utility possesses an important advantage over electricity in that gas can be stored in large quantities economically, whereas electricity must be generated and transmitted as consumed. This permits gas generating units and long distance transmission units to be designed for average rather than peak conditions, thereby reducing markedly the capital investment required. The long distance transmission of natural gas is maintained at high load factor in the summer season by moving large gas supplies to storage pools near the customers. Depleted gas fields or natural geological formations of porous rock completely capped by impervious rock formation can be used for this purpose. They may have storage capacities of billions of cubic feet. In the mid-1950s about 400,000,000,000 cu.ft. were pumped into storage annually to be withdrawn on "peak" demand days. There were at that time more than 167 underground pools with a total storage capacity of nearly 1,735,000,000,000 cu.ft.

The Use of Gas.—In the mid-1950s there were in the United States about 33,000,000 families who cooked with gas; 18,000,000 used gas to heat water, 15,000,000 heated their homes with gas, and 4,000,000 families owned gas refrigerators.

In industry, it was estimated that there-were more than 21,000 uses for gas. These included glassmaking, metal production and fabrication, food processing, printing, textile production, electronic equipment manufacture, plastics, paint and countless other products.

Petrochemicals.—Natural gas is an important raw material for the synthesis of petrochemicals. As the name suggests, these are chemicals that are synthesized from rock sources, such as natural gas, petroleum or coal. Important end products are ammonia, alcohols, synthetic rubber, plastics, fibres and detergents. The hydrocarbon-containing fuel is subjected to pyrolysis as in the formation of ethylene and benzene; or to reaction with steam over a catalyst, as in the formation of carbon monoxide and hydrogen, or to partial combustion as in the synthesis of phthalic acid by the partial combustion of naphthalene over a catalyst. The intermediate products are then used as building blocks to make the commercial petrochemicals.

GAS IN WARFARE: *see* Chemical Warfare; Chloropicrin; Mustard Gas; etc.

GASKELL, ELIZABETH CLEGHORN (1810–1865), English novelist and biographer, was born on Sept. 29, 1810, in a house in Lindsay row, Chelsea, London; now 93 Cheyne walk.

Her father. William Stevenson (1772–1829), had been successively Cnitarian minister, farmer. boardinghouse keeper for students at Edinburgh, editor of the *Scots Magazine,* and contributor to the *Edinburgh Review* before he received the post of keeper of the records to the treasury. which he held until his death His first wife. Elizabeth Holland, died a month after her daughter, Elizabeth, was born, and the babe was taken to Knutsford, Cheshire, to be adopted by her maternal aunt, Mrs Lumb. Thus her childhood was spent in the environment idealized in *Cranford.* From 1824 to 1826 Elizabeth went to school at Stratford-on-Avon, from 1827 to 1829 she lived in London with her father and his second wife; and after two winters at Neucastle-on-Tyne in the family of William Turner. a Cnitarian minister. and a third in Edinburgh. she married, on Aug 30, 1832, William Gaskell, minister of the Unitarian chapel in Cross street. Manchester. and from 1846 to 1853 professor of English history and literature in Manchester New college They lived first in Dover street, then in Rumford street. and finally. in 1850, at 84 Plymouth grove.

Mrs Gaskell and her husband thought to emulate George Crabbe and write the annals of the Manchester poor, but only one poetic "sketch" appeared (*Blackwood's Magazine,* 1837). In 1844, while they were visiting North Wales, their infant son died, and to distract Mrs Gaskell from her sorrow her husband suggested a long work of fiction. Hence *Mary Barton, a Tale of Manchester Life* was begun It was published in 2 vol., 1848; its appeal for neighbourly love, its dramatic power and humour winning for the author the friendship of Carlyle, Landor and Dickens. Dickens asked her, in 1850, to contribute to his new magazine, *Household Words,* and here the whole of *Cranford* appeared at intervals from Dec. 1851 to May 1853. exclusive of one sketch, which was published in *All the Year Round* for Nov. 1863. *Cranford* was published in book form in 1853. *Cranford* is an English classic. It is a picture of Knutsford indeed, but a work of imagination that has a place in literature beside the much earlier work of Jane Austen. In *Ruth* (1853) Mrs Gaskell again presents Knutsford, thinly disguised, and the little Unitarian chapel in that town.

North and South, a powerful tale of the industrial revolution, first published serially in *Household Words,* was separately published in 1855. Then came—in 1857—the *Life of Charlotte Bronte,* in two volumes. Two years earlier Miss Bronte had begged her publishers to postpone the issue of her own novel, *Villette,* in order that her friend's *Ruth* should not suffer. This biography, by its vivid presentation of the tragic story of the three Brontë sisters, gave its author a place among English biographers.

In 1863 Mrs Gaskell published her last long novel, *Sylvia's Lovers,* a romantic tale of Whitby smugglers and the press-gang riots. In the same year a one-volume story, A *Dark Night's Work,* and *Cousin Phyllis and other Tales,* appeared.

Mrs Gaskell died on Nov. 12, 1865, at Holyburn, Alton, Hants, and was buried in the graveyard of the Knutsford Unitarian church. Her unfinished novel, *Wives and Daughters,* was published in 2 vol. in 1866.

BIBLIOGRAPHY.—J. A. Payne, *Mrs. Gaskell* and *Knutsford,* and ed (1905); E H Chadwick, *Mrs. Gaskell,* 2nd ed. (1913); Gerard DeWitt Sanders, *Elizabeth Gaskell* (1930).

GAS MASK. Casualty gas, as a weapon of war, was first used in World War I by the Germans against Allied forces north of Ypres in Belgium, on April 22, 1915. (*See* CHEMICAL WARFARE.) The first military gas masks used by the Allies in that war were cumbersome affairs consisting of the mask proper. which fitted around the face, attached by a tube to a canister suspended around the soldier's neck and hung in front of his body. The wearer breathed air through a tube in his mouth from which the poison gases were filtered through charcoal contained in the canister. A nose clip prevented breathing through the nostrils. The use of this type of mask greatly impeded the soldier's movements and efficiency in battle and made it impossible for him to "hug the ground" closely when under attack by machine gun fire.

Considerable improvement in the gas mask was made after World War I and soldiers in World War II were provided with a mask that was lighter in weight, better fitting, ensured clearer and wider-range vision and, by eliminating the nose clamp and mouth inhaler, lowered breathing resistance. Another advantage of the World War II equipment was that the canister was slung over the shoulder and carried at the soldier's side, thus permitting greater freedom of action in combat.

A later type of military gas mask was known as the "assault type." Complete, it weighed less than three pounds. The canister fitted directly onto the side of the facepiece of the mask, thus eliminating the long connecting tube and the necessity for slinging the canister from neck or shoulder. The pure, filtered air came into the mask at the top and kept the glass eyepieces from blurring as it was drawn down to the nostrils. For soldiers with defective vision, specially prescribed lenses for the mask were provided. Although many improvements were made in the mask itself in the decades following World War I, the chemical agencies used to filter impurities from gas-infected air remained fundamentally the same. The canisters were filled with charcoal and soda lime which absorbs all gases known to be usable for tactical purposes. However, some of the chemicals used to produce poison gases on the battlefield remain suspended in the air as fine, solid particles for long periods. These particles were filtered from the air entering the canisters by pads of felt inserted in the air passage.

In addition to military uses, gas masks are widely used in industry to protect workmen employed in mining and in chemical and other types of plants where fumes and gases resulting from natural circumstances or manufacturing processes are known to be injurious. Firemen and members of rescue squads also carry gas masks as part of their normal equipment. During World War II masks designed for civilian use in the event of air raid or other form of attack delivering poison gases, were also provided, particularly in Europe. (M. B. H.)

GAS METER, a device for measuring gas volumes. Companies selling gas to the public commonly use a positive displacement meter, a rotary meter, an orifice meter or a heat capacity meter to compute charges for gas usage or purchase.

For small volumes of consumption as in residential premises or most commercial installations, a positive displacement dry meter is used. Its operation involves the alternate expansion and contraction of each side of a double bellows of leather or synthetic material. The meter case, of tin, iron or aluminum, houses two working compartments, each of which encloses a bellows. The compartments are separated by a vertical partition which intersects a horizontal above the bellows and below the gear mechanism. Valve parts and seats are located in the horizontal partition, one set for the two working spaces thus provided for each bellows, one space inside and one outside the bellows diaphragm in each compartment. As each bellows alternately fills from the meter inlet and empties through the meter outlet, the gas volume is measured through a gear mechanism to the meter index dial.

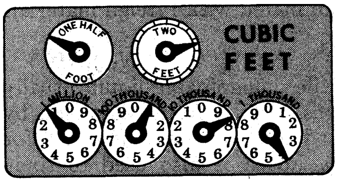

FIG. I.— TIN-CASE METER INDEX

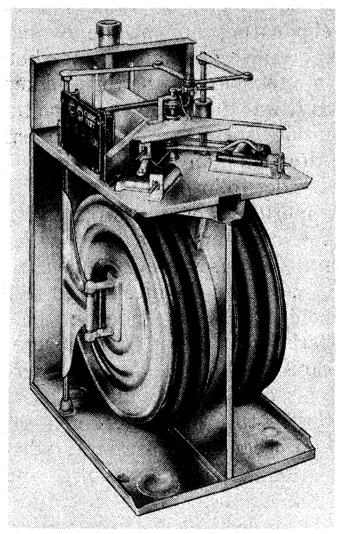
The number of index circles in the dial of the dry meter varies with the capacity of the meter. At the top are one or two test circles, usually two. For leak testing, one of the two makes a complete revolution for each cubic foot of gas or designated fraction thereof. The second dial registers two to five cubic feet and is used for checking the accuracy of the meter. The lower dials register the total volume passed. The right-hand index turns clockwise and adjacent indexes turn in opposite directions. The meter is read from left index to right by taking in each the figure behind the position of the index. Two ciphers are added, giving the result in cubic feet. Usually the customer is billed on company readings but prepayment meters are set by an inspector to deliver the purchased volume of gas. In another type, an inserted coin permits a definite volume to pass the meter.

For higher rates of delivery the rotary meter is used. This is a case with semicylindrical ends in which are two or three revolving impellers (rotors). Each rotor moves exactly counter to that adjacent. The entering gas is trapped and must move the rotors to be discharged. The trapped constant gas volume is recorded through gear mechanism to a dial. In some rotary meters the capacity may be large enough to supply gas to a small town.

For measurement of large volumes of gas, an orifice meter is used. Essentially, a steel plate in which a hole is machined and centred is fitted across and inside the gas pipe. This obstruction causes the gas to jet downstream, creating there a partial vacuum. A differential pressure can be measured by connecting the upstream space and the downstream space to the two sides of a recording manometer. The differential pressure varies with the flow through the orifice, thus measuring the volume of gas flowing. Orifice meters are relatively simple, sturdy and precise, but they have two disadvantages: there is a large loss of pressure, and the mathematical relations between the differential pressures and the volume of the gas passed are very complex. Fortunately, natural gas is often available at pressures much higher than is reauired bv consumers, so the loss of pressure may not be objectionable. The mathematical relationships have been carefully analyzed and compiled into tables that simplify the readings.



BY COURTESY OF AMERICAN METER CO.

FIG. 2.—CUTAWAY VIEW OF A TIN-CASE METER

Where the gas measured has a uniform known heat capacity per unit volume, a device for measuring the passing heat capacity can be employed as a gas meter. Two thermometers of the electrical grid type may be placed some distance apart in a gas pipe. Between these is placed a source of heat, such as an electrical heating coil. The thermometers control the heat input to the coil to maintain a constant rise of temperature between them. The readings of a recording electric wattmeter establish the volumes of gas flowing. An alternate but similar device measures the varying rise in temperature caused by a fixed rate of heat input. Heat capacity meters cannot be used on gas contaminated with foreign materials such as tar fog, moisture or dust.

See also GAS INDUSTRY. (W. J. HF.)

GASOLINE (PETROL). a volatile, inflammable liquid usually consisting primarily of hydrocarbons derived from petroleum by various processes. By far the most important use is as a fuel for internal-combustion engines (*q.v.*), but it is also used to some extent in special stoves and as a solvent.

In the early days of the oil industry, gasoline (termed "straight run") was simply the portion of petroleum that distilled off at a lower temperature than kerosene, the principal product desired. It was largely wasted until the advent of the automobile. Gasoline became the preferred motor fuel because of two important properties: it had the high energy of combustion typical of hydrocarbons, and it was sufficiently volatile to form a combustible mixture with air in a simple, relatively inexpensive carburetor. It was also cheap and plentiful.

As the demand for gasoline increased during the first two decades of the 20th century, it ceased to be a by-product, and more and more of the kerosene cut began to be included. By 1913 even this became inadequate and a gasoline shortage threatened the further rapid development of the automobile. Fortunately, the first commercial cracking process, the Burton process, was developed about this time to convert heavier oils, particularly the gas oils which boiled just above kerosene, into gasoline by subjecting them to temperatures of around 750° F. and pressures of around 100 lb. As a result of this and many later improvements in cracking processes, gasoline yields have increased to about 50% of the crude oil processed, a figure well over twice the amount of hydrocarbons of suitable boiling point found in average crude oil.

Gasoline is a complex mixture containing hundreds of different hydrocarbons. Most of them are saturated and contain 4 to 12 carbon atoms per molecule, but they differ widely in structure. Motor car gasoline boils mainly between 90° and 410° F., the precise blend being adjusted to the climate and the season. More light, volatile components are needed for quick starting and fast warm up when the weather is cold, but these are likely to cause high evaporation losses and vapour lock at summer temperatures. The heavier portions of the gasoline are valuable for their higher heating value, but in excess they may cause carbon deposits and uneven fuel distribution. Aviation gasoline is a "heart cut" containing less of both the lighter and heavier ends than motor car gasoline.

As engine designers sought greater efficiency through higher compression ratios, they encountered increasing trouble with engine "knock," a rapid detonation occurring toward the end of the combustion. The shape of the gasoline molecules was found to be very important in determining the knocking tendency of a gasoline. Straight-chain molecules knock much more readily than branched or ring-shaped molecules, especially of the saturated type naturally present in crude oil. It soon became evident that the extent to which the compression ratio, and hence the efficiency, of gasoline engines could be increased depended on changing the kind of molecules present in gasoline.

To establish a definite scale for measuring antiknock characteristics, iso-octane (2,2,4-trimethylpentane), a highly branched hydrocarbon, was assigned a value of 100 on the knock-rating scale, and normal heptane a value of 0. The octane number indicates simply that a gasoline has the same knocking tendency (in a standard engine under standard conditions) as a particular blend of heptane and iso-octane, the percentage of the iso-octane in the blend being termed the octane number. However, the actual behaviour in different engines is likely to vary somewhat from the results of the standard test.

The straight-run gasoline found in average crude oil has a low octane number. Needed high-octane components are made by a variety of processes which have been developed over the years. Branched hydrocarbons are plentiful in gasoline made by cracking — particularly if the cracking has been brought about by catalysts instead of by older processes using only heat and pressure. Branched structures are even more abundant in alkylate and polymer, both of which are made by joining together, nith the aid of catalysts, small molecules of gases made as a by-product in most cracking processes. Of the ring-shaped hydrocarbons, among the most valuable are benzene and toluene, which are obtained from coal tar or may be made by passing certain cuts of straight-run gasoline over platinum or other catalysts.

By the end of World War II about 60% of the average motor fuel was composed of synthetic molecules, and aviation gasoline was more than 90% synthetic. By the early 1960s most motor gasoline was fully 80% synthetic. This illustrates forcibly the revolution in refining methods brought about by the advent of cracking. The discovery that the cheap hydrocarbons in petroleum could be readily changed in composition and structure led also to a rapidly growing petrochemical industry *(see* PETROLEUM: *The Petrochemical Industry),* which makes from petroleum or natural gas a wide variety of chemicals for solvents, plastics, fibres, synthetic rubber and for many other purposes.

Another important way of increasing antiknock is by the addition of tetraethyl lead, as was discovered by Thomas Midgley in 1920. Though the amount used in motor fuel is less than 0.1% by volume, it may increase the octane number by as much as 15 points.

By the early 1960s the average octane number of U.S. gasoline had risen to about 91 for the regular grade and 99 for the premium grade, as compared with a figure of 55 octane or below before the advent of cracking. Military aviation gasoline reached the 100-octane level just before World War II, and still better fuels were later developed. Their antiknock quality is stated in terms of performance numbers. which indicate the knock-free power obtainable in an engine of suitable compression ratio as a percentage of the power obtainable from pure iso-octane. The most widely used grade of aviation gasoline had a performance number of 115 under cruising conditions, 145 under take-off conditions. However, further substantial increases in octane number promised to be quite expensive. As the result of these improvements, the compression ratios of new automobile engines have gone up from an average of 4.4 to 1 in 1925 to an average of 9.5 to 1 in 1958, with an improvement in the efficiency of gasoline utilization of about 60%. The average power generated per cubic inch of engine displacement has gone from .234 h.p. to .779 h.p. in the same period.

Additives are also used in gasoline for purposes other than antiknock improvement. Chlorine and bromine compounds convert the lead in tetraethyl lead to relatively volatile salts and thus assist in its removal by the exhaust gases and in reducing the build-up of deposits on exhaust valves, etc. Antioxidants are used to inhibit gum formation. Metal deactivators prevent deterioration caused by contact with the metal of the fuel tank. De-icers prevent engine stalling caused by the icing of carburetor throttle plates.

Although petroleum is the principal source of motor fuel, other raw materials are used. Natural gas often contains moderate amounts of liquefiable hydrocarbons, which are recovered as "natural" or "casinghead" gasoline. In Europe alcohol is sometimes included in motor fuel blends. Motor benzol recovered from coal tar is also used at times.

Gasoline can be produced by combining carbon monoxide and hydrogen at high pressure in the presence of a suitable catalyst. The needed mixture of gases may be produced by the partial oxidation of natural gas (methane) with pure oxygen. To be commercial the process requires cheap natural gas as the starting material, and good prices for the by-product alcohols, acids, ketones and other organic chemicals. In the distant future, coal may be used to provide the hydrogen and carbon monoxide. Direct hydrogenation of coal is also possible, but is expensive. Gasoline can likewise be made from tar sands, of which there are very large deposits in Canada. The most promising of the long-range sources, however, appeared in the early 1960s to be oil shale. The U.S. reserves of shale are much larger than the country's known reserves of petroleum.

In 1958 the U.S. oil refining industry produced about 1,500,000,000 bbl. of gasoline and the rest of the free world about 600,000,000 bbl. Of course, the yield of gasoline obtained in the United States is much higher than in the rest of the free world, which converts a much larger proportion of its crude petroleum into light and heavy fuel oil.

See PETROLEUM. (R. E. WN.)

GASPARRI, PIETRO (1852–1934), Italian cardinal and canonist, was born at Capovalazza de Ussita on May 5, 1852. He received the degrees of doctor of philosophy, theology and canon law after study at the pontifical seminary at Rome, and from 1880 to 1898 was professor of canon law at the Catholic institute in Paris. In 1904 Pius X, having decided to codify the canon law, confided to Gasparri the direction of the work. The new code was promulgated in 1917 *(see* CANON LAW).

In 1907 Gasparri was made cardinal, and in Oct. 1914 Benedict XV appointed him secretary of state, which office he held throughout the arduous World War I period and the almost equally strenuous reconstruction period which followed. He was retained by Pius XI and in 1926 began negotiations which resulted in the Vatican treaty. He resigned in Jan. 1930 and was succeeded by Eugenio Cardinal Pacelli (later Pius XII). Cardinal Gasparri died at Rome on Nov. 18, 1934. (B. TY.)

GASPÉ, PHILIPPE AUBERT DE (1786–1871), "the grand old man of French-Canadian literature," was the author of the first important novel published in French Canada, *Les Anciens Canadiens* (1863). Born on Oct. 30, 1786, into a distinguished Quebec family whose first Canadian ancestor had been ennobled by Louis XIV of France, de Gaspé was the epitome of gentlemanly dignity as hereditary *seigneur* of his estate on the St. Lawrence river. He received a classical education in Quebec, studied law there and later became sheriff of the city. Bankruptcy, for which he spent over three years in debtors' prison, forced him out of public life in his 40s.

After years of reading and meditation, inspired by a rebirth of nationalism in mid-19th century, de Gaspé composed *Les Anciens Canadiens* late in life. It is a romantic historical novel set in Canada at the time of the British conquest (1760), written to preserve the old French traditions for posterity. De Gaspé makes use of known historical material, personal family records, folklore and folksongs. The novel has a nostalgic charm spiced with avuncular humour. It was enthusiastically received and became a classic in French Canada. an aristocratic precursor of *Maria Chapdelaine* (1916) by Louis Hémon, and hence of the whole regionalist school that flourished into the 1930s. The common features are idealization of the "good, old days" and of the habitant farmer, loyalty to the soil and distrust of English Canada.

GASPÉ PENINSULA (GASPÉSIA) juts into the Gulf of St. Lawrence and comprises that part of eastern Quebec province which lies between the St. Lawrence river and the province of New Brunswick. It is a hilly to mountainous area with well-forested slopes. The central portion is occupied by the Shickshock range, a continuation of the Appalachians. which rises in places to over 4.000 ft. Settlement is light, occurring only in widely separated coastal villages. The area is best known as a tourist centre because of its rugged and picturesque coastal scenery, its striking hills and excellent hunting and fishing. Lumbering and coastal fishing are the principal occupations but there is some mining of copper, zinc and lead and a small production of pulp for paper making. (W. F. SS.)

GAS PLANT *(Dictamnus albus)*, a hardy perennial herb of the Rutaceae family. known also as Dittany. Fraxinella and as burning bush The stems are stout. woody at the base. bear alternate odd-pinnate leaves, with glossy leathery leaflets dotted with oil glands and surmounted by long, showy, terminal racemes of snouy white or rose-coloured fragrant flowers with a strong smell of lemon. The gas plant makes a sturdy upright growth, and a clump three feet high and as much in breadth makes a pleasing show when in floner. On a still, sultry summer evening a lighted match held under the flower cluster near the main stem will give a flash, whence the name. The gas plant is a well-knonn and popular old garden ornamental (J M. BL.)

GASQUET, FRANCIS NEIL (in religion AIDAN) (1846–1929) Roman Catholic historian and cardinal, was born in London on Oct 5, 1846. Educated at Downside school, he entered the Benedictine monastery there and was prior from 1878 until 1885. From 1888 onward he published works on monastic history, including the influential *Henry VIII and the English Monasteries* (1888–89), of considerable value but somewhat marred by inaccuracies and bias. He nas created cardinal in 1914, and became prefect of the Vatican archives in 1918. Cardinal Gasquet died in Rome on April 5, 1929.

See M D Knowles, *Cardinal Gasquet as a Historian* (1957); Shane Leslie, *Cardinal Gasquet* (1953) (J D. A.)

GASSENDI (GASSEND) **PIERRE** (1592–1655), French philosopher, scientist and mathematician, famous for his revival of Epicureanism, was born of poor parents at Champtercier in Provence on Jan. 22. 1592. Educated at Digne and Xix, he eventually took holy orders and became professor of philosophy at Aix (1617). After travels in Flanders and Holland (1628–31), he secured an appointment as provost of the cathedral at Digne (1634), which had been disputed for ten years. He then spent some time accompanying the duc d'Angoulême on a tour of his *gouvernement* of Provence. In 1645 Gassendi became professor of mathematics at the Collège Royal in Paris He died in Paris on Oct. 24, 1655.

Gassendi's writings include: *Exercitafionesparadoxicae adversus Aristotelaeos* (1623; new ed , 1649); *Epistolica ercrcitutio in qua principia philosophiae Roberti Fluddi reteguntur* (1630). written at the instance of Marin Mersenne; a letter on the parhelia observed in 1629 (1630); lives of Peiresc and Tycho Brahe (1641 and 1654); a series of objections to the *Meditationes de prima philosophia* of Descartes, which was likewise undertaken at Mersenne's behest and appended to the second edition of the work in question (1642) but republished separately (1644); *Institutio astronomica* (1647); *De vita et moribus Epicuri* (1647); *Animadversiones in decimum librum Diogenis Laertii, qui est de vita, moribus placitisque Epicuri,* with *Philosophiae Epicuri syntagma* as an appendix (1649); and the *Syntagma philosophicurn,* published posthumously among his collected works (1658). The last three works are those on nhich his lasting reputation depends.

As a philosopher, Gassendi opposed the blind acceptance of Aristotle, revived atomism and advocated an empirical realism. But he was not a consistent empiricist, for while he maintains "that there is nothing in the intellect which has not been in the senses" and that the imaginative faculty is the counterpart of sense, he admits that the intellect, which he affirms to be immaterial and immortal, attains notions and truths of which sensation or imagination can give us not the slightest apprehension. He instances the capacity of forming "general notions" and universals, the notion of God and the power of reflection.

The first part of the *Syntagma philosophicum,* which deals with logic and method, contains a praiseworthy sketch of the history of science and contends that the true method of research is the analytic, rising from lower to higher notions, though it admits that inductive reasoning, as conceived by Francis Bacon, rests on a general proposition not itself proved by induction. In the second part of the *Syntagma,* the physics, Gassendi approves of the Epicurean physics, but rejects the Epicurean negation of God, of particular providence and of an immaterial rational soul, endowed with immortality, capable of free determination and specially created. In the third part, the ethics, there is little beyond a milder statement of the Epicurean moral code and a mass of historical quotations. The final end of life is happiness, and happiness is harmony of soul and body.

GASSER, HERBERT SPENCER (1888–), U.S. physiologist and Nobel laureate. was born in Platteville, Wis., on July 5, 1888. After graduating from the University of Wisconsin, and in medicine from the Johns Hopkins school of medicine (1915), he taught at Washington university. St. Louis. Mo., beginning there, with Joseph Erlanger (*q.v.*), the brilliant series of researches on nerve fibres that led to their joint award in 1944 of the Nobel prize in physiology and medicine. In 1931 Gasser became professor of physiology at Cornell university medical college. and in 1935 director of the Rockefeller Institute for Medical Research, which position he held until his retirement in 1953.

Gasser pioneered in the use of the cathode ray oscilloscope as an inertialess instrument for recording the action potentials of nerve impulses. With it he demonstrated the compound nature of the action potential of nerves containing various types of nerve fibres, formulated the rules relating conduction velocity to diameter of the individual nerve fibres, and characterized the several groups of nerve fibres in terms of their electrical properties and conduction velocities. Crucial to this characterization was his study of the after-potentials, which he showed to be different in the several groups of nerve fibres and to be closely correlated with the excitability cycles during recovery of nerve fibres following impulse conduction. An outstanding contribution was his study of the finest of all nerve fibres, the unmyelinated fibres, in which he elucidated their functional properties and, with the aid of the electron microscope, their anatomical structure and relation to the sheaths in which they are imbedded. (D. P. C. L.)

GASTEIN, a side valley of the Salzach river in the province of Salzburg. Aus., is situated between 3.000 and 3,500 ft. above sea level and is crossed by the Gasteiner Ache river. The principal settlements in the valley are Badgastein and Bad Hofgastein on the main railway with direct connections to the lines Munich–Venice and Vienna–Ziirich.

BADGASTEIN at an altitude of 3,320 ft.. is Austria's most important spa and winter sports resort. Pop. (1961) 8.414. It has radioactive thermal springs with a natural temperature of 110° F.. an underwater therapy station and, since 1950, a thermal gallery. For skiers there is a gondola cable car leading to the Stubnerkogel (7,365 ft.) and four ski lifts. Badgastein is also known for its magnificent waterfalls.

BAD HOFGASTEIN, the capital of the valley commune, lying at a lower level, is also a spa, the waters being conveyed from Badgastein by a pipeline. Pop. (1961) 4,612. At one time it was. after Salzburg. the richest place in the province because of its gold and silver mines, which were worked from the Roman period until the 20th century. (H. ZG.)

GASTER, MOSES (1856–1939), Rumanian Jewish scholar, rabbi and Zionist. a noted folklorist and philologist, was born at Bucharest and educated at Bucharest university, where he became lecturer in Rumanian language and literature (1881–85). His championship of the cause of persecuted Jews, which included aiding projects for settling Jews in Palestine, led to his expulsion from Rumania, and he went to England, where he held a lectureship at Oxford in Byzantine and Slavonic languages (1886 and 1891). In 1887 he was appointed chief rabbi of the Sephardic communities of England. Gaster retired in 1919 because of failing eyesight. He died near Abingdon. Eng., on March 5, 1939.

Gaster was author of an enormous body of literature. Among his works were *The Folk Literature of Rumania* (1883); *The Hebrew Version of Secretum Secretorum of Aristotle* (1908); *The Samaritan Book of Joshzca* (1908); *Example of the Rabbis* (1924); and many Rumanian translations and contributions to learned journals. His monumental *Crestomatia Romana* was uncompleted at his death.

GASTONIA, an industrial city and seat of Gaston county, is 20 mi. W. of Charlotte in south-central North Carolina, U.S. Gaston county, a leading cotton-mill county in North Carolina since 1860. had at the time of the U.S. census of manufactures in 1954 more cotton mills than any county in the United States. The manufacturing establishments in the county produce principally textiles and textile machinery.

Gastonia was incorporated in 1877 and became the county seat in 1909. The county, named in honour of William Gaston, a member of congress and judge of the North Carolina supreme court, was formed in 1846. The state-operated Gaston Technical school, the Vocational Textile school and the North Carolina Orthopedic hospital are located in the city. Kings Mountain National Military park is 20 mi. S.W.

In 1929 Gastonia was the scene of a textile strike and severe labour disorders that attracted national attention. Following the death of the Gastonia police chief in a raid on the National Textile Workers union headquarters, union organizer Fred Beal and six associates were convicted of conspiracy to commit murder.

In 1919 Gastonia adopted the council-manager form of government.

For comparative population figures *see* table in NORTH CAROLINA: *Population.* (R. N. E.)

GASTRIC AND DUODENAL ULCER. Peptic ulcer is an inclusive term referring to a sharply circumscribed, punched-out defect or loss of tissue in the mucosa or lining of the stomach or duodenum. The ulcerative process occurs because of the inability of the mucosal lining of the stomach or duodenum to withstand the corrosive and digestive action of acid gastric juice. It is important to distinguish between gastric (stomach) ulcer and duodenal ulcer because of differences in diagnosis, treatment and prognosis.

Peptic ulcer is a common cause of recurring or persistent upper abdominal distress, especially in young men. Duodenal ulcer occurs five to ten times more frequently than gastric ulcer, and is commoner in men than in women; in gastric ulcer the sex ratio is about equal.

Gastric juice, consisting primarily of hydrochloric acid of a concentration of 0.45% and an enzyme, pepsin, which digests proteins, is secreted by glands in the mucosa of the stomach. It is capable of digesting all living tissue. including the stomach itself. Protective mechanisms, such as secretion of mucus by the stomach glands, dilution of the acid juice by swallowed food and saliva. and intermittency of the secretion, act to prevent digestion of the stomach in the normal person. The secretion of acid gastric juice is controlled primarily by nervous impulses traveling via the vagus nerve. These impulses are stimulated by the sight, taste or smell of food, by the hormone gastrin, which is liberated from the lower part of the stomach after contact with food, and by other hormones from the duodenum. A person with a duodenal ulcer usually secretes more gastric juice with a higher hydrochloric acid concentration than a normal person does. The fact that this is not true in the case of gastric ulcer indicates that gastric mucosa may be less resistant than duodenal mucosa to the action of gastric juice.

The causes of peptic ulcers are not completely understood. although many factors have been implicated. Nervous tension, ingestion of certain drugs (such as salicylates and corticoids) and hormonal factors may play roles.

The symptoms of gastric and duodenal ulcer are similar, consisting of gnawing, burning. aching, hungerlike pain or discomfort in the mid-upper abdomen, occurring from one to three hours after meals or when the stomach is empty. Pain frequently occurs at 1 or 2 A.M. This pain is characteristically relieved by ingestion of materials such as food, milk and baking soda, which dilute and neutralize acid.

Several complicating conditions may occur secondarily to peptic ulcer: obstruction of the stomach outlet, due to inflammation or scar formation. may cause vomiting; hemorrhage may occur, manifested by vomiting of bloody material or material resembling coffee grounds, or by black tarry stools; if the bleeding is excessive, weakness and anemia may occur. The wall of the stomach or duodenum occasionally may perforate, causing severe localized abdominal pain and peritonitis. This catastrophic event requires immediate surgery.

Gastric ulcer is diagnosed by the roentgenographic appearance of a crater or defect in the lining of the stomach. It may also be seen directly through the gastroscope. Gastroscopy, especially when biopsy or microscopic examination of aspirations from the stomach (cytological examination) is also performed. usually enables differentiation of a benign gastric ulcer from an ulcerating carcinoma, symptoms of which are similar. The diagnosis of a duodenal ulcer, invariably benign. is usually based upon the, roentgenographic appearance of a characteristic crater or deformity in the duodenum.

Treatment of peptic ulcer is based upon the principle of complete and prolonged neutralization of the gastric hydrochloric acid. This is accomplished by the use of antacids, such as calcium carbonate, aluminum hydroxide, dihydroxy aluminum aminoacetate. dihydroxy magnesium aluminate, or milk. In the acute phase, which may last two to three weeks, these agents are given every half hour; later they may be given every one to two hours. Anticholinergic or antisecretory drugs, such as belladonna. atropine or Pamine, nhich inhibit the secretion of gastric acid. are also valuable. In selected cases. roentgen therapy to the stomach is valuable in producing a decrease in gastric acidity. Sedatives and tranquilizers are used to allay tension and nervousness.

During the first several days of therapy only small feedings of bland foods are allowed. Following this period a full bland diet—meals including two cooked fruits, tno cooked vegetables and lean meat—is tolerated. Prolonged use of a strict diet of pureed foods is rarely necessary. It is. however, best to avoid spices, gas-forming foods and alcohol or other irritants. Since coffee, chewing gum and tobacco stimulate gastric secretion. their use should also be discontinued if possible. In addition, a person with an ulcer should understand the nature of the disease so that he may reorient himself to a life of moderation, relieve nervousness and anxiety and obtain adequate rest and sleep.

Surgical treatment may be necessary in approximately 10% of all cases, either because of complications or because of unwillingness or inability of patients to follow a medical regimen. When it is not possible to differentiate nith certainty a benign gastric ulcer from an ulcerating cancer of the stomach, surgery is indicated. In the surgical treatment of a gastric ulcer, the ulcer is is removed along with three-fourths of the stomach. In the case of a duodenal ulcer the stomach may be removed in a similar manner or else the more physiological procedure of vagotomy and gastroenterostomy is employed. In the latter procedure, the vagus nerves to the stomach are severed and an opening is made from the stomach to the small intestine. The purpose of this operation is to eliminate the secretion of gastric juice caused by nervous impulses.

For ulcers in other parts of the gastrointestinal tract, see ULCER.

GASTRITIS. The term gastritis signifies inflammation of the stomach, acute or chronic. Acute gastritis is caused usually by dietary indiscretions, excessive intake of alcohol, irritating drugs. food poisoning and infectious diseases. The smooth, glistening, orange-red appearing inner lining (mucosa) of the normal stomach becomes reddened, swollen and dulled; hemorrhages, adherent mucus and occasionally small superficial ulcerations also may develop. The chief symptoms are severe upper abdominal pain, nausea, vomiting. loss of appetite, thirst and diarrhea; the illness develops suddenly and subsides rapidly. The only treatment necessary is temporary avoidance of food. followed by a nonirritating diet, sedatives and antispasmodics; rarely, fluids by intravenous injection may be required. The intentional or accidental ingestion of corrosives (acids, alkalies) causes a severe chemical gastritis, necessitating immediate emptying and thorough washing of the stomach. general supportive care and. if the poison has systemic effects. administration of the specific antidote.

Chronic gastritis is classified into four varieties; mixtures of several types are not unusual. Superficial gastritis is characterized by redness. snelling and hemorrhage of the mucosa, nith adherent mucus and erosions. In atrophic gastritis the mucosa is thinned. grayish-green in colour and easily injured; the underlying blood vessels are abnormally visible. In hypertrophic gastritis the stomach wall is thickened, the folds are enlarged and irregular and the mucosa presents a swollen, spongelike appearance. The gastritis following operations upon the stomach combines features of these three types. The incidence of chronic gastritis in the general population is not known; in patients examined because of digestive symptoms the recorded frequency has varied from 15% to 60%. The cause of chronic gastritis and the conditions contributing to its development are not established; the eating of excessively hot or cold food. condiments, alcohol, tobacco, irritating medicines. stomach acids, allergy. infection. nutritional deficiencies and emotional disturbances all have been implicated. Since the stomach from early life is exposed continuously to various mechanical. chemical. thermal, bacterial. psychogenic and physiologic influences, chronic gastritis probably results from a combination of factors.

The symptoms in patients with chronic gastritis are indefinite and often resemble the manifestations of functional digestive disorders. They include discomfort, fullness or pain in the upper abdomen, poor appetite, flatulence, belching and variable bowel habits. In erosive gastritis the symptoms may be those of peptic ulcer; bleeding may occur. There are no characteristic laboratory or X-ray findings; these examinations are valuable chiefly to exclude serious organic disease.

There is no specific treatment for chronic gastritis; nor. indeed. is therapy usually necessary. Reassurance as to the absence of serious illness, a bland diet eliminating irritating foods and avoiding large quantities of alcohol, tea and coffee; and sedatives and antispasmodics to relieve nervous tension and quiet the congested, hyperactive stomach are helpful. Vitamins and other nutritional supplements are indicated when the food intake has been poor. Antacids and antisecretory drugs neutralizing and decreasing acid production in the stomach are useful in gastritis with erosions and with bleeding. Surgery is necessary when hypertrophic gastritis cannot be differentiated from tumour, for obstruction at the outlet of the stomach and for uncontrollable hemorrhage; however. such cases are rare. Chronic gastritis tends to be persistent or recurrent, with unpredictable variations in type, severity and distribution. However, it usually does not lead to serious disease. Minor surface alterations, such as congestion, hemorrhage and erosions, usually heal rapidly and completely.

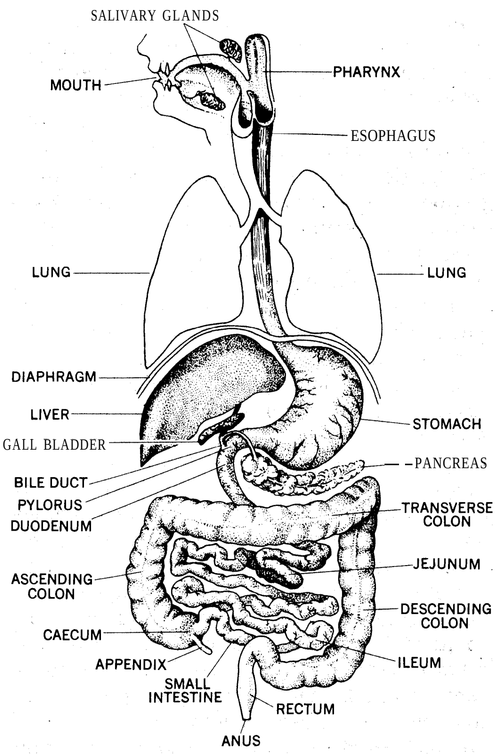
GASTROINTESTINAL TRACT, strictly speaking, is the term applied to that portion of the food canal that includes the stomach and the small and large intestines as an anatomical and a functional unit. The more inclusive term "alimentary canal" (formerly, digestive tube) includes also the esophagus, whereas "digestive tract" denotes the complete food canal, from the mouth through the anal canal. In the adult human being the digestive tract is 25 to 30 ft. long, and the food passes through the following parts one after the other: mouth, pharynx, esophagus, stomach, small intestine, caecum, colon, rectum and anal canal (the caecum, colon, rectum and anal canal constitute the large intestine). Into the digestive tract at various points the salivary glands, liver and pancreas (*qq.v.*) pour their secretions by special ducts.



ADAPTED FROM A. J. CARLSON AND V. E. JOHNSON, "THE MACHINERY OF THE BODY"; BY PERMISSION OF THE UNIVERSITY OF CHICAGO PRESS

FIG. 1.— ORGANS AND GLANDS OF THE DIGESTIVE TRACT. PART OF RESPIRATORY APPARATUS IS DRAWN TO INDICATE ITS RELATIONSHIP TO DIGESTIVE TRACT

This article deals chiefly with the anatomy, comparative anatomy and embryology of the gastrointestinal tract but includes also a discussion of the esophagus. The mouth (*q.v.*) and the pharynx (*q.v.*) are dealt with elsewhere. For the physiology of the digestive tract, *see* DIGESTION. *(See* also GASTROINTESTINAL *TRACT,* DISEASES OF.) The Anatomy section discusses structure in man exclusively; the other two major sections are more general in scope.

ANATOMY

Esophagus.—The esophagus or gullet, a muscular tube lined with mucous membrane, stretches from the lower limit of the pharynx or throat, at the level of the cricoid cartilage, to the cardiac orifice of the stomach. It is about 10 in. long (25 cm.) and $ in. to 1 in. in diameter. At first it lies in the lower part of the neck, then in the chest and lastly, for about an inch, in the abdomen. As far as the level of the fourth or fifth thoracic vertebra it lies behind the trachea, but when that tube ends it is in close contact with the pericardium and, at the level of the tenth thoracic vertebra, passes through the esophageal opening of the diaphragm (*q.v.*), accompanied by the two vagus nerves, the left being in front of it and the right behind. In the abdomen it lies just behind the left lobe of the liver. In both the upper and lower parts of its course it lies a little to the left of the mid-line. Its mucous membrane is thrown into a number of longitudinal pleats to allow stretching.

Stomach.—The stomach is an irregularly pear-shaped bag, situated in the upper and left part of the abdomen. When moderately distended, the thick end of the pear or fundus bulges up ard and to the left, while the narrow end is constricted to form the pylorus, by means of which the stomach communicates with the small intestine. The cardiac orifice, where the esophagus enters, is placed about a third of the way along the upper border from the left end of the fundus and between it and the pylorus; the upper border is concave and is known as the lesser curvature. From the cardiac to the pyloric orifice, round the lower border, is the greater curvature.

In front of the stomach are the liver *(see* fig. 1), the diaphragm and the anterior abdominal wall, while behind it are the pancreas, left kidney, left adrenal, spleen, colon and mesocolon. When the stomach is empty it contracts into a tubular organ and the transverse colon ascends to occupy the vacant space.

The pylorus is an oval opening, averaging one-half inch in its long axis but capable of considerable distention; it is formed by a special development of the circular muscle layer of the stomach, and during life is tightly closed, except during the periodic escape of gastric contents into the duodenum. The mucous membrane of the stomach is thrown into pleats or rugae when the organ is not fully distended.

Superficial to the mucous coat is a submucous, consisting of loose connective tissue, while superficial to this are three coats of unstriped muscle, the inner oblique, the middle circular and the outer longitudinal.

Small Intestine.—The small intestine is a tube, from 22 to 25 ft. long, beginning at the pylorus and ending at the ileocaecal valve; it is divided into duodenum, jejunum and ileum.

The duodenum is from 9 to 11 in. long and forms a horseshoe or C-shaped curve, encircling the head of the pancreas. It differs from the rest of the gut in being retroperitoneal. Its first part is horizontal and lies behind the fundus of the gall bladder, passing backward and to the right from the pylorus. The second part runs vertically downward in front of the hilum of the right kidney, and into this part the pancreatic and bile ducts open. The third part runs horizontally to the left in front of the aorta and vena cava, while the fourth part ascends to the left side of the second lumbar vertebra, after which it bends sharply downward and forward to form the duodenojejunal flexure.

The jejunum forms the upper two-fifths of the rest of the small intestine; it, like the ileum, is thrown into numerous convolutions and is attached by the mesentery to the posterior abdominal wall.

The ileum is the remaining three-fifths of the small intestine, though there is no absolute point at which the one ends and the other begins. Speaking broadly, the jejunum occupies the upper and left part of the abdomen below the subcostal plane, the ileum the lower and right part. At its termination the ileum opens into the large intestine at the ileocaecal valve.

Caecum.—The caecum is a blind sac occupying the right iliac fossa and extending down two or three inches below the ileocaecal junction. From its posterior and left surface the vermiform appendix protrudes, and usually is directed upward and to the left. This wormlike tube is blind at its end and is usually three or four inches long. Its internal opening into the caecum is about one inch below that of the ileum.

On transverse section it is seen to be composed of: (1) an external muscular coat; (2) a submucous coat; (3) a mass of lymphoid tissue, which appears after birth; and (4) mucous membrane. In many cases its lumen is wholly or partly obliterated, though this is probably due to disease. Guarding the opening of the ileum into the caecum is the ileocaecal valve, which consists of two cusps projecting into the caecum; of these the upper forms a horizontal shelf, while the lower slopes up to it obliquely. At birth the caecum is a cone, the apex of which is the appendix; it is bent upon itself to form a U, and sometimes this arrangement persists throughout life.

Colon. — The ascending colon runs up from the caecum at the level of the ileocaecal valve to the hepatic flexure beneath and behind the right lobe of the liver; it is about eight inches long and posteriorly is in contact with the abdominal wall and right kidney. It is covered by peritoneum except on its posterior surface (see fig. 1).

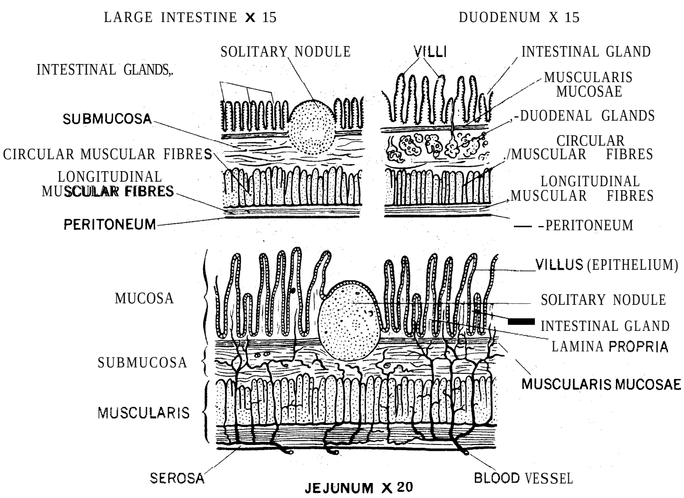


FIG. 2.—STRUCTURE OF INTESTINAL WALL AS SEEN IN LONGITUDINAL SECTIONS

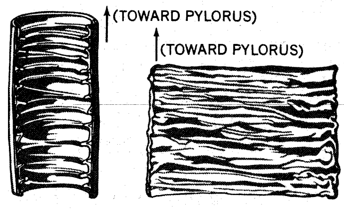
The transverse colon is variable in position, depending largely on the distention of the stomach, but usually corresponding to the subcostal plane. On the left side of the abdomen its ascends to the splenic flexure, which may make an impression on the spleen (*q.v.*), and is bound to the diaphragm opposite the 11th rib by a fold of peritoneum.

The descending colon passes down in front of the left kidney and left side of the posterior abdominal wall to the crest of the ilium; it is about six inches long and is usually empty and contracted while the rest of the colon is distended with gas; its peritoneal relations are the same as those of the ascending colon, but it is more likely to be completely surrounded.

The iliac colon stretches from the crest of the ilium to the inner border of the psoas muscle, lying in the left iliac fossa, just above and parallel to Poupart's ligament. Like the descending, it is usually uncovered by peritoneum on its posterior surface. It is about six inches in length.

The pelvic colon lies in the true pelvis and forms a loop, the two limbs of which are superior and inferior while the convexity reaches across to the right side of the pelvis. In the fetus this loop occupies the right iliac fossa, but, as the caecum descends and enlarges and the pelvis widens, it is usually driven out of this region. The distal end of the loop turns sharply downward to reach the third piece of the sacrum, where it becomes the rectum. Formerly the iliac and pelvic colons were spoken of as the sigmoid flexure.

Rectum. — The rectum, according to modern ideas, begins in front of the third piece of the sacrum. It ends in a dilatation or rectal ampulla, nhich is in contact with the back of the prostate in the male and of the vagina in the female and is in front of the tip of the coccyx. The rectum is not straight, as its name would imply, but has a concavity forward corresponding to that of the sacrum and coccyx.



FROM D J CUNNINGHAM, TEXTBOOK OF ANATOMY BY COURTESY OF OXFORD MEDICAL PUBLICATIONS

FIG. 3.—JEJUNUM OF THE SMALL INTESTINE SHOWING TRANSVERSE FOLDS. OR PLEATS

(Left) Section preserved or hardened In alcohol; (right) fresh portion spread out under water

At the end of the pelvic colon the mesocolon ceases, and the rectum is then covered only by peritoneum at its sides and in front; lower down the lateral covering is gradually reflected off and then only the front is covered. About the junction of the middle and lower thirds of the tube the anterior peritoneal covering is also reflected off onto the bladder or vagina, forming the rectovesical pouch in the male and the pouch of Douglas in the female. This reflection is usually about three inches above the anal aperture.

Anal Canal. — The anal canal, the termination of the digestive tract, runs downward and backward from the lower surface of the rectal ampulla between the levatores ani muscles. It is about an inch long and its lateral walls are in contact. Its opening is the anus.

(See also ANATOMY, GROSS.) (P. C. M.; X.)

Structure of the Intestine. — The intestine conforms to the general structural plan of hollow organs but shows some regional adaptations in agreement with local requirements. There are four coats: serous, muscular, submucous and mucous (see fig. 2). The tunica serosa is an external investment of peritoneum continuous with the mesentery, where present; it is incomplete on those surfaces of the intestine that are pressed against the body wall. Like serous membranes in general, it has a smooth, shiny surface and consists of a single layer of flat epithelial cells (mesothelium) lying upon a bed of connective tissue.

The tunica muscularis is composed of unstriped (involuntary) muscle fibres arranged in two sharply demarcated layers; the outer fibres' are directed longitudinally, whereas the inner fibres are disposed circularly. In the large intestine the longitudinal fibres, instead of being arranged evenly around the tube as in the small intestine, are especially concentrated in three longitudinal bands called taeniae.

In adapting itself to these shorter bands the remaining wall of the intestine is thrown into a series of sacculations named haustra. The taeniae of the caecum lead to the vermiform appendix, where they give way to an evenly disposed layer of muscle; in the rectum, on the other hand, the taeniae are effaced only partially. The circular layer of muscle is always thicker than the longitudinal; it is thickest in the duodenum and rectum.

The tela submucosa is a fairly thick layer of loosely arranged connective tissue in which many vessels form networks. In the duodenum it is characterized by containing closely packed duodenal glands (of Brunner), whose mucoid secretion is discharged into the intestinal lumen. In the duodenum and jejunum the submucosa elevates into a series of permanent, transverse pleats known as plicae circulares (see fig. 3) ; over these the mucous membrane drapes.

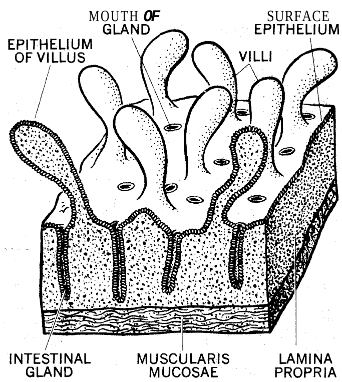


FIG. 4.—SAMPLE BLOCK OF MUCOUS MEMBRANE OF THE ILEUM (MAGNIFIED 35 TIMES)

The innermost coat is the tunica mucosa (see fig. 2, 4). The most important component of this membrane is its epithelium, nearest the lumen. This is a single layer of columnar cells, some of which have become specialized as unicellular slime glands (goblet cells). The epithelium rests upon a rather homogeneous basement membrane, beneath which is the lamina propria consisting largely of reticular tissue and lymphocytes. Most externally is a thin layer of unstriped muscle called the muscularis mucosae. The surface of the mucous membrane throughout the entire small intestine has a velvety appearance, due to the presence of closely set, minute, fingerlike elevations named villi. The myriad microscopic villi and the grossly folded plicae increase the secretory and absorptive area enormously.

The entire intestine, large and small, is specifically characterized by simple tubular intestinal glands (of Lieberkiihn) that are set close together vertically and extend through the thickness of the lamina propria. There are about 180,000,000 of these glands in both the small and large intestine; their length ranges from 0.1 mm. in the small intestine to 0.7 mm. in the large intestine. Each gland extends below the general surface as a tiny pit, narrow but relatively long. Its slender cavity is enveloped by a tube of epithelium, continuous with that covering the general internal surface of the organ. The glandular epithelium contains ordinary columnar and goblet cells, the latter preponderating in the large intestine; it also contains special Paneth cells and argentaffin cells, both of which are presumably secretory although their exact functions are still obscure.

Scattered throughout the entire intestinal mucosa, and sometimes intruding into the submucosa, are minute masses of lymphoid tissue termed solitary nodules; these are about the size of a pinhead and their number totals tens of thousands. Such nodules are especially abundant in the vermiform appendix. In the small intestine, but mainly in the ileum, they collect in oval groups called aggregate nodules (or Peyer's patches) which may attain a length of an inch or more.

Apposed folds of the mucosa and submucosa produce the ileocaecal valve between the small and large intestine. The rectum bears three shelflike transverse folds that project into the lumen. The anal canal contains a series of permanent longitudinal folds called rectal columns; the circular layer of muscle thickens to produce the internal sphincter of the anus. Outside the canal is an external sphincter of voluntary muscle.

Blood vessels reach the intestine by way of its mesentery and form an extensive plexus in the submucosa; arterial branches supply the muscular coat and mucous membrane, while venous branches return from the same regions. Lymphatic vessels provide a one-way drainage system for tissue fluids. The intrinsic nerve supply emanates from ganglion cells, located between the muscular layers and in the submucosa; extrinsic fibres come from the vagus nerves (and end on the intrinsic ganglion cells), and from the celiac sympathetic plexus (see NERVE; NERVOUS SYSTEM). (L. B. AY.)

Peritoneum. — For a discussion of the peritoneum, the membrane that surrounds the organs of the abdomen, see COELOM AND SEROUS MEMBRANES.

COMPARATIVE ANATOMY

The primitive condition of the vertebrate digestive tract may be described as a straight, simple tube, consisting of an anterior portion, formed by an ectodermal invagination, a long median portion lined by endoderm, and a short posterior portion formed by ectodermal invagination. In the lower vertebrates the primitive tube subserved also the purpose of respiration, and traces of the double function remain in the adult structure of all vertebrates. In fish, the pharynx, or branchial region, suddenly becomes narrower, posterior to the gill slits, to form the esophagus; in adults of higher animals the esophagus is separated from the primitive pharyngeal region and lies dorsal to it. In the primitive vertebrates, the entire digestive tract probably was lined with ciliated cells. Traces of this ciliation persist in many living forms.

Esophagus. — The esophagus is essentially merely a passage, as straight as may be, from the pharynx to the stomach, varying in length with the length of the neck and thoracic regions in different animals, and in calibre with the nature of the food. It is almost invariably lined with a many-layered epithelium, forming a tough coating, readily repaired and not easily damaged by hard food masses. There are only a few exceptions to this structural and functional simplicity. In fishes (see FISHES) the swim bladder is developed as a dorsal outgrowth of the esophagus and may remain in open connection with it. In many birds part of the esophagus may be temporarily dilated, forming a "crop," as for instance in birds of prey and hummingbirds. In the flamingo. many ducks, storks and the cormorant the crop is a permanent although not a highly specialized enlargement. Finally, in the vast majority of seed-eating birds, in gallinaceous birds, pigeons, sand grouse, parrots and many songbirds, particularly the finches, the crop is a permanent globular dilatation, in which the food is retained for a considerable time, mixed with a slight mucous secretion, and softened and partly macerated by the heat of the body. Many birds feed their young from the soft contents of the crop, and in pigeons, at the breeding season, the cells lining the crop proliferate rapidly and are discharged as a soft cheesy mass into the cavity, forming the substance known as pigeon's milk.

Stomach. — Where the esophagus passes into the stomach, the lining wall of the gastrointestinal tract changes to a mucous epithelium, consisting of a single layer of endodermal cells, frequently thrown into pits or projecting as processes; from being chiefly protective, it has become secretory and absorbing, and maintains this character nearly to the anus. The fundamental form of the stomach is a saclike enlargement of the canal, the whole forming an enlarged bent tube. At the distal end of the tube the intestinal tract proper begins, and the two regions are separated by a muscular constriction. In fishes the stomach may be a simple bent tube, or an expanded. globular or elongated sac. In amphibians and reptiles it is in most cases a simple sac, marked off from, the esophagus only by increased calibre. In the Crocodilia, however, the anterior portion of the stomach is much enlarged and very highly muscular, the muscles radiating from a central tendinous area on each of the flattened sides. The cavity is lined bv a hardened secretion and contains pebbles and gravel for mechanical trituration of the food, so that the resemblance to the gizzard of birds is well marked. This muscular chamber leads by a small aperture into a distal, smaller and more glandular chamber.

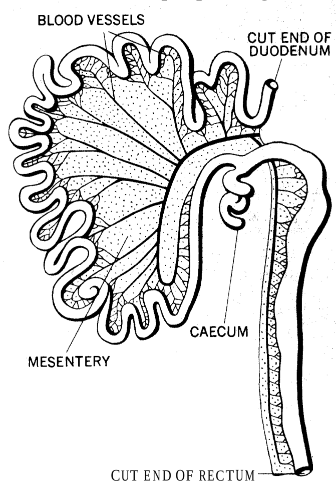

FIG. 5.—INTESTINAL TRACT OF THE FOX. SHOWING RELATIVELY SIMPLE SMALL INTESTINE. ADAPTED TO A CARNIVOROUS DIET

In birds the stomach exhibits two regions: an anterior glandular region, the proventriculus, the walls of which are relatively soft and contain enlarged digestive glands, and a distal region (gizzard). The distal region is larger and is lined in most cases by a more or less permanent membrane which is thick and tough in birds with a muscular gizzard, very slight in others.

In mammals the primitive form of the stomach consists of a more or less globular or elongated expansion of the esophageal region, forming the cardiac portion, and a forwardly curved, narrower pyloric portion, from which the duodenum arises. The whole wall is muscular, and the lining membrane is richly glandular. In many mammals one, two or three protrusions of the cardiac region occur, while in the manatee and in some rodents the cardiac region is constricted off from the pyloric portion. In the Artiodactyla the stomach is always complex, the complexity reaching a maximum in ruminating forms. In the chevrotains, which in many other respects show conditions intermediate between nonruminant artiodactyls and true ruminants. the esophagus opens into a wide cardiac portion, incompletely divided into four chambers. Three of these, toward the cardiac extremity, are lined with villi and correspond to the rumen or paunch; the fourth, which lies between the opening of the esophagus and the pyloric portion of the stomach, is the ruminant reticulum and its wall is lined with very shallow "cells." The fourth or true pyloric chamber is an elongated sac with smooth glandular walls and is the abomasum,

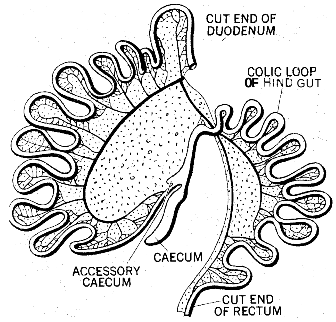

FIG 6.— INTESTINAL TRACT OF THE WALLABY, ADAPTED TO AN OMNIVOROUS DIET OF PLANT MATTER AND INSECTS

or rennet sac. In the camel the rumen forms an enormous globular paunch with villous walls and internally showing a trace of division into two regions. It is well marked off from the reticulum, the "cells" of which are extremely deep, forming the well-known water chambers.

In the true ruminants the rumen forms a capacious villous reservoir, nearly always partly sacculated, into which the food is passed rapidly as the animal grazes. The food is subjected to a rotary movement in the paunch, and is thus repeatedly subjected to moistening with the fluids secreted by the reticulum, as it is passed over the aperture of that cavity, and is formed into a rounded bolus The food bolus, when the animal is lying down after grazing, is passed into the esophagus and reaches the mouth by antiperistaltic contractions of the esophagus After prolonged mastication and mixing with saliva, it is again swallowed, but is now passed into the psalterium which. in true ruminants is a small chamber with conspicuous longitudinal folds. Finally it reaches the large abomasum where the last stages of gastric digestion occur.

In the whales the stomach is different from that found in any other group of mammals. The esophagus opens directly into a very large cardiac sac. the distal extremity of which forms a long caecal pouch. At nearly the first third of its length this communicates by a narrow aperture with the elongated, relatively narrow pyloric portion. The latter is convoluted and restricted into a series of chambers that differ in different groups of whales. In most of the pouched mammals (Marsupialia) the stomach is relatively simple; in the kangaroos, on the other hand the stomach is divided into a relatively small, caecal cardiac portion and an enormously long sacculated and convoluted pyloric region, the general arrangement of which closely recalls the large caecum of many mammals

Intestinal Tract. — It is not yet possible to discuss the general morphology of this region in vertebrates as a group. While the modifications displayed in birds and mammals have been compared and studied in detail, those in the lower groups have not yet been systematically coordinated.

Fishes.—In the cyclostomes (lamprey, hagfish), chimaeras and a few bony fishes the course of the gut is practically straight from the pyloric end of the stomach to the exterior, and there is no marked differentiation into regions. In the lungfishes a contracted sigmoid curve between the stomach and the dilated intestine is a simple beginning of the complexity found in other groups. In very many of the more specialized bony fishes the gut is much convoluted, exhibiting a series of watch-springlike coils.

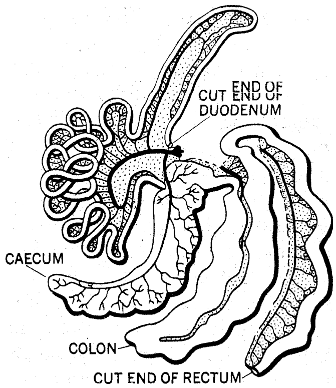

FIG 7 — INTESTINAL TRACT OF THE TAPIR, WITH WELL-DEVELOPED CAECUM, ADAPTED TO A DIET OF SOFT WATER PLANTS

In a number of different groups, increased surface for absorption is given, not by increase in length of the whole gut but by the development of an internal fold known as the spiral valve. A set of organs peculiar to fish, known as the pyloric caeca, is present in numbers ranging from 1 to nearly 200 in the vast majority of fish. These are outgrowths of the intestinal tract near the pyloric extremity of the stomach, and their function is partly glandular, partly absorbing.

In the amphibians the course of the intestinal tract is nearly straight from the pyloric end of the stomach to the cloaca; in the case of the salamanders that retain the gills through life (mud puppy, olm) there are no more than a few simple loops between the expanded "rectum" and the straight portion that leaves the stomach.

In fishes, amphibians and reptiles the intestinal tract is swung from the dorsal wall of the abdominal cavity by a mesentery which is incomplete because of secondary absorption in places. There are also traces, more abundant in the lower forms, of the still more primitive ventral mesentery.

Birds and *Mammals.*—The primitive gut must be supposed to have run backward from the stomach to the cloaca suspended from the dorsal wall of the body cavity by a dorsal mesentery. This tract, in the course of phylogeny of the common ancestors of birds and mammals, became longer than the straight length between its extreme points and, consequently, was thrown into a series of folds.

The mesentery grew out with these folds, but the presence of adjacent organs, the disturbance due to the outgrowth of the liver and the secondary relations brought about between different portions of the gut, as the outgrowing loops invaded each other's localities, disturbed the primitive simplicity.

Three definite regions of outgrowth, however, are to be recognized in the actual disposition of the gut in existing birds and mammals. The first of these is the duodenum. The second portion is Meckel's tract. It consists of the part generally known as the small intestines, the jejunum and ileum of human anatomy, and stretches from the distal end of the duodenum to the caecum or caeca. It is the chief absorbing portion of the gut. and in nearly all birds and mammals is the longest portion. It represents, however, only a very small part of the primitive straight gut, corresponding to not more than two or three somites of the embryo. The third portion of the gut should be termed the hind-gut, and lies between the caecum or caeca and the anus, corresponding to the large intestines, colon and rectum of human anatomy. It is formed from a much larger portion of the primitive straight gut than the duodenum and Meckel's tract together, and its proxirnal portion, in consequence, lies very close to the origin of the duodenum.

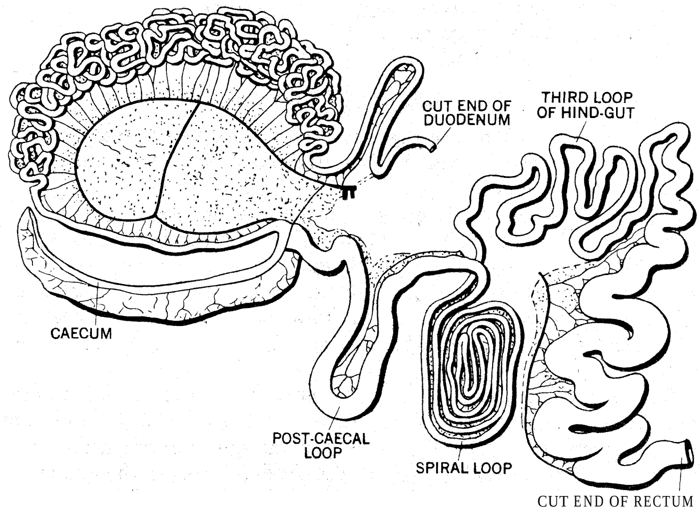

FIG. 8. — INTESTINAL TRACT OF THE GIRAFFE, COMPLEXLY DEVELOPED AND ADAPTED TO A DIET OF LEAVES OF SHRUBS AND TREES

Adaptations of *the* Intestinal Tract to Function. — The chief business of the gut is to provide a vascular surface to which the prepared food is applied so that the nutritive material may be absorbed into the system. Overlying and sometimes obscuring the morphological patterns of the gut are many modifications correlated with the nature of the food. Thus in birds and mammals alike there is a direct association of herbivorous habit with great relative length of gut.

In fish-eating birds and mammals the gut is very long, with a thick wall and a relatively small calibre, while there is a general tendency for the regions of the gut to be slightly or not at all defined. In fruit-eating birds the gat is strikingly short, wide and simple, while a similar change has not taken place in fruit-eating mammals. Carnivorous birds and mammals have a relatively short gut.

The **Colic** Caeca. — These paired or single organs lie at the junction of the hind-gut with Meckel's tract and are homologous in birds and mammals although their apparent position differs in the majority of cases in the two groups. The caeca are hollow outgrowths of the wall of the gut, the blind ends being directed forward. They vary in size within very wide limits and there is no invariable connection between the nature of the food and the degree of their development. The caecal wall is in most cases highly glandular and contains masses of lymphoid tissue. In birds and in mammals this tissue may be so greatly increased as to transform the caecum into a solid or nearly solid sac.

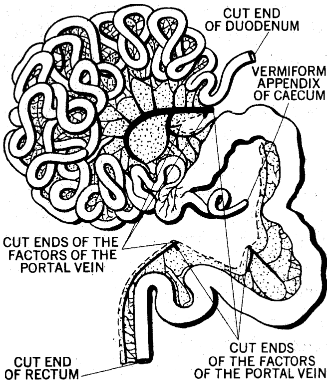

FIG. 9.—INTESTINAL TRACT OF THE GORILLA. ADAPTED TO A DIET OF FRUIT AND LEAVES

EMBRYOLOGY

The greater part of the digestive tract is formed by the closing in of the entoderm to make a longitudinal tube, ventral and parallel to the notochord.

This tube is blind in front and behind (cephalad and caudad), but the middle part of its ventral wall is for some distance continuous with the wall of the yolk sac, and this part of tlie tract, which at first opens into the yolk sac by a very wide aperture, is called the mid-gut. The part in front of it, which lies dorsal to the heart, is the fore-gut, while the part behind the aperture of the yolk sac is the hind-gut.

The pharynx, esophagus, stomach and part of the duodenum are developed from the fore-gut, a good deal of the colon and the rectum from the hind-gut, while the mid-gut is responsible for the rest. The cephalic part of the fore-gut forms the pharynx (see THROAT), and about the fourth week the stomach appears as a fusiform dilatation in the straight tube.

Between the two the esophagus gradually forms as the embryo elongates. The opening into the yolk sac, which at first is very wide, gradually narrows, as the ventral abdominal walls close in, until in the adult the only indication of the connection between the gut and the yolk sac is the rare presence (about 2%) of Meckel's diverticulum.

The stomach soon shows signs of the greater and lesser curvatures. the latter being ventral, but maintains its straight position. About the sixth week the caecum appears as a lateral diverticulum, and until the third month is of uniform calibre; after this period the terminal part ceases to grow at the same rate as the proximal, and so the vermiform appendix is formed. The mid-gut forms a loop with its convexity toward the diminishing vitelline duct, or remains of the yolk sac, and until the third month it protrudes into the umbilical cord. The greater curvature of the stomach grows more rapidly than the lesser, and the whole stomach turns over and becomes bent at right angles, so that what was its left surface becomes ventral. This turning over of the stomach throws the succeeding part of the intestine into a duodenal loop, which at first has a dorsal and ventral mesentery. The intestine now grows very rapidly and is thrown into a series of coils; the caecum ascends and passes to the right ventral to the duodenum, and presses it against the dorsal wall of the abdomen; then it descends toward its permanent position in the right iliac fossa.

From the ventral surface on the hinder (caudal) closed end of the intestinal tube the allantois grows to form the placenta and bladder (see URINARY SYSTEM; REPRODUCTIVE SYSTEM; PLACENTA), and this region is the cloaca into which the gastrointestinal, urinary and generative canals or ducts all open. Later, two lateral folds appear which, by their union, divide the cloaca into a ventral and a dorsal part, the former being genitourinary and the latter alimentary or intestinal. In this way the rectum or dorsal compartment is shut off from the genitourinary. Later an ectodermal invagination at the hind end of the embryo develops and forms the anal canal; this is the proctodaeum, and for some time it is separated from the hind (caudal) end of the rectal part of the mesodaeum (or part of the intestinal canal formed from the mesoderm) by a membrane called the anal membrane. This is eventually absorbed, and the digestive tract now communicates with the surface by the anus. See also references under "Gastrointestinal Tract" in the Index volume. (P. C. M.; X.)

GASTROINTESTINAL TRACT, DISEASES OF. Diseases of the gastrointestinal tract are numerous. Only the more important disorders affecting the stomach and intestines are considered in the discussion that follows.

STOMACH

Peptic Ulcer. — A peptic ulcer is a localized loss of tissue in the membrane that lines the stomach or the immediately adjacent portion of the duodenum. This disorder, which occurs much more often in the duodenum than in the stomach, affects from 5% to 10% of all people at some time in their lives. Though there are certain important differences between ulcers in the stomach and those in the duodenum, the two types are considered together here.

The precise cause of peptic ulcer is unknown. It is generally agreed, however, that the hydrochloric acid normally present in the gastric juice plays an important role. The prevailing concept is that the corrosive action of the gastric acid renders the affected area of the stomach or duodenum susceptible to digestion by pepsin, a digestive enzyme also found in gastric juice. The fact that ulcer patients, especially those with duodenal ulcer, invariably have free (excess) hydrochloric acid in their gastric juice lends support to the importance attributed to the acid-peptic mechanism. Emotional stress also appears to contribute to the formation of peptic ulcer and to the precipitation of ulcer attack.

Recurrent attacks of upper abdominal pain or distress occur periodically in ulcer patients. The pain generally occurs one to two hours after eating or during sleep. Characteristically, relief is temporarily obtained by food, milk or certain neutralizing drugs known as antacids. Each attack lasts several days or weeks and reappears after several weeks or months. Recurrences are especially frequent in the spring and fall. The ulcer may erode a blood vessel and give rise to hemorrhage; it also may extend through the wall of the stomach or duodenum and cause perforation; or it may form sufficient amounts of scar tissue to obstruct the outlet of the stomach.

The keystone of medical treatment is a program that rests the stomach. This includes physical and mental rest; mild sedation; a bland diet with frequent milk feedings between meals; drugs, such as atropine and belladonna, that reduce acid secretion; and acid neutralizers, such as calcium carbonate and aluminum hydroxide. Surgery is necessary in from 10% to 15% of patients with duodenal ulcer; surgery becomes necessary when patients fail to respond to intensive medical treatment or when they develop some complication of the disease. A gastric ulcer that does not heal in four to perhaps six weeks should be treated surgically, principally because of the possibility that it may represent an ulcerating cancer rather than a simple benign ulcer. This fear does not apply to duodenal ulcers, which practically never are cancerous. (See also GASTRIC AND DUODENAL ULCER; ULCER.)

Gastritis. — Gastritis is an inflammation, either acute or chronic, of the stomach, principally of its lining membrane. The acute variety is usually a temporary affair and is manifested principally by vomiting and upper abdominal distress. The inflammation usually clears up after removal of the exciting cause. which may be dietary indiscretion. excessive consumption of alcohol, the use of certain drugs or infection. The cause of chronic gastritis is unknown. Patients with this form of gastritis may experience little or no distress. or they may complain of vague dyspepsia or present symptoms simulating peptic ulcer. Erosive or ulcerative gastritis, whether acute or chronic. may on occasion cause hemorrhage. Inspection of the lining membrane of the stomach through a gastroscope may disclose one or several changes, each with its own characteristics. One of these, designated as chronic atrophic gastritis or gastric mucosal atrophy, is thought to predispose to the development of stomach cancer. The treatment of chronic gastritis consists chiefly of a bland diet and antacids. Liver extract and vitamins have also been reported to be beneficial. (See also GASTRITIS.)

Cancer. — Carcinoma of the stomach is one of the most frequent malignant diseases of the digestive tract, particularly in men over the age of 40 years. It occurs in all races and in all parts of the world. The disease usually appears in one of three anatomical forms: (1) an ulcer; (2) a projecting tumour; or (3) a diffusely infiltrating and spreading growth. Although the cause of gastric carcinoma is unknown, it is generally agreed, on the basis of present evidence, that a peptic ulcer of the stomach rarely, if ever, turns cancerous. The problem rather is to distinguish an ulcerating cancer from a benign ulcer of the stomach.

The symptoms of cancer of the stomach are often insidious in their development. Indeed, the disease is usually fairly well developed before the first symptoms appear. The patient may initially experience a diminution of appetite, some weight loss or mild upper abdominal discomfort or pain. The pain may resemble that of peptic ulcer and may be relieved by eating. Indigestion is especially suspect when it appears for the first time in a middle-aged or older person whose gastric secretion fails to show free acid after appropriate stimulation. The free acid secretion of the stomach is absent or diminished in most of the patients with gastric cancer. X-rays usually give evidence of the disease (80%–90% of the cases) when symptoms are present Additional methods of examination, notably gastroscopy and the search for cancer cells in gastric washings, increase diagnostic accuracy.

Cure depends upon early diagnosis and early removal of the cancer along with part or all of the stomach. See also CANCER; ABDOMEN, SURGERY OF: *Gastrointestinal* Surgery.

THE INTESTINES

Regional Enteritis (Ileitis).—This is a chronic inflammatory disease of one or more segments of the small bowel. In its classical form it is confined to the terminal portion of the ileum; *i.e.*, where the ileum joins the colon. In some cases, however, a major part of the small intestine may be affected, either continuously or irregularly with skip areas. In a type of enteritis known as enterocolitis, varying lengths of the adjoining colon also may be involved. In rare cases, the duodenum or even the stomach may be affected by the disease. Consequences of the disease are that the bowel is thickened. its channel is narrowed and its lining is ulcerated. The cause of regional enteritis is unknown. It affects both sexes of all ages but particularly those between 15 and 30 years. Patients may recover completely from an initial acute attack. but the usual course is one of progression with continuously smoldering disease for many years. Periods of relative freedom from symptoms are interrupted by acute exacerbations; or the patient is never entirely well and complications ensue.

The symptoms are extremely variable. The initial attack may simulate acute appendicitis. The usual picture is that of a continuous or intermittent diarrhea, sometimes bloody, accompanied by painful abdominal cramps. Fever is very common and sometimes overshadows the digestive symptoms. Chronic debility, weight loss and anemia produce progressive physical deterioration. Grave complications may occur, such as obstruction or perforation of the intestine, the formation of an abscess within the abdomen, or an abnormal communication (fistula) between the diseased gut and adjacent coils of small bowel, the colon. urinary bladder or vagina. Infections about the anus, particularly a perianal fistula, occur fairly commonly.

Diagnosis is confirmed by X-ray examination of the small bowel and colon. Uncomplicated cases are preferably managed by conservative, nonsurgical measures. These consist basically of physical rest and a bland, nutritious diet with minimal roughage, supplemented with vitamins and iron. Corticotrophin (ACTH), a hormone derived from the pituitary gland, and adrenal cortical hormones, such as cortisone. often produce gratifying improvement. These agents, however, do not cure the disease. Antibiotics are often helpful in the treatment of secondary infection but are not curative. Surgery is reserved for patients who do not benefit from medical treatment or who exhibit the more serious complications. The principle of surgery is to remove the diseased segment or to isolate it from the intestinal stream by connecting normal bowel above the level of the disease to the colon at a point well beyond the diseased segment.

Appendicitis (inflammation of the appendix) generally occurs as an acute attack; such attacks may culminate in perforation of the appendix with peritonitis or localized abscess formation. The typical picture is one of pain, tenderness and muscular spasm in the right lower quadrant of the ahdominal wall. This is often preceded by pain that is vaguely localized in the middle or upper abdomen. The patient's temperature is usually elevated and the white blood cell count is increased. If appendicitis is suspected, nothing should be taken by mouth; laxatives are especially hazardous. Treatment is surgical removal of the appendix as early in the disease as possible.

Chronic appendicitis, a term often used to describe low-grade, recurring pain in the right lo er quadrant of the abdomen, is infrequent. Usually the pain is found to result from a disorder other than chronic inflammation of the appendix. (See also APPENDICITIS.)

Functional Disorder of the Colon.––Functional disorder of the colon, also known as the "irritable colon syndrome," is probably the most common cause of abdominal discomfort, pain and irregular bowel action. The disorder is due predominantly to disturbed motility of the colon, but it may be associated with similar disturbance of function in other parts of the digestive tract. It results from a "nervous" or irritable state of the bowel and not from organic or structural disease. X-ray and other examinations do not disclose organic abnormalities. The terms "mucous colitis" and "spastic colitis" are popularly used to designate this condition. They are undesirable terms, however, because there is no true "colitis" (inflammation of the colon) in this disorder. The disturbed activity of the colon is usually related to nervous tension, worry and anxiety. The eating of irritant and laxative foods, the overuse of harsh laxatives. allergic response to certain foods and excessive smoking also may contribute to the irritability of the bowel.

The patient experiences abdominal discomfort, pain and irregularity of bowel evacuation. Constipation is more common than diarrhea, but both may occur alternately in the same individual. Excessive mucus in the stool is sometimes present. Abdominal distension or bloating, rumbling sounds and excessive passage of flatus are common symptoms. Usually the digestive complaints are accompanied by general symptoms of nervousness. weakness and fatigue.

Treatment begins with a thorough examination to exclude organic disease. Reassurance about the nature of the disorder and zttempts to alleviate emotional tension are important in treatment. A bland diet free of physically and chemically irritant foods and the use of mild sedatives and antispasmodic drugs are helpful. The patient is urged to discontinue the use of laxatives and enemas and is encouraged to adjust his daily routine so as to provide more rest and relaxation. Development of a regular bowel habit is desirable. Constipation is treated by providing a greater intake of cooked fruits and vegetables and such natural laxatives as prune juice. In addition, the ingestion of a simple hydrophiiic colloid may be useiul in providing a soft stool.

Constipation. — Constipation is actually a symptom and not a disease. Because of its frequency and the importance attached to it, however, it merits special consideration. Constipation may be defined as the infrequent evacuation of excessively hard, dry stools. Frequency is a less important criterion than the physical character of the stool since healthy persons vary greatly in the frequency of defecation. The mistaken notion that a daily evacuation is essential for good health has, unfortunately, led to colossal overuse of laxatives and cathartics. (See CATHARTIC.)

Constipation may be subdivided into functional and organic types. Functional constipation, in which there is no structural abnormality, is a major symptom of the irritable colon syndrome discussed above under Functional Disorder of the Colon. Organic causes are numerous and include such diverse conditions as carcinoma of the colon and rectum, diverticulitis, inflammatory diseases that produce constricting scars in the intestine, a pelvic mass pressing on the colon and painful diseases of the anus such as fissure or hemorrhoids. Treatment of organic constipation depends on its cause.

Diarrhea. — Diarrhea, like constipation, is a symptom and not a disease. Diarrhea may be defined as the frequent passage of loose or watery stools. It, too, may be either functional or organic in origin. Diarrhea frequently is a manifestation of the irritable colon and is commonly associated with emotional states, such as fear and anxiety. Laxative foods, cathartics, excessive alcohol and certain foods to which the individual is sensitive may produce or aggravate diarrhea. Organic causes of diarrhea are numerous. They include infection (*e.g.*, bacillary and amoebic dysentery, Staphylococcus food poisoning, cholera, paratyphoid fever, etc.); poisoning, as by mercury, arsenic or other chemical agents; regional enteritis and chronic ulcerative colitis; cancer of the intestinal tract; sprue (*q.v.*) and celiac disease, in which intestinal absorption of foodstuffs is impaired; and overgrowth of fungi or actual organic changes that develop as a complication of antibiotic therapy.

Diarrhea is treated basically by physical rest, clear fluids or soft bland foods and medication; this treatment is designed to relieve pain, reduce intestinal hyperactivity and soothe the inflamed or irritated bowel. More specific measures depend on the cause for the diarrhea. (See also DYSENTERY; BACTERIAL AND INFECTIOUS DISEASES.)

Chronic Ulcerative Colitis. — This is a chronic disease of unknown etiology in which the lining membrane of the colon and rectum is diffusely inflamed and studded with bleeding pinpoint ulcers. The disease affects the left (lower) half of the colon and rectum more often than the right (upper) side of the colon. However, the entire colon is affected in more than 50% of cases. In approximately 5% of all cases, the disorder is confined to segments of the colon above the rectum. Ulcerative colitis most commonly affects persons between 20 and 40 years of age. A few patients recover completely, but most suffer recurrent episodes or are chronically and continuously ill for many years. The disease may at any time become acute and fulminating.

No specific cause is known. It may well be that there are multiple causes, each playing some part. The resemblance of the disease to infection is striking, but no microorganism has been clearly implicated. Emotional disturbance is almost invariably present and probably plays an important role. There is some evidence suggesting that the malady may be an autoimmune disease. According to this concept, antibodies injurious to the colon develop as the result of an alteration in the colonic tissue brought about by some noxious agent.

The patient experiences intermittent or continuous diarrhea with blood commonly present in the stools. Fever, anemia, weight loss and malnutrition are common symptoms. Serious complications may occur. These include hemorrhage, perforation of the bowel, development of a perianal fistula or abscess and arthritis or arthralgia.

In addition to the classical multiple small ulcers, the lining of the affected colon often exhibits projecting tags or islands of tissue referred to as pseudopolyps. The incidence of colonic cancer is decidedly greater in patients who have had this disease for a number of years than it is in the general population. Sigmoidoscopic inspection of the lining membrane and an X-ray of the colon ordinarily establish the diagnosis.

Medical treatment is similar to that for regional enteritis. Physical rest and the alleviation or control of emotional factors are essential for good results. Corticotrophin and adrenal cortical hormones are even more helpful in this disease than in regional enteritis. Antibiotics and sulfonamides are used for secondary infection with some benefit.

Surgery is reserved for patients who remain debilitated or incapacitated despite prolonged and intensive medical treatment, or who suffer from certain of the complications. The operation usually employed consists of removing the colon and rectum and bringing the termination of the small intestine to the outside through the abdominal wall. This opening, termed an ileostomy, serves as a substitute for the anus. The fecal discharge from the ileostomy is collected in a rubber or plastic bag. In those few cases in which the rectum is spared, the diseased portion of the colon may be surgically removed and the continuity of the normal bowel re-established by joining the remaining portions of uninvolved colon.

Diverticulosis and Diverticulitis. — Diverticula (abnormal outpouchings or saccules) are frequently seen in the colons of older persons, especially those who are constipated. When these diverticula are present, a person is said to have diverticulosis. If the diverticula become inflamed, the condition is described as diverticulitis. Diverticula usually cause no symptoms. However, if they become inflamed or complicated by perforation or abscess formation, abdominal pain, diarrhea, bleeding, fever or intestinal obstruction may occur. Treatment of uncomplicated diverticulosis requires no particular measures other, perhaps, than those directed against constipation. Diverticulitis requires antibiotics and measures designed to keep the bowel at rest; in some cases removal of the inflamed segment of colon is necessary. (See also DIVERTICULITIS AND DIVERTICULOSIS.)

Cancer of the Colon. — This disorder occurs even more frequently than cancer of the stomach. Colonic polyps, the benign tumours (adenomas) of the colon and rectum that are found in about 10% of all persons beyond the age of 40, are considered to be potentially precancerous. This has led to the practice of removing polyps of the colon and rectum whenever they are found.

In the lower part of the colon, cancer tends to be constricting in type, producing symptoms of bowel obstruction. The manifestations of this change include abdominal discomfort and an alteration in bowel habit in the direction of constipation. Alternating attacks of diarrhea and constipation may occur. Blood is commonly seen in the stool. (See also INTESTINAL OBSTRUCTIONS.)

Cancer situated in the upper part of the colon is less apt to be obstructive and produces poorly defined symptoms. The patient often complains of vague dyspepsia and abdominal discomfort. Diarrhea and constipation are less frequent than in cancer of the lower colon. Weakness and fatigue, caused by anemia, are prominent. A tumour mass may be palpable.

Diagnosis is established principally by X-raying the colon (barium enema) and by direct visualization of the rectum and lower colon through a sigmoidoscope. The treatment of choice is surgical removal of the tumour with restoration of bowel continuity by end-to-end anastomosis of the remaining colon. The prognosis following curative resection is the most favourable of all cancers of the digestive tract. See also CANCER.

(J. E. BK.; I. A. W.)

GASTROLITH, a term given to concentrations of solid material formed in the digestive tract or, more commonly, to pebbles swallowed and retained in the gizzard by birds, reptiles and certain fish to help grind food which their teeth or beaks cannot chew.

Groups of pebbles found within or near the skeletons of dinosaurs and plesiosaurs, or in geologic formations in which such bones are numerous, are thought to be gastroliths and suggest that the stomachs of these ancient reptiles were gizzardlike, with thick muscular walls. These pebbles have common characteristics. maximum dimension one inch to four inches. shape ellipsoid, surface smooth and generally highly polished, material resistant (quartz. quartzite, chert, flint, jasper, agate, granite and gneiss), They are found almost entirely in strata of Cretaceous and Jurassic Ages; in the United States chiefly in Colorado. Kansas, Wyoming, Montana and Utah, also in France, Germany and other parts of central Europe.

These ancient gastroliths possess a higher polish than modern ones, perhaps because of the more powerful abrasive action they underwent, in which softer pebbles were crushed and served as polishing materials. along with primitive silica-bearing grasses

Another view is that many or all of these so-called gastroliths are merely deposits of wind-worn stones. However, the variety of rocks. often from distant sources. in a single assemblage and their isolation in fine-grained rocks makes this explanation difficult.

(L. W P.)

GASTRONOMY, MODERN. Is gastronomy an art or a science? This is a question on which epicures and cooks are at issue. La Rochefoucauld wrote that "eating is a necessity, but eating intelligently is an art." Vauvenargues admitted unhesitatingly that "great thoughts come from the stomach." The doctrine of Epicurus bids us find an agreeable employment ior our faculties in the intelligent enjoyment of the pleasures of the table. And finally, to go back still farther, Ecclesiastes himself teaches us that "a man hath no better thing under the sun, than to eat, and to drink, and to be merry. . . ."

Throughout the ages, meals have been made a time of relaxation, comfort and enjoyment. The feasts of the middle ages mere, as we know, assemblies of people desperately hungry after long days of hunting in the forests, trained to violent exercise, capable of wearing heavy armour and of doing justice to a prodigious bill of fare.

In the 17th century, the spirit of order, reason and dignity which characterized the literature of the period found a further outlet in the elaborate organization of banquets: these were conducted according to a regular program, involving a whole series of minute observances. The result was that the guests got nothing but congealed gravy.

The 18th century, witty, pugnacious, enthusiastic and volatile, introduced into cookery its elegance, its instinct for pleasure and refinement. But modern cookery really dates from the end of the First Empire, the time of Brillat-Savarin and Carême. It was they who substituted the "made dish" for masses of roast meat, piled in pyramidal form and held together by skewers. These enormous, barbaric accumulations of food were yet another Bastille nhich the French Revolution overthrew.

Gastronomy Is an Art.—It may fairly be said that modern gastronomy is an art, and that Molière talked like a Philistine when he made one of his characters say that "we eat to live, we do not live to eat." It is an art because it demands the cooperation of all the senses. The crispness of fried dishes and pastry is agreeable to the ear. The softness of well thickened sauces and melting *foies gras,* the succulent freshness of fruit, are pleasant to the touch. Is there anything more delightful to the eye than a dish *au* gmtin, with its captive flavours imprisoned under its golden dome? Do not odours like those of seasonings of herbs, or of truffles, afford the highest possible gratification to the sense of smell? Of the palate there is no need to speak.

It may even be said that gastronomy is a perfect art, for so wide a range of enjoyment could not, in the opinion of the present writer be derived from listening to a symphony. hearing a poem read, or gazing at a beautiful building. Indeed, it would not be unreasonable to maintain, not merely that gastronomy is a perfect art. but that it is the only art which is perfect.

Gastronomy Is a **Science.**—Unquestionably gastronomy is a science, for it has its laws, its formulas, its fixed processes. Art cannot be taught. nhereas the profession of cookery should be preluded by a long apprenticeship. Certain physico-chemical laws have to be observed in the preparation of our food; and cooks often make scientific discoveries without knowing it. Why does red wine go well with roast meat and cheese? Because tannin combines with albuminous substances in a manner propitious to digestion. Why do we put lemon juice on fried dishes, or in a salad? Because acids attack cellulose and saponify oil, and make them easier to digest.

Likenise, there are culinary processes uhich are scientific applications of the laws of nature. Roast meat, for example, must be exposed to great heat for a short time in order that a crust may form all over the surface, and then placed in a moderately heated oven and left there as long as possible in order that the browned skin may imprison all the juices of the meat and that these, by a slow process, as it were of digestion, may make the flesh tender.

Again, cooks know that a sauce the principal ingredient of which is the yolk of an egg must never be alloned to boil, or else its elements will become disunited: as we say, they will curdle. They knon, too, that, if need be, they can be reunited simply by the addition of the yolk of another egg and a little boiling water. If a dish is too salt. add at once a few spoonsful of milk or a little butter.

The Revival **of Cookery.**—For some time past a good deal has been heard about new dishes. **As** a matter of fact, there is hardly a dish which has not been attempted already.

Many people, it is certain, do not know that in the Middle Ages, at the Tour d'Argent, the oldest restaurant in Paris, dormouse pastry, mixed dishes of snakes, porpoise, roast swan and crane stuffed with plums were served to the guests. Nor that Frederick the Great made his coffee with champagne and added mustard to give the remarkable drink a still stronger taste. Nor that, before the war, a cook named Jules Maincave gave to the world fillets of mutton with crayfish sauce, beef cooked in kummel, bananas with Gruyère cheese, sardines with Camembert cheese and herring soup with raspberry jelly.

These last experiments, it must be confessed, are highly unpleasant; for the ingredients in question could not possibly be made to harmonize, any more than cat and dog. Nor is it at all clear how a mixture, for example, of chocolate and red wine could be rendered palatable.

At the same time, it would be a mistake to go to the opposite extreme and content ourselves with the stereotyped dishes turned out by cooks devoid of imagination. When a writer uses hackneyed words—a habit of which journalism affords only too frequent examples—we say that he writes in cliche's and that he writes badly. When a painter always paints the same picture over and over again, we are quick to compare him to a photographer lazily taking a succession of proofs from the same negative. Similarly, in the domain of cookery, the most modest dishes should afford a good housewife an opportunity of using her inventive faculty and her intelligence. There is no reason why the culinary fashions of years gone by should immobilize and enslave us, nor why the gastronomists of to-day should be less adventurous, less eager for knowledge than their predecessors who, throughout the ages, have enriched cookery with a stream of new discoveries. We should not abandon hope of improving on first results. We should pay no attention either to dogmatists who accept the existing order of things, repeat and solemnly hand on to posterity what they have heard from their elders, and irrevocably condemn the unknown as a matter of principle, or to those who take fright at an unfamiliar flavour, like children swallowing their first oyster. If men had always acted thus, if no risks had been taken and no experiments made, whereby alone the adventurous instinct learns self-restraint, the range of our enjoyments would to-day be exceedingly limited. We should be no more tolerant of the conservatism of people who will not eat roast chicken unless surrounded by watercress, or veal unless in the company of carrots or peas, or a leg of mutton with anything else than a dish of haricot beans.

What we should aim at doing is to combine with familiar recipes something which, while setting off their good qualities, yet introduces an element of surprise and provides what was wanting in them. We should not hesitate to transform a sauce possessing its traditional flavour into something more savoury and unexpected.

The harmonies which can be obtained from certain combinations of crisp and fatty substances and of watery and farinaceous vegetables are worth studying.

Here follow a few recipes in the new style of cookery; these will give an idea of the kind of dish which harmonizes with a modern dining room.

Tomato Tart. — This is a simple family dish which is sure to be appreciated by old and young alike. Make an open tart of unsweetened pastry. Fill it with a thick be'chamel (a sauce made of flour and butter) flavoured with cheese, mixed with concentrated tomato essence.

Place on this foundation tomatoes which have been cooked in butter flavoured with onion and stuffed with mushrooms and olives.

The tomatoes should have been put in the oven just before being placed in the tart. Then cover the whole with bread crumbs done with butter to a golden brown, and the tart is ready to be served.

It forms a dish of three storys and each of them succulent.

Cold Pork with **Truffles.**—*Foie* gras flavoured with truffles is excellent; but it seems a pity to mix two decided flavours. Surely it is better to use truffles to give flavour to something which in itself is comparatively tasteless. M. Verdier, former manager of the *Maison Dorée* and one of the greatest chefs of the day, recommended that pieces of raw truffle should be pressed as deeply as possible into a piece of fresh pork. Choose a piece which is close-grained and not too lean. When the pork is inlaid with a sort of mosaic of truffle, roll it, tie it up and roast it. Let it cool in its own fat and serve it cold the next day with whatever salad is in season.

Haricot Beans with Cream Sauce. — Schoolboys and soldiers learn to hate haricot beans, but they are a vegetable which can be either detestable or delicious according to the way in which they are cooked.

If you want to make haricot beans really exquisite, let them soak for 24 hr. and then boil them slowly.

Meanwhile, get ready in a saucepan a spoonful of good be'chamel (see above), half a litre of cream and plenty of grated Gruyère cheese.

Put in plenty of pepper and not much salt. When the sauce has been brought to a creamy consistency, pour it over the haricots after first straining them.

Sprinkle the whole with a little grated cheese and brown lightly in the oven.

Lettuce and Orange Salad. — You need to have the soul of a rabbit to eat salad as it is usually served — green leaves slightly lubricated with oil and flavoured faintly acid with vinegar. A salad is only a background; it needs embroidering. To give character to a lettuce salad, cut up slivers of orange rind as small as pine needles and sprinkle them over the salad. It you want something still more entertaining for your guests, cut up a carrot into equally small slips.

This will at once arouse the attention of any gourmet. Which is orange and which is carrot, he will wonder. How does the orange come to have a flavour of carrot and the carrot a flavour of orange?

You will find that you have given him a real gastronomic entertainment.

Stewed Apples Flavoured with Tangerine. — A dish of stewed apples, rust-coloured and unadorned, is usually a melancholy sight.

Yet this economical dish, which is to be found in the least pretentious homes, can be given an attractive flavour. All that is needed is to put in little pieces of the rind of tangerines after removing all the white pith. The dish can easily be decorated with slices of tangerine which have first been freed from their pips and soaked in rum.

These dishes are much easier to make than might be thought from the description. They are far less difficult than most of the recipes of high-class cookery, for which strong bouillon of meat or fish is usually required. Guests may at first be rather suspicious of their novelty, but the first mouthful will remove their apprehensions and they will soon be in the proper frame of mind to appreciate the new style of cooking. When an unfamiliar harmony of flavours forms itself on the palate, we should try to analyze the sensation just as we identify the different instruments in an orchestra.

This is the right way to train our taste. We shall create new sources of pleasurable sensation. and we may even enrich humanity by fresh progress in the culinary art.

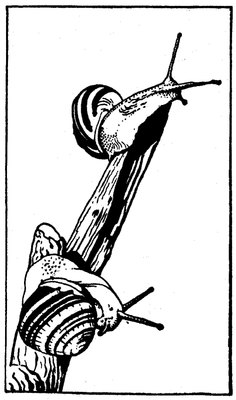
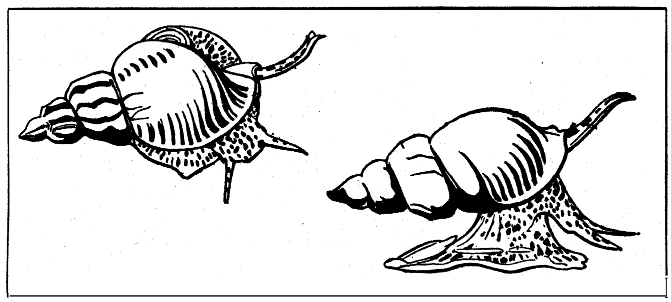
GASTROPODA, a large group of invertebrate animals ranked as a class of the phylum Mollusca and represented by such familiar forms as the limpet, the whelk, the common snail and slug. There is no single English name which can be given to this group. The land and fresh-water forms which have shells may all be termed "snails" and the shell-less land forms "slugs," and by a reasonable usage the name "snails" or "sea snails" may be given to marine Gastropoda with shells (whelks, periwinkles, etc.), and the shell-less marine forms (Nudibranchia, etc.) may be called "slugs" or "sea slugs."



BY COURTESY OF S. CROOK

FIG. 1.— GARDEN SNAILS CLIMBING (½ NAT. SIZE)

The Gastropoda are primarily distinguished from other molluscs by their shell, which is a single structure and is spirally coiled, at least in the larval state. In many Gastropoda, however, it is very much modified in the adult and, though it is spiral in a large number of genera, it may lose this appearance and become; *e.g.,* cup-shaped or tubular. In some forms it is covered over by the mantle and degenerate, and it may also be entirely absent. The Gastropoda are also distinguished from other molluscs by their asymmetrical organization. The latter is brought about by a process which takes place in larval development, during which the anus and the organs adjacent to the latter are moved forward ventrally from their originally posterior position and then twisted through 180°, so that they come to lie above and to one side of the head. The flexure of the intestine is a phenomenon seen in other molluscs; the twisting or "torsion" of the anal complex is peculiar to gastropods, and it is believed to bring about the asymmetry mentioned above. the chief feature of which is the atrophy or the complete disappearance of the kidney, gill and auricle originally situated on the right side of the body, those of the original left side persisting in a more or less unmodified condition. The clearly defined and well-developed head is likewise distinctive.

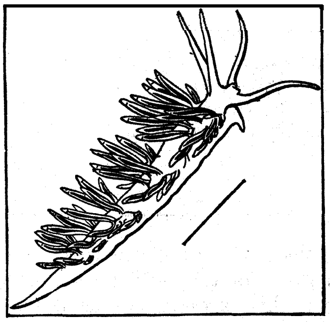


FROM MEHEUT, "ETUDE DE LA MER" (ALBERT LEVY)

FIG. 2.— THE WHELK. BUCCINUM UNDATUM (½ NAT. SIZE)

The Gastropoda constitute the largest class of molluscs and number about 30,000 living species, which range in size from giant whelklike forms 2 ft. in length, down to minute species of Vertigo barely a millimetre long in the adult state. An enigmatic fossil from the Wealden of Kent (Dinocochlea ingens) measuring over 6 ft. in length has been described as a fossil gastropod.

In all probability the earliest gastropods were marine animals and gastropods still constitute an important part of the marine fauna. They have also populated fresh-water and land habitats, and the familiar Helicidae, the Zonitidae and Bulimulidae are among the largest groups of land invertebrates. In general, their range of habitat is diversified. They are found at very great depths in the sea as well as in the shallower water, and the pelagic gastropods (Pteropoda and Heteropoda) form part of the marine plankton (minute floating organisms). The fresh-water and terrestrial Gastropoda occupy a great varietv of habitats and as a whole are to be reckoned as a very adaptable group, though the need for moisture and lime salts renders them less universally distributed than, *e.g.*, millepedes and Collembola.

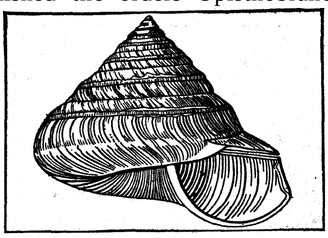


FROM ALDER AND HANCOCK, "BRITISH NUDIBRANCHIATA" (RAY SOCIETY)
FIG. 3.—HERMAEA DENDRITICA

Generally speaking, gastropods are sedentary, inactive animals that rely on their hard shells and unobtrusive habits for protection. The cumbrous shell and the absence of a jointed skeleton render them slow in their movements. On the other hand, they are capable of very considerable muscular exertion and tend to be very tenacious of life. A limited number of genera are more active and mobile and have taken to swimming, climbing and burrowing. Many marine gastropods and the majority of the terrestrial and fresh-water forms feed upon plants or on organic debris, and such a diet was no doubt characteristic of the primitive gastropod stock. Several groups, however, have become carnivorous and are modified accordingly in habits and structure.

Classification. — The classification of the Gastropoda has undergone many changes in the past. Even at the present time there is no universally accepted system so far as the main subdivisions are concerned, although there is a general measure of agreement as to the composition of certain of the lesser groups.

The class Gastropoda, including the orders Nudibranchiata, Tectibranchiata and Pulmonata, was created by Cuvier in 1795; later he created the Pteropoda as equal in rank with the Gastropoda. In 1812 Lamarck created the group Heteropoda, ranking it also equal with Gastropoda. In 1846–48 Milne-Edwards established the orders Opisthobranchiata and Prosobranchiata. The Pteropoda were held as a distinct class until Paul Pelseneer in 1888 showed their affinities to the Opisthobranchiata.

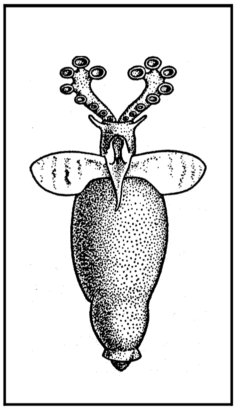


FROM MARTINI AND CHEMNITZ, "CONCHYLIEN CABINET" (GUSTAV FOCK)
FIG. 4.—PLEUROTOMARIA RUMPHII (⅔ NATURAL SIZE)

The diversity of opinion about the main subdivisions may be taken to imply that any natural groups of these dimensions (subclasses, orders) that may exist in the class have not yet been made apparent by morphological research. Nevertheless, certain broad groupings are recognized by those authors who in the last two decades have subjected the class to comprehensive treatment.

It will be convenient to contrast three such systems which have been proposed by Paul Pelseneer, H. Simroth and J. Thiele respectively. Different as these three schemes appear at the offset, they tend in fact to recognize the same main groupings. For table of systems see top of page 60.

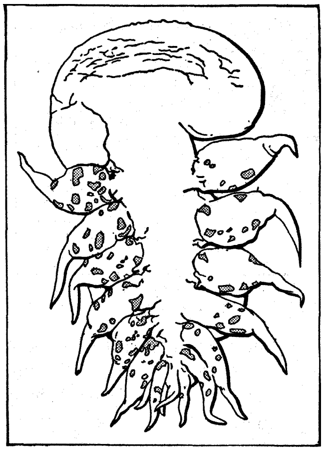
The Streptoneura of Pelseneer contain precisely the same families (limpets, trochids, periwinkles, whelks, etc.) as do the Prosobranchia of Simroth and Thiele. The rest of the class is treated as a single sub-class by Pelseneer. Thiele divides them into two sub-classes (as also seems to be the intention of H. Hoffmann, who is continuing Simroth's treatise in Bronn's *Tierreich*). But this does not involve any re-arrangement of the contents of Pelseneer's Euthyneura, as the latter are divided into two orders, equivalent in their contents to Thiele's sub-classes. In short, both authors recognize the distinction between the Opisthobranchia and the air-breathing pulmonata. Thiele's promotion of these two groups to the rank of sub-classes is advantageous, however, as it emphasizes the marked structural and bionomic differences between these groups. It is true that they resemble each other in certain distinctive features (*e.g.*, they are hermaphrodite and the visceral complex is detorted) in which they both differ from the Streptoneura. But they are otherwise very clearly defined and have a radically dissimilar evolutionary history.



FROM CHALLENGER, "ZOOLOGY" (H.M. STATIONERY OFFICE)
FIG. 5.—SPONGIOBRANCHAEA AUSTRALIS AUSTRALIS. NOTE THE SUCKERS (ABOUT NAT. SIZE). AFTER ORBIGNY & PELSENEER

Thiele's Archaeogastropoda contain the same families as Pelseneer's Aspidobranchia and Simroth's Scutibranchia. His Mesogastropoda are Pelseneer's Taenioglossa and his Stenoglossa are equivalent to Pelseneer's sub-order of that name. With regard to the status given to these groups Pelseneer's scheme seems at present more rational. While Thiele's elevation of the Stenoglossa to the rank of an order is to some extent justified by the marked specialization of these forms as carnivores and carrion-feeders, it leaves the Taenioglossa, a large and miscellaneous group with too great an appearance of uniformity. Probably Thiele's rating of the Stenoglossa is justifiable, and what is required is a more complete knowledge of the relationships of families constituting the Taenioglossa.

Little can be said concerning the numerous minor divisions. A great deal of work remains to be done in elucidating the constitution and relationships of families, the structure of which is imperfectly known. Many of the minor groups are probably very far from representing natural associations. The work of H. A. Pilsbry (1909–28) on the enormous group of land pulmonata has gone a long way towards disentangling the chaotic assemblages originally treated as Helicidae, Bulimulidae and Zonitidae, and the course of pulmonate evolution is becoming correspondingly clearer to us. But even so, this large and unwieldy order is in need of comprehensive treatment along bionomic as well as morphological lines.



FROM "ANIMALS OF ALL COUNTRIES" (HUTCHINSON'S PERIODICALS)
FIG. 6.—TETHYS LEPORINA, SHOWING COWL-LIKE FRONTAL VEIL FORMED FROM ANTERIOR TENTACLES (ABOUT ⅓ NAT. SIZE)

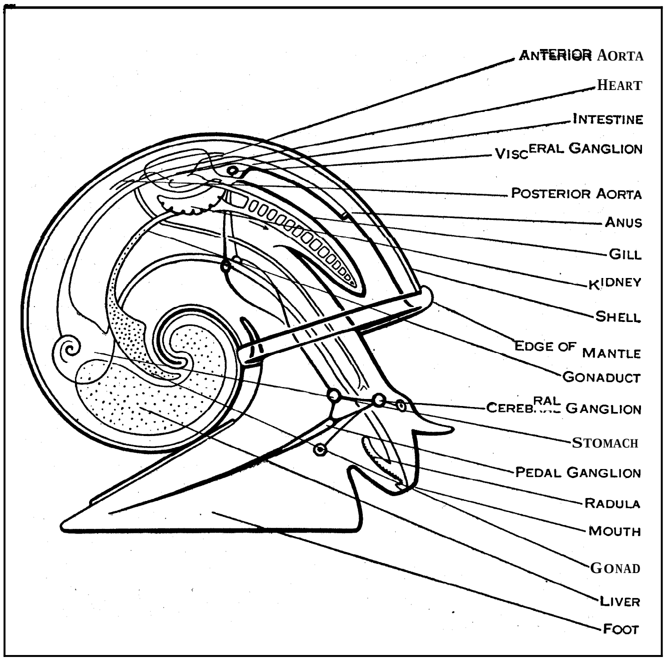
ANATOMY AND PHYSIOLOGY

The Gastrcpoda are divisible, as we have already seen, into a large number of groups, each distinguished by anatomical and bionomic peculiarities. The significances of these divisions will be easier to grasp, if the main evolutionary tendencies that have been manifested.within the class are briefly indicated in advance. The details of gastropod structure and morphology are well described in the standard textbooks on this subject, and the description given here consists of a selection of such of the more important modifications as illustrate the main evolutionary changes within the group. The most primitive of living gastropods are slow moving marine animals which feed upon algae, sea weeds or organic debris. They creep about by means of a flattened foot and rely for protection on an external shell, which is usually coiled in the adult. Their internal organization, though it is affected

CLASS GASTROPODA

	Pelseneer 1906	*Simroth* 1907	*Thiele* 1925–26
Sub-class 1.	Streptoneura.	Order Prosobranchia.	Sub-class 1. Prosobranchia.
Order 1.	Aspidobranchia.	Sub-order 1. Pectinibranchiata.	Order 1. Archaeogastropoda.
Sub-order a.	Docoglossa.	A. Siphonostomata.	
" 2.	Rhipidoglossa.	B. Heteropoda.	Order 2. Mesogastropoda.
		C. Holostomata.	Order 3. Stenoglossa.
Order 2.	Pectinibranchia.	Sub-order 2. Scutibranchiata.	Sub-class 2. Opisthobranchia.
Sub-order 1.	Taenioglossa.	A. Podophthamata.	Order 1. Pleurocoela.
" 2.	Stenoglossa.	B. Edriophthalmata.	Order 2. Saccoglossa.
		Order Pulmonata.	
Sub-class 2.	Euthyneura.		Order 3. Acoela.
Order 1.	Opisthobranchia.		Sub-class 3. Pulmonata.
Sub-order 1.	Tectibranchia.		Order 1. Basommatophora.
" 2.	Nudibranchia.		Order 2. Stylommatophora.
Order 2.	Pulmonata.		
Sub-order 1.	Basommatophora.		
" 2.	Stylommatophora.		

by the "torsion" already mentioned as far as the visceral nervous commissure and alimentary canal are concerned, is still more or less symmetrical. *Pleurotomaria, Fissurella* and *Haliotis* among the Rhipidoglossa exemplify this type of organization. In the course of evolution the main departures from the latter are as follows: (1) The visceral complex (heart, gills and kidneys) becomes asymmetrical through the atrophy and disappearance of those of the above named organs which are situated on the right



FROM SPENGEL, "ERGEBNISSE UND FORTSCHRITTE DER ZOOLOGIE" (FISCHER)
FIG 7.— DIAGRAM OF GASTROPOD ORGANIZATIONS

side of the adult body. (2) The shell may become internal and degenerate and finally disappear and a secondary external symmetry may be established. (3) A terrestrial and air-breathing mode of life has been adopted independently by several groups. (4) A carnivorous or carrion-eating habit has been acquired on several occasions. (5) The creeping mode of progression has been abandoned by certain families in favour of swimming and floating or of a truly sessile (adherent) mode of life.

These by no means exhaust the list of specialization exhibited by the class; but they are the most frequent and lead to the most striking modifications of structure.

External Features and General **Organization.**—The body of a gastropod is divisible, like that of nearly all molluscs, into four main parts—the visceral sac, the mantle which covers the latter, the head and the foot. The morphological unity of the head and foot has been suggested by A. Naef, and this subject is discussed in the article MOLLUSCA. The whole animal may be visualized as having an elongate and wormlike body with the head and foot at one end. The greater part of the body is spirally coiled, and the coiled portion (the visceral sac) is sheathed in a fleshy coyering, the mantle, which projects as a free fold at the anterior end and hangs down like a skirt around the head and foot. In the cavity thus formed between the mantle and head the function of respiration is normally carried out either by gills or by a lung. In the former case the mantle cavity is largely open to the exterior; in the second the edge of the mantle is adherent to the "neck," a small hole (the pneumostome) being left for the admission of air into the lung. In certain Rhipidoglossa the mantle edge is not complete anteriorly and dorsally, but is interrupted either by a longitudinal slit or a series of holes probably representing a slit, the edges of which have fused.

The mantle secretes a shell which consists of a single piece and is in most cases spirally coiled. The minute structure of the shell and its chemical composition is described in the article MOLLUSCA. In individual development the shell appears in the embryo as a plate or caplike rudiment which becomes coiled and grows in size by the deposition of mineral salts round the edge of the open end (aperture). It is likely that the forerunners of the Gastropoda had a cap-shaped shell in the adult state.

In the most archaic representatives of the class, however (*e.g. Bellerophon,* among the extinct Cambrian genera and *Pleurotomaria* among living forms) the shell is coiled. It is worthy of note that in *Bellerophon* the shell is not of an elongate or screw-like spiral shape, its coils being all in one plane (planospiral), like that of the primitive cephalopod *Nautilus.* The modifications of the adult shell are complex and manifold. The general plan and the terminology employed in describing shells are shown in fig. 9 and the various modifications are described and illustrated in text books and conchological treatises. It is sufficient here to allude to the most important change that is encountered in the class.

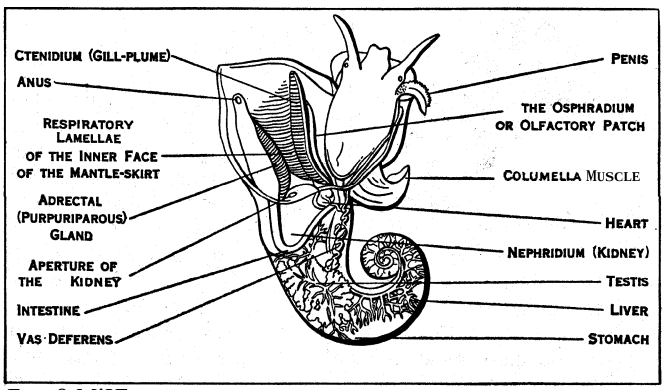


FIG. 8—MALE OF LITTORINA LITTOREA, REMOVED FROM ITS SHELL. SHOWING THE ORGANS ON ITS INNER FACE

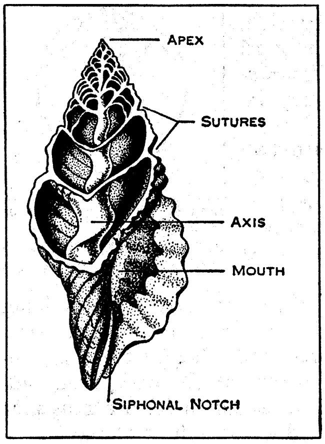
The shell, which is to be regarded as primitively spiral, becomes unwound and secondarily cap-shaped in many Streptoneura *(Patella, Capulus)*. Furthermore, the edges of the mantle may grow over the shell and cover a large part of its surface. This condition is found in such genera as *Fissurella, Cypraea,* and *Marginella* among the Streptoneura and in various Opisthobranchia (*Aplysia*) and Pulmonata (*Vitrina*). The overgrowth of the mantle may be complete and the shell is thus internal and degenerate (Lamellariidae and sluglike Pulmonata). Finally, the shell may disappear entirely (*Titiscania,* many nudibranchs, *Onchidium*). This progressive atrophy of the shell occurs in many groups of gastropods. Although it may become of advantage to the animal as allowing it greater freedom of movement, the loss of the shell is to be regarded at least at the offset as an innate tendency of the class and probably of the molluscan phylum as a whole.



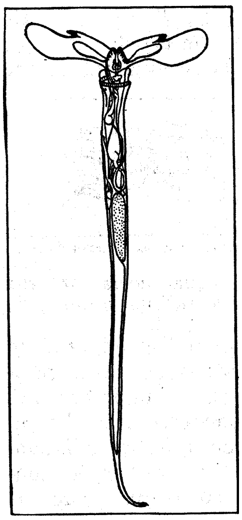
FROM SIR RAY LANKESTER, "TREATISE ON ZOOLOGY" (A. & C. BLACK)

FIG. 9.— SECTION THROUGH A TRITON SHELL (ABOUT ½ NAT. SIZE)

The head in the Gastropoda is well developed and clearly defined from the rest of the body to which it is connected by a mobile "neck." It is usually provided with sense organs, a snout or muzzle and one or two pairs of tentacles. The foot is a powerful muscular organ. Usually it is rather elongate and has a flat surface suitable for a creeping gait.

Notable modifications of the foot are seen in marine forms which dig in sand (*Natica,* Bullomorpha). These gastropods have the foot transformed into a "digging-shield" shaped like a snowplow. In heteropods and "pteropods," it is modified for use in swimming.

On the posterior dorsal surface of the foot there is in nearly all Streptoneura a solid plate, the operculum. When the animal withdraws itself into its shell, this plate by reason of its position and shape remains applied to the aperture of the shell which it closes like a lid. The operculum is absent in nearly all the Euthyneura, but certain terrestrial forms such as the Helicidae secrete a glutinous or calcareous plate over the mouth of the shell when they estivate or hibernate.



FROM MURRAY AND HJORT, "THE DEPTHS OF THE OCEAN" (MACMILLAN LTD.)

FIG. 10.—CRESEIS ACICULA.

The foot often exhibits along its sides a ridge (epipodium) which extends from the head to the posterior extremity. The epipodium is well developed in the Rhipidoglossa and often bears appendages and sense organs. It has been assumed to have a common origin with the funnel of the Cephalopoda. The head and foot are joined to the visceral mass by a narrow and highly mobile "neck." The animal is attached to the shell by the strong columellar muscle, and by the contraction of the latter the animal can withdraw itself into the shell. This muscle is inserted into the columella or axial pillar of the shell (*cf.* fig. 9).

The disposition of the chief external parts having thus been sketched, it will now be convenient to describe how the characteristic gastropod asymmetry is attained. Some details of the internal organization are given below; but it is necessary at this stage to recall the preliminary statement that, while some primitive forms are symmetrically organized, the main parts of the visceral complex (gills, kidneys, etc.) being paired, in most gastropods the organs of the right-hand side are atrophied or absent in the adult, and that in the Streptoneura the visceral commissure is twisted into a figure-of-eight. In addition, the spiral winding of the shell and visceral mass has to be accounted for.

Before considering how and in what circumstances this highly characteristic organization was developed in the course of gastropod evolution, it will be best to describe the main organization and metamorphosis of a gastropod larva.

As will be seen in the section on Reproduction and *Development*, the larva is symmetrical in the early stages of growth, the mouth and the anus lying at opposite ends of the body. At a stage which more or less corresponds with the appearance of the shell, the anus shifts downward and forward and ultimately comes to lie below and near the mouth. At this stage the mantle cavity is seen as a small space surrounding the anus. Such coiling as the shell may show at this stage is "exogastric," *i.e.,* the coils are situated above the head and away from the foot. Soon, however, the anus, the mantle cavity and the adjacent parts rotate upward and come to lie above the head and to the right of the latter. The coils of the shell at the same time roll downward and assume an "endogastric" position, *i.e.,* they lie over the foot and away from

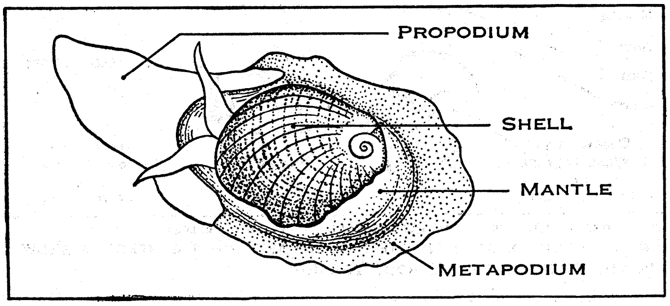


FIG. 11.—SIGARETUS LAEVIGATUS (NAT. SIZE). AFTER SOULEYET. 1841

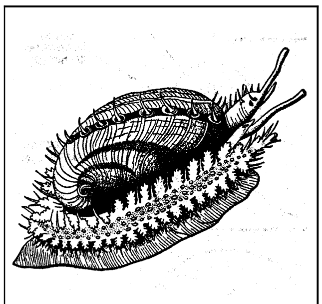
the head. It will be seen that there are two movements involved in this reorganization of the larval symmetry, viz., the ventral flexure of the intestine and the torsion or rotation of the pallial complex up the right side of the body. Though these two changes may be merged into one in individual development they must be carefully distinguished. The ventral flexure is found in the Gastropoda, Cephalopoda, Scaphopoda and Lamellibranchia, torsion is hound in the Gastropoda alone.

If processes of this kind, which occur in the course of individual development, may be taken to epitomize events which happened during the evolutionary history of the race, then it is to be inferred that metamorphosis is a summary of changes which took place in gastropod evolution. Many theories have been put forward to account for these processes. They agree in attributing great importance to the influence of the spiral shell and the acquisition of a flat and elongate sole. If it is true that the Gastropoda are descended from animals with a simple caplike shell and a relatively small foot, then it seems likely that, as the shell acquired a tubular shape, it became necessary to bring the originally posterior anus and associated organs into a position in which they would not be covered in by the growing shell. Hence the flexure of the intestine, the result of which was to bring the anus near the head. But it plainly could not persist in this position, as the elongation of the foot would tend to drive it backward. Its rotation up the side of the body, until it came to lie above and to the right of the head, brought it into the most convenient position. It is also likely that the change in the spire of the shell from an exogastric to an endogastric position may have influenced the torsional process. Naef assumes thbt the animals which gave rise to the primitive gastropods were swimming forms. In such a mode of life the exogastric spire would be no inconvenience. But with the advent of a creeping habit the heavy, forwardly directed shell could no longer maintain its position and would fall on one side. This displacement of the shell would almost inevitably affect the position of the pallial complex. The position ultimately taken up by the latter may be explained either as directly due to the displace-

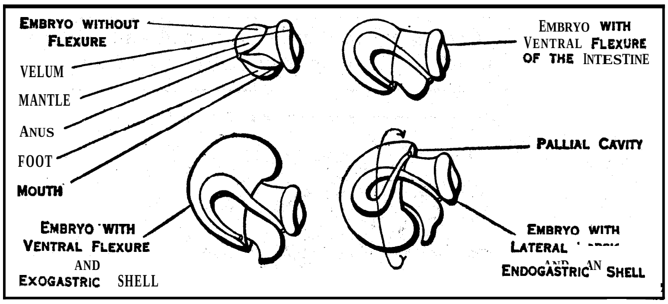


FROM LANKESTER, "TREATISE ON ZOOLOGY" (A. & C. BLACK)

FIG. 12 —HALIOTIS TUBERCULATA (⅓ NAT. SIZE)

ment of the shell or as an adaptation that placed the pallial complex in a less cramped and restricted situation. It is quite uncertain whether the rotation of the shell or growth of the foot was most influential in bringing about torsion. It is likely that both contributed.

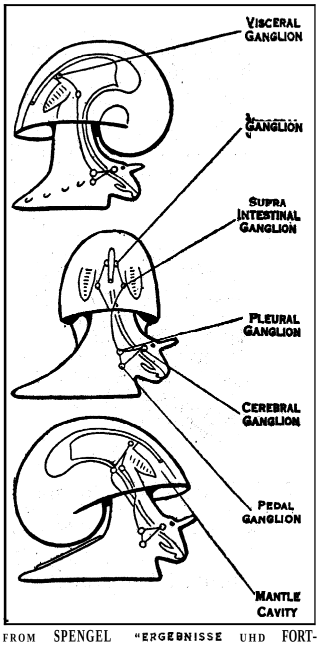
The foregoing account must not be taken as a description of actual events but of the factors which are likely to have been concerned in producing flexure and torsion. The spiral winding of the shell and the torsion of the viscera are to be carefully distinguished, as they are probably not causally connected. The main process of torsion, at least in ontogeny, takes place before the



AFTER ROBERT LANKESTER, "TREATISE ON ZOOLOGY" (A. & C. BLACK)
FIG. 13.— FOUR STAGES IN THE DEVELOPMENT OF A GASTROPOD SHOWING THE PROCESS OF THE BODY TORSION

spiral winding of the shell and visceral mass is manifest. The cause of the actual asymmetry of the internal organs is not entirely clear. The twisting of the visceral commissure may be due to the effect of the torsion; but the atrophy and reduction of the originally left-hand organs are not at first sight referable to the latter. They have been explained as due to the pressure of the shell after it has assumed the endogastric position.

In the Euthyneura the process outlined above tends to be reversed (detorsion). The visceral commissure is untwisted, the anus and pallial complex in certain forms are carried to the posterior end of the body, and with the loss of the shell a secondary symmetry may be attained. Naef wishes to distinguish between the detorsion of the Pulmonata and that of the Opisthobranchia and to refer them to different causes.

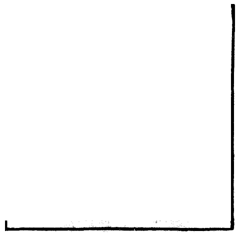


FROM SPENGEL "ERGEBNISSE UND FORTSCHRITTE DER ZOOLOGIE" (FISCHER)
FIG. 14.— DIAGRAM ILLUSTRATING TORSION IN THE GASTROPOD

INTERNAL ORGANIZATION

The Alimentary System, The mouth is situated at the anterior end of the head, which is usually snoutlike and bent somewhat downward. In many of the Streptoneura the mouth is at the end of a proboscis which can be thrust out or withdrawn into the cavity of the head. A proboscis is found in certain Taenioglossa (e.g., *Natica, Copulus*), the Rachiglossa and sundry opisthobranchs, notably the Gymnosomata, and is usually associated with a carnivorous diet.

The mouth leads into the buccal, or pharyngeal cavity, which is furnished in most cases with solid cuticular mandibles and a tonguelike organ, the radula, which is beset with numerous rows of teeth and is used for rasping the food. The mandibles are absent in certain forms—Toxoglossa, Helicinidae, Heteropoda—and are rudimentary in the Rachiglossa. It is uncertain whether the mandibles are to be correlated with a vegetarian diet, but they are without doubt absent or rudimentary in many carnivorous forms. The radula is secreted in a pharyngeal coecurn, and is a narrow, ribbonlike organ consisting of a basal membrane supporting a number of rows of teeth usually arranged in two symmetrical sets, one on each side of a median tooth. The number, arrangement and shape of the teeth are very characteristic and are of great systematic value as they serve to distinguish not only the larger groups (sub-classes, orders, etc.) but also genera and species. The range in the number of teeth is very wide. In some of the Eolids there are only 16 rows each with a single tooth. In *Umbraculum*, on the other hand, there may be as many as 750,000 teeth.



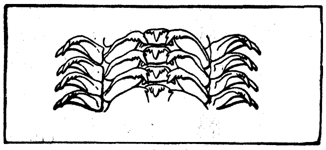
FROM LANKESTER, "TREATISE ON ZOOLOGY" (A. & C. BLACK)
FIG. 15.—MANDIBLES OF JANUS (MAGNIFIED)

On either side of the radula are two salivary glands which usually secrete only mucus, though in sundry carnivorous genera they contain an acid which dissolves the hard parts of animals which serve as food.

The oesophagus is generally long and tubular and its inner wall is thrown into numerous folds. In the Stenoglossa it bears a characteristic gland, which in *Conus* and other Toxoglossa constitutes the "poison gland." The portion of the oesophagus adjacent to the stomach is sometimes enlarged to form a muscular "gizzard," the walls of which are lined with teeth or plates.

The stomach is usually thin-walled, but it is lined with a hard cuticle in many genera. It has no digestive function other than that of containing food which is being digested. Digestion is effected by the liver and (when present) the crystalline style. The liver is usually a bilobed organ, the left lobe being larger than the right in most cases. It secretes a digestive ferment which is poured into the stomach by two ducts, and it also has absorptive and excretory functions. The crystalline style is a rod-shaped structure usually of tough, gelatinous consistency, which is either lodged in a special pyloric coecum or lies free in the proximal part of the intestine. It is composed of globulin and, according to Mackintosh, contains an amylolytic enzyme.

The intestine is long or short, according as the animal is herbivorous (e.g., Patella) or carnivorous (e.g., Pterocera). Its inner wall is raised into a prominent ridge, the typhlosole. The anus usually lies on the right side of the body adjacent to the head; but in "detorted" forms it is at the posterior extremity of the body.



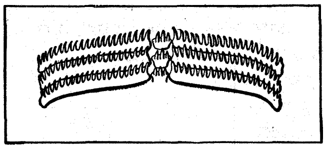
FROM "CAMBRIDGE NATURAL HISTORY" (MACMILLAN)
FIG. 16—FOUR ROWS OF THE RADULA OF VERMETUS (MAGNIFIED)

Circulatory and Respiratory Organs.—The blood is usually colourless and contains amoebocytes. Haemoglobin is found in the blood of certain species of *Planorbis* and haemocyanin in a few genera. The lymphatic tissue is either diffuse or concentrated in a special gland (*e.g.,* in certain Opisthobranchia). The heart is always dorsal in position. It is usually in front of the visceral mass, but it becomes posteriorly situated in some of the Opisthobranchia as the result of complete detorsion and the reacquisition of bilateral symmetry. In the Rhipidoglossa (with few exceptions) it consists of a ventricle and two auricles, but even in this group the left auricle is larger than the right. In *Fissurella* alone are the auricles equal in size. In all other Gastropoda there is only one auricle, the left.

There is a well-developed arterial system in nearly all Gastropoda. The venous blood, on the other hand, is carried to the gills through a system of irregular cavities that extends between and among the various organs. From these it is carried to the gills either directly or through the kidney by means of a "portal" system.

Respiration is aquatic in the majority of Gastropoda and is usually carried out by gills. The latter are expansions of the underside of the mantle and are primitively feather-like structures (Ctenidia), a number of delicate vascularized filaments being borne on each side of a central stem in which are situated two blood-vessels. By one of these the venous blood is carried to the filaments for oxygenation, after which it passes in the other to the heart.

In mare specialized Gastropoda the gills become comb-like owing to the suppression of the filaments of one side. There are two gills in the more primitive Rhipidoglossa (*Pleurotomaria, Fissurella* and *Haliotis*). In all other gill-bearing forms the topographically left gill alone persists.

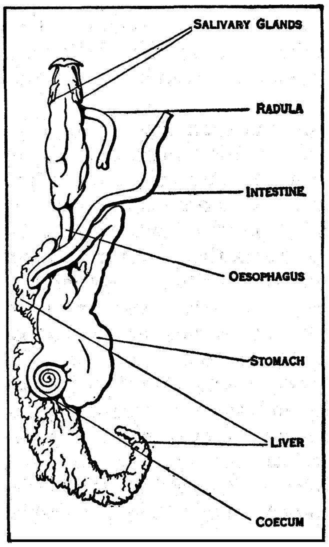


FROM "CAMBRIDGE NATURAL HISTORY" (MACMILLAN)

FIG. 17.—THREE ROWS OF RADULA OF FASCIOLARIA TRAPEZIUM (MAGNIFIED)

Although the respiration of the Gastropoda is primitively aquatic and is of this nature in the larger part of the class, several important groups have become terrestrial in their habitat and either breathe air or are amphibious. The consequent modifications of the respiratory apparatus are manifold and even among marine forms the normal gills are liable to curious and rather inexplicable modification. The mantle in fact retains to a surprising degree a generalized capacity for discharging the respiratory function and for putting forth respiratory organs not homologous with true gills. Thus respiration from the surface of the mantle may coexist with ctenidial respiration (Heteropoda, Acmaea) or a true gill may be found along with secondarily developed respiratory outgrowths (Scud). The true gill may disappear and be replaced by numerous secondary outgrowths (Patella) or there may be no special branchial organs at all, and respiration is effected by the surface of the mantle (*Lepeta*).

In the Gastropoda which have taken to living on land, the whole mantle cavity is transformed into a lung. Among certain marine and fresh-water Streptoneura there are sundry genera (Littorina, *Cerithium, Hypsobia*) which are accustomed to live out of the water for long periods. Their mantle cavity has an incipient lung-like structure, though the gill is still more or less normally developed. The fully developed lung is formed by the adhesion of the mantle edge to the "neck" and the consequent closure of the mantle cavity which remains in communication with the outer air by a small aperture (the pneumostome). The pulmonate condition has been acquired separately by at least three groups of Gastropoda, viz., the Helicinidae among the Rhipidoglossa, the Cyclostomatidae among the Taenioglossa and the Pulmonata among the Euthyneura.



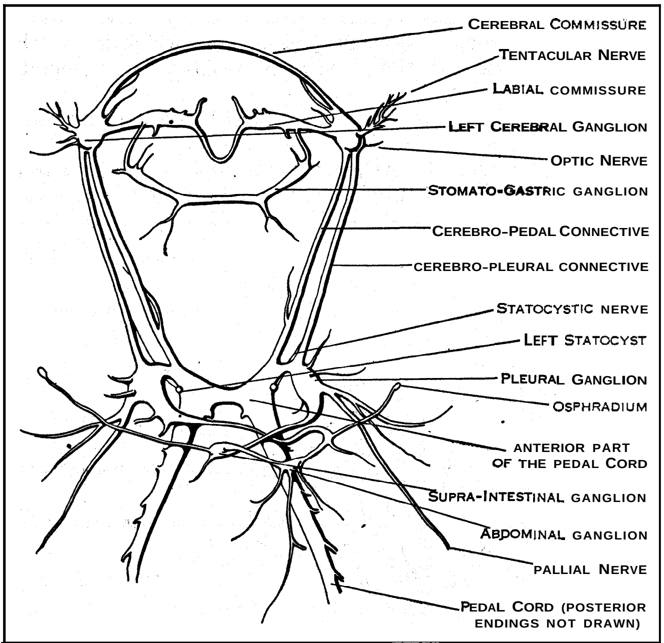
FROM BRONN, "KLASSEN UND ORDNUNGEN DES TIERREICHS"

FIG. 18.—ALIMENTARY CANAL OF TROCHUS GIBBOSUS

The Nervous System.—Except in certain parasitic forms the nervous system is well developed. It consists of nerve cords, ganglia connected by commissures and sense organs. The various ganglionic centres and commissures are those found in other molluscs, viz., cerebral, pleural, pedal, Visceral and stomatogastric. Archaic traits are seen in certain Rhipidoglossa, *e.g.,* the slight differentiation of some of the ganglia in *Pleurotomaria.* The more primitive Gastropoda are distinguished by the diffuseness of the system, the various ganglia being separated by fairly long commissures. In certain Taenioglossa and the Stenoglossa, among the Streptoneura, and in the Nudibranchia and Pulmonata, the commissures are shortened and the ganglia are concentrated in the head. The visceral commissure is twisted into a figure-of-eight in all the Streptoneura and in a few Tectibranchia (*Actaeon, Bulla,* etc.), but in nearly all the Euthyneura it is untwisted.

The sense organs are eyes, statocysts (organs of balance) and rhinophores or osphradia (olfactory organs). In addition to these organs there are special sensory tracts in various regions of the body which have a less defined and less complex structure.

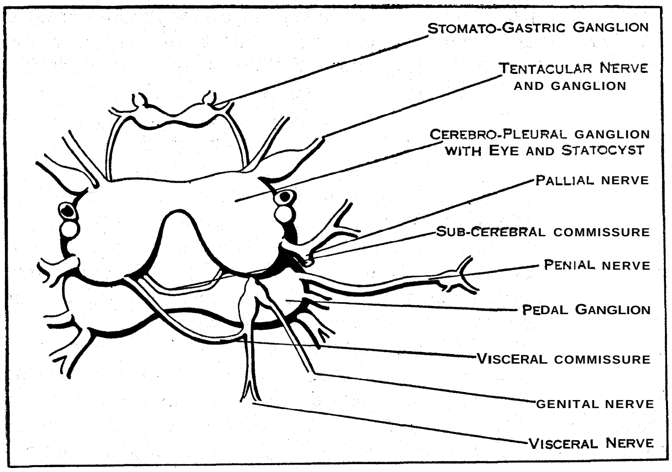
The eyes are found upon or at the base of the tentacles of the head. They are primitively cuplike invaginations with a pigmented retinal layer, which is thus exposed to the sea water. Such simply constructed eyes are seen in the limpets (Docoglossa). In



FROM LANKESTER, "TREATISE ON ZOOLOGY" (A. & C. BLACK)

FIG. 19.—NERVOUS SYSTEM OF PATELLA

other Rhipidoglossa the aperture of the cup is still open, though it is very small, and a lens is secreted. In most other Gastropoda the aperture is closed by the approximation and fusion of the edges of the original aperture, and a double cornea is formed. The olfactory function is discharged by the osphradia in nearly all aquatic Gastropoda. There are two of these organs in such Aspidobranchia as have two gills and in the Docoglossa, and a single osphradium in the rest of the class. They are situated in the mantle cavity near the gills or gill and are essentially organs for testing the respiratory quality of the water. In structure they may be described as ridges of ciliated epithelium. In terrestrial



FROM LANKESTER. "TREATISE ON ZOOLOGY" (A. & C. BLACK)

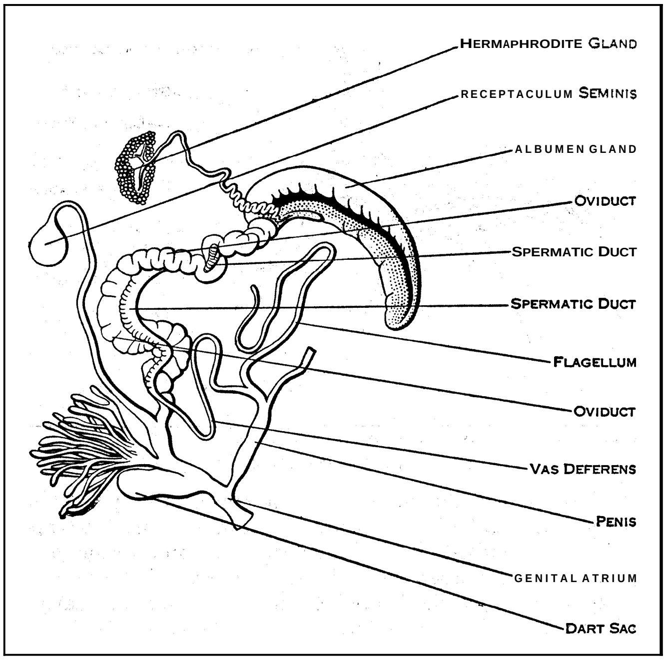
FIG. 20.—NERVOUS SYSTEM OF GONIODORIS

gastropods the osphradia are replaced by rhinophores which are borne on the tentacles. The organs of balance (statocysts) are hollow vesicles lined with ciliated epithelium in which sensory cells occur. They contain hard concretions (statoliths) which impinge on ciliated endings of epithelium and transmit stimuli to the sensory cells. Statocysts are found in the foot in creeping forms; but are sometimes nearer the cerebral ganglia.

Coelom, Renal and Reproductive Systems.—The coelom is represented by the pericardium, kidneys and, theoretically, by the reproductive gland. The latter, however, is a more or less solid or acinous gland, and the cavity from the walls of which it is developed is obliterated in the adult. The kidneys are paired in all the Aspidobranchia, except the Neritacea. In the latter and all other Gastropoda the right-hand kidney is aborted and, at least in such a form as Viviparus, in which its development has been studied, transformed into part of the generative duct.

The functional kidney communicates with the pericardium by a ciliated canal.

In all the Gastropoda the gonad or reproductive gland is unpaired. In certain Aspidobranchia it opens into the reno-pericardial canal, as in some of the Lamellibranchia, or into the kidney itself, which thus acts as a gonaduct. In the Neritacea and all other Gastropoda there is a separate gonaduct.



FROM MEISENHEIMER, "DIE WEINBERGSCHNECKE"

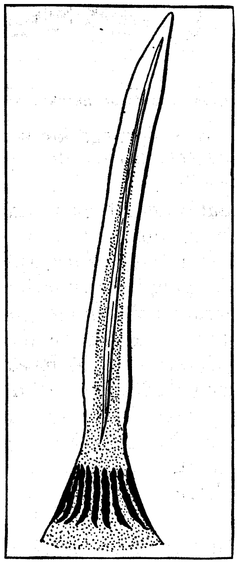
FIG. 21.—REPRODUCTIVE ORGANS OF HELIX POMATIA

The sexes are separate in the Streptoneura with the exception of a few genera, which include certain parasitic forms. Sexual dimorphism is only slightly marked. The male duct ends in a penis which is developed at different points at the anterior extremity of the body. The female system in certain groups exhibits accessory organs and in the forms in which the eggs are incubated in the maternal body there is a brood pouch. The Euthyneura are hermaphrodite and the gonad is an ovo-testis. In the more primitive Euthyneura the gonaduct passes both the eggs and spermatozoa to the exterior. By various stages a more specialized condition is attained in which the male and female ducts are separated and acquire separate openings (diaulic condition). In the stylommatophorous Pulmonata these are secondarily joined together. Certain Nudibranchia are "triaulic," *i.e.*, they have three genital orifices, the female duct being subdivided into vaginal and oviducal conduits. Accessory glands and organs are a marked feature of the Euthyneura. The latter are usually protandric hermaphrodites, *i.e.*, the spermatozoa come to maturity before the ova. Self-fertilization is not unknown, but usually one individual is fertilized by another. It is worth noting that in one or two cases (Patella, *Crepidula*) among the Streptoneura a change of sex may take place in the same individual and that in sexually differentiated forms hermaphrodite individuals are occasionally found (*Acmaea,* Lottia, *Ampullarius, Conus*). Parthogenesis (development of the ovum without fertilization) is known in one case (*Paludestrina jenkinsi*).

REPRODUCTION AND DEVELOPMENT

Breeding Habits, **Oviposition, etc.**—The breeding habits of very many Gastropoda are unknown and in few cases is the life history from fertilization onwards known in all its details.

In certain primitive Streptoneura the eggs are fertilized externally in the sea water; but in most members of the class the male has a penis and fertilization is internal. The courtship of certain land snails has been carefully studied, and as an example the complex behaviour of the Roman snail (Helix *pomatia*) which has been described by Meisenheimer should be studied. In many land snails courtship is usually accompanied by some act of violent stimulation, usually by means of a calcareous pointed rod (the dart) secreted in part of the male reproductive system.

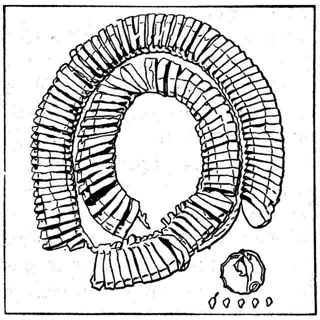


FROM MEISENHEIMER, "DIE WEINBERGSCHNECKE"

FIG. 22.—DART OF HELIX POMATIA (MAGNIFIED)

The eggs are usually laid soon after fertilization. They are either deposited singly (Haliotis, Gibbula, *Paludestrina*) or in clusters which sometimes form an elaborate "nidus." This may be a simple gelatinous mass (*Lymnaea*) or a ribbon (certain Opisthobranchia) or a series of horny capsules each containing many eggs may be accumulated in a mass or strung together as a sort of "roulette" (Rachiglossa). The capsules in the latter are formed by a special gland of the foot, a lengthy operation lasting many days. Certain Streptoneura attach their eggs to the external surface of their own shells or those of their neighbours (Paludestrina, some species of *Theodoxus, Capulus*) or deposit them inside the shell (Vermetus). *Ianthina* secretes a gelatinous raft on the under surface of which the eggs are suspended. Most of the land snails lay their eggs in holes underground. These are enclosed in a gelatinous envelope (*Limax*) or in a calcified shell (Helicidae). Certain Bulimulids lay eggs with calcified shells, 2–3 cm. long, resembling those of birds.

The habit of carrying the eggs on the shell may be perhaps considered as a prelude to more definite and protracted care of the young. Vermetus, as has been pointed out, carries the eggs inside the aperture of the shell and certain species of Libera (a pulmonate) places its eggs in the umbilicus of the shell and covers them over with a secretion rather like an epiphragm. There are, however, a good many viviparous or ovoviviparous gastropods, Viviparus, *Typhobia*, a certain species of *Melania*, and sundry pulmonates incubate their eggs in the terminal part of the oviduct (uterus), while in *Tanganyicia* and *Melania episcopalis* there is a special brood pouch which is separate from the oviduct.



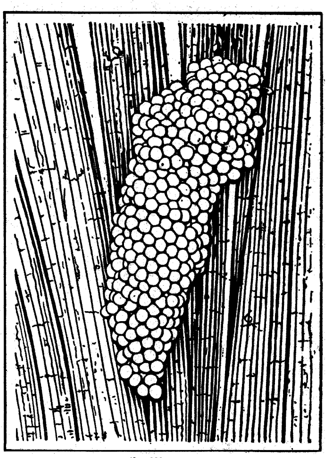
FROM ANIMALS OF ALL COUNTRIES' (HUTCHINSON S PERIODICALS)

FIG. 23 — EGG CAPSULES OF BUSYCON (ABOUT 1/5 NAT. SIZE)

The number of eggs varies according to the mode of life and oviposition. *Purpura lapillus* (the dog whelk) deposits up to 150,000 eggs in its capsules and sundry species of *Doris* lay as many as 600,000. It should be noted that in those Rachiglossa which form capsules containing many eggs some of the latter are devoured by those embryos which emerge first. Intrauterine cannibalism has been recorded in the pulmonate Lzmicolaria. The Pulmonata do not as a rule lay as many eggs as the Streptoneura and Opisthobranchia. *Helix aspersa* deposits up to 100

Development.—Although the Gastropoda display very considerable variation in the adult form, the cleavage of the eggs is more or less the same in all the cases in which it has been studied. Such variation as may have been observed is due to variation in the amount of yolk.

In all Gastropoda which have been so far studied cleavage is total and of the type known as spiral. The egg divides into two and then into four cells which are either equal in size (Patella) or approximately equal. A third division then cuts off four small cells (micromeres) from the four original cells (macromeres). There are now eight cells consisting of a "quartette" of micromeres and the four larger macromeres. The next division gives rise to 16 cells, viz., four more micromeres, which are given off from the macromeres (second quartette) and the products of the sub-division of the first quartette of micromeres. Division proceeds in this way until a cap of numerous micromeres is found lying on top of the four macromeres. In Patella, in which the development is well known, the embryo is at the 32-cell stage radially symmetrical. On the attainment of the 64-cell stage this is replaced by bilateral symmetry. Owing to certain features of the mode of cleavage, it is possible to trace the "lineage" (developmental history) of individual organs back to individual cells or quartettes produced by very early cleavage. This type of research has been a very fruitful source of embryological knowledge, but can only be summarily mentioned here. The micromeres give rise to the ectoderm and its derivatives, the macromeres to endoderm and mesoderm. In Patella gastrulation is by epibole (overgrowth) of the macromeres by the micromeres. At the end of 24 hours the embryo, which up till now has been contained in an egg membrane, escapes and begins its free-swimming period as a trochophore larva. It is more or less spherical and surrounded by a girdle of long cilia (the prototroch) developed from special trochoblasts.

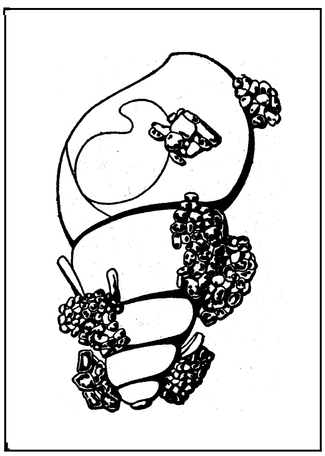


BY COURTESY OF F. W. BOND

FIG. 24.— EGGS OF THE AMPHIBIOUS SNAIL (AMPULLARIUS)

The gut is now developed, the endodermal cells dividing to form the stomach and the mouth and anus arising as ectodermal invaginations. Dorsally, a thickened plate of cells gives rise to the shell gland, the foot is indicated by two slight prominences on either side of the mid-ventral line, and the mesoderm bands are now formed.

Enlargement of the prototroch to form the velum and the growth of the foot characterize the veliger stage. The metamorphosis of the larva has already been described.

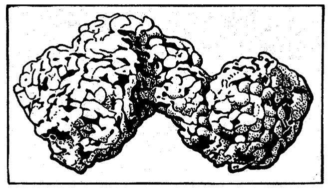


AFTER HENKING IN "BERICHTE" (NATURFORSCHENDE GESELLSCHAFT)

FIG. 25. — PALUDESTRINA ULVAE CARRYING EGGS COATED OVER BY A LAYER OF SAND-GRANULES (ABOUT 9/1 NAT. SIZE)

The detailed development of the individual organs is not very well known in marine molluscs. We owe the bulk of our knowledge on the subject to the studies of Raphael Slidell von Erlanger, James L. Drummond and C. Tönniges on *Viviparus,* the pond snail (originally called Paludina). The ganglia of the nervous system arise as thickenings of the ectoderm which subsequently become joined together by connectives. The statocysts and eyes are ectodermal invaginations. The pericardium originates as a hollow in the mesoderm and the heart is first seen as a vesicle projecting down from the dorsal wall of the pericardium. The kidneys are tubular extensions of the pericardial cavity; they are joined by ectodermal invaginations which constitute the ureters. The gill appears as a series of folds in the wall of the mantle cavity. The germ cells seem in the first instance to be budded off the pericardial wall and subsequently form a spherical vesicle, the gonad. The kidney of the originally left-hand side forms part of the genital duct. The origin of the mesoderm in Viviparus has been the subject of controversy. (See E. W. MacBride, Text Book of Embryology.)

The account of larval development and organogeny given above is founded very largely upon the study of Viviparus, but it probably represents the course of events in many other gastropods. Departures from this developmental history are mainly of secondary importance, and are due, for example, to the development of special larval organs (*e.g.,* the cephalic vesicle and "podocyst" of Stylommatophora), and the presence of a larger amount of yolk than is usual. The velum is suppressed in oviparous and viviparous forms; but traces of it can be seen in certain of the latter (*Cenia,* some of the Pulmonata). In certain highly modified pelagic larvae the velum is drawn out into extensive lobes (*e.g.,* in that of Dolium).

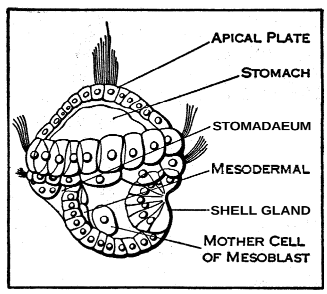


BY COURTESY OF F. W. BOND

FIG. 26.— EGG CAPSULES OF COMMON WHELK (ABOUT 1/3 NAT. SIZE)

DISTRIBUTION AND NATURAL HISTORY

The Gastropoda have practically a world-wide distribution and are found in the sea, in brackish and fresh water and on land. Marine gastropods occur in all seas. In high latitudes they live in the bays and fjords of the Antarctic continent (*e.g.,* in the Ross sea, 77° S.) and off the northern coasts of Greenland and Franz Josef Land. Exactly how far north they occur is uncertain; but in all probability they range right across the north Polar sea. The exclusively marine gastropods are limited in their distribution by salinity and other environmental factors. But, though it is true that the life zones that prevent them from invading fresh water and land interpose a strict barrier to their invasion of those habitats, there are certain groups which are intermediate between truly marine gastropods and those which habitually live in fresh water and on land. The common periwinkle (*Littorina* littorea) can tolerate very protracted exposure to air and the estuaries of most great rivers contain certain forms which can endure daily and seasonal changes of salinity, etc. Similarly, among terrestrial and fresh-water gastropods there are forms which are of wide tolerance and live indifferently in water or on land, either being structurally adapted, as in the case of the lung snail (*Ampullarius*) which lives in swamps, and has both a gill and a lung, or having a more or less generalized adaptability (certain species of *Lymnaea*). Hesse records that an exclusively terrestrial Pulmonate (*Lauria cylindracea*) has taken to living in springs in certain parts of Germany.

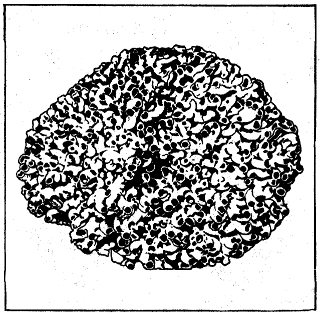


MACBRIDE "TEXT BOOK OF EMBRYOLOGY" (MACMILLAN)

FIG. 27.— LATERAL VIEW OF YOUNG TROCHOPHORE LARVA OF PATELLA COERULEA (MAGNIFIED)

The majority of the Streptoneura are marine, but the Helicinidae among the Rhipidoglossa, the Cyclophoridae and Cyclostomatidae among the Taenioglossa have become terrestrial. The members of the genus Theodoxus (*Neritina*) are the only Rhipidoglossa that have invaded fresh water; but many groups of Taenioglossa inhabit the latter, viz., the Viviparidae, Melaniidae, Ampullariidae, Valvatidae, etc. The Stenoglossa are exclusively marine. Among the Euthyneura the Opisthobranchia are likewise a marine group. The Pulmonata are mainly terrestrial, though certain large families (Planorbidae, Lymnaeidae) live in fresh water, and a few (Amphibola, Siphonaria) are marine or littoral (Auriculidae).

The horizontal distribution of marine gastropods can only be treated very summarily here. It is sufficient to say that certain main distributional areas can be recognized which have their peculiar and characteristic faunas, the latter being composed of genera and species which are either restricted to those areas or are more frequently found there than elsewhere. For example, in the region between Delagoa Bay and Cape Agulhas, which we may regard as the South African marine province, are found the following genera which occur nowhere else: *Abyssochrysos*, *Jeffreysiopsis*, Alcira, Cynisca, *Neptuneopsis* and *Alexandria*. Furthermore, *Bulla*, Terebra, *Ancilla*, Patella, *Mitra* and *Turritella*, though they occur in other parts of the world, are in this region very richly represented in species, so that South Africa may rightly be considered the metropolis of these genera.



FROM "ANIMALS OF ALL COUNTRIES" (HUTCHINSON S PERIODICALS)

FIG. 28.—SHELL-MASS OF VERMETUS SPIRATUS, A SESSILE GASTROPOD (ABOUT NAT. SIZE)

The range of individual species is, as in other groups, limited to special areas: but ambiguity as to the precise limits of species makes it difficult to define these areas with exactness in any particular case (see SPECIES), while our ignorance as to the opportunities for dispersal and of the physiological constitution and reactions of individual species usually make it impossible to state to what extent the range of species is the expression of a definite constitutional peculiarity.

The vertical distribution of marine Gastropoda shows a broad grouping of genera according to the preference of special habitats. At the landward limit of marine conditions and often beyond the high-water mark of spring tides are found semi-terrestrial forms, such as the Littorinidae. Well up to high-water mark forms like the marine Pulmonate Siphonaria are found, while the limpets (Patellidae) range up to the same level. Between tide marks (littoral zone) are found the Fissurellidae, ormers (*Haliotis*), Onchidium, the top shells (Turbo) and dog whelks (*Purpura*), as well as those which ascend further beyond the reach of maritime conditions, such as the Littorinidae. Farther down the strand in the shallow water of the Laminarian zone occur a great variety of forms, notably the Nudibranchia. Adaptation to a particular kind of bottom is here of great importance. Burrowing forms, like *Sinum*, Natica, Cypraea and *Bullia* are more frequently found in sand, while the less active creeping forms keep to fronds of *Laminaria* and other seaweeds, the surface of algae, smooth rocks, and the like. Vermetus, which is a sessile gastropod with an uncoiled shell, forms irregular masses on rock and coral. *Eulima* and other parasitic forms are found on the external surface or in the body cavity of starfishes and also in Holothuria. *Magilus* and *Coralliophila* burrow into corals. From the shallow waters downward the gastropod fauna becomes more sparse. The late W. H. Dall, in his report on the marine Gastropoda, obtained by the "Blake" in the gulf of Mexico and the Caribbean sea, gives the following numbers of shallow and deep-water forms: Littoral species, 280; species found down to the edge of the continental shelf (about 100 fathoms) 222; deep water species, 83. Among typical abyssal genera are *Mangilia*, *Margarita* and Pleurotoma. The greatest depth from which a gastropod has been taken so far is 2,845 fathoms (U.S.S. "Albatross" off the coast of Peru).

FIG. 29.—MUCRONALIA VARIABILIS, A PARASITIC GASTROPOD SHOWING LONG PROBOSCIS

The forms which have so far been considered are those which in adult life live permanently on the sea bottom. The larvae of very many of these are floating organisms which form part of the marine plankton until they metamorphose into the adult condition. There are, however, three groups and some isolated genera of Gastropoda which permanently live floating off the bottom. These are the Heteropoda, an interesting group of Taenioglossa, some of which are curious, highly modified creatures, and the Thecosomata and Gymnosomata. The last two groups, which are sometimes erroneously united into a single group called Pteropoda, form a very large part of the minute plankton of all seas. More than 4,000 specimens of *Limacina helicina* were obtained by the "Terra Nova" in a single haul in McMurdo Sound (antarctic). The purple snail *Ianthina*, which secretes a gelatinous float for its eggs, and the nudibranchs Phyllirrhoe, *Glaucus* and Scyllaea, are similarly pelagic, while several tectibranchs such as *Aplysia* and Tethys are modified for swimming, though they seem to keep near the bottom.

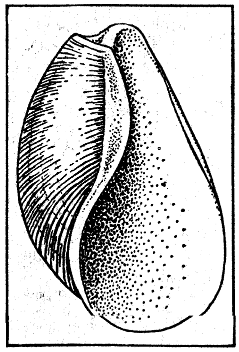

FIG. 30.—SCAPHANDER LIGNARIUS (ABOUT ½ NAT. SIZE). AFTER SARS, 1878

Fresh-water Gastropoda are omnipresent. They are found in high tarns in the Himalayas, where Lymnaea *hookeri* has been taken at a height of more than 18,000 ft. above sea level. *Aplecta hypnorum* reaches as far north as 73° N. in the Taimyr peninsula. The most characteristic and widely spread fresh-water Gastropoda are members of the *Viviparidae*, *Melaniidae*, *Theodoxus*, *Lymnaea* and Planorbis. They occupy a great variety of habitats—not only rivers, lakes, streams and smaller stretches of water, but also hot springs, torrents, the "trickles" down the faces of cliffs and marshes. They also invade cattle troughs, irrigation ditches, water mains and cisterns. As in the case of marine Gastropoda, there is some uncertainty as to the precise range and exact habitat of individual species, though in particular areas the habitat of certain species is fairly well defined. *Viviparus* viviparus, the common river snail of the British Isles, prefers slowly-flowing rivers and canals; Valvata macrostoma is usually found in marshes and ditches. Pilsbry and Bequaert record the fact that *Lymnaea natalensis* undussumae, *Physopsis* africana, and certain species of Planorbis prefer open shallow pools of small size. Certain great river systems are occupied by characteristic genera. For example, species of *Cleopatra* and Lanistes are peculiar to the Nile drainage area. Other genera are practically cosmopolitan, such as *Viviparus* and Lymnaea.

The Gastropoda which live on land are not so tolerant of external conditions as are certain other groups of terrestrial invertebrates. In Spitsbergen, which on account of divers adverse factors (low winter temperature, etc.) does not sustain a very large and varied animal population, there are no land Mollusca at all, though there are a number of Collembola, Diptera, spiders, mites and other invertebrates.

Extremes of temperature do not as a rule limit the distribution of land Gastropoda. Lack of moisture and of lime in the soil on which they live appear to be the most important factors in preventing their spread. In tropical countries lack of shade and suitable places for concealment from excessive heat and light act in a similar way. As a rule they are not found plentifully on "acid" soils. Alkins and Lebour found that of 27 species, 20 were found on rather alkaline soils (pH7.0), 14 tolerated rather more alkaline soils (pH8.0), while only four were found on acid soil (pH5). They are likewise poorly represented in deserts and other dry habitats, although they are not necessarily absent from the latter if there are opportunities for burrowing and a plentiful dewfall.

Apart from these limitations the terrestrial Gastropoda are almost world-wide in distribution. A slug *Anadenus* is found at 17,000 ft in the Himalayas, and *Chronos sublimis* was taken at more than 16 000 ft on Mt. Carstensz in New Guinea Land snails and slugs are found in well-vegetated areas, *e.g.*, woodland, pas-

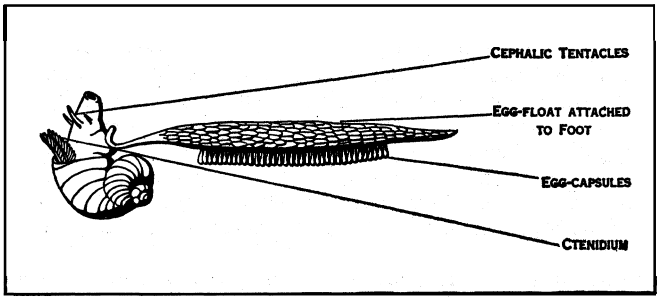
FIG. 31.—OXYGYRUS KERAUDRENI (MAGNIFIED)

tures, hedges and banks, jungle, among mosses and lichens and in more arid situations such as cliff faces, rocks and sand dunes. They burrow underground, climb trees and invade houses.

The means by which land Gastropoda are dispersed act rather more slowly than those by which marine and fresh-water forms are carried about. As a result, land snails and slugs are more localized in their distribution. Extreme cases of such restricted distribution are seen among the Achatinellidae (tree snails) of



FROM LANKESTER, "TREATISE ON ZOOLOQY" (A. & C. BLACK)

FIG. 92.— FEMALE JANTHINA WITH EGG FLOAT

the Hawaiian Islands and the Partulas of Tahiti. Many species of these groups are restricted to single valleys or ridges, and well marked mutational forms are even said to be restricted to a single tree or group of trees.

On the other hand, given suitable conditions, dispersal may be to a certain degree facilitated by their habits and constitution. Bartsch has pointed out that the Cerions of the Florida Keys, etc., which can live for four days in sea water and have the habit of fixing themselves to dead wood during estivation, have probably been transported from island to island after hurricanes which have washed away such timber from the low-lying coastal regions which the Cerions inhabit. The chief continental areas of the world are each characterized by a number of peculiar families and genera, and certain deductions as to former land connections between such areas may be made. Thus the Achatinidae, Dorcasiidae, Limicolaria, Burtoa, etc., are exclusively found in Africa and the Bulimulidae, *Drymaeus* and *Borus,* in South America. Among the land Mollusca of South America, however, are representatives of the Stenogyridae, a family characteristic of African fauna, and conversely there are *Bulimulus*-like genera in Africa.

Habits, etc.—The greater number of Gastropoda are passive animals of relatively small size and limited powers of locomotion. Usually increase of activity is associated with the carnivorous habit. Their inertia and lack of mobility are compensated by the shell, their more or less obscure appearance and secretive habits, which are their chief defenses against enemies. Among marine forms the great power of adhesion manifested by the foot prevents them from being washed away to unfavourable ground. On land the habits of burrowing and entering crevices, of estivation and hibernation are safeguards against climatic excess. Protection against drought is of great importance for animals which require much water. The shelled terrestrial forms are protected against desiccation, and in addition many have the faculty of secreting a covering (the epiphragm) to the aperture of the shell after they have retired into the iatter. The naked forms die very quickly if exposed to very dry air or strong sunlight. Both shelled and naked forms tend to secrete themselves in the daytime and to emerge in the evening or during rainy spells.

Apart from the dependence upon certain necessary external conditions Gastropoda seem to be adaptable animals and peculiarly tenacious of life. There are well-authenticated records of land snails which have lived for years without food.

Marine and terrestrial Gastropoda have to contend with other hostile forces besides the physical factors of their environment. Marine Mollusca are preyed upon by a variety of enemies. As eggs and larvae they are eaten by very many vertebrate and invertebrate animals. Fish and sea birds feed on them in the adult state and whales consume large quantities of the planktonic forms. Birds, carnivorous beetles and small mammals such as rats and mice, take a heavy toll of land snails. Ducks, geese and water beetles feed on pond and river snails.

The Gastropoda are vegetable eaters, carnivores or live on organic debris of all kinds. Most Aspidobranchia and Taenioglossa feed on plants, the marine forms browsing on algae. Natica, the Lamellariidae, and the Heteropoda are, however, carnivorous. Natica preys on lamellibranchs, through the shells of which it bores by means of an acid secretion. Captain F. Davis found that the clam *Spisula* elliptica is persistently preyed upon by *Natica alderi* on the Dogger Bank, about 88% of the clams taken on certain hauls having their shells bored by their enemy. The sessile Taenioglossa, like Vermetus, are plankton-feeders. The Stenoglossa are mainly carnivorous and prey upon other molluscs, or else they feed on carrion. Among the Opisthobranchia the Eolids feed on hydroids, the stinging cells (nematocysts) of which are retained and stored in the dorsal papillae, from which they are discharged when the animal is attacked. The majority of the land Pulmonata feed on green plants, fungi, lichens or vegetable debris. The snail slug (*Testacella*) feeds on earth worms, and *Glandina*, *Oleacina* and the Streptaxidae are similarly carnivorous.

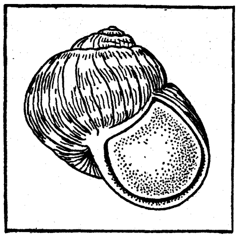


FIG. 33.—HELIX POMATIA, SHELL WITH EPIPHRAGM (ABOUT ½ NAT. SIZE)

Commensalism is not of such frequent occurrence among Gastropoda as it is among Lamellibranchia. A certain number of Taenioglossa are ectoparasitic (*Stilifer*, *Thyca*, etc.), and endoparasitic (*Entoconcha, Entocolax*) upon echinoderms. The only other animal that has so far been recorded as being the host of a gastropod is the stomatopod crustacean Gonodactylus *chiraja,* which harbours *Epistethe* gonodactyli. In their turn gastropods serve as hosts for parasites of various kinds. Certain trematode worms pass part of their life-cycle in marine and fresh-water gastropods, and in two cases the association is of serious consequence to man. The effect of these parasites on the snail is sometimes disastrous. The author of this article found a high percentage of a small gastropod *Paludestrina* ventrosa castrated

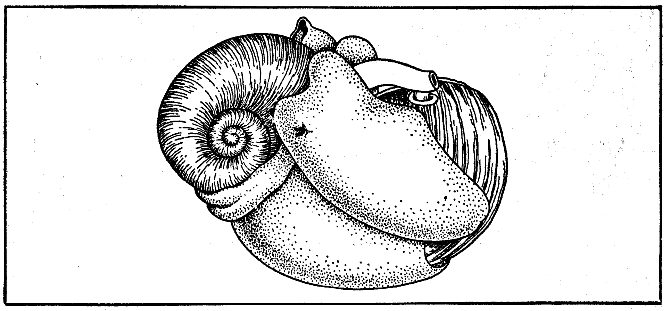

FIG. 34.—NATICA JOSEPHINIA, DRILLING A CLAM (ABOUT ¾ NAT. SIZE). AFTER ANKEL. 1938

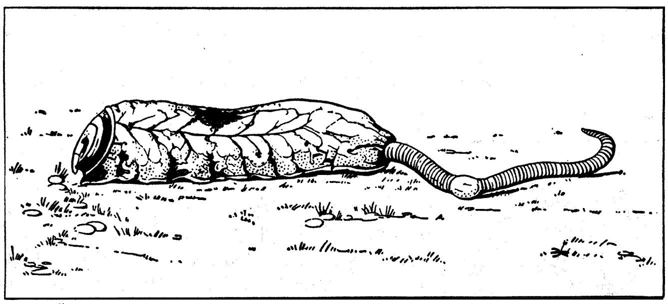
by a trematode which had invaded the reproductive organs of its host. Infection by such parasites is probably high when the parasite passes the rest of its life-cycle in a vertebrate host which preys on the gastropod, as in the case of sea birds which feed on small water snails in tidal ditches. Certain dipterous flies are parasitic on land snails and several kinds of mites are found on the latter, though it is uncertain if they are actually parasitic.

The Gastropoda are protected, as has been stated above, from the attacks of enemies by passive means (their shell and retiring habits). The shell, however, is not always an adequate safeguard from assault. Carnivorous beetles thrust their heads into the aperture and drag the inmate out. Boettger produced some very interesting and suggestive observations on the relation between attacks of this sort and the development of projections from the sides of the shell aperture in certain land snails (Otale) which are attacked by carabid beetles. Whether the colour-pattern and sculpture of the shell, which is often very elaborate, are of any protective value is uncertain at present. Observations upon the



FROM KÜKENTHAL, "HANDBUCH DER ZOOLOGIE," BY PERMISSION WALTER DE GRUYTER & CO.

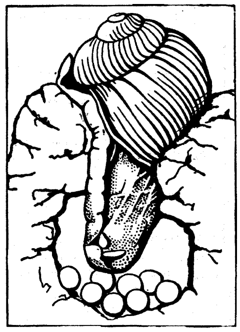
FIG. 35.— TESTACELLA EATING AN EARTHWORM

destruction of the common hedge snails (Cepaea) seem to show that birds do not discriminate between the banded and the unbanded varieties of C. *hortensis* and C. *nemoralis.* Few positive instances of protective or warning coloration are known, as the habits and enemies of the animals concerned are so imperfectly studied. Various species of *Cochlicella* certainly resemble the seed pods of the plant on which they mainly feed, and certain Clausilias are sufficiently like leaf buds; but it is difficult to decide if these resemblances are more than fortuitous. Sundry marine forms which feed on holothurians and tunicates resemble these animals in colour; but again the protective value of the resemblance is uncertain. Strombus *pugilis,* as indicated by its name, and other members of the same family, defend themselves by active blows dealt with the foot, to which the sharp-edged operculum is attached. An aggressor (such as a shell collector) may receive a deep wound.

PALAEONTOLOGY AND EVOLUTION

A great deal is known concerning the fossil remains of gastropod shells; but unfortunately we know practically nothing about the internal structure of extinct members of the class. The status of many interesting and important fossils cannot therefore be satisfactorily discussed in terms of the classification usually employed.

The earliest undoubted gastropod remains found in the Lower Cambrian (*Olenellus*) beds include spirally-coiled shells (*Raphistoma*) and others which are cup-shaped (Scenella, Palaeacmaea). The latter are usually treated as representatives of the Docoglossa (limpets) which, owing to the presence of a spiral protoconch (embryonic whorl), must be considered as descended from spiral ancestors. In somewhat later Cambrian horizons are found undoubted gastropod shells of a planospiral (nautiloid) shape (Cyrtolites, *Bel*lerophon). These were actually regarded as nautiloids by Deshayes and placed by him in the Cephalopoda. They are now held to be gastropods and have been compared with the pelagic Taenioglossan *Atlanta.* The slit at the edge of the shell-aperture comparable with that found in the rhipidoglossate *Pleurotomaria,* a genus which appeared in the Silurian (possibly in the Cambrian), justifies the inclusion of Bellerophon among the Rhipidoglossa rather than the Taenioglossa. Nevertheless, the similarity of their shell to that of the pelagic Atlanta suggests that they were of a swimming or floating habit and gives some support to the theory of Naef that the profound changes in symmetry and general organization that mark off the Gastropoda from the rest of the Mollusca were due to or associated with a change of habit, the floating pelagic life being abandoned for one spent creeping about on the sea bottom. We have, however, no grounds for believing that the Cambrian Bellerophontidae represent the most primitive grade of gastropod organization. In short, neither from these nor any other Cambrian genera do we obtain any clue as to the structure of the primitive Gastropoda.



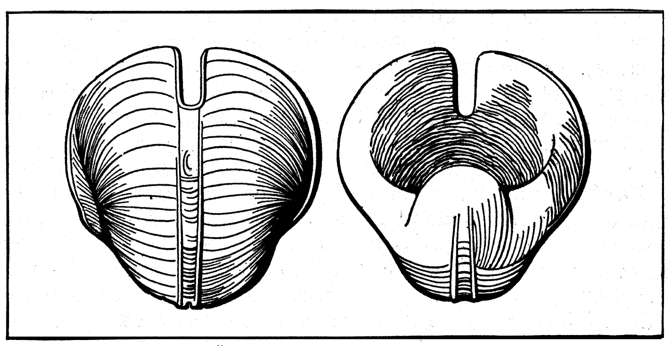
FROM MEISENHEIMER, "DIE WEINBERGSCHNECKE"

FIG 36.—OVIPOSITION OF HELIX POMATIA (ABOUT ½ NAT. SIZE)

Along with the undoubted Rhipidoglossa (Aspidobranchia) above described there are found gastropods which are usually held to be representatives of the Pectinibranchia. Stenotheca seems to be related to the taenioglossan *Capulus,* and the modern Pyramidellidae are traced to other Cambrian forms.

The Streptoneura are thus well represented in the oldest fossiliferous rocks. In lower and upper Silurian times they increased and many families still flourishing appeared at that epoch, *e.g.,* the Scalaridae, the Capulidae and Turbinidae. Many groups of Rhipidoglossa now extinct reached their developmental climax in mid-Primary times. The Pleurotomariidae, represented at the present day by four very rare species, numbered several hundred species.

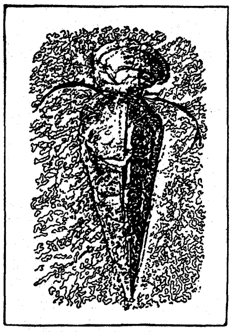
Undoubted Euthyneura do not appear until the Carboniferous, when tectibranchs like *Actaeon,* etc., are found. With this fact in mind, it is necessary for us to consider briefly one of the most



FROM A. V. ZITTEL, "GRUNDZÜGE DER PALAEONTOLOGIE"

FIG. 37.— SHELL OF A CAMBRIAN BELLEROPHON

puzzling series of fossils that have been found in Primary rocks. For a long time certain tubular shells resembling somewhat those of Pteropods have been known from Cambrian strata. They have variously been interpreted as thecosomatous pteropods, as cephalopods and tubicolous annelids. Broili (in the last edition of Zittel's *Grundzüge* der Palaontologie) retains them in the Gastropoda as an enigmatic class, the Conularida. In 1911 Walcott, in describing the Cambrian fauna of the Burgess shales (British Columbia) figured a species of the genus Hyolithes, *H.* carinatus, in which are seen structures somewhat resembling the fins of pteropods. It is not easy, however, to accept these structures as indicative of fins like those of thecosomatous pteropods, and as the shells of these forms are not in themselves sufficient clue to the identity of the animals it is better to accept Broili's verdict. Nevertheless, if these remains are subsequently proved to be those of pteropods, and if the hiatus in time between their appearance and that of the other Opisthobranchia is not merely due to the imperfection of the geological data, then we shall be driven to one of the two very interesting conclusions. It will be necessary to assume either that the Thecosomata were developed directly from the primitive streptoneuran stock and are not from the Opisthobranchia, as is usually believed, or that the Cambrian Thecosomata have nothing to do with modern "Pteropoda," but represent an early essay in pteropod-like specialization.

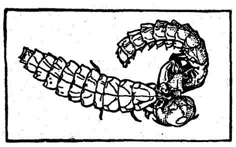


BY COURTESY OF THE SMITHSONIAN INSTITUTE
FIG. 5-. — HYOLITHES CARINATUS

The Pulmonata first appear in the Carboniferous. *Anthracopupa,* which seems to be undoubtedly a form of land pulmonate, referable to the modern family of the Ellobiidae, is found in the Carboniferous of North America. Undoubted Basommatophora (*Auricula, Lymnaea,* Planorbis) appear in the Jurassic; but it is by no means certain if the terrestrial Pulmonata actually preceded the fresh-water forms. Since their first appearance in the Carboniferous the Pulmonata, both terrestrial and aquatic, steadily increased through Secondary and Tertiary times until the present day, when they are one of the largest and most highly diversified groups of living animals.

ECONOMIC USES

Although the gastropods are not of outstanding service or disservice to man in any one respect they are of considerable importance in a number of ways. Their chief value is perhaps as an article of diet; for since the earliest stages in man's development they have been used as food. In middle and late Palaeolithic deposits in Europe, limpets, periwinkles and top shells occur. In certain "kitchen middens" of the Upper Palaeolithic in the west of Scotland they occur in such profusion as to lead one to suppose that the people who formed these deposits lived principally upon these molluscs. The natives of Tierra del Fuego, according to Tylor, used similarly to subsist on various kinds of shellfish, and gastropods of various kinds occur in their middens. At the present day H. Lang (quoted by Pilsbry) states that the Achatinas (large land snails) "are a welcome addition to the food supply of most tribes" in the Belgian Congo, and that their shells "are seen lying on refuse heaps and along the rivers." Among European peoples whelks, periwinkles and ormers are largely consumed; 889 tons of whelks and 3,245 tons of periwinkles were delivered at Billingsgate market, London, in 1922. Though land snails are eaten in only a few districts in England they are largely used in all Christian Mediterranean countries and in France and southwest Germany, where *Helix pomatia* (the Roman snail) is cultivated on snail farms.



FROM A PHOTOGRAPH BY HUGH MAIN
FIG 39 — GLOWWORM LARVAE EATING SNAIL

As bait and as the food of edible fishes, birds and whales, gastropods are of substantial indirect value to man.

The shells of Gastropoda have been put to a variety of uses by the different races of mankind. The mother-of-pearl obtained from large specimens of Turbo and *Haliotis* is imported into Europe for button-making, inlaying and sundry articles of virtu. Among native tribes shells are put to many uses. Those of *Cypraea* moneta (the money cowry) are used as currency in Africa and elsewhere, and other species of *Cypraea* are reserved as ornaments for kings and chieftains in the Pacific islands. The left-handed chank (*Turbinella rapa*) is used in the ritual of the god Vishnu in India. Trumpets are still made from Triton shells in Africa and the East, just as they apparently were among the early inhabitants of the Mediterranean. The natives of Central Africa use the large shells of various species of *Achatina* as drinking vessels and salt containers.

The rock whelk (*Murex*) is no longer fished in the Mediterranean for the sake of the dye which was used in preparing "Tyrian" purple; but other species of the muricids and of Fasciolaria are still employed for obtaining dye by various native races.

Gastropoda are obnoxious to man in at least two important connections. Considerable damage is done to crops by slugs and land snails. A small snail Zonitoides *arboreus* causes sugar-cane root disease in Louisiana. Marine gastropods are less obviously obnoxious to man, but one at least has proved itself a troublesome pest of oyster beds. This is the American slipper limpet (*Crepidula* fornicate), which was accidentally introduced many years ago into European waters and which has since then multiplied excessively and overruns the oyster beds. A more disastrous work is done by those fresh-water gastropods which harbour parasites harmful and even fatal to man and one of his more valuable domestic animals. (a) In the Middle East, in Japan, various parts of Africa and in South America and the West Indies, species of a trematode, *Schistosoma* (=Bilharzia) which cause bladder disease in man, pass part of their life cycle in various species of *Isidora* and Planorbis. A focus of this disease has been detected in Portugal, where Planorbis *metidjensis* is probably the intermediate host of the parasite. (b) The liver fluke (*Distomum hepaticum*) passes part of its life in the water snail *Lymnaea truncatula.* Sheep grazing in flooded meadows or near streams become infected with the fluke, which causes liver rot.

For the historical treatment of this subject see MOLLUSCA.

(*G.* C. R; X.)

GASTROTRICHA, a small group of fairly uniform animals which live at the bottom of ponds and the sea, hiding among the recesses of water plants or in sand and eating organic debris and Infusoria. They vary in size from one-fifteenth to one-threehundredths of an inch, and move by long cilia. Two ventral bands of regular transverse rows of cilia are usually found. The head often bears some especially large cilia. The cuticle which covers the body is usually raised into overlapping scales which may be prolonged into bristles. The body, otherwise circular in section, is slightly flattened ventrally. Chaetonotids have a protrusible pharynx armed with eversible bristles. This leads to a muscular oesophagus with a triradiate lumen, which acts as a sucking pump and ends in a funnel valve projecting into the oval stomach. The nitrogenous excretory apparatus consists of a coiled tube on each side of the stomach, ending internally in large flame cells. A cerebral ganglion rests on the oesophagus; it is continued backward as two dorsal nerve trunks. In some species there are eyes. The two ovaries lie at the level of the juncture of the stomach and rectum. The large eggs are laid among water weeds. Marine forms are hermaphrodite and fresh water forms parthenogenetic. The group is divided into two orders: Macrodasyoidea, marine, oesophageal pores present, no salivary glands: Chaetonotoidea, mostly fresh water, no oesophageal pores, salivary glands present. About 140 species are known. The group shows no clear affinities with any of the great phyla.

GATES, HORATIO (1728–1806), American general, was born at Maldon in Essex, England, in 1728. He entered the English army at an early age, and was rapidly promoted. He accompanied Gen. Braddock in his disastrous expedition against Ft. Duquesne in 1755, and was severely wounded in the battle of July g; he saw other active service in the Seven Years' War. After the peace of 1763 he purchased an estate in Virginia, where he lived till the outbreak of the American Revolution in 1775, when he was named by Congress adjutant-general. In 1776 he was appointed to command the troops which had lately retreated from Canada, and in Aug. 1777, as a result of a successful intrigue, was appointed to supersede Gen. Philip Schuyler in command of the Northern Department. In the two battles of Saratoga (*q.v.*) his army defeated Gen. Burgoyne, who, on Oct. 17, was forced to surrender his whole army. This success was, however, due largely to the previous manoeuvres of Schuyler and to Gates's subordinate officers. The intrigues of the Conway Cabal to have Washington superseded by Gates completely failed, but Gates was president for a time of the board of war, and in 1780 was placed in chief command in the South. He was totally defeated at Camden, S.C., by Cornwallis on Aug. 16, 1780, and in December was superseded by Greene, though an investigation into his conduct terminated in acquittal (1782). He then retired to his Virginian estate, then moved to New York in 1790, after emancipating his slaves and providing for those who needed assistance. He died in New York April 10, 1806. *See* J. H. Brandow, "Horatio Gates," N.Y. *State Hist. Assoc. Proc.*, vol. iii, pp. 9–19 (1903).

GATESHEAD, a municipal, county and parliamentary borough of County Durham, Eng., on the south bank of the Tyne (crossed there by five bridges), opposite Newcastle upon Tyne. Population 11961) 103,232. Gateshead is a closely built-up area rising steeply to 538 ft. above the river, the waterside being lined with wharves and quays used by coasting vessels and for shipbreaking and repairing. There is one of the largest flour mills in England. Many Gateshead residents still cross the Tyne to work in Newcastle, but as a consequence of the interwar depression there was developed after 1936 the Team Valley trading estate, an area of 700 ac. in the southwestern part of the borough, where there is a great variety of light industries which include light engineering (pumps, micro-switches, light sheet metal, etc.), clothing and packaging. Gateshead has iron, steel and engineering works, and coal mines in the vicinity. There is a large technical college specializing in engineering.

Gateshead probably grew up during Saxon times and Saxon grave covers are preserved in the present church of St. Mary. Except for a short period, the town was under the control of the bishop of Durham, who exercised the right of appointing the keeper of Gateshead tower on the 13th-century stone bridge across the Tyne. The first charter was granted by Bishop Hugh de Puiset (Pudsey) in 1164. The common seal of the borough is referred to in 1480, but under Edward VI Gateshead was merged for a time with Newcastle. The bishops of Durham incorporated nearly all the trades of Gateshead, and Oliver Cromwell continued this policy. As part of the palatinate of Durham, Gateshcad mas not represented in parliament until 1832. The county borough was created in 1889 and returns two members to parliament.

St. Mary's church dates mainly from the 14th century, but there was extensive restoration in 1854 after a fire which destroyed much of the town. Holy Trinity church, rebuilt in 18.37, incorporates the south aisle of the 13th-century monastic chapel. The Shipley art gallery was opened in 1917. The Saltwell Park museum, opened in 1933, has exhibits relating to local antiquities and industries and a natural history collection.

GATH, one of the five royal cities of the Philistines. It would seem to be identical with the Kn-tu in the lists of Thuthmose III and Gimtu (Gintu) of the Tell-Amarna letters. The name occurs several times in the Old Testament, especially in connection with the history of David. Goliath, the Philistine champion, hailed from Gath. Rehoboam is said to have fortified Gath, but Uzziah found it still a Philistine city. Sargon's records show that he took it in 712 B.C. Gath was evidently a place of importance, a walled city (2 Chr. on xxvi. 6), and it is surprising its exact location has been lost since the time of Sennacherib. The *Onomasticon* of Eusebius fixes the site near the road five Roman miles from Eleutheropolis (Beit Jibrin) on the way to Diospolis (Lydda). The Roman road is traceable and at the place indicated stands Tell es-Sāfi, a small mud village, having near it the mound marking the site of the Crusaders' castle, Blanchegarde. The village stands on a cliff about 300 ft. high in which are many caves. A fenced city on such an eminence would be remarkably strong, and surprise is felt at its complete disappearance.

The position of the village at Tell es-Sāfi has precluded a complete survey, but the excavations carried out there have, on the whole, proved disappointing and rendered the identification with Gath highly questionable. This and the fact that the sister Philistine cities do not occupy sites naturally strong, but are merely mounds on the plain, make it possible that Gath may yet be found between the coast and the Shephelah. Albright suggests 'Arāk el-Minshiyeh, or rather Ahmad el-'Araini a hill close beside it, as the site of Gath. Tell es-Sāfi he would identify with Makkedah.

See W. F. Albright, in ***Bulletin of the American School of Oriental Research,*** 1921 and 1924. (E. Ro.)

GATHAS, the name given to certain chapters of the Zend-Avesta of Zoroaster. It contains the discourses and exhortations of the prophet as well as 17 hymns written in an archaic metre. The language is of considerable antiquity, differing from that ordinarily used in the Avesta. *See* AVESTA and ZOROASTER.

GATINEAU, a river of southwestern Quebec, Canada, and long a highway for lumber trade. rises in a chain of large lakes due north of 48° N. lat., and continues southtlesterly until it merges into the Ottawa river, about one mile below the city of Ottawa. This is one of the main sites of hydroelectric power development in Canada.

GATLING, RICHARD JORDAN (1818–1903), U.S. inventor for whom the Gatling gun was named, was born in Hertford county, N.C., Sept. 12, 1818. He assisted his father in the construction and perfecting of machines for sowing cotton seeds. and for thinning the plants. In 1839 he perfected a practical screw propeller for steamboats, only to find that a patent had been granted to John Ericsson for a similar invention a few months earlier. He established himself in St. Louis in 1844, and taking the cotton-sowing machine as a basis he adapted it for sowing rice, wheat and other grains. The introduction of these machines did much to revolutionize the agricultural system in the country.

Becoming interested in the study of medicine through an attack of smallpox, he completed a course at the Ohio medical college in 1850. In the same year he invented a hemp-breaking machine, and in 1857 a steam plow. At the outbreak of the Civil War he devoted himself at once to the perfecting of firearms. In 1861 he conceived the idea of the rapid fire machine gun which is associated with his name. By 1862 he had succeeded in perfecting a gun that would discharge 350 shots per minute; but the war was practically over before the federal authorities consented to its official adoption. The invention was adopted by almost every civilized nation. Gatling died in New York city, Feb. 26, 1903.

See MACHINE GUN.

GATTY, MARGARET (1809–1873), English writer, daughter of the Rev. Alexander Scott (1768–1840), chaplain to Nelson, was born at Burnham, Essex, and married in 1839 the Rev. Alfred Gatty, vicar of Ecclesfield, near Sheffield. Mrs. Gatty is remembered for her many admirable books for children, the most famous of which is the *Parables from Nature* (5 vols. 1855–71). As "Aunt Judy" of *Aunt Judy's Magazine* she became the personal friend of thousands of her child readers and correspondents.

GAUCHOS, a nomadic South American race inhabiting the Argentine Republic and Uruguay of mixed Spanish and Indian descent. They are tall, handsome, strikingly dressed and of great endurance, with a combination of dignity and arrogance in their bearing. Their chief occupation is leather making and ranching, the wild conditions under which they live having made them excellent horsemen, skilled in the use of the lasso and bolas (*q.v.*).

GAUDEN, JOHN (1605–1662), English bishop and writer, reputed author of the *Eikon Basilike,* was born at Mayland, Essex, where his father was vicar. Educated at Bury St. Edmunds and at St. John's college, Cambridge, he seems to have been at Oxford until 1630. when he became vicar of Chippenham. His sympathies were at first with the parliamentary party. He was chaplain to Robert Rich, second earl of Warwick, and preached before the House of Commons in 1640. Apparently his views changed as the revolutionary tendency of the Presbyterian party became more pronounced, for in 1648/9 he addressed to Lord Fairfax *A Religious and Royal Protestation . . .* against the proceedings of the parliament. Under the Commonwealth he faced both ways. At the Restoration he was made bishop of Exeter. He complained to Hyde, earl of Clarendon, of the poverty of the see, and based claims for a better benefice on a certain secret service, which he explained on Jan. 20, 1661 to be the sole invention of the *Eikon Basilike, The Pourtraicture of his Sacred Majestie in his Solitudes and Sufferings,*put forth within a few hours after the execution of Charles I. as written by the king himself. To which Clarendon replied that he had been before acquainted with the secret and had often wished he had remained ignorant of it. Gauden was advanced in 1662, not as he had wished to the see of Winchester, but to Worcester. He died on May 23 of the same year.

See *Private Correspondence between Chas. I. and Sir Ed. Nicholas* pubd. as vol. v. of the *Memoirs of John Evelyn* (1827); C. Wordsworth, *Who wrote Eikon Basilike?* two letters addressed to the archbishop of Canterbury (1824), and *King Charles the First, the Author of Icon Basilikè* (1828); E. J. L. Scott's introduction to his reprint (1880) of the original edition; articles in the *Academy,* May and June 1883, by C. E. Doble; another reprint edit. by E Almack for the King's Classics (1904); and E. Almack, *Bibliography of the King's Book* (1896) which summarizes etc. the arguments on either side and gives a full bibliography.

GAUDÍ, ANTONIO (ANTONIO GAUDÍ Y CORNET) (1852–1926), Catalan architect, sculptor and ceramic artist, noted for the spatial freedom and organic unity of his work, was born at Reus, Tarragona, Spain, on June 26, 1852. He studied at the Barcelona school of architecture. Valued early in the 20th century primarily for his "bizarre" imagination, he became appreciated as a great architectural inventor, as a constructer and as a sculptor of organic form. He studied natural form and developed an expressive *art nouveau* by giving vitality to line, space and volume as well as by original constructions (sloping pillars to take diagonal pressure). Barcelona was the centre of this deeply religious man's steadfast and uncompromising life work. For his patron, Count Guell, he built there a town house (1885–89), the "Palace Güell," and "Park Güell" (1900–02). In this last he made brilliant use of raised ground to create a grandiose children's play terrace. This is bounded by a bench formed of swinging curves, which he encrusted with coloured tile mosaics, carrying out, even at that time, the Cubist "collage" principle in ceramic remainders.

The church of the Holy Family (1883–1926) was the problem of his life, and it remains a huge unfinished building, of significant plan, with brilliant tower construction and ornamental figures. Unfinished also was his best monumental building, the Guell colony church at S. Coloma de Cervello (1898–1914).

Gaudi deserts the original neo-Gothic elements and embodies new constructive ideas. His apartment houses and office buildings in the Paseo Gracia — Casa Batlló (1905–07) and Casa Milá (1905–10) — expound a style which simultaneously exploits façade and space. His fluid lines, the fantastic sculptural imagination of his chimneys and ventilators and the fluctuating iron trelliswork of gates and balconies here reach their highest expression.

Gaudi died at Barcelona on June 7, 1926. (C. G.-WR.)

GAUDIER-BRZESKA, HENRI (1891–1915), Franco-English sculptor, an outstanding exponent of the Vorticist movement, was born at St. Jean-de-Braye. Loire, Oct. 4, 1891, the son of a woodworker, Joseph Gaudier. (The name Brzeska was that of his devoted Polish companion Sophie Brzeska.) Although he was given a scholarship to study art at Bristol, he was largely self-taught. The poet Ezra Pound became his patron and propagandist; the writer and painter Wyndham Lewis drew him into the Vorticist movement just before World War I. The early carvings of Sir Jacob Epstein affected him, but he showed original attitudes toward form and content. He was an admirable linear draftsman. His letters are deeply moving.

Gaudier-Brzeska was killed in combat in World War I at Neuville-St.-Vaast, June 5, 1915. Much of his work is at the South Kensington museum.

See Ezra Pound, *Gaudier-Brzeska: His Life and Work* (1916); Harold S. Ede, *Savage Messiah* (1931); Horace Brodzky (ed.), *Gaudier-Brzeska, Drawings* (1946). (L. E. K.)

GAUDY, as a noun, in the sense of rejoicing or feast, a word used of a commemoration dinner at an Oxford college.

GAUGAMELA (ARBELA), BATTLE OF (Oct. 1, 331 B.C.). After his defeat at Issus, Darius assembled a vast horde of men at Babylon. Thence, marching northwards, he crossed to the left bank of the Tigris, and established his magazines and harems at Arbela (Erbil). From Arbela he moved forward to Gaugamela, some 32 miles westwards. Having conquered Egypt, Alexander marched northwards through Palestine, crossed the Tigris at Bezabdi, north of modern Mosul, and, learning of the Persian king's whereabouts, he at once moved forward with a picked force of cavalry. Having located the enemy, he rested his army for four days and fortified his camp. Whilst this was taking place, Darius deployed his army on the plains of Gaugamela, which he converted into a huge parade ground by levelling it. On the fourth night Alexander advanced, but when $3\frac{1}{2}$ miles distant from him he called a halt, and assembled his generals. Parmenio suggested that they should encamp where they were, and reconnoitre the ground and the enemy. To this Alexander agreed, and whilst the camp was being fortified, "he took the light infantry and the companion cavalry and went all round, reconnoitring the whole country where he was about to fight the battle." On his return he called together a conference at which he discussed what he had seen, and urged upon his generals the importance of the immediate execution of orders. Whilst the soldiers were resting, Parmenio came to Alexander's tent and suggested a night attack. This proposal Alexander refused to consider, his reason (more probable than the story of his disdaining such craft) being that in the approaching battle he had planned to deliver a decisive blow, and he knew well the difficulties coincident with night operations. Having rejected this advice, Alexander drew up his army. The phalanx was marshalled in the centre, the right wing consisting of its three right divisions, the hypaspists, the agema and the Companion cavalry; the left wing of the remaining three divisions of the phalanx, the Grecian cavalry and the Thessalian cavalry. Thus far the order of battle was normal. The problem which faced Alexander was very similar to that which confronted Cyrus in Xenophon's account of the battle of Thymbra. Alexander applied the tactics

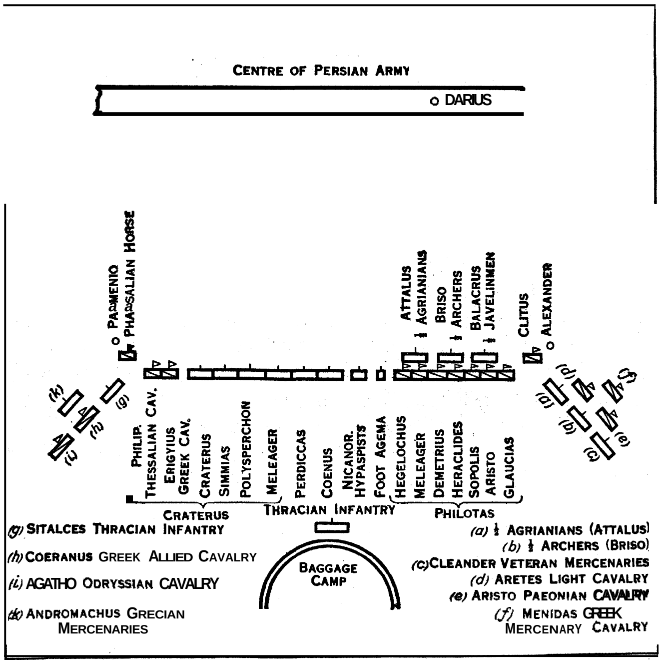

FIG. 1.—DIAGRAM OF BATTLE OF GAUGAMELA (ARBELA), OCT. 1, 331 B.C., SHOWING DISPOSITION OF ALEXANDER'S ARMY UNDER SEPARATE GENERALS

The Greeks numbered 7,000 cavalry and 40,000 foot, while the Persians were probably five times as strong. The battle ended in the complete shattering of the Persian army

made use of at Thymbra. Behind his front he drew up a reserve force consisting of two flying columns; these he posted one behind each wing at an angle to the front, so that they might take the enemy in flank should an attempt be made to turn the wings; or, if this did not take place, then they were to wheel inwards and reinforce the main army. In front of the Companion cavalry he posted half the Agrianians, archers and javelin-men to oppose the charge of the Persian chariots. The baggage guard consisted of Thracian infantry. In all Alexander's army numbered 7,000 cavalry and 40,000 foot, the Persians were, in all probability, about five times as strong. This order of battle should be kept clearly in mind, for, as it will be seen, it was through Alexander's ability to develop his tactics from it that he won the battle.

The Battle.—The initiative was taken by Alexander. He advanced, not directly on the Persians, but towards their left, and so compelled Darius to move on to the unlevelled ground. Darius, fearing that his chariots would become useless, ordered his left-wing cavalry to ride round Alexander's right and halt him. Alexander met this attack with his light cavalry, and a general cavalry engagement took place. Then Darius launched his chariots, but they never got home, as the charioteers were shot down by the light infantry in front of the Companion cavalry. The Persian left was now unmasked and in some confusion, whereupon Alexander wheeled round the Companion cavalry and with the four right divisions of the phalanx he led them towards the gap formed in the Persian front by the advance of their cavalry, and made straight for Darius. This cavalry charge, closely supported on its left by the dense array of bristling pikes in echelon, smote such terror into Darius that he fled the field. Meanwhile the Persian cavalry on Alexander's original right, finding their rear threatened took to flight, and the Macedonians, following up the fugitives, slaughtered them. The left wing, on account of the diagonal march, was in rear of the right, and the impetuous advance of Alexander appears to have created a gap between it and the right wing. Through this gap the Indian and Persian cavalry burst, and advanced towards the baggage camp. While this action was in progress, the Persian cavalry on Darius's right wing rode round Alexander's left wing and attacked Parmenio in flank. Parmenio, now completely surrounded, sent a messenger to Alexander informing him of his critical situation. He received this message whilst he was pursuing the fragments of the Persian left wing, and at once wheeled round with the Companion cavalry, and led them against the Persian right. The Persian cavalry, who were now falling back, finding their retreat menaced, fought stubbornly. "They struck and were struck without quarter" but were routed by Alexander. The pursuit was now taken up, and was continued until midnight, when a forced march was made on Arbela. About 32 miles were covered, but in vain, for Darius made good his escape. Arrian states that the Persians lost 300,000 in killed and Alexander only 100, and 1,000 horses. These figures are obviously unreliable.

Tactics.—This battle was not won by reckless courage but by audacity tempered by a wonderful grasp of what the enemy intended to do, and how his actions could be turned to advantage. This is clearly seen if the diagrams are studied. The order of battle is the normal one, but out of it is developed a very different type of attack to those of the battles of Granicus and Issus. Alexander is never obsessed by past successes, also he never invents what may be called experimental attacks. What he does is to measure up his antagonist and to act accordingly: First he seeks information; this is the foundation of his security, for in spite of his audacity security is always the foundation of his offensive action. Once he has made up his mind he distributes his force economically; his order of battle consists of a protective left and an offensive right, and in his right he concentrates his punch. Having secured his plan, he rapidly moves towards the Persian left flank, not only to get beyond the level ground, but to prevent a double envelopment, and to increase the distance between his left

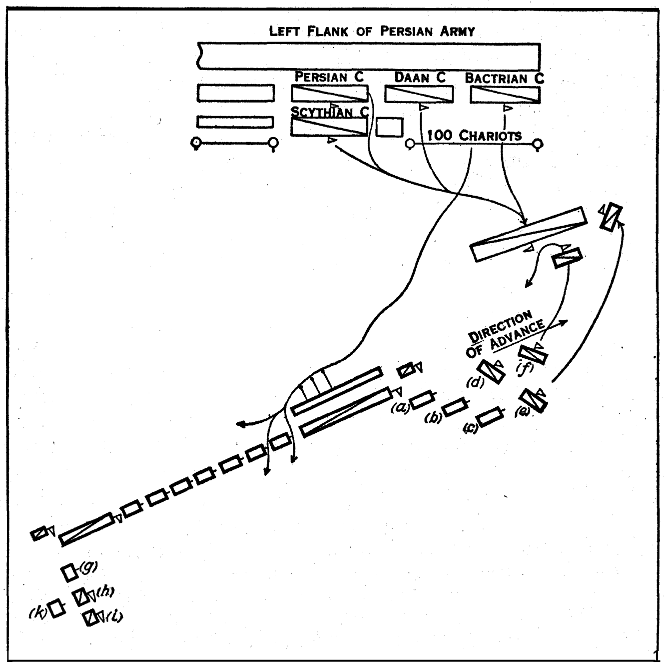

FIG. 2.—ALEXANDER'S FIRST ATTACK ON THE PERSIAN EXTREME LEFT

This manoeuvre compelled Darius to uncover his left centre, thereby leaving a gap, through which Alexander foresaw he could penetrate the Persian line

and the Persian right. This will enable him to shatter the Persian left before the Persian right can annihilate his own left. Also, if he can only draw the Persian right well inwards, should he be able to smash the enemy's left, he will then be in a position to take their right in reverse. In diagram 2, the position of Darius, the decisive point, is off the plan to the left, yet it is the point Alexander intends to strike. He opens the battle by moving away from it, and so compels Darius to uncover the immediate left flank of his centre. Though now well placed to attack in oblique order the outer flank of the Persian left wing he does not do so, for the decisive point is not the left wing but the centre. In diagram 3 it will be seen that under cover of his right flying column, he suddenly obliques inwards, and concentrates superiority of force opposite the gap once filled by the Scythian and Persian cavalry. Through this gap he charges at top speed and strikes Darius in *rear*. This charge succeeds, not because the Companion cavalry are advancing at top speed, but because their mobility is developed from the security afforded by the flying column and the phalanx.

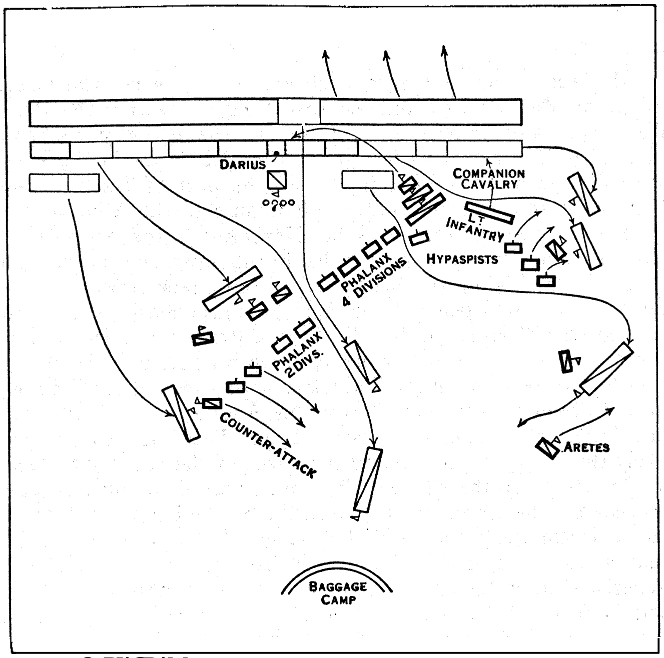

FIG 3—DIAGRAM SHOWING PENETRATION TACTICS OF ALEXANDER
By suddenly turning inwards, under cover of his right flying column, Alexander concentrated superior forces in the gap caused by his initial manoeuvre (see fig. 2) and was thus able to take the army of Darius in the rear

The penetration by shock is absolutely successful. Gaugamela is one of the most perfect examples of the tactics of penetration to be found in history.

GAUGUIN, PAUL (1848–1903), French painter, one of the pioneers of the Post-Impressionist movement. He was born in Paris on June 7, 1848, the son of a journalist from Orleans and of a mother partly of Peruvian descent He spent his childhood in Peru and at Orleans, and after having done his military service in the marines he entered the banking firm of Bertin in Paris in 1871. In 1873 he married Mette-Sophie Gad, a Danish lady. In 1875 he began to spend his free time in painting. Encouraged by his friend, C. Pissaro, he acquired the Impressionist technique. His interest in art took more and more hold of him, and in 1881 he decided to give up his appointment at the bank. His means soon gave out and after an unfortunate attempt to get assistance from his wife's relations at Copenhagen, he separated from her and his children, returning to Paris without means. A period of travel followed. He worked on the island of Martinique (1887–88) and then went to Pont Aven in the Bretagne, where he soon became the leading spirit of a group of painters.

The movement thus started was known as "Synthesism." Gauguin himself was not a theorist. He wished to be rid of all that might intervene between the artist's vision and his canvas; but the other members of the group felt otherwise. Emile Bernard lectured on the synthetic doctrine, Filiger contributed his mediaeval fancies, Sérusier propagated the new ideas; he clarified the vague doctrines of Gauguin The new tendency is explained by Maurice Denis, one of Sérusier's disciples in Paris; he says: "It was on our reassembling in 1888 that the name of Gauguin was revealed to us by Sérusier, who had just returned from Pont Aven and who allowed us to see not without a show of mystery the lid of a cigar box, on which we could make out a shapeless landscape synthetically designed in violet, vermillion, Veronese green and other unmixed colours, just as they are pressed out of a tube, almost without white in them. 'How does that tree appear to you,' Gauguin had asked—'very green?—Well then use green—the finest green on your palette—and that shadow is rather blue? Do not be afraid to paint it as blue as possible.' " "Thus," continues Denis, "was presented to us for the first time the fruitful conception of the plane surface covered with colours put together in a certain order . . . we learned that every work of art is a transposition, a caricature, the passionate equivalent of a sensation which has been experienced. . . . Gauguin freed us from all restraints which the idea of copying placed on our painter's instinct. . . . Henceforth we aspired to express our own personality. . . . If it was permissible to use vermillion in painting a tree which seemed to us at that moment reddish . . . why not stress even to the point of deformation the curve of a beautiful shoulder, exaggerate the pearly whiteness of a carnation, stiffen the symmetry of boughs unmoved by a breath of air?" *(Theories 1890–1910,* published in 1920.)

Thus Gauguin's ideas were taken up by a group of young students in Paris, which included Bonnard Denis, Ibels, Ranson, Vuillard and Maillol. In 1889 "the school of Pont Aven" moved to Pouldu near by. Their life there and the inn at Pouldu, the rendezvous of artists, which was adorned by Gauguin, was described by Mr. Ch. Chassé in *l'Occident* (1903). In 1888 Gauguin went to Arles to meet his friend, Van Gogh. The two artists had planned to work together, but Van Gogh succumbed to an attack of lunacy and Gauguin left him. *(See* P. Gauguin, *Avant et Après.)* Among Gauguin's best work of this period are "Le Christe Jaune," and "La Lutte de l'Ange avec Jacob." He copied Manet's "Olympia," which he considered one of the masterpieces of the age, he etched a portrait of Mallarmé, executed some lithographs and carved reliefs in wood. But in spite of all his efforts his financial position did not improve. His journey to Martinique had inspired him with a love for the tropics and he conceived a plan of going to the South Seas where he could live cheaply and devote himself to his vocation. He sold all his pictures by auction for 9,860 frcs. and went to the island of Tahiti in 1891. There he lived a simple life with the natives which he described in his autobiographical novel *Noa* Noa.

On his return to Paris he exhibited his paintings at Durand Ruel, but the life in the big city no longer suited him; he left for Tahiti in 1895 never to return. Out there, inspired by his admiration for primitive life, for the luminous colour of the tropical landscape, he produced paintings of great decorative beauty and originality. "L'esprit Veille," "Seule," "Devant la Case," "La Fuite" and "Jours Delicieux" are among his most notable works. They represent the bronzed native Maoris in their surroundings of exotic plants and primitive dwellings. In 1901 he moved to Dominiha on the Marquesas isles. He built himself a house and decorated it with carvings and paintings. The natives treated him as one of their own and he sided with them against the overbearing European representatives of the administration. The end of his life was approaching; he lived in extreme want; in order to pay his taxes he worked in a Government office for 6 frcs. a day; his health was failing. He died on May g, 1903, and was buried in the Mission cemetery. Victor Ségalen, a navy doctor and writer, who was in the Marquesas isles at the time, gave a vivid and sad account of his end *(Mercure de France,* June 1904).

His last important picture, entitled "D'où venons nous? Que sommes-nous? où allons-nous?" is one of his masterpieces. It was painted under the shadow of an attempted suicide. His description of this work in a letter to his friend, D. de Montfreid, is of interest, as it throws light on his artistic creed. "Before I died I wished to paint a large canvas that I had in mind, and I worked day and night that whole month in an incredible fever. To be sure it is not done like a Puvis de Chavannes, sketch after nature, preparatory cartoon, etc. It is all done straight from the brush on the sackcloth full of knots and wrinkles, so the appearance is terribly rough. . . . I put in it all my energy, a passion so dolorous, amid circumstances so terrible, and so clear was my vision that the haste of the execution is lost and life surges up. It does not stink of models, of technique, or of pretended rules, of which I have always fought shy, though sometimes with fear. It is a canvas four metres, fifty long and one metre, seventy high. The two upper corners are chrome yellow, with an inscription on the left and my name on the right, like a fresco whose corners are spoiled with age and which is appliquéed upon a golden wall. To the right at the lower end a sleeping child and three crouching women. Two figures dressed in purple confide their thoughts to one another. An enormous crouching figure, out of all proportion and intentionally so, raises its arms and stares in astonishment upon these two, who dare to think of their destiny; a figure in the centre is picking fruit; two cats near a child; a white goat; an idol, its arms mysteriously raised in a sort of rhythm seems to indicate the Beyond. Then, lastly, an old woman nearing death appears to accept everything. . . . She completed the story. . . . It is all on the bank of a river in the woods. In the background the ocean, then the mountains of a neighbouring island. Despite changes of tone the colouring of the landscape is constant-either blue or Veronese green. Where does the execution of a painting commence and where does it end? At that moment when the most intense emotions are in fusion in the depths of one's being, when they burst forth like lava from a volcano . . .? The work is created suddenly, brutally if you like, and is not its appearance great, almost superhuman?"

Gauguin, then, had left Impressionism behind; he had profited by its technique in the use of using colours pure and unmixed; but his work was impregnated with symbolism, his design was expressive, his colour arrangements decorative. His influence on modern art was far-reaching. Besides the school of Pont Aven and the Synthesists, he inspired such artists as Ed. Munch and Toulouse Lautrec. His ideas revolutionized poster design and design in all Arts and Crafts work (Van de Velde, Lemmen, Gallé-Nancy.) His primitive woodcarving and his terra-cotta figure called "Oviri," the Tahitan Diana, was admired by such artists as Picasso and led to the appreciation of nrgro sculpture. His lithographs and woodcuts opened new fields in the graphic arts.

GAUHATI, headquarters town of Kamrup district, Assam, India, on the Brahmaputra. Pop. (1951) 43,615.

During the 17th century it was taken and retaken by Mohammedans and Ahoms eight times in 50 years, but in 1681 it became the residence of the Ahom governor of lower Assam, and in 1786 the capital of the Ahom raja. On the cession of Assam to the British in 1826 it was made the seat of the British administration of Assam, and so continued till 1874, when the headquarters were moved to Shillong in the Khasi hills.

Two much-frequented places of Hindu pilgrimage are situated in the immediate vicinity, the temple of Kamakhya on a hill 2 mi. west of the town, and the rocky island of Umananda in the Brahmaputra.

Gauhati is an important centre of river trade, and the largest seat of commerce in Assam. It is the seat of the only university in the state, Gauhati university (established 1948).

GAUL, WILLIAM GILBERT (1855–1919), **U.S.** artist known for his Civil War scenes, was born in Jersey City, N.J., on March 31, 1855. He was a pupil of J. G. Brown and L. E. Wilmarth, and he became a painter of military pictures. He was elected an associate of the National Academy of Design in 1880, and in 1882 a full academician, and in the latter year became a member of the Society of American Artists. His important works include "Charging the Battery," "News From Home," "Cold Comfort on the Outpost," "Silenced," "On the Look-out" and "Guerrillas Returning From a Raid." He died in New York, Dec. 21, 1919.

GAUL, Lat. Gallia, the name of the two chief districts known to the Romans as inhabited by Celtic-speaking peoples, (a) Gallia *Cisalpina* or *Citerior, i.e.,* North Italy between Alps and Apennines and (b) the far more important Gallia *Transalpina* or Ulterior, usually called Gallia simply, the land bounded by the Alps, the Mediterranean, the Pyrenees, the Atlantic and the Rhine, *i.e.,* modern France and Belgium with parts of Holland, Germany and Switzerland.

(a) Gallia Cisalpina (*q.v.*) was mainly conquered by Rome by 222 B.C.; later it adopted Roman civilization, whence it was often known as "*Gallia* Togata"; about 42 B.C. it was united with Italy.

(b) Gaul proper first enters ancient history when the Greek colony of Massilia was founded (?600 B.C.). During the Punic Wars it became important to Rome as the highway to Spain (*q.v.*). In 121 B.C. the coast from Montpellier to the Pyrenees (*i.e.,* all that was not Massiliot), with its port of Narbo (mod. Narbonne) and its trade route by Toulouse to the Atlantic, was formed into the province of Gallia Narbonensis and Narbo itself into a Roman municipality. Gradually the province was extended north of Massilia, up the Rhone, while the Greek town itself became weak and dependent on Rome. Narbonensis was distinguished from "Gallia Togata" as "Gallia Bracata," from the long trousers (bracae, incorrectly braccae) worn by its inhabitants.

Gallia Narbonensis apart, Gaul was at that time divided among three more or less distinct peoples, the Aquitani, the Gauls (who called themselves Celts), and the Belgae. These occupied respectively the south, the centre and the north of the country between the Pyrenees and the Rhine. The tribes were numerous. Prominent among them were the Helvetii, the Sequani and the Aedui in the basins of the Rhone and the Saône; the Arverni in the Cévennes; the Senones and Carnutes in the basin of the Loire; the Veneti and other Armorican tribes between the mouths of the Loire and the Seine. These were all Celts. The Nervii, Bellovaci, Suessiones, Remi, Morini, Menapii and Aduatuci were Belgic; the Tarbelli and others were Aquitani; while the Allobroges inhabited the north of Gallia Bracata. (See CELT and articles on the chief tribes.)

As the result of the Gallic wars (58–51) of Caesar (*q.v.*) the whole of Gaul to the Rhine and the ocean became Roman territory, and in 49 Massilia was annexed. As settled by Augustus, and in part perhaps also by his successor Tiberius, Gaul fell into five administrative areas:—

(i.) Narbonensis, that is, the land between Alps, sea and Cévennes, extending up the Rhone to Vienne, is a sun-steeped southern region, the home of the vine and olive, of the minstrelsy of the Provençal and the exuberance of Tartarin. Augustus found it already familiar with Roman ways and civilized enough to need no garrison. Accordingly, it was governed by a proconsul and freed from the burden of troops, while its local government was assimilated to that of Italy. The old Celtic tribes were broken up; instead, municipalities of Roman citizens were founded to rule their territories. Thus the Allobroges now disappear and the *colonia* of Vienna (Vienne) takes their place; the Volcae vanish, and we find Nemausus (Nimes). By A.D. 70 the area was "Italia verius quam provincia" (Pliny). The Gauls obviously had a natural bias toward the Italian civilization, and there soon became no difference between Italy and southern Gaul.

(ii.-iv.) Across the Cévennes lay Caesar's conquests, Atlantic in climate, new to Roman ways. The whole area, often collectively styled "Gallia Comata," from the inhabitants wearing their hair long, often "Tres Provinciae," was divided into three provinces, each under a *legatus* pro praetore appointed by the emperor, with a common capital at Lugdunum (Lyons). The three were: Aquitania, reaching from the Pyrenees almost to the Loire; Lugdunensis, the land between Loire and Seine, reaching from Brittany in the west to Lyons in the southeast; and Belgica in the north. Here also it was found possible to dispense with garrisons, not because the provinces were as peaceful as Narbonensis, but because the Rhine army was close at hand, while the splendid system of roads rendered the movement of troops easy. As befitted an unromanized region, the local government was unlike that of Italy or Narbonensis. Roman municipalities were not unknown, though very few; the local authorities were the magistrates of the old tribal districts. In general, Roman civilization was accepted more or less rapidly; in particlar, the worship of "Augustus and Rome," devised by the first emperor as a bond of state religion connecting the provinces with Rome, was eagerly welcomed. It agrees with the vigorous development of this worship that the three provinces, though romanized, retained their own local feeling. As late as the 3rd century. the cults of Celtic deities (Hercules Magusanus, Deusoniensis, etc.) were revived, the Celtic *leuga* reintroduced instead of the Roman mile on official milestones, and a brief effort made to establish an independent, though romanized, Gaul under Postumus and'his short-lived successors (A.D. 259–273). The *chefs-lieux* of the tribes became practically, though not officially, municipalities, and many of these towns reached considerable size and magnificence of public buildings. But they attest their tribal relations by their appellations, which are commonly drawn from the name of the tribe and not of the town itself; to this day Amiens, Paris, Rheims, Soissons and others perpetuate the memory of tribes like the Ambiani, the Parisii, the Remi, and the Suessiones.

(v.) The fifth division of Gaul was the Rhenish military frontier, which was organized as two military districts. The northern one was the valley of the Meuse and that of the Rhine to a point just south of Bonn; the southern was the rest of the Rhine valley to Switzerland. Each district was garrisoned at first by four, later by fewer, legions, which were disposed at various times in some of the following fortresses: Vetera (Xanten), Novaesium (Neuss), Bonna (Bonn), Mogontiacum (Mainz), Argentorate (Strasbourg) and Vindonissa (Windisch in Switzerland). At first the districts, being purely military, were called after the garrisons "exercitus Germanicus superior" (south) and "inferior" (north). Later one or two municipalities were founded — the oldest, Colonia Agrippinensis, at Cologne in A.D. 51—and about A.D. 80–90 the two "Exercitus" were turned into the two provinces of Upper and Lower Germany (see GERMANY).

These provincial divisions were modified by Diocletian, but without seriously affecting the life of Gaul. The whole country continued Roman and fairly safe from barbarian invasions till after 400. In A.D. 407 a multitude of Franks, Vandals, etc., broke in; the three kingdoms of the Visigoths, Burgundians and Franks began to form, and in A.D. 486 Clovis the Frank brought Roman rule in Gaul to a final end. (F. J. H.; G. M.)

GAULLE, CHARLES ANDRÉ JOSEPH MARIE DE: *see* DE GAULLE, CHARLES ANDRÉ JOSEPH MARIE.

GAUR or LAKHNAUTI, a ruined city of India, in the Malda district of West Bengal. The ruins are situated about 8 mi. south of English Bazar, the civil station of the district of Malda, and on the eastern bank of an old channel of the Ganges. It is said to have been founded by Lakshman, the Sena king of Bengal, and its ancient name was Lakshmanavati, corrupted into Lakhnauti. Its known history begins with its conquest at the end of the 12th century by the Mohammedans, who retained it as their capital in Bengal for more than 300 years. The seat of government was transferred about 1340 to Pandua (*q.v.*), also in Malda district.

When Pandua was in its turn deserted (about 1455), Gaur once more became the capital, but in 1564 because of a change in the course of the Ganges it was abandoned for Tanda, a place somewhat nearer the main stream. Gaur was temporarily reoccupied by Akbar's general in 1575, when Daud Shah, the last of the Afghan dynasty, refused to submit to the Mogul emperor. This occupation was followed by a virulent epidemic, which depopulated the city and completed its downfall.

The finest ruin in Gaur is that of the Great Golden mosque, also called Bara Darwaza, or "12-doored" (1526). The Small Golden or Eunuch's mosque has fine carving and is faced with stone fairly well preserved. The Tantipara mosque (1475–80) has beautiful molding in brick, and the Lotan mosque is unique in retaining glazed tiles.

The citadel mas entered through a magnificent gateway called the Dakhil Darwaza (?1460–74). At the southeast comer was a palace surrounded by a wall of brick 66 ft. high.

GAUR (*Bibos gaurus*), the wild ox of India. The gaur, which extends into Burma and the Malay Peninsula, is the typical representative of an Indo-Malay group of wild cattle characterized by a ridge on the withers, compressed horns, and white legs. The gaur, which reaches a height of nearly 6 ft. at the shoulder, is characterized by the forward curve and great elevation of the ridge between the horns. The colour is blackish-gray. Hill forests are the resort of this species.

GAUSS, (JOHANN) CARL FRIEDRICH (1777–1855), German mathematician and scientist, to whom history has accorded a place with Archimedes and Newton as one of the three greatest mathematicians of all time, is frequently called the founder of modern mathematics. The importance of his work in astronomy and physics is scarcely less than that in mathematics. His full stature became known only in the 20th century since many of his discoveries were published long after his death. During his lifetime he published 155 titles. He was born at Brunswick, April 30, 1777, and died at Gottingen, Feb. 23, 1855.

Gauss was of Nether-Saxon peasant origin. Many anecdotes refer to his prodigious precocity, particularly in mental computation. As an old man he said facetiously that he could count before he could talk. In elementary school he soon impressed his teacher, who is said to have convinced Gauss's father that the son should not learn a trade, but follow a learned profession. In secondary school, after 1788, he rapidly distinguished himself in ancient languages and mathematics. At the age of 14 Gauss was presented to the duke of Brunswick at court, where he was permitted to exhibit his computing skill. On this occasion he was given several mathematical textbooks. Until his death in 1806 the duke generously supported Gauss.

Gauss conceived almost all his fundamental mathematical discoveries between the ages of 14 and 17. In 1791 he gave attention to the arithmetico-geometric mean. Gauss now manifested his outstanding trait of critical analysis and thus began to do creative work. He called this acuteness the *rigor antiquus*. In 1792, the year that he entered the three-year Collegium Carolinum in Brunswick, his interests led him to question the foundations of geometry. Gauss shunned controversy, and though a pioneer he published nothing on non-Euclidean geometry. In 1793–94 he did intensive research in number theory, especially on the frequency of primes. He made this study his life's passion and is regarded as its modern founder. Gauss obtained a copy of Newton's *Principia* in 1794; in that year he discovered the method of least squares. In 1795 he completed important research on quadratic residues.

Gauss studied at the University of Gottingen from 1795 to 1798; there he had access to the works of Fermat, Euler, Lagrange and Legendre, the masters in his field. He soon realized'that he too was a master and decided to write a book on the theory of numbers. It appeared in 1801 under the title *Disquisitiones arithmeticae;* this classic work, establishing the theories of cyclotomy and arithmetical forms, usually is held to be Gauss's greatest accomplishment. In studying the roots of the equation $x^p = 1$, Gauss discovered on March 30, 1796, that the regular heptadecagon (polygon with 17 sides) is inscriptible in a circle, using only compasses and straightedge — the first such discovery in Euclidean construction in over 2,000 years. Gauss had been undecided whether to make mathematics or philology his life work; he now resolved to devote his life to the former.

In late 1796 Gauss was busy with research in infinitesimal calculus and algebra and began an investigation of the lemniscate functions; he found a proof of Lagrange's theorem (reversion formula) and discovered the connection between the elliptic quadrant and the arithmetico-geometric mean, as well as its connection with the power series whose exponents are squares. The theories of elliptic functions and of linear differential equations were rediscovered some decades after Gauss had developed them for himself; he discovered double periodicity and operated with the general theta functions.

His interest then turned to astronomy as he developed formulas for the calculation of parallax in April 1799. He went to Helmstedt in Dec. 1799 to live in the home of the mathematician J. F. Pfaff and to use the university library. That month he found the relation of the arithmetico-geometric mean to the elliptic integral of the first order. He returned to Brunswick at Easter in 1800; in May he developed his formula for determining the date of Easter and promptly published it.

The discovery of Ceres, the first planetoid, by Giuseppe Piazzi in Palermo on Jan. 1. 1801, gave Gauss the opportunity of revealing, in a spectacular way, his remarkable mathematical superiority over all his contemporaries. His calculations of the orbit of Ceres began in Nov. 1801; on this problem he succeeded where others had failed. Gauss set up a speedy method for the complete determination of the elements of a planet's orbit from three observations; he elaborated it in his second major work, a classic in astronomy, published in 1809. He said that had it not been for Newton's *Principia* he could not have devised the new method.

Astronomy occupied Gauss's attention the remainder of his life. In 1807 he was appointed director of the University of Gottingen observatory and professor of mathematics, a position he never left in spite of many efforts to lure him away. He trained a considerable number of students who later distinguished themselves and always regarded him as a great teacher. The years 1816–17 marked the close of his work in theoretical astronomy; later he worked in spherical and observational astronomy.

In 1812 Gauss published the first rigorous treatment of the hypergeometric series. He was a pioneer in topology and contributed much to crystallography, optics, biostatistics, mechanics and the study of capillarity and fluids in a state of equilibrium. Gauss was commissioned in 1818 to make a geodetic survey of the kingdom of Hanover; this triangulation occupied him for many years, leading to his invention of the heliotrope and his brilliant work in the theory of surfaces. There he found full application for his method of least squares in solving the problem of determining the earth's figure.

After 1831, Gauss collaborated with Wilhelm Weber in basic research in electricity and magnetism. In 1833 they devised an electromagnetic telegraph. They stimulated others in many lands to make magnetic observations and founded the Magnetic union in 1836, the year that Gauss invented the bifilar magnetometer.

Gauss married twice and became the father of six children; two of his sons emigrated to Missouri in the 1830s. His private life was simple and harmonious although he had his share of grief and trouble. He did not like to travel. Gauss left an estate of 152,892 thalers. His personal and scientific correspondence was voluminous. As a celebrity, he had numerous visitors from abroad. Newton was his ideal. Frequently he meditated on religion and philosophy but was reluctant to talk on these subjects and published nothing on them. His *Collected Works* were published over a long period, from 1863 to 1933; they exhibit the elegant and concise form on which he insisted. He was well versed in the Greek and Roman classics, studied Sanskrit and read extensively in European literature, particularly English and Russian. His library contained 11,424 items. In later years he was showered with honours from scientific bodies and governments everywhere. He was extremely patriotic and politically conservative, though never active beyond watching current events. He served several terms as a dean at the University of Gottingen and always participated wholeheartedly in its affairs. Gauss enjoyed social life but usually limited this in favour of his research. He loved music, especially singing. His unusually strong character prevented others from trifling with him.

Gauss enjoyed good health until the last year of his life. His fame lives even more strongly than ever, for rarely has the mind of a commanding world figure been so richly furnished.

GAUTAMA BUDDHA (*c.* 563–483 B.C.), the historic founder of the religion known as Buddhism, lived, taught and died in northeast India, but his influence spread throughout central, northern and southern Asia, where it continues to provide a common cultural bond. Traditions of his life were not written earlier than 236 years after his death, but they are preserved variously in the Pali, Sanskrit, Chinese and Tibetan languages. From these, modern historical inquiry has been able to obtain a relatively stable outline of main events in a career still celebrated after 2,500 years.

Buddha was born among the Sakyas, a tribe of the warrior (Kshatriya) caste whose capital, Kapilavastu, was situated in what is now Nepal. His father, Suddhodana, was ruling noble (or king) of the Gautama clan, whence the name Gautama by which the son was later known, although his given personal name was Siddhartha. His mother, Maya, died soon after he was born. From poetic tales and legends surrounding his birth, infancy and youth, it may be inferred that the prince was a remarkable personality, that although reared in luxury he was of a serious, meditative turn of mind, and that he was early attracted to a nonworldly religious life. From this neither wife nor the birth of a son could divert him. Actually, in his 29th year, the prince renounced home and secular life to seek the "supreme peace of Nirvana." This goal envisaged deliverance from the painful realities of life's transitoriness, as evidenced by the ceaseless round of birth, old age, sickness and death, repeated according to Indian belief through countless successive rebirths. As monk he sought instruction under two religious teachers.

Unsatisfied, he next tried extreme ascetic practices for six years, equally fruitless. Returning to a natural regimen, he finally gained his great enlightenment through sitting quietly in concentrated meditation. He detected the cause of suffering in craving due to ignorance, and discovered a path to its removal through right living and mental discipline. Thus he became Buddha, or the Enlightened One.

Feeling compassion for all suffering mortals, he decided to share his wisdom. His remaining 45 years spent as wandering teacher among his own and neighbouring tribes earned him the title Sage of the Sakyas (Sakyamuni). From among his numerous followers he organized a community of monks (the sangha) to carry on after him. In old age he was menaced by a schismatic monk, Devadatta (*q.v.*), who plotted to seize leadership, but this danger was averted. In his 80th year, still exhorting his disciples to strive earnestly for what is beyond perishing things, Gautama Buddha died. History attests the deep and lasting impression left by his noble spirit and selfless, devoted life. See also BUDDHA AND BUDDHISM; LUMBINI; MAHAYANA; ZEN.

GAUTIER, LÉON (1832–1897), French literary historian, was born at Havre, educated at the École des Chartes and became successively keeper of the archives of the department of Haute-Marne and of the imperial archives at Paris under the empire. In 1871 he became professor of paleography at the École des Chartes. He was elected member of the Academy of Inscriptions in 1887 and became chief of the historical section of the national archives in 1893.

Léon Gautier rendered great services to the study of early French literature, the most important of his numerous works on medieval subjects being a critical text (1872) with translation and introduction of the *Chanson de Roland,* and *Les Epopdes françaises* (3 vol., 1866–67; 2nd ed., 5 vol., 1878–97, including a *Bibliographie des chansons de geste).* He died in Paris Aug. 25, 1897.

GAUTIER, THEOPHILE (1811–1872), French poet and miscellaneous writer, was born at Tarbes on Aug. 31, 1811. He was educated at the grammar school of that town, and afterward at the Collège Charlemagne in Paris, but was almost as much in the studios. He very early devoted himself to the study of the older French literature, especially that of the 16th and the early part of the 17th century. This study qualified him well to take part in the Romantic movement, and enabled him to astonish Sainte-Beuve by the phraseology and style of some literary essays which, when barely 18 years old, he put into the critic's hands. In consequence of this introduction he at once came under the influence of the great Romantic *cénacle,* to which, as to Victor Hugo in particular, he was also introduced by his gifted but ill-starred schoolmate Gérard de Nerval. With Gérard, Petrus Borel, Corot, and many other less known painters and poets whose personalities he has delightfully sketched in the articles collected under the titles of *Histoire du Romantisme*, etc., he formed a minor romantic clique who were distinguished for a time by the most extravagant eccentricity. A flaming crimson waistcoat and a great mass of waving hair were the outward signs which qualified Gautier for a chief rank among the enthusiastic devotees who attended the rehearsals of *Hernani* with red tickets marked "Hierro," performed mocking dances round the bust of Racine, and were at all times ready to exchange word or blow with the *perruques* and *grisâtres* of the classical party. In Gautier's case these freaks were not inconsistent with real genius and real devotion to sound ideals of literature. He began (like Thackeray, to whom he presents in other ways some striking points of resemblance) as an artist, but soon found that his true powers lay in another direction.

His first considerable poem, *Albertus* (1830), displayed a good deal of the extravagant character which accompanied rather than marked the movement, but also gave evidence of uncommon command both of language and imagery, and in particular of a descriptive power hardly to be excelled. The promise thus given was more than fulfilled in his subsequent poetry, which, in consequence of its small bulk, may well be noticed at once and by anticipation. The *Comédie de la mort*, which appeared soon aiter (1832), is one of the most remarkable of French poems, and though never widely read has received the suffrage of every competent reader. Minor poems of various dates, published in 1840, display an almost unequalled command over poetical form, an advance even over *Albertus* in vigour, wealth and appropriateness of diction, and abundance of the special poetical essence. All these good gifts reached their climax in the *Émaux et camées,* first published in 1856, and again, with additions, just before the poet's death in 1872. These poems are in their own way such as cannot be surpassed. Gautier's poetical work contains in little an expression of his literary peculiarities. There are, in addition to the peculiarities of style and diction already noticed, and extraordinary feeling and affection for beauty in art and nature, and a strange indifference to anything beyond this range, which has doubtless injured the popularity of his work.

But it was not, after all, as a poet that Gautier was to achieve either profit or fame. For the theatre, he had but little gift, and his dramatic efforts (if we except certain masques or ballets in which his exuberant and graceful fancy came into play) are by far his weakest. It was otherwise with his prose fiction. His first novel of any size, and in many respects his most remarkable work, was *Madenzoiselle de Maupin* (1835). Unfortunately this book, while it establishes his literary reputation on an imperishable basis, was unfitted by its subject, and in parts by its treatment, for general perusal, and created, even in France, a prejudice against its author which he was very far from really deserving. During the years from 1833 onward, his fertility in novels and tales was very great. *Les Jeunes-France* (1833), which may rank as a sort of prose *Albertus* in some ways, displays the follies of the youthful Romantics in a vein of humorous and at the same time half-pathetic satire. *Fortunio* (1838) perhaps belongs to the same class. *Jettatura,* written somewhat later, is less extravagant and more pathetic. A crowd of minor tales display the highest literary qualities, and rank with Mérimée's at the head of all contemporary works of the class. First of all must be mentioned the ghost-story of *La Morte amoureuse,* a gem of the most perfect workmanship. For many years Gautier continued to write novels. *La Belle Jenny* (1864) is a not very successful attempt to draw on his English experience, but the earlier *Militona* (1847) is a most charming picture of Spanish life. In *Spirite* (1866) he endeavoured to enlist the fancy of the day for supernatural manifestations, and a *Roman de la momie* (1856) is a learned study of ancient Egyptian ways. His most remarkable effort in this kind, towards the end of his life, was *Le Capitaine Fracasse* (1863), a novel, partly of the picaresque school, partly of that which Dumas was to make popular, projected nearly thirty years earlier, and before Dumas himself had taken to the style. This book contains some of the finest instances of his literary power.

Yet neither in poems nor in novels did the main occupation of Gautier as a literary man consist. He was early drawn to the more lucrative task of feuilleton-writing, and for more than thirty years he was among the most expert and successful practitioners of this art. Soon after the publication of *Mademoiselle de Maupin,* in which he had not been too polite to journalism, he became irrevocably a journalist. He was actually the editor of *L'Artiste* for a time: but his chief newspaper connexions were with *La Presse* from 1836 to 1854 and with the *Moniteur* later. His work was mainly theatrical and art criticism. The rest of his life was spent either at Paris or in travels of considerable extent to Spain, the Netherlands, Italy, Turkey, England, Algeria and Russia, all undertaken with a more or less definite purpose of bookmaking. Having absolutely no political opinions, he had no difficulty in accepting the Second Empire, and received from it considerable favours. in return for which. however. he in no way prostituted his pen, but remained a literary man pure and simple. He died on Dec. 23, 1872.

Accounts of his travels, criticisms of the theatrical and literary works of the day, obituary notices of his contemporaries and, above all, art criticism occupied him in turn. It has sometimes been deplored that this engagement in journalism should have diverted Gautier from the performance of more capital work in literature. Perhaps, however, this regret springs from a certain misconception. Gautier's power was literary power pure and simple, and it is as evident in his slightest sketches and criticisms as in *Émaux et camées* or *La Morte amoureuse.* On the other hand, his weakness, if he had a weakness, lay in his almost total indifference to the matters which usually supply subjects for art and therefore for literature. He has thus been accused of "lack of ideas" by those who have not cleared their own minds of cant; and in the recent set-back of the critical current against form and in favour of "philosophic" treatment, comment upon him has sometimes been uniavourable. But this injustice will, beyond all question, be redressed again. He was neither immoral, irreligious nor unduly subservient to despotism, but morals, religion and politics (to which we may add science and material progress) were matters of no interest to him. He was to all intents a humanist, as the word was understood in the 15th century. But he was a humorist as well, and this combination, joined to his singularly kindly and genial nature, saved him from some dangers and depravations as well as some absurdities to which the humanist temper is exposed. As time goes on it may be predicted that, though Gautier map not be widely read, yet his writings will never cease to be full of indescribable charm and of very definite instruction to men of letters. Besides those of his works which have been already cited, we may notice *Une Larme du diable* (1839), a charming mixture of humour and tenderness; *Les Grotesques* (1844), a volume of early criticisms on some oddities of 17th century literature; *Caprices et zigzags* (1845), miscellanies dealing in part with English life; *Voyage en Espagne* (1845), *Constaiztinople* (1854), *Voyage en Russie* (1866), brilliant volumes of travel; *Ménagerie intime* (1869) and *Tableaux de siège* (1872), his two latest works, which display his incomparable style in its quietest but not least happy form.

There is no complete edition of Gautier's works, and the vicomte Spoelberch de Lovenjoul's *Histoire des œuvres de Théophile Gautier* (1887) shows how formidable such an undertaking would be. But since his death numerous further collections of articles have been made: *Fusains et eaux-fortes* and *Tableaux à la plume* (1880); *L'Orient* (2 vols., 1881); *Les Vacances du lundi* (new ed., 1888); *La Nature chez elle* (new ed., 1891). In 1879 his son-in-law, E. Bergerat, who had married his younger daughter Estelle (the elder, Mme. Judith Gautier—herself a writer of distinction—was at one time Mme. Catulle Mendès), issued a biography, *Théophile Gautier,* which has been often reprinted. With it should be compared Maxime du Camp's volume in the *Grands Écrivains français* (1890) and the numerous reierences in the *Journal des Goncourt.* Critical eulogies, from Sainte-Beuve (repeatedly in the *Causeries)* and Baudelaire (two articles in *L'Art romantique*) downwards, are numerous. The chief of the decriers is Émile Faguet in his *Etudes littéraires sur le XIXe siècle.* In 1902 and 1903 there appeared two respectable academic *éloges* by H. Menal and H. Potez. (G. SA.)

GAUTIER D'ARRAS, French *trouvère,* flourished in the second half of the 12th century. Nothing is knoi-sn of his biography except what may be gleaned from his works. He dedicated his romance of *Éracle* to Theobald V, count of Blois (d. 1191); among his other patrons were Marie, countess of Champagne, daughter of Louis VII and Eleanor of Guienne and Baldwin IV, count of Hainaut. *Éracle,* the hero of which becomes emperor of Constantinople as Heraclius, is purely a *roman d'aventures* and enjoyed great popularity. His second romance, *Ille et Galeron,* dedicated to Beatrix, the second wife of Frederick Barbarossa, treats of a similar situation to that outlined in the lay of *Eliduc* by Marie de France.

See the *Oeuvres de Gautier d'Arras,* ed. *E.* Löseth (1890); *Hist. litt. de la France,* vol. xxii (1852); A. Dinaux, *Les Trouvères* (1833–43).

GAUZE, a light, transparent fabric, originally of silk, and now sometimes made of linen or cotton, woven in an open manner with very fine yarn. It is said to have been originally made at Gaza in Palestine, whence the name. Some of the gauzes from eastern Asia were brocaded with flowers of gold or silver. In the weaving of gauze the warp threads, in addition to being crossed as in plain weaving, are twisted in pairs from left to right and from right to left alternately, after each shot of weft, thereby keeping the weft threads at equal distances apart, and retaining them in their parallel position. The textures are woven either plain, striped or figured; and the material receives many designations, according to its appearance and the purposes to which it is devoted. A thin cotton fabric, woven in the same way, is known as leno, to distinguish it from muslin made by plain weaving. Silk gauze was a prominent and extensive industry in the west of Scotland during the second half of the 18th century, but on the introduction of cotton-weaving it greatly declined. In addition to its use for dress purposes, silk gauze is much employed for bolting or sifting flour and other finely ground substances. The term gauze is applied generally to transparent fabrics of whatever fibre made, and to the fine-woven wire-cloth used in safety-lamps, sieves, window-blinds. etc.

GAVARNI, PAUL (1804–1866), pseudonym of GUILLAUME-SULPICE CHEVALIER, French lithographer and painter, was born on Jan. 13, 1804, in Paris. In early childhood he showed gifts for drawing and at the age of ten was working in the studio of the architect Dutillard and was later employed by a maker of precision instruments. All his life he regretted he could not devote his entire time to his principal interests : drawing, mathematics, literature and the stage. His first lithograph was published in 1824 and attracted the attention of E. Blaisot, who gave him employment. From 1824 to 1828 he traveled in the Pyrenees and at that time he adopted the name Gavarni. Upon his return he worked for the fashion journal La Mode, made many contacts in the world of society and art and became the friend of Balzac, M. J. Sue and the duchesse d'Abrantès. About 1831 he began publishing his scenes of everyday contemporary life, and praise from writers such as Balzac gained him popularity in England as well as France In 1833 he began publication of the Journal des gens du monde which failed after 18 numbers and was responsible for Gavarni's imprisonment for debt in 1835 for almost a year. He maintained his cheerful outlook, however, and from 1839 to 1846 he issued his famous series "Les Lorettes," "Les Débardeurs" and "Les Fourberies de Femmes." After the death of his mother and his marriage, about 1845. his style changed. deepening in seriousness and observation. Gavarni then turned his mirror to the grotesque sides of family life and of humanity. While showing the same power of irony as his former works, enhanced by a deeper insight into human nature, Gavarni's compositions of this time generally bear the stamp of a bitter philosophy. In 1847 he left for London, described as "the best-dressed man in France." but spent his time in England observing the life of the poor and producing some of his most compelling work. He traveled in Scotland in 1849 and did much work for English publications. After his return to Paris he devoted more time to water colour and in 1851 met the Goncourt brothers who had long been his admirers and were preparing their book for him. Again Gavarni took up lithography and brought forth another of his great series, "Thomas Vireloque." At the time of his death, on Nov. 24, 1866, he was working energetically in etching, lithography and the new and popular process, electric engraving.

Although Gavarni's work lacks the power of his great contemporary Daumier it can be appreciated for its polished wit, the finesse of his cultured observation and the all-embracing panorama he presents of the life of his time.

GAVAZZI, ALESSANDRO (1809–1889), Italian preacher and patriot, was born at Bologna on March 21, 1809. He at first became a monk (1825), and attached himself to the Barnabites at Naples, where he afterward (1829) acted as professor of rhetoric. Driven into exile on account of his liberal views he found refuge in England, where he joined the Evangelical church, and became head and organizer of the Italian Protestants in London. Returning to Italy in 1860, he served as army chaplain with Garibaldi. In 1870 he became head of the Free Church (*Chiesa libera*) of Italy, united the scattered Congregations into the "Unione delle Chiese libere in Italia," and in 1875 founded in Rome the theological college of the Free Church, in which he himself taught dogmatics, apologetics and polemics He died in Rome on Jan. 9, 1889.

His publications include *No Union with Rome* (1871) ; *The Priest in Absolution* (1877) ; *My Recollections of the Last Four Popes*, etc, in answer to Cardinal Wiseman (1858); *Orations* (1851).

GAVELKIND, a peculiar system of tenure associated chiefly with the county of Kent, but found also in other parts of England. In Kent all land was presumed to be holden by this tenure until the contrary was proved, but some lands have been disgaveled by particular statutes. It is more correctly described as "socage tenure. subject to the custom of gavelkind." The chief peculiarities of the custom were: (1) A tenant could alienate his lands by feoffment at 15 years of age. (2) There was no escheat on attainder for felony. (3) Generally the tenant could dispose of his lands by will. (4) In intestacy the estate descended to the sons (or, in the case of deceased sons, their representatives) in equal shares: "Every son is as great a gentleman as the eldest son is." Though females claiming in their own right were postponed to males, yet by representation they inherited together with them. (5) A wife was dowable of one-half instead of one-third of the land. (6) A widower might be tenant by courtesy of one-half without having had any issue, but only so long as he remained unmarried. Gavelkind was, previous to the Conquest, the general custom of the realm, but was then superseded by the feudal law of primogeniture. It mas abolished by the Law of Property act, 1922, and the Administration of Estates act, 1925.

Irish gavelkind was a species of tribal succession, by which the land, instead of being divided at the death of the holder among his sons, was thrown again into the common stock, and redivided among the surviving members of the sept.

GAVESTON, PIERS (d. 1312), earl of Cornwall, favourite of the English king Edward II, was the son of a Gascon knight and was brought up at the court of Edward I as companion to his son. Early in 1307 he was banished by the king; but he returned after the death of Edward I a few months later, and at once became the chief adviser of Edward II. Made earl of Cornwall, he received lands and money, and married Edward's niece, Margaret de Clare (d. 1342). He was regent during the king's short absence in France in 1308, and was conspicuous at Edward's coronation. These proceedings and Gaveston's own arrogance aroused the anger and jealousy of the barons. They demanded his banishment; and the king, forced to assent, sent him to Ireland as lieutenant, where he remained about a year.

Returning to England in July 1309, Gaveston showed himself more insolent than ever. In 1311 the king was forced to agree to the election of the "ordainers," and the ordinances they drew up provided inter alia for the perpetual banishment of Gaveston, who retired to Flanders, but returned secretly to England at the end of 1311. Soon he was publicly restored by Edward, and the barons had taken up arms. Deserted by the king he surrendered to Aymer de Valence, earl of Pembroke (d. 1324), at Scarborough in May 1312, and was taken to Deddington in Oxfordshire, where he was kidnapped by Guy de Beauchamp, earl of Warwick (d. 1315). He was beheaded on Blacklow hill near Warwick on June 19, 1312. Gaveston, whose body was buried in 1315 at King's Langley, Hertfordshire, left an only daughter.

GAVIAL (from the native name gharial), a long-snouted fish-eating crocodilian inhabiting northern India. The snout is extremely slender and elongate, with numerous equal-sized teeth. Various crocodiles have relatively slender snouts, and the Malayan false gavial (Tomistoma), a close relative of the true crocodiles, approaches the gavial in this respect. See CROCODILIAN.

(K. P. S.)

GAVIIDAE: see LOON.

GAVOTTE, properly the dance of the Gavots or natives of Gap, a district in the upper Alps, in the old province of Dauphiné. It is a dance of a brisk and lively character, somewhat resembling the minuet, but quicker and less stately (see DANCE) ; hence also the use of this name for a form of musical composition.

GAWABRA: see ARABS.

GAWAIN, son of King Loth of Orkney, and nephew to Arthur on his mother's side, the most famous hero of Arthurian romance. The first mention of his name is in a passage of William of Malmesbury, recording the discovery of his tomb in the province of Ros in Wales. He is there described as *Walwen qui* fuit *haud* degener *Arturis* ex *sorore nepos*. Here he is said to have reigned over Galloway; and there is certainly some connection, the character of which is now not easy to determine, between the two. In the later *Historia* of Geoffrey of Monmouth, and its French translation by Wace, Gawain plays an important and "pseudo-historic" rôle. On the receipt by Arthur of the insulting message of the Roman emperor, demanding tribute, it is he who is despatched as ambassador to the enemy's camp, where his arrogant and insulting behaviour brings about the outbreak of hostilities. On receipt of the tidings of Mordred's treachery, Gawain accompanies Arthur to England, and is slain in the battle which ensues on their landing. Wace, however, evidently knew more of Gawain than he has included in his translation, for he speaks of him as

> Li quens Walwains
> Qui tant fu preudom de ses mains (11. 9057–58);

and later on says

> Prous fu et de mult grant mesure,
> D'orgoil et de forfait n'ot qure
> Plus vaut faire qu'il ne dist
> Et plus doner qu'il ne pramist (10. 106–109).

The English Arthurian poems regard him as the type and model of chivalrous courtesy, "the fine father of nurture," and as Prof. Maynadier has well remarked, "previous to the appearance of Malory's compilation it was Gawain rather than Arthur who was the typical English hero." It is thus rather surprising to find that in the earliest preserved mss, of Arthurian romance, *i.e.,* in the poems of Chrétien de Troyes, Gawain, though generally placed first in the list of knights, is by no means the hero *par excellence.* The latter part of the *Perceval* is indeed devoted to the recital of his adventures at the *Chastel Merveilleus,* but of none of Chrétien's poems is he the protagonist. The anonymous author of the *Chevalier à l'épée* indeed makes this apparent neglect of Gawain a ground of reproach against Chrétien. At the same time the majority of the short episodic poems connected with the cycle have Gawain for their hero. In the earlier form of the prose romances, *e.g.,* in the *Merlin* proper, Gawain is a dominant personality, his feats rivalling in importance those ascribed to Arthur, but in the later forms such as the *Merlin* continuations, the *Tristan,* and the final *Lancelot* compilation, his character and position have undergone a complete change, he is represented as cruel, cowardly and treacherous, and of indifferent moral character. Most unfortunately our English version of the romances, Malory's *Morte d'Arthur,* being derived from these later forms (though his treatment of Gawain is by no means uniformly consistent), this unfavourable aspect is that under which the hero has become known to the modern reader. Tennyson, who only knew the Arthurian story through the medium of Malory, has, by exaggeration, largely contributed to this misunderstanding. Morris, in *The Defence of Guinevere,* speaks of "gloomy Gawain"; perhaps the most absurdly misleading epithet which could possibly have been applied to the "gay, gratious, and gude" knight of early English tradition.

The truth appears to be that Gawain, the Celtic and mythic origin of whose character was frankly admitted by the late M. Gaston Paris, belongs to the very earliest stage of Arthurian tradition, long antedating the crystallization of such tradition into literary form. He was certainly known in Italy at a very early date; Prof. Rajna has found the names of Arthur and Gawain in charters of the early 12th century, the bearers of those names being then grown to manhood; and Gawain is figured in the architrave of the north doorway of Modena cathedral, a 12th-century building. Recent discoveries have made it practically certain that there existed, prior to the extant romances, a collection of short episodic poems, devoted to the glorification of Arthur's famous nephew and his immediate kin (his brother Gaheris, or Gareth, and his son Guinglain), the authorship of which was attributed to a Welshman, Bleheris; fragments of this collection have been preserved to us alike in the first continuation of Chrétien de Troyes *Percevpl,* due to Wauchier de Denain, and in our vernacular *Gawain* poems. Among these "Bleheris" poems was one dealing with Gawain's adventures at the Grail castle, where the Grail is represented as non-Christian, and presents fe'atures strongly reminiscent of the ancient Nature mysteries. There is good ground for believing that as Grail quester and winner, Gawain preceded alike Perceval and Galahad, and that the solution of the mysterious Grail problem is to be sought rather in the tales connected with the older hero than in those devoted to the glorification of the younger knights. The explanation of the very perplexing changes which the character of Gawain has undergone appears to lie in a misunderstanding of the original sources of that character. Whether or not Gawain was a sun-hero, and he certainly possessed some of the features—we are constantly told how his strength waxed with the waxing of the sun till noontide, and then gradually decreased; he owned a steed known by a definite name le Gringalet; and a light-giving sword, Excalibur (which, as a rule, is represented as belonging to Gawain, not to Arthur)—all traits of a sun-hero—he certainly has much in common with the primitive Irish hero Cuchullin. The famous head-cutting challenge, so admirably told in *Syr Gawayne and the Grene Knighte,* was originally connected with the Irish champion. Nor was the lady of Gawain's love a mortal maiden, but the queen of the other-world. In Irish tradition the other-world is often represented as an island, inhabited by women only; and it is this "Isle of Maidens" that Gawain visits in *Diu Crone;* returning therefrom dowered with the gift of eternal youth. The Chastel Merveilleus adventure, related at length by Chrétien and Wolfram, is undoubtedly such an "other-world" story. It seems probable that it was this connection which won for Gawain the title of the "Maidens' Knight," a title for which no satisfactory explanation is ever given. When the source of the name was forgotten its meaning was not unnaturally misinterpreted, and gained for Gawain the reputation of a facile morality, which was exaggerated by the pious compilers of the later Grail romances into persistent and aggravated wrong-doing; at the same time it is to be noted that Gawain is never, like Tristan and Lancelot, the hero of an illicit connection maintained under circumstances of falsehood and treachery. Gawain, however, belonged to the pre-Christian stage of Grail tradition, and it is not surprising that writers bent on spiritual edification found him somewhat of a stumbling-block. Chaucer, when he spoke of Gawain coming "again out of faerie," spoke better than he knew; the home of that very gallant and courteous knight is indeed Fairy-land, and the true Gawain-tradition is informed with fairy glamour and grace.

BIBLIOGRAPHY.—F. Madden (ed.), *Syr Gawayne,* the English poems relative to that hero (1839); intro. and summary of episodic "Gawain" poems by Gaston Paris in *Histoire littkraire de la France,* vol. xxx (1888); J. L. Weston, *Legend of Sir Gawain* (1897) and *Legend of Sir Perceval* (1906); *Sir Gawain and the Green Knight* (1898), *Sir Gawain at the Grail Castle* (1904), *Sir Gawain and the Lady of Lys* (1907), all three trans. by J. L. Weston in Nutt's *Arthurian Romances,* vol. i, vi and vii. For the Celtic derivation of this and other Arthurian characters *see* R. S. Loomis, *Celtic Myth and Arthurian Romance* (1927).

GAWAMA'A: *see* ARABS.

GAWLER, a town of Gawler county, South Australia, on the Para river, 2 j mi. by rail N.E. of Adelaide. It is one of the most thriving places in the colony, being the centre of a large wheat-growing district; it has also engineering works, foundries, flour-mills, breweries and sawmills. Some gold, silver, copper and lead are found in the neighbouring hills. Pop. (1954) 5,117.

GAY, JOHN (1685–1732), English poet and dramatist, author of *The Beggar's Opera,* was born on June 30, 1685, at Barnstaple, Devonshire, and educated at the local grammar school. He was apprenticed to a silk mercer in London, but was released early from his indentures and, after a further short period in Devonshire, returned to London where he lived most of his life. Among his early literary friends were Aaron Hill and Eustace Budgell, whom he helped in the production of *The British Apollo,* a question-and-answer journal of the day. His journalistic interests are clearly seen in a pamphlet, *The Present State of Wit* (1711), a survey of contemporary periodical publications.

From 1712 to 1714 he was steward in the household of the duchess of Monmouth, which gave him leisure and security to write. He had produced a burlesque of the Miltonic style, *Wine,* in 1708 and in 1713 his first important poem, *Rural Sports,* appeared. This is a descriptive and didactic work in two short books dealing with hunting and fishing, but containing also descriptions of the country-side and meditations on the Horatian theme of retirement. Here

Gay strikes at once his characteristic note of delicately absurd artificiality. In discussing bait, for example, he tells the reader:

> Those baits will best reward the fisher's pains.
> Whose polish'd tails a shining yellow stains
> Cleanse them from filth, to give a tempting gloss,
> Cherish the sully'd reptile race with moss. . .

He is, of course, aware of the comic disproportion between his language and the subject. But the contrast, while it produces the effect of a *reductio ad absurdum,* does so in a good-humoured way and in a tone of underlying sympathy. This note of sympathetic comedy is the staple one in Gay's poetry. It is strongly marked in his finest poem. *Trivia: or, the Art of Walking the Streets of London* (1; 16), a work modeled on Virgil's *Georgics* and fully alive today for the detailed observation of urban life which it displays. and for its assured technical dexterity. Something of its flavour can be gained from this couplet, describing a sophisticated lady crossing the street:

> Her shoe disdains the street; the lazy fair
> With narrow step affects a limping air.

The force of character observation in "disdains." and the way in which the rhythm of the second line echoes the angular movements of the lady. indicate the precision of Gay's craftsmanship. The effect is not to "startle with a fine excess," but to make the reader apprehend one facet of experience more clearly. It is this effect which Gay is constantly achieving. The full significance of a couplet often depends upon a literary parallel and references back to the *Georgics* are common. Virgil, for example, says that the influence of spring is felt throughout the whole of creation, a thought which Dryden renders by the lines:

> From hence proceeds the birds' harmonious voice;
> From hence the cows exult, and frisking lambs rejoice.

Gay varies the lines in *Trivia:*

> The seasons operate on ev'ry breast;
> 'Tis hence that fawns are brisk, and ladies drest,

and the effect is complex, at once satirical. sympathetic and. by its correlation of the animal and human kingdoms, philosophical. It is in this sort of delicate probing of the surface of apparently mundane social life that Gay excels.

Apart from *Trivia* and *Rural Sports,* Gay's most important works are *The Shepherd's Week* (1714), a series of mock classical pastorals, his two series of *Fables* (1727 and 1738) and *The Beggar's Opera* (1728). The *Fables* went through about 350 editions and until the 20th century were the best known of his poems. They are brief octosyllabic illustrations of moral themes, often satirical in tone and frequently directed at the court and courtiers.

Gay's most famous work. *Tlze Beggar's Opera,* was produced on Jan. 29, 1728. at Rich's theatre in Lincoln's Inn fields, where it was said to make "Gay rich, and Rich gay." Its basic idea was to mirror the moral degradation of society by means of a story about thieves and highwaymen, and more particularly to caricature Robert Walpole and his administration. It also makes fun of the prevailing fashion for Italian opera. The play is kept alive, however, not so much by the pungency of its satire as by the effective situations of the plot. and above all by the "singability" of the songs. It ran for 62 nights (not all consecutive) and temporarily drove Italian opera from the stage. Gay wrote a sequel, *Polly,* which is set in the West Indies and in which poetic justice is more clearly seen to be done than in *The Beggar's Opera,* but its production was forbidden by the lord chamberlain. no doubt through the influence of Walpole. The suppression proved an excellent advertisement. Gay's cause found support among his friends and indeed among all who were antagonistic to the government When it was decided to print the play, subscriptions were canvassed even in the court itself. John Arbuthnot describes the extent of the interest in a letter to Swift (March 19. 1729): "The inoffensive John Gay is noa become one of the obstructions to the peace of Europe. the terror of the Ministers, the chief author of . . . all the seditious pamphlets which have been published against the government . . . If he should travel about the country. he would have hecatombs of roasted oxen sacrificed to him." As a result of this uncharacteristic notoriety Gay made well over £1.000 from subscriptions and *Polly* sold nidely. The play was not produced until 1777 when it had a moderate success. Gay's less famous plays include *The What d'ye Call It* (1715), *Three Hours After Marriage* (1717) and *Achilles,* posthumously produced in 1733.

The adjective most often applied to Gay by his friends is "honest," and they agree that this was accompanied by a certain naïveté in the face of practical problems. He lost almost all his money on South Sea stock and suffered disappointments of official patronage. Nonetheless when he died, Dec. 4, 1732, in London, he was worth £6,000, a modest but not negligible fortune. He had been helped by various patrons, including the third earl of Burlington and the third earl of Queensberry; the duchess of Queensberry mourned his death deeply. He was buried in Westminster abbey, next to Chaucer. His monument is by John Rysbrack, his epitaph by Alexander Pope.

Gay's reputation remained high throughout the 18th century; during the 19th he was remembered chiefly as the author of the *Fables* but, following Nigel Playfair's enormously successful revival of *The Beggar's Opera* in 1920, Gay's general reputation gradually rose again and he became valued as a poet of a varied and considerable achievement.

BIBLIOGRAPHY.—The *Poetical Works,* including plays, were edited by G. C. Faber (1926). *See* also W. H. Irving, *John Gay, Favourite of the Wits* (1940); J. R. Sutherland, in *Pope and His Contemporaries* (1949). (JN. C.)

GAY, WALTER (1856–1937), **U.S.** artist who painted scenes of French interiors and French peasant life, was born at Hingham, Mass.. on Jan. 22, 1856. Most of his career was spent in Europe. In 1876 he became a pupil of Léon Bonnat in Paris. He received an honourable mention in the salon of 1885; a gold medal in 1888, similar awards at Vienna (1894), Antwerp (1895), Berlin (1896) and Munich (1897). He became an officer of the Legion of Honour and a member of the Society of Secession, Munich. His works are in the Luxembourg, the Tate gallery and the Boston and Metropolitan museums of art. He died July 14. 1937, in Paris.

GAYA, a city and district in the Patna revenue division of Bihar state. India, about 57 mi. S. of Patna city, with a station on the Grand Chord line of the Eastern railway. With a population in 1961 of 13'0.884 it is. next to Patna, the most populous city in the state. Gaya is a celebrated place of Hindu pilgrimage; it is a sacred duty for Hindus to make offerings there for the salvation of their parents and ancestors, and about 300.000 pilgrims come annually. There are 45 sacred places between (and including) Pretsil hill on the north and Bodh (Buddh) Gaya on the south, a distance of 1j mi., but most are in Gaya itself. The principal shrine is the Vishnupad temple built by the Mahratta princess, Ahalya Bai, in 1787. Others are the rocky temple-crowned hills of Ramsila (372 ft.) and Brahmajuni (450 ft.). The last, which overlooks the civil station, has been identified with the Gayasirsa hill on which Buddha preached. Gaya college is a constituent of Bihar university.

GAYA DISTRICT, with an area of 4,766 sq.mi. and a population (1961) of 3,647,268, consists of a wide plain, with wooded hills along the southern boundary, from which the country falls with a gentle slope toward the north. The hills in the south, which contain scenes of the most picturesque beauty, rise to a height of 2,202 ft. at Durvasarhi and to 1,832 ft. in the Mahabar hills. A long range extends from near Bodh Gaya northeastward, and elsewhere in the open plain, rocky hills occur, either detached or in groups, such as Maher, 1,620 ft.; Kauwadol and the Barabar hills. The northern part of the district is highly cultivated; the portions to the east and west are less fertile. In the south the country is thinly peopled; in the jungles covering the hills and the country below them: tigers, leopards. bear and deer are found. The principal rivers are the Sone (Son). which marks the boundary between Gaya and Shahabad districts, the Punpun and the Phalgu, formed by the junction of two large hill streams! the Nilajan and Mohana. The last three rivers are subject to heavy floods. Agriculture depends largely on irrigation, which is mainly effected by an indigenous system of channels leading from the rivers and storage reservoirs made by building embankments across the line of drainage. The northwest of the district is irrigated by part of the Sone canal system. Mica mines are worked in the southeast of the district, which contains part of the Bihar mica belt, one of the largest sources of the world's supply. Other industries are the production of shellac, which centres on Imamganj, the weaving of carpets and blankets, notably at Obra. and the manufacture of brass utensils and of black stoneware. chiefly ornaments sold to pilgrims at Gaya. The district is traversed by the Grand Chord line of the Eastern railway. the South Bihar railway running into the Monghyr district. and a branch to Patna. Gaya district is rich in ancient sites and has many archaeological remains associated with the early history of Buddhism. Bodh Gaya (6 mi. S. of Gaya), famous for the Bo-tree, is one of the holiest sites of Buddhism. A mound on the Sobhnath hill has been identified with the burial place of Kasyapa, the greatest of Buddha's disciples; the remains of a monastery are in a valley (Hasra Kol) near by. where fine sculptured figures have been found. In the Barabar hills there are rock-cut caves or rooms. in some of which the rock has been wrought to an extraordinary polish. An inscription of Asoka in one group shows they were dedicated to the use of ascetics called Ajivikas. The other group was hewn out of the rock for the use of the same sect by his grandson, Dasaratha; they are called the Nagarjuni caves, after a Buddhist teacher of that name who is believed to have lived in them in the 2nd century A.D.

GAYAL, a domesticated ox allied to the gaur (*q.v.*) but distinguished by the more conical and straighter horns, and the straight line between them. Gayal are kept by the natives of the hill districts of Assam, Tenasserim and Upper Burma.

GAY-LUSSAC, JOSEPH LOUIS (1778-ISSO), French chemist and physicist. pioneered in the study of the gaseous state. He was born at St. Léonard, in the *département* of Haute-Vienne, on Dec. 6, 1778. His father. Antoine Gay, added Lussac to the name to avoid confusion with others named Gay. (Lussac is an estate near St. Lemand.) He entered the École Polytechnique at the end of 1797; two years later he was transferred to the École des Ponts et Chaussées, and at the same time he assisted Claude L. Berthollet (*q.v.*) in his researches. In 1802 he was appointed demonstrator to Antoine F. Fourcroy at the École Polytechnique. He succeeded Fourcroy as professor of chemistry on Jan. 1, 1810. From 1808 to 1832 he was professor of physics at the Sorbonne, a post which he resigned for the chair of chemistry at the Jardin des Plantes. In 1806 he was made an academician. In 1831 he was elected to represent Haute-Vienne in the chamber of deputies, and in 1839 he entered the chamber of peers. He died in Paris on May 9, 1850. He lies buried in Père Lachaise cemetery.

Gay-Lussac's earlier researches were mostly physical in character and referred mainly to the properties of gases. vapour tensions, hygrometry, capillarity, etc. His first memoir, published in 1802, dealt with the expansion of gases. In 1803 the French academy, desirous of securing some observations on the force of terrestrial magnetism at great elevations above the earth, obtained the use of a balloon, and entrusted the task to him and Jean B. Biot. In their first ascent from the garden of the Conservatoire des Arts on Aug. 24. 1804 an altitude of 13,120 ft. was attained; Gay-Lussac made a second ascent by himself on Sept. 16, when the balloon rose 23,012 ft. above sea level. At'this height. he made observations not only on magnetism, but also on the temperature and humidity of the air, and collected several samples of air at different heights. The magnetic observations led him to the conclusion that the magnetic effect at all attainable elevations above the earth's surface remains constant; and on analyzing the samples of air he could find no difference of composition at different heights. This work places him among the founders of meteorology. In the same year, in conjunction with Alexander von Humboldt, he read a paper on eudiometric analysis (*Ann. de Chim.*, 1805); it contained the germ of his most important generalization, the law of combination of gases by volumes, which was. however. not enunciated in its general form until after his return from a journey through Switzerland. Italy and Germany.

In 1809 his important memoir on gaseous combination was published. In it he pointed out that when gases combine they do so in the simplest proportions by volume, and that the volume of any gaseous product formed bears a simple ratio to that of the constituents (*see* CHEMISTRY: *The Development of the Theory of Molecular Structure*). This is Gay-Lussac's law. He was one of the discoverers of the fact that all gases have approximately the same coefficient of expansion (Charles's law).

About this time Gay-Lussac's work became more purely chemical. In 1808. he succeeded. with the collaboration of Louis J. Thénard, in preparing potassium by the action of red-hot iron on fused potash. The properties of the element were studied and in 1809 he used it for the isolation of boron from boric acid. Gay-Lussac carried out some work on chlorine (1809) and iodine (1814) which brought him into direct rivalry with Humphry Davy (*q.v.*). He considered "oxymuriatic acid" (chlorine) to be a compound. whereas Davy saw no reason to suppose that it contained oxygen and regarded it as an element, a view which Gay-Lussac was reluctantly compelled to accept.

In 1810 Gay-Lussac published a paper which contains some classic experiments on fermentation, a subject to which he returned in a second paper published in 1815. At the same time he was working with Thénard at the improvement of the methods of organic analysis. and by combustion with oxidizing agents, first potassium chlorate and subsequently copper oxide, he determined the composition of a number of organic substances. His last great piece of pure research was on prussic acid. In a note published in 1811 he described the physical properties of this acid, but he said nothing about its chemical composition until 1815, when he described cyanogen as a compound radicle. prussic acid as a compound of that radicle with hydrogen alone. and the prussiates (cyanides) as compounds of the radicle with metals. The proof that prussic acid contains hydrogen but no oxygen was a most important support to the hydrogen-acid theory, and completed the downfall of Lavoisier's oxygen theory. Gay-Lussac proposed the prefix "hydro" for these oxygen-free acids. He discovered ethyl iodide and chlorcyanogen: The isolation of cyanogen was of importance for the subsequent era of compound radicles in organic chemistry.

As a result of his success as an investigator Gay-Lussac's services as a technical adviser became in great demand. He had been a member of the consultative committee on arts and manufactures after 1805. He was attached to the "administration des poudres et salpêtres" in 1818, and in 1829 he received the lucrative post of assayer to the mint. His services to industry included his improvements in the processes for the manufacture of sulfuric acid (1818) and oxalic acid (1829); methods of estimating the amount of real alkali in potash and soda and for estimating the available chlorine in bleaching powder by a solution of arsenious acid; directions for the use of the centesimal alcoholometer published in 1830 and specially commended by the institute; and the elaboration of a method of assaying silver by a standard solution of common salt. Among his research work of this period may be mentioned the improvements in organic analysis and the investigation of fulminic acid made with the help of Liebig, who gained the privilege of admission to his private laboratory in 1823–24.

The most complete list of Gay-Lussac's papers is contained in the Royal society's *Catalogue of Scientific Papers,* which enumerates 148. exclusive of others written jointly with Humboldt, Thénard, Welter and Liebig. Many were published in the *Annales de chimie,* which. after it changed its title to *Annales de chimie et physique* he edited, with Arago, up to nearly the end of his life; but some are to be found in the *Mémoires d'Arcueil* and the *Comptes rendus,* and in the *Rechevches physiques et chimiques,* two volumes. published with Thénard in 1811.

For biographical details *see* W. Tilden, *Famous Chemists* (1921); F. Arago, *Eloge de Gay-Lussac* (1854); Riot et Gardem le Brun, *Notice biographique de Gay Lussac* (1850); E Blanc and L. Delhoume, *La vie émouvante et noble de Gay-Lussac* (1950). (H. S. V. K.)

GAZA, the most southerly city of the Philistine Pentapolis. separated from the sea by 3 mi. of sand dunes. It was a centre where ancient trade routes met, and through it passed the frankincense from Arabia on its way to the Mediterranean world. It is on the railway from Egypt to Palestine and was capital of the southern province of Palestine. The town is well supplied with water. Before World War I it was a prosperous town with good bazaars, a considerable manufacture of black pottery, and a growing export trade in barley. It was more than half destroyed by the war, and the population, although somewhat replenished immediately after the war, dwindled away northward in search of sustenance. The small harbour of Gaza (El-Mineh) is used mainly for the export of grain.

History. — The Egyptian monarch, Thutmose III (c. 1500 B.C.) found in Gaza a convenient base for operations against Syria. Gaza's king was a vassal of the Pharaohs in the Tell Amarna period about a century later. Joshua's victories brought him to its neighbourhood but not within its walls. It was one of the strongholds from which the Philistines harassed Israel; and Gaza, famous for the worship of Dagon and Derketo, was the scene of Samson's glorious death. Solomon and Hezekiah gained a footing there without being able to retain it. Traffic in slaves evoked the curse of Amos. In 735 B.C. Tiglath-Pileser made it tributary to Assyria. Gaza coquetted with Egypt and received condign punishment from Sargon. In the three centuries following it was bandied between Babylon and Egypt. Gaza resisted Alexander the Great only to be broken and made a "desert." From the third to the first centuries B.C. Egyptian, Syrian and Jewish armies fought for its possession. The Romans made Gaza into an important place (named Minoa) and Augustus presented it to Herod. New Gaza was built on another site in the first century A.D.

Although it showed itself ill-disposed to accept Christianity, a Christian community settled there early, and the Philemon, to whom St. Paul addressed a letter, was said to have been its first head.

In A.D. 634 it surrendered to Omar's troops, and since Hashim the great-grandfather of the Prophet was buried there it became a sacred Moslem city. In the 12th century the crusaders found it almost desolate. Baldwin III erected a fortress (1149) but after Hattin Gaza surrendered. The Khwarismians inflicted a painful defeat there on the Christian and Saracen armies whom dire necessity drove into a strange and fleeting alliance. In the 16th century the Turks crushed the Mamelukes and Egypt lay open to Salim I. Gaza fell to Bonaparte (1799). Three battles were fought at Gaza during World War I (see PALESTINE, OPERATIONS IN). In 1948 Gaza came under Egyptian control. Israeli troops captured Gaza in the Sinai campaign of 19j6, but withdrew in March 1957. A special UN emergency force then moved in to police the Egypt-Israel border area near Gaza. For the Sinai campaign and its aftermath, see EGYPT; ISRAEL; SUEZ CANAL; UNITED NATIONS.

(E. Ro.; X.)

GAZELLE, the name given to a group of antelopes forming the genus *Gazella* (see ANTELOPE).

GAZETTE, a name given to newssheets or newspapers having an abstract of current events which were forerunners of modern newspapers (*q.v.*). The word came into English from the French, having been adapted from the Italian gazzetta, a name given to informal news or gossip sheets first published in Venice in the mid-16th century. Similar sheets soon made their appearance in France and in England. The type of gazette originating from the private newsletter existed in England before the middle of the 16th century, but was confined mainly to detailed accounts of diplomatic maneuvers or to the circulation of courtly verse among a restricted group of readers. Upon the accession of Queen Elizabeth I, however, a far greater variety of such sheets began to appear. Aimed at a wide popular audience, they disseminated gossip, trivia, unofficial news accounts from nongovernment sources, news of recent explorations, commercial advertisements and the more sensational news items of the day — reports of lurid crimes, supposed miracles, witchcraft and the like. The news collected in these sheets was contributed by volunteers, frequently based on the accounts of anonymous witnesses, and was notorious for its inaccuracy.

In the 17th century the term was increasingly applied to official government publications, such as the Oxford, *London,* Edinburgh and Dublin Gazettes.

See Matthias A. Shraaber, *Some Forerunners of the Newspaper in England, 1476–1622* (1929).

GAZIANTEP (AINTAB or AYINTAP), a city of Gaziantep, Turk. Pop. (1960) 125.498, all of which are Moslem Turks of Turkoman origin. During the second millennium B.C. Gaziantep was in the Hittite area and is probably of Hittite origin. The modern city stands high in the green valley of the Sajur, a tributary of the Euphrates, some 65 mi. N.E. of Aleppo. The city is connected to a main railway system. Dülük, the site of Doliche, famous for the worship of Zeus Dolichenus (Baal), is marked by a mound two hours distant to the northwest. In crusading times its strong castle (*Hamtap*) was a strategic point of importance and was captured by Saladin in 1183. Subsequently the city came under the rule, in turn, of Mamelukes and Seljuk Turks and in 1516 mas made a part of the Ottoman Turkish empire. Gaziantep served as the last base of Ibrahim Pasha before his victory over the Turks at Nezib (25 mi. E.) in 1839. In the winter of 1920–21 the armed opposition of the Turkish nationalists to the French occupation of north Syria centred in Gaziantep, which became the "Verdun of Anatolia," whence the prefix Gazi ("hero") is added to its name. After a siege lasting six months, despite determined Turkish efforts to relieve it, the city surrendered to the French troops. France returned it to Turkey under the Ankara treaty of Oct. 20, 1921.

The main industries of Gaziantep are the dyeing of yarn and the manufacture of striped dress materials (chiefly a mixture of silk and cotton), black goats' hair cloth for tents, morocco leather (*sakhtiyan*) made from goats' skins, Aleppo soap from olive oil and *pekmez,* a sweet paste made from grapes. Exports include pistachio nuts, tobacco, cotton and cereals.

GDYNIA, a Polish seaport and naval base, on the bay of Gdynia, opening out into Danzig bay, on the Baltic. It is 12 mi. N.W. of Danzig, with which it is connected by railway. The Polish government in building a railway to the port passing over territory entirely Polish, had also a scheme for a canal to the port from a convenient port on the Vistula, thus tapping the whole waterway system of Poland.

In 1924, when the port of Danzig proved insufficient for Poland's overseas trade, the Polish state decided to build another port in the bay of Gdynia, at that time a small fishing village. In ten years this port became one of the largest harbours in Europe.

The town was occupied by Germany during World War II.

GEAR-CUTTING MACHINES: see MACHINE TOOLS.

GEARS are machine parts, operating in pairs, which transmit motion and force from one rotating shaft to another, or from a shaft to a slide (rack), by means of successively engaging projections called teeth. The smaller of a gear pair is called the pinion and the larger is the gear. When the pinion is on the driving shaft, the pair acts as a speed reducer; when the gear drives, the pair is a speed increaser. Gears are more frequently used as speed reducers than as increasers.

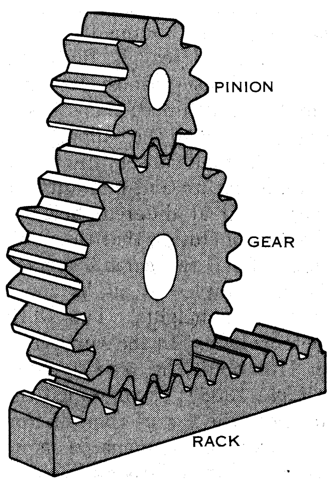

FIG. 1.—MESHING ACTION OF PINION. GEAR AND RACK

The gears in fig. 1 have teeth equally spaced on circles. If the pinion has 10 teeth and the gear 20, the pinion will rotate twice as fast as the gear. The speed ratio mill be 20/10 = 2. In general, if a pinion having T_P teeth rotates at N_P r.p.m. and a gear having T_G teeth rotates at N_G r.p.m., the speed ratio R will be

$$R = \frac{T_G}{T_P} = \frac{N_P}{N_G}$$

For gears of the type shown in fig. 1, there are physical limitations to both the minimum number of teeth on the pinion and the maximum number of teeth on the gear.

For a large speed ratio, two or more gear pairs may be required. Fig. 2 shows two pairs arranged in a compound train. If $T_A = T_C = 10$ and $T_B = T_D = 20$, the speed ratio will be

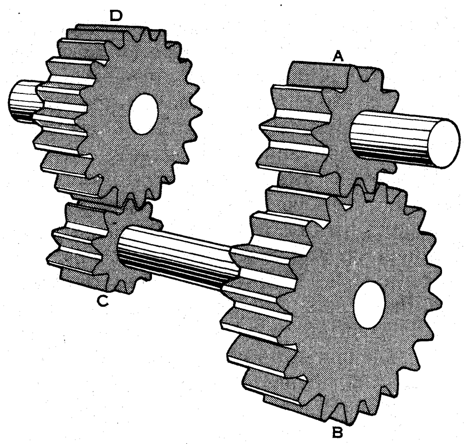

FIG. 2.—TWO GEAR PAIRS ARRANGED IN A COMPOUND TRAIN

$$R = \frac{T_B}{T_A} \times \frac{T_D}{T_C} = \frac{N_A}{N_D} = 4$$

The gears in fig. 1 rotate in opposite directions. If another gear is placed between them, the gear and pinion will rotate in the same direction. The intermediate or idler gear has no effect on the speed ratio. In many cases idler gears (one or more) are used to fill the space when the shafts are too far apart to be connected by one pair.

When the shafts are close together and must rotate in the same direction, a pinion and internal gear may be used, as shown in fig. 3. Teeth on the internal gear are cut on the inside of a cup-shaped member.

If it is required that the input and output shafts be co-axial, the arrangement shown in fig. 4 may be used; this is known as a planetary, or epicyclic, gear train. The sun gear S on the shaft B meshes with two or more planet gears P. which are carried on bearings on a carrier A attached to the shaft C. The planet gears also mesh with an internal gear I.

It can be shown that the speeds of the shafts N_B, N_C and the internal gear N_I are related in the following way:

$$N_C = \frac{N_B}{T_I/T_S + 1} + \frac{N_I(T_I/T_S)}{T_I/T_S + 1}$$

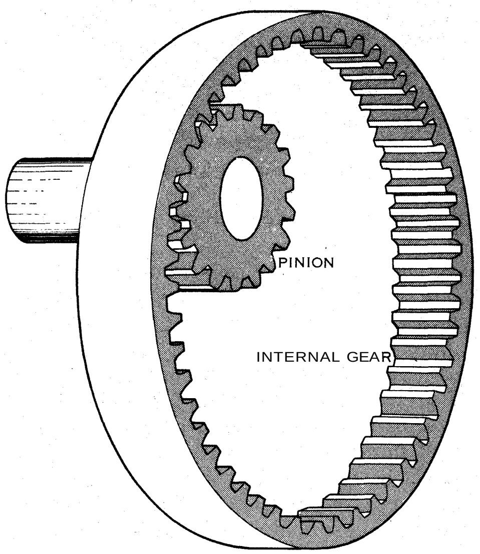

FIG. 3.—INTERNAL GEAR AND PINION

If $T_I = 60$, $T_S = 20$, and the internal gear is prevented from rotating by a brake, then $N_I = 0$ and $N_B = 4N_C$. If the sun gear rotates clockwise it will cause the planet gears to roll around on the inside of the fixed internal gear and rotate the arm and shaft C in a clockwise direction. If B is the input shaft and C the output shaft. the unit becomes a compact. symmetrical speed reducer, with a comparatively high-?ewer transmitting capacity, since the load is shared by three planet gears. For this reason planetary transmissions are used on aircraft where space is limited and weight must be kept to a minimum.

If the sun gear instead of the internal gear is fixed, $N_B = 0$ and $N_I = 4/3N_C$. If the gear I is the input, the output shaft C will rotate in the same direction at a slower speed.

If the arm is fixed, $N_C = 0$ and $N_B = -3N_I$. In this case, the term -3 indicates that shaft B rotates three times faster than gear I and in the opposite direction.

Lastly, if the sun gear and the arm are coupled together by means of a clutch so as to prevent gear tooth action and all members are allowed to rotate about the central axis, $N_I = N_C = N_B$.

Thus, with the three-element planetary system of fig. 4, the speed ratio obtained (4, 3, 4/3 or 1) depends on which element is fixed. It is this feature which makes planetary arrangements valuable in the automatic transmissions of automobiles. In these, the fixing and interconnecting of the members is accomplished automatically by brakes and clutches.

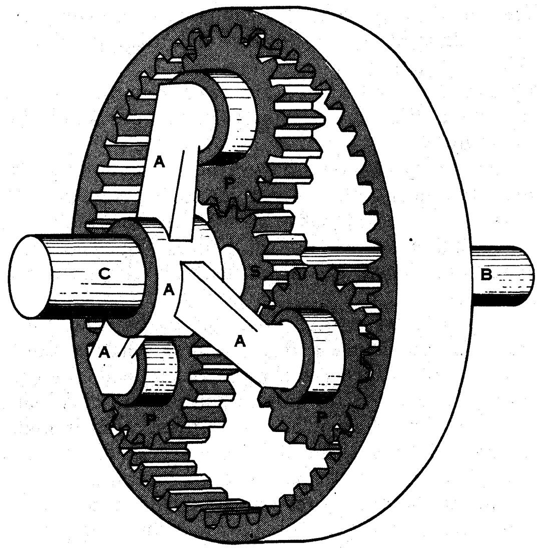

FIG. 4.—PLANETARY,OR EPICYCLIC. GEAR TRAIN

The number of ways in which the gears may be arranged in a planetary system is infinite. The planet gears may be compounded (*i.e.,* have more than one gear on the same shaft) and mesh with other sun and internal gears. None of the gears may be fixed. In this case any two (including the arm) may be attached to input shafts and the remainder to output shafts. Speed ratios of 10,000 are easily obtained in planetary transmissions.

All of the gears shown in figs. 1 to 4 are used for connecting parallel shafts. The shapes of the ends of the teeth shown in fig. 1 are involutes—the curve traced by any point on a taut string when the string is unwrapped from a cylinder (fig. 5[A]). Along their length, the teeth may be either straight and parallel to the shafts, as in fig. 5(A) or curved, as in fig. 5(B). Gears with straight teeth are called spur gears, while those with curved teeth are called helical gears. The latter may be thought of as twisted spur gears, the teeth curving around the gear like the threads on a screw.

On account of the overlapping action between the teeth, helical gears are less noisy in operation and have a higher load-carrying

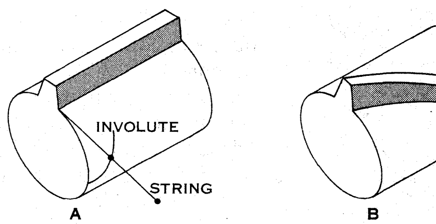

FIG. 5.—GEAR TEETH
(A) Straight or spur; (B) helical

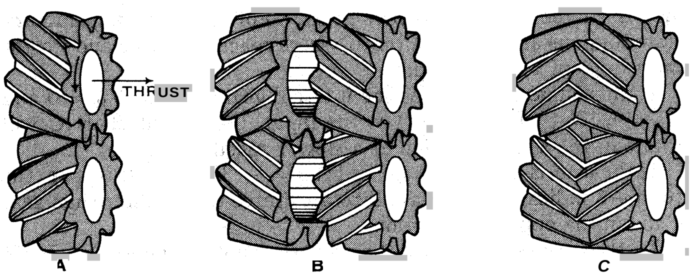

FIG. 6.— HELICAL GEARS
(A) Single helical; (B) double heiical; (C) herringbone

capacity than equivalent spur gears. If used singly, however, an axial thrust load is produced as shown in fig. 6(A). This thrust load is ineffective in turning the shaft and results in an undesirable thrust load on the shaft bearings. This may be overcome by having the teeth slope in opposite directions on the two halves of the gear, as shown in figs. 6(B) and 6(C).

On ships, for the transmission of power from high-speed turbines to low-speed propellor shafts, double helical gears are almost universally employed.

Helical gears may also be used to connect nonintersecting shafts at any angle to one another. Fig. 7 shows an arrangement for connecting shafts inclined at go°. This is the commonest angle for which such gears are used. If the helices sloped in the opposite direction to that shown, the lower shaft would rotate in the opposite direction.

When the shafts are parallel, the contact between the teeth on mating gears is "line contact" regardless of whether the teeth are straight or helical. When the shafts are inclined, the contact becomes "point contact." For this reason crossed-axis helical gears are never used when the power being transmitted is high. However, they are relatively insensitive to misalignment and are frequently employed in instruments and positioning mechanisms where friction is the only force opposing their motion.

There is another aspect in which gears connecting parallel shafts differ from those connecting nonparallel shafts. When the shafts are parallel, there is always one—and only one—pair of imaginary friction disks which would transmit the power with the same speed ratio as the gears. The diameters of these disks are called the pitch diameters of the gears. These diameters must be proportional to the numbers of teeth and fill the space bttween the shafts, and the gear teeth must be equally spaced on both gears. This spacing is known as the circular pitch and is equal to the circumference of the pitch circle divided by the number of teeth.

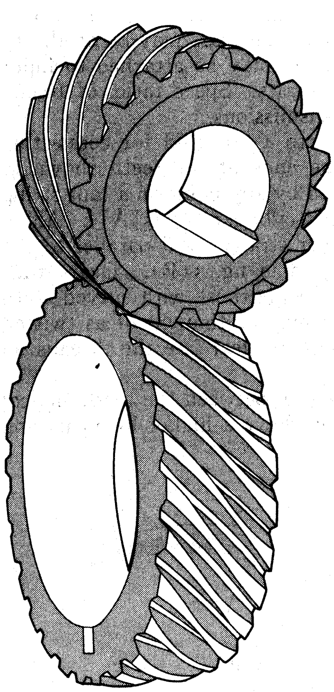

FIG. 7.— CROSSED-AXIS HELICAL GEARS

On crossed-axis helical gears the circular spacing of the teeth need not be the same on both gears of a pair. It follows that the pitch diameters need not be inversely proportional to the speeds. Consequently, if a large speed ratio is required on one pair of gears—say, 100—this large ratio is more easily obtained when the shaft axes are crossed than when they are parallel. With parallel shafts, the pinion pitch diameter would have to be 1/100 of the gear pitch diameter, which is an impractical proportion. With crossed axes, the pinion could have only one helical tooth (called a thread in this case) and be as large as necessary for adequate strength. The pinion would look like a screw, and the gear would have 100 teeth.

In order to achieve line contact and improve the load-carrying capacity of the pair, the gear could be made to partially curve around the pinion in somewhat the same way that a nut envelops a screw. The result would be a worm and gear (fig. 8). It is also possible to make worms of an "hourglass" shape, instead of cylindrical, so that they envelop the gear. This results in a further increase in load-carrying capacity.

Worm gears provide the simplest means of obtaining large ratios in a single pair. However, they are usually less efficient than parallel-shaft gears because when the shafts are parallel there is a sliding movement up and down the teeth only; on crossed-axis gears there is also a sliding movement along the teeth.

On parallel-shaft gears, the friction loss in each pair seldom exceeds 5% of the transmitted power and on helical gears it may be as low as 1%. The losses in worm gears may exceed 75% and are seldom less than 5%. They are greatly affected by the diameter of the worm and the number of threads, single thread worms of large diameter having the highest losses (*i.e.,* the loaest efficiencies). When the efficiency of a worm and gear is more than 50%, the gear can drive the worm. With multiple-thread. hardened and ground steel worms meshing with bronze worm gears, efficiencies exceeding 50% are easily obtained, thus providing compact speed

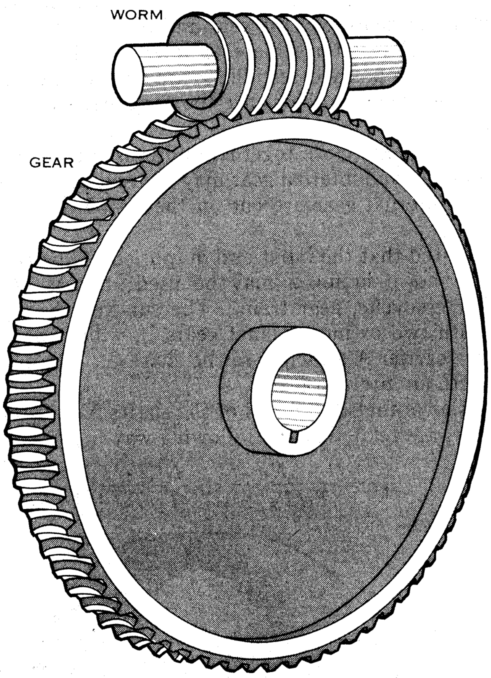

FIG. 8.— WORM AND GEAR

increasers that can be used for driving superchargers on aircraft engines.

For connecting shafts whose axes would intersect if extended, bevel gears are used. The pitch surfaces of bevel gears are frustums of cones, and the teeth, which must be tapered, may be either straight or curved (fig. 9). Although curved-tooth bevel gears are called spiral bevel gears, the curve of the teeth is usually a circular arc. The curvature of the teeth results in overlapping tooth action and creates less noise than straight bevel gears. For the transmission of power at high speeds, spiral bevel gears are superior to straight bevel gears, just as helical gears are superior to spur gears for connecting parallel shafts. Spiral bevel gears are invaluable when power is being transmitted at an angle, as on helicopter transmissions.

When adapted for use on shafts which do not intersect, spiral bevel gears are called hypoid gears (fig. 10). On automobiles they are used to connect the engine drive shaft to the rear axles. The offset permits lowering of the centre of gravity of the body. In some respects, hypoid gears resemble worm gears. There is more sliding movement than on spiral bevel gears, and the pitch surface diameters are not inversely proportional to the speeds. This permits high-speed ratios, since the pinion may be made as large as necessary for adequate strength.

An interesting application of a planetary gear arrangement incorporating bevel gears is found in the differential gears of an automobile (*q.v.*) rear axle. The ring gear, which is driven by the drive shaft pinion, is fixed to the differential carrier which carries the different gears. Bevel pinions are carried on bearings in the carrier and mesh with bevel gears to which the axle shafts are fixed.

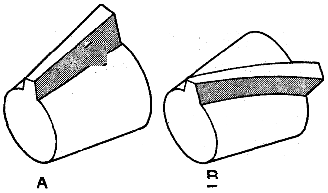

FIG. 9.— BEVEL GEAR TEETH
(A) Straight; (B) spiral

On a straight road, the differential gears revolve as a unit, without meshing action, and the axles revolve as if they were fixed to the ring gear. When turning a corner, the outside wheel (and axle) must turn faster than the inside wheel, and the differential gears rotate relative to one another to permit this. If the angular speeds of the carrier, left axle shaft and right axle shaft are N_C, N_L and N_R respectively, it can be shown that $2N_C = N_L + N_R$. If the rear wheels are jacked up, with the engine stopped. then $N_C = 0$ and $N_L = -N_R$. If the left rear wheel is turned clockwise, the right wheel will turn counterclockwise. Bevel gear differentials are extensively used in computing machines such as adders. If N_L and N_R are the input speeds, N_C will represent one half of their sum. (AR. C.)

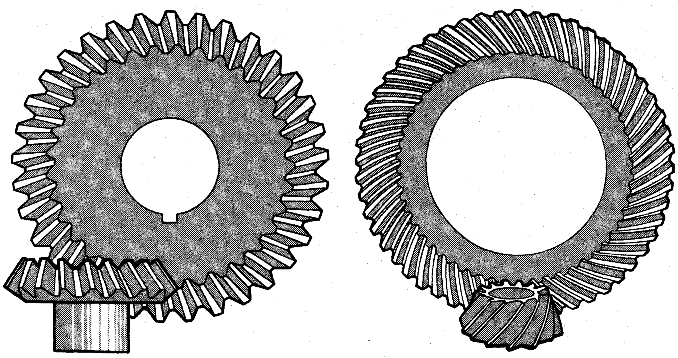

FIG. 10.— SPECIAL GEAR-AND-PINION DESIGNS

GEBER (JABIR; more fully JABIR IBN HAYYAN), was the most celebrated chemist of medieval times. There is reason to believe that he belonged to the famous south Arabian tribe of al-Azd, some members of which settled in the town of Kufa shortly after its foundation by the caliph Omar in A.D. 638. Jabir's father, Hayyan, was a druggist in Kufa and an ardent supporter of the Abbasid family, at that time plotting to secure the caliphate. It is probable that Jabir was born at the town of Tus (near the present Meshed) in the year A.D. 721 or 722, while his father was in Persia as an Abbasid agent. Shortly afterward, Hayyan was arrested and executed by Umayyad officers, and the younger Jabir was sent to Arabia, where he studied under Harbi at Himyari. In later life, Jabir became a friend of Harun al-Rashid's powerful ministers, the Barmakides, and, according to tradition, shared their banishment from Baghdad in 803. Retiring to Kufa, he spent the rest of his life in obscurity, though one authority maintains that he survived until the accession of the caliph al-Ma'mun in 813. His laboratory at Kufa came to light about two centuries later, during building operations in a quarter of the town known as the Damascus Gate.

Jabir was a voluminous writer, and fortunately made a list of the titles of his books, which was reproduced in part by Ibn al-Nadim in his *Kitab al-Fihrist,* a Moslem encyclopaedia of the 10th century A.D. Many of these books are still extant, nearly 100 having been reported as existing in manuscript or native lithographs in various European, Indian and north African libraries. They are, however. for the most part unedited (1928), and it is therefore impossible to express a final conclusion upon Jabir's scientific knowledge.

Jabir's thought is often confused and superstitious, yet he has a twofold importance for the history of chemistry. In the first place he was a skilled and ingenious experimentalist, and describes for the first time the preparation of nitric acid, the method of conducting certain essential chemical operations, and many other things of the same kind. He more clearly than any other early chemist recognized and stated the importance of experiment. Secondly, he suggested the comprehensive theory that all metals are composed of two principles resembling sulfur and mercury. This theory, which was a development of the Aristotelian conception of two "exhalations," persisted for many centuries and was at last modified into the phlogiston theory of Johann Becher and Georg Stahl (17th and 18th centuries). Jabir explained the existence of different varieties of metals by assuming that the sulfureous and mercurial principles are not always pure and that they do not always combine together in the same proportion. If they are perfectly pure, and combine together in the most perfect natural equilibrium, then the product is the most perfect of metals, viz.. gold. Defects in purity or proportion or both result in the formation of silver, lead, tin, iron or copper; but since these metals are all essentially composed of the same constituents as gold, the accidents of combination may be removed by suitable treatment. Such treatment, which Jabir believed could be effected by means of elixirs, was the object of *Alkimia* or alchemy.

Jabir's chemical theory was thus a development of Greek scientific and occult philosophy. Etymological and other evidence renders it likely that his contact with Hellenism was made through Persian channels rather than through Syria and Egypt. The reputation he acquired has never since been equaled in the whole development of chemistry; there is. indeed, scarcely a single later Arabic alchemical work in which he is not quoted, or at least mentioned. When, in the 12th and 13th centuries, Islamic science was transmitted to Latin Christianity, the fame of Jabir went with it; and, at least one of his books was translated into Latin.

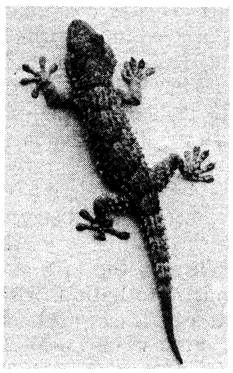
GEBHARD, TRUCHSESS VON WALDBURG (1547–1601), elector and archbishop of Cologne, was born on Nov. 10, 1547, at Cologne, studied at Ingolstadt, Perugia and Louvain, and took orders. He held various positions at the cathedrals of Augsburg, Strasbourg, Cologne, and again at Augsburg, and in Dec. 1577 was elected elector archbishop of Cologne. He became a convert to the Reformed doctrines, but it was suspected that his conversion was due to his desire to marry Agnes, countess of Mansfeld. The marriage was celebrated in Feb. 1583. Gebhard declined to give up his see, and collected an army. In April he was deposed and excommunicated by Pope Gregory XIII. A Bavarian prince, Ernest, bishop of Liège, Freising and Hildesheim. was chosen elector, and war broke out between the rivals. The Lutheran princes of Germany gave no real support to Gebhard, who had Calvinistic leanings, and the only armed assistance he received was from John Casimir, administrator of the Rhenish Palatinate. Early in 1584 he was driven from Bonn. He found refuge in the Netherlands. In 1589 Gebhard went to live in Strasbourg, where he died on May 31, 1601.

GEBHARDT, EDUARD VON (1830–1925), German painter, was born in Estonia, and studied at Diisseldorf, where he became a professor in the academy in 1873. He depicted scriptural subjects, using the German costume of the 15th and 16th centuries for his figures. But his heads were drawn from nature. His art constituted a reaction toward realism after the staged and vapid productions of the Piloty school. Among his more important works are the "Last Supper," and the "Ascension," in the National gallery at Berlin; the "Crucifixion" in the cathedral at Reval. He died at Dusseldorf on Feb. 3, 1925.

GECKO is any lizard of the family Gekkonidae. The names gecko, tokay and cheechak are based on the calls of various species. They are small, usually nocturnal reptiles, rarely over six inches in length, with a soft skin, a short, stout body, large head and weak limbs often equipped with suction-padded digits. Most geckos lack movable eyelids, the eyes, usually large and prominent. being protected by a transparent covering which is probably a modified nictitating membrane. The family is cosmopolitan in distribution, occurring everywhere in warmer climates, even on the remotest oceanic islands, and is adapted to very diverse habitats. All species are insectivorous.

Most geckos have the digits modified for climbing; the fingers and toes are dilated either terminally or at their bases and the lower surface of the dilation is covered with transverse plates whose arrangement is diverse in the various genera; each plate is beset with numerous tiny, hairlike processes which give the whole surface a velvety appearance. When the feet are placed on any surface the velvety pile accommodates itself to the slightest irregularities and pressure forces the air out from between the hairs; the resulting vacuum gives sufficient adhesion to enable many species to climb absolutely smooth and vertical surfaces and even to run across a whitewashed ceiling and even ordinary glass surfaces.



ERIC HOSKING

,,,,, ■, ,, ,,,,, (TARENTOLA MAURITANICA)

Claws are well developed in most species and, in a few, are provided with a special sheath, into which they are retractile. The most remarkable modification of the feet is found in the genus Palmatogecko from the deserts of central South-West Africa; they have no adhesive apparatus but the toes are webbed to their extremities to enable the animal to walk over and partially burrow into the loose sand.

Often the tail is peculiar in shape; it may be long and tapering or short and blunt, or even globular; in one species (*Gymnodactylus* platyurus) it is leaf-shaped. It seems highly probable that in many instances, particularly where it is large and globular, the tail serves as a storehouse of reserve nutriment on which the animal can draw during unfavourable conditions. The tail is extremely fragile and is quickly regenerated, the new one having roughly the same shape and scale pattern as the original.

As a rule the skin is soft and delicate, and covered with minute granules, but frequently there are large tubercles intermixed with these. Teratoscincus, a western Asiatic desert dweller, has. however, developed large, overlapping smooth scales which enable it to slip through the sand with the minimum of friction. Colours as a rule are drab, grays, browns. and dirty whites predominating though one genus, Phelsuma, of Madagascar, comprises the bright green day-active geckos.

Although these curious looking lizards are completely inoffensive, in many regions they have been erroneously regarded as being poisonous, probably from their weird and forbidding appearance. They are actually exceedingly useful because of their insect-eating habit.

Many species have a voice, the call differing with the species and ranging from a feeble click or chirp to a shrill cackle or bark. All species are oviparous, the eggs being white, hard-shelled and usually laid beneath the bark of trees or attached to the under side of leaves. See LIZARD. (H. W. P.; X.)

GED, WILLIAM (1690–1749), Scottish goldsmith, the inventor of stereotyping, was born in Edinburgh in 1690. In 1725 he perfected a system by which printing plates could be cast from type forms but, not being able to interest Edinburgh printers in his venture, he entered into partnership with William Fenner, a London stationer, and Thomas James, a typefounder. They obtained from Cambridge university the privilege of printing Bibles and prayer books by Ged's method, but the partnership was undermined by the typefounder and the process hindered by compositors who saw in it a threat to their trades. Ged returned to Edinburgh where he died on Oct. 19, 1749. A Cambridge prayer book was possibly printed from Ged's plates and certainly an edition of Sallust in Edinburgh. His sons briefly carried on the process but eventually it was abandoned until taken up by others later in the century. (J. C. MN.)

GEDDES, SIR ERIC CAMPBELL (1875–1937), British businessman and administrator remembered for his reforms in economy known as the "Geddes axe," was born at Agra, India, on Sept. 26, 1875. Educated at Merchiston Castle school, Edinburgh, and the Oxford Military college, he went to the United States at 17 and worked in lumber camps, in steel mills and on railways. He also worked on railways in India before returning to England in 1906 to join the North Eastern Railway Co. During World War I Geddes, under Lloyd George as minister of munitions, held several posts in which he brought the British lines of communication in France to a high standard of efficiency. In 1917 he was elected to parliament for the borough of Cambridge and appointed first lord of the admiralty, and in 1919 he became the first minister of transport. Geddes' best-known work was as chairman of the committee on national expenditure, its suggested measures of widespread economy in the nation's finances being called the Geddes axe. In 1922 he left parliament to resume a business career. He died at Hassocks, Sussex, on June 22, 1937.

GEDDES, NORMAN BEL (1893–1958), U.S. designer, particularly influential in the development of theatrical and industrial design, was born in Adrian, Mich., April 27, 1893. Following brief study at the Cleveland Institute of Art and the Art Institute of Chicago, he became interested in the theatre and staged his own first play, Nju, and five others for the Los Angeles Little theatre in 1916. In New York in 1918 he did scenic designs for the Metropolitan Opera. He designed, produced or directed some 200 operas, films: plays and musical comedies. His sets included those for Max Reinhardt's The Miracle (1923); Jeanne *d'Arc*, produced in Paris with Eva Le Gallienne (1925); and Dead End (1935), which were said at the time to have been "more convincing than reality." He changed the whole artistic concept of scenic design from the ornamental to the clean, functional effect—that the audience would "not be conscious of any scenery or background other than the mood in which the characters of the play should move." Toward the end of the 1920s he adapted his ideas to the area of industrial design, gradually building an organization that employed 2,000, and designed such a variety of things as skyscrapers, inkwells, yachts, radios, interiors and refrigerators. He did as much as any U.S. designer to popularize "streamlining" as a style of industrial design (*q.v.*). He designed the General Motors Futurama building and exhibit at the New York world's fair (1939–40), which drew greater crowds than any other exhibit. Geddes also designed theatres all over the world, staged circuses, developed equipment and techniques for the armed services and wrote books on a number of subjects. He died on May 8, 1958, in New York city. One of his daughters, Barbara Bel Geddes, gained fame as an actress. (CD. BN.)

GEDDES, SIR PATRICK (1854–1932), British biologist and sociologist, a pioneer theorist in civic and regional planning, was born at Ballater, Scot., on Oct. 2, 1854, and died at Montpellier, France, on April 17, 1932. He trained in biology in London (under T. H. Huxley) and in France, becoming (1883) professor of botany at University college, Dundee, and (1919) of sociology and civics at Bombay university. His chief biological work is a pioneer study of sex. In sociology his originality is shown by his thesis, based upon surveys in Scotland, India, Israel and elsewhere, that the development of human communities presents essentially biological problems which for solution depend first upon diagnosing the complex interactions between people, their environments and their activities. Novel when first published, Geddes' thesis and many of his ideas for its application were later accepted as fundamental for wise civic and regional planning. His works include The Evolution of Sex (with J. A. Thomson, 1900) and Cities in *Evolution* (1913).

See A. D. Peacock, "Patrick Geddes: Biologist," *Alumnus* Chronicle, St. Andrews (1955); P. Mairet, Pioneer *of* Sociology: *Life* and *Letters* of Patrick *Geddes* (1957). (A. D. P.)

GEDYMIN, or GEDIMINAS (d. 1341), grand duke of Lithuania, was supposed by some to have been the servant of Witen, prince of Lithuania, but more probably he was Witen's younger brother and the son of Lutuwer. Gedymin inherited a vast domain, comprising Lithuania proper and parts of Russia, but these lands were environed by powerful foes, the most dangerous being the Teutonic Knights and the Livonian Knights of the Sword. The systematic raiding of Lithuania by the knights under the pretext of converting it had long since united all the Lithuanian tribes against the common enemy; but Gedymin aimed at establishing a dynasty which should make Lithuania not merely secure but mighty, and for this purpose he began negotiations with the Holy See. At the end of 1322 he wrote to Pope John XXII soliciting his protection against the persecution of the knights, informing him of the privileges already granted to the Dominicans and the Franciscans in Lithuania, and desiring that legates should be sent to receive him also into the church. Gedymin then issued circular letters, dated Jan. 25, 1325, to the principal Hanse towns, offering a free access into his domains to settlers. The immigrants were to choose their own settlements and be governed by their own laws. Similar letters were sent to the Wendish or Baltic cities, and to the bishops and landowners of Livonia and Esthonia. In short Gedymin anticipated Ivan the Terrible and Peter the Great by throwing open the semisavage Russian lands to western culture.

In Oct. 1323 representatives of the archbishop of Riga, the bishop of Dorpat, the king of Denmark, the Dominican and Franciscan orders, and the Grand Master of the Teutonic Order assembled at Vilna, when Gedymin confirmed his promises and undertook to be baptized as soon as the papal legates arrived. A compact was then signed at Vilna confirming the promised privileges. But the christianizing of Lithuania was by no means to the liking of the Teutonic Knights, and they strove to nullify Gedymin's design. Gedymin's chief object was to save Lithuania from destruction at the hands of the Germans. But he was still a pagan reigning over semi-pagan lands; he was equally bound to his pagan kinsmen in Samogitia, to his orthodox subjects in Red Russia, and to his Catholic allies in Masovia. His policy, therefore, was necessarily tentative and ambiguous. Thus his raid upon Dobrzyn, the latest acquisition of the knights on Polish soil, gave them a weapon against him. The Prussian bishops, who were devoted to the knights, at a synod at Elbing questioned the authority of Gedymin's letters and denounced him as an enemy of the faith; his orthodox subjects reproached him with leaning towards the Latin heresy; while the pagan Lithuanians accused him of abandoning the ancient gods. Gedymin then repudiated his former promises; he refused to receive the papal legates who arrived at Riga in Sept. 1323, and dismissed the Franciscans. Gedymin saw that the pagan element was still the strongest force in Lithuania, and could not yet be dispensed with in the coming struggle for nationality. But, through his ambassadors, he privately informed the papal legates at Riga that his difficult position compelled him to postpone his own baptism, and the legates showed their confidence in him by forbidding the neighbouring states to war against Lithuania for the next four years, besides ratifying the treaty made between Gedymin and the archbishop of Riga. Nevertheless in 1325 the Order, disregarding the censures of the church, resumed the war with Gedymin, who by the marriage of his daughter to Casimir, son of Wladislaus Lokietek, king of Poland, had improved his position.

While on his guard against his northern foes, Gedymin from 1316 to 1340 was extending his rule over neighbouring Russian principalities. The principality of Halicz-Vladimir was obtained by the marriage of his son Lubart with the daughter of the Haliczian prince; Kiev seems to have been acquired by conquest. Gedymin also secured an alliance with the grand duchy of Muscovy by marrying his daughter, Anastasia, to the grand duke Simeon. He was strong enough to counterpoise the influence of Muscovy in northern Russia, and assisted the republic of Pskov, which acknowledged his overlordship, to break away from Great Novgorod. His internal administration bears all the marks of a wise ruler. He protected the Catholic as well as the orthodox clergy, encouraging them both to civilize his subjects: he raised the Lithuanian army to the highest state of efficiency then attainable; defended his borders with a chain of strong fortresses; and built numerous towns including Vilna, the capital (1323).

Gedymin died in the winter of 1342 of a wound received at the siege of Wielowa. Married 3 times, he left 7 sons and 6 daughters.

(Cracow, 189;); Vladimir Boniiatovich Antonovich, *Monograph concerning the History of Western and South-western Russia* (Rus.) (Kiev, 1885). (R. N. B.; X.)

GEELONG, a city in Victoria, Austr., and second port of the state, is on a land-locked part of Port Phillip bay known as Corio bay. It lies 45 mi. S.W. of Melbourne. Pop. (1954) 20,034. Geelong is a rail junction and manufacturing centre with woollen mills, cement, salt and heavy engineering works; rope is manufactured and there are oil refineries. It is the outlet for the wool-growing area in the state's Western district and wool sales are held several times a year. In the surrounding country agriculture is carried on. Corio bay, a safe and commodious harbour, has a depth of 32 ft. at low water. There is extensive quayage and the largest ships are able to unload at modern wharves, which are connected by rail with all parts of the state. The city is an educational centre and in the mid 1950s contained the only textile college in the commonwealth. Torquay, Lorne, Barwon Heads and Queenscliff are seaside resorts in the vicinity.

GEERTGEN, TOT SINT JANS (*c.* 1465–*c.* 1493), Dutch painter active in Haarlem, one of the most interesting Dutch artists of the 15th century and important as representing a school of which very few works have survived destruction. He was surnamed "tot Sint Jans," as he lived with the knights of St. John at Haarlem. According to K. van Mander, the authority on his life, he was a pupil of Ouwater at Haarlem. Neither the year of his birth nor of his death is known, but only that he was 28 years old when he died. Geertgen painted a large triptych for the high altar of the knights of St. John. The central panel with the Crucifixion and one of the wings were destroyed in religious skirmishes; but the other wing has been identified with the aid of Van Mander's description. This wing is now in the Vienna gallery, sliced into two separate panels, front and back. The front represents the dead Christ being mourned by His friends. The pathos of the scene is expressed with deep feeling. The influence of Rogier van der Weyden is seen in the Magdalen wringing her hands. In the background is a realistic burial scene on Mount Calvary. Here the artist broke away from the traditional symbolical assemblage of emblematic figures on the altarpieces of his time and felt his way toward the more vivid and dramatic style of the next generation of Dutch painters.

The same is true of the other panel (the back of the wing) on which the emperor Julian the Apostate is directing the burial of the bones of St. John the Baptist. In the mid-distance of this panel is an admirable group of portraits of the knights of St. John at Haarlem among whom the artist lived. They are lifelike studies of individual characters and seem to presage those great democratic portrait groups famous in Dutch paintings of the 17th century.

A number of pictures are ascribed to him on stylistic grounds. Among these is the "St. John the Baptist" of the Berlin museum, where the pensive saint is sitting in beautiful parklike scenery. In the same collection is "Virgin and Child." The Louvre contains the "Resurrection of Lazarus," the Amsterdam museum, "The Virgin's Kindred" and the "Adoration of the Magi." The "Man of Sorrows" at Utrecht is a painful but wonderful picture; a triptych at Prague represents the "Adoration of the Magi" in the centre and "Donors and Saints" on the wings. It is distinguished for the original conception of some of its figures and for its animated background. The National gallery, London, has one of his most attractive pictures. It represents "Nativity," a night scene, remarkable for its rendering of chiaroscuro. One of the most striking of Geertgen's achievements is his harmonious fusion of the elements of the landscape.

GEEZ is the language of an ancient nomadic Semitic race of Ethiopia. *See* Ethiopian Literature; Semitic Languages.

GEFLE (Gavle), a seaport of Sweden on an inlet of the Gulf of Bothnia. chief town of the district of Gavleborg, 112 mi. N.N.W. of Stockholm. Pop. (1950) 46,919. It is the chief port of the district of Kopparberg, with its mines and forests.

The exports consist principally of timber and wood pulp, iron and steel, imports of coal. grain and machinery. The harbour is usually icebound from January to April. There are slips and shipbuilding yards, and a manufacture of sailcloth. The town is an important industrial centre, having tobacco and textile mills, and breweries. At Skutskar at the mouth of the Dal river are wood pulp mills and sawmills, dealing with the timber floated down the river.

The principal buildings are a castle, founded by King John III (1568–92), but rebuilt later, and a council house erected by Gustavus III.

GEGENBAUR, KARL (1826–1903), German anatomist, was born on Aug. 21, 1826, at Wurzburg and was educated at the university there. In 1855 he was appointed professor of anatomy at Jena, and in 1873 at Heidelberg, where he was also director of the Anatomical institute until 1901.

In his best-known work. *Grundriss der vergleichenden Anatomie* (1874, Eng. trans. 1878), Gegenbaur laid stress on the high value of comparative anatomy as the basis of the study of homologies. A distinctive piece of work was effected by him in 1871 in supplementing the evidence adduced by Thomas Huxley in refutation of the theory of the origin of the skull from expanded vertebrae. Huxley demonstrated that the skull is built up of cartilaginous pieces; Gegenbaur showed that "in the lowest (gristly) fishes, where hints of the original vertebrae might be most expected, the skull is an unsegmented gristly brain box, and that in higher forms the vertebral nature of the skull cannot be maintained, since many of the bones, notably those along the top of the skull, arise in the skin."

In 1875 he founded the *Morphologisches Jahrbuch,* which he edited for many years. In 1901 he published a short autobiography under the title *Erlebtes und Erstrebtes.* Gegenbaur died at Heidelberg on June 14, 1903.

See M. Furbringer, "Karl Gegenbaur," in *Heidelberger Professoren aus dem ryten Jahrhundert* (1903).

GEGENSCHEIN (or Counterglow), is a slightly oval patch of faint luminosity just opposite the sun in the night sky. As the sun moves in its apparent annual path among the stars, the gegenschein moves along the ecliptic. always in the region where the sun was six months earlier or will be six months later. The patch of light is so faint that it can be seen only in the absence of moonlight, away from city lights and with the eyes adapted to darkness. Most observers use averted vision in order to utilize the peripheral regions of the retina which are relatively sensitive to very faint light. The gegenschein is lost in the light of the Milky Way in the summer and winter. The best observing periods are February, March, April and August, September, October.

The gegenschein and the zodiacal light (*q.v.*) form a continuous band of light along the ecliptic. The spectrum of the gegenschein is similar to that of the sun, and it is generally believed that it is the result of the back reflection of sunlight from meteoric material located in a region of the solar system opposite the sun and, therefore, outside the earth's orbit. The enhanced intensity in the counter-sun direction may be attributed to an increase in the concentration of particles in that direction, to an increased reflecting efficiency for direct back reflection or perhaps to a combination of these two causes. (F. E. R.)

GEIBEL, EMANUEL (1815–1884), German poet, was born at Lubeck on Oct. 17, 1815. He studied theology, but his real interests lay in classical and romance philology. In 1838 he accepted a tutorship at Athens, where he remained until 1840. His first poems, *Zeitstimmen,* political poems directed against radicalism, appeared in 1841; a tragedy, *Konig Roderich,* in 1843. In the same year he received a pension from the king of Prussia, which he retained until his invitation to Munich by the king of Bavaria in 1851 as honorary professor at the university. Meanwhile he had produced *Konig Sigurds Brautfahrt* (1846), an epic, and *Juniuslieder* (1848, 33rd ed., 1901), lyrics which both in content and in poetic form showed a great advance on his early work. A volume of *Neue Gedichte* (Munich, 1857) mainly on classical subjects, was followed by the *Spätherbstblätter* (1877). His later years were spent in Lubeck, where he died on April 6, 1884. His works further include two tragedies, *Brunhild* (1858, 5th ed.. 1890), and *Sophonisbe* (1869). and translations of French and Spanish popular poetry. Beginning as a member of the group of political poets who heralded the revolution of 1848, Geibel became gradually conservative. He was the chief poet to welcome the establishment of the empire in 1871 and mas one of the early singers of German imperialism. His strength lay not, however, in his political songs but in his purely lyric poetry, such as the fine cycle *Ada* and his still popular love songs.

Geibel's *Gesammelte Werke* were published in 8 vol. (1883, 4th ed. 1906); his *Gedichte* have gone through about 130 editions. An excellent selection in one volume appeared in 1904.

GEIGER, ABRAHAM (1810–1874), Jewish theologian and orientalist, a leader in the Reform movement in Germany, was born at Frankfort-on-Main on May 24, 1810, and educated at the universities of Heidelberg and Bonn. In 1832 he went to Wiesbaden as rabbi of the synagogue, and in 1835 helped to found, and thereafter edited, the *Zeitschrift fur jiidische Theologie.* From 1838 to 1863 he lived in Breslau (being after 1843 first rabbi), where he organized the reform movement in Judaism and wrote some of his most important works. These include *Lehr-and Lesebuch zur Sprache der Mischna* (1845), a translation into German of the poems of Juda ha-Levi (1851), and *Urschrift und Übersetzungen der Bibel in ihrer Abhangigkeit von der innern Entwicklung des Judentums* (1857). In 1863 Geiger became head of the synagogue of Frankfurt, and in 1870 he moved to Berlin, where he took the principal charge of the newly established seminary for Jewish science. His later works included a history of Judaism, *Das Judentum und seine Geschichte* (1865–71). He died on Oct. 23, 1874, at Berlin.

See the memorial volume, *Abraham Geiger, Leben und Lebenswerk,* prepared by his son Ludwig Geiger in collaboration with others on the 100th anniversary of his birth (1910).

GEIGER, THEODOR (1891–1952), German sociologist, outstanding for his studies of social stratification, was born in Munich on Nov. 9. 1891, and received his early training in law and statistics. The upheavals of the 1920s in Germany led him to inquiries into mass behaviour and the sociology of political movements but the coming to power of the Nazi party in 1933 drove him into exile in Denmark. After some years in Copenhagen, he was appointed to the first chair in sociology in the country in the University of Aarhus. During the German occupation of Denmark in World War II he again lived in exile, in Sweden, returning to Aarhus in 1945. He then began a series of studies in social stratification and social mobility, culminating in a detailed work on the social origins of the population of Aarhus. Through UNESCO and the International Sociological association, of which he was a founder member, such studies led him to cross-national comparisons in this field. He died on June 19, 1952, at sea while returning from a visiting professorship in the University of Toronto.

His principal works include *Die Masse und ihre Aktion* (1926), *Die Soziale Schichtung des deutschen Volkes* (1932) and *Soziale Umschichtungen in einer dänischen Mittelstadt* (1951). (J. My.)

GEIJER, ERIK GUSTAF (1783–1847), Swedish historian, poet and phiiosopher, the inspiration of the national movement after the political upheavals in 1809, and of liberal thinking in the 1840s, was born Jan. 12, 1783, at Ransater, Värmland. His father owned a foundry and the home mas musical and sociable. A happy childhood instilled in Geijer an independence and harmony which he retained throughout life. Another important influence was a year's stay in England (1809–10). There he listened to parliamentary debates, through which he gained insight into the political life of a great state, and was impressed by the spirit of national unity and freedom. A collection of his diaries and letters was published as *Geijer i England, 1809–10* (1914; Eng. trans. 1932). Geijer continued to follow political and industrial developments in England in British journals, among them *The Edinburgh Review,* and events there were partly responsible for his famous "defection" in 1838, when, having long been the leading theorist of Swedish conservatism, he went over to the liberal camp. The political defeat which Sweden suffered in 1809 through the loss of Finland to Russia had led him to abandon his earlier liberalism for nationalism. In 1811 he was one of the founders of the *Gotiska förbundet,* which aimed at furthering a deeper national feeling through historical studies. He contributed to its journal *Iduna* (1811) a number of famous poems on national themes, *e.g.,* "Vikingen" and "Odalbonden" ("The Yeoman").

In 1817 Geijer became professor of history at Uppsala. His main historical works are *Svea Rikes Havder* (1825) and *Svenska folkets historia* (3 vol., 1832–36; Eng. trans., abridged, 1845). Geijer's historical writings are objective, sparing in comment! and show both a grasp of each period's special problems and a sense of the inner continuity of Swedish history in the context of events in Europe. In the posthumously published philosophical *Människans historia* (1856), Geijer interprets historical events as a combination of tradition and creation. His reflections on creation reveal kinship with Henri Bergson's philosophy of half a century later, and his ideas on the unpredictability of events and individual responsibility in historical development are echoed in Isaiah Berlin's *Historical Inevitability* (1954). Geijer developed these ideas in his "philosophy of personality," based on the principle of reciprocity: the "I" and "Thou" develop through reciprocal influence. This led to the conclusion that only in a free community can the social character of the individual fully develop; oppression restricts it.

The isolation which followed Geijer's break with conservative friends led to a new flowering of his lyric poetry. Some of his poems written between 1838 and 1841, and set to his own music, belong to the masterpieces of Swedish verse, expressing the feelings of a farmer, a wanderer and a seeker after truth. They were printed in his collected works (1849–55).

Geijer died at Stockholm, April 23, 1847.

The most comprehensive edition of Geijer's works is that edited by J. Landquist, 13 vol. (1923–31).

Landquist, *Geijer. En levnadsteckning* (1954); *Geijer-studier,* 3 vol., published by the Geijer society (1951–58). (J. LT.)

GEIKIE, SIR ARCHIBALD (1835–1924), Scottish geologist, was born at Edinburgh on Dec. 28, 1835. He was educated at the high school and University of Edinburgh, and in 1855 was appointed an assistant on the geological survey. His ability at once attracted the notice of his chief, Sir Roderick Murchison, with whom some of his earliest work was done on the complicated regions of the Highland schists; the small geological map of Scotland published in 1862 was their joint work, and a larger map was issued by Geikie in 1892. In 1863 he published his essay "On the Phenomena of the Glacial Drift of Scotland" *(Trans. Geol. Soc. Glasgow)* in which the effects of ice action in that country were for the first time clearly and connectedly delineated. His *Scenery of Scotland* (1865; 3rd ed., 1901), was, he claimed, "the first attempt to elucidate in some detail the history of the topography of a country." In the same year he was elected fellow of the Royal society. At this time the Edinburgh school of geologists — prominent among them Sir Andrew Ramsay, with his *Physical Geology and Geography of Great Britain*—were maintaining the supreme importance of denudation in the configuration of land surfaces, and particularly the erosion of valleys by the action of running water. Geikie's book was an able contribution to the doctrines of the Edinburgh school.

In 1867, when a separate branch of the geological survey was established for Scotland, he mas appointed director. He was the first holder (1871) of the Murchison professorship of geology and mineralogy at Edinburgh. These two appointments he held till 1881, when he succeeded Andrew Ramsay in the joint offices of director general of the geological survey of the United Kingdom and director of the museum of practical geology, London, from which he retired in Feb. 1901. A feature of his tenure of office was the impetus given to microscopic petrography, a branch of geology to which he had devoted special study, by a splendid collection of sections of British rocks. Later he wrote two important and interesting survey memoirs, *The Geology of Central and Western Fife and Kinross* (1900), and *The Geology of Eastern Fife* (1902).

In 1871 Geikie brought before the Geological society of London an outline of the Tertiary volcanic history of Britain. He traveled not only throughout Europe, but in western United States to examine volcanic formations. While the canyons of the Colorado confirmed his long-standing views on erosion, the eruptive regions of Wyoming, Montana and Utah supplied him with valuable data in explanation of volcanic phenomena. The results of his further researches were given in his paper on "The History of Volcanic Action During the Tertiary Period in the British Isles," *Trans. Roy. Soc. Edin.* (1888). His mature views on volcanic geology were stated in his presidential addresses to the Geological society in 1891 and 1892, and afterward in his book, *The Ancient Volcanoes of Great Britain* (1897). Other results of his travels are collected in his *Geological Sketches at Home and Abroad* (1882).

Geikie was president of the British association in 1892 and of the Royal society in 1909; he received the Order of Merit in 1914. He died near Haslemere, Surrey, on Nov. 10, 1924. His experience as a field geologist resulted in an admirable textbook, *Outlines of Field Geology* (5th ed. 1900). His *Text-Book* (1882, 4th ed. 1903), and *Class-Book* of geology are standard works.

His other works include *Memoir of Edward Forbes* (with G. Wilson), and memoirs of his old chiefs Sir R. I. Murchison (1875) and Sir Andrew Crombie Ramsay (1895); *Founders of Geology* (lectures at Hopkins University 1897); *Geological Map of England and Wales, With Descriptive Notes* (1897); *Types of Scenery and Their Influence on Literature,* Romanes lectures (1898); *The Teaching of Geography* (1887); *Scottish Reminiscences* (1904); and *Landscape in History and Other Essays* (1905).

GEILER VON KAISERSBERG, JOHANN (1445–1510), "the German Savonarola," noted as an exceptionally forceful and impressive preacher, was born at Schaffhausen on March 16, 1445, but in 1448 went to live at Kaisersberg in Upper Alsace. He studied at Freiburg university, where he afterward lectured until 1478, when he accepted a call to fill an office as preacher, created for him, at the cathedral of Strasbourg. There his sermons — bold, incisive, denunciatory, abounding in quaint illustrations and based on texts by no means confined to the Bible—won for him a wide fame. Although he was much interested in reform, there is no evidence that he ever considered leaving the church. Geiler died at Strasbourg on March 10, 1510.

See L. Dacheux, *Un Réformateur catholique à la fin du XVe siècle* (1876).

GEISHA, the name of a professional class of women in Japan whose occupation is to entertain men, particularly at businessmen's parties in public restaurants *(ryôri-ya).* The word geisha literally means "art-person," and many of the women sing, dance or play musical instruments, but the majority are merely adept in the art of conversation. The main function of the geisha in society is to provide an atmosphere of chic and gaiety. The women are usually exquisitely dressed, delicately mannered and have a knowledge not only of the past and its elegance but of contemporary gossip. The geisha system is a form of indentured labour, although some girls, attracted by the glamour of the life, volunteer. Usually, a girl at an early age is given by her parents for a sum of money to an organization. She is taught, trained, fed and clothed for a period of years. Then she emerges into the society (known as *karyukai,* the "world of flowers and willows") and begins earning money to repay her parents' debt and her past keep. Inadequate geisha may be hired for the equivalent of a few dollars an hour, while famous ones can command as much as several hundred dollars for a single dance. Geisha are often associated with the theatre (many marry actors), and plays frequently dramatize a geisha as a heroine.

When a geisha marries, she retires from the profession. If geisha do not marry, they usually retire as restaurant owners, teachers of music or dance. or trainers of younger geisha. (F. Bs.)

GEISLINGEN, a town in Baden-Württemberg, on the Thierbach. 38 mi. by rail E.S.E. of Stuttgart. Pop. (1950) 22,535. It has shops for the carving and turning of ivory and wood, besides iron works, machinery factories, glassworks and brewing. The church of St. Mary contains fine wood carving. Above the town lie the ruins of the castle of Helfenstein, which was destroyed in 1552. The town, which passed to Mi'urttemberg in 1810, has chalybeate springs.

GEL. A gel is an elastic coherent mass consisting of a liquid in which ultramicroscopic particles are either dispersed or arranged in a fine network extending throughout the mass. The particles may be, for example, large molecules, such as proteins; or small crystals, such as bentonite; or polymer particles, such as polystyrene. Gels swell in suitable liquids. Depending on the gel and on the liquid, the swelling (that is, the increase in gel volume) may be minute or very large. Extensive swelling results in a gradual transformation of the gel into a colloidal solution. The rheological properties of a gel vary between those of a viscous or elastic liquid and those of a solid. Some gels can be transformed into very fluid colloidal solutions by heat. Others, known as thixotropic gels, can be liquefied by mechanical action. Removal of the liquid phase, *e.g.*, by evaporation, leads to xerogels. Xerogels are often called aerogels if the air-filled capillaries crisscrossing the system are numerous and wide. For a clearer distinction between gel and xerogel, the presence of liquid in the former may be emphasized by use of the term lyogel instead of the term gel. The terms hydrogel, alcogel, etc., may be used instead, if, in addition, the type of liquid is of interest. Gelatine forms typical lyogels. Dry silicagel is a typical xerogel. The term gel is also used even when it may not be certain whether a second phase such as air or a liquid is present in the system prior to swelling. A typical gel of this type is rubber. The ability of such systems to swell extensively and to change to typical lyogels in the course of swelling, and, in addition, their characteristic elastic properties are considered a sufficient justification to classify them as gels. Precipitates from colloidal solutions are also occasionally called gels. This usage is not recommended since the precipitates do not form a coherent mass. If the individual units of a precipitate conform to the definition of a gel, each unit may be called a microgel. A microgel may represent an aggregate of colloidal particles or a crosslinked complex of macromolecules. (WI. H.)

GELA, a town of Sicily on the S. coast, province of Caltanisetta. 74 mi. by rail and 41 mi. direct E.S.E. of Girgenti. Pop. (1951) 43.326 The poorly built modern town stands on a sandhill near the sea, with a fertile plane (the ancient Campi Geloi) to the north of it. It has only an open roadstead. Outside the town to the east are scanty remains of a Doric temple (480–440 B.c.?) which was still standing in the 18th century, of which a single pillar only remains (height about 26½ ft., lower diameter 5⅔ ft.). Between it and the modern town the stylobate of a large and earlier temple was found. This seems to have been constructed toward the end of the 7th century B.C. on the site of a still earlier edifice. The stylobate measures 115 by 58 ft. A large number of decorative terra cottas were found. Both buildings were probably dedicated successively to Athena. On the west of the town. on the Capo Soprano, was the ancient necropolis, where many tombs of the Greek period have been discovered.

The ancient city was founded by Cretan and Rhodian colonists in *c.* 688 B.C., and itself founded Acragas (see AGRIGENTUM) in 582 B.C. It also had a treasure house at Olympia. The town took its name from the river to the east. The Rhodian settlers called it Lindioi (see LINDUS). Gela enjoyed its greatest prosperity under Hippocrates (498–491 B.C.), whose dominion extended over a considerable part of the island. Gelon seized the tyranny on his death, soon became master of Syracuse and transferred his capital there with half the inhabitants of Gela, leaving his brother Hieron to rule over the rest. Its prosperity returned, however, after the expulsion of Thrasybulus in 466 B.C., but in 405 it was abandoned by Dionysius' order (see SYRACUSE). The inhabitants returned and rebuilt the town but it was only refortified in the time of Timoleon. In 311 B.C. Agathocles put to death over 4,000 of its inhabitants; and finally, after its destruction by the Mamertines about 281 B.C., Phintias of Agrigentum transferred the remainder to the new town of Phintias (now Licata, *q.v.*). In Roman times they still kept the name of Gelenses or Geloi in their new abode. The modern town was formerly known as Terranova di Sicilia. It was heavily bombed by the Allies in World War II.

Remains of a temple of Athena of the 6th century B.C. with five terra cottas have been found; also scanty remains of another, a century later (perhaps that of Apollo). (T. A.)

GELADA, a large baboonlike animal, Theropithecus gelada, differing from the true baboons (*q.v.*) by the nostrils being situated some distance from the tip of the muzzle. The gelada, sometimes called lion baboon, resembles the Arabian or hamadryas baboon in having a heavy mantle of long blackish-brown hair covering the forequarters of the old males. with the exception of the bare chest, which is reddish flesh-colour. The gelada inhabits the mountains of southern Ethiopia, where it lives in the steep cliffs of rocky ravines. It seldom climbs trees, preferring to forage for its food — leaves, roots and tubers — on open ground. See also PRIMATES.

GELASIUS, the name of two popes.

ST. GELASIUS I (d. 496), pope from 492 to 496, succeeded Felix III in March 492. The date and place of his birth are not known, though it is probable that he was born a Roman citizen in Africa. His pontificate was devoted mainly to combating the Acacian schism which had arisen in the east during the patriarchate of Acacius (471–489) as a result of the Roman see's refusal to accept the Henoticon, a peace formula designed by the emperor Zeno to reconcile the dissident Monophysites (*q.v.*). During this long bitter struggle with the Eastern Church, Gelasius maintained openly and firmly the primacy of jurisdiction and the apostolic origin of the papacy. This difficult contest, though not settled during his pontificate, earned him the distinction of being one of the great architects of the Roman primacy. His writings, which show clearly the influence of Augustine and Leo I, include various decrees, six theological treatises and some 60 letters, of which the most celebrated is the letter addressed to Anastasius I in 494, in which Gelasius sets forth his understanding of the relation of the church to the empire: "There are two powers by which this world is chiefly ruled: the sacred authority of the priesthood and the authority of kings." Gelasius' doctrine that both sacred and civil power are of divine origin and independent, each in its own sphere, is the most progressive thinking on this subject up to that time and for many centuries afterward. If the Gelasian formula had taken firm root in Christian tradition, it is very likely that the subsequent history of the papacy would have been different. Falsely attributed to Gelasius are the Decretum Gelasianum (on the canonical books of the Bible) and the Sacramentarium Gelasianum. Gelasius died on Nov. 19, 496. His feast is kept in the west on Nov. 21. See also PAPACY : The First Six Centuries. (R. E. McN.)

GELASIUS II (John of Gaeta) (d. 1119), pope from 1118 to 1119, nas called to Rome from Monte Cassino and created cardinal (c. 1082). then papal chancellor (1089). He was elected pope Jan. 24, 1118. at an advanced age, as successor to Paschal II. whom as leader of the moderate cardinals he had defended against his critics. Gelasius had a reign of unending misfortunes; he was grossly maltreated by the pro-imperial Frangipani, and twice driven from Rome by Henry V, who installed the antipope Gregory VIII. Gelasius died in France on Jan. 28, 1119, as he planned for a council at Reims, leaving the close of the struggle to his successor, Calixtus II.

See H K Mann, ***The Lives** of **the Popes in the Middle Ages***, vol. viii, 2nd ed (1925). (J J. RN.)

GELATIN, one of the commoner proteins, is most .familiar as a food; it has, however, many industrial uses which do not require the high purity of the edible grades. Its name is derived from the Lat. gelata, and describes its most characteristic property; *i.e.*, gel formation in water. Contrary to the popular but erroneous concept, gelatin has not been and cannot be prepared from such proteins as horns, hoofs, lungs, muscle tissue and blood. Gelatin is derived from collagen, which is the prime constituent of all white fibrous connective tissue occurring in the animal body. Upon hydrolysis, collagen yields a series of degradation products which are never found in the living animal body and which are called gelatin. This connective tissue is well known in the form of cartilage, sinews, skin or ossein (protein matrix of bone).

Although the relative proportions of constituent amino acids in collagen and gelatin are substantially the same, the physical and chemical properties of these two proteinaceous materials differ widely. Whereas collagen swells and hydrates in dilute acid or alkaline solution, it will not dissolve without hydrolytic cleavage to form the more soluble gelatin. This transformation of collagen into gelatin is rather analogous to the hydrolysis of starch:

$$\text{Collagen} \rightarrow \text{gelatins} \rightarrow \text{proteoses} \rightarrow \text{peptones} \rightarrow \text{peptides} \rightarrow \text{amino acids}$$
$$\text{(high viscosity} \longrightarrow \text{low viscosity)}$$
$$\text{Starch} \longrightarrow \text{dextrins} \longrightarrow \text{glucose.}$$

Gelatin, like dextrin, can vary in molecular size, and therefore a tremendous number of different qualities of gelatin, as of dextrin, are possible. No definite structure or size has been determined for the gelatin molecule since gelatin is a mixture of degradation products resulting from the hydrolytic splitting of the more complex collagen.

Composition. — Both gelatin and its precursor collagen show identical composition when analyzed. The ultimate composition of each is approximately: carbon (50%), nitrogen (18%), oxygen (25%), hydrogen (7%) and sulfur (trace). The constituent amino acids and their relative amounts are approximately: glycine (25%), alanine (9%), leucine (7%), serine (0.5%), phenylalanine (1%), methionine (1%), proline (19%), hydroxyproline (14%), aspartic acid (3%), glutamic acid (6%), histidine (1%), arginine (9%) and lysine (6%). The amino acids valine, isoleucine, tyrosine, tryptophane and cystine are either entirely absent or present only in negligible quantities.

Uses in Foods. — In the food industry advantage is taken of the jellying properties in the manufacture of gelatin desserts, jellied meats and soups, marshmallows, jellied candies and other forms of confectionery. Gelatin exerts a powerful protective colloid action and for this reason is used in commercial ice cream, thereby increasing this product's resistance to "heat shock"; that is, to the formation of ice crystals by sudden changes in temperature. Gelatin has diversified uses in medicine. It is not known to have any therapeutic value beyond that of being a protein food. In pharmacy its most important use is in the manufacture of capsules in which glycerin may be incorporated if a soft capsule rather than a hard one is desired.

Use in Nonfood or Chemical Industries. — Nonfood uses vary from photography to fabric printing. Gelatin is an important ingredient in the preparation of photographic emulsions. For this use it must be particularly free from those impurities which would impair the functions of the silver salts used in the process. Protective colloid uses are found in the dye industry, where gelatin tends to prevent the uneven deposition of colour, and in the manufacture of chemical compounds having a chloramine functional group.

A sheet of flexible jelly, containing seven parts glycerin to one part gelatin, deposited on a paper or fabric back for use as a hectograph or duplicator roll, has the property of absorbing hectograph ink from a master copy and redepositing the impression about 7j times.

Production of Gelatin. — In the United States about 45,000,000 lb. of gelatin are produced annually. Of this 90% is manufactured from hide stock and the remaining 10% is from ossein. According to the U.S. department of commerce the total production is classified as follows: edible (60%–65%); technical (3%–5%); pharmaceutical (15%–20%); photographic (15%–20%).

COMMERCIAL MANUFACTURE OF GELATIN

Preparation of Raw Stock. — The raw material may be hides, skins, bones, sinews or any other suitable collagenous substance. Ran. materials preserved by freezing, such as fresh pork skins, must be defrosted prior to processing. Chrome leather waste or similar material which is not suitable to the production of edible gelatin may be processed for technical or industrial gelatin. The ram material, exclusive of bones, is washed to remove surface soil and water-soluble impurities.

Bones are processed somewhat differently in that, after washing, crushing and rewashing, they are subjected to countercurrent treatment with mineral acid (hydrochloric acid). This process. known as demineralization, serves to decalcify, or leach out the calcium phosphates, and to leave a residue consisting of bone protein (ossein).

This concentrated raw material may be processed directly as is other raw stock, or it may be dried and stored. From this preliminary treatment the stock is put in "cure," which is either acid or alkaline depending upon the ultimate use to which the gelatin is to be put. Acid curing results in gelatin possessing somewhat higher jelly strength but lower viscosity than alkaline curing.

Acid Cure. — In this method the washed hydrated stock is immersed in cold dilute mineral acid (*p*H 1.5–3.0) and held for 8 to 12 hours depending upon the thickness or degree of comminution of the stock. During this period the protein raw material swells to about two or three times its original volume. After curing, the acidulated stock is washed in running water until excess acid has been rinsed away.

Alkali Cure. — Although alkaline agents ranging from caustic soda to soda ash may be used in the curing of hide or bone proteins, it is conventional practice to use saturated limewater (*p*H 12.0) as the curing liquor. The washed stock is placed in pits or vats along with the lime liquor and sufficient hydrated lime to maintain saturation. Temperatures are maintained under 75° F. (24° C.) and occasional agitation is effected by use of poles or other mechanical means. The curing time may be from three to five weeks, depending upon the thickness of the stock and its type.

When curing is completed, the limed stock is washed with water until excess lime is removed. Then this washing is continued with dilute mineral acid until the external areas are acidic. Washing with pure water is then resumed until the whole lot is approximately neutral.

Extraction. — The cured and washed stock is placed in extraction kettles and covered with hot water. Several extractions are made with consecutive lots of water. A series of 8 to 12 extractions, "runs" or "cooks" may be made, each extraction being somewhat hotter than the preceding one; *i.e.*, 110° F. (43° C.), 120° F. (49° C.), 130° F. (54° C.), etc., until the boiling point is reached. Since the extraction depends upon the conversion of collagen to gelatin by hydrolysis, care must be exercised to avoid excessive hydrolytic breakdonn of the gelatin. Highest test gelatin is extracted at the lower temperatures whereas use of higher temperatures produces the lower testing gelatins. At the end of each run all possible grease is removed by skimming. Each run of liquor is then removed prior to the addition of fresh water for the subsequent extraction. These liquors, known as "light" because of low solids (2% to 4%) content, are then allowed to settle for a short time, after which more grease may be skimmed. The various runs are then combined according to the quality of gelatin desired and are processed through filtering equipment whereby grease and foreign suspended material are removed. Active carbon is sometimes used to minimize high colour. The light liquors, which are sparklingly clear and almost water-white, are then continuously evaporated until the increased viscosity makes further evaporation impractical. This situation is reached at concentrations of 8% to 12% in high-test liquors and of 15% to 20% in low-test liquors.

Most film type evaporators tend to break down the jelly strength of gelatin if allowed to concentrate the liquors beyond certain limits. If necessary the heavy liquors from the evaporators may be filtered again and bleached depending upon the quality desired.

Following the evaporating stage the usual drying procedure is based upon the characteristic ·jelling property of the protein. Heavy liquors are run onto a wide endless belt which conveys the gelatin through a refrigerated chamber. The resultant stiff jelly is placed on metal nets and blown with cold air until it has developed a skin. Hot air is then used to finish the drying process and the final clear sheets are comminuted as required. Other methods of drying, making use of sprays, hot rolls, etc., may be employed.

All equipment in the manufacture of gelatin should be so constructed as to avoid contamination by heavy metals. Aluminum for acid-cure processes and nickel or stainless steel for either acid or alkali processes are preferred materials of construction. Certain grades of technical gelatin for industrial use can be processed in equipment made from iron. Extremely pure grades can be made by dialysis (*q.v.*), but this procedure is not commercially practical.

Properties.—The protein gelatin, as manufactured, may be marketed as thin, clear flakes or after grinding to various degrees of fineness. In the U.S. a 30-mesh gelatin is considered standard for most uses. Crystal clarity and slight yellow or amber colour are customary. The dry product normally contains from 85% to 12% of moisture, depending upon atmospheric humidity. Commercial gelatins are substantially free from heavy metal and bacterial contamination. Mineral constituents as represented by ash are less than 2%.

Specifications of the U.S. Pharmacopoeia are satisfactory in general although additional specifications may be required for certain uses (photography, hectography).

Gelatin is insoluble in pure cold water, but will absorb moisture, with swelling. The swollen gel will pass completely into solution when warmed to about 120° F. (49° C.), forming a gel again when cooled. The swollen gel will dissolve in hot water, hot aqueous glycerin, hot acids, alkalies and salts. It is insoluble in all organic solvents other than the water-soluble phenols and carboxylic acids. In dilute mineral acid (0.5N HCl) and in dilute alkali (0.15N NaOH), a 1% solution of gelatin can be formed at room temperature. Concentrated mineral acids or alkalies will dissolve larger amounts of gelatin, considerable hydrolysis taking place. Concentrated acetic and formic acids will dissolve gelatin in the cold as will concentrated aqueous solutions of urea, thiourea, calcium chloride, calcium nitrate and other peptizing agents. Aqueous glycerin will swell gelatin slowly in the cold and will dissolve it when heated. The viscous mass will set to a stiff gel when cooled and is the basis for manufacture of printer's rollers, hectograph jellies and capsules.

The isoelectric point of a given gelatin is 4.85 or 7.8 depending upon whether it is derived from acid- or alkaline-cured material. Any gelatin at its isoelectric point exhibits minimum solubility, minimum viscosity, minimum electroconductivity and minimum swelling. Similarly to other water-soluble proteins, gelatin will swell or puff like popcorn when heated dry. At a temperature of 300° F. (149° C.), it will polymerize with corresponding increase in viscosity and decrease in solubility.

Tanning agents normally used in leather manufacture will act upon gelatin to produce insolubility in water. Heavy-metal salts, aldehydes and sugars having active aldehydic functions act in the same way. In such cases water insolubility does not mean moisture resistance, since insolubilized gelatin will absorb almost as much water as will the untanned gelatin from the same source.

Two forms of gelatin are believed to exist. These differ only in the specific rotation of their solutions. Form A has a specific rotation $[\alpha]_D$ of $-313°$ and is stable above 95° F. (35° C.). Form B has a specific rotation $[\alpha]_D$ of $-141°$ and is stable only below 59° F. (15° C.). Outside the range of 59°–95° F. (15°–35° C.) the specific rotation does not vary with changes in temperature. These two forms are believed to be the sol, 95° F. (35° C.), and gel, 59° F. (15° C.), forms.

For detailed accounts of the more specific physical and chemical properties of gelatin, see the references at the end of this article.

Commercial Grades and Tests of Gelatin.—As emphasized, many different qualities of gelatin can be prepared from a given collagenous raw material. The less vigorous the hydrolytic treatment used in its preparation, the higher is the quality of the resulting gelatin.

Uniformity in gelatin of commerce is maintained through process control and by the blending of selected lots of gelatin so that the over-all average molecular weight and other properties remain quite constant.

As a general rule, the product is evaluated on the basis of two colloidal properties, viscosity of solution and stiffness of gel. Viscosity is measured at 6.67% concentration (anhydrous basis) and is expressed in millipoises. Stiffness of gel, or "jelly strength," is determined for the same concentration by the Bloom test; it is expressed as the weight in grams required at 50° F. (10° C.) to impress the jelly surface a given distance. Both determinations are necessary for commercial evaluation since it is quite possible to produce extractions of gelatin of different qualities from the same lot of raw material, one having higher jelly strength and lower viscosity than the other; for instance, 300 g. and 50 millipoises or 240 g. and 60 millipoises. The end use of the gelatin determines which characteristic is of more importance.

High jelly strength is obviously needed for the production of gels. Gelatins are primarily blends of individual lots or extractions. These blends have a jelly strength from 75 g. to 300 g. The higher the Bloom test the greater is the utility, since proportionally less of a high jelly-strength gelatin is required for producing a gel under a given set of conditions.

The United States government specifications issued in Jan. 1945 listed the following limits for dessert gelatin:

1. Ground to pass 90-mesh sieve.
2. Hot aqueous solution should be clear, of light colour and free from foreign odour or taste.
3. Free from chemical preservatives, grit, dirt and foreign matter.
4. Jelly strength not less than 220 g.
5. Total bacteria count not exceeding 5,000 per gram.
6. Free of the organism *E. coli*, gas-forming anaerobes and liquefiers.

Additional specifications covering heavy metals and other impurities in foods must be met by all gelatin sold for edible purposes.

(See *U.S.P. XIII Standards*, 1942.)

In addition to gelatin for desserts or sweets, there are the edible ice cream, marshmallow, confectionery and capsulating gelatins. Hectographic, photographic and other technical gelatins are not required to meet food specifications.

GELDER, AERT (Arent) **DE** (1645–1727), Dutch painter, who, except for a stay in Amsterdam where he became Rembrandt's pupil around 1661, lived at Dordrecht. De Gelder is remarkable in Dutch art as the only artist who kept to the Rembrandt tradition in the late 17th and early 18th century. His biblical scenes especially are full of strong colours and fantastic light effects. He varies Rembrandt's compositional ideas in a personal way (series of the Passion c. 1715, Amsterdam and Munich). As a portrait painter he is equally unconventional and the broad character of his painting contrasts strongly with the polished and refined surface paint of his contemporaries.

See K. Lilienfeld, *Arent de Gelder, sein Leben und seine Kunst . . .* (1914). (H. K. Gn.)

GELDERLAND (*Guelders*), a province of the Netherlands, bounded south by North Brabant, west by Utrecht and South Holland, northwest by the Ijselmeer, north by Overysel and southeast by North Rhine-Westphalia. It has an area of 1,932 sq.mi. and a pop. (1957 est.) of 1,223,434, the density per square mile being 633.

The main portion of Gelderland north of the Rhine and the Old Ysel forms an extension of the province of Overysel and is composed of diluvial sand and gravel, covered with heaths and patches of fen. South of this line, however, the soil consists of fertile river-clay. The northern portion is divided by the New (or Gelders) Ysel into two distinct regions, namely, the Veluwe ("bad land") on the west, and the former countship of Zutphen on the east. In this last division the ground slopes downward from southeast to northwest (131 to 26 ft.) and is intersected by several fertilizing streams which flow in the same direction to join the Ysel. The extreme eastern corner is occupied by older Tertiary loam, which is used for making bricks, and upon this and the river banks are the most fertile spots, woods, cultivated land, pastures, towns and villages. The highlands of the Veluwe lying west of the Ysel really extend as far as the Crooked Rhine and the Vecht in the province of Utrecht, but are slightly detached from the Utrecht hills by the Gelders depression, which forms the boundary between the two provinces. This extends from the Rhine along the Grift, the Luntersche Beek and the Eem to the Zuider Zee, and would still offer an outlet in this direction to the Rhine at high water if it were not for the river dikes. The two main ridges of the Veluwe hills (164 and 360 ft.) extend from the neighbourhood of Arnhem northwest to Harderwyk and north to Hattem. In the south they stretch along the banks of the Rhine, forming a strip made up of sandhills and trees, claylands and pastures. All over the Veluwe are heaths, scantily cultivated, with fields of rye and buckwheat, cattle of inferior quality and sheep, and a sparse population. There is also a considerable cultivation of wood, especially of fir and copse, while tobacco plantations are found at Nykerk.

The southern division of the province is watered by three large rivers, the Rhine, the Waal and the Maas, and has a level clay soil, varied only by isolated hills and a sandy, wooded stretch between Nijmegen and the southern border. The region enclosed between the Rhine and the Waal and watered by the Linge is called the Betuwe ("good land") and gave its name to the Germanic tribe of Batavians. There is here a denser population, occupied in the cultivation of wheat, beetroot and fruit, the breeding of excellent cattle, shipping and industrial pursuits. The principal centres of population, such as Zutphen, Arnhem (the chief town of the province), Nijmegen and Tiel, as well as smaller old towns, lie along the rivers. (X.)

History.— It was formerly a duchy of the empire, bounded by Friesland, Westphalia, Brabant, Holland and the Zuider Zee, part of which has become the province of Holland. The territory of the later duchy of Gelder formed part of the Frankish kingdom of Austrasia. In 843, by the treaty of Verdun, it became part of Lotharingia (Lorraine), and in 879 was annexed to the kingdom of East Francia by the treaty of Mersen. The nucleus of the later county and duchy was the district surrounding the town of Gelder or Gelre, lying between the Meuse and the Niers, and after 1715 included in Rhenish Prussia.

There were in the 11th century a number of counts ruling in various parts of what was afterward known as Gelderland. Toward the close of that century Gerard of Wassenburg acquired a dominant position and is generally reckoned as the first hereditary count of Gelder (d. 1117–18). His son, Gerard II (d. 1131), married Irmingardis, daughter and heiress of Otto, count of Zutphen, and their son, Henry I (d. 1182), inherited both countships. His successors, Otto I (1182–1207) and Gerard III (1207–29), were lovers of peace and strong supporters of the Hohenstaufen emperors, through whose favour they were able to increase their territories by acquisitions in the districts of Veluwe and Betuwe. Otto II (1229–71) became a person of so much importance that he was urged to be a candidate for the dignity of emperor, but he preferred to support the claims of his cousin, William II of Holland. In return for the loan of a considerable sum of money William gave to him the city of Nijmegen in pledge. His son Reinald I (d. 1326) married Irmingardis, heiress of Limburg, and in right of his wife laid claim to the duchy against Adolf of Berg, who had sold his rights to John I of Brabant. War followed, and on June 5, 1288, Reinald was defeated and taken prisoner at the battle of Woeringen and surrendered his claims to John of Brabant. In 1310, Reinald received from the emperor Henry VII the exemption of his subjects from the liability to be sued before any court outside his jurisdiction, and in 1317 he was made a prince of the empire.

Reinald II., his son (1326–43), was one of the foremost princes in the Netherlands of his day. He married (1) Sophia, heiress of Mechlin, and (2) in 1331 Eleanor, sister of Edward III of England. By purchase or conquest he added considerably to his territories. He did much to improve the condition of the country, to foster trade, to promote the prosperity of the towns and to maintain order and security in his lands by wise laws and firm administration. In 1338 the title of duke was bestowed upon him by the emperor Louis the Bavarian, who at the same time granted to him the fief of East Friesland. He died in 1343, leaving three daughters by his first marriage, and two sons, Reinald and Edward, by Eleanor of England. His elder son was ten years of age and succeeded to the duchy under the guardianship of his mother, Eleanor. Declared of age two years later, Reinald III found himself involved in a struggle between two rival factions which ended only after his death in 1374, with the recognition as duke of his nephew William of Julich, son of his younger sister, Maria.

Duke William was able, restless and adventurous. He took part in no less than five crusades with the Teutonic order against the heathen Lithuanians and Prussians. In 1393 he inherited the duchy of Jiilich and died in 1402. He was succeeded by his brother, Reinald IV (d. 1423), in the united sovereignty of Gelder, Zutphen and Jiilich. On his death Gelder passed to the young Arnold of Egmont, grandson of his sister Johanna, whose daughter Maria (d. 1415) was wife of John, count of Egmont (d. 1451). Arnold was recognized as duke in 1424 by the emperor Sigismund, but in the follo ing year the emperor revoked his decision and bestowed the duchy upon Adolf of Berg. Arnold in retaliation laid claim to the duchy of Jiilich, which had likewise been granted to Adolf by Sigismund, and a war followed which ended in Arnold's retaining Gelder and Zutphen, and Gerard, the son of Adolf (d. 1437), being acknowledged as duke of Julich. To gain the support of the estates of Gelder in this war, Arnold had made many concessions limiting the ducal prerogatives and granting large powers to a council consisting of representatives of the nobles and the four chief cities; his extravagance and exactions led to continual conflicts, and in his later years a conspiracy was formed against him, headed by his wife and his son Adolf, which gave an opportunity of intervention to Charles the Bold of Burgundy. For 92,000 golden gulden, Arnold sold the reversion of the duchy to Charles (1471). On Feb. 23, 1473, Arnold died and Charles became duke of Gelder. His succession was not unopposed. Nijmegen offered an heroic resistance and only fell after a long siege. After Charles's death in 1477 Adolf was released from the captivity in which he had been held and placed himself at the head of a party in the powerful city of Ghent, which sought to settle the disputed succession by forcing a match between him and Mary, the heiress of Burgundy. On June 29, 1477, however, he was killed at the siege of Tournai; and Mary gave her hand to the archduke Maximilian. Catherine, Adolf's sister, made an attempt to assert the rights of his son, Charles, but by 1483 Maximilian had crushed all opposition and established himself as duke of Gelder.

Charles of Egmont, however, did not surrender his claims, but with the aid of the French collected an army, and in the course of 1492 and 1493 succeeded in reconquering his inheritance. 'In 1507 he invaded Holland and Brabant, captured Harderwijk and Bommel in 1511, threatened Amsterdam in 1512 and took Groningen. It was undoubtedly a great and heroic achievement for the ruler of a petty state like Gelder thus to assert and maintain his independence against the overwhelming power of the house of Austria. It was not till 1528 that the emperor Charles V could force him to accept the compromise of the treaty of Gorinchem, by which he received Gelder and Zutphen for life as fiefs of the empire. In 1534 the duke, who was childless, attempted to transfer the reversion of Gelder to France, but was compelled by the estates in 1538 to appoint as his successor William V of Cleves (d. 1592). Charles died the same year. William, with the aid of the French, succeeded in maintaining his position in Gelder for several years, but was forced to cede the duchy to Charles V by the treaty of Venlo (Sept. 7, 1543).

Gelder was definitely amalgamated with the Habsburg dominions in the Netherlands, until the revolt of the Low Countries led to its partition. In 1579 the northern and greater part, comprising the three "quarters" of Nijmegen. Arnhem and Zutphen, joined the Union of Utrecht and became the province of Gelderland in the Dutch republic. Only the quarter of Roermond remained subject to the crown of Spain, and nas called Spanish Gelderland. By the treaty of Utrecht (1713) this was ceded to Prussia with the exception of Venlo, which fell to the United Provinces, and Roermond, which with the remaining Spanish Ketherlands passed to Austria Of this, part was ceded to France at the peace of Basle in 1795, and the whole by the treaty of Lunéville in 1801, uhen it received the name of the department of the Roer By the peace of Paris of 1814 the bulk of Gelderland mas incorporated in the United Netherlands, the remainder falling to Prussia, where it formed the circle of Dusseldorf

The rise of the towns in Gelderland began in the 13th century, river commerce and markets being the chief cause of their prosperity, but they never attained to the importance of the larger cities in Holland and Utrecht, much less to that oi the great Flemish municipalities. They differed also from the Flemish cities in the nature of their privileges and immunities, since they did not possess the rights of communes but only those of "free cities" of the Rhenish type. The power of the feudal lord over them was much greater. The states of Gelder first became a considerable pouer in the land during the reign of Arnold of Egmont (1423–73). From this time the absolute authority of the sovereign in Gelder was broken The states consisted of two members—the nobility and the towns. The towns were divided into four separate districts or "quarters" named aiter the chief town in each—Kijmegen, Arnhem, Zutphen and Roermond Each quarter had peculiar rights and customs, and their representatives met together in a separate assembly before taking part in the diet of the states. The nobility possessed great influence in Gelder and retained it in the time of the republic. (G E.; X.)

GELIMER or GEILAMIR (*fl.* 530–534), last king of the Vandals in Africa. a great grandson of Gaiseric, succeeded when Hilderic was deposed in 530. Justinian, who invited him to allow the old king to remain sovereign in name and to content himself with the actual power, was in reality desirous of an excuse for interference in Africa. In j33 Justinian sent against him a great expedition under Belisarius (*q.v.*). Gelimer was defeated and in 534 taken prisoner. He was then permitted to settle in Galatia.

GELLERT, CHRISTIAN FÜRCHTEGOTT (1715–1769). German poet, born at Hainichen. Saxony, on July 4, 171j, studied at Leipzig became *Privatdozent* there in 1745 and in 1751 extraordinary professor. He died at Leipzig on Dec. 13. 1769. His best work is to be found in the admirable Fnbeln und *Erzählungen* (1746–48), for which he took La Fontaine as his model. His Geistliche Oden und Lieder (1757) were among the great religious poems of their time. Some of them mere set to music by Beethoven. Gellert also wrote a few comedies.

GELLERT or KILLHART, in Welsh traditional history, the dog of Llewellyn, prince of Wales. The dog, a greyhound. is left to guard the cradle in which the infant heir sleeps. A wolf enters and is about to attack the child, when Gellert flies at him. In the struggle the cradle is upset and the infant falls underneath. Gellert kills the wolf, but when Prince Llewellyn arrives and sees the empty cradle and blood all around, he thinks Gellert has killed the baby. He at once stabs him and then finds his son safe under the cradle and realizes the dog's bravery. Gellert is supposed to have been buried near the village of Beddgelert ("grave of Gellert"), Snowdon. uhere his tomb is pointed out to visitors. The date of the incident is traditionally given as 1205. The story is only the Welsh version of a tale which is traced to the Indian Panchatantra and perhaps as far back as 200 B.C.

GELLIGAER, a town and urban district in the Caerphilly parliamentary division of Glamorgan, Wales, in the heart of the south Wales coal fields Pop (1961) 34.572. Area 26 2 sq mi. The chief town of the district is Bargoed. about 16 mi. N of Cardiff by road, which contains a large public park. Gelligaer takes its name from the Roman fort which lies northwest of the 8th-century parish church of St. Cattwg and is 780 ft. above sea level. Many of the relics found when the fort was excavated are in the National Museum of Wales in Cardiff. Charles I stayed at the 16th-century manor house of Llancaiach when he visited Glamorgan in 1645.

The three coal mining valleys of Taff Bargoed, Deri and Rhymney lie nithin the district which is bounded on the east by the river Rhymney, there the boundary between Glamorgan and Monmouthshire. and on the west by the river Taff Bargoed. Besides coal mines there are automobile and rubber works.

GELLIUS, AULUS (b. c. A.D. 130), Latin author, who composed a miscellany entitled Noctes Atticae in which are preserved many fragments of lost works. He is an interesting source of information about the knowledge and studies of his own day. Both in Rome, where he received instruction in literature (*grammatica*) and rhetoric, and in Athens, where he studied philosophy, his teachers and friends included many distinguished men. He was appointed a judge in private cases in Rome. It was in Athens, during the long winter evenings, that he began his practice of excerpting from authors, and after his return to Rome he continued this work which led to the publication of his Noctes *Atticae*. Written partly for the benefit of his children it comprised 20 books. The beginning of the preface and the end of the last book are lost and of the eighth book only the chapter headings have survived. It is a miscellany with no systematic order touching on the most diverse matters of language, literature, dialectic, philosophy, arithmetic, geometry, antiquities, law, history and other subjects. Gellius' aim was to provide interesting but not exacting reading. He seems to have been a modest and amiable man. He had neither a profound mind nor much critical power, but he was a diligent and accurate student whose delight was in books and learning.

GELLIVARA (GÄLLIVARE), a mining town of Sweden in the district (lan) of Norrbotten, 815 mi. N. of Stockholm by rail. It lies in the well-nigh uninhabited region of Swedish Lapland, 43 mi. N. of the Arctic circle. Pop. (1960) 10.159. There are iron mines in the mountain hfalmberget $4\frac{1}{2}$ mi. to the north, rising to 2.024 ft. above sea level (830 ft. above Gellivara town). After the mines: which had been previously begun and abandoned, were reopened late in the 19th century a provisional railway was built from Malmberget to Luleå at the head of the Gulf of Bothnia (127 mi. S.S.E.). In 1891 the Swedish government bought the railway. The output of ore was insignificant until about 1892 but later increased considerably. (See KIRUNA.)

GELNHAUSEN, a town formerly in the Prussian province of Hesse-Nassau, after 1945 in Hesse, Federal Republic of Germany, 27 mi. E.N.E. of Frankfurt-on-Main, on the railway to Bebra. Pop. (1959 est.) 7,739. Gelnhausen became an imperial town in 1169. and diets of the empire were frequently held there. In 1803 the town became the property of Hesse-Cassel and in 1866 passed to Prussia. Ancient walls still stood in modern times.

On an island in the river are ruins of the palace built by Frederick I (Barbarossa) before 1170 and destroyed by the Swedes in the Thirty Years' War. The beautiful Marien Kirche, with four spires was built in the 13th century and restored in 1876–79; among other ancient buildings are the town hall, the Fiirstenhof (later administrative offices) and the Hexenthurm.

GELON, son of Deinomenes, tyrant of Gela and Syracuse. On the death of Hippocrates, tyrant of Gela (491 B.C.), Gelon, who had been his commander of cavalry, succeeded him, and in 485, his aid having been invoked by the Gamori (the oligarchical landed proprietors) of Syracuse, who had been driven out by the populace: he seized the opportunity of making himself despot. From this time Gelon paid little attention to Gela and devoted himself to the aggrandizement of Syracuse, which attained extraordinary wealth and influence. When the Greeks solicited his aid against Xerxes. he refused it, since they would not give him command of the allied forces (Herodotus vii, 171). In the same year the Carthaginians invaded Sicily, but were totally defeated at Himera, the result of the victory being that Gelon became lord of all Sicily. After he had thus established his power, he made a show of resigning it; but his proposal was rejected by the multitude. and he reigned without opposition till his death (478).

GELSEMIUM (YELLOW JASMINE ROOT), a drug consisting of the dried root of Gelsemium sempervirens (family Loganiaceae). The plant is a woody twining shrub having a milky juice; opposite, lanceolate, shining leaves; and clusters of from one to five large, funnel-shaped, fragrant yellow flowers. It is native to the southeastern United States, where it is known as wild, yellow or Carolina jasmine; it is not related in any way, however, to the true jasmine, which is a member of the family Oleaceae. Commercial supplies are collected in Virginia, North and South Carolina, Tennessee and Georgia. The roots and underground stems are dug up in the autumn, washed and dried. The plant was first described in 1640 but was not used medicinally until about 1821.

Three alkaloids have been isolated in crystalline state, gelsemine, gelsemicine and sempervirine. All three have similar pharmacologic properties, gelsemicine being the most potent and toxic. Gelsemium depresses the motor nerve cells of the brain and spinal cord, resulting in generalized muscular weakness. Death from action of this drug is caused by respiratory failure resulting from paralysis of the respiratory muscles. The drug is little used medicinally, though formerly it was used in treating various neuralgic conditions. (V. E.)

GELSENKIRCHEN, an industrial town in the Land North Rhine-Westphalia in the German Federal Republic. Pop. (1950) 315,460. In the mid-19th century Gelsenkirchen was a village with only about 650 inhabitants. It developed as a mining and industrial town only after 1870. Early in the 20th century the towns of Buer and Horst were amalgamated nith Gelsenkirchen. Buer, north of the river Emscher which bisects the tonn, is surrounded by a 1,000-ac. green belt; at Horst there is a Renaissance palace, built in 1558, which survived the heavy bombing of World War II in which 38% of the public buildings in Gelsenkirchen were destroyed. The Hans Sachs house and the Buer tonn hall are the seats of the municipal administration. The town possesses a museum, a zoological garden (opened in 1949), a number of public gardens and two race-courses. The Institute of Hygiene for the Ruhr is situated in Gelsenkirchen. The railway connecting Hamburg uith the south and Cologne with the east, the Cologne-Berlin *Autobahn* and two federal highways, and the Rhine-Herne canal all pass through the town. At Gelsenkirchen is a port on the canal. To the south is the large conglomeration of mines which made Gelsenkirchen one of the largest coal mining and coking centres of Germany. There is also a variety of industries of considerable importance; the chief of these are the iron and steel works. chemical, glass and clothing industries. (P. Z.)

GEM, a mineral used for adornment. The true gem stone is a product of nature and is often referred to as a natural gem to distinguish it from synthetic gems and artificial gems. A synthetic gem is a man-made product which has the same chemical composition, crystallographic and physical properties as the mineral occurring in nature. It differs from the true gem only in its origin and in those features which reflect the different environment of its growth. An artificial gem is a man-made product whose composition and properties are different from the gem stone it imitates but which simulates its appearance. The term manufactured gem not only includes any man-made product but also treated gems. A mineral which has been heated, subjected to the influence of radioactive material, dyed or has had its appearance changed by some other process is properly called a treated gem. Most gems are inorganic minerals, but pearl, amber, coral and jet originate in life processes. The diamond, ruby. sapphire. emerald and sometimes chrysoberyl are commonly designated as precious, and all others as semiprecious stones. This distinction, in general, denotes the relative value of the respective gems. but there is a wide variation in the quality and, therefore, in the value of different specimens of the same gem. Because the finer qualities of amethyst, opal, topaz and zircon may be more valuable, weight for weight, than the inferior qualities of the so-called precious stones, this classification has lost much of the significance formerly attached to it.

The desire to wear gems has been characteristic of all ages and all groups of mankind. For generations the diamond has been preeminent in the western world. the ruby in India and the jade in China. Custom or fashion has influenced the relative popularity of other gems. While fashion plays an important role in their use, changes are measured in decades rather than in seasons. The gems of lesser importance often achieve an extensive use locally in the districts in which they are produced, such as turquoise in southwestern United States.

This article discusses gems under the following main headings: Natural Gems, Synthetic Gems, Imitation Gems and Gems in Art.

NATURAL GEMS

Of the approximately 2,000 inorganic minerals, only the following 16 achieved importance as gems: beryl, chrysoberyl, corundum, diamond, feldspar, garnet, jade, lazurite, olivine, opal, quartz, spinel, topaz, tourmaline. turquoise and zircon. The quasi mineral pearl completes the list of important gems. All except zircon, which gained widespread popularity in the 1930s, have been worn for centuries.

When the same mineral is found in two or more colours, a specific gem name is commonly given to each variety; hence, two gems may be identical in every respect except in the small amount of impurity that acts as a pigmenting agent. Emerald is the green, aquamarine the blue variety of beryl; ruby the red, sapphire the blue variety of corundum. However. in the case of diamond and topaz, individual gem names are not given to the variously coloured stones.

Because wealth can be conveniently concentrated in gems, for which there is a ready market in all parts of the world, persons of wealth have commonly invested portions of their fortunes in gems. Centuries ago, this motive was more compelling than in modern times, but this practice was again demonstrated during the invasion of the Netherlands, Belgium and France in World War II.

The general properties and characteristics of minerals, which are fully discussed in the article MINERALOGY, are applicable to gems. Only those properties which have special significance when attached to gems will be considered here. Gem minerals have certain characteristics that set them apart from nongem minerals—beauty, durability and rarity. No mineral lacking in any of these characteristics has ever achieved distinction. However, beauty only is essential in a gem. Some gem minerals of minor importance, such as satin spar and malachite, are too soft to be durable. and others like rock crystal and pyrope are not uncommon. Among those qualities that give beauty to gems, colour is the most important.

Colour.—Only a few gems are idiochromatic; that is, with a colour which is distinctive and inherent in the chemical constitution of the mineral. Most gem minerals are allochromatic; that is, they are colourless when pure, and their colour is dependent upon impurities which act as pigmenting agents. In most instances, allochromatic gems are also transparent or translucent.

Gem minerals generally occur in well-developed crystals (*see* CRYSTALLOGRAPHY). Such crystals are apt to be pure and, therefore, transparent. Opal is the only important gem mineral which is amorphous, that is, not found in the crystalline state. An even distribution of pigment is desirable in transparent gems, but in some translucent stones, such as agate and heliotrope (bloodstone), their mottled appearance, caused by an uneven distribution of pigment, is characteristic.

Because of its other unusual properties, diamond is the only gem which is valuable when colourless. Those varieties which are coloured red, green or blue are, however, much more valuable and are called fancies, bringing a higher price than any other gem. But a trace of yellow pigment will lower the value to one-half or one-third of that of the diamond devoid of colour. Such diamonds are called Capes. Conversely, the colourless variety of topaz is worth little more than the cost of cutting, while the most highly prized topaz possesses a distinct yellow colour faintly tinged with wine. In 1956 the U.S. Federal Trade commission ruled that any colour term, such as blue-white, could not be used in describing a diamond unless the stone had a tinge of the colour mentioned. The so-called blue-white diamond contains no blue pigment.

The play of colours characteristic of opal and labradorite is caused by the interference of light waves reflected from successive layers within the stone. It is analogous to the coloured reflections from thin films of oil on water. Similarly, the asterism of star rubies and sapphires and the chatoyancy of cat's-eye, satin spar and tiger's-eye are structure phenomena.

Asterism in the ruby and sapphire is produced by minute inclusions oriented with respect to the hexagonal crystal structure of the mineral; hence, the six-pointed star. Chatoyancy, a single band of light which moves across the surface of the stone as its position is changed, is produced by the parallel orientation of inclusions. The flashes of red and blue which one observes on properly cut diamonds, zircons, rutile, sphenes and demantoid garnets when held in a beam of parallel light are called fire. Like the rainbow, fire is caused by dispersion (see LIGHT).

As recovered from the earth, few gem stones are attractive. Only after the gem cutter has given the stone proper proportions and a high polish to emphasize its pleasing characteristics may it be called a gem. All types of cutting are classified either as (1) cabochon, curved surfaces; (2) faceted, flat surfaces; or (3) carved, cameo (relief), intaglio (engraved). The styles and methods of cutting are described below under *Gems* in ***Art*** and under LAPIDARY AND GEM CUTTING; and SEALS.

Colour Improvement.——Proper treatment often improves the colour of a gem. This was practised in India centuries ago by heating faintly coloured chalcedony to produce the attractive yellow-red of carnelian. Similarly, amethystine to smoky-coloured quartz may be changed to the yellow citrine, which then is commonly but improperly sold as topaz. The colours of many amethysts and aquamarines and some rubies and tourmalines are the result of heat treatment.

Zircon, when mined, is commonly reddish-brown. Many zircons develop a fine blue colour when heated in a reducing atmosphere at 900° C. to 1,000° C.; an occasional stone becomes red or green, others colourless. Practically all of the zircons marketed are the result of heat treatment.

X-rays, cathode rays, radium emanations and cyclotron bombardment induce many colour changes in gems. Of these, the production of a green colour in diamonds by radium or cyclotron bombardment is the most important. This green colour is only skin deep, and may be removed by heating the diamond at 900° C. Diamonds treated with radium develop a similar green colour and also a secondary radioactivity, which persists for years and serves to distinguish them from diamonds treated in the cyclotron.

Nearly any colour can be produced in chalcedony, agate and onyx by staining with appropriate chemicals or dyes. Agates were first dyed in the Idar-Oberstein district, Germany, in the early part of the 19th century by soaking them in sugar or honey solutions and subsequently placing them in concentrated sulphuric acid. The acid chars the absorbed sugar to carbon, staining the various layers of agate from light brown to black, depending on their porosity. The nonporous layers remain colourless, accentuating the banded structure of the agate.

Red hues are commonly produced by ferric oxide; greens by chromium and nickel compounds; blue by ferric ferrocyanide. Solutions of other inorganic compounds and organic dyes may be used. Practically all agate and onyx of gem quality have been artificially coloured.

Brilliancy.— This depends upon the amount of incident light that is reflected from the surface and the interior of the stone. The amount of light reflected by surfaces with equal polish varies with the indices of refraction of the gem. The index of refraction of rock crystal (quartz) is 1.55; sapphire 1.76; zircon 1.95; and diamond 2.42. The percentage of normally incident light reflected from the polished surfaces of these gems is roughly in the ratio of 1 : 1.5 : 2 : 4.

If a gem has been properly cut, the light which enters the stone will be twice totally reflected by the back facets, and will emerge at the front surface. The stone will appear to have a silvered back. The amount of totally reflected light increases with the index of refraction and, therefore, a greater amount of light will be reflected from the interior of the diamond than from any other natural gem; hence, it is the most brilliant.

Identification of Gems.--Uncut gem stones may be identified by crystal form, hardness, cleavage, fracture, structure or chemical tests. When cut, many of these properties are not visible, or their determination would damage the gem, though, under the microscope, minute cleavages or fractures and the presence of characteristic inclusions and their distribution may give evidence as to the stone's identity. However, a positive identification is made only after one or more of the physical constants have been determined. In most instances, the determination of the density (specific gravity) and the index of refraction will suffice.

Various methods of determining density are described under the article DENSITY. The Jolly balance is unsatisfactory, except for the larger stones. Accurate determinations can be made on very small stones by suspending the gem in water from the arm of a chemical balance in a spiral coil at the end of a fine wire.

The index of refraction can be conveniently measured by the method of total reflection. Several small, hand-sized refractometers have been specially designed for this purpose. They consist of either a hemisphere or prism of high-index glass, upon which the gem is placed. A beam of light is directed from the undersurface toward the gem. The totally reflected rays fall upon a calibrated ground-glass scale. A numerical value is directly read which is the refractive index of the gem. It is essential that the film of air between the high-index glass and the gem be displaced by a liquid the refractive index of which is greater than that of the gem. A solution of sulphur in methylene iodide with a refractive index of 1.793 is commonly used. Diamond, titanite, zircon, rutile and some garnets have greater indices than this liquid and, consequently, cannot be differentiated by this method.

A determination of the density and refractive index will give a positive identification of an unknown gem, except in those rare instances, such as ruby and almandite, where the values are the same for both gems. However, almandite crystallizes in the cubic system and hence is optically isotropic (singly refractive). while ruby is hexagonal and anisotropic (doubly refractive). Two convenient instruments! the polariscope and the dichroscope. were designed for differentiating gems on the basis of these optical properties. Their use in the determination of gems is discussed under the article CRYSTALLOGRAPHY: *Optical Crystallography.* It has been noted that the refractive indices of diamond, titanite. zircon, rutile and some garnets cannot be determined on the refractometer. However, because garnet and diamond are optically isotropic. and zircon and titanite are strongly anisotropic, a positive determination can be made by using the polariscope in conjunction with density determinations.

Of all the diagnostic properties, the determination of the index of refraction is the most useful and, at the same time, the most readily determined. Satisfactory readings may often be obtained from the curved surfaces of a cabochon-cut stone by carefully adjusting the position of the stone on the refractometer so that the point of contact with the high-index glass is at the optical centre of the instrument.

Trade.—Because of their nearly indestructible character, gems are sold and resold from generation to generation. The available supply is not greatly affected by the production of newly mined gems in any year. However, as with other luxury items, demand fluctuates markedly with business conditions. Hence, price variations are determined largely by demand.

Science and modern industrial processes have had but slight influence on the gem-cutting industry. In the gem-cutting centres of Europe, the family is still the basic business unit. Knowledge and skills are passed on from father to son, and the traditions of the guild survive in many forms. The fine craftsman combines both mechanical and artistic skills.

The Gemmological Association of Great Britain (1931) and the Gemological Institute of America (1931) instituted courses of study based on a scientific approach to gemology. The American Gem society (1934) was organized to maintain and raise professional standards and to promote education and research in its field. The Gemmological Association of Australia (1946) was established for similar purposes. These organizations were founded in the retail trade with which their efforts are primarily concerned, but their influence extends to the producers, manufacturers and wholesalers.

Banded agate, 5th century. 4. Horses. Carnelian, probably 4th century. 5–7. **ROMAN, 3rd–1st CENTURY B.C.:** 5. Eros. Brown glass paste. 6. Man working on prow of ship. Carnelian. 7. Dioskouroi at battle of Regillus. Carnelian. 8–11. **ROMAN, 1st CENTURY B.C.–1st CENTURY A.D.:** 8. Portrait. Carnelian. 9. Head of Herakles, signed by Gnaios. Blue beryl. 10. Theseus. Sard. 11. Gryllos. Carnelian. 12–13. **CAMEOS:** 12. Bacchic scene. Roman, Sardonyx. 13. Mars and Venus with cupid. Onyx, Renaissance, middle of 16th century. **LATE ROMAN, 2nd CENTURY A.D.:** 14. Roma holding a victory. Red jasper. **19TH CENTURY:** 15. Jason and Cheiron, inscribed Kromos. Carnelian. **GNOSTIC:** 16. Abraxas. Heliotrope. **SASSANIAN:** 17. Portrait. Carnelian. **EARLY CHRISTIAN:** 18. The Good Shepherd. Jasper

Baptise Tavernier (1676), Eng. trans. by John Phillips (1677), is the first comprehensive account of the gem industry. Robert Boyle, *An Essay About the Origin and Virtues of Gems* (1672), and David Jeffries. *A Treatise on Diamonds and Pearls,* 2nd ed. (1751), are also of historical importance. Max Bauer, *Edelsteinkunde* (1909), revised by Karl H. Schlossmacher (1932), is the most detailed work on gems. L. J. Spencer, *A Key to Precious Stones* (New York. Glasgow, 1937), G. F. Herbert Smith, *Gemstones,* 9th ed. (London, Toronto. 1940), E. H. Kraus and C. B. Slawson, *Gems and Gem Materials,* 5th ed. (New York, 1947), are comprehensive texts. H. P. Whitlock, *The Story of the Gems* (New York, 1936), is a popular but authoritative work on the more important gems. G. F. Kunz, *The Curious Lore of Precious Stones* (Philadelphia, 1913), *The Magic of Jewels and Charms* (Philadelphia, 191j) and *Shakespeare and Precious Stones* (Philadelphia. 1916), and C. W. Cooper, *The Precious Stones of the Bible* (New York, 1924), contain much interesting information. J. Escard, *Les Pierres précieuses* (Paris, 1914), and H. Michel. *Die kunstlichen Edelsteine* (Leipzig, 1926), are authoritative. *The Minerals Yearbook,* U.S. Bureau of Mines, includes a chapter on gem stones giving world-wide annual production figures on gems. A comprehensive survey of the diamond industry appears annually in the *Jewelers' Circular-Keystone.*

SYNTHETIC GEMS

In the U.S. the Federal Trade commission has restricted the use of the adjective synthetic when applied to gem stones. to manufactured materials that possess the same chemical, physical and optical properties as the naturally occurring stone.

In the earliest recorded attempts to produce gems. natural stones were planted in the ground in the hope that they mould either reproduce or grow larger. Later, the alchemists attempted to imitate the processes of nature. Microscopic crystals of rubies were produced in 1857 by Marc Antoine Augustin Gaudin by fusing alum to which a little chromium sulphate was added to give the proper red color. Edmond Fremy and Charles Feil in 1878 produced crystals from which small gem stones were cut by fusing aluminum oxide (Al_2O_3) and lead oxide (PbO). In 1895 Michaud fused fragments of natural rubies to produce larger stones known as reconstructed rubies. For a short time this was a commercially successful process. The method of August Victor Lewis Verneuil (1902) of producing synthetic rubies and sapphires by an oxyhydrogen flame was highly successful and is used today with only slight modification.

This process is also known as the flame-fusion method and is used to produce not only rubies and sapphires but also variously coloured synthetic spinels ($MgO.Al_2O_3$), rutile (titania TiO_2) and the imitation gem, strontium titanate. Chrysoberyl ($BeO.Al_2O_3$) crystals large enough to cut into gems have also been made by this process but it has not been commercially successful.

Jaeger and H. Espig of the I. G. Farbenindustrie, Bitterfeld, Ger., synthesized emerald ($3BeO.Al_2O_3.6SiO_2$) in 1930 and made crystals, by fusion. large enough to be cut into small gems. The same year Carrol F. Chatham of San Francisco, Calif., also synthesized emerald and in 193j succeeded in producing crystals large enough to be cut and marketed.

Because of its greater value, many attempts have been made to synthesize diamond. It was generally accepted prior to the 1930s that several of the experimenters had made diamond. Of these, J. B. Hannay (1880) in England, Henry Moissan (1893) in France and Sir William Crookes (1906) in England were most widely credited with success. Hannay heated organic material with water in sealed glass tubes. Moissan dissolved carbon in molten iron in an electric furnace and plunged the molten iron into a brine solution. The cooling and shrinking of the outside layer while the interior was still molten created terrific pressures which supposedly produced diamonds in the interior. Crookes exploded cordite containing excess carbon in a cylinder and momentarily attained calculated pressures of 100,000 lb. per square inch at a temperature of 5,100° C.

In attempts to duplicate the processes no diamonds have ever been produced. Microscopic crystals of metallic carbides which resemble diamond in many ways have been obtained and identified by modern scientific methods not available to those earlier scientists. Edward G. Acheson, while attempting to make diamonds in 1891, produced and identified SiC (carborundum), the second hardest known crystal.

The first synthetic diamonds were produced by the General Electric company at Schenectady. N.Y. The discovery was announced in Feb. 195j but the details of the process were not released.

Verneuil or Flame-Fusion Process. — Originally developed to manufacture synthetic rubies and sapphires! this method with only slight modifications is used to produce spinel. rutile (titania) and strontium titanate, an imitation gem. It consists essentially of an inverted oxyhydrogen torch (fig. 1j which opens into a ceramic muffle and forms the "boule" on a support which can be lowered as the boule grows.

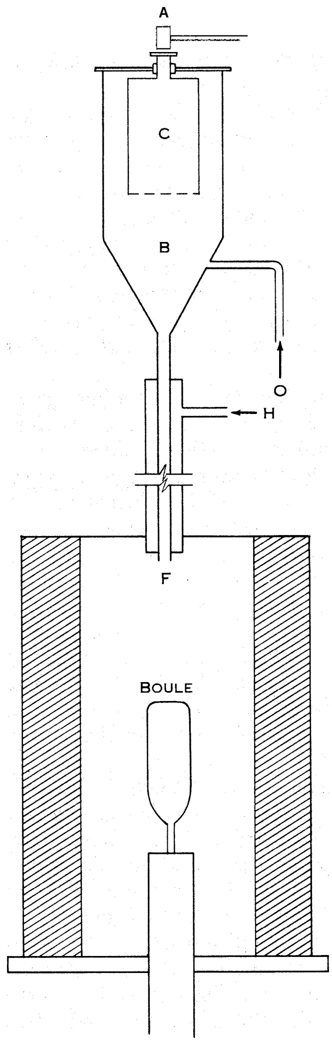

FIG. 1.—THE VERNEUIL, OR FLAME-FUSION, PROCESS FOR MANUFACTURING SYNTHETIC GEM STONES. (SEE TEXT FOR EXPLANATION OF SYMBOLS AND THE PROCESS)

For the formation of a clear single crystal boule it is essential to start with a highly purified alumina. This is prepared by repeated crystallization of ammonium alum and subsequent calcination which leaves pure alumina (Al_2O_3). The alumina is placed in the container C (fig. 1) which has a fine sieve at the base. When the container is tapped by the mechanically actuated hammer, A, the alumina sifts down into the enclosed chamber. B. Oxygen passes into this chamber at O and carries the finely divided alumina down to the tip of the torch. F, where it burns with the hydrogen which enters at H. the larger tube which encloses the central tube. The oxygen carries the fine alumina particles into the intense heat of the central part of the flame where they fuse and fall on the molten upper surface of the boule as droplets.

To start the operation a sintered mass of alumina is built up on a fire-clay support using a low heat and a high rate of powder flow. The flame temperature is raised. the rate of powder flow adjusted and the sintered mass lowered at the proper rate until the spine at the base of the boule grows. By controlling the powder flow and the rate of lowering the boule the boule begins to form with a mushroomlike top. When the desired diameter is reached flame characteristics and the rate of powder feed and boule lowering are adjusted to produce a boule of uniform diameter. The temperature of the upper surface of the boule is held just above the melting point, which for colourless sapphire is 2,030° C.

To initiate boule growth the continuous attention of the operator is required. Once started, the boule growth proceeds under automatic control and one operator can attend several furnaces. When a boule reaches the desired size. normally 150–200 carats, the operator shuts off the furnace and allows the boule to cool. During the cooling process the boule develops internal strains nhich would eventually cause the boule to crack. These are relieved by splitting the boule longitudinally. which is induced by snapping off the elongated stem of the boule. Some residual strain ahich is not disadvantageous for gem and most industrial uses is left in the half-boule developed by splitting. Strain free whole boules may be produced by annealing at 1,950° C.

The strain develops during cooling because the outer surface cools faster than the interior, and causes considerable loss from cracking during the manufacturing process. Most successful boule growth takes place when the principal axis of the crystal lies 60° from the vertical axis.

For many scientific and technical uses it is desirable to have boules oriented crystallographically. In the U.S., the Linde Air Products company developed the use of an oriented seed crystal on which boule growth was started. The boule then has the same crystallographic orientation as the seed crystal. The company also developed a semiautomatic process of making rods by continuing the uniform growth of the spine at the base of the boule. Rods 18 in. long and 0.1–2.0 in. in diameter are commercially available. They are ground to uniform diameters and flame polished in an oxyhydrogen flame. Short mushroomlike boules up to 4 in. in diameter are also grown from which circular transparent disks up to 0.2 in. thick are cut and polished.

Corundum (Rubies and Sapphires). — Prior to 1940 all synthetic boules were made in Switzerland, Germany and France. For several years after the discovery of the process of manufacture all of the production was used for gem stones. Synthetic ruby was the chief product and was produced by adding chromium sulphate to the purified alum before calcining (at 1,000° C.) in fused quartz dishes, yielding an intimate mixture of aluminum and chromium oxide. Five per cent of Cr_2O_3 gives a pale pink boule and 6% a deep red boule. The higher the percentage of chromium oxide the more difficult it is to control boule growth and the greater the loss from boules cracking on cooling.

Blue sapphire was produced by adding iron and titanium, green by cobalt and yellow by nickel and magnesium oxides. Various other colours were produced from mixtures of these oxides.

Star rubies and sapphires, first developed in the U.S. in 1947, are made by adding 1% of titanium oxide to the starting powder and forming the boules in the usual manner. The boules are then heat treated at temperatures between 1,100° C. and 1,500° C. depending on the colour of the "star" to be made. The titanium oxide develops small needlelike crystals of rutile (TiO_2) which are oriented along the hexagonal crystal planes within the boule similar to the same needlelike crystals in natural "stars." After cutting en cabochon with the principal crystal axis normal to the base the finished gem has a centred six-ray star. The synthetic gems have sharper and more distinctly developed stars than the natural crystals.

Identification. — It is very difficult to distinguish between natural colourless sapphires and synthetic colourless sapphires, but this determination is rarely necessary because these stones have little value. The natural crystals have microscopic irregularly shaped gas and liquid inclusions while the synthetic gems may have minute spherical gas bubbles. The cut synthetic gems usually show microscopic cracks along and normal to the intersection of facets. Coloured gems may be differentiated under the microscope by characteristics of the pigmentation inherent in the processes of growth in addition to the above features present in the colourless gems.

Synthetic coloured boules are purer than the coloured natural stones. The only inclusions seen in synthetics are spherical gas bubbles of microscopic size and rutile needles in "stars." Under the microscope, natural stones show irregular cavities filled with gas or liquid inclusions with both often present in the same cavity. Impurities such as iron or titanium oxide may be segregated in hexagonal plates or elongated needles respectively.

Synthetic stones show curved lines parallel to the upper growth surface of the boule. They represent uneven distribution of pigmentation caused by minor fluctuations in the rate of growth. Occasionally, especially in blue sapphire, this banding is visible to the unaided eye. In cut stones they should not be confused with the polishing striations on the surface of the facets often visible under the microscope. Structure lines are only seen when viewing the stones nearly parallel to their plane, and can be followed by focusing the microscope down into the interior of the stone. Unlike polishing striations they are continuous beneath adjacent facets. Some natural stones show straight parallel twinning striations, often in a hexagonal pattern in three directions, which may be confused with the structure lines of synthetics.

On examining faceted gems, reflections from the facets hide the interior features of the stone. It is usually necessary to rotate the stone under the microscope and view it in several directions before evidence of the true nature of the stone is found.

About 1920 the industrial use of synthetic rubies and sapphires began to be of more importance than the gem use when they began to replace the natural stones for jewel bearings in watches and electrical instruments. By 1935 synthetics had replaced natural jewels in both Europe and the United States. Every household electric meter had at least two bearings jeweled with synthetics. Although colourless sapphire is easier to grow, ruby is preferred for industrial jewels because of the greater ease in handling it.

The Linde Air Products company pioneered in the U.S. in other industrial uses uhich take advantage of the superior hardness of Al_2O_3, second only to diamond. Colourless sapphire rods were introduced as thread guides in the textile industry, followed by the sapphire stylus for phonograph needles. Drilled blanks are used as orifices for injection nozzles in oil-fired furnaces because they resist wear and maintain a constant diameter. Small spherical balls of clear sapphire are superior to metal spheres in ball-point pens.

Other industrial uses of sapphire take advantage of its high dielectric constant for electronic devices and of its high melting point for heat resistant windows. Because sapphire transmits not only visible light but ultra-violet and infra-red (heat) waves with little absorption loss, it has been used in optical systems needing such characteristics. It resists corrosion by both alkalis and acids. The combination of these properties in a single material has made possible the development of many specialized scientific and technical instruments for high temperature and pressure control and regulation.

Spinel. — Spinel boules have a square cross section with round corners but otherwise are like A1203 boules in manufacture, size and appearance although they do not develop internal stresses during manufacture. Spinel has a hardness on Mohs's scale of 8 (Al_2O_3 has a hardness of 9; diamond, 10) which gives it adequate durability for gem stone use. Spinels are easier to cut and polish than synthetic rubies and sapphires which can only be worked with diamond powder. They are made in all colours by adding appropriate pigments. The popular "aquamarine" blue is made by adding small amounts of cobalt, nickel, and titanium and vanadium oxides

The problem of differentiating between natural and synthetic spinels rarely arises because the natural gem is not a popular or valuable one. The natural gems are usually red or blue in colour and have irregular cavities with liquid or gas inclusions and microscopic crystalline inclusions similar to those of natural rubies and sapphires, while the synthetic have only spherical gas bubble inclusions.

Because it is singly refractive, spinel is preferred for some industrial uses but for most the greater hardness of sapphire is desirable.

Rutile (Titania). — Synthetic rutile, first produced in 1948 by the Verneuil process, is far superior to the natural crystals as a gem because natural rutile is dark in colour and was only occasionally cut as a gem stone. The pure synthetic boules have a faint tinge of yellow colour but may be produced in nearly any colour by the addition of appropriate colorants. The pure titanium oxide used in the flame-fusion process is prepared by calcining hydrolyzed titanium tetrachloride at 500° C. in an oxygen atmosphere for several hours.

The furnace is the same as that used in the manufacture of synthetic rubies, sapphires and spinel although it is sometimes modified by adding a third outer tube through which oxygen passes. The single crystal boules are tetragonal with the principal axis parallel to the boule axis. They have a square cross section similar to the spinel boules but rarely exceed 100 carats in weight. When removed from the furnace they are black in colour and semiconductors of electricity because some titanium is still unoxidized On heating in an oxygen atmosphere oxygen is slowly absorbed, the colour decreases until only a faint yellow tinge is left and the boules become nonconductors

Because synthetic rutile has a higher index of refraction and greater dispersion than diamond, cut gem stones are more brilliant and show more fire. Its double refraction $\omega_D = 2.616$, $\epsilon_D = 2.903$ exceeds that of any other known substance. Nearly all the titania boules produced are used for cutting into gem stones They can be readily distinguished from diamond because of the strong double refraction and the prismatic flashes of red and blue due to the strong dispersion. The hardness, 6.5, is much inferior to the diamond.

Emerald. — The details of the Chatham process for synthesizing emerald is a closely guarded secret. From the character of the crystals it is thought that the process depends on fusing appropriate chemicals under pressure in the presence of water. Only a small percentage of the emeralds made are suitable for cutting into gems but several hundred carats are marketed annually. Synthetic emeralds may be distinguished from the natural gems because they fluoresce with a deep red colour under ultra-violet rays while natural emeralds do not.

Diamonds. — No synthetic diamonds suitable for gems have been made Not only is the possible production of crystals suitable for gems fraught with serious technical difficulties, but experience indicates that the public will not buy such synthetic gems unless they are cheap in price.

For industrial purposes, quality and perfection of crystal growth are not important because a major market ior abrasive grits and powder is available which needs only the superior hardness of the diamond. At the time diamond was first synthesized, abrasive diamond grits and powder sold for $3 per carat (nearly $7,000 per pound). The better qualities of synthetic diamond are suitable for wheel dressers and for the manufacture of diamond drill bits used in the mining and oil industries.

IMITATION GEMS

Prior to World War II most imitation gems were made from glass. Usually a special high lead glass was used which was often referred to as paste. The word paste was applied to such glasses because the components of the mixture—silica, lead oxide, potassium carbonate, borax and arsenic oxide with appropriate pigmenting materials—were mixed wet to ensure a thorough and even distribution of each.

These glasses were softer than ordinary or crown, glass but had a higher index of refraction and dispersion which gave them greater brilliancy and fire. "Fire" is the flashes of red and blue seen in cut stones with the proper prismatic distribution of facets. The cheaper imitations were pressed or moulded gems but on the better qualities the facets were cut and polished. Moulded glass imitations can be identified with a hand lens because the edges between the iacets are rounded while cut glass has sharp edges.

Glass imitations can be readily identified because they are singly refractive, and the index oi reiraction and specific gravity, both of which vary with the composition of the glass, are unlike those of the gems they imitate. Most gem stones are doubly reiractive. Usually small spherical bubbles are visible in the interior of glass imitations when examined with a lens. Because of the inferior hardness, glass is easily scratched with a file. This test can be applied along the girdle where it will do little damage. Because glass is a poorer heat conductor than natural gems it feels warmer to the touch. Glass imitations that have been worn show under the lens fine scratches on the facets and small conchoidal chips along the edges between the facets.

The finer qualities of imitation gems are made irom variously coloured synthetic sapphires or spinels. The superior hardness of these materials makes them much more durable than glass. A new imitation of the diamond was introduced in 1955 that closely resembles diamond in all properties except hardness. Strontium titanate produced in boules by the Verneuil process has an index of refraction of 2.40 while diamond is 2.42. Like diamond it is singly refractive. It has considerably more dispersion which is not noticeable to the layman but which to the trained observer serves to distinguish it from the diamond. Its hardness of only 5.5 as against 10 ior a diamond keeps it from being a serious competitor of the diamond as a gem stone.

Before World War II most costume jewelry was made with glass imitations. After World War II glass was displaced by the many newly developed plastics. which are of two kinds. Thermosetting plastics, such as Bakelite, permanently harden when moulded and will not soften on reheating. Thermoplastics, such as Lucite and Plexiglas, soften on heating and can be moulded and remoulded. With proper pigmenting agents both types of plastics can be given any desired colour. Plastic jewelry can be readily identified because it is light in weight and is easily scratched with a knife. Because of their cheapness and easy workability the many new plastics profoundly changed the market for the cheaper forms oi jewelry.

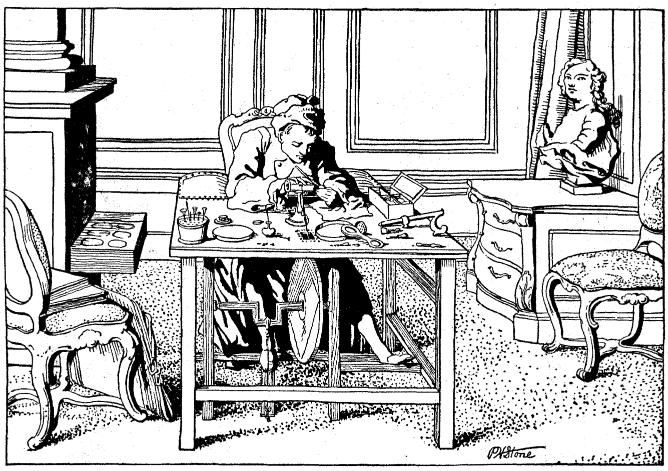
GEMS IN ART

Gems engraved with designs for sealing (intaglio) or for decoration (cameo) exist in large numbers from the early Sumerian period to the decline of the Roman civilization and again irom the Renaissance to modern times They exercise a strong appeal in many ways. The inherent beauty of the material, with its rich and varied colours, its lustre and brilliance. gives pleasure at first sight The hard and durable quality oi the stones has made for unusually good preservation, so that we can appreciate in many cases the artist's work in its original state—a rare opportunity in ancient art Moreover, the smallness and preciousness of the gems invited exquisite workmanship, and in certain periods, when art was at a high level, the achievements in this field mere very notable. The best ancient gem engravers combined minuteness and accuracy of detail with a largeness of style that is indeed remarkable. A gem engraving of this class possesses the nobility and dignity of a marble or bronze sculptural work, though it is often confined to the space of less than half a square inch.

The Technique of Gem Engraving.—Only soft stones and metals can be worked ireehand with cutting tools, the harder stones require the wheel technique. This technique was known in Mesopotamia



FROM MARIETTE TRAITE DES PIERRES *GRAVEES*

FIG 2—A GEM ENGRAVER OF THE 18TH CENTURY AT WORK IN HIS SHOP SURROUNDED BY THE VARIOUS TOOLS OF HIS TRADE

as early as c. 4000–3000 B.C., as well as to the Minoans from the middle Minoan 111 period (c. 1800–1600 B.C.). The method of work seems to have been similar to that in use in the 20th century, to judge by the references we have in classical literature, especially in the writings of Pliny and Theophrastus, and an examination of the stones themselves (fig. 3, A, B, C, D). By this method the stones were worked with variously shaped drills ending in balls, disks, cylinders, etc., which were made to rotate by the help of the wheel (fig. 2). In modern practice the stone to be engraved is fastened to a handle and held to the head of the rotating drill and moved as the work requires. It has been suggested that the ancients reversed the process and held the stone stationary while the rotating tools were guided by the hand, as in modern dentistry. The cutting is not actually done by the drills but by the powder which is rubbed on the stone with the drill. This is in modern practice diamond powder, mixed with oil; it was known also to the Romans, but in the period beiore Alexander emery powder was probably used. The wheel used in the 20th century either worked by the foot (fig. 2) or by an electric motor lathe. The iormer, though more cumbersome, has the advantage of giving the artist more direct control over the speed. On the gravestone of a gem cutter of the Roman empire found at Philadelphia in Asia Minor (fig. 3, N) a tool is represented which looks like the bow used by modern jewelers and which, by being drawn back and forth, could impart a rotating movement similar to that of the wheel. But since we know that the rotating wheel was used by the ancients in the making of pottery, it is probable that they made use oi it in gem engraving also. After the cutting oi the gem was complete the suriace was often polished, a practice especially popular among the Etruscans and in the later Greek and Roman periods. Naxian stone (*naxium*) mas used for polishing, according to Pliny.

We do not know definitely whether the ancient gem cutters made use of the magnifying glass but it is probable that they did. The general principle of concentrating rays was known to Aristophanes. Pliny several times mentions the use of balls of glass or crystal brought in contact with the rays oi the sun to generate heat, and Seneca speaks more specifically of this principle applied for magnifying objects.

What seem to he ancient lenses, some going back to the 2nd millennium B.C., were found in Egypt and Crete.

HISTORY

Mesopotamia.—The art of engraving stones probably originated in south Mesopotamia. There it attained a high degree oi proficiency as early as the 4th millennium *E.C.; i.e.,* during the Elamite and Sumerian civilizations. The engravings were worked on stones mostly of cylindrical shape which were suspended by a string and used as seals. The materials were petrified shell and marble, and the subjects are chiefly heroes fighting animals, deities with worshippers and decorative motives. Aiter the Akkadian invasion (c. 2800 B.C.) the art of seal engraving reached its greatest height, and such semiprecious stones as rock crystal were cut in masterly fashion. The mythical King Gilgamesh (see GILGAMESH, *EPIC OF*) performing his great exploits was the favourite representation, and cuneiform inscriptions began to appear. After the decline of the Akkadian empire the representations become more and more conventionalized. Hematite gradually became the prevailing material. The most frequent subjects were the "Introduction Scene"—a seated goddess toward whom a second deity leads a worshipper, the Gilgamesh legend and other mythical representations. During the Amorite dynasty (c. 2100–1800 B.C.), to which belonged the famous King Hammurabi, there was a highly artistic period, hut probably one of short duration. The representations were mostly the same as during the preceding epoch, and the use oi cuneiiorm inscriptions became important, until in the Kassite period (c. 1800 B.C.) it constituted the most conspicuous feature.

After the downfall of the Amorites in Babylonia (1758 B.C.), southern Mesopotamia no longer played an important part politically. serving only as a cultural centre. The other oriental countries which now came into prominence naturally profited by the older civilization, and the Hittites (2nd millennium B.C.), the Assyrians (first half of 1st millennium B.C.) and other peoples of Asia Minor all became conversant with the art of gem engraving. They carried on the southern Mesopotamian tradition with some contributions of their own. The favourite subjects were adoration scenes and heraldic groupings oi deities and animals. Decorative motives were popular. The cylinder form remained in vogue, but conical and dome-shaped seals with a flat base for the intaglio were the most popular (fig. 3, J, M). The coloured quartzes were the favourite material. When the power of Assyria gave, way to that of Persia, the Persian gem engravers followed in the footsteps oi their predecessors in both technique and style; but the favourite theme became the exploits of Darius the Great, king of Persia (d. 486 B.C.).

Egypt.— The Egyptians early adopted the art of engraving, employing first the cylinder form, then, from about the 9th dynasty on, the scarab or beetle and kindred shapes. As subjects for their engravings they used chiefly symbols, script and ornaments, only occasionally pictorial scenes. Though historically, thereiore, these scarabs are oi great importance—especially as they have been found in great numbers and form a continuous series—the artistic value is frequently secondary. The great majority lack the interest of subject treatment, though the finish of their execution is remarkable. The commonest materials were glazed steatite and faïence, but the coloured quartzes—carnelian, amethyst, jasper, etc.—were also employed.

Crete.— From the earliest times we find Greece treading an independent path influenced but not conditioned by its oriental neighbours. In Crete gem engraving occupied an important place. The stones of the early Minoan period (c. 3500–2200 B.C.) show a great variety of shapes—including cylindrical, pyramidal, conoid, quadrilateral and three-sided rounded beads—and are engraved with rude pictographs, consisting of primitive renderings of human beings, animals, ships and floral and linear patterns. It was clearly an experimental stage without traditional forms. The stone was invariably of a soft variety, *i.e.*, steatite oi different colours worked by hand. As time went on—during the first arid second middle Minoan periods (c. 2000–1800 B.C.)—the three-sided elongated bead became the standardized shape and the pictographs were transformed into less rude, more conventionalized forms. Several symbols now generally occur together, showing that from mere ideographic meaning they had acquired a phonographic value as syllables or letters. In other words, the primitive pictographs had evolved into hieroglyphs. The material was still the soft steatite. During the middle Minoan III period (c. 1800–1600 B.C.) the hieroglyphic script reached its full development, the symbols appearing in highly systematized form, executed often with great nicety. The stones were no longer steatite but hard varieties, such as carnelian, chalcedony and green jasper. They mere worked with the wheel, the use of which was apparently learned from the orient.

In the next period (late Minoan, *c.* 1600–1100 B.C.) we note a great change. The Minoan written language had finally evolved into a linear script and concurrently it disappeared from the seal stones. In its stead we find naturalistic designs—animals, cult and sacrificial subjects, deities and demons, hunting and war scenes; *i.e.*, the stock subjects of Cretan art, executed with amazing spirit and vivacity. The stones are now regularly the hard quartzes, of lentoid and glandular forms (fig. 3, E, F). Similar engraved gems as well as gold rings with engraved bezels have been found at Mycenae and other places within the range of Cretan influence. Toward the end of the late Minoan period the art deteriorated. The soft steatite again took the place of the harder stones, and the subjects became merely conventionalized representations. Gradually there was established the geometric style in which linear designs were engraved by hand on soft stones of the prevalent oriental forms. In the 7th century B.C. a revival in artistic conceptions is noticeable. Highly decorative animals were carved with considerable feeling for liie on steatites of glandular and lentoid forms. This was the prelude to several centuries of a flourishing output, lasting throughout the classical civilizations.

Greece.— The study of Greek and Roman gems is the study of classical art in miniature; for the gems reflect faithfully the styles of the various periods to which they belong, so that they represent an accurate picture of the development, the prime and the decadence of classical art. In the gems of the 6th and early 5th century B.C. the dainty charm of archaic Greek art found a happy expression. The chief iorms were the scarab and the scaraboid (fig. 3, H, I) regularly set in swivel rings (fig. 3, K, L, O). The subjects were the same as in other branches of archaic art. At the beginning oi the period the human figure in kneeling posture was the most popular, but soon a greater variety was attempted. Representations of gods and goddesses are comparatively rare, but Herakles was a favourite: and various demons, the Silenus, the Siren and the Sphinx were also common subjects. Among the figures without mythological significance, the commonest were warriors, archers, athletes and horsemen; and among the animals the lion, bull, boar, deer, ram, cock and horse were favoured. The coloured quartzes, such as the carnelian, chalcedony and agate, are the chiei materials used.

The second half of the 5th and the 4th centuries mark another climax in the history of Greek gem engraving. We find the same conception oi serene beauty in the minute products of the gem cutters as in the contemporary statues. The favourite shape employed is no longer the scarab but the scaraboid (fig. 3, I), generally large and thick, and perforated to be worn on a swivel (fig. 3, L, O) or as a pendant (fig. 3, G). With regard to the choice of suhjects the chief theme was now the daily life of the people, especially of the women. A woman taking a bath, making music, playing with animals, etc., were all favourite representations; animals were likewise common subjects; mythological subjects were less popular. The favourite deities were Aphrodite, Eros and Nikē. By far the commonest stone of this period was the chalcedony. Less irequently used were the carnelian, agate, rock crystal, jasper and lapis lazuli.

The inscriptions which occur on Greek gems form an interesting study. They generally give the name of the owner, often only the beginning oi his name being recorded. Occasionally they refer to the people represented or they contain a greeting. Sometimes the name of the artist is given. Of the latter the most prominent are Epimenes and Dexamenos (fig. 3, O). Their works rank among the best which have been produced in Greek gem cutting.

The Greek gems of the Hellenistic period, about 323–30 B.C., reflected the heterogeneous styles of contemporary sculpture; but there were also some notable representations, including a portrait of Philetairos. A change took place in the shape of the stones used. Instead of the perforated scarabs and scaraboids the unperforated ringstone, generally flat on one side and convex on the other, became the accepted form. The stones were often of considerable size and many of the large rings in which they were mounted are preserved. The favourite stones were the hyacinth, garnet, beryl, topaz, amethyst, rock crystal, carnelian, sard, agate and sardonyx, many of them introduced into the Greek world from the east after the conquests of Alexander the Great. Glass, as a substitute for more precious material, was often used. Among the subjects represented the most important is the portrait, which acquired great popularity. Scenes from daily life and mythology both were represented.

A great technical innovation introduced in this period is the cameo, in which the representation instead of being engraved in the surface of the gem is carved in relief. It is therefore the converse of the intaglio. These cameos naturally did not serve as seals, as did the intaglios, but were used purely ior decorative purposes. In such work the coloured quartzes were generally employed, their various layers being skilfully and effectively utilized; but imitations in glass paste also occur. The technique was popular in Roman times.

Graeco-Phoenician and Graeco-Persian Gems.—A class of gems in which the influence of Greek art is shown is that of the Graeco-Phoenician scarabs, chiefly found in the Carthaginian cemeteries of Sardinia, Carthage and Iviza. The stones discovered there show that at first Phoenician art was strongly subjected to Egyptian influence, but from the 6th century B.C. onward both the Greek style and Greek subjects were adopted. The archaic Greek style prevailed in the Phoenician stones throughout the 5th century and into the 4th, long after a freer style had been introduced in Greece itself—a phenomenon with which we are familiar from Carthaginian coins. The shape of stone used is regularly the scarab and the favourite material green jasper. The representations consist chiefly of the favourite Greek types of youths and men, and of mythological creatures. Fantastic combinations of heads and masks probably had significance as a means of averting evil.

The Graeco-Persian gems illustrate the influence of Greek art in the east. In Persia the gems of purely Persian style are followed in the second half of the 5th and the first half of the 4th century by gems in which Persian and Greek elements commingled. They were evidently made by Greeks for Persians. The subjects were taken from the daily life of the Persian nobles, preferably contests of Persians and Greeks, or hunting scenes, or single figures of Persian nobles or ladies. Animals were also favourite subjects. These representations were executed in a broad, spirited style, chiefly on chalcedony stones of scaraboid form. A rectangular shape with one faceted side was also popular.

Etruria.—Etruscan gems made their appearance toward the end of the 6th century B.C. and remained in vogue until the 4th. They closely copied Greek styles, forms and subjects. At times their execution was excellent, but there is always a certain dryness and stiffness which serve to distinguish even their best products from pure Greek work. The shape used is invariably that of the scarab, worked often with minute care, while to the Greek artist the backs of the engraved gems were of secondary interest. Moreover, the edge of the base on which the beetle stands, which in the Greek examples is left plain, is ornamented in the Etruscan gems, except in the earliest period and in the more careless specimens. By far the commonest material is the carnelian. The subjects chosen are chiefly taken from Greek mythology. Homeric and Theban heroes predominate (Peleus, Achilles, Odysseus, Ajax, Tydeus and Kapaneus). Inscriptions sometimes occur; they do not, as in the Greek gems, give the name of the owner or of the artist but of the figure represented.

At the end of the 5th century another class of scarab became prevalent, lasting until the beginning of the 3rd century B.C. It was not confined to Etruria but occurred also elsewhere in Italy. The distinguishing characteristic is that it is roughly worked with the round drill, evidently merely for decorative effect, which is heightened by the brilliant polish. Herakles, Silenus and animals were popular subjects.

Roman Gems.—The Etruscan scarabs were superseded in Italy in the 3rd and 2nd centuries B.C. by ringstones in which we can distinguish two styles, according as they imitate Etruscan or Hellenistic art. There are no great artistic achievements among them but they are nevertheless of interest in that they form an important source of knowledge for the Roman art of the earlier republican period. In the 1st century B.C. the two styles became merged, with Greek elements predominating and growing gradually into the classicist style of the Augustan age.

Engraved gems enjoyed a great popularity in Rome during the late republican and early imperial periods. We know this not only from the large number of examples which have survived, but also from literary sources. Gem collecting became a passionate pursuit. Wealthy men vied with one another in procuring fine specimens and paid enormous prices for them. The keenness of this rivalry can be gauged by the story that the senator Nonius was exiled from Rome because he refused to give a certain gem (valued at 20,000 sesterces) to Mark Antony. Public-spirited men, then as nowadays, after having formed their collections would deposit them in the temples for all to enjoy. Scaurus, the son-in-law of Sulla, is said to have been the first Roman to have a collection of gems. Julius Caesar was an eager and discriminating collector and deposited as many as six separate collections in the temple of Venus Genetrix. The style of the representations is that of the classicist art of the early imperial period which we encounter in other contemporary products. Its dominant characteristic is a quiet, cold elegance. The subjects have a wide range comprising mythological and everyday themes, including portraits of distinguished men, copies and adaptations of famous statues, symbols and grylli—fantastic combinations of heads and figures, probably with superstitious import. The prevalent form throughout is the ringstone. The variety of stones used is large, for at this time of Roman world dominion and increased commercial facilities a wide range of stones could be obtained from all parts of the empire. The commonest were the carnelian, sard, sardonyx, chalcedony and amethyst; especially fine engravings are often found on garnets, hyacinths, beryls, topazes and peridots, more rarely on emeralds and sapphires. The nicolo and red jasper, which occurred only occasionally in former periods, now enjoyed great popularity. The Roman enthusiasm for this wealth of beautiful stones can be gauged from the remarks of Pliny who declared that some gems are considered "beyond any price and even beyond human estimation, so that to many men one gem suffices for the contemplation of all nature."

Cameos continued in use throughout this period, chiefly of sardonyx, onyx and glass paste. The favourite subjects are portraits and mythological scenes. Among the former are valuable representations of emperors and princes.

Signatures of artists are found not infrequently on both the intaglios and cameos. In fact, by far the majority of ancient gem cutters known to us belong to early imperial times. The most distinguished artist was Dioskourides, of whom we know from Pliny that he made the imperial seal-ring of Augustus. Other well-known names are Gnaios, Aspasios, Eutyches, Aulos, Apollonios and Agathangelos. (*See* ROMAN ART.)

Late Roman Period.—By the 2nd century A.D. the art of gem engraving was on the decline. Of the large number of gems of that period which have survived very few have any artistic value. The majority show hasty, careless workmanship and the representations are lifeless and monotonous. The shape of the gems used is always the ringstone and the materials are very much the same as those in use during the preceding period. Nicolo and jasper became specially common, probably on account of supposed magical properties.

The same deterioration is noticeable in the early Christian and Gnostic gems. The commonest materials were hematite and jasper. More important artistically are the Sassanian gems (3rd to 7th century A.D.) which indeed represent the last important product yet found of gem engraving in the ancient world. The representations are a mixture of oriental traditions and late Roman forms. Especially fine are some of the portraits.

In north India the Ephthalites (White Huns) established a civilization about A.D. 475 which lasted until about A.D. 550. That they too practised the art of gem engraving was ascertained by the discovery of a stone with the portrait of an Indian king.

Postclassical Times.—In postclassical times there are two epochs in which the art of gem engraving again flourished, the Renaissance and the 18th and early 19th centuries. The artists of both periods borrowed freely from the antique. Those of the Renaissance were too individual to keep very closely to the ancient spirit, and Renaissance works are therefore seldom difficult to distinguish from ancient gems. The gem engravers of the 18th and 19th centuries, on the other hand, consciously tried to copy ancient work as exactly as possible in style and in subject. And though at first this copying was done out of admiration for the antique, it soon developed with unscrupulous people into an extensive output of forgeries. At times it is extremely difficult to tell definitely whether a certain piece is ancient or a faithful copy. Mostly, however, the copyist betrayed himself by a slight innovation characteristic of the spirit of his own time rather than that of the antique; and in a large number of cases, notably in the famous Poniatowski gems, including a representation of Jason and Cheiron inscribed Kromos, the spirit and composition are so far removed from ancient work that few people would be deceived by them.

An interesting feature of the gems of this period is presented by the inscriptions which often appear and give the signatures of the artist or would-be artist. For besides signing their own names, often in Greek or Roman letters, artists inscribed their works with names of famous ancient artists. Generally such forged inscriptions are easily detected, but sometimes they are cut with great care and present a difficult problem. Moreover, at times genuine ancient gems are supplied with forged signatures. The best-known gem cutters of this period are the famous Johann Lorenz Natter, the three Pichlers (Giovanni, Giuseppe and Luigi), Nathaniel Marchant and Edward Burch.

In modern times the art has a certain limited vogue, not comparable, however, with the great periods we have described.

GEMBLOUX, a town in the province of Namur, Belgium, 25 mi. S.E. of Brussels on the main line to Namur. Pop. (1947) 5,350. There on Jan. 31, 1578, Don John of Austria defeated the army of the provinces under Antony de Goignies. In 1860 the State Institute of Agriculture was founded there. Gembloux became a busy railway centre with engine works.

GEM CUTTING: *see* LAPIDARY AND GEM CUTTING.

GEMINI (the Twins; *i.e.,* Castor and Pollux), in astronomy, the third sign in the zodiac) denoted by the symbol II. By the Egyptians this constellation was symbolized as a couple of young kids; the Greeks altered this symbol to two children, variously said to be Castor and Pollux, Hercules and Apollo or Triptolemus and Iasion; the Arabians used the symbol of a pair of peacocks. The two brightest stars are known as Castor and Pollux; Pollux (β Geminorum) is slightly brighter than Castor (a Geminorum). The latter is a remarkable multiple system consisting of at least six stars. The two brightest members are each spectroscopically double and the faint, distant component (Castor C) is an orange-coloured dwarf eclipsing system in which the two stars revolve about each other once in every 19 hours. The system of Castor is located at a distance from the sun of about 45 light-years. The two brightest stars form an interesting double for a small telescope. Pollux is a yellow giant located at a distance of the order of 30 light-years from the sun. There are two bright variable stars in the constellation: the Cepheid variable. ζ Geminorum, whose light varies in a period of about ten days, and the red irregular variable star. η Geminorum. At the time of its discovery (1930) the planet Pluto was in the neighbourhood of the star δ Geminorum.

GEMINIANI, FRANCESCO (*c.* 1667–1762), Italian violinist. was a native of Lucca. and studied the violin under Carlo Lunati (Gobbo) and afterward under Ancangelo Corelli. He may also have had lessons in composition from Scarlatti. In 1714 he arrived in London, where he found a patron in the earl of Essex. In 1715 he played his violin concertos with George Frederick Handel at the English court and later spent much time in Dublin: where he had a fine house in which he gave private concerts.

Geminiani brought to England great improvements in the technique of violin playing. His chief contribution was his *Art of Playing the Violin,* the first book on the subject, which he wrote in English. He died Sept. 1:, 1762.

GEMISTUS PLETHO, GEORGIUS (*c.* 1355–1452), the leading scholar and philosopher of the last century of the Byzantine empire, is chiefly notable for his influence upon the Renaissance in western Europe and for the attempt that he made in his principal work, the *Laws* (*Nomoi*), to establish a new polytheistic religion based upon Platonic and Neoplatonic principles, which, he hoped, mould supersede both Christianity and Islam. He was born and trained in Constantinople but spent the most important years of his life in Mistra, then an important citadel in the Peloponnese.

During the Council of Ferrara-Florence (1438–39), which, despite his hostility to the proposed union between the Greek and Roman churches, he attended as lay adviser to the Greek delegation, he fired the humanists with new interest in Plato (who had been ignored in the west during the middle ages because of the preoccupation with Aristotle) and inspired Cosimo de' Medici with the project of founding the Platonic Academy of Florence.

More momentously, in his talks with the astronomer Paolo del Pozzo Toscanelli and others and by his *Excerpts fsom Strabo,* Pletho introduced the *Geography* of Strabo to the west (where it had hitherto been unknown) and led the way to the overthrow of Ptolemy's erroneous geographical theories. He thus greatly affected the Renaissance conception of the configuration of the earth and so played an important, if indirect, role in the discovery of America by Christopher Columbus, who cites Strabo among his principal authorities.

Besides the *Laws,* he composed orations, two memoirs advocating social and economic reform for the defense of the Peloponnese numerous excerpts from ancient Greek authors and essays on the differences between Plato and Aristotle, on Zoroaster, on the *Oracula Chaldaica* and on astronomy, music, history, rhetoric, the virtues and various theological subjects. Nearly all his writing is marked by passionate devotion to Greece and a desire to restore its ancient glory.

GEMSBOK (GEMSBUCK), African antelope of the genus *Oryx* (*see* ANTELOPE; ORYX); also German for chamois (*q.v.*).

GENE. Gene is the unit of heredity, first exactly demonstrated in J. Gregor Mendel's experiments in plant breeding (1865). The word gene (in the form "gen") was applied to this unit by Wilhelm W. Johannsen in 1909. The method of reappearance of diverse characters in successive generations, following crosses between two contrasting parental types, was found by Mendel to conform to certain laws, of "segregation" and "random assortment" (*see* HEREDITY; GENETICS). According to these laws, the characters must be determined by definite units that persist, multiply and enter into various combinations, from generation to generation, without themselves becoming changed thereby. Later in the 19th century, though Mendel's laws were forgotten, microscopic observations of chromosomes—small bodies of characteristic number and shape in the nuclei of all cells—led several biologists independently to the conclusion that these are transmitted as self-reproducing units, or rather as collections of units of diverse kinds, both in the process of multiplication of cells occurring during development, and also in heredity. Soon after 1900, when Mendel's laws were rediscovered, evidence was obtained that the chromosomes are probably to be identified with, or contain, the Mendelian units. And gradually, through a comprehensive series of studies on normal and abnormal hereditary transmission, coupled with observations of the chromosomes and chromosome parts in question, the case for this conclusion became convincingly established (*see* CYTOLOGY).

The newer work showed that the chromosomes are in reality exceedingly fine, relatively long filaments that are almost invisible in the ordinary nucleus. For cell division, or mitosis, (*see* CYTOLOGY) each filament coils up into a dense helix which, covered by a pellicle, assumes the sausagelike shape formerly thought of as characteristic of a chromosome. The filament, or "chromonema," consists of, or contains, hundreds or thousands of diverse genes connected permanently in line, single file, in a given order, either by direct attachment to one another or possibly joined together by a fine fibre. Before each ordinary cell division, each filament has doubled, by virtue of the reproduction of each gene within it, to form two identical filaments, and at cell division one of each of these "sister chromosomes," now in its sausagelike form. is pulled into one daughter cell, the other into the other cell. Thus both cells come to contain all the chromosomes and genes which the "mother cell" possessed.

In an immature germ cell which is about to undergo its last divisions (those of "meiosis") prior to becoming a mature egg or sperm, each chromosome derived originally from one parent of the individual becomes attached side by side to the nearly identical "homologous" chromosome derived from the other parent. This process, called "synapsis,)' is undoubtedly due to some kind of attraction or attachment mechanism exerted between like genes. In an ensuing cell division the synapsed chromosomes are pulled apart again, to opposite daughter cells, in such a way that each mature germ cell comes to contain one but not both of each of the previously paired genes (*see* CYTOLOGY). The separation of these corresponding genes fulfils Mendel's first law, segregation. The fact that a given gene, whether of maternal or paternal origin, lying in a chromosome of one pair, is equally likely to be pulled into either the same or a different daughter cell from any given gene of another pair of chromosomes, results in the fulfilment of Mendel's second law, random assortment.

But for the relations of the genes lying at different places in the same chromosome (or homologous chromosomes), a new principle of heredity emerges. All genes of the same chromosome are not always pulled into the same daughter cell, and so are not always inherited together, though they do tend to be. For two homologous filaments, during their synapsis with one another, are apt to break, at identical points, and to become joined up again with their corresponding pieces interchanged, a process called "crossing over." Thus a given gene of paternal origin may in the mature germ cell find itself in the same chromosome with some other gene of maternal origin, instead of with its former associate gene. The proportion of germ cells in which this separation of two previously connected genes will have happened will depend largely upon how far apart the two genes considered are from one another in the chromonema. For they can become separated only if the breakage occurs at some point lying between them, and since breakage may occur at any point it will be more apt to happen between them if they are located far apart in the thread than if they are near together. So by studying just how often the different genes that tend to be inherited together actually separate in heredity, an estimate may be made of the relative distances apart, or positions, of these genes in the chromonema. The validity of these "chromosome maps" has in recent years been verified by observations of chromosomes that were visibly broken in various ways. In addition to the genes of the chromosomes there are also self-reproducing hereditary units, genes, in some of the plastids of plants, and in some other cell constituents. They have not been found in higher animals, unless we include infectious agents ("viruses"). Lacking the precise Mendelian method of distribution, they appear to have played but a minor role in evolution. Apparent derivatives of chromosomal genes, having a limited power of self-reproduction themselves, have recently been found to exist in the protoplasm of some micro-organisms, but they appear to be subject to vicissitudes of cell functioning, and liable to loss and replacement by fresh derivatives of the chromosomal genes.

The "self-reproduction" of a gene is in reality self-copying. That is, each gene must have such an effect upon materials of the medium around it as to cause them to become rearranged into another particle, identical in its internal configuration with the original gene, and lying next to it. Whatever configuration the old gene has to start with, that configuration is caused to be repeated in the new gene. On rare occasions, to be sure, a gene, subjected to some unusual stress, undergoes a sudden permanent change, a "mutation," in it: inner constitution, or, alternatively, the new gene may be fashioned with some "mistake" in its pattern. Yet after a mutation of either of these kinds has occurred, the gene of modified type, whenever it reproduces, accurately incorporates the new feature into its own daughter gene. A gene may thus be defined as a particle having a capacity of self-copying of such a nature as to be retained despite the occurrence of any number of permanent changes in its configuration. In a chromonema, a single gene would, theoretically, be a portion too small to be divided without the loss of this property by one or both pieces. This unique property of self-copying, conformable with change, is known for no other substance or particle than the hereditary unit, It is this which makes the gene not only the unit of heredity and the material out of which all biological evolution is fashioned, but the foundation of growth, development and reproduction, and even, according to the growing conviction of many biologists, the primordial basis of life itself.

Chemical investigations of the gene indicate that, whether in chromosome, plastid or precellular micro-organism, it consists of a combination of protein with nucleic acid. As yet, however, these studies have not led to a satisfactory explanation of the gene's fundamental property, self-copying. This property may, however, be related to the chromosomal gene's second most distinctive peculiarity: that of exerting a specific attraction, or power of attachment, at synapsis, for a second gene of like configuration. For if this force were exerted even between like gene parts, then a given gene might attach, next to its own parts, corresponding pieces that lay scattered in unorganized fashion in the medium, and so cause them to become placed in an integrated arrangement identical with that existing in itself. Unfortunately, as little is known about the mechanism of gene synapsis as about that of self-copying.

A gene appears to be a large molecule, or closely connected group of different molecules, the whole of ultra-microscopic size, and a "gene-mutation" to be a largely fortuitous chemical change within it. This change is ordinarily caused by localized, individually uncontrollable microchemical accidents, such as may result from thermal agitation, reactions of metabolism that get out of control, the incidence of high-energy radiation like X-rays, and the impact of certain special foreign substances. The direction taken by mutation seldom, if ever, depends upon the type of environment or physiological state experienced by an individual; still less is the mutation an adaptive response to such a situation. Nevertheless, given conditions, including those brought about by the presence of given genes, may greatly influence the over-all frequency of mutations.

In this conception, there is no room for evolution through the inheritance of acquired characters. Being accidental, most mutations are harmful to the organism, but the smaller their effects, the less harmful they are apt to be. Hence the very rare ones which chance to be useful, and so to survive and take part in the evolution of a species, usually represent small steps. Evolution thus tends to proceed by slow accretions, under the guidance of natural selection, as Darwin thought. In any particular gene, mutations are very few and far between, with intervals of thousands of years between them, but the individual contains so many different genes, and the species so many individuals, that sufficient "building blocks" are nevertheless provided for evolution. And the rate of their accumulation is increased by the processes of Mendelian recombination and crossing over that form the essence of sexual reproduction. Besides the mutations in individual genes ("gene-mutations"), there are inheritable changes caused by the addition, subtraction or rearrangement of groups of genes en bloc. The rearrangements sometimes occasion changes in the functioning of the genes tnat have acquired new neighbour genes ("position effect"). Because of hindered interchange with normal chromosomes, the rearranged ones may facilitate the divergence of new varieties. More important, perhaps, the rearrangement sometimes involves the insertion of a group of genes that is the duplicate of a group already present and thus increases the total number of genes. In later evolution the inserted genes often mutate differently from their duplicates, and so the organization increases in complexity.

So effective does this process of duplication followed by differential mutation appear, that the view has gained ground that by the continuation of this process a single "naked" archetypal gene may in the course of ages have given rise to all the complex chromosomal systems of today. On this conception, protoplasm first appeared as a series of by-products of mutated genes that were naturally selected because of the usefulness of these by-products in furthering the survival and multiplication of the genes that produced them. The nucleoprotein molecules of virus that cause some plant diseases seem to be the nearest existing counterparts of these hypothetical primordial genes.

The relation of the genes to the protoplasm, and to the characters of the organism "determined" by them, are highly complex as well as disputatious. Suffice it here to say that there are many genes which affect several or many characters at once and, conversely, that all morphological characters and physiological processes depend upon the combined action of numerous genes, together with environmental factors, any one of which, if not held constant, can produce a change in the final result (see HEREDITY; GENETICS). And since all parts of the body have, by mitosis, been allotted the same genes, it is evident that this lot of genes must have reacted very differently in producing the different parts. (H. J. M.)

GENEALOGY, a pedigree or list of ancestors, or the study of family history (from the Gr. γένος, family, and λόγος, theory).

Biblical Genealogies. — The aims and methods of ancient genealogists require to be carefully considered before the value of the numerous ancestral lists in the Bible can be properly estimated. Many of the old "genealogies," like those of Greece, have arisen from the desire to explain the origin of the various groups which they include. The subdivision of tribes, their relation to each other, the intermingling of populations and the like are thus frequently represented in the form of genealogies. The "sons" of a "father" often stand for the branches of a family as they existed at some one period, and since in course of time tribal relations would vary, lists will present discrepancies. Many of the Biblical names are nothing more than personifications of nations, tribes, towns, etc., grouped together to convey some idea of the bond by which they were believed to be connected. Thus we find among the "sons" of Japhet: (the nations) Gomer, Javan, Tubal; Canaan "begat" Sidon and Heth; the "sons" of Ishmael include the well-known tribes Kedar and Jetur; Jacob, or the synonym Israel, personifies the "children of Israel." The recognition of this usage often furnishes an ethnological interpretation to those genealogical stories which obviously do not relate to persons, but to tribes or peoples personified. The Edomites and Israelites are regarded as "brothers" and since Esau (Edom) was born before Jacob (Israel) it would appear that the Edomites were held to be the older nation. The union of two clans is expressed as a marriage, or the wife is the territory which is dominated by the husband (tribe); see CALEB. If the woman is not of noble blood, but is a handmaiden or concubine, her children are naturally not upon the same footing as those of the wife; consequently the descendants of Ishmael, the son of Hagar (Sarah's maid), are inferior to Isaac and his descendants, while the children of Keturah, Abraham's concubine, are still lower—from the Israelite point of view. This application of the terms of relationship is characteristic of the Semites. The "father" of the Rechabites is their head or founder and a common bond, not necessarily physical, unites all "sons," whether they are "sons of the prophets" (members of prophetic guilds) or "sons of Belial" (worthless men).

Every case has to be judged upon its own merits, and allowance made both for the ambition of the weaker to claim or to strengthen an alliance with the stronger, and for the desire of clans or individuals to magnify the greatness of their ancestry. The first step must always be the careful comparison of related lists in order to test the consistency of the tradition. Next, these must be critically studied in the light of all available historical material, though indeed such evidence is not necessarily conclusive. Finally, (a) literary criticism must be employed to determine if possible the dates of such lists, since obviously a contemporary register is more trustworthy than one which is centuries later; (b) a critical estimate of the character of the names and of their use in various periods of Old Testament history is of importance in estimating the antiquity of the list—for example, many of the names in Chronicles attributed to the time of David are indubitably exilic or post-exilic; and (c) principles of ordinary historical probability are as necessary here as in dealing with the genealogies of other ancient peoples, and attention must be paid to such features as fluctuation in the number of links, representation of theories inconsistent with the growth of national life, schemes of relationship not in accordance with sociological conditions, etc. G. B. Gray's Hebrew Proper *Names* (1896), with his article in the Expositor (Sept. 1897), pp. 173–190, should be consulted for the application and range of Hebrew names in O. T. genealogies and lists.

The Biblical genealogies commence with "the generations of the heaven and earth," and by a process of elimination pass from Adam and Eve by successive steps to Jacob and to his sons (the tribes), and finally to the subdivisions of each tribe. According to this theory every Israelite could trace back his descent to Jacob, the common father of the whole nation. Such a scheme, however. is full of manifest improbabilities. It demands that every tribe and every clan should have been a homogeneous group which had preserved its unity from the earliest times, that family records extending back for several centuries were in existence, and that such a tribe as Simeon was able to maintain its independence in spite of the tradition that it lost its autonomy in very early times (Gen. xlix, 7). The whole conception of the unity of the tribes cannot be referred to a date previous to the time of David. and in the older writings a David or a Jeroboam was sufficiently described as the son of Jesse or of Nebat. The genealogical zeal as represented in the Old Testament is chiefly of later growth, and the exceptions are due to interpolation (Josh. vii, 1–18, contrast v. 24), or to the desire to modify or qualify an older notice. This, in the case of Saul (1 Sam. ix, 1), has led to textual corruption; a list of such a length as his should have reached back to one of the "sons" of Benjamin (*cf. e.g.* Gen. xlvi, 21), else it were purposeless. The genealogies, too, are often inconsistent amongst themselves and in contradiction to their object. They show, for example, that the population of southern Judah, so far from being "Israelite" was half-Edomite (see JUDAH), and several of the clans in this district bear names which indicate their original affinity with Midian or Edom. Moreover, there was a free intermixture of races. and many cities had a Canaanite (*i.e.* pre-Israelite) population which must have been gradually absorbed by the Israelites (cf. Judg. i). That spirit of religious exclusiveness which marked later Judaism did not become prominent before the Deuteronomic reformation and it is under its influence that the writings begin to emphasize the importance of maintaining the purity of Israelite blood, although by this time the fusion was complete (see Judg. iii 6) and for practical purposes a distinction between Canaanites and Israelites within the borders of Palestine could scarcely be discerned.

Many of the genealogical data are intricate. Thus, the interpretation of Gen. xxxiv is particularly obscure (see LEVITES ad *fin.*; SIMEON). As regards the sons of Jacob, it is difficult to explain their division among the four wives of Jacob; viz. (a) the sons of Leah are Reuben, Simeon, Levi and Judah (S. Palestine), Issachar and Zebulun (in the north), and Dinah (associated with Shechem); (b) of Leah's maid Zilpah, Gad and Asher (E. and N. Palestine); (c) of Rachel, Joseph (Manasseh and Ephraim, *i.e.*, central Palestine) and Benjamin; (d) of Rachel's maid Bilhah, Dan and Naphtali (N. Palestine). It has been urged that (b) and (d) stood upon a lower footing than the rest, or were of later origin; or that Bilhah points to an old clan associated with Reuben (Gen. xxxv 22) or Edom (Bilhan, Gen. xxxvi 27), while Zilpah represents an Aramaean strain. Tradition may have combined distinct schemes, and the belief that the wives were Aramaean at least coincides with the circumstance that Aramaean elements predominated in certain of the 12 tribes. The number "12" is artificial and can be obtained only by counting Manasseh and Ephraim as one or by omitting Levi, and a careful study of Old Testament history makes it extremely difficult to recover the tribes as historical units. See, on these points, the articles on the several tribes, B. Luther, *Zeit.* d. alttest. *Wissens.* (1901), pp. 1 sqq.; G. B. Gray, Expositor (March 1902), pp. 225–240, and in Ency. Bib., art. "Tribes"; and H. W. Hogg's thorough treatment of the tribes in the last-mentioned work.

The ideal of purity of descent shows itself conspicuously in portions of Deuteronomic law (Deut. vii, 1–3, xxiii, 2–8), and in the reforms of Nehemiah and Ezra. The desire to prove the continuity of the race, enforced by the experience of the exile, gave the impetus to genealogical zeal, and many of the extant lists proceed from this age when the true historical succession of names was a memory of the past. This applies with special force to the lists in Chronicles which present finished schemes of the Levitical divisions by the side of earlier attempts, with consequent confusion and contradiction. Thus the immediate ancestors of Ethan appear in the time of Hezekiah (2 Chron. xxix, 12), but he with Asaiah and Heman are contemporaries of David, and their genealogies from Levi downwards contain a very unequal number of links (1 Chron. vi). By another application of genealogical method the account of the institution of priests and Levites by David (1 Chron. xxiv) presents many names which belong solely to post-exilic days, thus suggesting that the scribes desired to show that the honourable families of their time were not unknown centuries previously. Everywhere we find the results of much skill and labour, often in accordance with definite theories, but a thorough investigation reveals their weakness and often quite incidentally furnishes valuable evidence of another nature.

The intricate Levitical genealogies betray the result of successive genealogists who sought to give effect to the development of the hierarchal system. The climax is reached when all Levites are traced back to Gershon, Kehath and Merari, to which are ascribed respectively Asaph, Heman and Ethan (or Jeduthun). The last two were not originally Levites in the later accepted sense of the term (see 1 Kings iv, 31). To Kehath is reckoned an important subdivision descended from Korah, but in 2 Chron. xx, 19 the two are distinct groups, and Korah's name is that of an Edomite clan (Gen. xxxvi, 5, 14, 18) related to Caleb, and thus included among the descendants of Judah (1 Chron. ii, 43). Cases of adjustment, redistribution and "Levitizing" of individuals are frequent. There are traces of varying divisions both of the singers (Neh. xi, 17) and of the Levites (Num. xxvi, 58; Ezr. ii, 40, iii, 9; 1 Chron. xv, 5–10, xxiii), and it is noteworthy that in the case of the latter we have mention of such families as Hebroni (Hebronite), Libni (from Libnah)—ethnics of south Judaean towns. In fact, a significant number of Levitical names find their analogy in the lists of names belonging to Judah, Simeon and even Edom, or are closely connected with the family of Moses; *e.g.* Mushi (*i.e.*, Mosai'te), Gershon and Eleazar (cf. Gershom and Eliezer, sons of Moses). The Levites bear a class-name, and the genealogies show that many of them were connected with the minor clans and families of South Palestine which included among them Moses and his kin. Hence. it is not unnatural that Obed-edom, for example, obviously a southerner, should have been reckoned later as a Levite, and the work ascribed by the chronicler's history to the closing years of David's life may be influenced by the tradition that it was through him these mixed populations first attained importance.

In the time of Josephus every priest was supposed to be able to prove his descent, and perhaps from the time of Ezra downward lists were carefully kept. But when Anna is called an Asherite (Luke ii, 36), or Paul a Benjamite (Rom. xi, 1), family tradition was probably the sole support to the claim, although the tribal feeling had not become entirely extinct. The genealogies of Jesus prefixed to two of the gospels are intended to prove that He was a son of David. But not that alone, for in Matt. i He is traced back to Abraham the father of the Jews, while in Luke iii He, as the second Adam, is traced back to the first man. The two lists are hopelessly inconsistent; not because one of them follows the line of Mary, but because they represent independent attempts. That in Matthew is characteristically arranged in three series of fourteen generations each through the kings of Judah, while Luke's passes through an almost unknown son of David; in spite of this, however, both converge in the person of Zerubbabel.

See A. C. Hervey, *Genealogies of Our Lord;* H. von Soden, *Ency. Bib.* ii col. 1666 *sqq.;* B. W. Bacon, Hastings' *Dict. Bib., ii* pp. 138 *seq.;* J. F. M'Lennan's *Studies* (2nd ser., ch. ix); S. Modern.—Two forces have combined to give genealogy its importance during the period of modern history: the laws of inheritance, particularly those which govern the descent of real estate, and the desire to assert the privileges of a hereditary aristocracy. But it is long before genealogies are found in the possession of private families. The succession of kings and princes is in the chronicle book; the line of the founders and patrons of abbeys is recorded by the monks with curious embellishment of legend. But the famous suit of Scrope against Grosvenor will illustrate the late appearance of private genealogies in England. In 1385 Sir Richard Scrope, lord of Bolton, displaying his banner in the host that invaded Scotland, found that his arms of a golden bend in a blue field were borne by a knight of the Chester palatinate, one Sir Robert Grosvenor. He carried the dispute to a court of chivalry, whose decision in his favour was confirmed on appeal to the king. Grosvenor asserted that he derived his right from an ancestor, Sir Gilbert Grosvenor, who had come over with the Conqueror, while an intervening claimant, a Cornish squire named Thomas Carminowe, boasted that his own ancestors had borne the like arms since the days of King Arthur's Round Table. It is remarkable that in support of the false statements made by the claimants no written genealogy is produced. The evidence of tombs and monuments and the reports of ancient men are advanced, but no pedigree is exhibited in a case which hangs upon genealogy. It is possible that the art of pedigree-making had its first impulse in England from the many genealogies constructed to make men familiar with the claims of Edward III to the crown of France, a second crop of such royal pedigrees being raised in later generations during the contests of York and Lancaster. But it is not until after the close of the middle ages that genealogies multiply in men's houses and are collected into volumes. The mediaeval baron, knight or squire, although proud of the nobility of his race, was content to let it rest upon legend handed down the generations. The exact line of his descent was sought only when it was demanded for a plea in the king's courts to support his title to his lands. From the first the work of the genealogist in England had that taint of inaccuracy tempered with forgery from which it has not yet been cleansed. The mediaeval kings, like the Welsh gentry of later ages, traced their lines to the household of Eden garden, while lesser men, even as early as the 14th century, eagerly asserted their descent from a companion of the Conqueror. Yet beside these false imaginations we find the law courts, whose business was often a clash of pedigrees, dealing with genealogies centuries long which, constructed as it would seem from worthy evidences, will often bear the test of modern criticism.

Genealogies in great plenty are found in manuscripts and printed volumes from the 16th century onward. Remarkable among these are the descents recorded in the Visitation Books of the heralds, who, armed with commissions from the crown, the first of which was issued in 20 Hen. VIII, perambulated the English counties, viewing arms and registering pedigrees. The notes in their register books range from the simple registration of a man's name and arms to entries of pedigrees many generations long. To the heralds these visitations were rare opportunities of obtaining fees from the visited, and the value of the pedigrees registered is notably unequal. Although it has always been the boast of the College of Arms that visitation records may be produced as evidence in the law courts, few of these officially recorded genealogies are wholly trustworthy. Many of the officers of arms who recorded them were, even by the testimony of their comrades, of indifferent character, and even when the visiting herald was an honourable and industrious man he had little time to spare for the investigation of any single genealogy. Deeds and evidences in private hands may have been hastily examined in some instances—indeed, a herald's summons invites their production—and monuments were often viewed in the churches, but for the most part men's memories and the hearsay of the countryside made the backbone of the pedigree. The further the pedigree is carried beyond the memory of living men the less trustworthy it becomes. The principal visitations took place in the reigns of Elizabeth, James I, Charles I and Charles II. No commission was issued after the accession of William and Mary, but from that time onward large numbers of genealogies have been recorded in the registers of the College of Arms, the modern ones being compiled with a care which contrasts remarkably with the unsupported statements of the Tudor heralds.

Outside the doors of the College of Arms genealogy has now been for some centuries a favourite study of antiquaries, whose researches have been of the utmost value to the historian, the topographer and the biographer. County histories, following the example of Dugdale's Warwickshire folios, have given much space to the elucidation of genealogies and to the amassing of material from which they may be constructed. Dugdale's great work on the English baronage heads another host of works occupied with the genealogy of English noble families, and the second edition of "G.E.C.'s" *Complete Peerage* shows the mighty advance of the modern critical spirit. Nevertheless, the 20th century has not yet seen the abandoning of all the genealogical fables nourished by the Elizabethan pedigree-mongers, and the ancestry of many noble houses as recorded in popular works of reference is still derived from mythical forefathers. Thus the dukes of Norfolk, who, by their office of earl marshal are patrons of the heralds, are provided with a 10th century Hereward for an ancestor; the dukes of Bedford, descendants of a 15th century burgess of Weymouth, are traced to the knightly house of Russell of Kingston Russell, and the dukes of Westminster to the mythical Gilbert le Grosvenor who "came over in the train of the Conqueror."

Genealogical research has, however, made great advance during the last generation. The critical spirit shown in such works as Round's *Studies in Peerage and Family History* (1901) has assailed with effective ridicule the methods of dishonest pedigree-makers. Much raw material of genealogy has been made available for all by the publication of parish registers, marriage-licence allegations, monumental inscriptions and the like, and above all by the mass of evidences contained in the volumes issued by the Public Record office.

Within a small space it is impossible to set forth in detail the methods by which an English genealogy may he traced. But those who are setting out upon the task may be warned at the outset to avoid guesswork based upon the possession of a surname which may be shared by a dozen families between whom is no tie of kinship. A man whose family name is Howard may be presumed to descend from an ancestor for whom Howard was a personal name: it may not be presumed that this ancestor was he in whom the dukes of Norfolk have their origin. A genealogy should not be allowed to stray from facts which can be supported by evidence. A man may know that his grandfather was John Stiles who died in 1850 at the age of 45. It does not follow that this John is identical with the John Stiles who is found as baptized in 1795 at Blackacre, the son of William Stiles. But if John the grandfather names in his letters a sister named Isabel Nokes, while the will of William Stiles gives legacies to his son and daughter John Stiles and Isabel Nokes, we may agree that reasonable proof has been given of the added generation. A new pedigree should begin with the carefully tested statements of living members of a family. The next step should be to collate such family records as Bible entries, letters and diaries, and inscriptions on mourning rings, with monumental inscriptions of acknowledged members of the family. From such beginnings the genealogist will continue his search through the registers of parishes with which the family has been connected; wills and administrations registered in the various probate courts form, with parish registers, the backbone of most middle-class family histories. Court rolls of manors in which members of the family were tenants give, when existing and accessible, proofs which may carry back a line, however obscure, through many descents. When these have been exhausted the records of legal proceedings, and notably those of the court of chancery, may be searched. Few English households have been able in the past to avoid an appeal to the chancery court, and the bill and answer of a chancery plaintiff and defendant will often tell the story of a family quarrel in which a score of kinsfolk are involved; the pleadings may contain the material for a family tree of many branching generations. Coram Rege and De Banco rolls may even, in the course of a dispute over a knight's fee or a manor carry a pedigree to the conquest of England, although such good fortune can hardly be expected by the searcher out of an undistinguished line. In proving a genealogy it must be remembered that in the descent of an estate in land must be sought the best evidence for a pedigree.

At the present time the study of genealogy grows rapidly in English estimation. It is no less popular in the United States, where societies and private persons have of late years published a vast number of genealogies, many of which combine the results of laborious research in U.S. records with extravagant and unfounded claims concerning the European origin of the families dealt with. A family with the surname of Cuthbert has been known to hail St. Cuthbert of Lindisfarne as its progenitor, and one surnamed Eberhardt has incorporated in its pedigree such German princes of old times as were found to have Eberhardt for a Christian name.

Genealogy in modern France has, with a iew honourable exceptions, fallen into the hands of the popular pedigree-makers, whose concern is to gratify the vanity of their employers. Italy likewise has not yet shaken off the influence of those venal genealogists who sold pedigrees cheaply to all comers. But much laborious genealogical inquiry had been made in Germany since the days of Hubner, and even in Russia there was some attempt to apply modern standards of criticism to the chronicles of the swarming descendants of the blood of Rurik.

In no way is the gap made by the dark ages between ancient and modern history more marked than by the fact that no European family makes a serious claim to bridge it with its genealogy. The unsupported claim of the Roman house of Massimo to a descent from Fabius Maximus is respectable beside such legends as that which made Lévis-Mirepoix head of the priestly tribe of Levi, but even the boast of such remote ancestry has now become rare. The ancient sovereign houses of Europe are, for the most part, content to attach themselves to some ancestor who, when the mist that followed the fall of the western empire begins to lift, is seen rallying with his sword some group of spearmen.

BIBLIOGRAPHY.—Genealogical works have been published in such abundance that the bibliographies of the subject are already substantial volumes. Amongst the earlier books from the press may be noted Benvenuto de San Georgio's *Montisferrati marchionum et principum regiae propagium successionumque series* (1515); Pingonius's *Arbor gentilitiae Sabaudiae Saxoniaeque domus* (1521); Gebweiler's *Epitome regzi ac vetustissimi ortus Caroli V. et Ferdinandi I., omniumque archiducum Austriae et comitum Habsburgiensium* (1527); Meyer's work on the counts of Flanders (1531), and Du Boulay's genealogies of the dukes of Lorraine (1547). Later in the same century Reineck of Helmstadt put forth many works having a wider genealogical scope, and we may cite Henninges's *Genealogiae Saxonicae* (1587) and *Theatrum genealogicum* (1598), and Reusner's *Opus genealogicum catholicum* (1589–1592). For the politically inconvenient falseness of François de Rosières's *Stemmata Lotharingiae ac Barri ducum* (1580), wherein the dukes of Lorraine were deduced from the line of Charlemagne, the author was sent to the Bastille by the *parlement* of Paris and his book suppressed.

The 17th century saw the production in England of Dugdale's great *Baronage* (1675–1676), a work which still holds a respectable place by reason of its citation of authorities, and of Sandford's history of the royal house. In the same century André Duchesne, the historian of the Montmorencys, Pierre d'Hozier, the chronicler of the house of La Rochefoucauld, Rittershusius, Imhoff, Spener, Lohmeier and many others contribute to the body of continental genealogies. Pierre de Guibours, known as Pbre Anselme de Ste Marie, published in 1674 the first edition of his magnificent *Histoire généalogique de la maison royale de France, des pairs, grands officiers de la couronne et de la maison du roy et des anciens barons du royaume*. Of this encyclopaedic work a third and complete edition appeared in 1726–1733. A modem edition under the editorship of M. Potier de Courcy began to be issued in 1873, but remains incomplete. Among 18th-century work Johann Hubner's *Bibliotheca genealogzca* (1729) and *Genealogische Tabellen* (1725–1733), with Lenzen's commentary on the latter work (*c.* 1756), may be signalized, with Gatterer's *Handbuch der Genealogie* (1761) and his *Abriss der Genealogie* (1788), the latter an early manual on the science of genealogy. Hergott's *Genealogia diplomatica augustae gentis Habsburgicae* (1737) is the imperial genealogy compiled by the emperor's own historiographer.

Modern peerages in England may be said to date from that of Arthur Collins, whose one-volume first edition was published in 1709. The fifth edition appeared in 1778, in eight volumes, to be republished in 1812 by Sir Egerton Brydges, the "Baptist Hatton" of Disraeli's novel, who corrected many legendary pedigrees, besides inserting his own forged descent from a common ancestor with the dukes of Chandos. From this work and from the Irish peerage of Lodge (as re-edited by Archdall) most of the later peerages have quarried their material. With these may be named the baronetages of Wotton and Betham. Of modern popular peerages and baronetages that of Burke has been published since 1822 in many editions and now appears yearly. Most important for the historian are the *Complete Peerage* of G. E. C[ockayne] (2nd ed., 1910), and the *Complete Baronetage* of the same author. The *Peerage of Scotland* (1769) of Sir Robert Douglas of Glenbervie came to a second edition in 1813, edited by J. P. Wood, and the whole work has been revised and re-edited by Sir James Balfour Paul (1904, etc.). Of the popular manuals of English untitled families, Burke's *Genealogical and Heraldic Dictionary of the Commoners* (1833–1838) is now brought up to date from time to time and reissued as the *Landed Gentry*.

Lists of pedigrees in English printed works are supplied by Marshall's *Genealogist's Guide* (1903), while pedigrees in the manuscript collections of the British Museum are indexed in the list of R. Sims (1849). Valuable genealogical material will be found in such periodicals as the *Genealogist*, the *Herald and Genealogist*, the *Topographer and Genealogist, Collectanea topographica et genealogica, Miscellanea genealogica et heraldica* and the *Ancestor*. In Germany the *Deutscher Herold* is the organ of the Berlin Heraldic and Genealogical Society. The *Nederlandsche Leeuw* is a similar publication.

Modern criticism of the older genealogical methods will be found in J. H. Round's *Peerage and Pedigree*, 2 vols. (London, 1910), and in other volumes by the same author. The Harleian Society has published many volumes of the Herald's Visitations; and the British Record Society's publications, supplying a key to a vast mass of wills, chancery suits and marriage licences, are of still greater importance. The *Victoria History of the Counties of England* includes genealogies of the ancient English county families still among the land-owning classes. English pedigrees before the Conquest are in W. G. Searle's *Anglo-Saxon Bishops, Kings and Nobles* (1899).

Genealogical dictionaries of noble French families include Victor de Saint Allais's *Kobiliaire universel* (21 vols., 1872–1877) and Aubert de la Chenaye-Desbois' *Dictionnaire de la noblesse* (15 vols., 1863–1876). A sumptuous work on the genealogy and heraldry of the ancient duchy of Savoy by Count Amédée de Foras began to appear in 1863. Spain has Lopez de Haro's *Nobiliario genealogico de los reyes y títulos de España*. Italy has the *Teatro araldico* of Tettoni and Saladini (1841–1848), Litti's *Famiglie celebri* and an *Annuario della nobilità*. Such annuals are now published more or less intermittently in many European countries. Finland has a *Ridderscap och Adels Kalender*, Belgium the *Annuaire de la noblesse*, the Dutch Netherlands an *Adelsboek*, Denmark the *Adels-Garbog* and Russia had the *Annuaire* of Ermerin. But chief of all such publications is the ancient *Almanach de Gotha*, containing the modern kinship oi royal and princely houses, and now accompanied by volumes dealing with the houses of German and Austrian counts and barons, and with houses ennobled in modern times by patent. A useful modern reference book for students of history is Stokvis's *Manuel d'histoire et de généalogie de tous les états du globe* (1888–1893). The best manual for the English genealogist is Walter Rye's *Records and Record Searching* (1897). G. Gatfield's bibliography (1892) is helpful. (O.B.)

Data for American genealogies may be found in the *New England Historical and Genealogical Register; New York Genealogical and Biographical Record; Genealogical Magazine of New Jersey; Publications of the Genealogical Society of Pennsylvania; Mayflower Descendant: New Haven Genealogical Magazine; William and Mary College Quarterly; Maryland Historical Magazine; Virginia Magazine of History and Biography; South Carolina Historical and Genealogical Magazine; Nebraska and Midwest Genealogical Record; Utah Genealogical and Historical Magazine; National Genealogical Society Quarterly; Americana; Vineland Historical Magazine; Magazine of American Genealogy; Lineage Books of the Daughters of the American Revolution.*

GENÉE, ADELINE (1878–), Danish dancer, was born at Aarhus, Jutland, and began to study her steps when a child. After appearing in Berlin, Copenhagen and Paris, she went to London. The precision and technical perfection of her dancing made her a great favourite. For many seasons she was *première danseuse* at the Empire, London.

Adeline Genée was in America in 1908–13.

GENERAL, a high military rank. Army officers holding this rank usually command units larger than a regiment or its equivalent or units consisting of more than one arm of the service *(see* OFFICERS). This applies also to officers commanding comparable units of air forces. In many instances, however, a general is a staff officer who does not command troops but who plans their operations in the field. General, lieutenant general and major general are the first, second and third grades of general officers in most armies. The U.S. army, air force and marines have a fourth grade, brigadier general. The highest U.S. army rank, that of general of the army, was created during World War II and is the equivalent of the rank of field marshal in the British and other armies. Its counterpart in the U.S. air force is general of the air force. *(See* INSIGNIA, MILITARY.)

The term is also included in the titles of various civil offices of high responsibility such as postmaster general, attorney general and governor general. (LN. Ms.)

GENERAL AGREEMENT ON TARIFFS AND TRADE (G.A.T.T.): *see* TARIFFS AND TRADE, GENERAL AGREEMENT ON (G.A.T.T.).

GENERAL AVERAGE: *see* AVERAGE.

GENERAL ELECTRIC COMPANY, one of the largest electrical manufacturers in the world, designs, produces and sells thousands of diversified products. General Electric participates actively in most of the basic industries possible in manufacturing and its products afford power for all basic industries. An important pioneer in industrial research, General Electric also contributed much to fields not directly allied with the electrical industry through research in physics, metallurgy and chemistry.

The General Electric company was established on April 15, 1892, by the consolidation of the Edison 'General Electric company and the Thomson-Houston company, with Charles A. Coffin as the first president. The Edison Electric Light company had been formed in 1878 by Thomas A. Edison for the purpose of developing an electric light. After the organization of the Thomson-Houston company in 1883, a merger of the two companies was effected since the parallel developments of each tended to result in infringement upon individual patent rights. The company contributed not only to the extensive electrification of all industry in the three primary fields—lighting, electric railways and power—which was its initial aim but also to the discovery of hundreds of new applications for electricity.

In 1879 Edison had demonstrated his first successful incandescent lamp, to which he won all patent rights in 1891 by court order. Contingent upon this first main step, progress in lighting advanced, after the merger, with the first practical demonstration of the mercury vapour arc lamp and the magnetic arc lamp (1903). General Electric subsequently began the manufacture of the metalized-carbon filament lamp (1905); the tantalum-filament lamp (1906); the tungsten lamp (1911); the water-cooled lamp (1931); and the fluorescent light (1938).

Other improvements included the development of lamp bulbs without tips (1919) and the use of inside frosting for lamp bulbs (1924)—later improved by the white, inside-finish lamp which diffused light with almost perfect uniformity.

Edison's first electric railway was tested in 1880. In 1895 a General Electric locomotive pulled the first trains through the Baltimore and Ohio railway tunnel in Baltimore. General Electric operated the first fully automatic substation for the Elgin and Belvidere Electric railway in 1914. The Great Northern railway's Cascade tunnel, which traverses the Cascade mountain range in Oregon for the length of three miles, was placed under General Electric operation in 1929, and in 1934 the company equipped the "Zephyr," a new type of streamlined diesel-electric train.

General Electric. moreover, made vast progress in the comprehensive field of power In 1903 the company tested the first steam turbine and in 1926 produced the largest turbine-generator in the world, a 208.000-kw. unit. The U.S.S. "Jupiter," the first electrically driven ship of the U.S. navy, was launched in 1912, powered by General Electric engines.

Other major accomplishments include the demonstration of the hot-cathode X-ray tube (1913); the first domestic refrigerator with a sealed mechanism (1925); the introduction of the oil furnace and air conditioner (1932); a mobile two-way radio system (1934); the manufacture of metal radio tubes and the first sets to use them (1935); and the electric blanket (1936). In 1952 General Electric became the largest manufacturer of jet aircraft engines in the U.S.

During World War II General Electric mobilized its facilities for the production of war weapons. Among the defense products which the company manufactured were propulsion units to drive navy and merchant marine ships; turbosuperchargers for the air force; radar and radio equipment; electrical control apparatus; and electric motors.

General Electric also participated in research aimed at the development of atomic weapons and of peaceful applications of atomic energy. General Electric was among the first firms to volunteer its services for research in nuclear power.

GENERAL MOTORS CORPORATION, the world's leading producer of motor vehicles, also manufactures a wide variety of household appliances and commercial products such as electric refrigerators, ranges, clothes washers and dryers; oil burners; diesel locomotives. diesel engines for highway, marine and stationary use; turbo-jet and prop-jet aircraft engines; and earth-moving equipment.

When called upon, the company has undertaken major assignments for the armed forces, including production of complete tanks, guns and airplanes; ammunition and military vehicles; gun-bomb-rocket sights, bombing navigational computers and guidance systems for missiles.

General Motors also makes many of the special smaller parts and accessories for its principal products, such as starting, lighting and ignition systems, spark plugs, fuel pumps, shock absorbers, car radios, heaters, locks, horns, headlights, ball and roller bearings, carburetors, etc.

Research in General Motors has been emphasized since the GM Research laboratories were founded in 1920. Company research has contributed a number of pioneering developments in fields such as fuels, refrigerants, quick-drying lacquers, internal combustion engines of all types and metallurgy. It developed the lightweight two-cycle diesel engine, which after the mid-1930s all but completely replaced steam on U.S. railroads.

The General Motors company (New Jersey) was incorporated on Sept. 16, 1908. Buick was the nucleus company but was soon joined by Oldsmobile, Oakland (now Pontiac) and Cadillac. Chevrolet joined the by then reorganized General Motors corporation (Delaware) in 1918. In that reorganization General Motors changed from a holding to an operating company. Subsequently, the corporation pioneered in the development and application of a decentralized concept of management. Under this concept, since widely emulated by other major industrial enterprises. the various operating units, called divisions. have a substantial degree of autonomy within a framework of over-all policy.

In Nov. 1954 General Motors produced its 50,000,000th motor vehicle in the United States and the following year attained the highest annual sales ever reported by any company—more than $12,000,000,000. In the late 1950s General Motors was employing about 600,000 persons world-wide, and was owned by well over 750,000 shareholders. In the United States alone, General Motors company purchases goods and services from more than 26.000 suppliers, who receive approximately 50 cents out of each sales dollar.

General Motors scholarship programs aid 350 colleges and 1.600 students annually. (H. H. C.)

GENERAL STAFF, a military term denoting the staff of officers who assist a commander by performing detailed duties of administration. planning, supply and co-ordination. The general staff concept emerged in European armies during the 19th century, the first and most successful being the general staff of the Prussian army.

The U.S. army created a general staff in 1903, largely resulting from the efforts of the secretary of war, Elihu Root. Soon thereafter, in 1906, the British army also formally established a general staff. In most air forces the counterpart of the army general staff came to be known as the air staff.

See STAFF, MILITARY.

GENERAL STRIKE. A general strike does not necessarily imply a strike of all workers in *every* industry, but the term does mean that a substantial proportion of workers in each of a number of industries have ceased work in a common endeavour to achieve a certain objective, which may be economic or political. While the description may not be properly applied to a strike covering only one industry, there may be considerable variations in the degree of generality of such a strike.

Early Radicals and Chartists.—The idea of the strike as a means of influencing conditions of employment is as old as civilized man and antedates the trade-union movement by centuries. However, as a deliberate part of the tactics of collective bargaining the strike came into regular use with the growth of the trade unions in Great Britain in the late 18th century. The history of the general strike also seems to begin in Great Britain. When the term was first used is not clear. but both the idea and the expression were brought into popular currency at the time of the Chartists. John Doherty, one-time leader of the cotton spinners, used the term in 1834 in a newspaper which he edited. and again when giving evidence before a parliamentary committee in 1838 on the cause of the strikes which had occurred after the repeal of the Combination acts in 1824. Doherty, however. seems to have meant nothing more than a strike which was not confined to a single district, but embraced the whole cotton trade.

In the 1820s and 1830s the idea of a general stoppage of work was canvassed by radical orators as a means of securing the reform of parliament and achievement of the "rights of labour." The first conception was that of a "national holiday" or "sacred month." In Jan. 1832 William Benbow published a pamphlet entitled *Grand National Holiday and Congress of the Productive Classes*, describing how the workers, if they would act with unity of "thought and action." could by ceasing to work for one month secure "equal rights, equal liberties. equal enjoyments, equal toil, equal respect. equal share of production." The national holiday or sacred month was to be a peaceful affair and achieve its objectives by the simple process of the workers remaining "at leisure."

There was much talk of the sacred month by the Chartists at the time of the great convention in 1839. and a great deal of dispute as to whether it should take the form of a national holiday or an armed insurrection. In the event. little came of the agitation, though it caused considerable apprehension to the government. In 1842 the Chartist executive tried to turn an outbreak of strikes in Lancashire into a general strike for the charter. They were successful in spreading the stoppage to neighbouring counties. but the strike eventually collapsed in the face of the show of force organized by the government.

Syndicalism.—After the failure of the Chartist agitation interest in the general strike declined in Britain until the early years of the 20th century. Discussion of the theory of the general strike as a method of social revolution was mainly conducted in France, and the doctrines of Syndicalism (*q.v.*) subsequently developed there gave it a philosophic basis. The question was discussed at the Geneva congress of the International Association of Workingmen in 1866, but it was not until 1893 that the next significant manifestation of the general strike occurred. On the refusal of the Belgian parliament to agree to universal manhood suffrage the Labour party issued orders calling on the workers to stop work immediately, and more than 200,000 workers went on strike. the stoppage only being called off when parliament relented and agreed in a modified form to the workers' demands. Again in 1902 there mas another general strike in Belgium which led to riots and the shooting of some strikers.

In the same year, a large-scale strike took place in Sweden in support of universal suffrage and the reform of parliament, and in 1909 there occurred the most complete general strike for economic ends which had, up to that date. ever taken place in any country. The 1909 general strike in Sweden was largely the result of the high degree of organization and centralized control of both workpeople's and employers' federations. Falling profits had led the employers to agree betneen themselves on a nation-wide basis not to raise wages and in some instances to cut them. This policy was resisted by the unions, which had also other scores to settle, and they eventually decided to attempt to defeat the employers by calling a general strike.

The stoppage lasted a month and more than 300,000 workers out of a total of 800,000 ceased work. Industry was brought almost completely to a standstill, but the railway workers did not join the strike, though road and river transport stopped. The strike was entirely peaceful and aroused world-wide interest, large sums of money being subscribed by unions in other countries to assist the striking Swedish workers.

Though the results of the Swedish general strike could not be described as either failure or success, it encouraged the growth of the idea in other countries that major economic reforms could be achieved thus nithout violence necessarily being involved.

Widespread support for the general strike began to develop in Great Britain after the return from Australia of Tom Mann—one of the leaders of the great 1889 dock strike. (*See* also STRIKES AND LOCKOUTS). Mann came back to Britain inspired by the doctrines of Syndicalism which had spread from France to America, later being adopted by the Industrial Workers of the World (founded in Chicago in 1905), and re-exported to Europe and Australasia. Mann established in 1911 the Revolutionary Syndicalist league and had a hand in most of the large-scale strikes which occurred in 1910, 1911 and 1912.

The essence of the Syndicalist belief was that the workers could not achieve social revolution by democratic political means, but only by the direct overthrow of the capitalist owners of industry through a general strike. Once the power of the capitalists had been destroyed any re-emergence of centralized authority could be prevented by the unions taking over the control of industries and running each of them for the benefit of the norkers. To attain these ends the first essential step was the reorganization of the trade unions on the pattern of industry, since combinations based on craft or occupational differences only weakened the power of the working class.

These ideas were perhaps most brilliantly expressed in the pamphlet published by the south Wales miners in 1913 entitled The *Miners' Next Step*. Between 1910 and 1914 industrial Syndicalism secured a considerable following, and on the eve of World War I the road transport, railway and miners' unions came together to form the "triple alliance," with the object of securing, by strike action if necessary. major improvements in wages and working conditions.

The progress of Syndicalism was arrested by the war, and the changes wrought by the conflict were such that the Syndicalist movement was never able to recapture its pre-1914 attraction. However, the upheaval in social conditions and the problems of social and economic readjustment left by the war to some extent promoted militant ideas. There was much talk of "the day" among shop stewards and other radical elements in the trade-union movement, and when Ernest Bevin organized the councils of action it is almost certain that there would have been a complete stoppage of work throughout the country had not David Lloyd George changed his policy of sending troops to Poland. It was this easily earned victory of 1920 that perhaps led Bevin astray when weighing up the situation in 1926.

The General Strike of 1926 in Britain.—The British general strike of 1926 stemmed from the background of developments already sketched and from the conditions of employment in the coal industry. It was not a deliberately planned strike and the policy of the leaders of the trade-union movement was not determined by theoretical considerations, but they and the rest of the active workers did believe that the mineowners and the government could be coerced by a show of peaceful force.

Much had been expected of the triple alliance by militant members of the unions immediately after the end of the war. However, the miners were persuaded not to call upon its aid by the appointment of the Sankey commission, and then, when this proved abortive from their point of view, disagreement between the members of the alliance prevented action. The end of the alliance came when in 1921 the railwaymen and transport workers refused to strike with the miners.

The fundamental weakness of the triple alliance lay in the refusal of each organization to give up final autonomy. The result was that the miners struck alone against wage reductions and a long struggle followed after which they eventually returned to work, bitter at their defeat. The problems faced by the coal industry grew no easier, and with the return of the German. Polish and Belgian coal fields to full production the export market grew even more difficult. The coal owners sought to bring down costs by again reducing the standards of employment of the miners. The conflict came to a head in 1925 and the government staved off another stoppage by granting a temporary subsidy while another royal commission under Herbert Samuel made a further investigation of the industry's sickness.

The report of the commission, which made a number of compromise proposals to tide the industry over its difficulties, was published in March 1926. It was immediately rejected by both sides and a strike appeared inevitable when the government subsidy came to an end on April 30. Meanwhile, the Industrial committee of the Trades Union congress had met the prime minister and explored the possibility of getting negotiations restarted. Nothing was achieved. houever, in the face of the intransigence of both the miners and the owners. On April 29 the T.U.C. pledged its support to the miners and called a national conference of trade-union executives. The general council then took a roll call of its affiliated unions; 3,653,000 votes were cast in favour of giving the council full powers to act on behalf of the whole movement, and 49,911 against.

Further attempts were made by the Trades Union congress to negotiate with the government, which had invoked the Emergency Powers act passed in 1920 to meet just such a situation as this. Some progress seemed to have been made. but while the general council of the T.U.C. was meeting the miners' executive a summons was received from Downing street. and when the T.U.C. delegates arrived they were handed a letter stating that negotiations could not be continued since the machine operators at the Daily Mail had refused to print the leading article of the following day's issue. Despite the fact that this action had been taken spontaneously without the knowledge of the T.U.C., the government held it sufficient reason for refusing further discussions and insisted that all strike notices be withdrawn before any further talks could be held. Faced with this situation the general council decided that there was nothing further it could do but give the order for the strike to commence.

The unions had talked about making preparations, but in fact little had been done, and a hurriedly improvised organization had to be created. The only possibility of winning the strike lay in frightening the government and so persuading it to intervene, in order to get talks going once again, by the offer of some compromise solution.

The government, however. had long made preparations to meet an emergency of this kind, and it was determined to force the unions to capitulate. In spite of the calling out of troops, arming of special constables and the arrest of hundreds of strikers, the whole affair was remarkably peaceful and very few serious incidents were reported.

At this time there were about 5,000,000 trade-union members out of a total wage-earning population of 15,000,000; about 3,000,000 were eventually involved in the strike. The main industries to be stopped included railways, road transport, iron and steel. building and printing; the rest were to be called out later if necessary. The closing of the press led to the government's producing its own paper, the *British Gazette,* and the T.U.C. published a strike newspaper called the *British Worker.* In the absence of the daily press many rumours circulated and the effect nas to weaken the resolution of the workers and increase the fears of the middle class.

The general council rapidly realized that the government was not likely to be stampeded and began to look for a way of ending the strike. Sir Herbert Samuel, who had returned posthaste from the continent. acted as an intermediary on his own initiative, and made certain suggestions to the T.U.C. The miners, however, refused to consider them, and therefore the general council decided to call off the strike as it felt that no solution was possible if the miners would not compromise at all. The general council believed that the miners had violated their agreement with the T.C.C. when it accepted the responsibility of calling the strike, since in their view this also implied the right of the general council to decide on the settlement.

The general strike was thus brought to an end on May 12, having lasted nine days. But the miners refused to return and remained on strike throughout the summer until they were starved into submission.

The Legal Issue.—The general strike raised many important issues. How far is it possible for a strike to go before it in fact becomes a revolutionary action directed against the state? Lord Simon held that the strike was illegal since it was not a trade dispute but an attempt "to make the public and parliament and the government do something," and this was not legally permissible under the trade-union acts.

On the other hand Arthur Lehman Goodhart challenged this interpretation of the law, holding that the fact that the T.U.C. did not have a trade dispute with the government was irrelevant. The real question was whether the trade unions on strike were furthering a trade dispute, which obviously existed so far as the miners were concerned, in which case the sympathetic strikers were acting legally.

This legal dispute has never been resolved. The government tried to clarify the issue by passing the Trade Disputes and Trade Unions act in 1927, but since this act was repealed in 1946 the position became as it was in 1926.

Later Tendencies—The effect of the general strike was to make both sides realize the danger to themselves in allowing industrial relations to become so strained. During the following years industrial relations improved considerably and this was to a great extent the result of wise leadership shown by both sides of industry. The *modus vivendi* which unions and employers gradually worked out for themselves in Britain was not achieved in France, which went through a period of bitter industrial unrest involving general stoppages in the 1930s. At the end of World War II there were several instances of general strikes in a number of European countries for both political and economic reasons; however, the Syndicalist notion had long been abandoned in most western European countries. So long as there is free trade unionism, with the right to bargain, a general strike is always possible. but it is extremely unlikely to occur if political democracy flourishes and prosperous economic conditions are sustained. When a general strike does occur, however, whatever the legal situation may be, it does constitute a challenge to the authority of the state and no government could in fact refrain from taking drastic action to bring it to an end.

(B. C. R.)

UNITED STATES

American labour has accepted in principle the inviolability of the collective contract and consequently it has in general always opposed the general strike. A general strike would lead to universal breaches of existing agreements, and would expose weaker unions to reprisals from employers. This kind of opposition by union leaders, based upon pragmatic grounds, has been reinforced by their strong opposition to the use of what is essentially a revolutionary weapon.

There have, nevertheless, been a number of local general strikes, all of which were opposed by the national officers of many of the participating unions. In the period folloning World War I, mounting radicalism as well as the belief that the employers of the shipyards were out to destroy the newly built unions in their plants led to a strike on Feb. 6, 1919, involving virtually all labour in Seattle, Wash. The walkout lasted five days, and the opposition of the national officers of many of the unions mas an important factor in ending the general strike. Local general strikes later took place in Terre Haute. Ind., in July 1935; in Pekin, Ill., in Feb. 1936; and in Oakland, Calif., in 1946; but the most important local general strike took place in San Francisco. Calif.. in July 1934. This was caused by the attempt of the stevedores and shipowners to break the maritime strike for union recognition. Violence against the strikers, followed by efforts to carry on stevedoring operations by strikebreakers and the use of the national guard to protect them, precipitated the general walkout. It lasted four days, and the national heads of a number of unions as well as the American Federation of Labor disclaimed any support for this walkout.

General strikes are to be distinguished from industry-wide strikes, which are general as far as the affected industry is concerned. In the period after World War II, there were a number of industry-wide strikes in the bituminous coal and steel industries, but no general strikes of even the local variety. The reason is that local general strikes can only be called when there is widespread conviction among the organized workers in a community that an attack is being made upon the right of a large body of workers to organize and that united action is necessary to frustrate the employer's effort. With the acceptance of unions as a normal part of the industrial scene, the possibility for local general strikes are sharply reduced.

GENERATOR, ELECTRIC, a device in which mechanical power is converted into electrical power, utilizes the principle that a voltage is induced in the turns of a coil of wire while the number of magnetic lines (the flux) linking the turns of the coil are changing. The principle can be illustrated with a horseshoe magnet, a coil of perhaps 50 turns of wire and a galvanometer. Connect the ends of the coil to the terminals of the galvanometer. Then observe the galvanometer pointer as the magnet, is placed so that its legs enclose one side of the coil. A pointer deflection in one direction occurs while the magnet is moved toward the coil; a deflection in the opposite direction occurs while the magnet is moved away from the coil. Moving the magnet more rapidly increases the deflection. With the magnet held stationary in any position relative to the coil no pointer deflection is observed. If the magnet is held stationary and the coil moved, it is found that a deflection occurs only while the coil is moving. If the coil is placed about a leg of the magnet and both are held stationary, and if a piece of steel is now moved to make and break contact with the poles, galvanometer deflection occurs when the steel is being moved —in one direction as the steel approaches the poles and in the opposite direction as it leaves the poles. In some generators the coils are stationary and the magnetic lines are moved across them, in others the coils are moved across the magnetic lines, and in still others both the coils and the source of the magnetic lines are stationary and steel in the magnetic path is moved.

History. — In 1831 Michael Faraday rotated a copper disk edgewise between the poles of a horseshoe magnet and obtained a continuous (direct) voltage between two rubbing contacts, one on the periphery and the other on the shaft of the disk. In this first electric generator the electromotive force was obtained by moving the conductors (*i.e.,* the elements of the disk) across the magnetic flux, not by a change in the amount of flux linking a turn. In this disk generator, of the type now called homopolar or acyclic, the electromotive force generated in any element of the disk maintains a fixed direction with respect to the element for a given direction of disk rotation. Homopolar generators are low-voltage machines; they are not of commercial importance because their efficiencies are lower and their costs of construction are higher for a given power output than for other types of generators.

In 1832 Hippolyte Pixii constructed a generator using permanent magnets and wire armature windings. This type, in which alternate poles have alternate magnetic polarities, is known as heteropolar. In Pixii's generator the electromotive forces generated in the windings are alternating in sign. To obtain a direct current output he contrived the first commutator, a device using moving contacts to reverse the connections at the ends of an armature coil at the instant the voltage in the coil is reversing.

In 1845 Charles Wheatstone replaced the permanent magnets with electromagnets excited with direct current from a battery. In 1857 he added the feature of self-excitation, whereby the field windings received current from the armature terminals. The ring winding of Antonio Pacinotti (1860) and Zénobe Théophile Gramme (1870) made it possible to add the voltages of many conductors of a multipolar generator and thus obtain higher voltages than were feasible earlier. The winding method was such that the conductors were held in place on the surface of the revolving armature. Ring windings were superseded by the more cheaply constructed barrel or drum-type winding of Friedrich von Hefner-Alteneck (1872), a development from the earlier shuttle winding of Ernst Werner von Siemens (1856). Placing an armature winding in slots (first proposed by Pacinotti in 1860) made possible a reduction in the effective length of the air gap in the path of the magnetic lines and a consequent increase in the strength of the magnetic field produced by a given field winding. Rotation of the armature structure causes alternating voltages to be generated not only in the conductors but also in the steel, where circulating or eddy currents cause losses. Eddy current losses were reduced by laminating the armature steel.

Edward Weston and Thomas A. Edison were among the first to recognize all the factors contributing to generator losses, and the latter's bipolar generator raised the standard of generator efficiency from about 50% to the then unheard of value of 90%. This machine had a much greater ratio of steel to copper weight than earlier ones and had the first mica-insulated commutator. In 1886 John and Edward Hopkinson devised the first rational method of generator design. Edison's bipolar generator in 1878, the incandescent lamp in 1879 and the Edison system of central station power production in 1882 gave commercial impetus to electric generator and power development.

In 1881 Charles F. Brush added a second field winding—about the field poles and connected in series with the armature circuit—to form a compound generator. The voltage of this generator automatically remained at a nearly constant value regardless of the amount of current drawn by connected loads.

Brushes used on early generators were of strap copper, copper mesh and metal alloy. Enough sparking occurred to cause burning of the commutator bars and the brushes in addition to friction wear. In 1888 Charles J. Van Depoele invented the carbon brush, which greatly reduced the sparking and the wear on the commutator. In the early 1890s parallel operation of compound generators by means of external equalizer connections was devised, and in 1896 Benjamin Garver Lamme invented internal equalizer connections, which ensure an equal division of the current between parallel armature paths, and made really large generators practical. Thereafter larger and larger multipolar generators, directly connected to reciprocating steam engines, came into use, reaching a peak of development about 1900.

The invention of the first A.C. (alternating current) system of power generation and distribution by Lucien Gaulard and John Dixon Gibbs in Europe and by William Stanley in the U.S. (1885), and of the induction motor by Kikola Tesla (1888), led to A.C. generator developments. Steam engines and, occasionally, water wheels were the early prime movers.

Among the earliest developments was Stanley's inductor generator with stationary field and armature windings which generated voltages from pulsations in a unidirectional magnetic field caused by revolving a toothed rotor. Elihu Thomson's A.C. generator of 1878 was similar to D.C. (direct current) generators, except that a commutator was not required and collector rings were connected to the armature winding in a manner such that alternating voltages were obtained between brushes riding on the rings. Ultimately the advantages of having the armature winding stationary, avoiding high voltages between collector rings, led to universal use of the modern revolving field structure for a synchronous generator.

The frequency of the voltage delivered by early A.C. generators was probably determined by the number of poles that could be readily constructed and the speed of an available prime mover. During the early years of alternating current, installations were made using frequencies ranging from $16\frac{2}{3}$ to $133\frac{1}{3}$ c p.s. (cycles per second). Changes in the application of alternating current led to changes in the frequencies. The need for a restriction in the number of frequencies led to the almost universal adoption of 60 c.p.s. for lighting and power purposes in the U.S., although 25 and 50 c.p.s. remained in use in some installations.

For a given number of poles and a given speed of rotation, an inductor generator delivers twice the frequency of the present common types of A.C. generators. In the early years of radio telegraphy the inductor generator was the best source of the frequencies required. Generators with a frequency of 100,000 c.p s. and capacities up to 100 kw. were built. The advent of the electronic tube and the discovery that it could be used to produce a high-frequency output from a D.C. source enabled it to supplant the inductor generator. New applications requiring frequencies ranging from 1,000 to 10,000 c.p.s. for inductive heating and the use of 400-c.p.s. control equipment and motors for aircraft created a demand for which the inductor generator was an economic answer.

Among the first polyphase generators were the three-phase, 100-kw. Lauffen generators designed by C. E. L. Brown (1891) and the two-phase, 5.000-kw. Niagara generators built by the Westinghouse company (1894), both vertical shaft machines with external revolving fikld structures.

In the late 1890s, when polyphase alternating current was replacing D.C. supply, and before the advent of the steam turbine, steam-reciprocating-engine-driven A.C. generators were built with ratings up to several thousand kilowatts.

The first large steam-turbine-driven A.C. generator in the U.S. was built by the American General Electric company and installed in Chicago. Ill., in 1903. It was of the vertical shaft type and rated at 5,000 kw. Its satisfactory operation led to the almost universal adoption of steam-turbine-driven polyphase generators for central stations. After a few years, turbine-driven generators were designed almost entirely with horizontal shafts and internal revolving field structures. Improved materials and design refinements enabled larger and larger machines to be built, ratings up to 50,000 kw. at 13,200 v. and 3,600 r.p.m. being common. Two-hundred-thousand-kilowatt single-shaft generators at 3,600 r.p.m. have been built, and up to 33,000 v. have been used.

Modern water-wheel generators are almost universally of the salient-pole, revolving field structure type, with drum windings in open slots and welded steel frame structures. Typical of the large machines in modern hydroelectric projects are the 77,500-kva., 88-r.p.m. Dnieprostroi generators, the 82,500-kva., 180-r.p.m. Hoover dam generators and the 108,000-kva., 120-r.p.m. Grand Coulee dam generators.

Some power plants have diesel or other oil engines as prime movers. A.C. generators for this service must have damper or amortisseur windings and often extra flywheels to limit the electric oscillations set up by the pulsating torque of the engine.

Hydrogen cooling of synchronous machines was introduced first in 1928. By the 1950s almost every steam-turbine-driven generator with a rating above 20,000 kw. was hydrogen cooled. An innovation of 1952 was to make the armature conductors hollow so that they could be cooled by blowing hydrogen through them.

DIRECT-CURRENT GENERATORS

A D.C. generator consists of a field structure, a series of alternate north and south magnetic poles equally spaced around a circular periphery and an armature structure built up of laminated steel sections (laminations) with slots in its surface in which a system of electrical conductors (a winding) is placed. A common lamination thickness is 0.025 in. Although either the field or the armature structure can be made the moving part, mechanical considerations cause a D.C. generator to be built with the armature structure as the moving part. An elementary D.C. generator is represented in fig. 1. Here a battery is represented as the source of direct current that flows through the turns of the field winding surrounding the field poles. In this manner the magnetic lines are established in the paths as shown. That the magnetic lines pass through the pole pieces from left to right is determined from the principle that if one coils the fingers of the right hand about an iron core in the direction current flows in turns about the core, the extended thumb is parallel to the lines in the core. The enlarged portions of the poles near the armature are the pole shoes, and the areas facing the armature are the pole faces. The spaces between the pole faces and the armature are the air gaps.

In fig. 1 the number of magnetic lines passing through the armature coil varies from zero when the plane of the coil is horizontal to a maximum when it is vertical. The voltage generated in the coil at a given instant depends not upon the number of lines through the coil but upon the rate at which the number of lines is changing. Just before the plane of the coil reaches the horizontal position the lines are passing through it in one direction; just after it passes that position the lines are passing through it in the opposite direction. At the horizontal position the rate of change of the lines is the greatest and the voltage generated is a maximum. When the plane of the coil is vertical the rate of change of the number of lines through it is zero and no voltage is generated in it at that instant. For nearly one-half revolution, one brush is in contact with the commutator bar attached to one end of the coil and the other brush is in contact with the commutator bar attached to the other end of the coil. Note that the brushes are set so that the left-hand brush makes contact through the commutator bar to a coil side when it is on the left side of the vertical and the right-hand brush makes contact through a commutator bar to a coil side when it is on the right side of the vertical. As soon as a coil side moves from one side of the vertical to the other it ceases contact with one brush and establishes contact with the other. Thus the polarity of a brush remains fixed even though an alternating voltage is being generated in the coil.

The polarities of the brushes in fig. 1 are determined by Fleming's right-hand rule. Place the thumb, the first finger, and the second finger of the right hand mutually at right angles, thereby forming the axes of a three-co-ordinate system. Now, while pointing the first finger toward the right in the direction of the magnetic

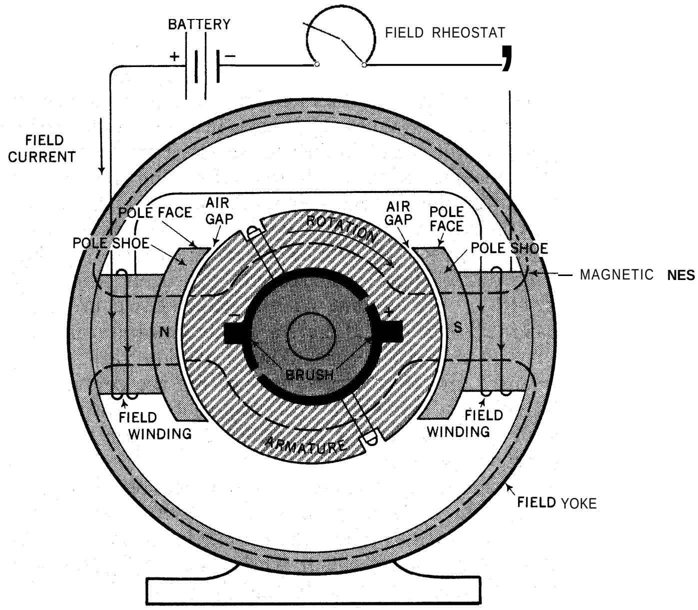

FIG. 1.— ELEMENTARY D.C. GENERATOR WITH ONE-TURN ARMATURE COIL AND TWO COMMUTATOR BARS

lines from the N pole, turn the hand until the thumb points upward in the direction the left-hand coil side moves in front of the N pole face. Then the second finger points into the page as the direction of the generated voltage in the left-hand side of the coil. The right-hand coil side moves downward in front of the S pole through magnetic lines directed from right to left, so the voltage generated in that coil side is directed out of the page. The right-hand brush is the positive one since it is the one toward which the voltage generated in a coil side acts.

The time variation (wave form) of the voltage between brushes in fig. 1 depends upon the length of the air gap, the contour of the pole face and the percentage of the armature surface covered by a pole face. A D.C. voltmeter between brushes in fig. 1 would read the average value of the voltage. This would probably be more than one-half the maximum voltage, although the exact value would depend upon the wave form.

The voltmeter reading would increase in direct proportion if the speed of rotation were increased. The current in the field circuit could be changed by adjusting the setting of the field rheostat shown. Increasing the field current would increase the voltmeter reading, not in direct proportion with the current but in direct proportion with the number of magnetic lines. Starting with zero current, as the current is increased, the number of lines at first increases approximately in direct proportion. As higher values of current are reached, the rate of increase of lines becomes less than

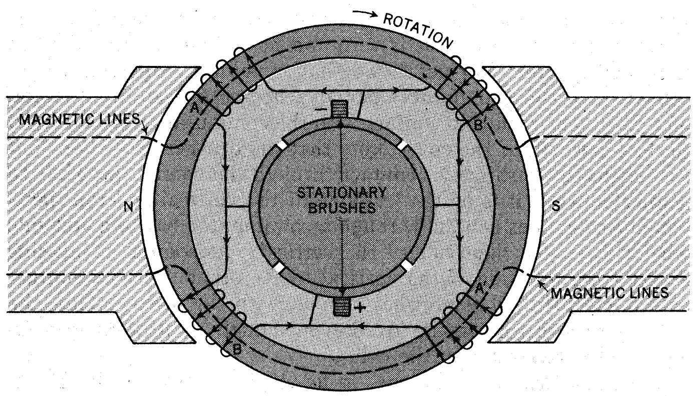

FIG. 2.— RING WINDING FOR D.C. GENERATOR

that of the current because of magnetic saturation in steel.

If the brushes in fig. 1 were shifted 90° from the position shown, a brush would make contact with a coil side while the side moves from the centre of one pole to the centre of the other. The voltage between brushes would be alternating with an average value of zero, as would be proved by a zero reading on a D.C. voltmeter.

Ring Winding. — If the one-turn coil of fig. 1 were replaced by a coil of more turns wound in the slots and the coil ends connected to the commutator bars, the voltage between brushes would be increased in proportion with the number of turns. For most applications of D.C. generators it is desired that the percentage variation with time of the voltage delivered from the brushes be small. The one-coil generator of fig. 1 would have too great variation for most applications. To reduce the variation, the number of coils and commutator bars is increased. An early means of doing this was with a ring winding such as that shown in fig. 2. This winding has four sections and there are four commutator bars. Here the number of magnetic lines linking a section varies from zero when the centre turn of a section is opposite the centre of a pole to a maximum when the centre turn is opposite a brush. The voltage generated in a section is a maximum in the first position and zero in the second position.

The voltages in the four sections have identical wave forms. The voltage in section A' is zero when that in A is zero, and the voltage in A' is a maximum when that in A is a maximum. The voltage in section B' is zero when that in B is zero, and the voltage in B' is a maximum when that in B is a maximum. However, the voltages in A and A' differ in time position from those in B and B' by the time for one-quarter revolution. Note that the four sections form a closed circuit. In that circuit the voltage of A is always equal to and opposed to that of A', and the voltage of B is always equal to and apposed to that of B'. As a result, no current flows in the windings when no external connections are made to the brushes.

During the part of a revolution that the brushes are in contact with the commutator bars that they touch in fig. 2, the voltages of sections A and B add in one path between the brushes, and the voltages of sections A' and B' add to an exactly equal value in the other path. Hence there are two paths in parallel as far as the brushes are concerned.

The voltage between brushes varies from a minimum at one position of the armature to a maximum at another position. When the armature has turned about one-eighth revolution from the position shown, two commutator bars touch one brush and the other two touch the other. Then section A is short-circuited by one brush and section A' is short-circuited by the other. At this instant the voltage between brushes is that of section B in one path and that of section B' in the other path. As the armature turns on beyond this position, coil A comes under the influence of the S pole, its voltage reverses from the previous direction and now adds to that of section B'in the right-hand path. At the same time section A' comes under the influence of the N pole, its voltage reverses from the previous direction and it now adds to that of section B in the left-hand path. As rotation continues the transfer of sections from one path to another continues. By using more winding sections and more commutator bars than are shown in fig. 2, the percentage time variation in the voltage between brushes can be reduced to a relatively small value.

When a load (a conducting element) is connected between brushes in fig. 2, the total current drawn divides equally between the two paths, entering the armature at the negative brush and leaving it at the positive brush. As a winding section is being transferred from a path on one side of a brush to a path on the other side, the current in it reverses direction. This reversal occurs during the time a section is short-circuited by a brush, an interval called the time of commutation. Although the generated voltage in a section becomes zero and then reverses during the time of commutation, the current in the section does not become zero and reverse simultaneously. The self-inductance (electrical inertia) of the section causes the current to decrease more slowly to zero than the voltage does.

After the current in the section has become zero, the reversed generated voltage causes the current to increase in the reversed direction. This rate of growth is limited by the self-inductance of the section. If, by the end of the time of commutation, the current in a section has not had time to reverse to a magnitude equal to that of the current in the path in which it is inserted, a spark occurs between a brush and the commutator bar from which it has just parted contact. Some sparking can be tolerated, but excessive sparking causes objectionable heating and pitting of the commutator bars. Most modern D.C. generators have one or more interpoles (commutating poles), which are located midway between the main poles. The winding on an interpole is connected in series with a lead from a brush in order that the number of magnetic lines passing from the interpole to the armature will vary in approximate proportion with the current in the armature coils. The location of an interpole is such that its magnetic lines generate a voltage in an armature coil during the time of commutation. The direction of the voltage is that required to reduce the current in a coil to zero and then establish it in the reverse direction.

Drum Winding. — For economic and mechanical reasons, the ring winding has been superseded by the drum winding. In fig. 3 are represented the form and the connections of coils in a lap type of drum winding. One coil with sides numbered 1 and 10, respectively, is placed so that side 1 occupies the upper half of one slot and side 10 occupies the lower half of another four slot pitches distant. This coil may consist of one or more turns of insulated copper wire taped together as shown. The ends of the coil are connected to adjacent commutator bars. A second coil with sides numbered 3 and 12 is displaced one slot pitch from the first with connections to the commutator being advanced by one bar. With this arrangement of coils continued around the armature a closed winding results, having as many commutator bars as there are coils. The ends of each coil connect to adjacent commutator bars.

With a drum winding the number of magnetic lines linking a coil is a maximum when the centre of the coil is opposite the centre of a pole. At that instant the rate of change of lines is zero and

FIG. 3. —LAP WINDING ON ARMATURE OF D.C. GENERATOR

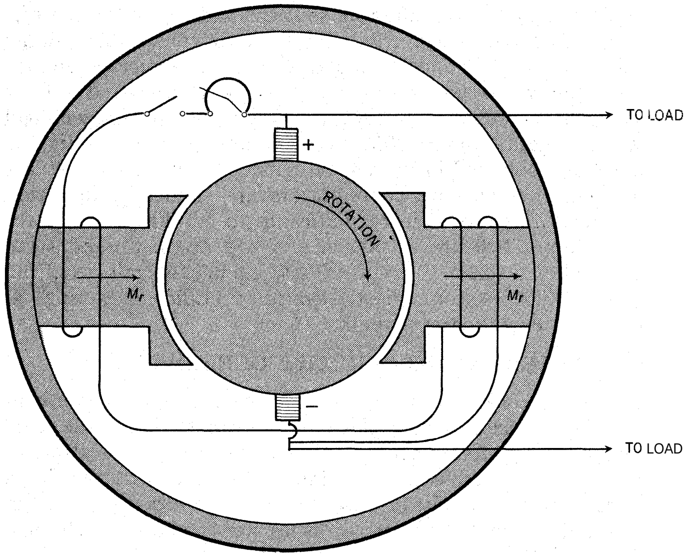

FIG. 4.— CONNECTIONS OF A SHUNT-WOUND GENERATOR

the generated voltage is zero. The maximum number of lines would be all those entering or leaving a pole if the span of a coil is equal to the distance from the centre of one pole to the centre of the next. The number of lines linking a coil is zero when the centre of the coil is midway between the centres of two adjacent poles. At that instant the rate of change of lines is a maximum and the generated voltage is a maximum.

Self-Excited Generators.— The generator of fig. 1 is separately excited since its field winding receives current from a source other than the armature terminals. Although the source is represented here as a battery, most separately excited generators receive their field current from a smaller D.C. generator known as an exciter. An exciter is often mounted on a shaft extension from the generator, both being driven by the same prime mover.

After current has been sent through the field winding of a D.C. generator and then removed. some residual magnetic lines remain in the magnetic circuit. As a result, when the generator is driven at rated speed a voltage that may be of the order of 5% of the rated voltage appears between the armature terminals. This voltage is used to produce a build-up to a higher value in a self-excited generator by using it to send current through the field winding.

In fig. 4 are represented the connections of a shunt-type self-excited generator. Normally no load is connected to the leads coming from the brushes until the voltage has been adjusted to a desired value. With the switch in the field winding circuit open and the armature driven at rated speed, it is assumed that the residual magnetic lines are from left to right as indicated by M_r and that the low voltage between brushes has the polarity indicated. When the switch is closed, current out of the positive brush flows through the field winding in such a direction as to produce an increased number of magnetic lines. This increase causes an increase in the voltage between brushes, which in turn causes a further increase of current. Saturation in the steel in the magnetic circuit prevents the voltage from increasing indefinitely. The value attained can be varied over a wide range by varying the resistance of the field rheostat. When the resistance is a maximum, the voltage may be only slightly greater than that with no current in the field winding. When the resistance is zero, the voltage is likely to be of the order of 50% above rated value. The value of field current required to produce rated voltage is likely to be of the order of 5% of the current rating of the generator.

If in fig. 4 the connections of the field windings to the brushes were to be interchanged and if the switch were closed, the current would flow in the field windings in such a direction as to reduce the number of magnetic lines below the residual value. As a result the voltage would reduce.

Consider a shunt generator Chat is being driven at rated speed with the field rheostat set so that rated voltage is obtained between brushes when no current is being drawn by a load. Under that condition the only current delivered by the brushes is that to the field windings. This is obtained equally from the various paths in the armature winding. When a load is connected it draws additional current from the brushes and the currents in the armature winding paths increase. These currents cause a magnetic action that in turn causes a reduction (usually small) in the number of magnetic lines and a corresponding reduction in the voltage produced in the winding. In addition, some of the voltage produced is used in sending the current through the resistance of the winding. These two factors cause the voltage between brushes to be reduced below its value when no load is connected. This reduction in voltage causes a reduction in the field current and a further reduction in the number of magnetic lines. Hence the voltage reduces more than it would have if the generator had been separately excited. With a given load current being delivered, it would be possible to bring the voltage back to its no-load value by cutting resistance out of the field rheostat. Because the percentage variations in its output voltage are rather great when changes in the load current occur, a shunt generator is best suited to applications where the load current required is nearly constant.

The connections of a series D.C. generator are shown in fig. 5. Here, if there is no connected load there is no current in the field winding. Under that condition, with the generator driven at rated speed, the residual magnetic lines cause the voltage between brushes to be about 5% of rated value. If a load is connected, the current drawn flows through the field winding and produces a magnetic action to cause voltage build-up just as in a shunt generator.

Because all the load current flows through it, the series winding needs fewer turns and a larger cross section of wire than the shunt winding to deliver an equal rated voltage at rated speed. The output voltage of a series generator varies from a low value with a small load current to rated value when rated current is delivered. Since most applications require a generator whose voltage output is nearly constant, regardless of the amount of current delivered, the series generator is not widely used.

A cumulative compound D.C. generator has both a shunt and a series field winding, connected as in fig. 6. With the proper connections of the shunt winding to the brushes, the generator builds up with no load connected, just as a shunt generator does. The rheostat can be adjusted so that rated voltage is obtained. When a load is connected, the current drawn through the series field winding causes a magnetic action that may increase the number of magnetic lines and consequently the voltage between lines to the load, even though the magnetic action of the current in the armature windings tends to reduce the number of magnetic lines, and some

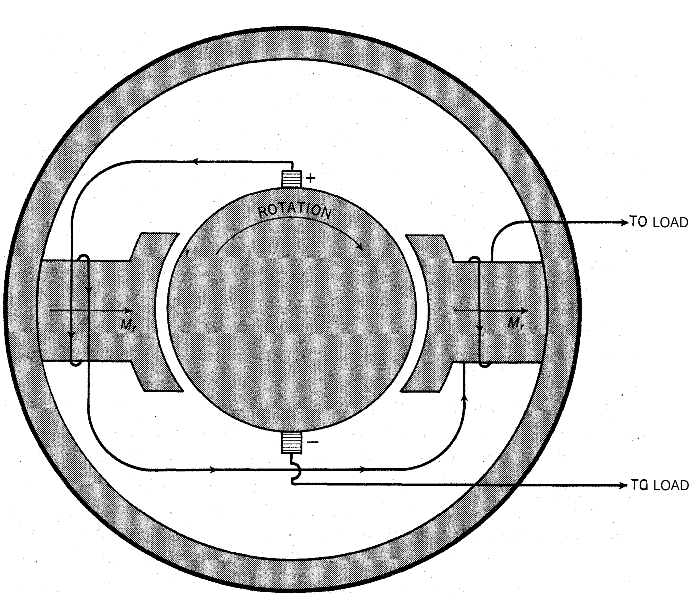

FIG. 5.— CONNECTIONS OF A SERIES-WOUND D.C. GENERATOR

of the voltage produced in the armature windings is used in sending current through the resistance of the armature and series field windings. If the magnetic action of the series field winding is

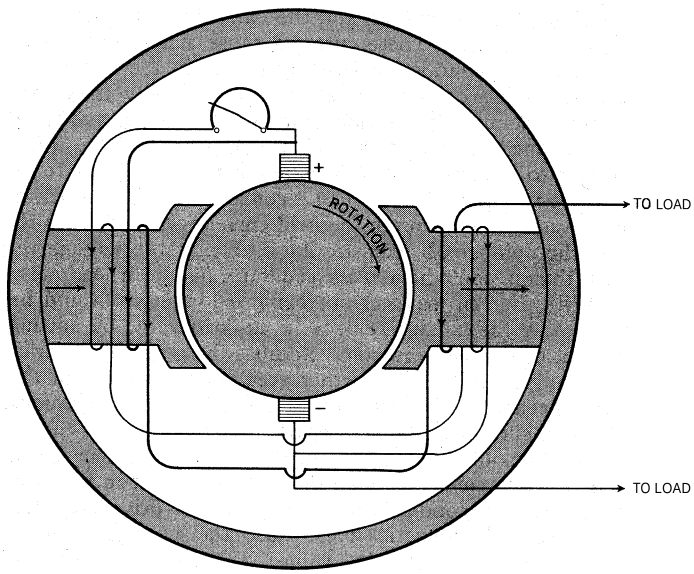

FIG. 6.— CONNECTIONS OF CUMULATIVE COMPOUND D.C. GENERATOR

enough to cause a rise in the voltage between brushes when the load current is increased, a rise in the shunt field winding current occurs. As a result the voltage rises more than it would have if no change in the shunt field current had occurred. If the voltage delivered to a load by a generator is greater when rated current is being delivered than with no current, the generator is overcompound If the magnetic action of the series field winding is such that the voltage delivered at rated current is equal to that with no current, the generator is flat compound.

D.C. Generator Construction.— A typical armature for a D.C. generator has a shaft on which are mounted two spiders, one to support the armature core and the other the commutator. The core is built up of thin steel laminations, insulated from each other and held together by end flanges. In the slots in the core are placed copper conductors which are insulated from the core with treated fabric or paper materials, or pasted mica flakes, and held in the slots by insulating wedges. The portions of the conductors that extend beyond the slots at each end are held down on the end flanges by steel wire. The commutator is made of a number of copper segments, insulated from each other and from the spider and clamping flanges by pasted mica flakes. In small machines the ends of the armature coils may be connected directly to the segments. In large machines the ends are connected to risers which are copper strips extending outward from the segments.

The field structure is composed of a steel ring to the inside of which are bolted the main and the commutating poles. The main poles are built up of steel laminations, thicker than those in the armature core. The lower portion of the pole is broadened to spread the magnetic lines over most of the armature surface. Above the pole shoe and around the pole core are placed the field coils. The shunt field coils, consisting of a large number of turns of insulated wire, are usually connected in series with a field rheostat between the brushes. The series field coils, consisting of a few turns of heavy copper wire, are usually supported with the shunt coils.

Graphitized carbon brushes are used with an area such that the normal current density is about 40 amp. per square inch. These are arranged in axial rows, one row for each main pole, equally spaced around the commutator periphery. The brushes fit into metal brush holders and are held against the commutator by spring pressure. The holders are bolted to brackets that are supported by a brush yoke. The centrifugal forces present limit the permissible peripheral speeds of an armature and a commutator to about 10,000 and 6,000 ft. per minute, respectively. The terminal voltage is limited by the commutator segment width and the permissible voltage between segments. Mechanical construction limits the minimum segment width to about 0.1 in. The average voltage between segments is limited to about 20 v. by the sensitivity of the commutator to arcing between brushes at times of sudden load current changes. About 2,000 v. from one commutator is the highest value obtained in normal designs. When higher voltages are needed, two or more commutators are connected in series. D.C. generators are built in capacities up to 300 kw. at 12 v. for electroplating, 5,000 kw. at 600 v. and 240 r.p.m. for industrial power. 1,500 kw. at 1,500 v. and 400 r.p.m. for railways, and 100 kw. at 15,000 v. for radio transmitters. Efficiencies range as high as 94% on the largest units.

ALTERNATING-CURRENT GENERATORS

Let the two commutator bars of fig. 1 be replaced by two continuous rings mounted side by side on, but insulated from, the shaft that rotates the armature coil. Let one end of the coil be attached to one ring and the other end be attached to the other ring. With this arrangement the voltage between rings is alternating and can be obtained externally between brushes riding one on each ring. Few modern generators are constructed in this manner. It is cheaper to brace and insulate the armature winding when the armature structure is stationary and the field poles are rotated. Windings on the poles are attached to collector rings mounted on and insulated from the shaft and separately excited with direct current from an exciter connected to brushes that ride on the rings.

In an A C. generator it is desired that the wave form of voltage produced be a sine wave. This can be approximated closely by shaping the contour of the pole pieces and by the proper connections of the armature coils. Most A.C. generators are of the three-phase type with three armature terminals. The armature windings are divided into three distinct sections that generate voltages that are one-third cycle apart in time phase. The magnitude of the voltage produced can be varied by varying the field current, usually by means of a rheostat in the exciter field circuit. Let the voltage be set at rated value when no current is being delivered by the armature. Now let a load be connected that draws equal currents from the three terminals. The magnetic action of the currents depends upon the nature of the connected load. If it has a lagging power factor, such as is characteristic of induction motors, the action is to reduce the number of magnetic lines. This reduction, plus the fact that some voltage is used in sending the current through the windings, causes a decrease in the voltage between a pair of terminals. If the load has a leading power factor, the magnetic action may increase the number of magnetic lines enough to cause an increase in the voltage between terminals.

Steam-Turbine-Driven Generators.— High turbine efficiency requires high speed, and high speed produces centrifugal stresses that make it necessary to construct a generator with a large output so that the rotating part (rotor) is long compared with its diameter. To make them rigid, large rotors are usually made from solid steel forgings. In European practice, only the rotor body is made from a forging, and the separate, laminated teeth are inserted in dovetailed slots cut in this body. The field windings are concentric coils of strip copper, insulated with mica and laid in deep radial slots in the rotor. The coil ends are usually held in place by shrunk-on retaining rings of forged nonmagnetic steel. Fans attached to the end of the rotor blow the cooling medium—air or hydrogen—along the rotor surface and out through radial ducts in the stationary portion (stator). Small channels are provided below the rotor slots, or adjacent to the slot walls, through which the cooling medium is driven, leaving the rotor through radial openings. When air is used for cooling, about 100 cu.ft. per minute are required for each kilowatt of loss, or about 200,000 cu.ft. per minute for a 100,000-kva. generator of 98% efficiency. To prevent excessive dirt accumulation, large generators are completely enclosed and the air is recirculated after passing through finned water tube coolers.

Hydrogen has seven times greater thermal conductivity and 30% lower surface temperature drop for a given transfer rate than air and permits about 25% greater output rating for a given machine. The lower density of hydrogen reduces the windage loss to about 10% of that with air and yields about 1% gain in the generator efficiency. Automatic devices control the hydrogen pressure and purity, replacing gas lost by leakage to avoid a possible explosion by admixture of air. Shaft seals hold the loss of hydrogen to low values, usually by means of lubricating oil pumped through the small shaft clearance, the entrapped air and hydrogen being continuously removed by a pumping system through which the oil is circulated.

The stator frame that supports the segmental armature punchings is usually built up of steel plates and ribs welded together. Machines are sometimes made with split frames, or with separate inner and outer frames, to facilitate shipment. The outside of the frame is covered with steel sheeting. The interior space serves as a ventilating passage. The armature punchings are of 2% to 4% silicon steel, 0.025 in. or less in thickness and insulated from each other by thin paper or enamel. Because of the great core length, armature windings usually are made of half coils or bars that are soldered together at the ends after insertion in the slots. To reduce the eddy current losses in them, the armature conductors are made of several insulated strands transposed at regular intervals throughout the length of the core so that each strand occupies each of the possible positions in a slot for equal portions of the length.

Armature winding insulation usually is made of mica flakes cemented to paper tape or sheets, a number of layers being taped or wrapped on the conductors and bonded with varnish. The varnish solvent is removed later by vacuum treating and baking processes. Asphalt-base varnishes are commonly used. A layer of asbestos tape and conducting varnish is applied to coil exteriors to prevent damage from electrical discharges that might otherwise occur between a coil surface and slot edges.

Armature coil end connections must be well braced to withstand the forces that may act on them when a short circuit occurs on the system supplied from the generator. The force beween two adjacent coil ends is proportional to the square of the current in the coils. The not unusual short-circuit current of 10 times normal value results in 100 times the normal force. The magnitude of the short-circuit current is limited not only by resistance of the winding but also by what is called its reactance. High reactance is undesirable insofar as it affects the change in generator voltage with change in armature current, but it is necessary to hold short-circuit currents to values that can be tolerated. Armature slots are very deep in proportion to their width to increase the reactance and to provide large cooling surfaces.

A steam-turbine-driven generator has a cylindrical or non-salient pole rotor, in contrast to the salient (or projecting) pole rotor used on slower speed generators.

Water-Wheel-Driven **A.C.** Generators. — Both horizontal and vertical shaft machines are used as water-wheel-driven A.C. generators. In the vertical shaft machine, the weight of the rotor and the downward thrust of the water are carried by a thrust bearing at the upper end of the shaft, while guide bearings above and below hold the rotor in a central position. A thrust bearing carries a load of about 400 lb. per square inch and is cooled by oil. The field structure is usually revolved inside the stationary armature structure. The armature frame ordinarily is built up of welded steel plates. As a water wheel may attain nearly double normal speed before the water can be shut off after a full load is dropped, the generator rotor must pass severe overspeed tests. A pilot exciter at the top supplies the field current of the main exciter below it. That in turn supplies the field current of the generator. As water may leak through closed turbine gates, brakes are provided to stop and hold the rotor when it is taken out of service. These are mounted below the rotor. The generator is cooled by air drawn in between the poles from the ends and blown out through radial ducts in the stator.

In Europe, and to an increasing extent in the U.S., amortisseur windings are used. These consist of copper bars passing through slots in the pole faces and solidly connected by short-circuiting rings at both ends. If a momentary oversupply of water to the wheel should cause the generator frequency to tend to exceed that of the system with which it is connected, currents are induced in the windings in a direction to produce braking action on the rotor. If a momentary undersupply of water should cause the generator frequency to tend to be less than that of the system, the induced currents produce an accelerating force on the rotor.

Water-wheel-driven generators, except for small ones, have a full-load efficiency ranging from 95% to 98%. The Kaplan propeller turbine with adjustable pitch blades yields higher generator speeds in low-head installations than was feasible with fixed blade turbines. These turbines have runaway speeds that may be as great as 280% of rated speed.

Water-wheel generators are so constructed as to make the inertia of the rotating structure high. The high inertia is necessary to reduce to a value that can be tolerated the fluctuations in the speed that accompany sudden changes in the load or the water supply.

Engine-Driven **A.C.** Generators. — This type of machine is similar to a water-wheel generator. The main differences are that engine-driven generators have horizontal shafts and amortisseur windings (unless the poles are solid). Most of them operate at low speeds and have cast-iron spiders and bolted poles. Some are made with the revolving field structure outside the stationary armature to increase the inertia or flywheel effect. Since the engine torque varies during a revolution, it produces oscillations above and below the uniform speed desired, a phenomenon known as "hunting."

When a generator operates alone, hunting may cause flickering of connected lights or undesirable surges in the speeds of connected motors. When two or more generators are in parallel, it may be that one engine is accelerating at an instant when another is decelerating; and this may cause a large interchange of current between the generators.

In an extreme case, continued parallel operation may be impossible because of the tripping of overcurrent devices in the connecting circuits.

Special Types of Generators. — Although the homopolar generator was the first developed and is the only one that generates direct current without a commutator, it is of no commercial importance because it costs more and has a lower efficiency than a commutator machine of equal rating.

A generator with permanent magnet field poles has some application in measuring speed, for control purposes and as a magneto for an ignition system.

On the automobile, a special type of D.C. generator or control is required so that sufficient current is delivered at low driving speeds and yet not too much is delivered at high speeds. Early third-brush generators made use of a differential magnetizing effect of the armature current to limit it to a permissible value. Modern generators have only two brushes and have a regulator that automatically limits the voltage and current output to permissible values. However, even the most efficient small D.C. generators proved incapable of meeting the demand of many added electrical accessories, and by the 1960s automotive manufacturers were resorting to A.C. generators coupled with converters to provide direct current for ignition and battery charging *(see* AUTOMOBILE: *Modern Automobiles: Mechanical Operation: Electrical System).*

A D.C. generator mounted under a railway car and belt-connected to a wheel axle is subjected not only to a wide range of speeds but also to a reversal of rotation when the direction of car travel is reversed. One type of generator for this application has the brushes attached to a rigging that will permit the brushes to be shifted through an arc equal to that from the centre of one pole to that of another. When the car is moved in one direction, the friction between them causes the commutator to shift the brushes to one extreme position at which the generator produces the proper polarity at the armature terminals. If the car is stopped and then started in the opposite direction, the commutator shifts the brushes to the other extreme position, and the generator produces the same polarity at the armature terminals as before.

If an induction motor, when connected to A.C. lines, is driven by a prime mover in the direction it would rotate if the prime mover were not connected, but faster than its synchronous speed, it becomes an induction generator and delivers electrical energy to the lines. This type of generator has only limited applications since another source of A.C. energy is always required.

GENESEE, a river rising in the hilly Allegheny plateau of northern Pennsylvania and southwestern New York, flows northward 158 mi. through Rochester, N.Y., to Lake Ontario. North of Mt. Morris it crosses flat to rolling plains and the New York Barge canal. The valley was the home of the Seneca Indian tribe of the Iroquois confederacy until after the Revolutionary War. The steep waterfalls produce hydroelectric power and the Genesee gorge, a meandering canyon 17 mi. long and nearly 600 ft. deep with numerous waterfalls (the highest 107 ft.), is preserved for tourists in Letchworth State park. The 205-ft, falls at Rochester early made it a flour-milling centre. (A. S. CN.)

GENESIS, the name of the first book in the Bible, derives its title from the Septuagint rendering of ch. ii, 4. It is the first of the five books (the Pentateuch) which cover the history of the Hebrews to their occupation of Canaan. The "genesis" or "becoming" (*i.e.*, coming into being) of history begins with records of antediluvian times: the creation of the world, of the first pair of human beings, and the origin of sin (i–iii), the civilization and moral degeneration of mankind, the history of man to the time of Noah (iv–vi, 8), the flood (vi, 9–ix), the confusion of languages and the divisions of the human race (x–xi). Turning next to the descendants of Shem, the book deals with Abraham (xii–xxv. 18), Isaac and Jacob (xxv, 19–xxxv), the "fathers" of the tribes of Israel, and concludes with the personal history of Joseph! and the descent of his father Jacob (or Israel) and his brethren into the land of Egypt (xxxvii–l). The book of Genesis, as a whole. is closely connected with the subsequent oppression of the sons of Israel, the revelation of Yahweh the God of their fathers (Ex. iii, 6, 15 scq., vi, 2–8), the "exodus" of the Israelites to the land promised to their fathers (Ex. xiii, 5, Deut. i, 8, xxvi, 3 sqq., xxxiv, 4) and its conquest (Josh. i, 6, xxiv); cf. also the summaries Neh. ix, 7 sqq., Ps. cv, 6 sqq.

Its **Compositeness.**—Only on the assumption that the book of Genesis is a composite work is it possible to explain the duplication of events, the varying use of the divine names Yahweh and Elōhīm, the linguistic and stylistic differences, the internal intricacies of the subject matter and the differing standpoints as regards tradition. chronology, morals and religion. The cumulative effect of the whole evidence is too strong to be withstood, and already in the 17th century it was recognized that the book was of composite origin. Immense labour has been spent upon the critical analysis of the contents, but it is only since the work of Karl Graf (1866) and Julius Wellhausen (1878) that a literary hypothesis has been found which explains the most obvious intricacies. According to the Graf-Wellhausen theory, Genesis is a postexilic work composed of a postexilic priestly source (P) and nonpriestly earlier sources which differ markedly from P in language, style and religious standpoint, but much less markedly from one and another. These sources can be traced elsewhere in the Pentateuch and Joshua, and P itself is related to the postexilic works Chronicles, Ezra and Nehemiah. In its present form Genesis is an indispensable portion of the biblical history, and consequently its literary growth can not be viewed apart from that of the books which follow. On internal grounds it appears that the Pentateuch and Joshua, as they now read, virtually come in between an older history by "Deuteronomic" compilers (easily recognizable in Judges and Kings), and the later treatment of the monarchy in Chronicles, where the influence of the circle which produced P and the present Mosaic legislation is quite discernible. There have been stages where earlier extant sources have been cut down, adjusted or revised by compilers who have incorporated fresh material, and it is the later compilers of Genesis who have made the book a fairly knit whole. The technical investigation of the literary problems (especially the extent of the earlier sources) is a work of great complexity. and. for ordinary purposes, it is more important to obtain a preliminary appreciation of the general features of the contents of Genesis.

Value.—That the records of the prehistoric ages in Gen. i–xi are at complete variance with modern science and archaeological research is unquestionable. But although it is impossible to regard them any longer either as genuine history or as subjects for an allegorical interpretation (which would prove the accuracy of any record) they are of distinct value as human documents. They reflect the ideas and thoughts of the Hebrews, they illustrate their conceptions of God and the universe, and they furnish material for a comparison of the moral development of the Hebrews with that of other early races. Some of the traditions are closely akin to those current in ancient Babylonia, but a careful and impartial comparison at once illustrates in a striking manner the relative moral and spiritual superiority of our writers.

The records of the patriarchal age, xii–l, are very variously estimated, although the great majority of scholars agree that they are not contemporary and that they can not be used as they stand, for pre-Mosaic times. Apart from the ordinary arguments of historical criticism, it is to be noticed that external evidence does not support the assumption that the records preserve genuine pre-Mosaic history. There are no grounds for any arbitrary distinction between the prehistoric pre-Abrahamic age and the later age. External evidence, which recognizes no universal deluge and no dispersal of mankind in the third millennium B.C., throws its own light upon the opening centuries of the second. It has revealed conditions which are not reflected in Genesis, and important facts upon which the book is silent—unless, indeed, in Gen xiv, there is a passing allusion to the great Babylonian monarch Hammurabi in the name Amraphel. A perusal of modern attempts to recover historical facts or historical outline from the book will show how very inadequate the material proves to be, and the reconstructions will be found to depend upon an interpretation of the narratives which is often liberal and not rarely precarious, and to imply such reshaping and rewriting of the presumed facts that the cautious reader can place little reliance on them. Whatever future research may bring, it can not remove the internal peculiarities which combine to show that Genesis preserves, not literal history, but popular traditions of the past. External evidence has proved the antiquity of various elements. but not that of the form or context in which they now appear; and the difference is an important one. We have now a background upon which to view the book, and, on the one hand, it has become obvious that the records preserve (as is only to be expected) oriental customs. beliefs and modes of thought. But it has not been demonstrated that these are exclusively pre-Mosaic. On the other hand, a better acquaintance with the ancient political, sociological and religious conditions has made it increasingly difficult to interpret the records as a whole literally, or even to find a place in pre-Mosaic Palestine for the lives of the patriarchs as they are depicted. Nevertheless though one can not look to Genesis for the history of the early part of the second millennium B.C., the study of what was thought of the past is more instructive than the facts of the past, and it is more important to understand the thought of the ages immediately preceding the foundation of Judaism in the jth century B.C. than the actual history of many centuries earlier.

Characteristics.—A noteworthy feature is the frequent personification of peoples, tribes or clans. (See GENEALOGY.) Midian (*i.e.*, the Midianites) is a son of Abraham; Canaan is a son of Ham (ix, 22); and Cush, the son of Ham, is the father of Raamah and grandfather of the famous south Arabian state Sheba and the traders of Dedan (x, 6 sq., *cf.* Ezek. xxvii, 20–22). Bethuel, the father of Rebecca, is the brother of the tribal names Uz and Buz (xxii. 21 seq., *cf.* Jer. xxv, 20, 23). Jacob is otherwise known as Israel and becomes the father of the tribes of Israel; Joseph is the father of Ephraim and Manasseh, and incidents in the life of Judah lead to the birth of Perez and Zerah, Judaean clans. This personification is entirely natural to the oriental, and though "primitive" is not necessarily an ancient trait (cf. 1 Chron. iv, 10). It gives rise to what may be termed the "prophetical interpretation of history" (S. R. Driver, *Genesis,* p. 111), where the character, fortunes or history of the apparent individual are practically descriptive of the people or tribe which, according to tradition, is named after or descended from him. The utterance of Noah over Canaan, Shem and Japheth (ix, 25 seq.), of Isaac over Esau and Jacob (xxvii), of Jacob over his sons (xlix) or grandsons (xlviii), would have no meaning for Israelites unless they had some connection mith and interest for contemporary life and thought. Herein lies the force of the description of the wild and independent Ishmael (xvi, 12), the "father" of certain well-known tribes (xxv, 13–15); or the contrast between the skilful hunter Esau and the quiet and respectable Jacob (xxv, 27), and between the tiller Cain who becomes the typical nomad and the pastoral Abel (iv, 1–15). The interest of the struggles between Jacob and Esau lay, not in the history of individuals of the distant past, but in the fact that the names actually represented Israel and its near rival Edom. These features are in entire accordance with oriental usage and give expression to current belief, existing relationships, or to a poetical foreshadowing of historical vicissitudes. But in the effort to understand them as they were originally understood, it is very obvious that this method of interpretation can be pressed too far. It would be precarious to insist that the entrances into Palestine of Abraham and Jacob (or Israel) typified two distinct immigrations. The separation of Abraham from Lot (cf. Lotan, an Edomite name), of Isaac from Hagar-Ishmael, or of Jacob from Esau-Edom scarcely points to the relative antiquity of the origin of these non-Israelite peoples who, to judge from the evidence, were closely related. Or, if the "sons" of Jacob had Aramaean mothers, to prove that those derived from the wives were on a higher level than the "sons" of the concubines is more difficult than to allow that certain of the tribes must have contained some Aramaean blood (*cf.* 1 Chron. vii. 14, and see TWELVE TRIBES OF ISRAEL; GAD; MANASSEH, TRIBE OF). Some names are clearly not those of known clans or tribes (*e.g.,* Abraham, Isaac), and many details of the narratives obviously have no natural ethnological meaning. Stories of heroic ancestors and of tribal eponyms intermingle; personal, tribal and national traits are interwoven. The entrance of Jacob or Israel with his sons suggests that of the children of Israel. The story of Simeon and Levi at Shechem is clearly not that of two individuals, sons of the patriarch Israel; in fact the story actually uses the term "wrought folly in Israel" (cf. Jud. xx, 6, 10), and the individual Shechem, the son of Hamor, can not be separated from the city, the scene of the incidents. Yet Jacob's life with Laban has many purely individual traits. And, further, there intervenes a remarkable passage mith an account of his conflict with the divine being who fears the dawn and is unwilling to reveal his name. In a few verses the "wrestling" (ʿ-b-k) of Jacob (*yăʿăkōb*) is associated with the Jabbok (*yabbōk*); his "striving" explains his name Israel; at Peniel he sees "the face of God," and when touched on his vulnerable spot (the hollow of the thigh) he is lamed, hence "the children of Israel eat not the sinew of the hip which is upon the hollow of the thigh unto this day" (xxxii, 24–32). Other examples of the fusion of different features can be readily found. Three divine beings appear to Abraham at the sacred tree of Hebron, and when the birth of Isaac (from ṣāḥaḳ, "laugh") is foretold, the account of Sarah's behaviour is merely a popular and trivial story suggested by the child's name (xviii, 12–15; see also xvii, 17, xxi, 6, 9). An extremely fine passage then describes the patriarch's intercession for Sodom and Gomorrah, and the narrative passes on to the catastrophe which explains the Dead sea and its desert region and has parallels elsewhere (*e.g.,* the Greek legend of Zeus and Hermes in Phrygia). Lot escapes to Zoar, the name gives rise to the pun on the "little" city (xix, 20), and his wife, on looking back, becomes one of those pillars of salt which still invite speculation. Finally the names of his children Moab and Ammon are explained by an incident when he is a cave-dweller on a mountain.

To primitive minds which speculated upon the "why and wherefore" of what they saw around them, the narratives of Genesis afforded an answer. They preserve, in fact, some of the popular philosophy and belief of the Hebrews. They furnish what must have been a satisfactory origin of the names Edom, Moab and Ammon, Mahanaim and Succoth, Bethel, Beersheba, etc. They explain why Shechem, Bethel and Beersheba were ancient sanctuaries (*see* further below); why the serpent writhes along the ground (iii, 14); and why the hip sinew might not be eaten (xxxii, 32). To these and a hundred other questions the national and tribal stories (of which no doubt only a few have survived, and of which other forms, earlier or later, more crude or more refined, were doubtless current) furnish an evidently adequate answer. Myth and legend, fact and fiction, the common stock of oral tradition, have been handed down, and thus constitute one of the most valuable sources for popular Hebrew thought.

The book is not to be judged from any one-sided estimate of its contents. By the side of much that seems trivial, and even nonmoral (for the patriarchs themselves are not saints) it is noteworthy how frequently the narratives are didactic. The characteristic sense of collective responsibility, which appears more incidentally in xx, 7, is treated with striking intensity in a passage (xviii, 23–33) which uses the legend of Sodom and Gomorrah as a vehicle for the statement of a familiar problem (cf. Ezek. xviii, Ps. lxxiii, Job). It will be observed that interviews with divine beings presented as little difficulty to the primitive minds of old as to the modern native; even the idea of intercourse of supernatural beings with mortals (vi, 1–4) is to-day equally intelligible. The modern untutored native has a not dissimilar undeveloped and childlike attitude towards the divine, a naïve theology and a simple cultus. The most circumstantial tales are told of imaginary figures, and the most incredible details clothe the lives of the historical heroes of the past. So abundant is the testimony of modern travellers to the extent of which Eastern custom and thought elucidate the interpretation of the Bible, that it is very important to notice those features which illustrate Genesis. "The oriental," writes S. I. Curtiss (*Bibl.* Sacra, Jan. 1901, pp. 103 *sqq.*), "is least of all a scientific historian. He is the prince of story-tellers; narratives, real and imaginative, spring from his lips, which are the truest portraiture of composite rather than individual oriental life, though narrated under forms of individual experience." There are, therefore, many fundamental facts which combine to show that the critical student can not isolate the book from oriental life and thought; its uniqueness lies in the manner in which the material has been shaped and the use to which it has been put.

Questions of Date.—The Book of Jubilees (not later than *c.* 100 B.C.) presents the history in another form. It retains some of the canonical matter, often with considerable reshaping; it omits many details (especially those to which exception could be taken), and adds much that is novel. The chronological system of the latest source in Genesis becomes an elaborate reckoning of heavenly origin. Written under the obvious influence of later religious aims, it is especially valuable because one can readily compare the two methods of presenting the old traditions. The Book of Jubilees (*q.v.*) also enables the student to test the arguments based upon any study restricted to Genesis alone. Thus it shows that the "primitive" features of Genesis afford a criterion which is sociological rather than chronological. This is often ignored. For example, the conveyance of the field of Machpelah (xxiii) is conspicuous for the absence of any reference to a written contract in contrast to the "business" methods in Jer. xxxii. This does not prove that Gen. xxiii is early, because writing was used in Palestine about 1400 B.C., and, on the other hand, the more simple forms of agreement are still familiar after the time of Jeremiah (*e.g.,* Ruth, Proverbs). Similarly, no safe argument can be based upon the institution of blood-revenge in Gen. iv, when one observes the undeveloped conditions among the Trachonites of the time of Herod the Great (Josephus, *Ant.* xvi, 9, 1), or the varying usages among modern tribes. In the Book of Jubilees there is the same kind of personification; there are fresh examples of the "prophetical interpretation of history," and by the side of the older "primitive" thought are ideas which can only belong to this later period. In each case we have merely a selection of current traditional lore. For example, Gen. vi, 1–4 mentions the marriage of divine beings with the daughters of men and the birth of Nephilim or giants (cf. Num. xiii, 33). Later allusions to this myth (*e.g.,* Baruch iii, 26–28, Book of Enoch vi, sqq., 2 Peter ii, 4, etc.) are not based upon this passage: the fragment itself is all that remains of a more complete written myth. Old myths underlie the account of the Creation and the garden of Eden, and traces of other versions or forms appear elsewhere in the Old Testament. Again, the Old Testament throws no light upon the redemption of Abraham (Is. xxix, 22), although the Targums and other sources profess to be well informed. The isolated reference to Jacob's conquest of Shechem in Gen. xlviii, 22, must have belonged to another context, and later writings give in a later and thoroughly incredible form allied traditions. In Hosea xii, 4, Jacob's wrestling is mentioned before the scene at Bethel (Gen. xxxii, 24 *sqq.,* xxviii, 11 sqq.). The overthrow of Sodom and Gomorrah is described in Genesis (xviii, seq.), but Hosea refers only to that of Admah and Zeboim (xi, 8, cf. Deut. xxix, 23, Gen. x, 19)—different versions of the great catastrophe were doubtless current. Consequently investigation must start with the particular details which happen to be preserved, and these not necessarily in their original or in their only form. Since the antiquity of elements of tradition is independent of the shape in which they appear before us, a careful distinction must be drawn between those details which do not admit of being dated or located and those which do. There is evidence for the existence of the names Xbram, Jacob and Joseph in early times, but this does not prove the antiquity of the present narratives encircling them.

Historical Backgrounds.—Popular tradition often ignores events of historical importance, or, as repeated experience shows, will represent them in such a form that the true historical kernel could never have been recovered aithout some external clue. The absence of definite references to the events of the Israelite monarchy does not necessarily point to the priority of the traditions in Genesis or their later date. Nevertheless, some allusion to national fortunes is reflected in the exaltation of Jacob (Israel) over Esau (Edom), and in the promise that the latter should break the yoke from his neck; later writers (in the Targums) bring this up-to-date. Israelite kings are foreshadowed (xvii, 6, xxxv, 11 P), and Israel's kingdom has the ideal limits as ascribed to Solomon (xv, 18, see I Kings iv, 21; but cf. art. SOLOMON). Judah is promised a world-wide king (xlix, 8–10), though elsewhere the supremacy of Joseph rouses the jealousy of his "brothers" (xxxvii, 8). Different dates and circles of interest are thus manifest. The cursing and dispersion of Simeon and Levi (xlix, 5–7) recall the fact that Simeon's cities were in the territory of Judah (Josh. xix, 1, 9), and that the Levitical priests are later scattered and commended to the benevolence of the Israelites. But the curse obviously represents an attitude quite opposed to the blessing pronounced upon Levi by Moses (Deut. xxxiii, 8–11). The Edomite genealogies (xxxvi) represent a more extensive people than the references in the popular stories suggest, and the latter by no means indicate that Edom had so important a career as we actually gather from a few allusions to its kings (xxxvi, 31–39). The references to Philistines are anachronistic for the pre-Mosaic age, and it is clear that the tradition of a solemn covenant with a Philistine king and his general (xxi, 22 seq., xxvi, 26 seq.) does not belong to the age or the circle which remembered the heavy oppressions of the Philistines. Similarly, the treatment of the covenant by the author of Jubilees (xxiv, 28 sqq.) is only intelligible when one recalls the attitude of Judah to the Philistine cities in the and century B.C. Finally, the thread of the tradition unmistakably represents a national unity of the 12 sons (tribes) of Israel; but this unity was not felt at certain periods of disorganization, and the idea of including Judah among the sons of Israel could not have arisen at a time when Israel and Judah were rival kingdoms. Thus in the original text of II Sam. xix, 43, the men of Israel claim to be the first-born rather than Judah; cf. also I Chron. v, 1 sq., where Joseph obtains the birthright. Insofar as the traditions can be read in the light of biblical history it is evident that they belong to different ages and represent different national, tribal or local standpoints.

Religious **Interests.**—Noteworthy is the interest taken in sacred sites. Certain places are distinguished by theophanies or by the erection of an altar (literally "place of sacrificial slaughter"). Mizpah in Gilead is the scene of a covenant or treaty between Jacob and his Aramaean relative commemorated by a pillar (*Maṣṣēbah*). It was otherwise known for an annual religious ceremony, the traditional origin of which is related in the story of Jephthah's vow and sacrifice (Judg. xi), and its priests are denounced by Hosea (v, 1). Shechem, the famous city of the Samaritans ("the foolish nation," Ecclus i, 50, 26), where Joseph was buried (Josh. xxiv, 32), had a sanctuary and a sacred pillar and tree. It was the scene of the coronation (a religious ceremony) of Abimelech (Judg. ix), and Rehoboam (I Kings xii, 1). The pillar was ascribed to Joshua (Josh. xxiv, 26 seq.), and although Jacob set up at Shechem an "altar," the verb suggests that the original object was a pillar (Gen. xxxiii, 20). The first ancestor of Israel, on the other hand, is merely associated with a theophany at an oracular tree (xii, 6). The Benjamite Bethel was especially famous in Israelite religious history. The story tells how Jacob discovered its sanctity (it was the gate of heaven), made a covenant with its God, established the sacred pillar and instituted its tithes (xxviii). The prophetess Deborah dwelt under a palm tree near Bethel (Judg. iv, 5), and her name is also that of the foster mother of Rebekah who was buried near Bethei beneath the "oak of weeping" (xxxv, 8). Bochim ("weeping") elsewhere receives its name when an angel appeared to the Israelites (Judg. ii, 1, Septuagint adds Bethel). To the prophets Hosea and Amos the cultus of Bethel was heathen and immoral, even though it was Yahweh himself who was worshipped there (see BETHEL). South of Hebron lay Beersheba, an important centre and place of pilgrimage, with a special numen by whom oaths were taken (Amos viii, 14, see Sept, and cf. the commentaries). Isaac built its altar, and Isaac's God guarded Jacob in his journeying (xxxi, 29, xlvi, 1). This patriarch and his "brother" Ishmael are closely associated with the district south of Judah; both are connected with Beer-lahai-roi (xxiv, 62, Sept. xxv, 11), whose fountain was the scene of a theophany (xvi). Their traditions are thus localized in the district of Kadesh, famous in the events of the Exodus (*cf.* xvi, 14, xxi, 21, xxv, 18, Ex. xv, 22). Abraham planted a sacred tree at Beersheba and invoked "the everlasting God" (xxi, 33). But the patriarch is more closely identified with Hebron, which had a sanctuary (*cf.* II Sam. xv, 7 seq.), and an altar which he built "unto Yahweh" (xiii, 18). The sacred oak of Mamre was famous in the time of Josephus (B. J. iv, 9, 7), it was later a haunt of "angels" (Sozomen), and Constantine was obliged to put down the heathenish cultus. The place still has its holy tree. Beneath the oak there appeared the three divine beings, and in the cave of Machpelah the illustrious ancestor and his wife were buried. There is a distinct tendency to emphasize the importance of Hebron. Taken from primitive giants by the non-Israelite clan Caleb (*q.v.*), it is predominant in the patriarchal traditions. Jacob leaves his dying father at Beersheba (xxviii, 10), but according to the latest source he returns to him at Hebron (xxxv, 27), and there, north of Beersheba, he continues to live (xxxvii, 14, xlvi, 1–5). The cave of Machpelah became the grave of Isaac, Rebekah and Leah (but not Rachel); and though Jacob appears to be buried beyond the Jordan, it is the latest source which places his grave at Hebron (1, 1–11 and 12 *seq.*). So, in still later tradition, all the sons of Jacob with the exception of Joseph find their last resting place at Hebron, and in Jewish prayers ior the dead it is besought that their souls may be bound up with those of the patriarchs, or that they may go to the cave of Machpelah and thence to the Cherubim. The increasing prominence of the old Calebite locality is not the least interesting phase in the comparative study of the patriarchal traditions.

The association of the ancestors of Israel with certain sites is a feature which finds analogies even in modern Palestine. There are old centres of cult which have never lost the veneration of the people; the shrines are known as the tombs of saints or *welis* (patrons) with such orthodox names as St. George, Elijah, etc. Traditions justify the reputation ior sanctity, and not only are similar stories told of distinct figures, but there are varying traditions of a single figure. Genesis preserves a selection of traditions relating to a few of the old Palestinian centres of cult. We cannot suppose that these first gained their sacred character in the pre-Mosaic "patriarchal" age; there is in any case the obvious difficulty of bridging the gap between the descent into Egypt and the Exodus; and it is clear that when the Israelites entered Palestine they came among a people whose religion, tradition and thought were fully established. It is only in accordance with analogy if stories were current in Israel oi the institution of the sacred places, and closer study shows that we do not preserve the original version of these traditions.

A venerated tree in modern Palestine will owe its sanctity to some tradition, associating it, it may be, with some saint; the Israelites in their turn held the belief that the sacred tree at Hebron was one beneath which their first ancestor sat when three divine beings revealed themselves to him. But it is noteworthy that Yahweh alone is now prominent; the tradition has been revised, apparently in writing, and, later, the author of Jubilees (xvi) ignores the triad. At Beer-lahai-roi an El ("god") appeared to Hagar, whence the name of her child Ishmael; but the writer prefers the unambiguous proper name Yahweh, and, what is more, the divine being is now Yahweh's angel—the Almighty's subordinate (xvi). The older traits show themselves partly in the manifestation of various Els, and partly in the cruder anthropomorphism of the earlier sources. Later hands have by no means eliminated or modified them altogether, and in xxxi, 53, one can still perceive that the present text has endeavoured to obscure the older belief that the God of Abraham was not the God of his "brother" Nahor *(see* the commentaries). The sacred pillar erected by Jacob at Bethel was solemnly anointed with oil, and it (and not the place) was regarded as the abode of the Deity (xxviii, 18. 22). This agrees with all that is known of stone cults. but it is quite obvious that this interesting example of popular belief is far below the religious ideas of the writer of the chapter in its present form. There were many places where it could be said that Yahweh had recorded his name and would bless his worshippers (Ex. xx, 24). They were abhorrent to the advanced ethical teaching of prophets and of those imbued with the spirit of Deuteronomy *(cf.* II Kings xviii, 4 with *v.* 22), and it is patent from Jeremiah, Ezekiel and Is. lvi–lxvi that even at a late date opinion varied as to how Yahweh was to be served. It is significant, therefore, that the narratives in Genesis (apart from P) reflect a certain tolerant attitude; there is much that is contrary to prophetical thought, but even the latest compilers have not obliterated all features that, from a strict standpoint, could appear distasteful. Although the priestly source shows how the lore could be reshaped, and Jubilees represents later efforts along similar lines, it is evident that for ordinary readers the patriarchal traditions could not be presented in an entirely new form, and that to achieve their aims the writers could not be at direct variance with current thought.

Southern Interests. — There is relatively little tradition from north Israel; Beersheba, Beer-lahai-roi and Hebron are more prominent than even Bethel or Shechem, and there are no stories of Gilgal, Shiloh or Dan. Yet in the nature of the case there must have been a great store of local tradition accessible to some writers and at some periods. Interest is taken not in Phoenicia, Damascus or the northern tribes, but in the east and south, in Gilead, Ammon, Moab and Ishmael. Particular attention is paid to Edom and Jacob, and there is good evidence for a close relationship between Edomite and allied names and those of south Palestine (including Simeon and Judah). Especially significant, too, is the interest in traditions which affected the south of Palestine, that district which is of importance for the history of Israel in the wilderness and of the Levites. It is noteworthy therefore, that while different peoples had their own theories of their earliest history, the first-born of the first human pair is Cain, the eponym of the Kenites, and the ancestor of the beginnings of civilization (iv, 17, 20–22). This "Kenite" version had its own view of the institution of the worship of Yahweh (iv, 26); it appears to have ignored the Deluge, and it implies the existence of a fuller corpus of written tradition. Elsewhere, in the records of the Exodus, there are traces of specific traditions associated with Kadesh, Kenites, Caleb and Jerahmeel, and with a movement into Judah, all originally independent of their present context. Like the prominence of the traditions of Hebron and its hero Abraham, these features are not fortuitous, though the problems they bring cannot be discussed here (see *Camb. Anc. History,* ii, 359 *sqq.,* iii, 472 *sqq.,* vi, 185 *seq.).*

BIBLIOGRAPHY.—S. R. Driver's commentary ("Westminster Series") deals thoroughly with all preliminary problems of criticism, and is the best for the ordinary reader ; Dillmann (6th ed., Eng. trans.) is technical, Ryle *(Cambridge Bible)* and Bennett *(Century Bible)* more popular. Spurrell, *Notes on the Text of Genesis,* and Ball (in Haupt's *Sacred Books of the O. T.)* appeal to Hebrew students. Addis, *Documents of the Hexateuch,* Carpenter and Harford-Battersby, *The Hexateuch,* and C. F. Kent, *Beginnings of Hebrew History,* are important for the literary analysis. J. Wellhausen's sketch in his *Proleg. to Hist. of Israel* (Eng. trans., pp. 259–342) is admirable, as also is the general introduction (trans. by W. H. Carruth, 1907) to Gunkel's commentary. Fuller bibliographical information mill be found in the works already mentioned, in the articles in the *Ency. Bib.* (G. F. Moore) and Hastings' *Dict.* (G. A. Smith), and in the volume by J. Skinner in the "International Critical Series." (S. A. C.)

GENET, EDMOND CHARLES (1763–1834), French minister plenipotentiary 'to the United States in 1793, was born on Jan. 8, 1763, at Versailles. He was for a time attached to the embassy at Berlin and later to the embassy at Vienna; and at the age of 18, following his father's death, succeeded him as secretary interpreter at the ministry of foreign affairs. In 1787 he was sent to the embassy at St. Petersburg where he remained until July 1792, when his liberal views made him *persona non grata.* After a brief stay in Paris. where he came more fully under the influence of the Revolution, "citizen" Genet was sent as French minister to the congress of the United States. He was assuming a position which would require much tact, but his impetuous nature, combined with the ovations accorded him by the Democratic-Republicans, led him into misjudging public opinion regarding U.S. neutrality. His activities in instigating military operations against the Spanish possessions of Florida and Louisiana and against Canada. the fitting out of privateers in U.S. ports, his acrimonious debates with the federal government and his caustic attacks on the president demonstrate conclusively his lack of diplomacy. Genet's threat to override the executive by appealing to the people caused Washington to ask the French republic to recall its representative. His successor, "citizen" Fauchet, brought orders to arrest him and send him back to France for trial, but Washington refused to permit the extradition. He subsequently became a naturalized U.S. citizen. In 1794 he married Cornelia Tappen Clinton, daughter of the governor of New York and in 1814, four years after the death of his first wife, married Martha Brandon Osgood, daughter of the first postmaster general. He died on July 14. 1834.

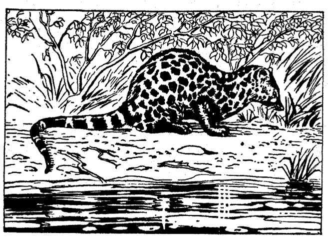
GENET, a catlike mammal belonging to the family Viverridae *(see* CARNIVORA), found chiefly in Africa. The common genet *(Genetta genetta)* occurs throughout Africa and also in southern Europe and Palestine; it is about the size of a cat, but more slender and longer of leg. The fur is dark gray. thickly spotted mith black and having a dark streak along the back, while the tail, which is nearly as long as the body, is ringed with black and white. It frequents the banks of streams and feeds on small mammals and birds. It differs from the true civets in that the anal pouch is a mere depression and contains only a faint trace of the characteristic odour of the former. (J E. HL.)



GENET (GENETTA SERVALINA) OF THE CONGO, AFRICA

GENETICS, the scientific study of heredity and variation, was so named by William Bateson in 1906, although its origins trace to the discovery by Johann Gregor Mendel *(q.v.)* (1866) of the first general laws of heredity. The experiments of Mendel, which lay unremarked by biologists until 1900, gave the first indication that an organization of living elements. the genes, constitutes the main transmission mechanism of heredity by which the generations of sexually reproducing organisms are connected. Following the experimental proof that genes are subelements within the visible system of chromosomes within the nucleus of each cell, including the sex cells (egg and sperm) through which the chromosomes with their genes pass to descendants, genetics could be more simply defined as the study of the gene in reproduction, heredity, development and evolution. The activities of the genes in these several processes may best be understood by considering them under three headings, which represent not divisions of the science, since all are concerned with the nature and activity of genes, but rather facets of gene activity in the processes of heredity, development and evolution.

Under *Transmission Genetics,* below. will be found a description of the mechanism of heredity, evidence for the existence and spatial arrangement of genes in the living cell, Mendel's first principles of segregation and independent assortment of genes, linkage of genes in groups each corresponding to a pair of chromosomes, linear arrangement of the genes in each linkage group, transmission of genes in the sex chromosomes with consequent proof of the genetic determination of sex, and the ways in which genes reproduce. giving rise to a continuous succession of like elements and occasionally to new gene forms by mutation.

Under *Physiological Genetics* (sometimes called phenogenetics or developmental genetics) the causal relations will be discussed which connect particular genes or systems of genes (genotypes) with the effects produced on the characters of the mature or embryonic individual. This division is essentially a study of the gene in the processes of life.

Under *Evolutionary Genetics* will be treated the forces which play upon the arrays of genes as they are transmitted and function in successive populations of animals or plants, leading to evolutionary changes. The understanding of this historical process is based upon the principles of population genetics.

Finally the applications of genetics in forms of special interest to man (human genetics, medical genetics, genetics of microorganisms, genetics of crop plants and of domestic animals) will be pointed out.

GENERAL VIEWS

Before dealing with any of these special features of genetics, it is necessary to have a clear view of certain general principles and assumptions which underlie the whole subject. The most important of these is the meaning of the terms heredity and hereditary. We may start from the fact that all organisms, considered as individuals or as populations distribute'd in space or in time, represent the outcomes of interaction between factors intrinsic to the organism and factors external to it. The usual way of stating this is to say that any individual is a joint product of his heredity and his environment. The intrinsic factors consist of an assemblage of genes derived from the parents. In cross-breeding populations like man, most higher animals and plants such as maize, every individual gets a unique assemblage derived from ancestors who are largely unrelated or distantly related, although some part of the system of genes which he inherits are those which he shares with all members of his species (since derived from a common ancestry) and by virtue of which he develops the distinguishing marks of his species. This array of genes which each individual receives is known as his "genotype." The same array of genes may produce different characters if the individuals carrying them develop in different environments. Thus the expression of a genotype which produces diabetes in the absence of insulin treatments fails to do so when regular injections of insulin become a part of his environment.

The sum total of the physical and behavioural characters of an individual is known as his "phenotype." The phenotype is, on the above view, the outcome of the interplay between the genotype and the environments in which development occurs. The genes appear to act as the regulators or modulators of this interplay. Each individual's response to his environment is thus determined by his genotype, but obviously not irrevocably or without some latitude in the range of responses. The range (or norm of reaction) varies with the character under consideration and may in some cases be very wide, as in the case of size, in which the same genotype may result in small size if some essential food requirement is withheld, or in much greater size if all essentials for maximum growth are freely available. On the other hand, a genotype which includes a gene or genes for dwarf size can respond within narrower limits unless the particular metabolic limitations due to the gene can be discovered and made good by special diet or other treatment. It is from such considerations that the general principle is derived which states that what is inherited is the potentiality of response during development to a range of environmental conditions. Heredity is thus to be viewed as the transmission of patterns of development. It is a corollary of this rule that all structures and functions of living organisms are inherited, and that all, in greater or lesser degree, are responsive to their environments. One task of genetics is thus to elucidate the relationships between genotypes and phenotypes. Results of studies directed to this end will be discussed further under *Physiological* Genetics.

A second important general view arises from considering the origins of hereditary variety. Variations in general are departures from the common or normal characteristics of the species. They may arise from encounters of the usual or established genotypes with new or unusual conditions, but if they are to add something which is both novel and hereditary in the above sense, they must involve new, transmissible modes or levels of response to the environments of the species, since in the course of sexual reproduction over many generations, the existing genes will be shuffled and reshuffled so that all possible genotypes and the responses that they make possible will have been exposed to a variety of environments.

A new potentiality will in general arise only when a new genotype arises and this will depend upon the occurrence of a new form of one or more genes. The change in the form of a gene, as deduced from its changed effects, is known as mutation and will be discussed under *Evolutionary Genetics*. It is this event which makes new gene forms available for recombination into a variety of genotypes, which may subsequently be winnowed by the environment in the process known as natural selection. Mutation and natural selection are the essential factors of evolution.

TRANSMISSION GENETICS

The **First Law of** Mendel.—The rules by which genes are transmitted to descendants all relate to the behaviour of these elements during reproduction. The system, revealed mainly since 1900 by breeding experiments combined with studies of the cell and its parts (cytology, *q.v.*), is referred to as the mechanism of heredity. The existence of this system was first indicated by Mendel's experiments (1856–65; published 1866). He collected from seedsmen varieties of the garden pea (*Pisum sativum*) differing in colour of flowers, height, form and colour of seeds and other sharply different characters which occur in alternative forms (such as white or coloured flowers) in different races. Each of these alternative forms bred true to its own type, and since the pea plant reproduced by self-fertilization, it could be assumed that all the descendants of a single plant (known as a pure line) receive the same heredity and exhibit only the variations due to variable environmental factors such as temperature, amount of water, fertilizer, etc. In crosses between different pure lines, however, Mendel found that the first generation plants (known as F,) showed the alternative character or characters of only one of the parents, whereas when the F_1 plants produced seed by self-fertilization some of the plants of the second generation (known as F_2) showed one of the alternative characters (such as coloured flowers) while other plants showed the other alternative (white flowers). When the numbers of plants of the two types in F_2 were counted in large experimental populations it was found that about three-fourths of them showed the alternative character of one grandparent while one-fourth of them showed the alternative character of the other grandparent. Mendel's actual results for the seven pairs of alternatives which he studied are shoan in Table I.

TABLE I.—*F_2 Results for Seven Alternative Characters* (*Mendel*)

Structure	Property	Characters		Ratio
		Dominant	Recessive	
Seed . . .	Form	5,474 round	1,850 wrinkled	2·96:1
Reserve material in cotyledons .	Colour	6,022 yellow	2,001 green	3·01:1
Seed-coats . .	Form	882 inflated	299 ivrinkled	2·95:1
Seed-coats . .	Colour	705 grey	224 white	3·15:1
Unripe pods .	Colour	428 green	152 yellow	2·82:1
Flowers . .	Position	651 axial	207 terminal	3·14:1
Stem . . .	Length	787 tall	277 dwarf	2·84:1
		14,949 (74·90%)	5,010 (25·10%)	2·98:1 or 3:1

The essential feature of these results was the proof of the existence of sharp discontinuous alternatives in inheritance, and of the particulate character of the hereditary material. Although the alternatives were revealed by the discontinuous, differentiating characters which could be observed in the plants at the end of development, Mendel's great contribution was to show that the essential discontinuity was in the invisible elements contained in the reproductive cells, ovum and pollen grain, or, as we shall subsequently refer to them, in the single pairs of cells, egg and sperm, "gametes," which unite at fertilization to form the new individual. He did this by showing, in further breeding of the F_2 plants, that the three-fourths of them which externally resembled one grandparent actually consisted of two genetically different kinds of individuals of which one duplicated the behaviour of the grandparental pure line by producing only progeny like itself, while the other resembled the F_1 by producing both of the altemative grandparental forms. If we represent the essential entities of inheritance by alternative forms of the same letter, we may symbolize the whole experiment as in Table II.

TABLE 11.—Representation of *Mendel's* Experiment

Parental generation P_1	*AA*	×	*aa*
Gametes of P_1	*A*		*a*
First filial generatioh (hybrid) F_1 . .	*Aa*	×	*Aa*
Gametes (sex cells) of F_1 (with random combinations at fertilization)		*A*----+*A* *a*——→*a*	
Second filial generation F_2	¼ *AA*	½ *Aa*	¼ *aa*
Third filial generation F_3	all *AA*	¼ *AA* ½ *Aa* ¼ *aa*	all *aa*

The assumptions involved in the representation are:

1. Each element of heredity (now called gene) exists in alternative forms called alleles. Where the parents have the same allelic form of the gene (technically known as being homozygous for this form, or as homozygotes *AA, aa)*, this form is transmitted in each gamete to each offspring. Where a parent contains two different alleles, such as *A* and *a*, each gamete receives, by chance, either one or the other but never both, so that half of the gametes transmit *A* and half *a*.

2. Each union of a male gamete with a female gamete is at random with respect to the allele which it contains; which is to say that where the parents form two different kinds of gametes with respect to *A*, all combinations, *AA, Aa, aA* and *aa,* are equally frequent.

These assumptions have been validated, since 1900, by observations of this process in all forms of life from bacteria and other fungi through green plants to higher animals including man. The principle involved is known as the first law of Mendel, or the principle of segregation, since its essential feature is the separation or segregation of alternative forms (alleles) of a gene into different sex cells (gametes). In the period before its general applicability was recognized, the operation of this system and the second, less general, rule discovered by Mendel was known as Mendelism.

The Second "Law" of Mendel.—By observing the results of crossing pairs of pure parents differing in two sets of altemative characters at the same time (such as parents homozygous for coloured flowers and tall growth crossed with parents homozygous for white flowers and dwarf growth), Mendel showed that each pair of alleles behaved as though independent in inheritance of each other pair. Thus parents *AABB* × *aabb* or *AAbb* × *aaBB* produce F_1 offspring *AaBb*. These produce gametes *AB, Ab, aB* and *ab* in equal numbers, and random union among these produces the array of genotypes shown in Table III.

TABLE III.—*Mendel's* Second "Law"

Eggs	Sperms			
	AB	Ab	aB	ab
AB.	**AABB**	**AABb**	**AaBB**	**AaBb**
Ab.	**AaBb**	Ahhb	**AaBb**	Aahb
aB	**AaBB**	***AaBb***	aaBB	aaBb
ah	**AaBb**	Xahh	aaBb	*aabb*

If a single allele A is sufficient to produce the character A (say coloured flowers) and a single allele B results in the character B (say tall growth) as Mendel found, then the F_2 from the above cross should consist of phenotypes as follows: 9/16 **AB** (bold face), 3/16 Ab (Roman face), 3/16 aB (Roman), and 1/16 *nabb* (italic). The resemblance of the actual proportions found by Mendel in F_2 to those expected on the above assumptions was sufficiently close to validate the above theory.

This is known as the principle of independent assortment of allele pairs; its essential feature is that segregation of one pair of alleles is independent of the segregation of other pairs, all possible combinations being formed at random by this process of recombination. If two independent pairs of alleles are observed, of which one produces three genotypes such as *AA, Aa* and *aa,* the other *BB, Bb* and *bb,* then the combinations of these should be 3 × 3 or 9. If a third pair (C-c) is observed at the same time, the numbers of different combinations should again be multiplied by 3 to produce 27 different genotypes. If *n* is the number of pairs of alleles observed, the number of independently different gene combinations (genotypes) should be 3^n. For 10 pairs of alleles (a small part of the existing number which for most organisms is in the thousands) $3^{10} = 59{,}049$ different combinations. This is obviously the cause of much of the genotypic variety found in crossbreeding species of animals and plants. Its sources trace to the occurrence of different forms of the same gene which arise by mutation, such as *A* giving rise to *a* or vice versa.

The principle of independent assortment is subject to the important limitation that it applies only to pairs of alleles belonging to different linkage groups *(see* below), that is, to genes located in different pairs of chromosomes. Since in man there are 24 pairs of chromosomes there can be 24 pairs of alleles showing independent assortment, and this alone would lead to 3^{24} random combinations or genotypes, a very large number indeed.

Dominance.—One of the "rules" discovered by Mendel turned out not to be of general applicability. This was his observation that in the case of all seven of the differentiating pairs of characters which he studied, one of the pair was dominant in the sense that it produced its phenotypic effect in the offspring when received from one parent only. Thus *AA* and *Aa* individuals showed character *A, aa* individuals character *a*. We know now that dominance is not a property of the transmission mechanism by which alleles are distributed to gametes and progeny but is affected by circumstances which intervene between the origin of the individual at fertilization and the time when his characters are observed. This is to say, dominance is decided during development. It is, therefore, discussed under *Physiological Genetics.*

Linkage and Crossing Over of Genes.—The period immediately follou-ing the rediscovery of Mendel's principles (they were independently arrived at by three different botanists in 1900 and this led to the unearthing of his forgotten publication of 1866) saw the confirmation of his genera1 theory by the results of experiments and observations on a wide variety of animals and plants, including man. In the decade 1910–20 several new principles were discovered, chiefly through the work of T. H. Morgan and his coworkers. C. B. Bridges, A. H. Sturtevant and H. J. Muller. The first new principle came to light through the discovery of exceptions to the principle of independent assortment. In experimental breeding of the vinegar fly, *Drosophila rnelanogaster,* it was found that certain genes tended to remain associated in the progeny more frequently in the same combinations in which they had been present in the parents. Thus parents *SSTT* × *sstt* gave rise to F_1 progeny *ST*, and those produced gametes *ST*, *sT*, *St* and *st*, as assumed by Mendel. but not in equal numbers as called for by his theory. The parental combinations *ST* and *st* in these cases always exceeded the new combinations *St* and *sT*. In fact, in male heterozygotes *ST/st,* only *ST* and *st* gametes were formed, and no recombinations *sT* or *St* at all. This led to the supposition that S and *T* were linked together in some common element which held them in association. In females *ST/st,* this association was only partial, and the linkage was occasionally broken, so that gametes *sT* and *St* were occasionally formed. These breaks in the linkage revealed by separation of the partners in the gametes and progeny were called crossovers, and the process of exchange, crossing over. In many animals and plants crossing over occurs in both sexes; its failure to occur in male *Drosophila* was a special feature of such species which greatly facilitated the detection of four groups of linked genes corresponding to the four pairs of chromosomes characteristic of *Drosophila,* and this led to the discovery of a new general principle, the limitation of the linkage groups, which states that the number of linkage groups is equal to the number of pairs of chromosomes. This has been confirmed for many species. Only genes belonging to different linkage groups show independent assortment. Members of the same linkage group which undergo recombination by crossing over also eventually enter into all possible combinations, but this process is retarded, in numbers of generations, by the associations between linked genes.

A third new principle was discovered when it was found that the frequency of recombination between linked genes was a measure of the relative "distance" between genes in the linkage group. Linked genes which infrequently recombine by crossing over are assumed to be closer together than genes which recombine more frequently. By use of these relations, as determined from breeding experiments, linkage "maps" can be constructed indicating the order in which the genes are arranged. The data for *Drosophila* and a number of other species in which many genes can be identified and studied together can be reconciled only by assuming a linear order so that for adjacent genes, the recombination "distance" ***A-B*** plus the distance B-C gives the "distance" (per cent of recombination) between A and C. This is the principle of linear arrangement of the genes in the linkage group. It appears to be of general application.

Subsequently, it was found that each linkage map corresponds to one particular chromosome and that linkage order expresses the actual order of succession of genes in the chromosome. Linkage distance also corresponds in a rough way to the actual distance of one gene from another in the physical structure of the chromosome, although apparent "distance" is affected by local peculiarities of structure and function within the chromosome, and by factors external to the chromosome (age, temperature, humidity, etc.) which influence the likelihood of occurrence of recombination and crossing over in different segments along the chromosome (see CYTOLOGY). The proof that a chromosome Consists of a linearly arranged succession or thread of genes, like beads on a string, was greatly facilitated by the discovery that the threads can break and recombine, a process that can'be influenced experimentally by exposure to radiations, including thermal effects.

Sex Linkage and Sex Determination.—In most animals and in some plants in which male and female gametes are produced by different individuals (separate sexes or dioecism), one of the chromosomes is differentiated from the others by carrying a set of genes which show sex-linked inheritance, and by having a preponderant influence on the determination of sex by affecting the development of the primary sex characters (ovary or testis). Consequences of this difference in the sex chromosomes are seen in the development of secondary sex characters (male or female habitus) associated with the primary difference. In man, for example, the female has two sex chromosomes, designated as X, while the male has one X chromosome (always derived from the mother) and one chromosome not exactly equivalent to its X partner which is known as the Y chromosome. Half of the spermatozoa, therefore, transmit the Y chromosome and half the X chromosome. The transmission of these chromosomes is diagrammed below:

Female XX by male XY
Gametes X→X fertilization gives XX female
↘
Y fertilization gives XY male

The sex-linked genes are borne in the X and pass from mother to both sons and daughters; the genes in the Y chromosomes pass only from father to sons. Genes in the X for which no equivalent alternatives (alleles) exist in the Y (which contains very few active genes) therefore exhibit their full effects in the sons only, as in the cases of red-green blindness, haemophilia and a number of other sex-linked peculiarities which generally go from mother to sons only.

Many such genes have been mapped in linear fashion in the X chromosomes of man and other animals. The X chromosomes also carry many other genes which influence early development to take place either in a female direction (in man and many other animals) or in a male direction (in birds and some other animals in which the male is XX and the female XY). Ordinarily, this early influence is decisive in determining the sex of the individual, so that sex appears to be inherited according to the same principle of segregation which governs inheritance generally; but the early influence of the sex chromosomes may be modified or even reversed by subsequent events in development, such as disease or aberrations in other chromosomes (see SEX).

In summary, the transmission system of genetics consists of an orderly arrangement of genes, or loci, at which elements within each chromosome may assume different alternative forms or alleles by which they may be identified. Each chromosome consists of hundreds or thousands of such loci, depending on size and other variables, each capable of mutating to forms having different physiological effects. This system is coextensive with the mechanism known as meiosis by which the chromosomes and their elements are distributed to the reproductive cells. The principles of transmission genetics are, therefore, consequences of the behaviour in reproduction of elementary particles—genes—and the integrated systems in which they are organized.

PHYSIOLOGICAL GENETICS

After the genes reach the new individual via the transmission system, their effects on that individual will be determined by three main contingencies. First is the contribution which the particular gene makes (or fails to make) to the physiological or metabolic processes of the individual; second is the physiological effect of the combination of genes or genotype of which the particular gene is a part; third is the set of circumstances, environmental and other, which the gene and the genotype encounter during development. The effects of a gene on development are outcomes of interactions among such influences as these.

Each gene affects some living process or processes, its several forms or alleles having different degrees of effectiveness. Thus the process leading to the development of dark pigment (melanin) in the hair and skin of vertebrates is dependent upon the condition of a gene, one allele of which permits completion of this process resulting in normal pigmentation. But if another form is present the conversion of a colourless substance, tyrosine, to melanin is interrupted at some point, and defective or no coloration (such as albinism) results. From studies of microorganisms it is known that certain individual genes exert a controlling influence on the synthesis of particular organic molecules such as amino acids and proteins from simpler compounds. One way in which the genes do this is by influencing the rate or efficiency of catalytic (enzyme) reactions which promote such processes. (See BIOCHEMISTRY.) Other genes produce antigens, molecular groupings which have specific relations (reactions) with antibodies. Genes affecting the blood group status of human beings have such effects. The first or primary effects of genes are unknown since the effects are recognized by measurement of secondary substances such as pigments or enzymes or antigens. It is suspected that substances given off by genes during their reproduction, or absorbed from the cell during this process, are responsible for their specific effects.

Since the essential feature of heredity is the self-reproduction of copies of the parental organisms, a primary question of physiological genetics concerns the mechanism of the copying process. This must require the self-reproduction or copying of each of the elements of heredity. How each element does this is not known and the ultimate solution of this problem would involve understanding the physics and chemistry of the synthesis of organic molecules in patterns determined by antecedent molecules such as genes. On the level of biological observation, however, it can be said that at each cell division, each gene produces a copy or replica of itself out of materials present in the cell. A demonstrable result of this is the replication of each chromosome which is an organized aggregation of genes in linear order. This operation lies at the bottom of all reproduction and of the continuity of living substance.

Some clues as to the copying process are obtained when slight imperfections in it occasionally occur. Mutation, the origin of a new and different gene form from an antecedent one, may be looked upon as due to defective gene copying. If the daughter gene is capable of further reproduction, then its changed character will be transmitted to its descendants, and a new pattern of development becomes possible, and this may be detected in changed characters of the embryo or the developed organism. If the defect in the daughter gene interferes with its subsequent replication, this gene uill not be found in the descendant cells, and this may prevent successful development from occurring at all. and the gene and its possessor are lost from the species. Studies of altered functions of particular mutated genes consequently provide information on the normal processes controlled by those genes. These are known to include the synthesis of certain chemical groupings such as amino acids, nucleic acids, proteins and carbohydrates on which living functions depend.

The products synthesized under the influence of particular genes react with each other in complex ways, so that different combinations of genes have different effects on the cells, thence on the individual. One result of the interaction of gene products is that under certain conditions, one member of a pair of alternative gene forms, such as *A*, may exert its effect on a character, even when the other member is different, such as *a*. This is the relation known as dominance. Thus the normal parents of an albino are of genotype *Aa*, yet are able to carry out the synthesis of pigment (melanin) in much the same way as persons with two normal genes *AA*. Albinos *aa*, with two recessive forms of this gene, are unable to carry out this synthesis in a normal way.

Both the elaboration of gene products and the reactions between them are influenced by the amount and kind of nutrients available, by heat, light and many other environmental variables. Thus it has been repeatedly shown that effects resembling those due to change in the form of a gene by mutation can be produced by altering the environment. Such imitations of the effects of mutations are known as phenocopies. Since the genes and the transmission system may remain unchanged after such treatments, the changed effects are not transmitted by inheritance.

Different forms of genes are known which influence key processes in the differentiation of the structures of the embryo or adult organism. It is through such channels that defective forms of certain genes lead to absence or abnormality of a part of the body. For normal development of the parts to be accomplished certain combinations of normal gene forms are required. When any of these change by mutation, abnormality may result, which may in some cases he corrected by supplying the missing or defective substance from the environment. Thus mutation in a gene may lead to a defect in a normal process, to cessation of development and death. (See HEREDITY.) Such mutant gene forms are known as lethals. Occasionally development of such organisms may be permitted to proceed under different environmental conditions or when the defective gene is combined in a different genotype.

EVOLUTIONARY GENETICS

The system by which genes are transmitted and the rules governing their physiological effects (which thus influence the kinds of structures and functions which the organisms exhibit) are obviously of primary importance in the historical process by which the succession of organisms become adapted to the environments in which they live. The principles by which genotypes change and adapt are those of population genetics. The elementary steps are the origin of new gene forms by mutation and the winnowing of the gene forms and combinations by natural selection.

In general, a population of crossbreeding animals or plants constitutes an integrated system (sometimes called a Mendelian population), consisting of a variety of genotypes which reproduces itself and remains in equilibrium as long as all effective factors remain constant. These factors are those which influence the relative frequencies of different gene forms in the population referred to as the gene pool. The conditions affecting equilibrium are: (1) mutation of alleles such as *A* to *a* and *a* to *A*; (2) migration into and out of the population; (3) the size of the population and its mating pattern (presence or absence of inbreeding, preferential or assortative mating, etc.); (4) selective forces acting on the population, tending to affect viability, fecundity and fertility of different genotypes. Changes in any one or more of these primary factors will give the opportunity for change in the frequency of one of the alleles relative to the other and thus lead to a change in the gene pool of the population. This constitutes an evolutionary change. The conditions of maintenance or change in the equilibrium are discussed under GENETICS OF POPULATIONS.

In general, if mutation occurs more frequently from *A* to ***a*** than the reverse, this will create a mutation pressure in favour of A and, other conditions being equal, will lead to replacement of *a* by *A* in the population. If more individuals with *A* enter or leave the population this will favour (or oppose) the spread of *A* in that population. If the population is very small. then by chance *A* or *a* gametes may fail to be included in those passed to the next generation. and either *A* or *a* will tend toward fixation to the exclusion of the other. Change in frequency by such accidents of sampling is known as random drift. If any genotype such as *AA* tends to leave more offspring by reason of some selective advantage, then the alternative genotype such as *aa* will tend, unless balanced by other factors, to be replaced by the more fit type. If *Aa* is superior to both *AA* and *aa* then both alleles *A* and *a* will tend to be retained in the population even though AA and *aa* are disadvantageous, and an equilibrium between *A* and *a* will be established, other things being equal.

Evolutionary changes by one or more of these methods have been observed in experimental populations. In nature, most populations are of limited size, have some mobility and inhabit environments which are subject to spatial and temporal variation. The normal state of crossbreeding populations is thus one of flux equilibrium among a variety of genotypes, and this is subject to change by one or more of the agencies mentioned above. Populations reproducing by self-fertilization are subject to somewhat different equilibriums, since new mutations (*A* to *a*, for example) are quickly resolved to homozygous states, *AA* and *aa,* and thus exposed promptly to natural selection which preserves the pure lines adapted to the given environment.

Populations reproducing by clonal (asexual) reproduction are subject to change by a variety of other factors. Since in the latter two methods no intercrossing and, hence, no recombination of genes is possible, the populations are likely to be more fixed in special environments and lack the plasticity associated with bisexual reproduction. (See also EVOLUTION, ORGANIC; GENETICS OF POPULATIONS; SELECTION.)

APPLICATIONS OF GENETICS

Although the principles of genetics appear to be coextensive with living matter, their consequences assume human or economic values which vary with different forms of life. Thus human genetics is especially concerned with the interplay of hereditary and environmental factors in determining the physical and mental characters of man, with the effects of heredity on diseases, abnormalities and special abilities, with the biological differentiation of interbreeding groups of man, such as races or subgroups separated by geographical or cultural factors such as language, religion or tradition.

Medical genetics is especially concerned with the influence of heredity on conditions of medical importance, and eugenics (*q.v.*) with means for the eradication of deleterious genes and for the improvement of human genotypes. Animal breeding and plant breeding utilize genetic principles in programs for improvement of livestock and useful plants. Genetics of microorganisms (bacterial genetics. genetics of fungi, of viruses and of protozoa) has assumed special importance both as an applied science concerned with control of pathogenic and parasitic forms, and with the utilization of microorganisms in fermentation, production of antibiotics and of food factors, and also as an avenue of approach to the understanding of such fundamental processes as mutation and the manner of effect of genes on metabolic processes, since these are more accessible to study in organisms with less complicated life cycles.

GENETICS OF POPULATIONS. Many of the pioneer geneticists to whom is due the extraordinary development of knowledge of heredity after 1900 entered the field because of interest in the theory of evolution or in practical problems of animal and plant breeding. It seemed to them that the simple rules that were found for the heredity of many conspicuous variations, and the parallel behaviour of the threadlike chromosomes, visible in the nuclei of cells, provided keys that would rapidly reveal the solutions of their problems. To some extent their expectations were directly realized. But the harmonious combination of many subtle differences by which one species usually differs from its closest allies, and which similarly characterizes a successful strain of livestock or crop plant, continued to present difficult problems.

It became necessary to consider the statistical properties of populations in which many genetic differences are present simultaneously as the cumulative result of past mutation and recombination.

The reader must be referred to the articles **HEREDITY; GENE;** and GENETICS for presentation of the principles upon which the intelligibility of the following discussion rests.

Gene Frequency.— The basic concept of the genetics of populations is that of gene frequency. Let A_1 represent a particular autosomal gene and A_2 its array of alleles. Let $(x_mA_1A_1+y_mA_1A_2+z_mA_2A_2)$ represent the array of genotypes and their relative frequencies $(x_m+y_m+z_m=1)$ in mature males and assume a similar array with subscript f in mature females. The frequencies of gene A_1 in gametes of males and females respectively may be written: $q_m=[x_m+(\frac{1}{2})y_m]$, $q_f=[x_f+(\frac{1}{2})y_f]$. Since there is equal inheritance of autosomal genes from both parents, the gene frequencies become the same in males and females in the next generation. In symbols, $q_m=q_f=(\frac{1}{2})(q'_m+q'_f)$, using primes to designate the preceding generation. In general we may write $q=(\frac{1}{2})(q_m+q_f)$ as the effective gene frequency of a population, irrespective of the absolute numbers of males and females. It is obvious from the symmetry of the Mendelian mechanism, and the absence of any contaminating influence of alleles on each other in heterozygotes, that gene frequencies tend to remain constant in populations $(q=q')$.

In the important special case of sex-linked genes, one sex (to be taken as male in what follows) has only one chromosome (transmitted to half the gametes) that carries the locus in question, while the other sex has the usual pair. As males inherit such genes only from their mothers, while females inherit equally from both parents, $q_m=q'_f$, $q_f=(\frac{1}{2})(q'_m+q'_f)$. The effective gene frequency of the population is here $q=(\frac{1}{3})(q_m+2q_f)=(\frac{1}{3})(q'_m+2q'_f)=q'$. While the frequencies of sex-linked genes tend to remain the same generation after generation in the population as a whole, the frequencies in the males and females separately do not come to immediate equilibrium. There are rapidly damped oscillations about the mean, $(q_m-q)=(-\frac{1}{2})(q'_m-q')$. In polyploids, also, the frequencies of the various genotypes (*e.g.*, $A_1A_1A_1A_1$, $A_1A_1A_1A_2$, $A_1A_1A_2A_2$, $A_1A_2A_2A_2$ and $A_2A_2A_2A_2$ in a tetraploid) approach equilibrium only gradually, while gene frequency tends to remain constant.

Departures from random mating do not affect gene frequencies, provided that all genotypes contribute proportionately to the next generation. The frequencies of genotypes are, however, affected. Thus the random union of the array of sperms $[qA_1+(1-q)A_2]$ with a similar array of eggs produces a population with the genotypic array $q^2A_1A_1+2q(1-q)A_1A_2+(1-q)^2A_2A_2$, which is stable in large populations as long as mating continues at random. But if the system of mating is changed to universal self-fertilization, the homozygotes, A_1A_1 and A_2A_2, produce only their own kind while the heterozygotes, A_1A_2, produce 25% of each of the homozygous classes and only 50% of their own kind. With a 50% reduction in the frequency of heterozygotes in each generation it requires only a small number of generations to convert the population practically wholly into a mixture of homozygous lines $[qA_1A_1+(1-q)A_2A_2]$. Gene frequency has not changed but the aspect of the population has changed enormously. Recessives that are manifested in only 0.01% of the individuals of the random bred population become fixed in 1% of the inbred lines. Random mating would, however, immediately restore the initial genotypic composition (assuming, of course, that there has been no selection).

The tendency toward indefinite persistence of variability under random mating and its rapid elimination within each closely inbred line, shown above to be immediate consequences of the Mendelian mechanism, are not expected under blending heredity, under which variability should fall off 50% in every generation of random mating unless replenished by mutation at this enormous rate. Comparative data from random bred and inbred lines, and from crosses between inbred lines, indicate the practical universality of Mendelian heredity.

The extension of these principles to systems of multiple alleles is obvious. Under random mating, the frequencies of genotypes are given by the appropriate terms in the expansion of the square of the gene array, $(\Sigma q_iA_i)^2$.

Recombination.—We must next consider the frequencies of combinations of genes at different loci. Suppose that a population produces gametes with combinations of alleles at the A and B loci in the array $[wA_1B_1+xA_1B_2+yA_2B_1+zA_2B_2]$. Let c_m and c_f be the frequencies of recombination in the reduction division in eggs and sperms respectively, with c the unweighted average. The quantity $D(=wz-xy)$ is a measure of the departure from random combination. This falls off at the rate c per generation under random mating. Thus if A and B are in different chromosomes, D is halved in every generation. With 1% crossing over it is halved every 69 generations. Randomness of combination is not only approached with respect to any two loci, it is approached with respect to all loci simultaneously. It is sometimes suggested that a correlation between two characters in a population may be due to genetic linkage. This may be true in a population that has arisen recently from a mixture of two strains that differ in both respects but there can be no appreciable correlation of this sort in a population that has bred within itself at random for many generations unless linkage is complete or the approach to random combination is hampered by severe selection.

The most probable genotypic frequencies under long continued random mating are given by the appropriate terms in the expansion of $\prod_{i=1}^{n}\left[\sum_{j=1}^{k} q_{ij} A_{ij}\right]^2$ where A_{ij} is used for the j'th of k alleles at the i'th of n loci and q_{ij} is used for its frequency. Actually all potential genotypes cannot be realized in a finite population. With only 4 alleles (10 combinations) at each of only 100 loci, the number of potential genotypes is the inconceivably great number 10^{100}. A very limited number of mutations thus provides a virtually infinite field of potential variability. It is probable that no two individuals in a species with exclusive sexual reproduction ever have exactly the same genetic constitution.

Systematic Changes in Gene Frequency.— The immediate causes of change of gene frequency may be grouped into three categories by degree of determinacy. (1) Systematic processes (wholly determinate in principle) include recurrent mutation, recurrent immigration and selection (a comprehensive term for all modes of disproportionate contribution by genotypes to following generations). (2) Random processes (determinate only in variance) include the effects of fluctuations in the coefficients describing the systematic processes, and also those of accidents of sampling. (3) Unique events such as a nonrecurrent mutation, a unique hybridization or a unique selective incident.

Recurrent mutation, immigration and selection exert directed pressures on each gene frequency. The rate of change per generation due to these will be symbolized by Δq. Random processes give rise to undirected changes in gene frequency that may be symbolized by δq. There may be a question whether gene mutations are ever more than superficially recurrent. In the case of structural mutations, which usually involve two chromosome breaks, exact recurrence must certainly be a very rare event. Nonrecurrent mutation is undirected, but in a different sense from the accidents of sampling. The former extends the number of alleles at the expense of a very slight reduction in the frequency of those already present, while the latter produces random changes within the group present.

Recurrent mutation from A_1 to A_2 at the rate u per generation with reversal at the rate v per generation obviously tends to change the frequency of A_1 at the net rate $\Delta q = v(1-q) - uq$. There is equilibrium, in the absence of other factors of change, at the value $\hat{q} = v/(u+v)$. If, however, A_2 represents an array of multiple alleles of A_1, v is the weighted average of the rates of mutation from these to A_1 and is thus a function of their varying frequencies. If all mutations are unique, $v=0$.

The effect of immigration depends on the extent (m) to which the immigrants displace the native population in each generation and on the difference between the gene frequency (q_I) of the immigrants and that of the natives (q). $\Delta q = m(q_I - q)$. The theory of immigration pressure may be identified with that of mutation pressure in the case of two alleles by substituting mq_I for v and $m(1-q_I)$ for u.

The effect of selection on gene frequency depends on the frequencies (f) of the genotypes and their selective values (w), defined as the net rates of reproduction per generation on taking account of mortality, emigration, rates of attainment of maturity, duration of reproductive period, success in mating and fecundity. Letting $\bar{w}$ $(=\Sigma wf)$ be the average selective value for the whole population and $\bar{w}_1$ that for gene A_1 (giving all combinations which involve A_1A_1 full weight and those involving heterozygosis of A_1 half weight), the frequency q_1 becomes $q_1\bar{w}_1/\bar{w}$ in the next generation and we may write $\Delta q_1 = q_1(\bar{w}_1 - \bar{w})/\bar{w}$ as the general expression for selection pressure.

Some of the special cases are instructive. We shall assume random mating and consider a pair of alleles with mean selective values w_{11} for A_1A_1, w_{12} for A_1A_2, and w_{22} for A_2A_2, and let q be the frequency of A_1. It may easily be verified that under these conditions $\Delta q = q(1-q)[w_{11}q + w_{12}(1-2q) - w_{22}(1-q)]/\bar{w}$, which may be written in the form $\Delta q = q(1-q)\Sigma w\frac{df}{dq}/2\bar{w}$. If the w's are constants this reduces to $\Delta q = q(1-q)\frac{d\bar{w}}{dq}/2\bar{w}$.

Assume that A_1A_1 has the selective disadvantage s relative to the heterozygote, and A_2A_2 the selective advantage t over the latter, $(w_{11}=1-s, w_{12}=1, w_{22}=1+t)$. Then $\Delta q = q(1-q)[q(t-s)-t]/\bar{w}$. An unfavourable gene may be maintained in the population by recurrent mutation. If A_1 is semidominant $(s=t)$, the net pressure may be represented approximately by $\Delta q = v(1-q) - sq(1-q)$, with equilibrium at $\hat{q} = v/s$. If recessive $(t=0)$, we have $\Delta q = v(1-q) - sq^2(1-q)$, approximately, with equilibrium at $\hat{q} = \sqrt{v/s}$, much higher than for a more or less dominant gene with the same values of v and s (see fig. 1).

The net effects of selection and immigration can be investigated similarly. In a population in which s (case of semidominance) is smaller than m, local differences in conditions of selection are largely swamped by crossbreeding $(\hat{q} = q_I - (s/m)q_I(1-q_I)$, approximately). Local selection dominates the situation, however, if s is larger than m, $\hat{q} = mq_I/s$, approximately, in localities in which selection is adverse.

Two alleles may both be kept at high frequencies if the heterozygote has an advantage over both homozygotes. Letting $w_{11} = 1-s_1$, $w_{12}=1$, $w_{22} = 1-s_2$ $\Delta q = -q(1-q)(q-\hat{q})$, approximately, where $\hat{q} = s_2/(s_1+s_2)$. If there are multiple alleles, and all heterozygotes have the same selective value, $w_{ij}=1$, while all homozygotes are selected against, $w_{ii} = 1-s_i$, $\Delta q_i = q_i[1-s_iq_i-\bar{w}]/\bar{w}$. Thus $s_1\hat{q}_1 = s_2\hat{q}_2$ etc., $\hat{q}_i = (1/s_i)/\Sigma(1/s)$. Each allele is maintained at a frequency inversely proportional to the selective disadvantage of its homozygote relative to the heterozygotes. There is reason to believe that complementary effects of alleles, somewhat of this sort, are not uncommon.

This is not, however, the only mechanism by which two or more alleles may all be maintained at high frequencies within a random breeding population. The territory occupied by the population may contain diverse ecological niches for each of which one allele is superior to the others. Each allele is favoured when rare, but selected against when abundant, assuming that the individuals that carry it can exercise some choice of abode. Suppose that $w_{11} = 1+s-tq$, $w_{12}=1$, $w_{22} = 1-s+tq$. The heterozygote is always exactly intermediate but $\Delta q = q(1-q)(s-tq)/\bar{w}$, giving stable equilibrium at $\hat{q} = s/t$. Multiple alleles may, of course, more easily be kept at high frequencies in a heterogeneous territory in which the effects of different local conditions of selection are not swamped by too much crossbreeding.

If selective values are constant, selection tends to drive the gene frequencies to a set of values at which the reproductive rate of the population as a whole is at a peak. This may not be true where the selective values are, as in the preceding case, functions of the frequency of the gene in question. As a more striking example, consider a case in which at all times A_2A_2 has a selective advantage s over A_1A_2 and 2s over A_1A_1. But assume on the other hand that increase in the frequency (q) of A_1 has a favourable effect (term $a+bq$) on the rate of increase of all individuals in the population through some product or activity of those that carry it. $w_{11} = (a+bq)(1-s)$, $w_{12} = (a+bq)$, $w_{22} = (a+bq)(1+s)$. In the formula for Δq in a random breeding population any factor such as $(a+bq)$ that is common to all w's, cancels leaving the result the same as if there were no such term. Thus a gene with effects that are of advantage to the population but disadvantageous to individuals cannot be fixed by selection within the group. It may be fixed, however, by intergroup selection in a population divided into small partially isolated groups.

So far we have disregarded the effects of other series of genes that may interact with the one under consideration. But selection applies to the organism as a whole (or to a group of organisms), not to separate genes. Most characters are affected by many genes and since the best-adapted grade may be expected to be near the mid-grade in a population that has lived long under about the same conditions, a gene that has a favourable effect in combinations below the mid-point should have unfavourable effects in combinations above the mid-point. Moreover if the mean selective values $(\bar{w})$ of populations are imagined to be plotted against locations in the many-dimensioned system of gene frequencies, it is to be expected that these will form a surface with a large number of distinct peaks, each centring about a different harmonious combination of genes. In the case cited above all of these give the same character, the optimum, but there may also be harmonious combinations that represent different ways of life open to the species in question and these peaks may differ greatly in height.

If random combination is assumed, the rate of change of a given gene A is given by the formula $\Delta q_A = q_A(1-q_A)\left(\Sigma w\frac{\partial f}{\partial q_A}\right)/2\bar{w}$, where the w's are the selective values of the combinations of all pertinent pairs of alleles, the j's the corresponding compound frequencies, and the summation has 3^n terms if n loci are involved. The w's may be functions of any or all of the gene frequencies. If constant, however, the rate formulas reduce to the type $\Delta q_A = q_A(1-q_A)\frac{\partial\bar{w}}{\partial q_A}/2\bar{w}$. Under this assumption, the mean selective value of the population tends to move toward its peak value in the surface $\bar{w}$ at the rate $\Delta\bar{w} = \Sigma\left(\frac{\Delta q\partial\bar{w}}{\partial q}\right)$, the summation applying to all pairs of alleles. The peak value toward which it moves is not necessarily the highest. On the other hand, as noted in the one-factor case, selection may carry the population to lower values of $\bar{w}$, if the w's are functions of the gene frequencies.

It should be pointed out that the assumption that all series of alleles are combined at random can only be an approximation, since selection itself disturbs the randomness of combination in the parental generation and the return among the offspring is not complete. It can be shown, however, that the effect is slight if the selective disadvantage of genotypes at one step from a mid-grade optimum is less than the proportion of crossing over.

While models based on pairs or finite numbers of alleles are convenient mathematically, the probability that all loci may, in the long run, evolve through an indefinitely extended branching series of alleles must not be forgotten. In this situation, all selection coefficients are subject to undefinable changes.

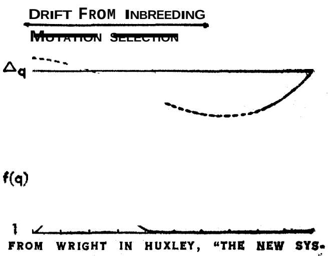
Random Changes in Gene Frequency.— We will illustrate this category by discussing the case of accidents of sampling. The composition of a population of N diploid individuals depends on $2N$ gametes produced by the preceding generation. If these are a random sample from the array $[qA_1+(1-q)A_2]$, the array of probabilities for the next generation is $[qA_1+(1-q)A_2]^{2N}$. The variance of q is $\sigma^2_{\delta q}=q(1-q)/2N$. In a k-ploid population $\sigma^2_{\delta q}=q(1-q)/kN$, approximately. For sex-linked genes, it is approximately $2q(1-q)/3N$ if there are equal numbers of males and females.

It might seem that these random deviations would be negligible in any reasonably large population; but the variance of the array of probabilities for later generations increases approximately linearly with the number of generations until damped by approach to the limiting value, $q(1-q)$, of complete fixation one way or the other. Moreover, the effective value of N should often be much smaller than its apparent value. It obviously applies only to individuals that reach maturity. If there is cyclic variation in population size, effective N is the harmonic mean of the numbers in the generations of the cycle, which is largely dominated by the population minimum. The sampling effect is, however, much more important in connection with a population structure in which there are numerous small partially isolated local strains than in a homogeneous random breeding population.

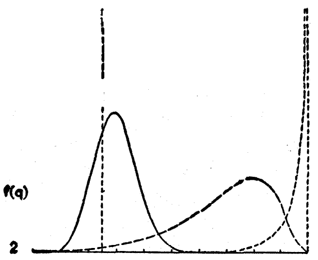
The tendency toward a stable equilibrium in gene frequency due to opposing systematic pressures and the tendency to drift away from the point of equilibrium due to the random processes result in a distribution of probabilities which one might expect to find realized by the values taken by the frequency of the gene in question over a long period of generations in the ideal case in which all conditions remain constant. Even if never actually realized, the distribution formula is important in reaching an appreciation of the degree of control by the systematic pressures.

The formula for this distribution must satisfy the conditions of persistence of the mean, $\Sigma(q+\Delta q+\delta q)f=\Sigma qf$, and of all higher moments $\Sigma(q+\Delta q+\delta q-\bar{q})^n f=\Sigma\ (q-\bar{q})^n f$. It can be shown that these conditions are satisfied to a first approximation by the differential equation $\frac{d}{dq}\ \sigma^2_{\delta q}\varphi(q)-2\,\Delta q\varphi(q)=0$, the solution of which is the probability curve $\varphi(q)=(C/\sigma^2_{\delta q})\ \exp\ [2\int(\Delta q/\sigma^2_{\delta q})\ dq]$, $\int_0^1\varphi(q)dq=1$. Since there are $(2N+1)$ possible values of q among $2N$ gametes, the frequency of a given class is approximately $f(q)=\varphi(q)/2N$. The formula gives good approximations even for the subterminal classes $f(1/2N)$ and $f[(2N-1)/2N]$ but the frequencies of fixation must in general be determined from the subterminal classes by consideration of the balance between loss of the gene in question or its allele by accidents of sampling (approximately half the subterminal class per generation) and reintroduction by mutation or immigration. Thus, $f(0)=f(1/2N)/(4N[mq_1+v])$.

As an illustration, consider a case in which there is systematic pressure from reversible mutation, immigration and selection measured by $\Delta q=v(1-q)-uq-m(q-q_1)+q(1-q)\frac{d\bar{w}}{dq}/2\bar{w}$ and accidents of sampling measured by $\sigma^2_{\delta q}=q(1-q)/2N$. Substitution yields $\varphi(q)=C\bar{w}^{2N}q^{4N(mq_1+v)-1}(1-q)^{4N[m(1-q_1)+u]-1}$. Examples are given in figs. 1 and 2.



FROM WRIGHT IN HUXLEY, "THE NEW SYSTEMATICS" (CLARENDON PRESS)



FROM WRIGHT IN THE BULLETIN OF THE AMERICAN MATHEMATICAL SOCIETY, VOL. 48

FIG. 1.—ABOVE: SYSTEMATIC RATE OF CHANGE (Δq) OF THE FREQUENCY (q) OF A DELETERIOUS RECESSIVE GENE FOR WHICH S=25V, AND RE. (U) IS NEGLIGIBLY LOW. THE SCALE OF Δq IS GREATLY EXAGGERATED. BELOW: DISTRIBUTION OF RELATIVE FREQUENCIES, F (q), OF THE VALUES OF q OVER A LONG PERIOD OF TIME IF V=1/N. FIG. 2.—DISTRIBUTION OF GENE FREQUENCIES q FOR GENE A IN THREE SUBGROUPS OF A POPULATION OF MEAN GENE FREQUENCY .25. THESE SUBGROUPS ARE ASSUMED TO BE OF THE SAME EFFECTIVE SIZE (N=1,000) AND SUBJECT TO THE SAME SELECTION PRESSURE ($W_{AA}=1$, $W_{Aa}=.9975$, $W_{aa}=.995$) BUT TO DIFFERENT DEGREES OF ISOLATION (SHORT DASHES AT .25: NO ISOLATION: SOLID LINE: $m=.01$; LONG DASHES: $m=.001$; SHORT DASHES TO RIGHT: $m=.001$)

This formula can be extended to the case of a finite number of multiple alleles, assuming that mating is at random and that the rate of mutation to each allele from each of the others, is the same (a severe restriction), $\varphi(q_1, q_2 \ldots q_n)=C\bar{w}^{2N}\Pi q^{4N(mq_1+v)-1}$, where the product includes terms for all alleles. This is also the frequency distribution for all series of alleles considered simultaneously, if the product term includes all loci. This formula describes a frequency surface in a space of $\sum^{n}(k_i-1)$ dimensions where k_i is the number of alleles per locus and n is the number of loci. There are in general a large number of peak frequencies, corresponding roughly to the peaks in the surface $(\bar{w})$ of selective values. Under certain conditions there is an appreciable chance of drifting from control by one peak value to control by a higher one.

The number of alleles that may be carried by a population under various conditions is important. Consider first a series in which each mutation yields a new allele and assume that alleles that are completely neutral, as regards selection, are arising at a constant rate u. The distribution for such alleles is $f(q)=Cq^{-1}(1-q)^{4Nu-1}$ with $f(0)$ infinite. The number of new alleles of the above sort per generation is $2Nu$. The number lost by accidents of sampling is approximately $(n/2)f(1/2N)$ where n is the number present. Putting $\Sigma f(q)=1$ in this case, there is equilibrium between mutations and loss if $n=2u\Sigma q^{-1}\ (1-q)^{4Nu-1}$ with summation including values of q from $1/2N$ to 1. With $u=10^{-6}$, a population of 250,000 may be expected to carry an average of 13.7 alleles. In larger populations, there should be a somewhat less than proportional increase, *e.g.*, 132 alleles if N is increased tenfold. These results are not changed appreciably for mutations that are slightly selected against.

Most of the alleles in these cases are present at very low frequencies. The chance that a single completely neutral mutation will reach approximate fixation is $1/2N$. Even if selected against, there is specifiable chance of displacing the type allele, $2s/(e^{4Ns}-1)$, in case the selective disadvantage of heterozygotes is s, of homozygotes 1s. With a corresponding selective advantage, the chance is approximately $2s$. It is approximately $\sqrt{s/2N}$ for a completely recessive mutation with an advantage s when homozygous.

Population Structure.—Departures from random mating have important consequences which it is now desirable to consider. A population has a structure in time that consists of a 'complicated network of paths of descent. An adaptation of the theory of multiple correlation, the method of path coefficients, is convenient in dealing with such networks.

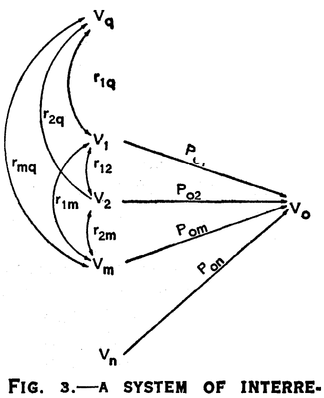


FIG. 3.—A SYSTEM OF INTERRELATED VARIABLES

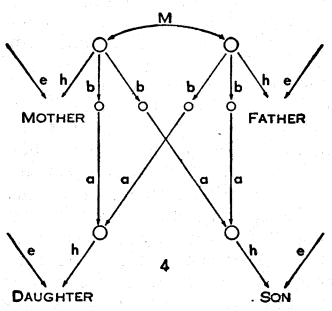
The basis for application of this method is a diagram which represents a point of view as to which variables in a system of linear relationships are to be treated as immediate functions of which others. Fig. 3 is a simple diagram of this sort. A single-headed arrow indicates the direct effect of one variable upon another while double-headed arrows are used for residual relations tracing to unrepresented factors which may be considered as located at the mid-points of such "arrows." Assume that x_o, x_1, etc., are variables measured in standard form, $x_o=(V_o-\bar{V}_o)/\sigma_o$, where V_o is the original variable, $\bar{V}_o$ its mean and σ_o its standard deviation. Assume that x_o is a linear function of known variables x_1 *to* x_m and that the array of factors is made formally complete by addition of a hypothetical variable x_n, independent of the others. In the expression $x_0=p_{o1}\ x_1+p_{o2}\ x_2+\ldots p_{om}\ x_m+p_{on}\ x_n$, the coefficients are path coefficients. The correlation (r) between two variables is defined as their average product when expressed in standard form. Thus $r_{oq}=\sum_{i=1}^{n}p_{oi}\ r_{iq}$. The special case of self-correlation $r_{oo}=1$ yields the equation $\sum_{i=1}^{n}p_{oi}\ r_{oi}=1$. This may be analyzed into two components, $p_{on}\ r_{on}(=r^2_{on})$ which measures the portion of the variance (σ^2_o) determined by unknown factors and $\sum_{i=1}^{m}p_{oi}\ r_{oi}$ expressing that due to known factors. The latter is the squared coefficient of multiple correlation.

Factors xi, x_2, x_q, etc., may in turn be represented as linear functions of variables a step farther back in this network, making possible analysis of the correlation terms, in the above equations. However extensive the network, the following principle holds. Any correlation between variables in a network of directed linear relations can be analyzed into contributions from each of the paths by which the two variables are connected through a common factor. The value of each contribution is the product of the coefficients (of which only one may be a correlation coefficient) pertaining to the elementary paths.

Fig. 4 represents the relations between parents and offspring in the network of descent in the case of an autosomal factor. Variations in the characters of individuals are represented as determined by additive effects of environmental and genotypic variations (path coefficients e and h respectively, $e^2 + h^2 = 1$. The path coefficient a relates genotype to one of the gametes that produced it. Assume that each allele at the locus under consideration is assigned a value and that the value of a genotype is the sum of the values of the two gametes that produced it. As there is complete determination $2a(a + aF) = 1$, where F represents the correlation between uniting gametes. Thus, $a = \sqrt{(1/2)/(1+F)}$. The path coefficient b relates gamete to the genotype that produced it. This is also the correlation coefficient since there is only one connecting path. This correlation must be the same as



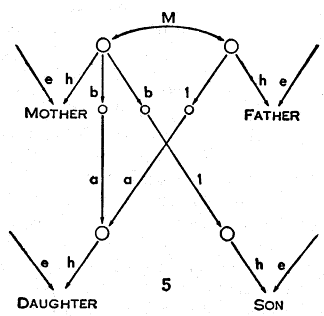


FIG. 4.—RELATIONS AMONG GENOTYPES AND CHARACTERS OF PARENTS AND OFFSPRING, AS DETERMINED BY AUTOSOMAL GENES. FIG. 5.—RELATIONS AMONG GENOTYPES AND CHARACTERS OF PARENTS AND OFFSPRING AS DETERMINED BY SEX-LINKED GENES

that between parental genotype and one of the gametes that produced it, with respect to the series of alleles in question. Thus, $b = a + a'F' = \sqrt{(1+F')/2}$ where primes are used to indicate the preceding generation. The compound path coefficient relating a gamete to one of those back of it a generation earlier is $ba' = 1/2$.

It may readily be seen by tracing the connecting paths that the correlation between parent and offspring is $h^2 ab(1+M)$ relative to a locus and that between brothers is $2h^2a^2b^2(1 + M)$ where $M (= F/b^2)$ is a correlation coefficient that sums up all possible connections between the parental genotypes. These results apply to the combined effects of multiple loci, provided that these are associated at random and that effects are throughout additive. In a random breeding population ($M = F = O$) both of the above correlations reduce to $.50h^2$.

Sex-linked genes can be treated similarly, noting that the coefficient relating male genotype to egg must equal 1 and that relating X-bearing sperm to genotype producing it must also be 1 since there is complete determination in both cases (fig. 5). Coefficients a and b in other cases have the same values as with autosomes. The correlation between any relatives can be found from a diagram that shows all of the ancestral connections.

In actual cases, nonadditive relations are likely to be involved in the relations between genotype and character (as a consequence of dominance or factor interactions) and there may he nonadditive relations between genotype and environment. These introduce complications which can not be discussed in the scope of this article.

The structure of a population is perhaps best expressed in terms of F, which, as the correlation between uniting gametes, is the most appropriate coefficient of inbreeding. The array of genotypes relative to a pair of alleles may be expressed as follows in terms of the frequency, q, of one of the alleles (A_1), and the proportion of heterozygotes p:

$$[(q - \tfrac{1}{2}p)A_1A_1 + pA_1A_2 + (1 - q - \tfrac{1}{2}p)A_2A_2].$$

It may easily be verified that the correlation between the gametes whose union is here indicated is $F = (p_o - p)/p_o$ where p_o $(= 2q(1-q))$ is the proportion of heterozygosis under random mating. It may be shown that with multiple alleles as well as with mere pairs the frequencies of homozygotes are of the type $[(1-F)q^2_1 + Fq_1]$ for A_1A_1 and of heterozygotes of the type $[2(1-F)q_1q_2]$ for A_1A_2. The correlation between uniting gametes comes out $F = (p_o - p)/p_o$ where p is the total frequency of all heterozygous classes, irrespective of the values assigned the various alleles.

The value of F can be obtained from inspection of the appropriate diagram in simple cases. Thus for the progeny of an isolated brother-sister mating it is one-fourth and for progeny of a first-cousin mating one-sixteenth. Recurrence formulas can be obtained in cases of regular systems of mating. Thus if a population is broken up into lines of exclusive brother-sister mating, $F = b^2a'^2(2F' + 2b'^2) = \tfrac{1}{4}(1 + 2F' + F'')$; $p = (\tfrac{1}{2})p' + (\tfrac{1}{4})p''$. Putting $p/p' = p'/p''$, $p/p' = (\tfrac{1}{4})(1 + \sqrt{5}) = .809$, indicating that heterozygosis decreases about 19.1% per generation under continued brother-sister mating. In populations of size N with completely random union of gametes $F = \frac{1}{N}b^2 + \frac{N-1}{N}F' = \frac{1}{2N} + \left(\frac{2N-1}{2N}\right)F'$, $p = \frac{(2N-1)}{2N}p$, indicating fixation at the rate of $1/2N$ per generation in this case. With N_m males and N_f females similar analysis gives $p = p' - \left(\frac{N_m + N_f}{8N_mN_f}\right)(2p' - p'')$ with fixation at rate $[(1/8N_m) + (1/8N_f)]$ if the N's are large.

A case of great importance is that in which a population has a uniform distribution over a large area but dispersion is limited to small neighbourhoods. The ancestors of any given individual are drawn from ever widening circles as one goes back in time. With random union of gametes within neighbourhoods of size N, the value of F relative to a population of size KN (that from which the Kth ancestral generation was drawn) is $[\Sigma t/(2N - \Sigma t)]$ where Σt is the sum of K-1 terms of the series $\left[1 + \tfrac{1}{2}\left(\frac{N-1}{N}\right) + \tfrac{1}{3}\left(\frac{N-1}{N}\right)\left(\frac{2N-1}{2N}\right)\ldots\right]$ which can be evaluated. Its limiting value is N and that of F is thus 1. If the effective value of N is less than 100 there is considerable differentiation not only of neighbourhoods but also of large territories. If on the other hand, N is more than 1,000, the situation differs little from universal random mating. If there is continuity along only a narrow strip such as a shore line or a river instead of over an extensive area, there is, however, enormously more differentiation with a given size of neighbourhood.

It can readily be seen that the general formula for the inbreeding coefficient, F, applicable to irregular pedigrees is $\Sigma[(\tfrac{1}{2})^{n+n'+1}(1 + F_A)]$ where n and n' are the numbers of generations from sire to dam respectively to a common ancestor with inbreeding coefficient F_A, and the summation applies to all connecting paths which include only one common ancestor. By taking random lines of ancestry back of the sires and dams of animals chosen at random and noting the proportion (T) of cases in which those include the same animal, it is possible to estimate $F(= (\tfrac{1}{2})T(1 + F_A))$ for a whole breed. This has been done for several breeds of horses, cattle, sheep and hogs with rather similar results. The inbreeding coefficient rises at rates between 0.2% and 1.2% per generation, indicating that concentration on the sons and grandsons of noted animals has given a system equivalent to the use of only 10 to 60 sires in the whole breed. (Rate $= 1/8N_m$, assuming N, males and indefinitely many females.)

The inbreeding coefficient measures inbreeding relative to a certain foundation stock. Thus the coefficient 26.0% in Shorthorn cattle of 1920 implies that heterozygosis was 26.0% less than expected from random mating within the cattle population of northern England of about 1780, the period to which the pedigrees trace. The correlation between random pedigree lines of 1920 was 24.6%, indicating that the departure from random mating within the breed in 1920 was not great. The extensive loss of heterozygosis indicated by the value 24.6% applies to the breed as a whole. If we let $F_{I \cdot T}$ be the inbreeding coefficient of individuals relative to some comprehensive population, $F_{I \cdot G}$ that of individuals relative to groups within the latter and $F_{G \cdot T}$ the correlation between random gametes within the groups, $(1 - F_{I \cdot T}) = (1 - F_{I \cdot G})(1 - F_{G \cdot T})$. The structure of a population may be analyzed by application of this formula.

The subdivision of a population into numerous partially isolated groups leads to differentiation of these in gene frequencies, measured by $\sigma^2_q = q_T(1 - q_T)F_{G \cdot T}$ where q_T is the gene frequency of the comprehensive population. The differentiation with respect to characters is, of course, closely related. The variance of a character due to semidominant genes in a population breeding at random is $\sigma^2_R = 2\Sigma[q(1-q)(\alpha^2)]$ where α is the effect of replacement of a gene by its allele and the summation relates to all pertinent series of alleles. If the population is divided into partially isolated groups, breeding at random within themselves ($F_{I \cdot G} = 0$, $F_{G \cdot T} = F_{I \cdot T} = F$), the variance of group means is $2F\sigma^2_R$, the variance within groups is $(1-F)\sigma^2_R$ and the variance of individuals in the total is $(1 + F)\sigma^2_R$.

The primary consequence of subdivision of a population into more or less isolated groups is, of course, that differences in the conditions of selection may bring about direct differentiation. But even if the conditions of selection are everywhere the same, such groups may be expected to drift apart as a result of the accidents of sampling. This would not be likely to go far by itself but may initiate trends toward diverse ways of meeting the conditions and thus create differences in direction of selection. In terms of the mathematical model, the systems of gene frequencies of different groups may come under the control of different peak adaptive values. If isolation is not complete, the stage is set for selection at the group level. The localities, in which the most successful genetic systems have been arrived at, become the principal sources of migrants to other regions. In a random breeding population selection operates merely according to the net effects of the genes in all combinations. In a population of vegetatively reproducing clones, the genotype as a whole is the object of selection. This process may be very effective, especially in a form capable of rapid multiplication under favourable conditions if associated with occasional crossbreeding to provide new clones for trial more rapidly than by the slow process of mutation. In a large population divided into numerous partially isolated groups the object of selection is the entire genetic system and the situation is that most favourable for an indefinitely continuing evolutionary process. (See EVOLUTION, ORGANIC.)

American Mathematical Society, vol. 48, pp. 223–246 (1942). (S. WT.)

GENEVA, a canton of southwest Switzerland situated between the Jura and the Alps and consisting mainly of the city of Geneva.

With an area of 108.9 sq.mi. of which 11½ sq.mi. are lake, it is, except for Zug, the smallest canton in the Swiss confederation. In the extreme north it borders on the Swiss canton of Vaud for 3½ mi., but is otherwise surrounded by French territory, the *département* of Haute Savoie to the south, and that of the Ain west and north. The Rhbne flows through it from east to west and then along its southwest edge. The turbid Arve which flows from the snows of the chain of Mont Blanc is its largest tributary and joins the Rhbne within the city of Geneva. The climate is healthful, the vicinity of the lake regularizing the temperature. Market gardens, orchards and vineyards occupy a large proportion of the soil, the apparent fertility of which is largely due to the unremitting industry of the inhabitants. In 1956 there were 10,620 cattle, 1,108 horses, 8,719 swine, 296 goats and 6,605 sheep. Besides building materials, such as sandstone and slate, the only mineral to be found within the canton is bituminous shale.

Geneva was admitted into the Swiss confederation in 1815 and ranks as the junior of the 22 cantons. In 1815–16 it was increased by adding to the old territory belonging to the city 16 communes (to the south and east, including Carouge and Chêne) ceded by Savoy and 6 communes (to the north, including Versoix) from the French district of Gex. Geneva made an important contribution to the confederation in the person of General Guillaume Henri Dufour (*q.v.*), who defeated the seceding league of conservative cantons, the Sonderbund. Democratic agitation in the 19th century against a reactionary government resulted in the constitution of 1842, which set up the *conseil d'état* as the executive authority and the grand *conseil* as the legislative body, and established municipal autonomy. In 1847 James Fazy instituted a radical régime; his failure to obtain re-election to the *conseil d'état* led to disturbances in 1864.

The radical party returned to power under Antoine Carteret, and supported the church iounded by Père Hyacinthe Loyson against the Catholics. The Catholic prelate Gaspard Mermillod, who later became a cardinal, was exiled in 1873. A later radical leader, Henri Fazy, was more in sympathy with thr Catholics. The separation of church and state was voted in 1907. The conservative party, known as the Democrats, introduced certain reforms such as the referendum, the popular initiative and proportional representation. The Socialist party and other party formations later came into existence.

In 1960 the population of the canton was 259,234; in 1950 it was 202,918. As to religion the 19.50 population was divided as follows (1941 figures for the canton are within brackets): Roman Catholic 85,856 (75,448), Protestants 102,625 (95,373) and Jews 2,897 (2,439).

Nationality was as follows: 83,751 (65,040) were Genevese citizens, and 76,856 (82,543) Swiss citizens of other cantons. In 1919 the canton contained 62.611 foreigners, but by 1930 the number had fallen to 51,727 in consequence of the emigration during and after World War I, and fell to 40,888 as a result of World War II; in 1950 foreigners numbered 42,311 of whom 12,366 were French, 12,357 Italians, 1,492 Germans and 16,096 citizens of various other countries.

In point of language, among a population of 202,918 in 1950 (174,855 in 1941), 138,627 (140,909) inhabitants were French-speaking, French being the mother tongue of the Genevese, the official language of the State; 24,983 (23,716) were German-speaking, while there were also 215 (176) Romansch-speaking. (G. VR.)

GENEVA, a city of Switzerland and capital of the canton of Geneva, lies in the Rhône valley at the extreme southwestern corner of the Lake of Geneva or Lac *Léman*. To the west of the canton boundary is the range of the Jura mountains while to the south and east are the steep limestone slopes of Mont Salève. Pop. (1950) 145,473, (1960) 176,183.

, The river Rhône, spanned by eight bridges, flows south from the lake and divides the city into two parts. On the left bank, to the south, is the hill where Geneva first stood, surmounted today by the town's civic buildings and at the highest point by the cathedral of St. Pierre. This picturesque area of the old city is reached by a long and narrow street bearing several names, Rue de la Cité, Grand' Rue and Rue de l'Hôtel de Ville, which winds uphill from the Pont de l'Ile. In this street there are some beautiful 17th- and 18th-century houses and the very simple house where Jean Jacques Rousseau was born. The hôtel de ville itself is a Renaissance building with 17th-century frontage and cloistered courtyard. An unusual feature is the 16th-century paved slope serving instead of a staircase and leading up to a square tower. Inside are the room of the council of state with its 15th-century paintings, and the "Salle de l'Alabama" where the arbitration between Great Britain and the United States was awarded in 1872 and where the first international convention for the relief of wounded soldiers (Red Cross) was signed in 1864. Parallel with the Grand' Rue is the aristocratic Rue des Granges with its line of beautiful 18th-century mansions built by rich Genevese bankers. The Rue du Puits St. Pierre, facing the town hall, runs along a former corn granary. In it stands the Tavel house, decorated with amusing carved heads, one of the oldest houses of the city. It has a lovely turret and 12th-century cellars. Nearby in the Rue Calvin is the site, now built on, of the house where the reformer lived and died (1564). This street leads toward the spacious Cour St. Pierre where the former cathedral stands. This 12th- to 13th-century building has a classical frontage added in the 18th century with a columned portico by Benoît Alfieri (1749). Next to St. Pierre, on the Place de la Taconnerie, is the Temple de l'Auditoire (the former 14th-century church of Notre Dame-la-Neuve) where John Knox preached and where John Calvin and Theodore Beza used to teach; to the south is a chapel in Aamhoyant Gothic style, the Chapelle des Macchabees, built by the cardinal of Brogny, bishop of Geneva (c. 1404). East of the cathedral is the Place du Bourg-de-Four, a picturesque and irregular square, which was once the Roman forum. Below are the law courts, a fine classical building (1707), iormerly a hospital. The Collège de Geneve, founded by Calvin in 1559, is nearby. Farther east is the Musée d'Art et d'Histoire, a large white neoclassic building (1910) housing, in particular, remarkable collections of Genevese and Swiss paintings (C. Witz, J. E. Liotard, A. Calame, F. Diday, F. Hodler), collections of laces, watches, ancient vases, enamels and art relics of the old city. Below the hill to the north and close to the lake is the Place du Molard which, in ancient times, was a harbour. The medieval tower formerly standing at its entrance has been restored.

Toward the southern part of the city overlooking the river Arve is the Promenade des Bastions with its monument of the Reformation (1909–17) and the statues of the great reformers. In this promenade are the university buildings (1863–72). Founded by Calvin in 1559, the old academy acquired university status in 1872. Within its walls are the natural history museum and the public and university library containing many valuable books and illuminated mss. There are rooms housing the Calvin and Rousseau collections.

West of the Promenade is the Place Neuve, the finest square in Geneva. In the centre is the equestrian bronze statue of General Guillaume Henri Dufour, commander of the federal army in the Sonderbund mar (see SWITZERLAND: History). Among buildings in the square are the Conservatoire, the Grand Theatre (1879) inspired by the opera house in Paris, and the Musée Rath (1824), once the home of the International Agency for Prisoners of War. From the Place Neuve, the Rue de la Corraterie, once flanked by the city wall where the famous escalade took place (1602), leads down to the river and the Pont de l'Ile.

On this bridge is the Tour de l'Ile, the remnants of a bishop's castle of the 13th century; across the river is the Place de Coutance in the district of St. Gervais, where the workers and the craitsmen of the watchmaking, enamel and jewelry industries established themselves in the 18th and 19th centuries. The 15th-century church of St. Gervais containing wall paintings of the same period has a monument to those Genevese killed during the *escalade*. The Quai drs Bergues leads along the river bank toward the lake with the Pont des Rergues and the Ile Rousseau with Pradier's statue of the philosopher (1835) on the right.

In the Quai du President Wilson along the northern shore is the former Hôtel National which was the first home of the League of Nations. The International Labour office, a massive building completed in 1925, stands in the wide Avenue de la Paix. This road mounts to the Palais des Nations which is the European office of the United Nations and the headquarters of the World Health organization. Built originally for the League of Nations (1929–1937), the Palais des Nations has imposing frontages facing the lake. The interior of the Palais is decorated with contributions from various nations (stone, wood, carpets, paintings, et~.).Among its chief rooms are the pillared assembly hall and the council chamber, adorned with a fresco by the Spanish painter José Maria Sert. Next to the Palais is the Musée Ariana housing a ceramic collection. Across the road is the headquarters of the International Red Cross society which was founded at Geneva in 1864 by Henri Dunant. On the right bank of the lake, in a district which in the 18th century lay outside the city walls, is the house where Voltaire lived 1755–58. This house, called "Les Delices" (now the name of the district), has been restored and contains the Musée et Institut Voltaire where Voltaire's first publications and manuscripts are kept.

Among Geneva's beauties are its parks, which form a green belt around the citp; along the shore of the right bank are the Parc Mon Repos, the Parc de la Perle du Lac and the Parc Barton which extends as far as the grounds of the International Labour office On this bank, too, are the Botanic gardens and the Conservatoire Botanique. On the opposite shore of the lake is the Jardin Anglais or Promenade du Lac with the monument erected in 1864–69 commemorating the entrance of the canton into the Swiss confederation; the Parc der Eaux-Vives and the adjoining Parc de la Grange with its beautiful 18th-century house and rose garden. Offshore on the Jetée des Eaux-Vives there is a fountain the jet of which rises nearly 330 ft. To the east of the old city is the extensive Parc Bertrand.

Celebrated Residents. — In the 16th century besides Calvin and Bonivard there were in Geneva the printers Robert and Henri Estienne and the scholars Isaac Casaubon and Joseph Scaliger, the latter only for a short time from 1572 to 1574. J. J. Rousseau is, of course, the great Genevese of the 18th century. Voltaire, Rousseau's rival, made the chbteau of Ferney, not far from Geneva, a centre of European intellectual society. In the 18th and 19th centuries Geneva was an acknowledged centre of scientific study. Scholars in this field include the botanists A. P. de Candolle and P. E. Boissier; the geologists Alphonse Favre and L. A. Necker; J. C. G. de Marignac, the chemist, J. A De Luc, the physicist, E. Plantamour, the astronomer, and Horace Bénédict de Saussure (*q.v*), best known for his conquest of Mont Blanc in 1787. In the arts, too, many famous names are linked with that of the city: the sculptor J. Pradier and the artists J. A. Arlaud, F. Diday and A. Calame On her exile, Madame de Stael transferred to the chbteau at Coppet, near Geneva, the salon she had held at Paris.

Trade and Communications. — Geneva, known primarily as a centre of Swiss cultural life and as the headquarters of international movements, is also an industrial city. Jewelry, watches and enamels are the chief manufactures: others include electrical machines and water turbines, medical instruments and precision tools. There are important clothing, food, chemical and printing industries and a prosperous banking business. The hotel trade also contributes largely to the city's income Geneva is linked by rail with the rest of Switzerland and with France (Lyons, Paris, Marseilles). The station is at Cornavin. The station of Eaux-Vives on the left bank connects Geneva with Savoy. The airport is at Cointrin, 3 mi. N.W. of the city. Served by international airlines, it is one of the largest airports in Switzerland. The Swiss and French sides of the lake can be reached by lake steamers.

HISTORY

In prehistoric times (4th or 5th millennium B.C.) a great lake city built upon piles, some of which may still be seen, existed at the western end of the lake where the waters narrow into the channel of the Rhône. After the period of the lake dwellings, the inhabitants established themselves on the hill on the left bank of the lake and of the river.

Caesar states that Genua was a walled town (*oppidum*) in the extreme north of the country of the Gallic people of the Allobroges; the Rhône separated it from the territory of another Gallic people, the Helvetii, whose invasion Caesar repelled. Later inscriptions refer to Geneva as a *vicus* (community) of the Viennese province. It had temples, aqueducts, ports and ships and was evidently of some importance judging by the many Roman remains found on the original site of the city (in the vicinity of the cathedral). About A.D. 400 it is described as a *civitas*. This rise in status was probably connected with the establishment of a bishop's see there. A letter of St. Leo in 450 states that the see was then a suffragan of the archbishopric of Vienne.

In the mid-jth century A.D. Geneva came into the possession of the Burgundians; in 534, however, Gundibald was defeated by Clovis, king of the Franks. After the barbarian invasions the city shrank to half its former size. It was then concentrated on the high ground During the feudal period the Burgundian kings had more to fear from the hereditary counts of Geneva than from the elected bishops; Rudolf III, therefore, conferred estates on the bishops, favouring them at the expense of the counts. The kingdom of Burgundy was bequeathed by Rudolf III (d. 1032) to the emperor Conrad II. Temporal sovereignty of the city was finally granted to the bishop, who, in 1162, was raised to the rank of a prince of the Holy Roman empire. Like many other prince-bishops, the ruler of Geneva had to defend his rights: against powerful neighbours without, and against the rising power of the citizens from within.

The Genevese attempted toward the end of the 13th century to create a municipal organization for themselves. They were able to play off against one another the rival rulers of the district. In Maurienne, a remote district of the country, there presently came to the fore a count assuming the title of count of Savoy. He tried to win land and power at the expense of both the count of Geneva and the bishop. It was natural, therefore, that the citizens should invoke the aid of Savoy against their bishop. But the count of Savoy, Amadeus V, not merely seized the castle of the bishops, but also the office of vidomne, the official through whom the bishop exercised his minor judicial rights. By calling in the count of Savoy, the Genevese had succeeded in freeing themselves from the count of Geneva and in defying the bishop; they soon discovered, however, that their "protector," not content with the office of vidomne, intended to make himself "prince" of the citp.

In 1401 Amadeus VIII of Savoy bought the county of the Genevois, the dynasty of its rulers having become extinct, and then attempted to purchase the bishopric of the city. This move was rejected, but Amadeus VIII achieved his object. Having been elected pope under the name of Felix V, he named himself to the vacant see of Geneva in 1444. Until 1522 the see was almost continuously held by a cadet of the house of Savoy.

Geneva might soon have become an integral part of the realms of the house of Savoy had it not been for the appearance of a new protector–the Swiss confederation. Early in the 15th century the town of Fribourg negotiated with Geneva for commercial purposes, as the cloth manufactured at Fribourg found a market in the long-established fairs of Geneva. This took on a political significance in the treaty of combourgeoisie (1526) which included not only Fribourg and Geneva but Berne also.

The Genevese, wishing to rid themselves now of domination by the duke of Savoy, the self-appointed "protector" of the city, turned to the Swiss for help. Their armed intervention (1530) forced the duke to sign the treaty of St. Julien by which he engaged not to trouble the Genevese any more, agreeing that if he did so the two towns of Fribourg and Berne should have the right to occupy his barony of Vaud. A legal tie was thus established between Geneva and two of the Swiss cantons. The municipal authorities of the city greatly developed and included a grand conseil and petit conseil.

The Reformation and Independence. — The situation was complicated by the Reformation, in which Fribourg remained loyal to the old faith, while Berne supported the Reformation. In 1535 Geneva formally adopted the Protestant faith. The bishop, Pierre de la Baume, had already left the city (July 14, 1533), never to return. The syndics and the council assumed authority and claimed the sovereign powers of the bishop The Fribourgeois, who had come to the help of Geneva in 1530, remaining Catholics, now seceded from the alliance. The bishop joined forces with the duke of Savoy to attack Geneva. The Genevese were on the point of succumbing in the unequal struggle when, in Jan. 1536, the Bernese at last came to their aid, acquiring the barony of Vaud and the bishopric of Lausanne. They seized the Gex district, the Chablais, and, in combination with the Genevese, took the castle of Chillon, from which they delivered Bonivard, the prior of St. Victor. Meanwhile, Guillaume Farel had been advancing the cause of religious reform, which was definitively adopted on May 21, 1536.

In July 1536 a French refugee, John Calvin (*q.v.*), came to Geneva and was persuaded by Farel to remain. He was not immediately successful, however, and was obliged to leave the town. Later recalled by his partisans (1541), he undertook the task of imposing on the Genevese, intoxicated with their newly won freedom, a severe moral discipline. One of his most lasting achievements was the foundation of the Academy of Geneva, which he set up with the assistance of Théodore Beza (1559). It was virtually a training school for Protestant missionaries and Geneva became the acknowledged stronghold of Protestantism and the city of refuge for the persecuted from Italy, England and France. Calvin was the virtual ruler of the city, and from that fastness, through his emissaries and a voluminous correspondence, he directed his disciples in all parts of Europe.

The gains of the war of 1536 were not lasting. Emmanuel Philibert of Savoy recovered his lands; Berne only retained the Vaud; Geneva was once more encircled by enemies; and finally, Calvin died in 1564. On the other hand, Berne renewed the treaty of combourgeoisie and Zurich entered the alliance in 1584. Some time before this Henry III of France had made an alliance with Berne and Solothurn for the "conservation" of Geneva (1579). When civil war broke out in France, Henry III's envoy N. H. de Sancy brought a Swiss contingent to his aid, and Geneva entered the struggle. Sometimes in concert with Sancy's troops and the Bernese, sometimes alone, the Genevese fought and held their ground. Henry of Navarre, the former Huguenot leader, presently succeeded Henry III. Despite his former friendship with Geneva, he deprived the Genevese of the Gex district, which they had conquered, when he made peace with Savoy (1601).

With complete disregard of treaties, Duke Charles Emmanuel made a final attempt to take Geneva by surprise by scaling the walls with ladders (night of the escalade, Dec. 12, 1602). He was repelled with considerable losses, while only 17 Genevese perished. Overjoyed at this victory, the citizens crowded into their cathedral; they sang the 124th psalm which has ever since been sung on the anniversary of this great delivery. The peace of St. Julien (July 21, 1603) marked the final defeat of the duke of Savoy in the long struggle waged (since 1290) by his house against the city of Geneva.

18th, 19th and 20th Centuries. — Geneva then entered on a period of tranquillity. Industry prospered, particularly the clockmaking industry, with the assistance of the refugees who fled to Geneva at the time of the St. Bartholomew massacre (*q.v.*) and the revocation of the Edict of Nantes (*q.v.*). There grew up a patrician class which constantly became more exclusive, and several attempts were made by the cultivated middle classes to gain some share in the aristocratic government of the town. Following the French revolution, Geneva, imitating the example of Paris, had its "Terror." An attempt was made to remedy the situation by the egalitarian constitution of 1794, but an end was not put to disorder until a short time before the French occupation of 1798.

On the fall of Napoleon (1814) the city recovered its independence, and finally, in 1815, mas received as the-junior member of the Swiss confederation. The constitution of 1814 set up a common form of government for the city and the canton, the city not obtaining its municipal independence until the constitution of 1842. A more advanced and liberal constitution was accepted by popular vote on May 21, 1847.

After World War I Geneva, with its tradition of independence and Swiss neutrality, was chosen as the seat of the League of Nations (*q.v.*). Although a nucleus of League officials remained after the outbreak of World War II, no meetings of the council or the assembly were held, and the League's activities largely ceased. The International Labour office was at first housed at Pregny, 1½ mi. outside Geneva, and in 1926 in a new building near Ariana park. The departure after 1939 of League officials and Labour office personnel dealt a blow to the prosperity of Geneva. By 1942 more than 11% of its houses were unoccupied.

The situation improved considerably after World War II; the population substantially increased and unemployment disappeared. In 1947 the city mas designated as the European centre of the United Nations. In the following year the International Labour office, the secretariat of the International Labour organization, returned to its headquarters in Geneva, and the World Health organization established its headquarters in the Palais des Nations, followed by other international organizations. It was in Geneva that the Asian conference (United States, France, United Kingdom, Soviet Union) took place in 1955 to settle the situation in Vietnam. During that same year the European Centre ior Nuclear Research began the construction of a research laboratory at Meyrin.

GENEVA, LAKE OF, the largest lake in central Europe. It is *Lacus Lemannus* of classical writers: but from the 16th century onward Lac de *Genève,* though from the end of the 18th century the name Lac *Léman* was revived. Its area is 224½ sq.mi., of which about 134 sq.mi. are Swiss and 90½ sq.mi. French. The French part takes in nearly the whole of the south shore, save its west and east ends, which belong respectively to Geneva and to Valais.

The lake is formed by the Rhône, which enters it at its east end, between Villeneuve and St. Gingolph and quits it at its west end, flowing through the city of Geneva. The only important tributaries are the Drance (S.), the Venoge (N.) and the Veveyse (N.). The length from the east end to Geneva is 45 mi., the maximum depth is 1,017 ft., mean depth 500 it., greatest width (between Morges and Amphion) 8½ mi., normal width 5 mi. The lake forms two well-marked divisions separated by the strait of Promenthoux, and as a bar, divides the Grand Lac from the Petit Lac. The "Grand Lac" is to the east and the "Petit Lac" (W.) is the special Genevese portion. The unusual blueness of the waters has long been remarked, and transparency increases away from the Rhône entry as the river-borne mud sinks to the bottom. The lake level is highest in summer. There are remarkable temporary disturbances of level known as *seiches* both longitudinal and transverse, in which the whole mass of water in the lake rhythmically swings from shore to shore. The currents are irregular. The principal minds that blow over the lake are the *bise* (northeast), the *vaudaire* or *Föhn* (southeast), the *sudois* or *vent de pluie* (southwest) and the *joran* (northwest). The storm winds are *molan* (from the Arve valley) and the *bornan* (from the Drance valley). The lake is not as rich in fish as the other Swiss lakes. Prof. Forel knows of but 20 indigenous species (of which the *Féra,* or *Coregonus fera,* is the principal) and six that have been introduced by man in the 19th century. Lake dwellings, of varying dates, have been found on the shores.

Despite steamers first placed on the lake in 1823, and railways along each shore, the red lateen sails of minor craft still brighten the landscape. The railway along the northern shore runs from Geneva past Nyon, Rolle, Morges, Ouchy (the port of Lausanne), Vevey and Montreux to Villeneuve (56½ mi.). That on the south shore gains the edge of the lake at Thonon only (22¼ mi. from Geneva), and then runs past Evian and St. Gingolph to Le Bouveret (20 mi. from Thonon). In the harbour of Geneva two erratic granite boulders project above the water, and are named *Pierres du Niton* (supposed to be altars of Neptune). The lower of the two has been taken as the basis of the triangulation of Switzerland.

GENEVA CONVENTIONS, a series of four international agreements for the protection of war victims, signed on Aug. 12, 1949, by 58 governments and the Holy See. Convention I, "for the amelioration of the condition of the wounded and sick in armed forces in the field," had a history intimately linked with the founding of the International Committee of the Red Cross. In response to an appeal by Henri Dunant in his book *Un souvenir* de *Solférino* (1862), dramatically recalling the suffering of the wounded in the battle of Solférino, the International Red Cross committee was created in 1863. The original convention came out of a conference called by the Swiss Federal council in 1864. Twenty-six governments in attendance agreed to respect war wounded, neutrality of hospitals bearing the Red Cross sign and other humanitarian rules.

The development from the convention of 1864 to the comprehensive series of agreements of 1949 reflected the appalling growth of total warfare. The 1864 convention, revised in 1906, was adapted to naval warfare at The (Second) Hague Peace conference of 1907 and, the previous British objections withdrawn, adopted there as Convention X. In its 1949 version, it became known as Convention II (Armed Forces at Sea). Convention III of 1949 (Prisoners of War) was first agreed upon also in Geneva, in 1929. It reflected the problems of treatment and repatriation of war prisoners. which came to the fore in World War I. (See PRISONERS OF WAR.) Finally, the new technology of warfare, which carried its effects among the noncombatants in World War II, resulted in the addition in 1949 of Convention IV (Protection of Civilian Persons in Time of War).

As long as war, though legally outlawed, continued to exist de facto, the Geneva conventions were an indispensable part of the effort to keep warfare within some confines. During the Korean war (1950–53), all the parties involved declared themselves bound by the conventions, even if they had not signed or ratified them. The cause *célèbre* of Korea, the repatriation of prisoners of war, involved Convention III. Although tightened in 1949 to favor the prisoners' rights, this convention was susceptible of literalist interpretation, which would have worked a forcible repatriation.

This was the drawback of engagements of this type, responding only to past stimuli, rather than assaying a forward-looking regulation. The ideological dimension of contemporary warfare and the postulate of international protection of human rights, although extant as factors and likely to increase in prominence, were not positively incorporated into the Prisoners of War convention. Convention IV (Civilians) appeared also outdated in some particulars by developments in war technology. Yet it was also true that the fundamental value of the Geneva conventions was their humanitarian spirit, which was ageless and not letterbound.

GENEVA SUMMIT CONFERENCE (1955), a conference held in Geneva, Switz., from July 18 to July 24, 1955. The 1955 Geneva conference was the first meeting of the heads of government of the four principal powers which had fought national socialist Germany in World War II since the conference held in Potsdam, Ger., in July 1945. The Geneva conference became generally known as the "summit conference." Its purpose was to lessen the serious tension which had developed after World War II between the U.S.S.R. on one side and the western democracies — the United States, Great Britain and France — on the other.

In May 1953 British prime minister Winston Churchill had proposed a conference of the principal heads of government with the aim of bridging the widening gulf between democracy and communism. The subsequent settlement of the conflicts in Korea and Indochina and the signing of the Austrian peace treaty in Vienna on May 15, 1955, helped to create a climate of opinion in which there seemed to be some hope for the success of a summit conference.

At the conference the four governments were represented by Pres. Dwight D. Eisenhower of the United States, Prime Minister Anthony Eden of Great Britain. Premier Edgar Faure of France and, on the Soviet side by Prime Minister Nikolai Bulganin and Party Chiei Nikita Khrushchev. Before leaving for Geneva, President Eisenho er stated in a broadcast that a change in spirit uould be "the greatest step towards peace, towards future prosperity, and tranquility that has been taken in all the history of mankind," adding "we shall be conciliatory . . . we shall be tolerant." Eisenhouer's conciliatory attitude during the conference made a deep impression on world public opinion and seemed to convince the Soviet leaders of the peaceful intentions of the west. Yet, the negotiations ended without any concrete achievement, although a joint statement on Germany was approved—"The heads of government . . . have agreed that the settlement of the German question and the reunification of Germany by means of free elections shall be carried out in conformity with the national interests of the German people and in the interests of European security." "For the purpose of establishing European security," the foreign ministers of the four powers were instructed to discuss, in addition to reunification, "a security pact for Europe or for a part of Europe, including provision for the assumption by member nations of an obligation not to resort to force and to deny assistance to an aggressor." President Eisenhower made proposals for exchanging military blueprints, publicizing military expenditures, and for establishing control posts and aerial inspection of military installations.

The "spirit of Geneva" evaporated quickly as soon as the discussions were brought down from generalities to concrete measures. The foreign ministers of the Big Four—John Foster Dulles Harold Macmillan, Antoine Pinay and Vyacheslav Molotov—met in Geneva from Oct. 27 to Nov. 16, 1955. No agreement could be reached on German reunification or on European security, the western demand for reunification of Germany being countered by the Soviet demand for a security pact which would have involved the abandonment of NATO. Molotov rejected free elections for Germany and regarded all concrete proposals for inspection of disarmament as interference with the internal affairs of the C.S S.R. By the end of 195j it became evident that the disagreement on all fundamental and all practical questions between the U.S.S.R. on the one hand, as leader of the communist bloc. and the uestern democracies on the other hand, was as complete as it had been in the last years of Stalin's regime. (H. Ko.)

GENEVIÈVE, SAINT (*c.* 422–*c.* 500), patron saint of Paris, was born, according to tradition, at Nanterre near Paris. At the age of seven she was induced by St. Germain, bishop of Auxerre, to dedicate herself to the religious life. and on the death of her parents she moved to Paris, where she distinguished herself by her benevolence, as well as by her austere life. She is said to have predicted the invasion of the Huns; and when Attila with his army was threatening the city, she persuaded the inhabitants to remain on the island and encouraged them by an assurance. justified by subsequent events. that the attack would come to nothing (451). She is also said to have had great influence over Chiideric. father of Clovis, and in 460 to have caused a church to be built over the tomb of St. Denis.

She was buried in the church of the Holy Apostles, popularly known as the church of Ste. Genevittve. In 1793, when the church that had been built in her honour (in 1764) became the Panthéon, her body was removed from it and burned on the Place de Grève; but the relics were enshrined in the church of St. Étienne-du-Mont, where they still attract pilgrims.

Her festival is celebrated on Jan. 3.

See C. H. Lesêtre, *Les Saints* (1900); *A.* **D.** Sertillanges, *Sainte Genevikve* (1917).

GENEVIÈVE (GENOVEVA or GENOVEFA) OF **BRABANT,** heroine of a legend first recorded by Jacobus de Voragine (d. 1298) in his *Legenda sanctorum* ("The Golden Legend"). On the return of her husband, Siegfried of Trèves, from an expedition against the Saracens. Genevittve was falsely accused of infidelity by his steward Golo who had tried to seduce her. Condemned to death but spared by her executioners, she lived with her child for six years in a cave in the Ardennes, nourished by a roe. Eventually Siegfried hunted the roe, which led him to his wife; her innocence was recognized and Golo was executed, but Geneviève died shortly after. Popularized by the Jesuit René de Ceriziers (1603–62) in *L'innocence reconnue dans la vie de Sainte Genevikve, princesse de Brabant* (1634), the legend, in various forms, inspired novels and plays in France, Germany and elsewhere and a light opera by Offenbach (1875).

GENGA, GIROLAMO (*c.* 1476–1551), Italian painter and architect, a transitional figure between Renaissance and mannerism, was born in Urbino and studied under Signorelli (working with him on the frescoes in Orvieto cathedral), later under Perugino and at Florence. The "Martyrdom of St. Sebastian" (Uffizi, Florence) exemplifies his style thus formed. Toward 1509 he painted tno frescoes in Pandolfo Petrucci's palace at Siena (Siena gallery), and in 1510 the "Transfiguration" (Museo dell'Opera del duomo, Siena). His plastic mature style is seen in the altarpiece painted for the church of S. Agostino, Cesena (1513–18; Brera, Milan, predella panels at Bergamo and Washington), the "Marriage of St. Catherine" (Barberini palace, Rome) and in his masterpiece, the already Mannerist "Resurrection," in the church of Sta. Caterina da Siena, Rome (1519 or later). From the 1520s Girolamo Genga was in the service of the dukes of Urbino, and by 1530 was supervising the fresco decoration of the Villa Imperiale near Pesaro and constructing large additions to it. He was architect of S. Giovanni Battista. Pesaro (1543), the work being continued by his son. Bartoiomeo (1516–59), a military as well as civil architect. Preparatory drawings by Girolamo for the Cesena altar are in the British museum. London, the Uffizi, and the Louvre. He died in Urbino on Aug. 11, 1551. (P. M. R. P.)

GENISTA, a Eurasian and North African genus of about 100 species of unarmed or armed shrubs usually evergreen in appearance, belonging to the family Leguminosae. The leaves are simple or trifoliolate. The small, usually yellow flowers occur in terminal racemes or panicles. The genus is frequently confused with *Cytisus,* many species of both groups being designated commonly as brooms. In the United States it is cultivated from Maine to Virginia. Several species are geographically limited; *e.g.,* in Sicily, Syria and Palestine, etc. The petty whin or needlefurze, an armed plant. is common on the moors of England. The well-known ornamental of Eurasia, *G. tinctoria,* the woad-waxen or dyer's greenweed, yields a yellow dye. (J. D. DR.)

GENITIVE, in grammar, one of the cases or declensions of nouns to indicate their relationship with other words in a sentence. Latin contained the genitive—indicating origin or source—and five other declensions of nouns. In English the genitive (the only declension used regularly) usually indicates possession and is also called the possessive case, though it may indicate other relationships.

See GRAMMAR.

GENIUS, meaning literally in Latin "the begetter," is a word of several meanings derived from and having some relation to the original use of the word in Roman religion.

Roman Usage.—In its earliest meaning in private cult, the *genius* of the Roman housefather and perhaps the *iuno (see* JUNO) of the housemother were worshiped. These certainly were not the souls of the married pair, as is clear both from their names and from the fact that no early document mentions the *genius* or *iuno* of a dead person. As no cult was paid to the *genius* of any other member of the family, it seems reasonable to suppose that they were the male and female forms of the family's, or clan's, power of continuing itself by reproduction, which were in the keeping of the heads of the family or clan for the time being and passed at death to their successors. In this as in all forms of his cult, the *genius* was often conceived as appearing in the form of a snake, although he is also shoun in art as a young man, generally engaged in sacrificing. At every wedding a bed, the *lectus genialis,* was made for the *genius* and *iuno* of the husband and wife, and its presence in the house was a sign of matrimony.

Individual Genius.—Because of the rise of individualism and also of the prevalence of Greek ideas concerning a guardian spirit or daimon, the genius lost its original meaning, and came to be a sort of personification of the individual's natural desires and appetites; hence the phrases *indulgere* genio, *genium* dejrudare, signifying respectively to lead a pleasurable and a stingy life. However. the development did not stop there. The genius came to be thought of as a sort of guardian angel, a higher self; and, as the Greek *daimon* was sometimes rationalized into the individual's character or temper, so also Horace half-seriously in one of his Epistles says that only the *genius* knows what makes one person so different from another, adding that he is a god who is born and dies with each one of us. This individual *genius* was worshiped by each individual, especially on his birthday. A few inscriptions even mention the genius of a dead person, as Christian epitaphs sometimes speak of the dead person's angel.

Genius of the Emperor.--To show reverence for the genius of another, or to swear by it, was a mark of deep respect; hence it is not unnatural that the genius of Augustus and of his successors formed objects of popular cult. Thus to worship the *genius Augusti* avoided the feeling against worshiping any living emperor, which remained fairly strong in Italy; for of course all genii were divine and might properly be worshiped.

Further Developments.—As Greek *daimones* were by no means always the guardian spirits of individuals, so also there were a vast variety of genii, *i.e.,* guardian spirits, of places, *genius* loci, including buildings (*genius balneorum,* etc.) and corporations of all sorts, from the state (genizrs *populi Romani*) to small bodies of troops, guilds of tradesmen and so forth. A very curious development is that the *genius* of a god, even of Jupiter, or of the iuno of a goddess, is sometimes referred to.

Modern English Usage.—The word genius is used in two closely related but somewhat different senses. In the first sense, as popularized by Lewis M. Terman, genius refers to high intellectual ability as measured by performance on a standardized intelligence test. The exact- intelligence quotient designating genius varies. Terman set the intelligence quotient for "potential genius" at 140 or over, a level reached by about 1 in 250 of the general population. This seemed to some writers an insufficiently stringent criterion. Leta S Hollingworth set it at 180 or over, a level reached by perhaps no more than 6 in 1,000,000 of the general population, and this seemed to other writers too stringent. In any event, genius here means simply high intellectual ability and refers to potentiality rather than to attainment In this sense, the term may be used to characterize children who have not yet had an opportunity to gain eminence by achievement. A growing and probably more practicable usage is to refer to children of this sort as "gifted," and to make a distinction between first-order gifted children, those in the upper 0.1% of the general population, and second-order gifted children, those in the upper 10% of the remaining population.

In the second and more popular sense, as derived from Sir Francis Galton, "genius" is used to designate creative ability of an exceptionally high order as demonstrated by actual achievement In this sense, men of genius are identified by the eminence of their accomplishment. Although eminence alone may be an imperfect measure of genius, it is held to be the best available, always provided that such eminence is not merely transitory or the result of accident of birth, as in the case of hereditary rulers. To be a sign of genius, eminence must have been won through personal attainment of a superior order.

Genius is distinguished from talent both quantitatively and qualitatively. Talent refers to a native aptitude for some special kind of work. It implies the relatively quick and easy acquisition of a particular skill. Genius is more than this. It involves originality, creativeness and the ability to think and work in areas not previously explored and thus to give to the world something of pre-eminent value it would not otheraise possess. Although men of genius have usually left their unique mark in a particular field, and some writers accordingly include in the term genius persons with special aptitudes independent of more generalized intelligence. studies of the early development of these people appear to show that the general intelligence of the highly talented individual is also exceptionally high. It may very well be that the two senses in nhich the concept genius has been used represent two sides of the same coin.

There have been a variety of attempts to explain the nature and source of genius. One theory holds that the man of genius belongs to a separate psychobiological species, differing as much from ordinary man in his mental and emotional processes as man differs from the ape. Another theory looks upon genius as closely related to neurosis and psychosis. Cesare Lombroso is perhaps the most widely cited among those who held or hold this point of view. Although modern psychoanalytic theory would also hold that genius, like neurosis and psychosis, has its source in basic conflict between the self and environment, in the genius these conflicts are resolved in such way that the symptoms and products are socially useful and valued. Investigations indicate that the man of genius is actually somewhat less prone to mental disorders, physical weakness and bodily deformities than are people in general. Children who show exceptionally high general intelligence of the sort that may be classified as "gifted" or "potential genius" are on the average superior to other children in physique and health and in emotional and social adjustment.

Galton, aho inaugurated the systematic study of genius, formulated the theory that genius is a very extreme degree of three combined traits—intellect, zeal and power of working—that are shared by all men in various "grades." In his *Hereditary Genius,* ahich appeared in 1869, he presented the first clear statistical evidence that genius, as measured by outstanding accomplishment, tends to run in families. Since then the extent to which biological heredity. as distinct from education and opportunity, is responsible for the great differences in achievement of different individuals has been the subject of scientific controversy. The question of how much "nature" and how much "nurture" remains unsettled. However, the consensus is that genius is a function of both hereditary and environmental factors. The original potentiality for exceptional achievement comes from heredity, but whether or not this potentiality mill be brought to fruition depends, at least to some extent, upon opportunity and training.

Studies of famous men and women show that there is no country and no period of time that has not produced some persons of genius calibre. Perhaps the greatest proportion of men of genius to total population that has ever occurred was found in Athens during the period extending roughly from the 5th to the 2nd century B C . when the city-state aith a population averaging not more than 25,000 gave to the world such men as Pericles. Plato, Aristotle, Themistocles and others of equal or near-equal rank.

In all countries and all periods there have been families, social classes and communities that have produced more than their quota of genius. The chance that men who have themselves achieved prominence will have children who rank in the genius group, either by reason of their exceptional endowment as children or on the basis of exceptional accomplishment as adults, is unquestionably greater than that for the population in general. It is, however, impossible to say with any certainty whether this is due to superior heredity or to superior environment. What must always be borne in mind is that in all places and at all times men of genius have arisen from all ranks of society. John Bunyan's father was a poor tinker; the father of Pierre Simon Laplace was a farmer of limited means. A place in Who's *Who* is by no means reserved from father to son.

GENLIS, STÉPHANIE-FÉLICITÉ DU CREST DE SAINT-AUBIN, COMTESSE DE (1746–1830), French writer and educator, was born at Champcéry, Autun. France. At six years of age she was received as a canoness into the noble chapter of Alix, near Lyons, with the title of Madame la Comtesse de Lancy, taken from the town of Bourbon-Lancy. Her entire education, however, was conducted at home. In her 16th year she was married to Charles Brûlart de Genlis, a colonel of grenadiers, who afterward became marquis de Sillery. Some years later, through the influence of her aunt, Madame de Montesson, who had been clandestinely married to the duke of Orleans, she entered the Palais Royal as lady-in-waiting to the duchess of Chartres (1770). She acted with great energy and zeal as governess to the daughters of the family, and was in 1781 appointed by the duke of Chartres to the responsible office of gouverneur of his sons, a step which led to the resignation of all the tutors as well as to much social scandal. She wrote several works for the use of her pupils, the best known of which are the *Théâtre d'éducation* (4 vols., 1779–80), a collection of short comedies for young people, Les *Annales* de la vertu (2 vols., 1781) and *Adèle* et *Théodore* (3 vols., 1782). She anticipated many modern methods of teaching. History was taught with the help of magic lantern slides and her pupils learned botany from a practical botanist during their walks. Madame de Genlis welcomed the Revolution, but the fall of the Girondins in 1793 compelled her to take refuge in Switzerland along with her pupil Mademoiselle d'Orléans. In this year her husband, from whom she had been separated since 1782, was guillotined. In 1794 Madame de Genlis fixed her residence at Berlin, but was expelled by order of King Frederick William, and afterward settled in Hamburg, where she supported herself for several years by writing and painting. After the 18th Brumaire (1799) she returned to France, and was well received by Napoleon, who gave her apartments at the arsenal and assigned her a pension of 6,000 fr. Her government pension was discontinued by Louis XVIII. Her Diners du Baron *d'Holbach* (1822) set forth with a good deal of sarcastic cleverness the intolerance and fanaticism of 18th century "philosophes." She died on Dec. 31, 1830.

GENLISEA: see PITCHER PLANTS.

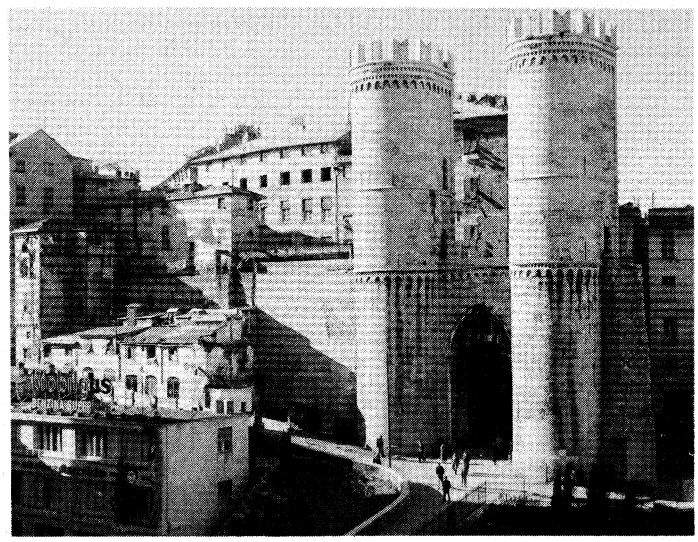
GENNADIUS II or GEORGIOS SCHOLARIOS (d. *c.* 1468). patriarch of Constantinople, 1454–56, philosopher and theologian. was one of the last representatives of Byzantine learning. He appears to have been born at Constantinople and to have served the emperor John VII Paleologus as counsellor. He was present at the great council held in 1438 at Ferrara and Florence with the object of uniting the Greek and Latin Churches, and there met the Platonist, Gemistus, Pletho. In church matters, as in philosophy, the two were opposed—Pletho maintaining strongly the principles of the Greek Church, Georgios being more willing to compromise. On his return to Greece, however, Georgios opposed the union. In 1448 he became a monk at Pantokrator. and in 1453 was elected patriarch of Constantinople by Mohammed II. A few years later he found his position under a Turkish sultan so irksome that he retired to the monastery of John the Baptist near Serrae in Macedonia, where he died about 1468.

GENOA (anc. GENUA, Ital. GENOVA, Fr. GÊNES), capital of the province of Genoa, It. Pop. (1951) of greater Genoa (from Nervi to Voltri), 688,447; of the city, 648,078 (1937 est.) 736.135 (commune). Situated on the Gulf of Genoa, it is the chief port of Italy, the seat of an archbishop and a university and a strong fortress. The city, as seen from the sea, is "built nobly." The original nucleus is that portion which lies to the east of the port in the neighbourhood of the old pier (Molo Vecchio). In the middle of the 12th century, it was found necessary to extend the line of circumvallation, but it was not till 1320–30 that a third line took in the greater part of the modern site of the city proper. This presented about 3 mi of rampart toward the land side which can still be traced. though large portions. especially toward the east, have been dismantled. The present line of circumvallation dates from 1626–32, the period when the independence of Genoa was threatened by the dukes of Savoy. From the mouth of the Bisagno in the east and from the lighthouse point in the west, it stretches inland over hill and dale to the great fort of Sperone (the Spur) on the summits of Monte Peraldo at a height of 1,604 ft. The circuit is little less than 12 mi.

HISTORY

The discovery of a Greek cemetery of the 4th century B.C. is the only proof that Genoa was ever occupied by the Greeks. The city was destroyed by the Carthaginians in 209 B.C. but restored by the Romans, who made it and Placentia their headquarters against the Ligurians. An inscription of 117 B.C. (now preserved in the Palazzo Municipale at Genoa and called the "Bronze tablet") refers to the decision of the judges sent from Rome to settle the boundaries between the Genuates and the Veturii, the inhabitants of a neighbouring hill town. It is known only from inscriptions of other places that Genoa had municipal rights. The city was a *municipium* and the headquarters of the Roman fleet which, among its admirals, had the famous Agrippa whose house is thought to have been in the Piazza Cavour. Strabo (iv, 6, 2, p. 202) states that Genoa exported wood, skins and honey and imported olive oil and wine, though Pliny speaks of the wine of the district as the best of Liguria (*Hist. Nat.*, xiv, 67).

The history of Genoa during the dark ages, throughout the Lombard and Carolingian periods, is but the repetition of the general history of the Italian communes. The patriotic spirit and naval prowess of the Genoese, developed in their defensive wars



SILBERSTEIN FROM MONKMEYER

THE PORTA SOPRANA OR PORTA DI S. ANDREA. GATE OF THE OLD CITY WALL IN THE CENTRE OF GENOA. THE GATE WAS BUILT IN 1155

against the Saracens, led to the foundation of a popular constitution and to the rapid growth of a powerful fleet, and earned Genoa its title of La Superba, "the proud." From the necessity of leaguing together against the common Saracen foe, Genoa united with Pisa early in the 11th century in expelling the Moslems from the island of Sardinia; but the Sardinian territory thus acquired soon furnished occasions of jealousy to the conquering allies, and there commenced between the two republics the long naval wars which terminated fatally for Pisa in the battle of Meloria (1284). Genoa secured great advantages from the trade stimulated by the crusades. The seaports wrested at the same period from the Saracens along the Spanish and Barbary coasts became important Genoese colonies, while in the Levant, on the shores of the Black sea and along the banks of the Euphrates were erected Genoese fortresses of great strength.

The commercial and naval successes of the Genoese during the middle ages were the more remarkable because, unlike their rivals, the Venetians, they were the unceasing prey to internal discord—the Genoese commons and nobles fighting against each other, rival factions among the nobles themselves striving to grasp the supreme power in the state, nobles and commons alike invoking the arbitration and rule of some foreign captain as the sole means of obtaining a temporary truce. From these contests of rival nobles, in which the names of Spinola and Doria stand forth with greatest prominence, Genoa was soon drawn into the great vortex of the Guelph and Ghibelline factions; but its recognition of foreign authority—successively German, Neapolitan and Milanese—gave way to greater independence in 1339, when the government assumed a more permanent form with the appointment of the first doge, an office held at Genoa for life, in the person of Simone Boccanera. Alternate victories and defeats of the Venetians and Genoese—the most terrible being the defeat sustained by the Venetians at Curzola (1298) where the famous Venetian traveller. Marco Polo, dictated his book of voyages, *Il Milione,* during his four years of captivity—ended by establishing the inferiority of the Genoese rulers, who fell under the power now of France, now of the Visconti of Milan. The Banca di S. Giorgio, uith its large possessions, mainly in Corsica, formed during this period the most stable element in the state, until in 1528 the national spirit appeared to regain its ancient vigour when Andrea Doria succeeded in throwing off the French domination and restoring the old form of government. The government as restored by him, with certain modifications tending to impart to it a more conservative character, remained unchanged until the outbreak of the French Revolution and the creation of the Ligurian republic.

Between Aug. 26 and Oct. 30, 1451, the great navigator Christopher Columbus was born in Genoa, in the Piazza de Ferrari. The original house was demolished in 1684 and the House of Columbus built on the site. Nearby a cloister has been constructed in the Roman style of the former monastery of S. Andrea, which had links with Columbus.

The Ligurian republic was soon swallowed up in the French empire, but not before Genoa had experienced terrible privations in the siege when André Masséna held the city against the Austrians (1800). In 1814 Genoa rose against the French, on the assurance given by Lord William Bentinck that the allies would restore to the republic its independence. It had, however. been determined by a secret clause in the treaty of Paris that Genoa would be incorporated with the dominions of the king of Sardinia. The discontent so created kept alive in Genoa a republican spirit which, through the influence of a young Genoese citizen, Giuseppe Mazzini, was a permanent menace not only to the Sardinian monarchy but to all the established governments of the peninsula. A republican outbreak occurred in 1848, but after a short and sharp struggle the city, momentarily seized by the republican party, was recovered by Gen. Alfonso la Marmora.

In World War II Genoa was heavily bombed by the Allies; its port and industrial areas were virtually demolished by the repeated aerial attacks.

THE CITY

Architectural Features.—The main architectural features of Genoa are its mediaeval churches, with striped faqades of black and white marble, and its magnificent 16th-century palaces.

The earlier churches show a mixture of French Romanesque and the Pisan style—they are mostly basilicas with transepts and as a rule a small dome; the pillars are sometimes ancient columns and sometimes formed of alternate layers of black and white marble. The faqades are simple, without galleries, having only pilasters projecting from the wall, and are also alternately black and white. This style continued in Gothic times also. The oldest church is Sta. Maria di Castello (11th century), the columns and capitals of which are almost all antique. S. Cosma and S. Donato (with remains of the 10th-century building) belong to the 12th century, and S. Giovanni di Pre, S. Agostino (with a fine campanile) and S. Stefano to the 13th. S. Matteo, the church of the Doria family, was founded in 1126 by Martino Doria. The faqade dates from 1278, and the interior from 1543; in the crypt is the tomb of Andrea Doria by Giovanni Montorsoli, and above the high altar hangs the dagger presented to the doge by Pope Paul III. To the left of the church is an exquisite cloister of 1308 with double columns. in which a number of sepulchral inscriptions of the family and the statue of Andrea Doria by Montorsoli are preserved. The little square in front of the church is surrounded by Gothic palaces of the Doria family. The cathedral of S. Lorenzo was reconstructed about the end of the 11th century and consecrated in 1118. The faqade has three elaborate doorways (13th century), the interior was rebuilt in 1307, the campanile, which rises above the right-hand doorway, was completed in 1522, and the cupola was erected after the designs of the architect Galeazzo Alessi in 1567. The fine Early Renaissance (1448) sculptural decorations of the chapel of St. John the Baptist were due to Domenico Gaggini of Bissone on the Lake of Lugano. In the treasury of the cathedral is an octagonal bowl, the Sacro Catino, brought from Caesarea in 1101, which corresponds to the descriptions given of the Holy Grail and was long regarded as an emerald of matchless value, but is in reality a remarkable piece of ancient glass. The church of St. Ambrose, rebuilt by the Jesuits (1587), has a richly decorated interior (16th century). The Annunziata del Guastato (1587), one of the largest churches in the city, is a cruciform structure with a dome; its interior is covered with gilding and frescoes of the 17th century. S. Siro was rebuilt by the Benedictines in the 11th century and restored and enlarged by the Theatines in 1576, the faqade being added in 1830. Sta. Maria di Carignano belongs mainly to the 16th century and was designed by Alessi in imitation of St. Peter's at Rome; the highest gallery of the dome is 368 ft. above sea level and 194 ft. above the ground.

The palaces of the Genoese patricians, famous for their sumptuous architecture, their general effectiveness and their artistic collections, were many of them built in the latter part of the 16th century by Alessi, a pupil of Michelangelo, whose style is imposing and displays marvellous ingenuity in using a limited or unfavourable site to the greatest advantage. Several of the villas in the vicinity of the city are also his work. The Via Garibaldi is flanked by a succession of magnificent palaces, chief among which is the Palazzo Rosso. It was presented by the duchess of Galliera to the city in 1874, along with its valuable contents, its library and picture gallery, which includes fine examples of Van Dyck and Paris Bordone. The Palazzo Municipale, built by Rocco Lurago at the end of the 16th century, once the property of the dukes of Turin, has a beautiful entrance court and a hanging terraced garden fronting a noble staircase of marble which leads to the spacious council chamber. In an adjoining room are preserved two autograph letters of Christopher Columbus, and the violin of Nicolo Paganini (*q.v.*), both natives of Genoa. Opposite the Palazzo Rosso is the Palazzo Bianco, bequeathed to the city by the duchess of Galliera in 1889 and subsequently converted into a museum. In the Via Balbi is the Durazzo Pallavicini palace, with a noble faqade and staircase and a rich picture gallery, also the Palazzo Balbi-Senarega, which has Doric colonnades and an orangery. The Palazzo dell' Universita has an extremely fine court and staircase of the early 17th century. The Palazzo Doria in the Piazza Principe, presented to Andrea Doria by the Genoese in 1522, was remodelled in 1529 by Montorsoli and decorated with frescoes by Perino del Vaga. Its garden was destroyed by the building of the railway. The old palace of the doges, originally a building of the 13th century, to which the tower alone belongs, stands near the cathedral. Another very fine building is the Gothic Palazzo di S. Giorgio, near the harbour, dating from about 1260, occupied from 1408 to 1797 by the Banca di S. Giorgio, now completely restored and occupied by the offices of the port authority. The Cimitero di Staglieno, about 1½ mi. from the city on the right bank of the Bisagno, contains a collection of remarkable modern sepulchral monuments.

The centre of the university is the old palace of Via Balbi, but the great number of students (10,200 in 1955) necessitates the distribution of many faculties in various parts of the city. Other institutions include the academy of arts, the archives of the fathers of the commune, the Mazzinian institute for the study of the Renaissance and the headquarters of the hydraulic institute of the Italian navy, founded in 1872. Genoa's hospitals and the asylum for the poor are among the finest in Italy.

Forced by the narrowness of the level shore to climb the lower hills of the Ligurian Alps, and having been surrounded for many centuries by walls of fortification, Genoa is now a picturesque confusion of narrow streets, lanes and alleys, with stairways climbing the steeper slopes and bridges spanning the deeper valleys. Much of the city is inaccessible to cars and many of the important streets have very little room for traffic. To unite certain quarters three tunnels had to be dug through the hills and other tunnels serve the harbour. The Piazza de Ferrari is the centre of the stock exchange and general business of the city and from there the Via XX Settembre, famous for its elegance and beauty, slopes down to end between the Piazza della Vittoria, with its fine memorial to World War I, and the Piazza Verdi, where one of the two big railway stations stands. The Theatre Carlo Felice, destroyed in World War II, is to be rebuilt. The Corso Buenos Ajres connects the city with the new residential quarter that extends practically to Nervi. The Via Roma runs from near the Piazza de Ferrari to the Piazza Corvetto, with its equestrian statue of Victor Emmanuel II. which lies between the two main parks, Acquasola and Villetta Di Negro. In front of the principal station is the Piazza Acquaverde, with a statue of Columbus, at whose feet kneels the figure of America. The T'ia di Circonvallazione a Monte leads up to the hills at the back of the town, where new suburbs have been constructed. Three funicular railways from different points of the city give access to the highest parts of the hills behind the town. In the east the covering in of the Bisagno from the Piazza Verdi to the sea, and in the west the cutting of a road through the lighthouse promontory (S. Benigno) have enabled the city to be more intimately connected to the nearby communes. In 1926 the communes were fused to form greater Genoa.

Commerce and Industry.— Though its existence as a maritime power was originally due to its port, it was only after 1870 that Genoa provided the conveniences necessary for the modern development of its trade, the duke of Galliera's gift of £800,000 to the city in 187j being devoted to this purpose. A further enlargement of the harbour became necessary after the opening of the St. Gotthard tunnel in 1882, which extended the commercial range of the port of Genoa through Switzerland into Germany.

The old harbour is semicircular in shape, 232 ac. in area, with numerous quays, and protected by moles from southern and southwesterly winds. An outer harbour, 247 ac. in area, has been constructed by extending the Molo Nuovo by the Molo Duca di Galliera. and another basin, the San Pier d'Arena basin, for coaling vessels. with an area of 96 ac.. has been formed to the west of this, between it and the lofty lighthouse which rises on the promontory at the southwestern extremity of the harbour. A further extension in front of San Pier d'Arena as far as the mouth of the Polcevera river was in progress in the mid-1950s.

The largest ships can enter the harbour, which may be divided into three parts: the eastern zone for yachts, fitting out and repairs to naval ships, with four graving docks; the central zone which is the old harbour, with a graving dock; and the western zone which comprises the industrial ports of San Pier d'Arena, Cornigliano and Sestri Ponente. In the harbour between 8,000,000 and 9,000,000 tons of goods are handled yearly. Imports are mainly raw materials such as oil, coal, iron ore, hides, wool and cotton. Heavy industries, including steelworks, have developed near the harbour in the valley and at the mouth of the Polcevera.

Genoa is an important rail centre for Milan, Turin, Ventimiglia (France) and La Spezia (Rome). The road connecting Rome with the Azure coast (Via Aurelia) passes through the city and other major roads are the Scoffera pass to Piacenza, the Dei Giovi pass to Serravalle and the Turchino pass to Ovada. The connection of the harbour with the hinterland is, however, made very difficult by the presence of the Apennines. There is a marshalling station, connected directly with the harbour by tunnels, at Campasso north of San Pier d'Arena. Genoa is the most important harbour in the western Mediterranean with the exception of Marseilles, with which port it carries on a keen competition.

Bibliography.—Among Genoese chroniclers and historians the most important are Caffarus, J. Bracellus, J. Bonfadio, A. Giustiniani, F. M. Casoni, F. M. Accinelli, C. Varese *(Storia della Repubblica di Genova, dalla sua origine sino al 1814*, 7 vol.; 1835–37) and C. Manfroni. For the social, religious, economic and political history *see* the publications of the *Società Ligure di Storia Patria* (1857–), the Commune, the Chamber of Commerce and the Consorzio Autonomo del Porto. *See* also F. Podestà, *Il Porto di Genova* (1913); G. Monleone and G. Pessagno, *Cristoforo Colombo* (1931, Eng. version, 1932); P. Revelli, *Il Genovese* (1951); O. Grosso, *Genoa* (1950) and other guide books; A Issel, *Liguria geologica e preistorica (1892).* (Ao. B.)

GENOA, CONFERENCE OF (April 10–May 19. 1922). a meeting of representatives of the British dominions and of 29 European states, including not only the Allies and former neutrals, but all the former enemy powers except Turkey (which was excluded on the ground that it was an Asiatic country). Above all, the conference mas attended by representatives of Soviet Russia. and the dominant issue was the renewal of relations between Russia and Europe. Before the conference met. Aristide Briand had been succeeded as premier by Raymond PoincarC. Since the project of the Genoa conference had already been accepted by the supreme council. Poincaré could not reject it altogether, but he sought to interpret the agreed program in the narrowest sense and to hedge the participation of Russia with the fullest possible restrictions. He gave detailed and stringent instructions in this sense to his representative, Louis Barthou.

The general conference was preceded by a meeting between PoincarC and D. Lloyd George at Boulogne, on Feb. 2j, a meeting of Allied economic experts in London from March 20 to 28, which drew up detailed agenda for Genoa, and two other preliminary meetings of a regional character, one between the members of the little entente at Belgrade, and another at Warsaw between Poland, Latvia, Estonia and Finland. The parties represented at Warsaw subsequently conferred at Riga with representatives of Soviet Russia. The invitation to Genoa was accepted by the Soviet government with alacrity. but was declined by the United States.

The conference set up four commissions, the first to examine methods of putting into practice the principles of the Cannes resolution of Jan. 6, 1922 (see Cannes, Conference of), while the other three were to deal respectively with financial subjects. economic and commercial subjects and transport. These three latter commissions all reported before the conference came to an end; but their reports were bound to remain academic unless the first commission achieved positive results. The task of the first commission was more difficult, because it was general and political in character, and its work was soon suspended in favour of informal discussions between the three principal Allied powers and Belgium on the one side and the Russians on the other. Meanwhile the Germans signed. on April 16, a separate treaty with the Russians at Rapallo (*q.v.*), in which the objects of the Genoa conference were achieved as between these two parties by a mutual renunciation of reparation claims and a resumption of normal consular and diplomatic relations.

This separate Soviet-German treaty damaged the general prospects of the conference by the fear it instilled into the Allies. In these circumstances there was little prospect of success for a general pact of nonaggression, which Lloyd George suggested on April 25. But the conference actually broke down through the intransigence of Belgium, which insisted upon the integral restitution of foreign-owned private property in Russia. France supported the Belgian contention. Eventually a formula on the British lines was carried, even Belgium finally giving way; but it was so evident that, with Great Britain and France divided, no positive result could be achieved, that the Genoa conference was quietly wound up by remitting its agenda to a mixed commission of experts, who duly met at The Hague from June 26 to July 20, 1922, but also foundered on the rock of foreign-owned private property in Russia.

The Genoa conference was interesting because economic and financial problems were approached from the point of view of reconstruction, and not of reparation. It was also the first attempt at a settlement between the European governments and Soviet Russia.

See Sir C. Gordon and E. Montpetit, *The Genoa Conference,* Joint Report of the Canadian Delegates *(1922)*; J. S. Mills, *The Genoa Conference (1922).*

GENOVESI, ANTONIO (1712–1769), Italian philosopher and economist who proposed reforms in the kingdom of Naples in a spirit that sought to combine the ideas of the Enlightenment with an extremely radical Christianity, was born at Castiglione, near Salerno. on Nov. 1. 1712. Ordained priest in 1737, he went to Naples in 1738 and was in 1741 appointed to teach metaphysics in the university there. His *Disciplinarum metaphysicarum elementa* (1743–52) incurred some suspicion of heresy, and in 1748 he decided not to publish the companion work on theology (his treatises on logic and on physics had both appeared in 1745). In

1753, however, he dedicated his *Discorso sopra* alcuni trattati *d'agricoltura* . . . in cui si tratta del vero fine delle lettere to the influential Bartolomeo Intieri, with the result that in 1754, when Intieri founded at Naples the first European chair of "commerce and mechanics" (*i.e.,* political economy), he stipulated that Genovesi should be its first occupant. Thenceforward Genovesi wrote and lectured mainly in Italian instead of Latin. His subsequent publications included Meditazioni *filosofiche* sulla religione e sulla morale (1758), Lettere accademiche (1764) and, most important of all, Delle *lezioni* di *commercio* (1765; new ed., 1768), the first Italian work on his subject. Genovesi died in Naples on Sept. 23, 1769.

For his metaphysics Genovesi took much from Leibnizian monadism. His theory of knowledge was largely empiricist. His mercantilist system of economics is distinguished by his remarkable analysis of demand, by his high valuation of labour and by his efforts to reconcile protectionism with free competition. In the political field his contention that ecclesiastical authority should be strictly limited to spiritual matters and that the state should dispossess the clergy and religious orders of their lands was most welcome to Bernardo Tanucci's "enlightened" administration in Naples.

See E. Gambini, Antonio Genovesi (1910); G. Monti, Due grandi riformatori del settecento (1926); A. Tisi, *Il* Pensiero religioso *d'Antonio* Genovesi (1932).

GENRE PAINTING has primarily to do with a type of subject, but the proper application of the term is limited also by the painter's attitude toward the subject. (See also STILL-LIFE PAINTING.) In genre painting, intimate scenes and subjects from ordinary daily life are dealt with. The elimination of imaginative content focuses attention upon the shrewd observation of types. costumes and settings and upon the beauty and appropriateness of colour, form and texture. In true genre painting such subjective qualities as the dramatic, historical, ceremonial, satirical, didactic, romantic, sentimental and religious should be reduced to a minimum. Characteristic works by Jan Steen, Honoré Daumier, Thomas Rowlandson and William Hogarth would thus be too satirical or didactic to be called genre, while those of Francis Wheatley, George Morland and J. H. Fragonard would be too sentimental and those of J. F. Millet too romantic.

In Europe, genre painting does not begin clearly to emerge until the late middle ages, when illuminated calendars showing the occupations appropriate to the months or seasons are found in manuscript books (see ILLUMINATED MANUSCRIPTS). These little genre pictures give intimate glimpses of the life of the time. Soon the taste for genre became so keen that Petrus Christus, Pieter Aertsen and Pieter Brueghel painted scenes in shops and kitchens occasionally thinly disguised as religious subjects. The greatest home of genre painting was indeed 17th-century Holland, when Adriaen van Ostade, Gerard Dou, Gabriel Metsu, Jan Vermeer, Pieter de Hooch and Gerard Terborch flourished. Among later exponents are J. B. S. Chardin in France and Pietro Longhi in Italy. Although in modern times colour photography has practically usurped the place of genre painting, the term might include interiors by Jean Édouard Vuillard and Pierre Bonnard, leaders of the French *Intimiste* school, and similar works by Henri Matisse.

(D. L. FR.)

GENTIAN, botanically Gentiana, a large genus of herbaceous plants belonging to the family Gentianaceae (*q.v.*). The genus comprises about 400 species, most of them perennial plants with tufted growth, growing in hilly or mountainous districts, chiefly in the northern hemisphere, but also in New Zealand and South America. The leaves are opposite, entire, smooth and often strongly ribbed. The flowers have a persistent four- to five-lobed calyx and a four- to five-lobed tubular corolla; the stamens are equal in number to the lobes of the corolla. The ovary is onecelled, with two stigmas, either separate and rolled back or contiguous and funnel shaped. The fruit when ripe separates into two valves and contains numerous small seeds. The majority of species are remarkable for the deep or brilliant blue colour of their blossoms, comparatively few having yellow, white or, more rarely, red flowers; the last are almost exclusively found in the Andes.

About 60 species occur in North America, widely distributed throughout the continent, but most numerous in the Rocky mountain region. Of about 18 species found from the Great Plains eastward, among the best known are the fringed gentian (G. *crinita*), one of the most beautiful American wild flowers; the closed or bottle gentian (G. andrewsii), the commonest species; the downy gentian (G. *puberula*), of the prairie region; and the stiff gentian or agueweed (G. *quinquefolia*), which extends southward to Florida. Of the many Rocky mountain species, those with fringed flowers, as G. elegans and G. barbellata, are among the most conspicuous. Representative of the 12 or more species found in California and northward in the coastal mountains are the single-flowered gentian (G. simplex), with slightly fringed flowers, and the explorer's gentian (*G.* calycosa), which throughout the summer forms sheets of intense blue in alpine meadows from California to British Columbia and eastward to Montana.

There are ten species of gentian native to Great Britain. Three of them are perennials belonging to the genus Gentiana, while seven, all of which are annuals or biennials, are credited to the genus Gentianella, a name preferred by British botanists for annual and biennial gentians but not widely accepted in the United States.

Of the perennial species the marsh gentian (Gentiana *pneumonanthe*), also called the Calathian violet, is six to nine inches high, has blue flowers and is rather rare from Cumberland to Dorsetshire. The spring gentian (G. verna) and the small gentian (G. *nivalis*) are much lower plants, have bright blue flowers and are more widely distributed throughout the British Isles.

The annual or biennial gentians of the genus Gentianella comprise the felwort (G. amarella), often called autumn gentian, which has dull purple flowers and is widely distributed; G. *campestris,* two to nine inches high, with blue or white flowers and found throughout Great Britain; G. anglica, confined to southern England, has purple flowers and is only three to five inches high; *G. uliginosa,* a low annual, rare in Pembroke and Glanmorgan; and G. germanica, a biennial, with blue flowers, rather common on calcareous grasslands throughout Great Britain.

Some of these, but more especially the much finer species from North America, the Himalayas, Burma, Tibet, China and Japan, are much cultivated for ornament in England, where over 150 species are known. Less than 50 of these are much grown in the United States, where the climate is far less suited to gentians than that of England. None of them is particularly easy to grow, and many of them need the specialized conditions of scree or moraine in the rock gardens. All require coolness and moisture, especially the perennials.

Several preparations obtained from the root of Gentiana lutea are used in medicine to stimulate the alimentary tract, thus improving digestion. The chief of these is compound gentian tincture, comprising 100 g. of powdered gentian root, 40 g. of bitter orange peel and 10 g. of cardamom seed, mixed with glycerin, alcohol and water. In Germany and France other species of gentian, notably G. *purpurea,* G. punctata and *G. pannonica,* are sometimes permitted substitutes of G. lutea.

G. lutea is a large handsome plant three or four feet high, growing in open grassy places on the Alps, Apennines and Pyrenees, as well as on some of the mountainous ranges of France and Germany, extending as far east as Bosnia and Asia Minor. It has large, oval, strongly ribbed leaves and dense whorls of conspicuous yellow flowers. Its use in medicine is of very ancient date. Pliny and Dioscorides mention that the plant was noticed by Gentius, a king of the Illyrians, living 180–167 B.C., from whom the name Gentiana is supposed to be derived. During the middle ages it was much employed in the cure of disease, and as an ingredient in counterpoisons. In 1552 Hieronymus Bock (Tragus), a German priest, physician and botanist, mentions the use of the root as a means of dilating wounds.

The root is tough and flexible, scarcely branched and of a brownish colour and spongy texture. It has a pure bitter taste and faint distinctive odour. The bitter principle, known as gentianin, is a glucoside, soluble in water and alcohol. It can be decomposed into glucose and gentiopicrin by the action of dilute mineral acids. It is not precipitated by tannin or subacetate of lead. A solution of caustic potash or soda forms with gentianin a yellow solution, and the tincture of the root to which either of these alkalis has been added loses its bitterness in a few days. Gentian root also contains gentianic acid, which is inert and tasteless. It forms pale yellow, silky crystals, very slightly soluble in water or ether but soluble in hot strong alcohol and in aqueous alkaline solutions. This substance is also called gentianin, gentisin and gentisic acid.

The root also contains 12% to 15% of an uncrystallizable sugar called gentianose, of which fact advantage has long been taken in Switzerland and Bavaria for the production of a bitter cordial spirit called Enzianbranntwein. The use of this spirit, especially in Switzerland, has sometimes been followed by poisonous symptoms, which have been doubtfully attributed to inherent narcotic properties possessed by some species of gentian, the roots of which may have been indiscriminately collected with it, but it is quite possible that it may be due to the contamination of the root by that of hellebore (Veratrum album), a poisonous plant growing at the same altitude and having leaves extremely similar in appearance and size to those of G. lutea. See VERATRUM; HELLEBORE. (N. TR.)

GENTIANACEAE (GENTIAN FAMILY), of subclass Sympetalae of dicotyledons, includes some of the most beautiful flowering plants of woodlands, meadows and moors. The fringed gentian (Gentiana crinita) is a popular favourite but the Andean genus Lagenanthus, with showy scarlet tubular flowers four to five and a half inches long, is virtually unknown. The family contains about 1,000 species in 80 genera; mostly temperate or montane in all continents except Africa, with epicentres in the Alps, Himalayas, western North America and the Andes; mostly annual or perennial herbs of erect tufted habit by the repeatedly dichotomous branching. Less frequent growth forms include vines (Cuban genus Goeppertia and Asiatic Crawfurdia), rhizomatous perennials (Menyanthes, etc.), water lilylike aquatics (Nymphoides, etc.), weedy short-lived annuals (Centaurium, Hoppea, etc.), ericoid subshrubs (Enicostema) and shrubs attaining a height of 12 ft. or more (Macrocarpaea, Symbolanthus). Rock gardeners value low, clump-forming alpines (Gentiana acaulis, bavarica, etc.) displaying large campanulate flowers of intense shades of blue. Cytologically the family is prevailingly polyploid, with recorded diploid base numbers of 5, 7, 9 and 13.

1. HORACE MCFARLAND CO.
FRINGED GENTIAN (GENTIANA CRINITA)

The leaves are generally in two-ranked opposite pairs, smooth and shining, the margins without teeth, rarely in whorls (Curtia and Frasera) or trifoliate (Menyanthes). Reduced scalelike leaves occur in anomalous genera of slender nongreen saprophytes (Voyria, etc.); these are often confused with Burmanniaceae. The inflorescence is generally cymose, but the flowers may be densely spicate (Coutoubea spicata) or even solitary (some true gentians). The flowers are perfect and regular with parts in fives (less often in fours), the pistil bicarpellate (uniloculate in Menyanthes and allies). The sepals generally form a tubular calyx, but in the primitive neotropical genus *Chorisepalum* they are separate. The corolla varies widely but is plaited or smooth, and most often bell shaped, funnelform or salverform, or sometimes rotate (British genus Chlora). Yellow is the primitive flower colour, retained in Gentiana lutea, but more numerous are species that have evolved with hues from pale blue to ultramarine. The throat is frequently provided with fringed scales, nectaries, appendages or colour streaks (nectar guides). Stamens, which equal in number but alternate with the corolla segments, are inserted at various levels on the tube, the slender filaments bearing delicate versatile anthers which dehisce by longitudinal slits. In Centaurium the stamens coil tightly after anthesis. Exceptional variation in pollen grains occurs among genera but this character is evidently not closely correlated with any other floral character although it has been used unsatisfactorily in support of phylogenies. Gelatinous pollen is produced in Gentiana *parryi* and others, where the orientation of the anthers may vary between the closed gentian type and those species with open corollas. The style, which may be short to long, undivided or bilobed, usually terminates in a distinct stigma. Placentation is parietal. The superior ovary contains numerous anatropous (or half-anatropous) ovules; these mature into minute seeds, each provided with copious endosperm in which the small embryo is embedded.

Insect pollination is general in the family. Both oligotropic species (*i.e.,* obligate to specific insects), for example, Gentiana subgenus Cyclostigma where such long-tongued Lepidoptera as the diurnal hawk moths are vecters, and facultative species (*i.e.,* non-obligate), for example, Gentiana lutea where the nectar is accessible to all visitors, are recognized. Although Centaurium and Chlora are nectarless, they are visited by Lepidoptera; perhaps here the twisting of the stamens which are easily intercepted by the insect aids in pollination. Dimorphism obtains in Menyanthes, Nymphoides and some true gentians. It has been observed in the dimorphic Menyanthes that when only long-styled flowers occur in a marsh, ripe fruits fail to be produced.

Bitter principles are widespread in the vegetative parts, especially in the rhizomes and roots, and have fostered their use in medicine; *e.g.,* in Gentiana lutea and others. See GENTIAN. (J. A. EN.)

GENTILE, GIOVANNI (1875–1944), Italian philosopher and politician, was born at Castelvetrano (Trapani) on May 30, 1875. He studied literature and philosophy at the University of Pisa and, after a series of university appointments, became in 1917 professor of the history of philosophy in the University of Rome. From 1903 to 1922 he collaborated with Benedetto Croce in editing the periodical La *Critica.* Though he soon developed a philosophy of his own, he remained a friend of Croce until 1924, when they disagreed over Fascism. As minister of education in the Fascist government from Oct. 1922 to July 1924, Gentile carried out an organic reform of Italian education; and as president of two commissions for the reform of the constitution he contributed to laying the foundations of the Fascist corporative state (1925). Later, though he was made president of the supreme council of education (1926–28), a member of the Fascist grand council (1925–29) and president of various cultural institutions, his political influence steadily declined. From 1925 to 1943 he planned and edited the Enciclopedia *Italiana.* After Sept. 8, 1943, he adhered to the Fascist government established at Salò and was made the president of the Accademia d'Italia. He was killed in Florence by anti-Fascist partisans on April 15, 1944.

Gentile's philosophy is an extreme form of monistic idealism. He denies the existence of individual minds and of any distinction between theory and practice, subject and object, past and present. blind is the absolute, and education is the process of revelation of the absolute. In this sense education is always self-education and is ultimately identical with philosophy. Gentile's interest in education and his warm and forceful style of writing explain his great popularity among teachers and educational reformers before 1935. Later his pupils went their own ways; their views continued to be expressed in the Giornale critico della filosofia italiana, founded by Gentile in 1920.

Among Gentile's numerous works, which include editions of Giordano Bruno, Tommaso Campanella, G. B. Vico, Vincenzo Cuoco. Antonio Rosmini, Vincenzo Gioberti and Spinoza (with a commentary) and a translation of Kant's Krifik der *reinen Vernunft,* are: La filosofia di Marx (1899); Dal Genovesi *al Galluppi* (1903), a volume of the Storia della filosofia italiana; *Il* modernismo (1909); Bernardino Telesio (1911); I problemi della scolastica e *il pensiero italiano* (1913); La riforma della dialettica hegeliano (1913); Sommario di pedagogia come scienza *filosofica,* 2 vol. (1913–14); *Teoria generale dello spirito come atto puro* (1916; Eng. trans., *Theory of Mind as Pure Act,* 1922); *I fondamenti della filosofia del diritto* (1916); *Sistema di logica come teoria del conoscere* (1917–23); *Le origini della filosofia contemporanea in Italia,* 4 vol. (1917–23); *Il problemo scolastico del dopoguerra* (1920); *La riforma dell' educazione* (1920; Eng. trans., *The Reform of Education,* 1923); *Studi sul Rinascimento* (1923); *Bertrando Spaventa* (1924); *Il fascismo al governo della scuola* (1924); *Che cosa è il fascismo* (1925); *Manzoni e Leopardi* (1928); *La filosofia dell' arte* (1931); *Memorie italiane* (1936); and *La mia religione* (1943). (A. D. Mo.)

GENTILE, in the English Bible, the term generally applied to those who were not of the Jewish race. It is an adaptation of the Lat. *gentilis,* of or belonging to the same *gens,* "the clan" or "family." In post-Augustan Latin *gentilis* meant "national," belonging to the same race. Later it meant "foreign," *i.e.,* other than Roman, and was used in the Vulgate with *gentes,* to translate the Hebrew *goyyim,* "nations," the non-Israelitish peoples. It is also used by Mormons of all who are not Mormons. (A. L. W.)

GENTILE DA FABRIANO (*c.* 1370–1427), Italian painter, was the first great Umbrian master. He was born at Fabriano and about 1411 went to Venice, where by order of the doge and senate he was engaged to adorn the great hall of the palace with frescoes from the life of Barbarossa. He executed this work so entirely to the satisfaction of his employers that they granted him a pension for life and accorded him the privilege of wearing the habit of a Venetian noble. These paintings, which influenced the development of Venetian art, are unfortunately no longer extant. About 1320 Gentile went to Florence, where in 1423 he painted an "Adoration of the Magi" for the church of Sta. Trinita, which is preserved in the Gffizi at Florence and is considered his best work now extant. Another fine example of his work is a "Madonna and Child" (1425), the central panel of an altarpiece, in Buckingham palace, London. The wings of this altarpiece are in the Uffizi. Gentile attained a wide reputation, and was engaged to paint pictures for various churches, more particularly Brescia, Siena. Perugia and Orvieto. In 1427 he was called to Rome by Pope Martin V to adorn the church of St. John Lateran with frescoes. Michelangelo said of him that his works resembled his name, meaning noble or refined. They are full of a quiet joyousness, and show a naïve delight in splendour and in gold ornaments.

GENTILESCHI (Lomi), **ARTEMISIA** and **ORAZIO,** Italian painters.

Orazio Gentileschi (*c.* 1562–*c.* 1647) is commonly named Orazio Lomi de' Gentileschi. He was born in Pisa and studied under his half brother Aurelio Lomi. He afterward went to Rome and painted frescoes in Sta. Maria Maggiore, in the Lateran and in S. Niccolo in Carcere; he was associated with the landscape painter Agostino Tassi, executing the figures for the landscapes of this artist. Among his best works are: "The Circumcision" in the church of Gesu at Ancona; "The Madonna and St. Clara" in the Casa Rosei at Fabriano; "The Annunciation" in S. Siro, Genoa; "The Finding of Moses" in the Prado, Madrid; "SS. Cecilia and Valerian" in the Brera. Milan; a "Flight Into Egypt" in the Louvre, Paris, and another in the Belvedere, Vienna; and "Joseph and Potiphar's Wife" at Hampton court. At an advanced age Gentileschi went to England at the invitation of Charles I, being employed in the palace at Greenwich. Van Dyck included him in his portraits of a hundred illustrious men. His works generally are strong in shadow and positive in colour. He died in England about 1647.

Artemisia Gentileschi (1597–after 1651), Orazio's daughter, studied first under Guido Reni, acquired much renown for portrait painting and considerably excelled her father's fame. She was a beautiful and elegant woman; her likeness, painted by her own hand, is to be seen in Hampton court. Her most celebrated composition is "Judith and Holofernes," Wadsworth Atheneum. Hartford, Conn., certainly a work of singular energy. She went to England about 1638 and painted many portraits there. Artemisia refused an offer of marriage from Agostino Tassi and married Pier Antonio Schiattesi, continuing, however, to use her own surname. She settled in Naples, to which she returned from England, and was commissioned to paint three pictures for the cathedral of Pozzuoli. Her style was violent. characterized by brilliant colour.

GENTILI, ALBERICO (1552–1608), Italian jurist who has great claims to be considered the founder of the science of international law, was born on Jan. 14, 1552. at San Ginesio, Macerata, Italy. After taking the degree of doctor of civil law at the University of Perugia, and holding a judicial office at Ascoli, he returned to San Ginesio and was entrusted with the task of recasting its statutes. In 1579, however, as a result of his Protestant opinions, he was obliged to flee, first to Carniola in Austria and then to England. By the autumn of 1580 he had reached Oxford, and shortly afterward was qualified to teach by being admitted to the same degree which he had taken at Perugia. His lectures on Roman law soon became famous. The dialogues, disputations and commentaries which he published henceforth in rapid succession established his position as a civil lawyer and secured his appointment in 1587 to the regius professorship of civil law. It was, however, by his application of the old learning to the new questions suggested by modern international relations that Gentili produced his most lasting results. In 1584 he was consulted by the government as to the proper course to be pursued with Bernardino de Mendoza, the Spanish ambassador, who had been detected in plotting against Elizabeth I. Shortly afterward he developed his opinion on this question into a book, the *De legationibus libri tres* (1585). In 1588 Alberico published in London the *De jure belli commentatio prima.* A second and a third *Commentatio* followed, and the whole of this material, with many additions and improvements, appeared at Hanau, Prussia, in 1598 as the *De jure belli libri tres.* It nas doubtless in consequence of the reputation gained by these uorks that Gentili became henceforth more and more engaged in forensic practice, resided chiefly in London and left his Oxford work to be partly discharged by a deputy. In 1600 he was admitted to Gray's Inn, and in 1605 was appointed standing counsel to the king of Spain. He died on June 19. 1608, and was buried in the churchyard of St. Helen's, Bishopsgate. His notes of the cases in which he was engaged for the Spaniards were posthumously published in 1613 at Hanau as *Hispanicae advocationis libri duo.* This was ın accordance with his last wishes; but his direction that the remainder of his manuscripts should be burned was not complied nith Fifteen volumes of them found their way, in 1805, from Amsterdam to the Bodleian library at Oxford.

In contrast with earlier writers who had dealt with various international questions singly and with submission to the decisions of the church, Gentili examined as a whole the relations of states to one another and attempted the solution of the problems involved by principles entirely independent of the authority of Rome. He used the reasonings both of the civil and of the canon law, combined them with the *Jus Naturae* and identified this with the consent of the majority of nations, by which historical precedents were to be criticized and, when this appeared to be necessary, set aside.

His writings have many faults. His style is prolix, obscure and to the modern reader pedantic; but a comparison of the De jure belli with the treatises of Pierino Belli. Dominico Soto or even Balthasar Ayala shows that he greatly improved upon his predecessors, not only by the fullness with which he worked out points of detail, but also by clearly separating the law of war from martial law, and by placing the subject upon a foundation independent of theological differences. A comparison of the same work with the De *jure* belli ac *pacis* (1625) of Hugo Grotius, moreover, reveals the latter's indebtedness to Gentili not only for much of his illustrative erudition but also for what is commendable in his method and arrangement.

The principal works on international law by Gentili have been republished and translated in the "Classics of International Law Series" on behalf of the Division of International Law of the Carnegie Endowment for International Peace: De legationibus libri tres, two volumes, English translation by G. J. Laing, introduction by E Nys (1924); De *jure* belli libri tres, two volumes, English translation by J. C. Rolfe, introduction by C. Phillipson (1933); and Hispanicae advocationis libri duo, two volumes. English translation and introduction by F. F. Abbott (1921). (T. E. HD.; X.)

GENTILI, LUIGI (ALOYSIUS BONAVENTURA FRANCESCO CAMILLUS GENTILI) (1801–1848), Italian Roman Catholic missionary to England, was born in Rome on July 14. 1801, the son of a Roman lawyer. As a young advocate, Gentili showed strong social ambitions, especially among the aristocratic English colony in Rome, and taught languages privately with notable success. But he suddenly abandoned society to join Antonio Rosmini-Serbati (*q.v.*) in 1830 in his new Institute of Charity. which trained priests dedicated to special duties. In 1835 Gentili went to England, at the request of Bishop P. A. Baines, to assist in organizing the new Roman Catholic college at Prior Park. near Bath. Later (1840) he went to Leicestershire, to undertake missionary work in the district surrounding Grace Dieu. which Ambrose Phillipps had made the focus of a Roman Catholic revival. Through Phillipps, Gentili became acquainted with the leaders of the Tractarian movement at Oxford. Gentili's great gifts as a preacher led to demands for his services all over England, particularly in the new industrial cities, which contained large numbers of Irish immigrants. In 1846 he was appointed an itinerant missionary, to work in England and Ireland. On a mission in the Dublin slums in 1848 he contracted cholera and died on Sept 28 of that year. In addition to bringing the Rosminians to England and Wales, Gentili was responsible for introducing in England such popular devotions as the Stations of the Cross and the Forty Hours exposition of the Blessed Sacrament.

See D. R. Gwynn, Father Luigi Gentili and His Mission (*1801–1848*) (1951). (D. *G.)*

GENTLEMAN, in its original and strict signification, a term denoting a man of good family (from Lat. gentilis, "belonging to a race or gens," and "man"; the Lat. *generosus* [its invariable translation in English-Latin documents]). In this sense it is the equivalent of the Fr. gentilhomme, "nobleman," which latter term has in Great Britain been long confined to the peerage (*q.v.*): and the term "gentry" ("gentrice" from O.Fr. *genterise* for gentelise) has much of the significance of the Fr. noblesse or the Ger. *Adel.* Selden (Titles of Honor, 1672), discussing the title "gentleman," speaks of "our English use of it" as "convertible with nobilis," and describes in connection with it the forms of ennobling in various European countries. William Harrison, writing a century earlier. says "gentlemen be those whom their race and blood, or at the least their virtues, do make noble and known." But for the complete gentleman the possession of a coat of arms was in his time considered necessary.

In this way Shakespeare himself was turned, by the grant of a coat of arms, from a "vagabond" into a gentleman.

The fundamental idea of "gentry," symbolized in this grant of coat-armour, had come to be that of the essential superiority of the fighting man; and, as Selden points out (p. 707), the fiction was usually maintained in the granting of arms "to an ennobled person though of the long Robe wherein he hath little use of them as they mean a shield." At the last the wearing of a sword on all occasions was the outward and visible sign of a "gentleman"; and the custom survives in the sword worn with "court dress." This idea that a gentleman must have a coat of arms, and that no one is a "gentleman" without one is, however, of comparatively late growth, the outcome of the natural desire of the heralds to magnify their office and collect fees for registering coats; and the same is true of the conception of "gentlemen" as a separate class. That a distinct order of "gentry" existed in England very early has, indeed, been often assumed, and is supported by weighty authorities. Thus, the late Professor Freeman (Ency. Brit. xvii. p. 540 b, 9th ed.) said: "Early in the 11th century the order of 'gentlemen' as a separate class seems to be forming as something new. By the time of the conquest of England the distinction seems to have been fully established." Stubbs (*Const. Hist.,* ed. 1878, iii. 544, 548) takes the same view. Sir George Sitwell, however, has conclusively proved that this opinion is based on a wrong conception of the conditions of mediaeval society, and that it is wholly opposed to the documentary evidence. Even so late as 1400 the word "gentleman" still only had the sense of generosus, and could not be used as a personal description denoting rank or quality, or as the title of a class. Yet after 1413 we find it increasingly so used; and the list of landowners in 1431, printed in Feudal Aids, contains, besides knights, esquires, yeomen and husbandmen, a fair number who are classed as "gentilman."

Sir George Sitwell gives a lucid explanation of this development. The immediate cause was the statute 1 Henry V. cap. v. of 1413, which laid down that in all original writs of action, personal appeals and indictments, in which process of outlawry lies, the "estate, degree or mystery" of the defendant must be stated, as well as his present or former domicile. Now the Black Death (1349) had put the traditional social organization out of gear. Before that the younger sons of the *nobiles* had received their share of the farm stock, bought or hired land, and settled down as agriculturists in their native villages. Under the new conditions this became increasingly impossible, and they were forced to seek their fortunes abroad in the French wars, or at home as hangers-on of the great nobles. These men, under the old system, had no definite status; but they were generosi, men of birth, and, being now forced to describe themselves, they disdained to be classed with franklins (now sinking in the social scale), still more with yeomen or husbandmen; they chose, therefore, to be described as "gentlemen." On the character of these earliest "gentlemen" the records throw a lurid light. According to Sir George Sitwell (p. 76), "the premier gentleman of England, as the matter now stands, is 'Robert Erdeswyke of Stafford, gentilman,'" who had served among the men-at-arms of Lord Talbot at Agincourt (ib. note). He is typical of his class. "Fortunately — for the gentle reader will no doubt be anxious to follow in his footsteps — some particulars of his life may be gleaned from the public records. He was charged at the Staffordshire Assizes with housebreaking, wounding with intent to kill, and procuring the murder of one Thomas Page, who was cut to pieces while on his knees begging for his life." If any earlier claimant to the title of "gentleman" be discovered, Sir George Sitwell predicts that it will be within the same year (1414) and in connection with some similar disreputable proceedings.

From these unpromising beginnings the separate order of "gentlemen" was very slowly evolved. The first "gentleman" commemorated on an existing monument was John Daundelyon of Margate (d. c. 1445); the first gentleman to enter the House of Commons, hitherto composed mainly of "valets," was "William Weston, gentylman"; but even in the latter half of the 15th century the order was not clearly established. As to the connection of "gentilesse" with the official grant or recognition of coat-armour, that is a profitable fiction invented and upheld by the heralds; for coat-armour was but the badge assumed by gentlemen to distinguish them in battle, and many gentlemen of long descent never had occasion to assume it, and never did. This fiction, however, had its effect; and by the 16th century, as has been already pointed out, the official view had become clearly established that "gentlemen" constituted a distinct order, and that the badge of this distinction was the heralds' recognition of the right to bear arms. It is unfortunate that this view, which is quite unhistorical, has of late years been given a wide currency in popular manuals of heraldry.

In this narrow sense, however, the word "gentleman" has long since become obsolete. The idea of "gentry" in the continental sense of *noblesse* is extinct in England, and is likely to remain so, in spite of the efforts of certain enthusiasts to revive it *(see* A. C. Fox-Davies, *Armorial Families,* Edinburgh, 1895). That it once existed has been sufficiently shown; but the whole spirit and tendency of English constitutional and social development tended to its early destruction. The comparative good order of England was not favourable to the continuance of a class, developed during the foreign and civil wars of the 14th and 15th centuries, for whom fighting was the sole honourable occupation. The younger sons of noble families became apprentices in the cities, and there grew up a new aristocracy of trade. Merchants are still "citizens" to William Harrison; but he adds "they often change estate with gentlemen, as gentlemen do with them, by mutual conversion of the one into the other." A frontier line between classes so indefinite could not be maintained, especially as in England there was never a "nobiliary prefix" to stamp a person as a gentleman by his surname, as in France or Germany. The process was hastened, moreover, by the corruption of the Heralds' College and by the ease with which coats of arms could be assumed without a shadow of claim; which tended to bring the "science of armory" into contempt. The word "gentleman" as an index of rank had already become of doubtful value before the great political and social changes of the 19th century gave to it a wider and essentially higher significance. The change is well illustrated in the definitions given in the successive editions of the *Encyclopedia Britannica.* In the 5th edition (1815) "a gentleman is one, who without any title, bears a coat of arms, or whose ancestors have been freemen." In the 7th edition (1845) it still implies a definite social status: "All above the rank of yeomen." In the 8th edition (1856) this is still its "most extended sense"; "in a more limited sense" it is defined in the same words as those quoted above from the 5th edition; but the writer adds, "By courtesy this title is generally accorded to all persons above the rank of common tradesmen when their manners are indicative of a certain amount of refinement and intelligence."' The Reform Bill of 1832 has done its work; the "middle classes" have come into their own; and the word "gentleman" has come in common use to signify not a distinction of blood but a distinction of position, education and manners. The test is no longer good birth, or the right to bear arms, but the capacity to mingle on equal terms in good society. In its best use, moreover, "gentleman" involves a certain superior standard of conduct, due, to quote the 8th edition once more, to "that self-respect and intellectual refinement which manifest themselves in unrestrained yet delicate manners." The word "gentle," originally implying a certain social status, had very early come to be associated with the standard of manners expected from that status. Thus by a sort of punning process the "gentleman" becomes a "gentle-man." This use develops through the centuries, until in 1714 we have Steele, in the *Tatler* (No. 207), laying down that "the appellation of Gentleman is never to be affixed to a man's circumstances, but to his Behaviour in them," a limitation over-narrow even for the present day. In this connection, too, may be quoted the old story, told by some—very improbably—of James II., of the monarch who replied to a lady petitioning him to make her son a gentleman, "I could make him a nobleman, but God Almighty could not make him a gentleman." Selden in referring to similar stories "that no Charter can make a Gentleman, which is cited as out of the mouth of some great Princes that have said it," adds that "they without question understood Gentlemen for *Gcnerosus* in the ancient sense, or as if it came from *Gentilis* in that sense, as *Gentilis* denotes one of a noble Family, or indeed for a Gentleman by birth." For "no creation could make a man of another blood than he is." The word "gentleman," used in the wide sense with which birth and circumstances have nothing to do, is necessarily incapable of strict definition. For "to behave like a gectleman" may mean little or much, according to the person by whom the phrase is used; "to spend money like a gentleman" may even be no great praise; but "to conduct a business like a gentleman" implies a standard at least as high as that involved in the phrase *"noblesse oblige."* In this sense of a person of culture, character and good manners the word "gentleman" has supplied a gap in more than one foreign language.

The evolution of this meaning of "gentleman" reflects very accurately that of English society; and there are not wanting signs that the process of evolution, in the one as in the other, is not complete. The indefinableness of the word mirrors the indefinite character of "society" in England; and the use by "the masses" of "gentleman" as a mere synonym for "man" has spread *pari passu* with the growth of democracy. It is a protest against implied inferiority, and is cherished as the modern French *bourgeois* cherishes his right of duelling with swords, under the *ancien régime* a prerogative of the *noblesse.* Nor is there much justification for the denunciation by purists of the "vulgarization" and "abuse" of the "grand old name of gentleman." Its strict meaning has now fallen completely obsolete. Its current meaning varies with every class of society that uses it. But it always implies some sort of excellency of manners or morals. **(W. A. P.; X.)**

GENTZ, FRIEDRICH VON (1764–1832), German publicist and statesman, was born at Breslau on May 2, 1764. His father was an official, his mother an Ancillon, distantly related to the Prussian minister of that name. On his father's transference to Berlin, as director of the mint, the boy was sent to the Joachimsthal gymnasium there; his brilliant talents, however, did not develop until, at the university of Konigsberg, he fell under the influence of Kant. But though his intellect was sharpened and his zeal for learning quickened by the greater thinker's influence, Kant's "categorical imperative" did not prevent him from yielding to the taste for wine, women and high play which pursued him through life.

His interest in public affairs was first aroused by the outbreak of the French Revolution, which he greeted at first with enthusiasm; but its subsequent developments cooled his ardour and he was converted to more conservative counsels by Burke's *Essay on the French Revolution,* a translation of which into German (1794) was his first literary venture. This was followed (1795) by translations of works on the Revolution by Mallet du Pan and Mounier. He also founded and edited a monthly journal, the *Neue deutsche Monatssckrift,* in which for five years he wrote, mainly on historical and political questions, maintaining the principles of British constitutionalism against those of revolutionary France. The knowledge he displayed of the principles and practice of finance was especially remarkable. His literary output at this time, all inspired by a moderate Liberalism, included an essay on the results of the discovery of America, and another, written in French, on the English financial system *(Essai sur l'état de l'administration des finances de la Grande-Bretagne,* London, 1800). Especially noteworthy, however, was the *Denkschrift* or *Missive* addressed by him to Frederick William III on his accession (1797), in which, *inter alia,* he urged upon the king the necessity for granting freedom to the press and to commerce. Opposition to France was the inspiring principle of the *Historisches Journal* founded by him in 1799–1800, which once more held up English institutions as the model, and became in Germany the mouthpiece of British policy toward the revolutionary aggressions of the French republic. In 1801 he ceased the publication of the *Journal,* and issued instead, under the title *Beiträge zur Geschichte,* etc., a series of essays on contemporary politics. The first was *Uber den Ursprung und Charakter des Krieges gegen die franzosische Revolution* (1801), by many regarded as Gentz's masterpiece.

This activity brought him reputation and gifts of money from the British and Austrian governments; but it made his position as an official in Berlin impossible, for the Prussian government had no mind to abandon its attitude of cautious neutrality. A separation from his wife also made it desirable for Gentz to leave the Prussian service. In May 1802, accordingly, he took leave of his wife and left with his friend Adam Miiller for Vienna. In Berlin he had been intimate with the Austrian ambassador, Count Stadion, whose good offices procured him an introduction to the emperor Francis. The immediate result was the title of imperial councillor, with a yearly salary of 4,000 gulden (Dec. 6, 1802); but he was not actively employed until 1809 Before returning to Berlin to make arrangements for transferring finally to Vienna, Gentz paid a visit to London, where he made the acquaintance of Pitt and Granville, who guaranteed him an annual pension by the British government in recognition of the value of his writings against Bonaparte. From this time forward he was engaged in a ceaseless polemic against every fresh advance of the Napoleonic power and pretensions; he denounced the recognition of Napoleon's imperial title, and drew up a manifesto of Louis XVIII against it. The formation of the coalition and the outbreak of war for a while raised his hopes, in spite of his lively distrust of the competence of Austrian ministers; but the hopes were speedily dashed by Austerlitz and its results. Gentz used his enforced leisure to write a brilliant essay on "The relations between England and Spain before the outbreak of war between the two powers" (Leipzig, 1806); and shortly afterward appeared Fragmente aus der neuesten Geschichte des *politischen Gleichgewichts* in *Europa* (trans. Fragments on the Balance of Power in Europe, London, 1806). This latter, the last of Gentz's works as an independent publicist, was a masterly expose of the actual political situation, and at the same time prophetic in its suggestions as to how this should be retrieved: "Through Germany Europe has perished, through Germany it must rise again."

He realized that the dominance of France could only be broken by the union of Austria and Prussia, acting in concert with Great Britain. He watched with interest the Prussian military preparations and, at the invitation of Count Haugwitz, went at the outset of the campaign to the Prussian headquarters at Erfurt, where he drafted the King's proclamation and his letter to Napoleon. The writer was known, and it was in this connection that Napoleon referred to him as "a wretched scribe named Gentz, one of those men without honour who sell themselves for money." In this mission Gentz had no official mandate from the Austrian government, and whatever hopes he cherished of privately influencing the situation in the direction of an alliance between the two German powers were dashed by the Jena campaign.

The downfall of Prussia left Austria the sole hope of Germany and of Europe. Gentz, who from the winter of 1806 onward divided his time between Prague and the Bohemian watering-places, occupied himself with a series of essays on the future of Austria and the best means of liberating Germany and redressing the balance of Europe.

In 1809, on the outbreak of war between Austria and France, Gentz was for the first time actively employed by the Austrian government under Stadion; he drafted the proclamation announcing the declaration of war (April 15), and during the continuance of hostilities his pen was ceaselessly employed. But the peace of 1810 and the fall of Stadion once more dashed his hopes, and he again retired to Prague. It was not till 1812 that there sprang up between him and Metternich the close relations that were to ripen into life-long friendship. But when Gentz returned to Vienna as Metternich's adviser. he was no longer the fiery patriot who had sympathized and corresponded with Stein in the darkest days of German depression and called upon all Europe to free itself from foreign rule. Disillusioned and cynical. though clear-sighted as ever, he was henceforth before all things an Austrian, more Austrian on occasion even than Metternich; as when, during the final stages of the campaign of 1814, he expressed the hope that Metternich would substitute "Austria" for "Europe" in his diplomacy and secure an Austro-French alliance by maintaining the husband of Marie Louise on the throne of France.

From 1812, for ten years Gentz was in closest touch with all the great affairs of European history, the assistant, confidant and adviser of Metternich. He accompanied the chancellor on all his journeys; was present at all the conferences that preceded and followed the war; no political secrets were hidden from him; and he drafted all important diplomatic documents. He was secretary to the congress of Vienna (1814–1815) and to all the congresses and conferences that followed, up to that of Verona (1822). and his vast knowledge of men and affairs made him a power. He was under no illusion as to their achievements; his memoir on the work of the congress of Vienna is at once an incisive piece of criticism and a monument of his own disillusionment. But the liberalism of his early years was gone and he had become reconciled to Metternich's view that, in an age of decay, the sole function of a statesman was to "prop up mouldering institutions." It was the hand of the author of that offensive Missive to Frederick William III, on the liberty of the press, that drafted the Carlsbad decrees; he inspired the policy of repressing the freedom of the universities; and noted in his diary as "a day more important than that of Leipzig" the session of the Vienna conference of 1819, in which it was decided to make the convocation of representative assemblies in the German states impossible, by enforcing the letter of article XIII of the Act of Confederation. He died June 9, 1832.

Gentz has been described as a mercenary of the pen, but he was more than the "wretched scribe" sneered at by Napoleon. That he was in the habit of receiving gifts from all who hoped for his backing is beyond dispute. Yet he never made any secret of these gifts; Metternich was aware of them, and he never suspected Gentz of writing or acting in consequence against his convictions. No man was more free or outspoken in his criticism of the policy of his employers than this apparently venal writer.

Indeed, the very impartiality and objectivity of his attitude make the writings of Gentz such illuminating documents for the period. Allowance must of course be made for his point of view, but less so perhaps than in the case of any other writer so intimately concerned with the policies which he criticizes.

A selection ot Gentz's works (*Ausgewählte Schriften*) was published by Weick in 5 vol. (1836–38); his lesser works (Mannheim, 1838–40) in 5 vol. and *Mémoires* et lettres *inédites* (Stuttgart, 1841) were edited by G. Schlesier. Subsequently there have appeared Briefe an *Chr. Garve* (Breslau, 1857), correspondence (*Briefwechsel*) with Adam Muller (Stuttgart, 1857); Briefe an Pilat, 2 vol. (Leipzig, 1868), Aus dem *Nachlass Friedrichs* von Gentz, 2 vol., ed. Count Anton Prokesch-Osten (Vienna, 1867); *Aus* der alten Registratur der *Staats-Kanzlei*; Briefe *politischen Inhalts* von und an Frzedrzch von *Gentz,* edited by C. von Klinckowström (Vienna, 1870); *Dépêches inédites du* chev. de Gentz *aux* Hospodars de *Valachie 1813–1828* (a correspondence on current affairs commissioned by the Austriar government), ed. Count Anton von Prokesch-Osten the younger, 3 vol. (Paris, 1876), incomplete, but partly supplemented in *Oesterreichs Teilnahme an* den *Befreiungskriegen* (Vienna, 1887), a collection of documents of the greatest value; *Zur* Geschtchte *der orientalischen* Frage: *Briefe aus* dem *Nachlass* Friedrtchs von Gentz (Vienna, 1877), ed. Count Prokesch-Osten the younger; Briefe von und an *Friedrich* von Gentz, ed F. C. Wittichen, 4 vol. (1909–13). Finally Gentz's diaries, from 1800 to 1828, an invaluable mine of authentic material, were edited by Varnhagen von Ense and published after his death under the title Tagebucher, etc. (Leipzig, 1861), new ed, 4 vol. (Leipzig, 1873).

GENUS, a category of classification ranking between the family and the species. used in biology to include a group of structurally or phylogenetically related species, or sometimes consisting of an isolated species showing unusual differentiation (monotypic genus, as *Rhoeo* discolor). Thus the species of roses collectively form the genus *Rosa*, of horses and zebras, the genus *Equus*. The genus name is the first word of a binomial scientific name and is always capitalized. *See* SPECIES. (J. M. BL.)

GEOCHEMISTRY. Geochemistry is the study of the chemistry of the earth. Chemists, geologists and geochemists have presented various definitions of the scope of geochemistry, some of which are greatly divergent, but Victor M. Goldschmidt gave the most precise definition. He formulated the three tasks of geochemistry as follows: (1) to establish the terrestrial abundance relationships of elements; (2) to account for the terrestrial distribution of elements in the geochemical spheres, for instance, in minerals and rocks of the lithosphere and in natural products of various kinds; and (3) to detect the laws governing the abundance relationships and the distribution of elements. Still another task of geochemistry is the study of the chemical evolution of the earth.

C. F. Schönbein, in 1838, was the first to use the name geochemistry. He also mapped out a program for research. K. G. Bischof and J. Roth discussed extensively the field and problems of geochemistry in books published in 1847–54 and 1879–93, respectively. F. W. Clarke and H. S. Washington, V. L. Vemadsky and A. E. Fersman, G. von Hevesy, Ida and W. Noddack and P. Niggli were among the scientists who contributed toward the making of modern geochemistry. From the 1930s, there developed a worldwide interest in the various branches of the science which is closely allied to physics, chemistry, astrophysics, geology and the biological sciences.

Further discussion of theories and concepts involved in the study of geochemistry will be found in the articles CRYSTALLOGRAPHY and MINERALOGY. Crystallization processes which are basic to understanding the geochemistry of the earth's crust are also discussed in PETROLOGY and in articles on various rocks and minerals, as FELDSPAR; PEGMATITE; OLIVINE; QUARTZ. Additional references to related articles will be found in the various sections of this article which are as follows:

I. CHEMISTRY OF THE EARTH

A. METEORITES AND GEOCHEMISTRY

Meteoritics, or the science of cosmic matter captured by the earth, supplies information about the properties and composition of nonterrestrial matter. Because the meteorites are believed by many to be fragments from the interior of a broken planet comparable with the earth in size and in general physical chemical properties, they are used to give evidence of the internal structure of the earth and of the general geochemical character and abundance of the elements. The meteorites are chiefly composed of three phases—metal, silicate and sulfide.

According to the predominance of the metal or the silicate phase, the meteorites are divided into three principal groups: irons (siderites), stony-irons (siderolites) and stones (aerolites). The tektites, commonly believed to be glass meteorites, make a fourth group. The constituents of the meteorites are called meteorite minerals, and many of them are identical with the minerals found in terrestrial rocks of a corresponding chemical composition. Several meteorite minerals have no terrestrial counterparts.

The most important meteorite minerals are kamacite and taenite (both nickel-iron); olivine, clinoenstatite-clinohypersthene, diopside-hedenbergite, augite, enstatite-hypersthene, and plagioclase (silicates); and, as accessory constituents, troilite and oldhamite (sulfides), schreibersite (phosphide), cohenite (carbide), graphite and quartz.

*From FeO and Fe_2O_3.

The chemistry of the meteorites is of geochemical importance. The average chemical composition of irons, the metal phase of stones and the silicate phase of stones is presented in Table I according to H. Brown and C. Patterson.

The average chemical composition of all meteorites serves as a basis of computation of the relative terrestrial and cosmic abundance of the elements. An uncertainty affecting all such calculations is the difficulty of estimating the relative amounts of meteorite phases.

TABLE II.—*Average Chemical Composition of All Meteorites**

Element	Per cent by weight	Element	Per cent by weight

metamorphic. The last two groups are composed of material ultimately derived from igneous rocks. Consequently, the average chemical composition of the uppermost lithosphere is very nearly equal to the average chemical composition of igneous rocks. Beginning in the 1880s, calculations have been made of the mean chemical composition of igneous rocks. Among the representative ones. the averages of Clarke and Washington, based on 5,159 analyses of igneous rocks from all parts of the world, along with some other computations, are presented in Table III. The averages of J. J. Sederholm and F. F. Grout include also sedimentary and metamorphic rocks. It appears that the areal averages in which the quantitative distribution of the various rock types is considered are all more silicic than the world-wide average. Sederholm's and Grout's averages indicate a granodioritic composition, that is, granitic with more plagioclase feldspar than orthoclase, for the rocks of the Pre-Cambrian areas investigated.

The calculations in Table III show that eight elements constitute the bulk of the uppermost lithosphere. These main elements are oxygen, silicon, aluminum, iron, calcium, sodium, potassium and magnesium. When calculated as elements, the values of Clarke and Washington yield the composition for igneous rocks indicated in Table IV. All other elements, collectively called accessory or minor or trace, make 1.72% of the total mass of the igneous rocks. Table IV also shows the composition of the igneous rocks in percentage by volume, as recalculated by T. F. W. Barth on a water-free basis. The high oxygen content indicates that oxygen fills out most of the space in the lithosphere; the lithosphere is actually an oxysphere.

TABLE IV.—The Eight Main Constituents of Igneous Rocks

Element	Per cent by weight	Per cent by volume	Element	Per cent by weight	Per cent by volume
O	46.42	91.83	Ca	3.61	1.50

			Mg	2.09	[illegible]
Fe	5.08	0.58	Total	98.28	99.94

The trace-element content of igneous rocks is usually determined by means of physical methods used in analytical chemistry. such as spectrochemical and colourimetric analysis and radioactivity methods. The abundance of all elements in them is listed in Table V. The abundance values for several elements are rather unreliable, and some have been determined only in composite mixtures of argillaceous, or clayey, rocks. The investigation of the abundance relationships of the elements reveals a picture that differs from the conventional opinion of abundance.

*Present. †Presence unsettled. ‡Presence probable.

In everyday life, the commonness or rarity of an element is usually mistaken for the commonness of its use in technical products and the like, that is, for its apparent abundance. For instance, gold and silver are less abundant in igneous rocks than are the relatively little used rare-earth metals (lanthanoids, or lanthanides) and hafnium.

There are considerable differences in the abundance of elements in terrestrial igneous rocks (Table V) and in meteorites (Table II). The meteoritic and cosmic abundance values indicate that the chemical composition of the uppermost lithosphere does not agree with the average chemical composition of matter in the universe. The reason for this difference is the manner of formation of the lithosphere by a process of chemical differentiation.

Table V shows that elements with an even proton number (atomic number, Z) are nearly always more abundant than their odd-numbered neighbours. This regularity, known as the rule of Oddo and Harkins, is based on observations made by G. Oddo and W. D. Harkins. The rule is still more evident when the cosmic abundance of elements is considered; this is well illustrated by Goldschmidt's graph in fig. 1. Geochemically coherent elements (*i.e.,* elements accompanying one another in nature) give examples of the rule. The abundance of the lanthanoids is particularly illustrative. (See fig. 2, which is based on analyses of E. Minami.)

The abundance values of Table V refer to the elements as natural mixtures of nuclides. Tabulations showing the relative cosmic abundance of the nuclides are based on the cosmic abundance of the elements and on their isotopic constitution. The abundance graph showing the abundance as a function of the mass number of the nuclides describes the general trend in cosmic abundance adequately. It shows a rapid, approximately exponential, decrease in abundance with increasing mass number up to a mass of approximately 100 and its essential constancy thereafter. The rule of Oddo and Harkins is valid also with reference to mass number.

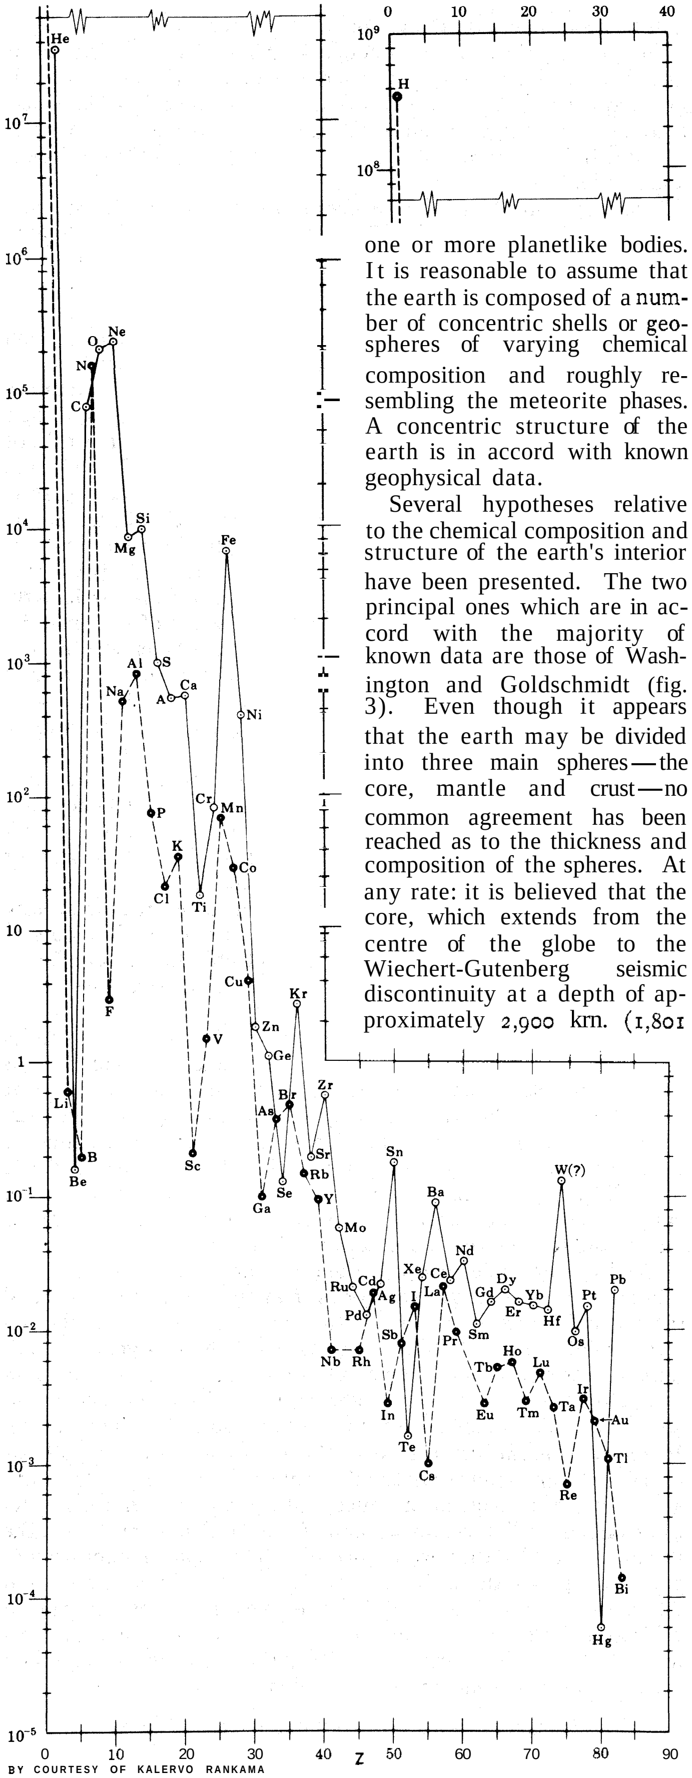
Numerous rules exist correlating the abundance with the proton, neutron and mass numbers of the nuclides; however, they possess a number of exceptions marked by abrupt changes in abundance. Such exceptions are connected with changes in the structure of the atomic nucleus.

2. Origin of Elements.— The existence of radioactive nuclides indicates that elements have not always existed in their present form. The relationships between cosmic abundance and nuclear properties make the basis of many speculations dealing with the origin of elements and the abundance of nuclides at the time of their formation. It is generally agreed that the relative abundance of nuclides was determined by physical conditions existing in an early stage of the expansion of the universe, when the density of matter and temperature were exceedingly high.

The hypotheses dealing with the origin and abundance distribution are of two principal categories, namely, the equilibrium and the nonequilibrium hypotheses. According to the former, the observed abundance distribution represents a thermodynamic equilibrium between nuclei. The equilibrium hypothesis explains in a satisfactory way only the abundance of the light and heavy nuclides and fails to explain reasonably the whole abundance range. In the nonequilibrium category, the neutron-capture hypothesis explains the abundance distribution chiefly as a result of the radiative capture of neutrons by nuclei, of a number of nuclear reactions among the lightest nuclei, and of radioactive decay among the unstable nuclides that were formed. The neutron-capture hypothesis explains the deficiency of lithium, beryllium, boron and fluorine (fig. 1) and many abundance rules, including the rule of Oddo and Harkins. None of the hypotheses is capable of answering completely the question of the making of the nuclides and the origin of their abundance distribution.

C. Geochemical Structure of the Earth

A. Boisse in 1850 was the first to suggest that the bulk chemical composition of the earth is comparable with the average chemical composition of the meteorites. This qualitative analogy has been used in the construction of various earth models, because it is most likely that the meteorites are derived from the different depths of



BY COURTESY OF KALERVO RANKAMA

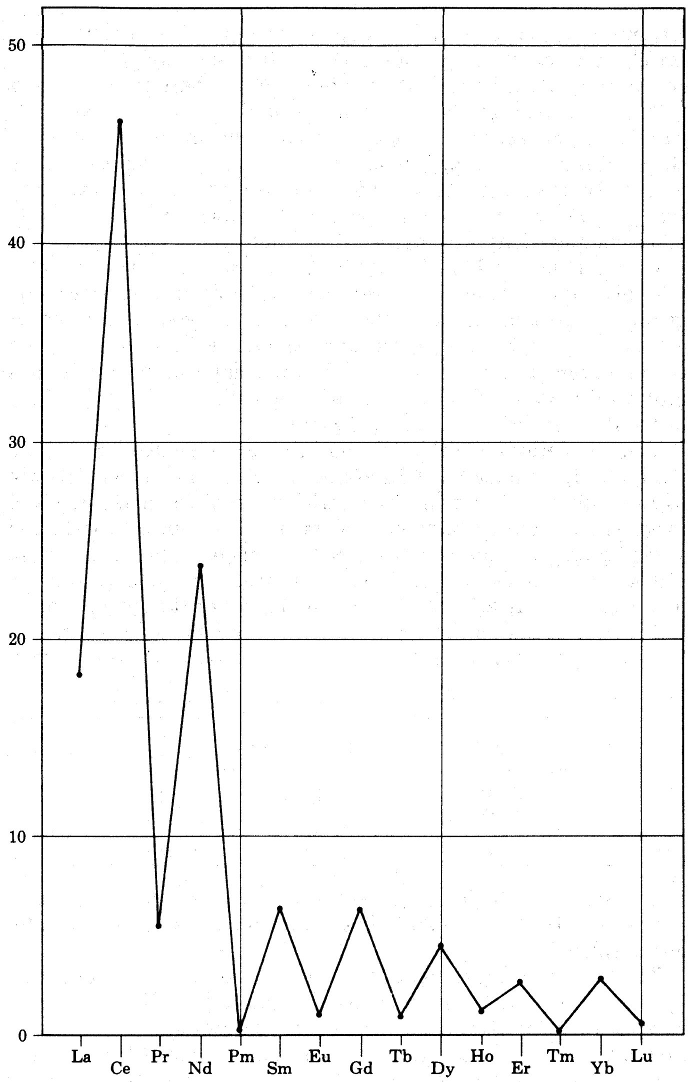
Open circles represent an even proton number, filled circles an odd number. The two sections of the graph join as indicated by broken line

one or more planetlike bodies. It is reasonable to assume that the earth is composed of a number of concentric shells or geospheres of varying chemical composition and roughly resembling the meteorite phases. A concentric structure of the earth is in accord with known geophysical data.

Several hypotheses relative to the chemical composition and structure of the earth's interior have been presented. The two principal ones which are in accord with the majority of known data are those of Washington and Goldschmidt (fig. 3). Even though it appears that the earth may be divided into three main spheres—the core, mantle and crust—no common agreement has been reached as to the thickness and composition of the spheres. At any rate: it is believed that the core, which extends from the centre of the globe to the Wiechert-Gutenberg seismic discontinuity at a depth of approximately 2,900 km. (1,801 mi.), consists of metallic nickel-iron and corresponds to the pure iron meteorites. Most geophysicists and geologists agree in principle on a mantle composed of silicates and interstitial nickel-iron that increases in amount with depth. The mantle occupies the depth zone between approximately 2,900 km. (1,801 mi.) and approximately 30 km. (18.6 mi.) or 50 km. (31.1 mi.), the Mohorovicic discontinuity, or the upper boundary of the earth's mantle (see EARTHQUAKES: Earthquake Waves). In the crust, the continental areas consist of three continental layers, namely: a deep-seated intermediate layer, probably intermediate between basalt and granite in composition; a granitic layer above the intermediate layer; and a sedimentary layer composed of sediments, sedimentary and metamorphic rocks. In the Pacific basin, the continental layers are totally absent, and the uppermost gabbroic (basaltic) layer of the mantle is in almost direct contact with the ocean.



BY COURTESY OF KALERVO RANKAMA

FIG. 2.— ABUNDANCERELATIONS OF LANTHANOIDS IN SHALES

In addition to the shells or geospheres mentioned, three outermost geochemical spheres are distinguished. They are the hydrosphere, which consists of the salt and fresh waters and the continental ice; the atmosphere, or the gaseous outer envelope of the earth; and the biosphere, which comprises the living matter and is the part of the earth capable of sustaining biological activity. The biosphere occupies the lower part of the atmosphere and probably the whole hydrosphere, and makes a thin layer on the lithosphere.

D. DISTRIBUTION OF ELEMENTS

If shells of different composition exist in the earth, the elements will be distributed among them in fixed proportions. Their distribution is studied by means of meteorites and the separation of metal, sulfide and silicate phases in ore-smelting furnaces. Three elements—iron, oxygen and sulfur—their mutual affinity relationships, and the affinity of other elements for them are largely responsible for the distribution of the elements in the core, the mantle and the crust.

In Goldschmidt's geochemical classification the elements are divided into three main affinity groups. The siderophile elements are preferentially enriched in the nickel-iron core (siderosphere), the chalcophile elements in the sulfide-oxide shell (chalcosphere), and the lithophile elements in the silicate crust (lithosphere). The most typical elements of the atmosphere are called atmophile elements and those typical of the biosphere, biophile elements.

Thermochemical considerations indicate that lithophile elements have higher free energy of formation of oxide than does bivalent iron, while the elements with lower energy of formation of oxide are siderophile or chalcophile. Several exceptions to this rule indicate that the distribution is controlled also by isomorphic substitution. In the observed distribution of the elements between metal and sulfide phases there is little or no agreement with free-energy data of sulfides. In general, the geochemical character of an element depends largely on the electron configuration of its atom.

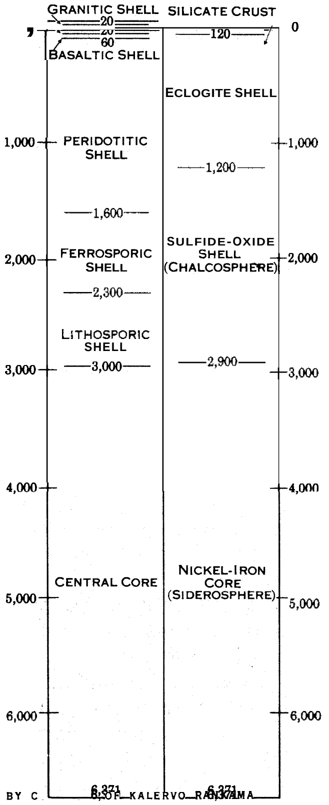


FIG. 3.—INTERNAL CONSTITUTION OF THE EARTH
(A) Hypothesis of H. S. Washington; (B) of V. M. Goldschmidt. Numbers refer to depths in kilometres

Used in a purely chemical sense without reference to any supposed distribution among the geochemical spheres the terms siderophile, chalcophile and lithophile are illustrative and prove useful for many geochemical purposes. The geochemical classification of the elements is shown in Table VI. It appears that the geochemical character is not sharply established for all elements, not even in strictly specified surroundings.

II. GEOCHEMISTRY OF THE LITHOSPHERE

The elements present in the lithosphere are appropriately divided into two groups on the basis of their most important manner of occurrence. The first group comprises the elements that occur largely or exclusively combined with oxygen in oxides, silicates, phosphates, carbonates, nitrates, borates, sulfates, etc. They are called oxyphile elements. Oxygen may be replaced by fluorine and chlorine to some extent. Elements of the second group, the sulfophile elements, form preferentially minerals free of oxygen (fluorine, chlorine), that is, sulfides, selenides, tellurides, arsenides, antimonides, intermetallic compounds, native elements, etc. All intermediate steps between the two groups are represented among the minerals, because the chemical affinity of the elements for oxygen (fluorine, chlorine) and sulfur (selenium, arsenic, etc.) is determined by the free energies of formation of the corresponding natural silicates and sulfides. Isomorphic substitution, that is, replacement of an element by another related element, may in some instances cause an element to become distributed between the silicate and sulfide phases in a manner that deviates from that expected from its affinity properties. Consequently several siderophile and chalcophile elements possess a more or less oxyphile character in the lithosphere. (See Table VII.)

A. CRYSTAL CHEMISTRY

The quantity of an element in a mineral does not adequately explain its role in the mineral structure. The structural positions occupied by the atoms and ions of an element in minerals essentially affect the manner of occurrence of the element. The properties of atoms and ions and the crystal structures of minerals largely regulate the incorporation of elements in minerals and, consequently, strongly affect their geochemical behaviour. The effective size of an atom or an ion in a structure (its atomic or ionic radius) depends on the nature of the binding forces between neighbouring particles, the electronic configuration of the particle, its polarization properties and co-ordination, *i.e.*, the number and arrangement of the neighbouring particles. (See Table VIII.)

The ionic bond predominates in the structures of important rock-making minerals, and the structures of the feldspars, pyroxenes, amphiboles and many other minerals may be considered essentially ionic. But in some other minerals, for instance, in sulfides, the structure differs very considerably from an ionic structure, and the ionic radii cannot be applied to such structures.

The length of the ionic radius depends on the position of the element in the periodic system. First, the radius decreases in each period when passing from left to right, for instance, in the series Na^+, Mg^{2+}, Al^{3+}, Si^{4+}, P^{5+}, S^{6+}. Second, in the groups and subgroups the ionic radius increases toward the higher atomic numbers, as in the series Li^+, Na^+, K^+, Rb^+, Cs^+. The lanthanoids, or the elements from lanthanum to lutecium, inclusive, make an exception to this rule, as the radii of their trivalent cations decrease with increasing atomic number. This phenomenon is called lanthanoid contraction and is a result of changes in the atomic structure of the lanthanoids. It is of high geochemical importance because it affects the geochemistry of the lanthanoids and of the elements to follow them in the periodic system. The ionic radii of the last mentioned elements are smaller than they would be in the absence of lanthanoid contraction, *e.g.*, the radius of the Hf^{4+} ion resembles closely the radius of the Zr^{4+} ion, and the similarity in space requirements along with the close chemical similarity makes hafnium and zirconium a geochemically high coherent pair of elements. alnays accompanying each other in nature.

In the actinoid (actinide) series a similar contraction (actinoid contraction) exists. Its geochemical importance is limited to the actinoids. It explains the relationship between uranium and thorium in some minerals.

The radius of the Li^+ ion is abnormally great and explains the substitution of magnesium by lithium in many silicate minerals.

*The radii are given for 6-fold co-ordination. Cation radii are those of L. H. Ahrens, anion radii those of L. Pauling. (Exceptions: radii of $[NH_4]^+$ and $[OH]^-$)

1. Co-ordination of Particles. — The most fundamental feature of a crystal structure is the co-ordination of the particles present, *i.e.*, the number and arrangement of particles of one kind surrounding a given particle of another kind as its nearest neighbours. The co-ordination is different for different particles and structures, each particle attempting to occupy the co-ordination into which it fits best. A proper and fitting co-ordination results in strong bonds between the particles and in a stable structure. An ill-fitting and unsuitable co-ordination causes an unstable structure, *e.g.*, the co-ordination of the Zr^{4+} ion in the zircon $Zr[SiO_4]$ structure is not well suited to the space requirements of the ion and causes an unstable structure that is readily disintegrated by the action of alpha radiation (metamict alteration).

In an essentially ionic structure, the co-ordination of the cation, that is, the number and arrangement of the surrounding anions, depends largely on the cation/anion radius ratio. In the important rock-making minerals, oxygen is the principal anion, and such minerals are in fact aggregates of big oxygen ions whose interstices are filled up with the cations.

For instance, in quartz, SiO_2, oxygen makes up 98.7% by volume and silicon, only 1.3%. Consequently consideration of the co-ordination number of the cations with respect to oxygen in minerals is of importance. The co-ordination is variable, as illustrated in fig. 4, in which the cations, arranged according to their size, are plotted against the co-ordination number. The black areas indicate the approximate abundance of the co-ordinations of the ions in the upper lithosphere. The differences in the size of the area illustrate the fact that for big cations the co-ordination number is less definite because of the great size of the cation.

Because the crystal structures of almost all important minerals are known, they form a convenient basis for the classification of minerals. A structural classification of the complicated silicate minerals is particularly useful, and for the silicates the type of linkage of the silicon-oxygen tetrahedra present in their structures is a natural basis of classification. In nesosilicates the separate tetrahedral $[SiO_4]$ groupings do not share any oxygen atoms with neighbouring silicon-oxygen tetrahedra. In sorosilicates the separate groups of tetrahedra share one or more corners with neighbouring tetrahedra of the same group. The sorosilicates may consist of $[Si_2O_7]$ double tetrahedra, five tetrahedra in an open group, rings of three or six tetrahedra. The inosilicates are composed of infinite chains or double chains of silicon-oxygen tetrahedra. In the phyllosilicates there are infinite sheets of the tetrahedra, and in the tectosilicates there are continuous frameworks of linked tetrahedra sharing all four oxygen atoms with neighbouring tetrahedra.

2. Replacement of Elements. — Because minerals are rarely pure compounds, the chemical formulas usually given for them are idealized. Deviations from the ideal composition are partly a result of structural defects, but their main reason is the presence of impurities, either as mechanically admixed substances or in solid solution (in fixed positions or filling empty spaces in the structure) in the mineral. The solute may not belong to the structure of the solvent, as in the case of the occurrence of helium in beryl, or it forms a complete isomorphic (from the Greek *isos*, "equal," and *morphe*, "form") series with the solvent, as does ferrous orthosilicate $Fe_2[SiO_4]$ (fayalite), with magnesium orthosilicate $Mg_2[SiO_4]$ (forsterite), the Fe^{2+} ions occupying the structural positions of the Mg^{2+} ions. Between these t o extremes all intermediate types of solid solutions occur in minerals. Isomorphism and related phenomena are of high importance in geochemistry. If atoms and ions instead of compounds are considered. such atoms or ions occurring in a given structure are called diadochic (from the Greek diadochos, "successor") if they are capable of replacing each other, each occupying the position of the other. Consequently, forsterite and fayalite are isomorphic, but the Mg^{2+} and Fe^{2+} ions in their structures are diadochic. Diadochy may be complete or partial.

As a general rule, an ion may replace another ion diadochically if the difference in the size of their radii does not exceed approximately 15% of the radius of the ion to be replaced. Temperature affects the degree of diadochy; high temperature generally favours diadochic substitution. Complete diadochy usually requires a close similarity in ionization potential. The degree of diadochy depends on crystal structure. Finally, ionic charge affects the substitution. The charges may be similar, as in the important $Fe^{2+}-Mg^{2+}$ substitution, or the substitution ion may have lower (*e.g.*, $O^{2-}-OH^{-}-F^{-}$; $Ca^{2+}-Na^{+}$) or higher (*e.g.*, $K^{+}-Ba^{2+}-Sr^{2+}-Pb^{2+}$) charge than the ion to be replaced. If the charges are different, the electrostatic neutrality of the structure will be disturbed. Consequently, it must be re-established, for instance, by the simultaneous substitution of another ion in the structure, as in the substitution of $Ca^{2+}Al^{3+}$ by $Na^{+}Si^{4+}$ in the plagioclase feldspars (see FELDSPAR), or by the introduction of balancing ions outside the regular framework of the structure, or by leaving a structural position vacant.

Diadochic substitution in common rock-making minerals regulates the manner of occurrence of almost all elements in the upper lithosphere and is of particular importance for the geochemistry of the trace elements. Some trace elements may form independent minerals that are among the accessory constituents of rocks, among others, sulfur in sulfide minerals, phosphorus in apatite and monazite and fluorine in fluorite. Other trace elements, for instance, manganese, barium and vanadium, seldom, if ever, form independent minerals except in rocks in which they happen to be very strongly enriched. Theirs is a dispersed manner of occurrence. Some elements, such as lead and boron, are intermediate. Three types of diadochy regulate the dispersed manner of occurrence of the trace elements, namely camouflage, when a trace element diadochically replaces a common element of similar valence; capturing, when a trace element replaces a common element with a lower valence and is captured in the structure; and admission, when a trace element replaces a common element of higher valence. Examples are, among others, the substitution of silicon by germanium in silicate minerals (camouflage), of potassium by

FIG. 4—CO-ORDINATION NUMBER WITH RESPECT TO OXYGEN OF SOME GEOCHEMICALLY IMPORTANT CATIONS IN UPPER LITHOSPHERE

lead in potassium minerals (capturing) and of oxygen by fluorine in sphene and other minerals (admission).

B. Crystallization of Magma

1. Rock-Making Minerals.—Rocks are called igneous or magmatic if their material has been molten before attaining its present structure and composition. Their material may be primary magmatic or juvenile in the case of true igneous rocks, or secondary, derived by remelting of older rocks in the case of quasi-igneous or pseudoigneous rocks. Phenomena connected with the crystallization of rock melts are geochemically important.

The average chemical composition of igneous rocks approaches the composition of diorites or granodiorites. It indicates only the abundance of the elements and tells nothing about their manner of occurrence as characterized by the minerals in which they are incorporated. The mineralogy of the igneous rocks is illustrated by their average mineralogical composition presented, according to Clarke, in Table IX. The feldspars. pyroxenes, amphiboles and quartz are geochemically the most important minerals of the igneous rocks, while all other minerals are, both quantitatively and geochemically, of minor importance. The feldspars, the feldspathoids and quartz are the chief salic, or silica rich, rock-making minerals and contain Na^{+}, K^{+}, Ca^{2+} and Al^{3+} as their most typical cations. The femic, that is, comparatively low in silica, minerals contain Mg^{2+}, Fe^{2+}, Fe^{3+} and, in part, Ca^{2+} and Al^{3+}. The most important accessory minerals of igneous rocks are: zircon, sphene $CaTi\ [(O,Oh,F)|SiO_4]$, apatite $Ca_5[(F,Cl,OH)|(PO_4)_3]$; and opaque sulfides, such as pyrite FeS_2, pyrrhotite $FeS–Fe_5S_6$, chalcopyrite $CuFeS_2$, pentlandite $(Fe,Ni,Co)_9S_8$, bornite Cu_5FeS_4; also oxides (ilmenite, $FeTiO_3$; magnetite, Fe_3O_4; chromite, $FeCr_2O_4$).

Table IX.—*Average Mineralogical Composition of Igneous Rocks*
(In weight percentage)

Mineral	Content	Mineral	Content
Feldspars	59.5	Titanium minerals	1.5
Hornblende and pyroxene	16.8	Apatite	0.6
Quartz	12.0	Other rock-making minerals	5.8
Biotite	1.8	Total	100.0

Among the feldspars the most important are the various potash feldspars $K[AlSi_3O_8]$ and the plagioclase feldspars, mixtures of albite $Na[AlSi_3O_8]$ and anorthite $Ca[Al_2Si_2O_8]$. Structurally they are tectosilicates; chemically, typical aluminosilicates. The cations accommodated in feldspar structure include Na^{+}. K^{+}, Rb^{+}, Cs^{+}, Ca^{2+}, Sr^{2+}, Ba^{2+}, Pb^{2+} and Tl^{+}, also Fe^{3+} replacing Al^{3+}. In alkalic rocks, the feldspathoids are of equal importance as are the feldspars in calc-alkalic rocks, but their general geochemical importance is not too great. Nepheline $Na[AlSiO_4]$, and leucite β-$K[AlSi_2O_6]$, are the most important members of this petrographic group. Like the feldspars, the feldspathoids are aluminosilicates with a tectosilicate framework.

The pyroxenes and amphiboles are structurally closely related inosilicates. They consist of numerous minerals with the general formulas $R_2[Si_2O_6]$ for pyroxenes and $R_{14}[(OH)_4|Si_{16}O_{44}]$ for amphiboles. In these formulas R is Mg^{2+}, Fe^{2+}. Ca^{2+} and, in many minerals, Al^{3+}, Fe^{3+}, Ti^{3+}, Mn^{3+}, Mn^{2+}, Na^{+}, K^{+}, Li^{+}, etc. In amphiboles, the OH– group is partly replaced by O^{2-} or by F^{-}. Pyroxene species include, among others, enstatite $Mg_2[Si_2O_6]$ and augite, which contains Na^{+}, Ca^{2+}, Mg^{2+}, Fe^{2+}, Fe^{3+}, Al^{3+} and Ti^{3+} as cations, Three pyroxene series occur in igneous rocks and pyroxene minerals are always mixtures. The augites are among the most important mafic constituents of igneous rocks. The amphiboles are chemically more complicated than the pyroxenes, and no simple structural formulas can be given for them because of the great number of possible diadochic substitutions. The hornblendes, in which R is Na^{+}, K^{+}, Ca^{2+}, Mg^{2+}, Fe^{2+}, Fe^{3+}, Al^{3+} and Ti^{3+}, are geochemically the most important amphiboles. In augites and amphiboles, particularly in hornblende~as much as one-fourth of the Si^{4+} ions may become replaced by Al^{3+}.

Some igneous rocks contain olivines as their principal constituents. The most important olivines are members of the forsterite-fayalite series. Olivines are nesosilicates. Quartz is a tectosilicate. The existence of free silica in igneous rocks is the result of the high abundance of silicon in the upper lithosphere.

Among the micas, which are aluminosilicates with a phyllosilicate structure, biotite $K(Mg,Fe,Mn)_3[(OH,F)_2|AlSi_3O_{10}]$ and muscovite $KAl_2[(OH,F)_2|AlSi_3O_{10}]$ are the most important species. Biotite is the most common mica in igneous rocks. There also exist KMg, NaAl and CaAl micas, and some varieties are known that are characterized by a high content of trace elements, such as lithium, barium, chromium, vanadium, manganese and titanium. The possibilities of diadochic substitution in the micas are numerous, just as in the pyroxenes and the amphiboles.

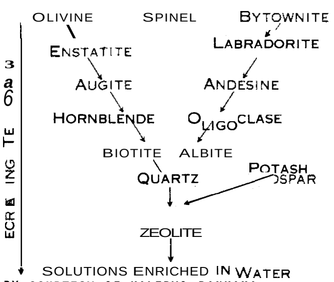
2. Chemical Differentiation of Rock Melts.—The igneous rocks are chemically widely variable, and rocks with a chemical composition similar to the average composition of igneous rocks are rare. Because it is believed that the original silicate crust of the earth was chemically rather homogeneous, the assumption follows that the igneous rocks are products of an extensive chemical differentiation in the crust. It is believed that the plateau basalts represent the parental magma that differentiated to produce all primary magmatic rocks present in the upper lithosphere. The changes in chemical composition caused by magmatic differentiation are geochemically important.

The general course of crystallization of a calc-alkalic basaltic magma comprises three stages: the early, the main and the late magmatic. Silicates (dunite, anorthosite), sulfides (pyrrhotite-pentlandite assemblage) and oxides (ilmenite, chromite, magnetite) will separate during this stage. The igneous rock series from gabbros through diorites to granites is the product of fractional crystallization during the main stage. The bulk of the volatile constituents of the magma will become enriched in the residual melts and solutions and separate in pegmatites and in pneumatolytic and hydrothermal deposits during the late magmatic stage. Escape of volcanic emanations completes the course of crystallization. The boundaries between the different stages are not very rigid becduse the processes are continuous.

The early magmatic stage incorporates the separation of much iron and sulfur, and the bulk of copper, nickel, titanium and chromium from the rock melt. Many ore bodies containing these elements are formed during this stage.

3. The Reaction Series.—The course of crystallization of calc-alkalic silicate rocks during the early and the main stage of differentiation may be described by the reaction series that contains both the mafic (dark) and the felsic (light) minerals. The reaction series, introduced by N. Bowen in 1922. is one of the cornerstones of petrology; fig. 5 shows it as a somewhat modified statement of the normal sequence of crystallization of calc-alkalic rocks.

In the right-hand branch containing the light constituents the framework of the Si-0-A1 tetrahedra in the mineral structures remains unchanged. whereas in the left-hand branch of the dark constituents the framework changes with proceeding crystallization from independent tetrahedra through chains and double chains to sheets. The stabilitv of the structures decreases in the same order.



BY COURTESY OF KALERVO RANKAMA

Fig. 5.—Reaction Series
(see text for further information)

The general course of crystallization proceeds from ultramafic rocks 'through subsilicic and intermediate types to the silicic rocks largely as a result of fractional crystallization. The principal types of calc-alkalic rocks produced are dunite and anorthosite. gabbro, diorite and granite. Among other chemical changes the Fe/Mg ratio increases toward the later stages of crystallization. Magnesium and calcium are concentrated during the early stages of crystallization, while silicon, sodium and potassium become enriched in the silicic rocks. With respect to crystal chemistry, the course of crystallization is governed by forces that tend to capture the structural constituents of minerals from the melt with a low degree of order and to arrange them into structures with a high degree of order. The formation of the various minerals may be explained, as F. E. Wickman has done, by means of kinetic reasoning with temperature as an essential function. A given amount of energy is required to move an ion from a position with a given co-ordination to another position with a different co-ordination. The energy required is called the migration energy (the activation energy of the migration of the ion) and depends on the co-ordination, size and charge of the ion, the degree of order in the structure, temperature and pressure. The fact that the migration energy depends on ionic size explains the general separation of Mg^{2+} during an early, and of Fe^{2+} during a late stage of crystallization. Both ions are 6-co-ordinated in the olivine structure, but the size of the Mg^{2+} ion is closer to the optimum size required by 6-co-ordination, and consequently the migration energy of Mg^{2+} in the olivine structure is greater than the migration energy of Fe^{2+} therein. If two cations are of equal size but of different charge, the cation with the higher charge has the greater migration energy. The difference in migration energy between Na^+ and Ca^{2+} explains the order of crystallization of the plagioclase feldspars. The Na^+ ion with the smaller migration energy is the more mobile of the two ions, and consequently calcic plagioclases separate at higher temperatures than do the sodic plagioclases.

The properties of the Si–O framework determine the order of crystallization of forsterite and enstatite. Enstatite will crystallize before augite because of the absence of Ca^{2+} in its structure and the ensuing higher stability thereof. The separation of the amphiboles after the pyroxenes may be explained by differences in the Si–O framework, chiefly by the linkage differences of the Mg^{2+} ions. Micas crystallize after hornblende because the mica structure is still weaker and more unstable than the amphibole structure. Also, the K^+ ion is rather loosely bound in the structure. In alkalic rocks, the sequence of separation may be entirely different, particularly when certain nepheline syenites are formed. The light constituents may then be the first minerals to separate.

4. Residual Melts and Solutions. — After the close of the main stage of crystallization residual solutions will often remain that are rich in hyperfusible constituents, especially water. Pegmatites are produced during the differentiation of these liquors. Pegmatites of granites and nepheline syenites, or of the last rocks to form during the main stage of crystallization, are rather common. Elements too scarce to make independent minerals and those of ionic size unsuitable for their being incorporated in the rock-making minerals become gradually concentrated in the magmatic residues and separate in the pegmatites. Such elements are, among others, lithium, beryllium, boron, fluorine, rubidium, cesium, niobium, tantalum, uranium and the lanthanoids. Uranium, niobium, tantalum and a part of the lanthanoids are predominantly concentrated in granite pegmatites, whereas other lanthanoids, zirconium and often thorium are enriched in the nepheline syenite pegmatites. The pegmatites may be divided chemically according to the abundance relationships of sodium and potassium **versus** aluminum. In agpaitic pegmatites $Na+K>Al$, while in plumasitic pegmatites $Na+K<Al$ (the names are from locations of occurrences of type specimens in Iceland and California respectively). The different pegmatites have different typical minerals.

Strictly speaking, the formation of pegmatites marks the end of magmatic crystallization. No sharp boundary can be established between the pegmatitic stage and the ensuing pneumatolytic and hydrothermal stages. When a superheated aqueous solution containing dissolved silicates and other substances crystallizes at a temperature higher than the critical temperature of water vapour (374.5° C.), the deposits formed are called pneumatolytic. If crystallization temperature is lower than the critical temperature, the minerals and rocks formed are said to be hydrothermal.

Alkali feldspars, micas, quartz and characteristic minerals containing rare elements are the chief minerals formed during the pegmatitic stage; mineral veins are the most important among pneumatolytic and hydrothermal deposits. Many heavy metals separate in the veins and may form ore bodies. The veins contain many sulfophile elements either in the native state or as oxides, sulfides, selenides, tellurides, arsenides, antimonides and various sulfosalts. After deposition of most of their metallic constituents the dilute hydrothermal solutions may deposit quartz and zeolites and minerals containing volatile constituents such as boron compounds and carbon dioxide, if these are present in the solutions.

5. Volcanic Emanations. — In volcanoes the volatile constituents of the magmas escape as volcanic emanations into the atmosphere, dissolve in water, and form volcanic sublimates around the craters and vents.

Water vapour, carbon dioxide, nitrogen and native and combined sulfur are the quantitatively most important constituents of the emanations, but notable local and areal changes in their constitution are observed. Some of the constituents derive from the magma (juvenile constituents), while others come from the earth's surface (superficial constituents) or from the atmosphere (meteoric constituents). The temperature of the emanations and the time elapsed since the start of the volcanic activity also affect the composition of the emanations.

Geochemically, the volcanic emanations are of high importance because of their character as products of the degassing of the earth. They affect essentially the manner of occurrence and the geochemical cycle of many elements. Such elements as chlorine, sulfur and boron (all abundant in volcanic emanations) are directly supplied to the atmosphere and hydrosphere by volcanic emanations and will participate in geochemical processes on the earth's surface.

FIG. 6. — THE MAJOR CYCLE OF MATTER

c. The Exogenic (Minor) Cycle

The upper lithosphere is the seat of numerous geochemical processes that affect its chemical composition both locally and areally. All matter on the surface of the earth and in the uppermost parts of the lithosphere participates in a slow complicated migration, or cycle, that causes more or less pronounced changes in the structure and chemical composition of rocks. New rocks with new properties are produced in this cycle. The migration of matter consists of the exogenic (the product of outside forces), or minor cycle taking place under the direct influence of atmospheric and hydrospheric agents and the major cycle, a material part of which is confined to the uppermost levels of the lithosphere.

In the exogenic cycle the elements behave differently, depending on their individual properties and in accordance with laws that differ basically from the rules valid for the crystallization of rock melts. The migration, consequently, yields products whose formation cannot be explained by the laws of magmatic crystallization. The exogenic cycle starts with solid crystalline rocks and ends in sedimentary rocks. It forms only a part of the major cycle. Unlike the major cycle, which is closed, the exogenic cycle, taking place only in one direction, is largely open and is closed only for sedimentary rocks. For all other rocks this cycle is irreversible.

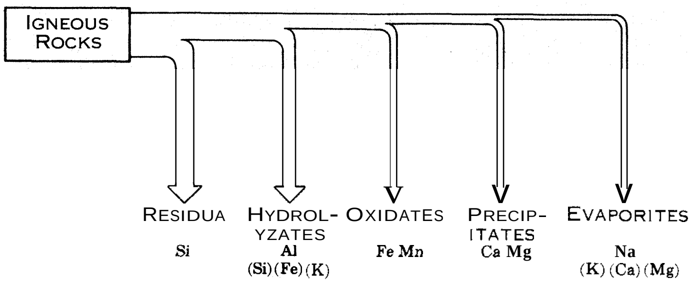
The course of the exogenic cycle as a part of the major cycle is schematized in fig. 6. It consists of the weathering of rocks, transportation of products formed during weathering, and redeposition of material, usually in new surroundings. These processes are in many respects similar to a gigantic semiquantitative chemical rock analysis involving separations on a large scale. Because of its role as a separating and concentrating agent for many elements, the exogenic cycle is of importance for the manner of their occurrence in the uppermost lithosphere and on the surface of the earth.

1. Weathering of Rocks.—Rock weathering consists of a number of physical and chemical processes that gradually break down the fresh solid rocks into an aggregate of loose material, a part of which is dissolved or changed chemically, uhile another part remains unchanged. The principal agents of physical (mechanical) weathering are changes in temperature and the action of frost and of crystallizing salts. Chemical weathering is caused by the action of rain, surface and ground water and of the solids and gases dissolved therein. Oxygen, carbon dioxide, nitric acid, sulfuric acid, humic complexes, ammonia and chlorides are the most important chemically active agents in natural waters. The chemical processes taking place during weathering are rather complicated. Oxidation, reduction and action of carbon dioxide are geochemically important weathering processes.

The rock making minerals are of different stability against weathering, the mafic minerals decomposing more rapidly than the felsic minerals. The stability series of the rock-making minerals proposed by S. S. Goldich is exceedingly similar to the reaction series (fig. 5), the stability increasing from olivine and calcic plagioclase to quartz.

The solid products of completed weathering include substances that are stable under conditions existing on the earth's surface. Clay minerals, the hydroxides of ferric iron and aluminum, and their derivatives are the most abundant weathering products. The loose weathering residues and products are transported and sorted by the action of wind, flowing water, ice and organisms, and a number of chemically and physically different continental and marine sediments are thereby formed. Sorting is according to particle size but includes also chemical separation. In the course of time, deposited loose sediments may change by consolidation, recrystallization and chemical processes in diagenesis (*q.v.*); thus a sedimentary rock is formed. Several sediments and their derivatives also form from the remains of organisms, such as calcareous mud, peat and guano; and limestone, coal and phosphorite formed from them through diagenesis or decay and incoalation. They are known as biogenic sediments.

2. Geochemical Classification of **Sediments.**—According to their manner of deposition the sediments may be divided into physical (mechanical) and chemical sediments. For geochemical purposes another classification is used—that based on geochemical principles first proposed by Goldschmidt (see fig. 7).



ADAPTED FROM K. RANKAMA AND T G. SAHAMA, "GEOCHEMISTRY," THE UNIVERSITY OF CHICAGO PRESS

FIG. 7.—GEOCHEMICAL CLASSIFICATION AND CHEMICAL CHARACTERISTICS OF SEDIMENTS FORMED DURING WEATHERING. TRANSPORTATION AND SEDIMENTATION

The residua consist of chemically undecomposed weathering residues, such as sands and gravels. The hydrolyzates consist partly of undecomposed. partly of hydrolytically decomposed matter. Clays are the foremost representatives of hydrolyzates. The crystalline clay minerals are the dominant constituents of clays. They are characterized by their capacity of exchanging their cations (anions) for other cations (anions) from aqueous solutions. The oxidates form by oxidation of Fe^{2+} into Fe^{3+} and of Mn^{2+} into Mn^{3+} and consist chiefly of hydroxides of the two metals. Iron and manganese ores of sedimentary origin belong to this group. The reducites, the opposites of oxidates, are formed in strongly reducing surroundings. Coal and petroleum, and muds and clays containing sulfides and carbonaceous matter are reducites. The precipitates form by inorganic precipitation from aqueous solutions. Deposits of inorganically precipitated calcium carbonate and magnesium carbonate are examples of precipitates. The evaporites are deposited from aqueous solutions as a result of evaporation of the solvent. They include extensive salt beds crystallized from sea water. The bioliths, or biogenic sediments often occur together with other sediments, *e.g.*, biogenic calcium carbonate may occur along with inorganically precipitated calcium carbonate. Because the sedimentation processes are continuous, sediments and their derivatives usually are mixtures belonging to two or three groups, and, consequently, the geochemical division of sediments is not categorical.

3. Chemistry of the **Exogenic** Cycle.—The total quantity of rocks decomposed and of sediments formed during the geological history of the earth is of great geochemical importance. The length of the time during which the exogenic agents have operated on the earth's surface is approximately 3.5×10^9 years (3,500,-000,000 yr.). Goldschmidt estimated, on the basis of the sodium content of sea water, that 160 kg. igneous rock per each square centimetre of the earth's surface have yielded a total of 169.6 $kg.cm.^{-2}$ (minimum value) of sediments. The argillaceous (clayey) and arenaceous (sandy) sediments are, quantitatively, the most important sediments produced. Another estimate based on the radioactivity of potassium gave 6,462 $kg.cm.^{-2}$ (maximum value) for the total quantity of weathered igneous rock.

The igneous rocks are formed by endogenic (produced by internal forces) differentiation deep under the earth's surface. Another kind of differentiation, called the exogenic differentiation, takes place on the surface and is intimately connected with the exogenic cycle of matter. Some elements become strongly enriched in certain types of sediments, even though a high degree of separation is not always reached. For many elements the exogenic differentiation is the most powerful concentrating and enriching agent. For instance, silicon and zirconium are concentrated in sandstones; aluminum, potassium and boron in shales; calcium, magnesium and carbon in limestones; iron, manganese and barium in oxidates; and sodium, chlorine, magnesium and sulfur in evaporites.

There are several factors of prime importance for the exogenic differentiation. Because most phenomena of the exogenic cycle are characterized by the presence of water, the physical and chemical properties of water are significant, such as the hydrogen ion concentration (pH). In most natural waters the pH is between 6 and 8. The changes in pH play an important role in the precipitation and mobilization of many elements in aqueous solutions, such as in the separation of iron and aluminum.

Because many elements occur in two or more oxidation states, oxidation and reduction are geochemically important processes. The presence of molecular oxygen and of reducing biogenic matter in the exogenic cycle indicates that here both oxidation and reduction occur in their geochemically most important surroundings. Along with the pH, the differences in the degree of oxidation or reduction cause many enrichment processes and the separation even of chemically closely related elements, such as sulfur and selenium. Iron, manganese and cobalt are often precipitated as a result of exogenic oxidation reactions. Many elements, such as sulfur. selenium and chromium, may become oxidized to complex anions that are readily transported in solution. Other elements become enriched under highly reducing conditions. For instance, descending weathering solutions from ore bodies deposit copper, silver and other metals as sulfides in reducing areas below the water table. Many rare elements are concentrated in bioliths in the original reducing environments. Biochemical processes may participate or dominate in the creation of oxidizing or reducing environments. Molecular oxygen liberated by green plants in photosynthesis is responsible for the highly oxidizing conditions on the earth's surface. On the other hand, decaying biogenic matter creates reducing conditions.

In the exogenic cycle the two extremes of the oxidizing and reducing conditions are represented by the highly oxidized residua and the strongly reducing bituminous sediments and their derivatives. During weak metamorphism, the degree of oxidation often remains unchanged, and a high degree of oxidation in rocks may afford proof of their superficial origin. With the higher grades of metamorphism, reduction will gradually take place and leads back to the reducing conditions of the rock melts.

During weathering a part of the chemically decomposed material going into solution is present as colloidal particles. A group of phenomena called geochemical sorption largely governs the properties of such particles in sediments and the distribution of elements among various sediments. The sorption of ions by colloidal particles is of high geochemical importance, for example, in the concentration of many elements (such as potassium) in clays.

Goldschmidt did show that a number of phenomena connected with the distribution of elements between sea water and sediments may be explained by considering the ionic potential of elements, that is. the charge of an ion divided by its radius. For instance, preferential adsorption of potassium in argillaceous sediments and preferential migration of sodium to the sea are in accordance with the loner ionic potential of potassium. The fixation of potassium in hydrolyzates may, however, be explained, according to C. S. Ross, by the incorporation of the K^+ ion in the structure of montmorillonite. a clay mineral. Goldschmidt divided the elements on the basis of their ionic potential into three groups, which become separated from one another during sedimentation in the sea. Wickman revised the division and gave a physical explanation to the phenomenon by means of the rules governing hydrogen and hydroxyl bonds in hydroxides. The cations with low ionic potential and ionic bonds in their hydroxides (*e.g.,* the alkali metals) generally remain in ionic solution. The cations with intermediate ionic potential and hydroxyl bonds in their hydroxides, such as aluminum, uranium and tantalum, are readily hydrolyzed and precipitate as hydroxides which are deposited in hydrolyzates. The cations nith the highest ionization potential form complex anions with oxygen, and these remain usually in solution. Nitrogen, carbon, sulfur and phosphorus, among others, belong to this group. Their complex anions have hydrogen bonds.

D. The Major Cycle

Along with the differentiation by crystallization of rock melts and the cycle of weathering, transportation and sedimentation, processes of still another kind take place in the uppermost lithosphere which cannot be included in either endogenic or exogenic differentiation. These processes, occurring at deeper levels in the crust. tend in part to distribute the elements among various rocks, but their essential role is in the opposite direction, inasmuch as they tend to level off the chemical differences already produced. They form the endogenic cycle of matter. The endogenic and exogenic cycles together form the major cycle.

The processes of the endogenic cycle start from sedimentary or igneous rocks and produce gradually a rock melt. These processes are largely, perhaps almost entirely, based on reactions taking place in the solid state. It is possible that the major cycle actually is the most important process in the chemical modeling of the upper lithosphere.

The course of the major cycle is presented in fig. 6. Unlike the exogenic. the major cycle is closed for all participating rocks. The hydrosphere, particularly the oceans, however, make a considerable leak in the cycle because of the (at least) semipermanent accumulation of many elements in sea water and in ocean-bottom sediments. The major cycle begins with molten rock and ultimately winds up with a regenerated rock melt. The melt, on cooling, will crystallize in the form of plutonic or volcanic rocks, according to the level of the seat of crystallization in the lithosphere. The true igneous rocks of juvenile origin must be distinguished from the quasi-igneous rocks that are partly or totally composed of remelted material. On the earth's surface, the rocks participate in the exogenic cycle whereby sediments are ultimately produced. The sediments and the sedimentary rocks formed from them by diagenesis may reparticipate in the exogenic cycle but may also be removed from immediate contact with the hydrosphere and the atmosphere by continuing deposition of sediments or by tectonic movements. If that is the case, they will depart from the exogenic cycle and, in the course of time, will take part in metamorphic processes.

1. Metamorphism **of** Rocks.—Metamorphism is the physical and chemical adjustment of rocks to conditions existing at the deeper levels of the upper lithosphere. Metamorphic changes are essential for the endogenic processes and may consist of purely mechanical (kinetic) metamorphism, or purely thermal metamorphism. or metasomatism, which is the introduction or removal of material by magmatic gases (pneumatolytic metamorphism), solutions (hydrothermal metamorphism), or molten rock (migmatitization in part). All these processes cause changes in both the mineralogy and chemistry of the rocks affected. Some metamorphic changes are termed autometamorphism, when they constitute reactions between a rock and the residual solutions from its crystallization. Complex controlling conditions cause regional metamorphism over wide areas under the combined influence of elevated temperature. variable pressure and high shearing stress, and plutonic metamorphism, which is the deep-seated regional metamorphism at high temperatures and pressures, often accompanied by strong deformation and augmented by injection or infiltration of molten rock or by incipient remelting. At a still greater depth, plutonic metamorphism merges into truly plutonic phenomena. Near the surface, regional metamorphism becomes gradually replaced by kinetic metamorphism. Deformation promotes and accelerates the chemical reactions incorporated in metamorphism.

Because of the complexity of the reacting system, chemical changes involved in metamorphism are usually complicated. When environmental conditions change, the minerals participating in a metamorphic reaction may become unstable and their structures mill be gradually torn down, ion by ion. Disorder is thereby created, but finally new structures different from the old ones will form. With reference to stability and composition, the new structures are adapted to new conditions. All these reactions may take place in a liquid phase, called the intergranular film, but structures may also react with one another in the solid state, whereby the ions are simply rearranged to make new structures. But some ions are alaays present that are not strictly and rigidly bound to any structure but form a separate phase, called the dispersed phase. The presence of a dispersed phase is the condition of all chemical reactions that take place in rocks. It may be a gas, or a liquid or ions temporarily detached from their original structural positions. Even in solid-state reactions the ions make up the new structure through a dispersed phase.

A process called migmatitization may set in with progressing regional metamorphism to produce migmatites. or mixed rocks, through the migration of the readily mobile elements, such as the alkali metals. and the intrusion of molten rock material into pre-existing rocks. The migmatites predominate in the deepest parts of mountain chains. The boundary of the zone of migmatitization is called the migmatite front. Many granites and associated rocks are believed to have formed by migmatitization (granitization). Metamorphism may, however, still increase in strength causing the partial remelting (anatexis) of rocks, followed by complete remelting. Thereby a rock melt is produced. and its crystallization, the starting phase of the major cycle, will set in. The most far-reaching and thorough metamorphic changes consequently mean the rebirth, or palingenesis, of rocks.

Regional metamorphism is the most common and petrologically the most important form of metamorphism. It may consist solely of changes that do not affect the bulk chemical composition of the metamorphosed rock. This is isochemical or internal metamorphism. It may also consist of substantial addition or removal of material. This is allochemical or metasomatic metamorphism, and in it the bulk chemical composition mill change.

Wholesale diffusion probably is important for the transfer of matter in metamorphism, but diffusion in the solid state. according to laboratory experiments, is insufficient to explain long-distance transport of matter. Migration through liquid and gaseous phases is also possible. and it appears that surface phenomena in the intergranular film are of great importance in controlling metasomatic metamorphism.

Metasomatic changes often pronouncedly affect the chemical composition of rocks. The substances introduced may consist of the alkali metals, calcium. iron with magnesium and silicon, boron, lithium, fluorine, chlorine, sulfur. silicon, tin and carbon dioxide, and the metasomatic changes are accordingly called alkali metasomatism, etc. These processes are little investigated quantitatively, but sometimes amounts of elements calculated in millions of tons are known to have been introduced or removed.

2. Migration in the Lithosphere. — The endogenic migration of matter in the lithosphere is characterized by its selectivity; this means that under given conditions certain elements are able to migrate more readily than others. The elements nith high atomic numbers are, in fact, relatively readily mobilized and become enriched in granites and in low-temperature assemblages in general, that is. in rocks and minerals that may be assumed to have formed through a rather notable circulation and migration of matter.

Migration is of importance in molding the chemical composition of the uppermost lithosphere. There is evidence of a global migration affecting many elements. During this migration, the elements become divided into two groups. The granitophile elements are known to be especially enriched in both igneous and quasi-igneous granites. They endeavour to concentrate in the outermost parts of the crust. The granitophobe elements. on the other hand, are pushed down toward the basaltic substratum.

Granitization (or the formation of granite by migration. anatexis and palingenesis) is one of the key processes in the geochemistry of metamorphism. P. Eskola proposed that granitization is caused by a fluid, called the granitic ichor and consisting of truly juvenile residual melts and of the melts first to become squeezed out during the partial remelting of already solidified rocks. The chief constituents of the ichor are silicon. aluminum, sodium and potassium; oxygen and hydroxyl ions also migrate therein. The ichor rises slowly into the superposed rocks giving them a granitic or granitelike composition. But it is probable that both pore solutions and ionic diffusion participate in granitization. The mobility of ions during regional metamorphism and granitization is a function of ionic radius. The Fe^{2+} and Mg^{2+} ions are very mobile and become concentrated in the so-called basic front which is the precursor of the fronts of migmatitization and granitization.

All gradations probably exist from juvenile granites to metasomatic and palingenetic granites. The formation of silicic and other rocks by metasomatic processes implies some loss of significance for the classic theory of differentiation by crystallization. This theory, however, is important as the basis of estimation of the mobility of elements in metasomatic metamorphism. See also METAMORPHISM; METASOMATISM.

III. GEOCHEMISTRY OF THE HYDROSPHERE

The lithosphere is partly covered by a water blanket called the hydrosphere: as much as 70.8% of the earth's surface is covered by water. The salt water bodies, the oceans, with a total volume of $1,370\,323 \times 10^6$ km^3 and a mass of $14,060 \times 10^{20}$ g., make by far the greatest and most important part of the hydrosphere. Salt water also occurs in some isolated areas on all continents, gathering in depressions to make alkaline or salt lakes.

Fresh water is present in the soil as ground water and in the pores of rocks as hygroscopic water. It flows to the surface of the earth as spring water, fills the ponds and lake basins. and flows in rivers and streams as surface water. The permanent fields of snon. the glaciers, inland ice and permanent ice at high altitudes all consist of frozen water. Ground water, mixed with juvenile water, that is, water that has never been to the surface, enters the volcanic emanations and hot springs. The cavities of rocks and minerals contain salt solutions that may be of primary magmatic origin, while other solutions consist of meteoric water trapped in the rocks.

According to Goldschmidt's estimate there are for every square centimetre of the earth's surface 278.11 kg of sea water. 0.1 kg. of fresh mater, 4.j kg. of continental ice and 0.003 kg. of water vapour. The absolute amount and relative proportions of the different kinds of water change continuously. Because the bulk of all water present in the hydrosphere consists of sea nater, it is appropriate to state that the composition of the hydrosphere equals the composition of ocean water. Natural waters in their various states are actually rocks formed by the mineral, water. H_2O, but they are never pure because they contain a number of dissolved gases and solids and particulate matter.

1. Ground Water. — Ground water is, essentially, of atmospheric (meteoric) origin. When the meteoric waters that contain oxygen. carbon dioxide and small amounts of dissolved substances derived from the atmosphere enter soil and rock, they incorporate the soluble inorganic and organic gases, liquids and solids available. The ground water charged with carbon dioxide and oxygen is a powerful weathering agent. Bicarbonates, sulfates and chlorides of the alkaline-earth and alkali metals are the chief constituents of ground water. Its chemical composition is constantly changed by the action of several physical and chemical agents and ranges from that of nearly pure rain water to that found in mineral wells and springs. Another kind of ground water, called connate water, contains substances that were present in solution at the time of deposition of the sediment beds soaked with such a uater.

Sulfates and carbonates are the most important constituents of spring water, whereas chloride is usually less important. Some spring waters may be rich in silica. Calcium is the most abundant cation. and consequently spring and well waters are hard. Their chemical composition and salinity depends on local conditions.

2. Surface Water. — Admixture of rain water, surface water and ground nater from elsenhere rapidly changes the chemical composition of the spring nater flowing to lakes and rivers. Precipitation, solution and pollution by sewage and industrial waste naters will affect the composition of river water, in small rivers in particular. Weathering products and the remaining original constituents of rain water are carried by rivers in their water. The amount of the ueathering products varies according to the climate and the chemical composition and physical properties of rocks and soils in the catchment area. Carbonates dominate in river water and are much in excess over sulfates and chlorides, and calcium is the principal cation. Sulfates and chlorides tend to prevail in naters from arid and semiarid regions. In tropical regions the salinity of river water is remarkably low and the dissolved solids are rich in silicon, the element essentially removed in lateritic weathering (see BAUXITE; LATERITE). With dissolved and colloidal inorganic substances surface waters contain dissolved gases, chiefly nitrogen, carbon dioxide and oxygen, and a number of organic substances.

River waters may be divided into two major groups—carbonate and sulfate. The former are the more common of the two. (See Table X.) While calcium preponderates among the cations in fresh waters, its content in the salts of sea water is rather low, and sodium predominates. Furthermore, carbonate and sulfate predominate among the anions in fresh-water salts, while chloride preponderates in sea-water salts. These differences result from the precipitation of calcium as carbonate and sulfate in lakes and seas and from incorporation of calcium carbonate in shells and skeletons by marine organisms. Removal of the compounds accounts for the relative enrichment of sodium and chlorine in sea water.

TABLE *X.—Average Chemical Composition of Dissolved Solids in Lake, River and Sea Waters*

(In weight percentage)

Constituent	Lake and River Water	Sea Water

Total	100.00	100.00

*As HCO_3^-

3. Mineral Springs and Hot Springs.—Waters in mineral springs and hot springs differ from ordinary well and spring waters in either concentration or composition, or both. chiefly as a result of local conditions. These waters may be classified into chloride, sulfate, carbonate and acid waters as the main types. Furthermore, there are silicate, borate, nitrate, sulfide, phosphate and mixed waters. Many mineral waters contain dissolved gases, such as carbon dioxide, hydrogen sulfide, nitrogen and inert gases. Natural brines of high salinity may contain salts dissolved from salt beds by percolating waters, salt solutions associated with petroleum deposits, or connate waters. Some trace elements are present in mineral waters, partly derived from volcanic emanations and partly leached out from surrounding rocks; the therapeutic value of mineral waters is largely caused by their presence. Juvenile waters or those of deep-seated magmatic origin are usually characterized by a notable content of heavy elements, but in waters of superficial or vadose, that is, above the water table or upper level of ground water, origin such elements commonly are totally or almost totally absent. Other differences also exist in the chemical composition of juvenile and vadose waters. Hot springs represent the closing stage of thermal activity in volcanic regions; theirs is largely surface water.

4. Closed Basins.—In semiarid and arid regions, the soluble weathering products remain in the soil or are transported to depressions. If the rate of evaporation is too rapid to allow the accumulation of any considerable body of water, great quantities of dissolved matter are deposited in the depressions and finally form alkaline or salt lakes, or even dry salt beds usually consisting of sodium, magnesium and calcium as sulfates, and of some bicarbonate. The basins devoid of an outlet receive water by rivers and streams. In the continental areas of such internal drainage, permanent reservoirs are formed that contain water concentrated by evaporation of incoming water and with a composition entirely different from the composition of sea water. Many salt lakes are in a semisolid state, and the composition of their brines varies according to local conditions. The salt and alkaline lakes are divided, according to the dominant ion, into lakes with chloride waters, characterized mainly by sodium chloride; bittern lakes rich in magnesium salts; sulfate lakes; and carbonate and bicarbonate lakes. In general, alkaline lakes are connected with volcanic areas, and saline lakes, with sedimentary rocks.

5. The Ocean.—Sea water contains dissolved salts that have escaped adsorption during the cycle of dissolved substances, and precipitation and crystallization during the history of the ocean. More than 50 elements have been detected in sea water or in marine organisms, and it is probable that all elements are found in solution in the sea. The constituents given in Table XI make up more than 99.9% of the known dissolved solids in sea water. The salt content of ocean water is usually between 3.3% and 3.8%.

TABLE *XI.—Major Constituents of Sea Water*

Ion	Content (parts per 1,000)	Ion	Content (parts per 1,000)
Cl^-	18.9799	Na^+	10.5561
SO_4^{2-}	2.6486	Mg^{2+}	1.2720
HCO_3^-	0.1397	Ca^{2+}	0.4001
Br^-	0.0646	K^+	0.3800
F^-	0.0013	Sr^{2+}	0.0133
H_3BO_3	0.0260	Total dissolved solids	34.4816

The total amount of dissolved elements in sea water is colossal, and the oceans contain vast potential supplies even of many trace elements. The relative abundance of elements in sea water differs pronouncedly from their abundance in igneous rocks. The content of silicon, aluminum and iron in sea water is rather low. Almost all elements have been available in greater quantities than are now present in sea water, and, consequently, have been removed by physical chemical processes and biological activity. Many elements participate in a constant biological cycle in the sea, and their regeneration is relatively complete, even though the marine organisms cause their redistribution in sea water. Many elements, such as iodine, calcium, carbon, phosphorus, silicon and vanadium, are concentrated by marine plants or animals. A small amount of dissolved organic matter is present in sea water, and varying amounts of atmospheric gases are dissolved therein. The bulk of the dissolved gases is made of oxygen, nitrogen and carbon dioxide (chiefly as carbonate and bicarbonate ions).

Sea water is normally alkaline with a pH between 7.5 and 8.4, but variations also occur in pH caused, for instance, by biological activity. Regional changes are observed in the composition of sea water and are mainly connected with biological activity; for instance, the Antarctic ocean is rich in nitrate and the Pacific ocean in silicate. Furthermore, there exists a close connection between the content of phosphate and nitrate and the extent of biological activity in the sea.

The total quantity of carbon dioxide in sea water per square centimetre of the earth's surface is 50 times as high as the quantity of carbon dioxide in the atmosphere. The four forms of carbon dioxide in the sea, namely, free carbon dioxide, carbonate and bicarbonate ions and the undissociated H_2CO_3 molecules, form a buffer system. All these forms are in equilibrium with one another and with the hydrogen ions present in solution, as follows:

$$\begin{array}{ll} \text{Atmosphere} & CO_2 \\ & \Updownarrow \\ \text{Sea water} & H_2CO_3 \rightleftharpoons H^+ + HCO_3^- \rightleftharpoons H^+ + CO_3^{2-} \end{array}$$

The free (unbound and undissociated) carbon dioxide consists of CO_2 and H_2CO_3 molecules in solution and in equilibrium with each other. The carbon dioxide equilibrium depends on all physical, chemical and biological factors active in the sea. A change in the total concentration of carbon dioxide caused, for instance, by assimilation and respiration, results in a corresponding adjustment of all concentration constants until a new equilibrium is attained. The adjustments are also observable outside the phase boundary in the atmosphere and in solid carbonate phases. The atmosphere, however, regulates the tension of carbon dioxide in the sea. An exchange of other dissolved gases (certain nitrogen compounds) also takes place between the atmosphere and the sea.

Goldschmidt divided the elements into thalassophile (from the Gr. *thalassa,* "sea," and *philos,* "loved" or "having affinity for") and thalassoxene (from the Gr. *xenos,* "quest" or "stranger") groups according to their distribution between seas and continents. Chlorine, bromine. boron, sulfur (in sulfates), sodium and, partly, iodine are thalassophile, while all such elements are thalassoxene that precipitate in the hydrosphere because of the hydrolytic decomposition of their salts, *e.g.,* aluminum and iron. Some thalassophile elements, such as sodium, have increased in amount in the ocean during its history, while the amount of others (boron probably) has decreased. For still other elements, such as calcium, an equilibrium seems to be attained between the amount carried to the sea and the amount removed from the sea. Calculation of the geochemical balance of some elements in sea water (*i.e.*, the ratio between the total amount supplied and the amount now present) indicates that among the alkali metals only sodium is noticeably transferred to sea water, while the others are retained in clays. Other elements largely removed from sea water are calcium, aluminum, silicon, iron and manganese. The present content of chlorine, bromine, sulfur and boron in sea water is higher than the content calculated from the amounts actually transported into the sea. The four elements are added to the sea by volcanic emanations and juvenile waters.

Elements forming relatively readily soluble compounds, such as sodium. potassium, magnesium. carbon and nitrogen, remain in sea water in considerable quantities and finally crystallize out in the evaporites. Poisonous elements (mercury, arsenic and lead) are largely removed by incorporation in the hydrolyzates and the oxidates, in a process called depoisoning of sea water.

Particulate matter is carried by rivers into the sea, along with dissolved and colloidal substances. Physical chemical processes may take place between the particles and sea water. See also OCEAN AND OCEANOGRAPHY.

IV. GEOCHEMISTRY OF THE ATMOSPHERE

The atmosphere, or gaseous envelope surrounding the earth, is the outermost geochemical sphere. It consists of a mechanical mixture of gases and vapours extending up to approximately 1,600 km. (994 mi.) above the earth's surface and is in contact with the lithosphere and the hydrosphere. Air is present in the spaces between soil particles, in pores of rocks and is dissolved in water.

The lower limit of the atmosphere is determined by the depth of caves. mines and bore holes. In volcanoes the atmospheric gases are mixed with volcanic emanations. The gases in the cavities in rocks and minerals. occluded gases, petroligenic natural gas and the gases dissolved in the water of mineral springs and thermal springs all add to the atmosphere. Biochemical processes produce great quantities of gases, such as oxygen, nitrogen, carbon dioxide and methane.

1. Composition. — The atmosphere consists of four concentric layers without sharp boundaries. The lowermost layer, the troposphere, extends from sea level to approximately 11 km. (6.8 mi.) at middle latitudes. It is the convection region, and the atmospheric phenomena take place there. The next overlying layer is called the stratosphere, and the boundary between the troposphere and the stratosphere is called the tropopause. The stratosphere extends to an average altitude of 50 km. (31 mi.). In its upper reaches exists a high-temperature region, sometimes called the ozonosphere, caused by a concentration of ozone, which absorbs ultraviolet radiation of the sun. Above the stratosphere is the ionosphere that extends to about 600–700 km. (373–435 mi.) above sea level. The ionosphere is characterized by free electrical charges. Some of the gas particles in the ionosphere dissociate into ions and free electrons by the action of ultraviolet radiation. Furthermore, oxygen and nitrogen molecules dissociate into atoms. The temperature in the ionosphere is very high (2,200° C. at the height of 650 km. or 404 mi.). The outermost layer of the atmosphere is called the exosphere and is occupied by relatively freely moving gas particles.

It is believed that the earth's atmosphere is almost entirely of secondary origin and has been produced, like the hydrosphere, by volcanic emanations escaping from the lithosphere during the geological evolution of the earth. The first supply of free atmospheric oxygen formed in the photochemical decomposition of water vapour in the upper atmosphere, while the bulk was derived from water in photosynthesis by chlorophyll-bearing plants.

The total mass of the atmosphere is 51.3×10^{20} g. The average composition of dry air from the troposphere is presented in Table XII. Ozone content increases with height while radon (a gaseous radioelement) content decreases with height, and the content of water vapour varies from 0.02% to 4% by weight. The composition of the stratosphere is similar to the composition of

TABLE XII.—Average Composition of Dry Air from the Troposphere

Compound	Per cent by weight	Per cent by volume
Nitrogen (N_2)	75.51	78.09
Oxygen (O_2)	23.15	20.95
Argon (A)	1.28	0.93 } 100
Water vapour (H_2O)	Variable	Variable
Carbon dioxide (CO_2)	0.046	0.03
Seon (Ne)	0.00125	1.8×10^{-3}
Krypton (Kr)	0.00029	1×10^{-4}
Helium (He)	0.000072	5.24×10^{-4}
Xenon (Xe)	0.000036	8×10^{-6}
Hydrogen (H_2)	0.000003	5×10^{-5}
Ozone (O_3) (variable)	0.000002	1×10^{-6}
Radon (Rn) (variable)	4.52×10^{-17}	6×10^{-18}

the troposphere. Other constituents of the atmosphere are carbon monoxide, considerable amounts of which may be present in city air; formaldehyde; nitrogen oxides N_2O, NO_2 and N_2O_5; hydrogen peroxide; heavy waters HDO and D_2O; tritium, sulfur oxides SO_2 and SO_3; hydrogen sulfide; ammonia; iodine; methane; and radionuclides released by nuclear fission. These constituents originate in photochemical, electrochemical, biochemical and nuclear reactions. or are liberated in volcanic emanations or by the industrial activity of man. The composition of the atmosphere changes continuously because of the addition and removal of various substances. For example, helium actually slowly escapes from the atmosphere, as indicated by the fact that the amount of the isotope He^4 present in the atmosphere is much less than the amount generated by the alpha-decay of natural radionuclides during the geological history of the earth.

The elements notably enriched in the atmosphere are called atmophile (having an affinity for, or at home in the atmosphere) elements (see Table VI). Among the elements tabulated. only the inert gases and nitrogen are typically atmophile. Even though oxygen is enriched in the atmosphere, its amount is small compared with the huge amounts bound in the lithosphere and the hydrosphere. Consequently, the atmophile character of oxygen is not too pronounced

A certain amount of matter other than gaseous constituents is always present in the atmosphere. This matter consists of inorganic substances (*e.g.*, dust of various origin). organic constituents and organisms.

2. Rain Water. — The most important geochemical property of the atmosphere is the chemical disintegration of rocks and minerals caused by atmospheric oxygen and water vapour. Dry oxygen is rather inert. but in the presence of water vapour its reactivity increases. There is a continuous cycle of nater from the hydrosphere to the atmosphere and back to the former either directly in the form of rain water or indirectly by drainage. This cycle also includes the transport from sea water of salts, called cyclic salts, consisting chiefly of sodium chloride.

Rain water has a direct solvent action on minerals, and because it contains dissolved substances, it also acts indirectly as an effective carrier of denudation-promoting substances. Both inorganic and organic matter is dissolved in rain water, and particulate matter is often present. especially near cities. The most important among the dissolved inorganic constituents are chlorides, sulfates, nitrates and nitrites of sodium. potassium. calcium and magnesium. Nitrogen occurs also as free and albuminoid ammonia; humus and formaldehyde are frequently present. The gases dissolved in rain nater consist of approximately 63% nitrogen by volume, 34% oxygen and 3% carbon dioxide and other gases. The definite enrichment of oxygen and carbon dioxide in rain water over their content in air is the reason for the chemical activity of rain water. The chemical composition of rain water varies greatly and depends on the proximity of sea, character of the landscape, density of population and industrial activity. The purest water is obtained from rain falling after tropical thunderstorms. The average composition of rain nater is said to be as follows: chlorides, 3 o parts per 1,000,000; sulfates, 5 o; nitrates, 0.2; and free ammonia o 4 The nitrogen compounds in rain water are of importance as natural soil fertilizers. The composition of the other forms of atmospheric precipitation is similar to the composition of rain nater.

See also ATMOSPHERE.

V. GEOCHEMISTRY OF THE BIOSPHERE

The biosphere denotes organic nature as a whole and consists of plants, animals and microorganisms. It occupies the lower part of the troposphere, up to a height of approximately 5 km. (3.1 mi), probably the whole of the hydrosphere, and a thin layer on the lithosphere, with a lower limit at a depth of approximately 2 km. (1.2 mi.).

The biosphere is the region where reactions caused by solar radiation take place and is the part of the earth capable of sustaining life. It is the youngest among the geochemical spheres.

The branch of geochemistry dealing with the biosphere is called biogeochemistry. Unlike the hydrosphere, the biosphere is rather uniformly distributed over the whole surface of the earth. It is commonly divided into three habitats, or biocycles, which are the terrestrial, the fresh-water and the marine biocycle. The marine biocycle is, quantitatively, the most important of the three. Marine organisms play an important role in the cycle of inorganic and biogenic matter in the sea. The fresh-water biocycle is a small fraction of the terrestrial biocycle. Because of its lack of permanent life, the atmosphere does not form a biocycle.

If the weight of the biosphere is taken as unity, the relative weight of the atmosphere is 300, of the hydrosphere. 69,100, and of the uppermost part of the lithosphere, of the order of 10^6. Notwithstanding the negligible mass of the biosphere, its chemical activity is remarkable, and its geochemical role is important. For instance. most if not all of the free oxygen in the atmosphere is produced in the biosphere by photosynthesis. Chalk cliffs and coral reefs show profuse biological activity. All carbon deposited in the bioliths is collected from the atmosphere containing 0.03% carbon dioxide by volume, and there are mineral deposits of economic importance that are products of migration and concentration of elements in the biosphere.

The green chlorophyll-bearing plants synthesize organic compounds from carbon dioxide and water united in photosynthesis. The compounds synthesized are oxidized in living systems by respiration which is the main source of energy in animals.

1. Composition of Plants and Animals.— The biophile elements listed in Table VI are those occurring typically in the biosphere. Apart from the biophile elements proper, all those present in organisms are called biological elements. They vary considerably in importance, amount and distribution in the organisms. Some are basic elements present in all living matter, while others occur only in certain organisms. Among the basic elements. oxygen is essential for animals, nitrogen and carbon for plants and hydrogen and oxygen (as water) for all life. Approximately 60 elements are known to occur in the biosphere. Combined, they form all biological matter which is composed chiefly of water, carbohydrates, proteins and lipids, or fats and fatlike substances. The biological elements have a number of important functions in the organisms. Some (carbon and nitrogen) are found in the framework of plant and animal tissue. Others occur in shells and skeletons (calcium, magnesium, silicon, fluorine and phosphorus), as energy-exchange elements (hydrogen, oxygen), as electrolytes and osmotic regulators in cell liquors (sodium, potassium and chlorine as chloride), as catalysts in oxidation-reduction reactions (iron and copper, among others) and as enzyme activators (calcium, magnesium and cobalt). Some elements may be replaced by others in their functions, such as calcium by strontium or barium. The function of some elements is still unknown.

The presence or absence of an element in organisms depends primarily on its physiologic functions. Some elements are temporary constituents, while others are essential for the normal evolution and functions of the organism. The requirements as to essential elements even of closely related species may be different. Some just accumulate in organisms beyond all physiologic requirements, if any. Some nonessential elements may become concentrated in plants because of the defective selection power of the plants, which often cannot distinguish between essential elements and their nonessential fellow travelers.

The classificdtion of the biological elements according to their content in organisms is presented in Table XIII. The primary invariable elements make up the bulk of all living matter. They are essential constituents of carbohydrates, lipids and proteins. In lipids and proteins, some other invariable elements are always present. Among the variable elements, some are found in relatively high concentrations in certain species but are absent in other, even related, species. Plants and animals also differ notably in their composition. In general, the average chemical composition

of an organism is reminiscent of the composition of its environment. It is probable that the quantitative chemical composition of an organism is a specific feature.

The principal constituents of organisms are organic material, inorganic skeletal structures and inorganic compounds dissolved in body fluids. Organic material is largely composed of carbohydrates, lipids and proteins. Skeletal material consists mainly of calcium carbonate. calcium phosphate, or silica. Magnesium carbonate may occur as an important constituent of calcareous shells. The average total composition of living matter is presented in Table XIV for man and the alfalfa plant; apparently 11 elements

TABLE XIV.—*Average Total Composition of Living Matter*
(In per cent of dry weight)

Element	Adult Man (*Homo sapiens*)	Alfalfa (*Medicago sativa*)	Element	Adult Man (*Homo sapiens*)	Alfalfa (*Medicago sativa*)

make up this matter. Among the trace elements in man, iron, zinc, copper and manganese are the most abundant. Sodium and calcium are usually microconstituents in plants, but in many animals (vertebrates) calcium is a primary constituent. Compared with animals, plants are usually richer in manganese, nickel, aluminum, titanium and boron but are impoverished in iron, zinc and copper. In general, elements of low atomic number predominate in all organisms. Tables V and XIV indicate that many of the constituents of organisms (*e.g.*, silicon, aluminum and iron) are definitely impoverished with reference to their content in igneous rocks, while many trace elements (such as carbon, hydrogen and sulfur) are concentrated in living matter. The oxygen and calcium contents in igneous rocks and organisms are of a similar degree of magnitude. It appears that organisms select the necessary biological elements irrespective of their concentration in the environment. Tables XI and XIV validate this result for sea water also.

According to classic plant physiology, the following ten elements are essential for the healthy growth of plants: carbon, hydrogen, oxygen, nitrogen, sulfur, phosphorus, potassium, calcium, magnesium and iron. The seven last-mentioned elements are called the major nutrients or the mineral nutrients. They are taken up by plants as simple cations, complex cations and anions and as free molecules. Moreover, there is the group of the micronutrient elements known to be essential for plants or to promote their growth when administered in small amounts. Boron, manganese, copper, zinc, molybdenum and, perhaps, gallium are micronutrients. Finally, some elements promote in small quantities the growth of certain plants, among others, lithium, vanadium. fluorine. bromine and nickel. In greater concentrations nearly all of these are poisonous. Some elements. such as aluminum, silicon and chlorine accumulate at least in some species or genera and may be essential in such instances. The toxicity of elements. in general. increases with increasing atomic number in the groups and subgroup? of the periodic system, but the toxic effects depend also on the individual properties of the plants. Also in animals, the major nutrients of plants are indispensable. along with sodium and chlorine. In addition the following trace elements are essential: iodine. manganese, copper zinc and cobalt

2. Accumulation of Elements in Organisms.—Certain organisms are accumulators of definite elements. Some plants tolerate great quantities of elements that, even in small doses. are poisonous to other plants. Many elements, such as aluminum silicon. sodium and chlorine, even though not essential to the species in question, accumulate in, and are concentrated by, many plants. Their concentration is independent of their value as plant nutrients; they are called ballast elements. Numerous trace elements are present in exceptionally high contents in many coal and browncoal ashes as compared with their content in igneous rocks. The highest degree of enrichment is observed for boron, germanium, arsenic. molybdenum and bismuth, and the enrichment is independent of the chemical and geochemical character of the element A similar concentration of elements is observed in the ashes of many plants as in those from old forests Sometimes, as in the case of boron and manganese, the accumulation is biological and takes place in the living plant. but the concentration during decay of biogenic matter is geochemically more important. In this instance the rare elements present in the subsoil are taken up by soil solutions, enter the plants through the roots and are deposited at the sites of strongest evaporation, especially in the leaves. In leaves turning yellow and withering the content of most of the trace elements decreases. The readily soluble compounds of the major nutrients are leached away by rain water. while the sparingly soluble or insoluble compounds of the rare elements, such as hydroxides and protein and humic complexes are retained, partly by adsorption, in the humus layer. By such simple physical processes as recurrent evaporation and filtration the plants will finally cause the concentration of many elements in the topmost layers of forest soils.

The physical nature of the process is the reason why enrichment is independent of the chemical and geochemical properties of elements. Among others, silver, gold. zinc, thallium germanium tin, lead. cobalt and nickel become enriched in humus soils. The concentration principle, called the Goldschmidt enrichment principle, explains the concentration of elements in coal ashes in a similar uay The degree of enrichment depends on the plant species.

Prospecting.—Many plants are able to become accommodated according to the chemical composition of their substratum, that is. by concentrating certain elements (gold zinc copper and others) from soil above or near ore bodies. The ability of plants to indicate the chemical composition of soil is applied to prospecting for metal ores (geobotanical prospecting). The enrichment phenomena are also used for this purpose (biogeochemical prospecting). Compared with plants animals appear to be able to concentrate only a limited number of trace elements—copper vanadium. manganese, bromine and iodine. The absence of certain essential elements (cobalt, iron and copper) in the soil may cause regional deficiency diseases in plants. in grazing animals. and even in man. The accumulation of toxic elements. such as arsenic and selenium, by plants may also result in pathological conditions.

3. Photosynthesis.— >lost of the energy needed in the functions of organisms is produced by respiration nhich is the slow oxidation of organic matter. The ultimate principal products of oxidation are carbon dioxide, water and nitrogen. The rate of decomposition is high enough to destroy all biogenic matter in approximately 20 years. except for the fact that a corresponding quantity of matter is concurrently synthesized. This decomposition and regeneration forms a part of the geochemical cycles of the elements present in biogenic matter. The biochemical process by which organic compounds are formed from carbon dioxide and water is called photosynthesis (*q.v.*). It takes place under the action of sunlight and is the fundamental biochemical process. From the first photosynthetic products a number of fats. proteins. nucleoproteins, pigments, enzymes, vitamins, cellulose and other substances are produced. They are oxidized and decomposed before or after the death of the plant. Photosynthesis is an important part in the cycle of oxygen. All oxygen present in the hydrosphere and atmosphere has repeatedly circulated in the cycle from the atmosphere through the biosphere into the hydrosphere and back during the time of existence of chlorophyll-bearing plants on the earth.

4. Geochemical Activity of Bacteria.—Among biogeochemically active agents, bacteria are of great importance in the biosphere and the adjoining geospheres. Their high rate of multiplication and great physiological activity cause their participation in chemical reactions involving considerable amounts of matter. They affect principally the geochemical cycles' of carbon, nitrogen, phosphorus and sulfur. They are responsible for many changes in the pH of sediments and in the creation of reducing surroundings Such surroundings favour the reduction or hydrogenation of organic matter and the formation and preservation of reduced substances, such as the petroleum hydrocarbons. The acids produced by bacteria may dissolve calcium carbonate and other inorganic constituents of sediments, and consequently bacteria affect the cycles of calcium and other elements. Other bacteria favour the precipitation of calcium carbonate and thereby preserve calcareous sediments. Some are able to attack several inorganic substances and almost any kind of organic matter; for instance, sulfate- and nitrate-reducing bacteria are usually abundant in marine sediments. Some are capable of fixing free atmospheric nitrogen, others liberate nitrogen from nitrites and nitrates, and still others oxidize ammonia to nitrites and nitrates. Some species produce carbon monoxide. others methane or higher hydrocarbons, nhile others utilize methane in their metabolic processes. Bacteria may create environments harmful to other forms of life. but they also serve as sources of food and producers of plant nutrients. They are active in rock weathering and may be operative in the formation of sedimentary iron and manganese deposits.

5. Marine **Biocycle.**—The biosphere and the hydrosphere are closely connected biochemically because water is essential for all life. The marine biocycle is the most important part of the biosphere. Sea water is an especially suitable nutrient for algae, but the content of dissolved phosphate and nitrite regulates marine plant life and consequently affects animal life in the sea as well. The distribution of animals in the sea is also governed by the salinity of sea water

Plants are the most important consumers of marine inorganic matter and form the supply of food for animal life in the sea. There is a constant life cycle between plants and animals and between the formation and decay of biogenic matter. Changes in chemical composition are produced by the gron th and decay of marine organisms. The degree of enrichment of the elements by marine organisms is variable. Nitrogen and phosphorus have the highest degree of enrichment, but the content of carbon, silicon, fluorine, iron and copper is also considerably affected by biological activity.

***6.* Anthroposphere.**—The part of the biosphere inhabited and governed by man is called the anthroposphere. It is increasingly active chemically. Man causes changes in the geochemical cycles of the elements and disturbs the natural balance in the uppermost geospheres. Artificial inorganic and organic compounds, minerals and rocks are produced in the anthroposphere as are metals. such as aluminum and magnesium, that never existed in the native state in the earth. The atmosphere and the hydrosphere are used as sources of raw materials.

Many chemical processes in the biosphere are steered and controlled by man. Noble metals tend to accumulate in the anthroposphere, and new heavy radioactive elements are made artificially by man. The geochemical cycle of carbon, of all elements, is the one that is most strongly affected by the industrial activities of man.

7. Bioliths.—The sediments formed by the geochemical activity of the biosphere are called bioliths. They are divided into caustobioliths (Gr. kaustikos, "capable of burning") that are combustible and acaustobioliths that are incombustible. Carbonate, phosphate and siliceous sediments, among others, are acaustobioliths. The caustobioliths consist of humites, liptobioliths and sapropelites, which all are carbonaceous sediments containing native carbon or its oxidizable compounds. Some sulfur deposits of bacterial origin are also included. This group contains all solid, liquid and gaseous sediments used as fuel and is of great technical importance. The humites and liptobioliths are predominantly products of land and marsh vegetation. but the sapropelites contain decay products of many water organisms. The nature of the bioliths formed depends on the presence or absence of oxygen. If an adequate supply of oxygen is present, the decay of biogenic matter will produce carbon dioxide, water, sulfates and nitrogen, nitrates or ammonia. No solid carbon residue (coal) is produced, and only the resins and waxes of low reactivity may remain as liptobioliths. If the supply of oxygen is inadequate, the decomposition is incomplete, and small amounts of carbon-bearing substances will form. If oxygen is deficient at the start and completely absent later during the decomposition, peat will form. Peat is a typical humite sediment of vegetal origin, and humus is the final product of peat formation. If no oxygen is present at all, putrefaction mill take place, and sapropel or foul mud and sapropelites are formed as its final products. They are typically lacustrine or marine sediments formed in stagnant water. Putrefaction is a kind of slow distillation in which proteins, fats, oils and waxes are converted into methane and other hydrocarbons, hydrogen sulfide, ammonia, hydrogen, carbon dioxide and many organic compounds. The formation of sapropel affects the cycle of many sulfophile elements by precipitating them as sulfides. If the chemical decomposition of organic matter under reducing conditions is carried still further, petroleum will form as the final product.

Humus.—During the decomposition of biogenic matter some residues are resistant to the action of microorganisms and accumulate. causing the formation of substances called humus. The formation of humus involves the removal, from their cycles, of a part of carbon, nitrogen, phosphorus, sulfur, potassium and other elements nhich are made available for plants; consequently the formation of humus regulates plant life. It is a highly complex mixture of amorphous organic substances which contains some inorganic compounds of phosphorus, sulfur, iron, calcium and magnesium. It is also in a state of constant decomposition and forms a colloidal system. The colloidal humus-bearing solutions are of importance in weathering because of their dissolving action on detrital minerals; iron and manganese, for instance, are brought into solution as humic complexes. Humus is an important mother substance of coal. Various types called water humus form under water and may be converted into peat.

Soil.—Humus also plays an essential part in the formation of soil. Soils. composed of a mixture of inorganic and organic substances, support the continental plant life. Their general character depends on the nature of the weathering of their substratum, climate. relief, biological activity and time. Physical, chemical and biological processes are active in their formation. Quartz, clay minerals, limonite, haematite and some carbonate and sulfate minerals are the most important mineralogical constituents of soils. Organic matter greatly affects the physical properties and fertility of soil. The humic complexes are by far their most important organic constituents. Ammonia. carbon dioxide, phosphates and sulfates form during decomposition of soil humus. Ammonia is gradually converted into nitrates. These compounds greatly influence the fertility of soil and form a supply of elements essential for the synthesis of organic substances by plants.

See also SOIL.

Coal, *Petroleum* and *Other* Products.--Sapropel and peat (*qq.v.*) are accumulations from which coal is formed. Peat. brown coal or lignite and the different varieties of coal are the most important humite sediments. There is no sharp distinction between peat and coal. During coalification which finally produces anthracite, the carbon content increases. but the content of hydrogen, nitrogen and, especially, oxygen, decreases by the formation and escape of carbon dioxide, water, methane and nitrogen. The coals are divided into humic coals and sapropelic coals according to their origin. Various transitions exist between the sapropelic coals and from them to oil shales and humic coals. The coals are essentially colloidal substances consisting of highly complex compounds of carbon, hydrogen and oxygen. Other more important constituents include nitrogen, sulfur and phosphorus. Sulfides of iron, lead, copper, zinc, nickel and other metals are incidental constituents of coal. Silicon, aluminum and iron are the principal constituents of coal ashes, in which many trace elements are concentrated. The chemical composition of the plant material changes continuously after its deposition, and peat, brown coal, coal and anthracite represent different stages of incoalation or coal formation. The process is materially accelerated by elevated temperatures.

Waxes, resins, fats and oils are able to resist chemical decomposition and may become concentrated to make liptobioliths. They are also responsible for the characteristic properties of sapropel and sapropelic coals, and of some peats. Liptobioliths include resin, wax and spore coals and fossil amber or succinite.

Petroleum is a complex mixture of liquid hydrocarbons in which a number of gaseous and solid hydrocarbons are dissolved. The crude oils also contain small amounts of numerous organic compounds of nitrogen, oxygen, phosphorus. sulfur and some hydrogen sulfide, carbon dioxide and nitrogen. Many metals. notably nickel, vanadium, lead and iron. are present in petroleum, perhaps as metalorganic porphyrin complexes. Many trace elements are constituents of petroleum ashes. Few, if any, of the petroleum hydrocarbons are unsaturated, and all are optically active. The chemical composition of the crude oils varies according to the substances from which they were formed. The mother substance of petroleum consists of plant and animal remains in near-shore marine sapropelic sediments. The remains are partly of marine origin, partly carried to the sea by rivers and deposited under essentially anaerobic conditions. During the formation of petroleum, bacterial action occurred along with the work of physical, chemical and geological factors. The highly reducing environment favoured the hydrogenation of organic matter and the preservation of the petroleum hydrocarbons. Later changes in the composition of petroleum probably were caused by radioactivity. Brines related to petroleum both geologically and genetically occur in connection with most petroleum deposits.

Ozocerite and asphalt are often found together with petroleum and are regarded as solid oxidation and polymerization products of the crudes. Ozocerite is a mixture of solid hydrocarbons. Some asphalts are remarkably rich in nickel and vanadium.

Natural gases are either inorganic gases connected with igneous activity, gases produced by carbonization in the biosphere (marsh gas and gases from coal mines) and gases connected with petroleum deposits. or the natural gases proper. Petroligenic natural gas contains the most volatile constituents of petroleum deposits and is concentrated in the uppermost parts of the oil-bearing beds. Most of its constituents are of biogenic origin The chief constituents of petroligenic natural gas are highly volatile hydrocarbons. Nitrogen, oxygen, carbon monoxide and dioxide, hydrogen sulfide, helium and hydrogen in varying amounts are its normal constituents; radon and argon are sometimes present. Petroligenic natural gases are divided into hydrocarbon, nitrogen, carbon dioxide and heliurn types. Many of the rich nitrogen gases are rich in helium also.

VI. GEOCHEMICAL EVOLUTION OF THE EARTH

The study of the chemical evolution of the earth is one of the main tasks of geochemistry. For performing this task, the results of cosmochemistry, or chemistry of the universe, are particularly helpful, partly because of the role of geochemistry as a chapter in universal planetary chemistry, and partly because of the close relationships that link nuclear physics, physical chemistry and astrophysics together.

Traditional dogmatic geochemical speculation has dealt with the formation of a once totally molten earth largely according to the processes taking place in ore-smelting furnaces. This dogma, however, was slowly giving ground by the 1950s, and there is considerable evidence to indicate that the earth and other planets were formed by condensation and accumulation from a dust cloud at low temperatures. H. C. Urey developed the new approach in detail, largely on the basis of thermodynamic considerations.

The early stages of the primordial evolution of the earth are usually referred to as the astronomical time in the earth's history. The geological time started when a stable crust had formed and the exogenic processes first started thereon.

According to Urey, the final accumulation of the earth took place, at a temperature of approximately 0° C.. from small planetesimals containing metallic iron, carbon, iron carbide, titanium nitride and some ferrous sulfide. A gas phase had mainly been lost during the previous, high-temperature stage, and only small amounts of hydrogen, nitrogen, inert gases, water vapour, methane and hydrogen sulfide were left. The iron core of the earth accumulated slowly during the geological history of the earth from an almost uniform mixture of metallic iron and silicates. Consequently, the earth was not molten at the time of the accumulation of its materials.

See also COSMOGONY.

1. Evolution of the Lithosphere. — The lithosphere was formed by the separation of the iron and silicate phases and by fractional crystallization in the silicate shell. This differentiation is still going on. Crystallization caused the arrangement of the silicate shell according to the specific gravity of the crystallizing phases. The silicic magmas of low specific gravity and the aqueous residual solutions tend to rise upward. Heavy atoms actually should become concentrated in the lower levels of the lithosphere, but pneumatolytic and hydrothermal mineralization and metamorphism counteract the differentiation phenomena and concentrate these atoms in the uppermost parts of the lithosphere. The vertical movement of the phases of different specific gravity also explains the present distribution of the elements in the upper lithosphere. The modification of the surface layer by endogenic and exogenic processes started with the formation of a stable solid crust. During the earliest phase of geological history volcanic and plutonic activity probably took place on a larger scale than they ever did later. The exogenic cycle has grown in activity with the formation of the hydrosphere and the evolution of an atmosphere containing oxygen. Metamorphic and metasomatic processes are active in the present modification of the composition of the upper lithosphere, just as they were before. Metasomatic processes which involve the introduction of new substances into rock (see METASOMATISM) tend to equalize the composition, while exogenic processes cause a chemical differentiation. At present, differentiation predominates over equalization in the earth as a whole. Crystallization and differentiation by crystallization still cause chemical dissimilarity in the upper lithosphere, and light granitic magmas still wander upward through the crust.

The primary distribution of the elements in the various layers of the upper lithosphere may originally have been uniform in all parts of the globe, but at present there are many instances of an inhomogeneity in the upper lithosphere, in particular, among the granites which appear to be the more deficient in certain trace elements the higher their age. A secular migration of the elements on a global scale may take place in the crust causing the chemical inhomogeneity. The explanation of the global migration and differentiation is the continuous self-repeating granitization that is believed to take place in connection with the mountain-building processes. The granitization also enhances the silicic character of the uppermost layers of the lithosphere.

2. Evolution of the Atmosphere. — There is much evidence to indicate that the present atmosphere and hydrosphere of the earth are of secondary origin. It is unlikely that the primordial atmosphere contained free oxygen. According to Urey the primitive reducing atmosphere contained water vapour, hydrogen, ammonia, methane and some hydrogen sulfide. Hydrogen escaped from the gravitational field of the earth, and water was phntochemically decomposed into hydrogen and oxygen in the upper levels of the atmosphere. The oxygen formed was consumed in the gradual oxidation of ammonia to nitrogen and water, and of methane to carbon dioxide and water. Finally an excess of free atmospheric oxygen was formed, and an oxidizing atmosphere appeared, perhaps about 700,000,000 or 800,000,000 years ago. The formation of free oxygen is, geochemically, the most important step in the evolution of the atmosphere. Most or all free oxygen present in the atmosphere has been gradually produced from water by photosynthesis taking place in chlorophyll-bearing plants. The small initial supply of oxygen required by plants to make respiration possible was probably a product of the photochemical dissociation of water vapour. Carbon dioxide, like the bulk of water, was gradually added to the atmosphere by volcanic emanations, but its content has not remained stable. At the present time much carbon dioxide is added to the atmosphere as a result of various activities in the anthroposphere. The content of carbon dioxide is bound to increase until the regulating mechanism (*i.e.,* equilibrium between the hydrosphere and the atmosphere) becomes active. All carbon dioxide is finally bound in carbonates during weathering, and chances are small that it will ever be completely released by endogenic processes. Similarly, nitrogen also may be largely juvenile, and its supply has increased by nitrogen released from rocks during weathering. The inert gases are released into the atmosphere by volcanic emanations and weathering of rocks. Helium and argon are constantly produced by radioactive decay. Hydrogen and helium still escape from the uppermost levels of the atmosphere.

3. Evolution of the Hydrosphere. — The present hydrosphere is of secondary origin as is the atmosphere. The primeval hydrosphere must have been much smaller than the present hydrosphere. It is possible that the amount of water in the hydrosphere is still increasing. Even though much water is removed by weathering and sedimentation, it is, at least partly, returned during the slow vertical migration of matter in the upper lithosphere. Much water vapour is given off by the volcanoes, but this water is probably largely of meteoric origin. Changes have occurred in the chemical composition of the oceans during the geological evolution. Many substances, partly produced by rock weathering, accumulate constantly in the ocean. Vast amounts of volatile substances released by volcanic activity are finally transported into the sea. It is possible that all material deposited in the abyssal regions is permanently lost to the cycle.

4. Evolution of the Biosphere. — It is likely that life started soon after the earth had cooled to a proper temperature and that it covered the earth in a geologically short time. The oldest trace of biological activity is finely disseminated biogenic carbon in slates in Manitoba with an approximate age of 2.55×10^9 years. It appears that vast amounts of complex prebiological organic compounds were synthesized during the reducing stage in the atmospheric evolution in thermochemical, photochemical and electrochemical reactions. Life probably started during the change of the reducing atmosphere into an oxidizing atmosphere. Plant life probably could not start until there was some free oxygen in the atmosphere. A landmark in the development of animals is the appearance of the first calcareous skeletons in the Cambrian. about 500,000,000 years ago. The formation of animals is one of the most important processes in the evolution of the biosphere. The anthroposphere as a powerful geochemical agent has been operative but a few hundred years.

The geochemical evolution of the earth did not stop with the formation of a solid crust, the hydrosphere and the atmosphere. Actually, the evolution has continued throughout the geological history of the earth, and new stages have been added, such as the formation of the biosphere. The earth is changeable chemically, and its geochemical evolution still continues.

GEOCHRONOLOGY, a term first used by the geologist H. S. Williams in 1893 to designate studies in which the geological time scale in absolute time is applied to the evolution of the earth and its inhabitants. The term came to include the various methods of absolute dating in terms of years of those periods of time which precede historical records, thus comprising human prehistory as well as the whole geological. past *(see* GEOLOGY: *Historical Geology: Absolute Dates).*

Geochronological methods in use in the second half of the 20th century included the following:

Tree ring analysis or dendrochronology, a method which uses the cycle of the year as expressed in the formation of growth rings of wood. This method is applicable only in climates with pronounced seasonal fluctuations and areas covering historic and prehistoric phases, especially in North America. Its range is about 3,000 years.

Varve (a Swedish word meaning "layer") analysis, that is, analysis of annual layers of deposition by melting glaciers, is a method which relies mainly on the annual cycle and. to a lesser extent, on the sunspot cycle and precession of the equinoxes. Cycles of duration shorter than one year are also involved. Geological deposits of a rhythmic character, such as the layers formed by melt waters of the Pleistocene ice sheets, depend in thickness on the weather conditions of any particular year; hence cross identification of sequences of varves is possible. The method applies mainly to the last 15,000 years; *i.e.,* to the postglacial period, but it has been used also in earlier geological periods right back to Pre-Cambrian times.

The radiocarbon method relies on the radioactive disintegration of carbon 14 (C^{14}), an isotope of carbon created in the atmosphere under the influence of cosmic rays. A constant concentration which is present in living organic matter disintegrates at a constant rate with a half-life period (time required for one-half the initial number of atoms to decay) of about 5,600 years. The content of C^{14} found in dead organic matter thus gives an indication of its approximate age, the method being applied to about the last 30,000 years.

The per cent of equilibrium method is confined to the study of deep-sea cores and covers about 300,000 years. It relies on the rate of disintegration of radium precipitated in deep-sea sediments.

The solar radiation method approximately covers the Pleistocene period and with it the Old Stone Age of man. It is based on the comparison of geological evidence for climatic fluctuations within the Pleistocene period with the fluctuations of solar radiation received at various degrees of latitude in the summer half and the winter half of the year. It extends over a period of about 1,000,000 years.

Geological methods — this term comprises methods based on estimated time rates of sedimentation. denudation, erosion, weathering and chemical changes in minerals. Geological methods can be applied to all geological epochs but are, on the whole, not very reliable.

Uranium and other radioactivity methods take advantage of the disintegration of certain radioactive minerals with long half lives. The commonest methods rely on the accumulation of lead or helium, or both, formed by the disintegration of uranium. They have been applied to all geological periods before the Pleistocene and, in a modified form, to estimate the age of the earth's crust as a whole, the result being approximately [illegible] years. Other methods use the change of rubidium into strontium, and of potassium into argon. For a discussion of the archaeological applications of these methods of dating, as well as pollen dating, *see* ARCHAEOLOGY: *The Materials of Archaeology.*

GEODE, a hollow nodule of stone formed in sedimentary rock and having walls lined with crystals, among which calcite and quartz are the commonest. Other not uncommon minerals are dolomite, chalcedony. barite and celestite. Exterior surfaces of geodes are usually irregular. The wall minerals may have been deposited by circulating waters as the enclosing sediments became lithified or subsequent thereto.

A common method of origin of the cavities of geodes is by deposition of materials from solution along structural and fracture surfaces of shells, thus producing enlargement of original shell cavities and at the same time or subsequently lining the cavities with crystalline materials. Geode cavities of this origin are known to have formed from shells of brachiopods, crinoids and others.

If wall materials of geodes are more resistant to weathering than the enclosing rocks, the geodes are released and remain after the enclosing rocks have disappeared. If the opposite is the case: the minerals lining the cavities disappear and only cavities remain. Geodes range in size from very small to ten inches or more in diameter.

See R. S. Bassler, "The Formation of Geodes," *Proc. U. S. Nat. Mus.,* vol. 35, pp. 133–154. (W. H. TL.)

GEODESY. Geodesy, one of the oldest sciences of the world, has both scientific and practical purposes. Its scientific mission is to determine the size and shape of the earth and, in co-operation with other sciences, to study the internal structure of the earth. The practical task of geodesy is to carry out the measurements and computations needed for making accurate and reliable maps of the earth's surface.

This articleis divided into the following sections:

The most important practical objective of geodesy is the determination of the exact co-ordinates of control points on the earth's surface. When two co-ordinates of a control point are known. for instance, its geographic latitude and longitude and, in addition, its elevation above sea level, the exact position of this point on the earth's surface is known. In mapping large areas, such as a whole state or country, not only the curvature of the earth but also its flattening must be considered. The English usage of the word geodesy includes all the measurements, computations and objectives mentioned above.

A reliable control point system is a prerequisite for accurate maps. It may be compared with a skeleton which has to be covered with flesh and blood, *i.e.,* by a filling-in of details. The filling-in process also belongs to the domain of geodesy, though an essential part of this work can be done on the basis of aerial pictures, by the methods of photogrammetry (*q.v.*). The elevations of the control points and of other measured points are obtained by precise trigonometric or barometric leveling, methods which are discussed in the article SURVEYING.

I. OBJECTIVES

Although it may seem easy to determine control points on the earth's surface merely by making astronomical observations of the latitude and longitude at these points. this method is not satisfactory because astronomical observations are not sufficiently accurate. the highest accuracy obtained by the astronomic method being of the order 0″.2 to 0″.3 (arc seconds), or 6 to g metres along the earth's surface. Furthermore, serious errors will be caused by the irregularities of the earth's figure, to which the astronomical observations refer.

The earth's figure is that of a surface called the geoid, which over the sea is the average sea level and under the continents the imaginary continuation of sea level. The visible and invisible mass anomalies of the earth cause essential irregularities to the geoid and bring about essential errors, sometimes exceeding a mile, when distances between control points are determined astronomically.

Because of these facts we must use as a reference surface a regular mathematical surface that fits the geoid as closely as possible. This surface is an ellipsoid of revolution called a reference ellipsoid. Its surface is in some areas below. in other regions above, the geoid. The angle of tilt between the ellipsoid surface and geoid surface, or between the normal of ellipsoid and the normal of geoid, or plumb line, is called the deflection of the vertical, or deflection of plumb line.

Mathematically speaking the geoid is an equipotential or level surface, characterized by the fact that over its entire extent the so-called potential function is constant. This potential function is a result of the effect of the gravitational attraction of the earth mass, combined with the effect caused by the rotation of the earth about its axis. Since, if air masses are disregarded, there are at the oceans no masses above the sea level, mean sea level is a part of the geoid surface. In the continental areas the geoid is an imaginary sea level surface defined by spirit level. If small sea level canals were dug into the interior of the continents or if open-ended pipes, like inverted siphons, were run from the land out into the ocean, the surface sought would be defined physically at various points by the level of the water in these canals or pipes.

To get a system of geodetic control points it is necessary to have the geodetic datum for these points. The geodetic datum is completely determined when we know five quantities: the geographic latitude ϕ and longitude λ of the initial point of the geodetic datum, a direction (azimuth A of the direction between the initial point and some other control point) and finally the equator radius, a, and the flattening, f, of the reference ellipsoid. In other words, we need a point from which to compute, a direction in which to compute and a surface along which to compute. The co-ordinates of any control point computed in this geodetic system are comparable with one another. Their accuracy depends on the accuracy of the astronomical and geodetic measurements.

If only one of these five quantities changes, the whole geodetic system will also change. Until recent decades most countries had their own initial point of geodetic datum; therefore their geodetic systems were. of course, different even if they used the same reference ellipsoid.

One problem in geodesy is to obtain sufficiently accurate dimensions for the reference ellipsoid. Another .difficulty appears in converting the existing geodetic systems to one world system. A third difficulty is caused by the fact that all geodetic observations have to be referred to the geoid, but the computation of the co-ordinates must be carried out along the reference ellipsoid. To get rid of this "dualism" we have to know the distance, N, called warping or undulation of the geoid or the geoid distance, and the tilt between these two surfaces at the initial points of all these geodetic systems. It is also difficult to get the geodetic datum by precise leveling since the sea level is not constant but is affected by geological changes which raise or lower the continents and the ocean beds.

II. HISTORICAL

It is surprising that ancient civilized peoples, such as the Babylonians and Egyptians, who were interested in astronomy did not realize that the earth is a sphere, since its spherical shape should have been easy to deduce from several phenomena. The earth's shadow during the moon's eclipse has the shape of a circular arc, a shape that only a spherical earth can cause. The stars, while south in meridian, appear much higher in the sky when viewed from Alexandria than from Athens. When a ship approaches port, one first sees the'masts and only later the hull. But the significance of these phenomena dawned on mankind only slowly.

The co-ordinates of latitude and longitude were used at the suggestion of Hipparchus (*fl.* 146–127 B.C.). Because the world known to the ancients was long in the east-west direction from Spain to Persia and relatively short in the north-south direction from the Alps to North Africa, longitude was counted in the east-west direction, latitude in the north-south direction.

Still, Homer, in approximately 900–800 B.C., thought that the earth was a convex disk surrounded by the Oceanus stream. According to the other Greeks of that time the earth plate was supported by four elephants standing on a big turtle. But what supported the turtle they could not say. The philosopher Pythagoras (*fl* 532 B.C), was perhaps the first who thought the earth to be a sphere. Hipparchus and Aristotle (384–322 B.C.) came to the same conclusion. Eratosthenes (*c.* 276–194 B C.), however, is considered the founder of geodesy because he was the man who first measured the size of the earth, assuming that it was a sphere.

To determine the earth ellipsoid it is necessary to solve two problems, one geodetic and the other astronomical. The length, l, of an arc along the earth's surface must be measured in some direction. In the astronomical problem the central angle, v, corresponding to the measured arc. must be measured. By the aid of l and v the earth radius R can be obtained from the elementary formula $l:2\pi R = v^\circ:360^\circ$, or from $R = l/v$, if v is given in radians. The longer the measured arc and the more accurate the astronomical observations, the more accurately R can be obtained. Earlier the arcs l were measured at, or at least close to. the meridian directions, because v was relatively easy to determine in the north-south direction.

With the advent of accurate time signals and perfected clocks it became possible to determine the geographic longitude as accurately as the latitude, and arcs in any direction could be measured with equal accuracy.

This astrogeodetic method was used by Eratosthenes. He knew that in Upper Egypt in Syene, now called Aswan, on the Nile, the sun shone at noon in mid-summer vertically down into a well. His measurements showed that in Alexandria the direction of the sunbeams at the same time of the year at noon made with the vertical direction an angle 360°/50 or 7.2° (see fig. 1). Supposing that Syene and Alexandria were at the same meridian, he concluded that the centre angle v_1 between Syene and Alexandria was 7.2°.

As to the measurement-of the arc l he was told that a camel caravan needed 50 days to travel from Alexandria to Syene. Assuming that the rather constant speed of camels was 100 stadia a day, the distance between Alexandria and Syene would be 5,000 stadia and the length of the whole meridian circle 50 times larger. So he obtained for a meridian circle the length 250,000 stadia. If the Attic stadium, 185 metres, were used. the length of the whole meridian was, according to Eratosthenes, 46,250,000 m. This value is 16% too large, because the real length of the meridian by the definition of metre is, or at least used to be, 40,000,000 m. Fig. 1 also indicdtes how, by using the same principle, the U.S. army map service (F. W. Hough) determined the value for the equatorial radius of the earth as 6,378,260 m., using also the 100° long arc (central angle v_2), Tornio, Fin.-Cape Town, and the best available measuring instruments.

Considering that Alexandria and Syene are not at the same meridian, that the sun 2.200 years ago at noon in mid-summer could not shine in a vertical direction into the well of Syene. and that the measurement of the arc using the camel as a measuring instrument was certainly not accurate, it is surprising that Eratosthenes's result was not more in error. He deserves full credit, however, because his method was right in principle. Modern geodesists follow the same principle but make the astronomical observations with fine obiervation instruments and measure the length of the arc by triangulation. This important method was conceived by the Dutch scientist, Willebrord Snell (Snellius), in 1615.

The second known determination of the earth's radius was done by Poseidonius (*c.* 135–50 B.C), uho measured the distance between Rhodus and Alexandria on the basis of the time a boat needed to sail from Alexandria to Rhodus The corresponding central angle was measured astronomically. He realized that the star Canopus was on the horizon when seen from Rhodus island at the same time that the sunbeams in Alexandria made an angle of 7.j° with the horizon. Consequently, the central angle was, according to his observations, 7.5°. The radius value obtained by him was 11% too large

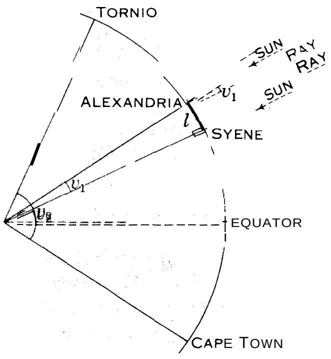

FIG. 1.—THE ARC MEASURING METHOD

Nine hundred years passed before the next measurement of the earth's dimensions was carried out at the suggestion of the caliph Abdullah al Mamun (A.D. 786–833) at the Zinjar plateau close to Baghdad. The Arabs made an actual measurement of the length of the arc by using wooden rods. They also made relatively accurate astronomical observations. According to the Arabs the following relation between the different length units exist:

$$1^\circ = \frac{170}{3}\text{ mi.}$$

1 mi. = 4,000 ell
1 ell = 24 in.
1 in. = 6 barley seeds
1 barley seed = 3.526 mm. (according to Snell)

Using these units, the Arabs obtained the meridian quadrant of 10,359 km., only 3.6% too long.

III. ELLIPSOIDAL ERA OF GEODESY

A new epoch began in geodesy with the use of triangulation. The idea of triangulation was apparently conceived by the Danish astronomer Tycho Brahe before the end of the 16th century and was used by him to establish a geodetic connection between Ven island and the main islands of Denmark. Triangulation was developed as a science, however, by Snell, who also first used it for measuring the dimensions of the earth. The triangle chain of Snell had 33 triangles and rendered for the meridian quadrant a value which was as much too small (3.4%) as that of the Arabs was too large.

The triangulation of Jean Picard (1620–82), which extended from Paris to north 1°.2 and consisted of 13 triangles, is methodically important because in it the telescope was first used for astronomical observations and logarithm tables were used in computing the results. Picard also measured by wooden rods a base line in the modern sense of this term. This measurement was significant also in that Sir Isaac Newton, when deriving his law of gravitation in 1665–66, used the equator radius value obtained by Picard.

The idea of triangulation is to measure only the angles of consecutive triangles. If in addition, as in fig. 2A, the length of one side, B_1B_2, of one triangle has been measured, all sides of the other triangles can be computed from the sine theorem. The triangulation points are chosen on hilltops and mountains so that the neighbouring points *A*, C, D, E can be seen from point B and thus the angles between them can be measured. When the length of the sides is known, the distance between any point (*e.g.*, between *A* and F) can be computed along the reference ellipsoid, and thus all points of the triangulation can be referred to the same geodetic system. Triangulation can have the shape of a triangle chain as shown in fig. 2A; or that of an "envelope chain" (fig. 2B), much used in the United States; also a triangle net as shown in fig. 2C.

One side of a triangle is obtained directly by measuring the field base line as accurately as possible. In principle, one base line for every triangulation system would be sufficient. Because of the impossibility of avoiding errors in observation, several base lines, each at an interval of 200 to 300 mi. are measured. Then an adjustment computation is made to take care of the observation errors. For instance, the sum of the angles of every triangle must be $180^\circ + \epsilon$; ϵ is a small quantity called the spherical excess of the triangle in question and is caused by the sphericity of the earth. In a similar way, for every measured base line, computation of its length along the triangles beginning from another base line must give exactly the same length as the measurement itself gives. When computing a closed loop of triangles it is necessary to get for the beginning point its original co-ordinates. So in triangulation there are numerous conditions that the observations must satisfy: the angle control, side control, base line control and co-ordinate control. All these will be handled in the geodetic adjustment computation based on the "least square" method, which means that the observations have to be corrected so that the sum of the squares of the corrections is a minimum. The main purpose of the adjustment computation is to eliminate the discrepancy in the triangulation net so that exactly the same co-ordinates will be arrived at for any of the triangulation points, regardless of which way they have been computed from the initial point. This does not mean, however, that the errors themselves have been eliminated. The observation errors exist but their effect has been made as harmless as possible.

The best results can be obtained, however, only when the observation errors are as small as possible. Therefore, in triangulation much attention is given to the accuracy of the measurements. For instance. the angles of every triangle are measured not once or twice but as many as 24 times. Similarly the base lines are measured several times and by different measuring wires to reduce the observation error.

Methods of triangulation have been so perfected that the accuracy of the base lines is from 1:2,000,000 to 1:4,000,000 of the length of the base line.

The period from Eratosthenes to Picard may be called the spherical era of geodesy. because the earth was thought to be a sphere. The geodetic problem was then relatively simple. It was necessary only to determine the radius of the sphere. The new era. the ellipsoidal era, began with the theoretical studies of Newton and his contemporary Christiaan Huygens. The physical

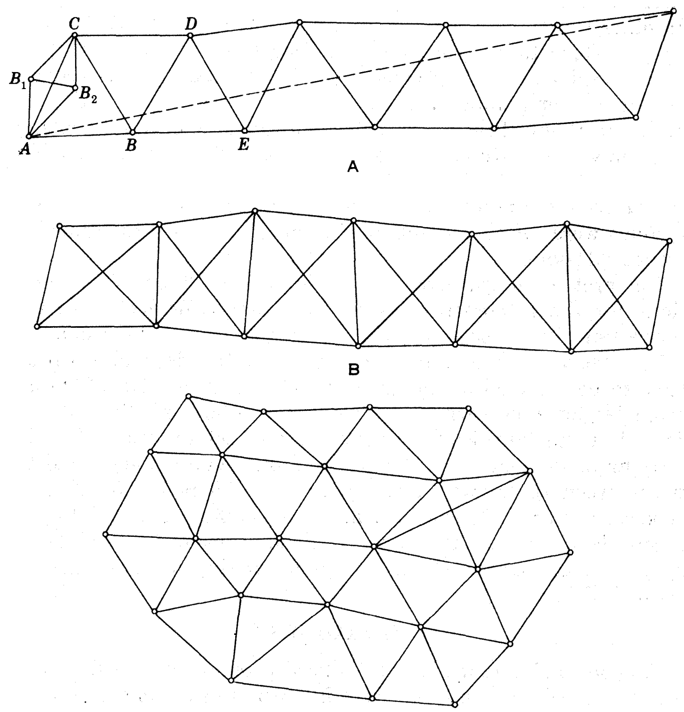

FIG. 2.— THE PRINCIPLE OF TRIANGULATION

(A) single triangulation chain, (B) "envelope" chain, (C) triangulation net proofs of the sphericity of the earth had so far been proofs of its general rotundity. In the Ptolemaic astronomy it had seemed natural to assume—for reasons usually of a metaphysical sort—that the earth was an exact sphere; but with the growing conviction that the Copernican system was true and that the earth rotates about its axis. and with the advance in mechanical knowledge due chiefly to Newton and Huygens, it seemed natural to think of the earth as an oblate spheroid flattened at the poles. There was also the experimental evidence of the astronomer Jean Richer (1630–1696), who found that his clock, regulated to keep time at Paris, lost $2\frac{1}{2}$ min. a day at Cayenne in South America, where he had been sent to make observations.

But the arguments from theory and the evidence of Richer's clock. confirmed by the experience of other observers, seemed to be contradicted by the work of Jean Dominique Cassini and his son Jacques, in France. If the earth is an oblate spheroid. the length of a degree of latitude must increase from the equator to the pole. but the Cassinis, continuing the arc of Picard north to Dunkirk and south to the boundary of Spain, came to the opposite conclusion. They divided the measured arc into two parts, one northn-ard, the other southward of Paris. The length of a meridian degree north of Paris was 111.017 m., or 265 m. shorter than one south of Paris (111.282 m.). This result could only happen either by a prolate (egg-shaped) earth or by errors in observation. In any case, their observations were strongly against the flattened earth.

It may seem strange that the length of the meridian degree is longer at the pole than it is at lower latitudes and at the equator. One might think that the reverse would be true, because the pole radius is shorter than the equator radius. Fig. 3 shows, however, why the length of a meridian degree increases with the latitude. The central angles v at the equator and pole are equal. but the radius EC_1 (radius of curvature) of the meridian AE at the equator E is shorter than the radius of curvature PC, at the pole P. Consequently, the meridian degree PB at the pole is longer than the meridian degree *Ed* at the equator. The pole radius PD and the equator radius ED are quite different from the radii of curvature EC, and PC,.

Because of the Cassinis' results a heated controversy began between the French and British scientists. The British scientists (the "earth flatteners") claimed that the rotating earth must be flattened as Newton and Huygens had theoretically shown. The Frenchmen, particularly the Cassinis, defended their own measurement and continued to believe the earth to be egg-shaped.

To settle this controversy, the French Academy of Sciences in 1735 sent an expedition led by Pierre Bouguer and Charles Marie de la Condamine. to a section of the Spanish province of Peru (which later became Ecuador) to measure the length of a meridian degree close to the equator. Another expedition in 1736, under P. L. M. de Maupertuis, was sent to Lapland to make a similar measurement near the Arctic circle. According to the resulting measurements the length of a meridian degree in Peru is 56.734 toise (French fathom); in Paris 57,060 toise; and in Lapland, 57,422 toise. The meridian degree was found to be longer the farther away from the equator the observations were carried out. These results showed irrefutably that the Cassinis were wrong and that the earth is flattened. The measurements in Peru and Lapland gave for the flattening the value 1:213, quite far from the value 1:297.0, used since 1924.

The general opinion of the geodesists was that the meridian arc measured by the Maupertuis expedition was not as long as the measurement indicated. The control measurements of the Swedish Geodetic Institute (Svanberg) in 1804, in fact, showed that the error was relatively large, according to him, 226 toise or 441 m. In 1928, the Finnish geodesist, Y. Leinberg, discovered that Maupertuis' measurement accumulated a number of errors that totaled 393 m. Unfortunately, all Maupertuis' errors were effected in the same direction, but it was fortunate that they gave him too long a meridian arc. Had his measurement been 441 m. too short, the problem concerning the shape of the earth would not yet have been solved definitely.

Eighteenth Century.—During the 18th century there were numerous measurements of arcs. The trigonometric survey of England was begun in 1783. primarily to establish geodetic connection between Greenwich and Paris. More important. honever, was the French arc measurement. In 1791 the French national assembly accepted a nen length unit replacing the toise. This unit was called a metre, by definition 1:10.000.000 part of the meridian quadrant from equator to pole along the Paris meridian. To get the length of this unit, additional accurate observations were needed. Therefore, a new arc measurement between Dunkirk and Barcelona. Sp , nas carried out by Pierre François Méchain and Jean Baptiste Delambre in 1792–98 Their publication in three volumes. *Base du système métrique decimal* (1806–10), in which the measurements carried out in France and Peru mere applied, gave for the length of a metre the following value: 1 metre = 443.296 Paris lines; 1 toise = 6 feet = 72 inches = 864 Paris lines. The ratio between toise and metre is therefore 864: 443.296, or 1 toise = 1.9490363 metres. Later arc measurements, however, showed that the metre does not correspond to its definition. In fact, the meridian quadrant of the international ellipsoid is 10,002,288.3 m. The metre is consequently 0.02% "too short." The following table may be used for reference:

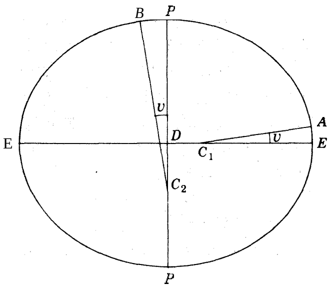

FIG. 3.—THE RELATIONSHIP BETWEEN MERIDIAN DEGREE AND LATITUDE

Fundamental Elements of the International Ellipsoid of Reference

a = semimajor axis (equatorial radius) = 6,378,388 metres

f = ellipticity (flattening) = $\frac{a-b}{}$ = 1/297 = 0.003,367,003,367

Derived Quantities

b = semiminor axis (Polar radius) = 6.356,911.946 m.

e^2 = square of eccentricity = $\frac{a^2-b^2}{a^2}$ = 0.006,722,670,022

Length of quadrant of the equator= 10,019,148 4 m.
Length of quadrant of the meridian= 10,002,288.3 m.
Area of the ellipsoid = 510,100,934 sq km
Volume of the ellipsoid = 1,083,319,780,000 cu.km.
Radius of sphere having same area as ellipsoid = 6,371,227.7 m.
Radius of sphere having same volume as ellipsoid = 6,371,221.3 m.
Mass of the ellipsoid = 5 988 $\times 10^{21}$ metric tons.

Nineteenth Century.—Of great significance were the arc measurements carried out in the 19th century by the survey of India under the leadership of the English surveyors general such as Sir George Everest, Sir Andrew Waugh and Sir Sidney Burrard; other scientists included G. H. Pratt, Sir George Airy and, later, F. deGraaff Hunter. In fact, this geodetic work made India the birthplace of isostasy (see below) and yielded detailed shape of the geoid over an area covering nearly all of India.

During the ellipsoidal era. which lasted to the 20th century, several geodesists computed reasonable values for the dimensions of the reference ellipsoid. In addition, the turn of the 19th century brought to geodesy, through the genius of 18-year-old K. F. Gauss (1795) and of A. M. Legendre (1806) development of the important adjustment computation as well as the definition of the metre and a preliminary value for it. The 19th century introduced the methodically basic triangulation work of Gauss and F. W. Bessel; the mathematical basis (Stokes' formula) of physical geodesy; as well as the international co-operation required for the development of geodesy.

IV. GEOIDAL ERA OF GEODESY

The period after 1900 can be called the geoidal era. because after this time it was possible to start the determination of the detailed shape of the geoid and its accurate dimensions to replace the approximations provided by the reference ellipsoid. During this geoidal era new instruments for geodetic, astronomical and gravimetric measurements were devised; the international ellipsoid and international gravity formula to be used in geodetic and gravimetric studies were adopted; extensive isostatic studies of basic significance to physical geodesy were carried out; several long-range triangulations were made; and electronic, celestial and gravimetric methods were applied to geodesy.

In the 19th century when every country was satisfied with a control point system of its own, the problems of geodesy were not too complicated. If a country was not too large, any reasonable reference ellipsoid could be used, since the effect of possible errors on its dimensions was quite small and not significant in practical mapping work. The reliability of the co-ordinates of the control points depended mainly on the accuracy of the astronomical, triangulation and traverse measurements. Relatively simple adjustment computation eliminated any inner discrepancy of the geodetic system in question. It did not matter how much the geodetic systems of different countries disagreed with one another. As late as 1947, for instance, the differences of the co-ordinates of the same control point amounted to 95 rn. between the Danish and Swedish systems, 250 m. between the Danish and German systems; 171 m. between the Danish and Norwegian systems; and 191 m. between the English and French systems. The exact extent of differences between the geodetic systems of the various continents and ocean islands is not known. They may be as great as 5 mi. or more.

World Geodetic System.—By mid-20th century it was clear that such confusion could not be allowed to continue. The demands of hydrographic surveying and aviation made it of basic importance that the co-ordinates of the different countries and continents be under the same system, that the existing geodetic systems, even across the oceans, be converted as accurately as possible to a single world geodetic system. It did not matter where the initial point of the world geodetic datum was located.

To standardize a world geodetic system the follo ing would be necessary: (1) a common scale or yardstick throughout the world; (2) new arc measurements along the continents and across the oceans; (3) exact localizing of these arcs on the reference ellipsoid; (4) more accurate dimensions of the reference ellipsoid; (j) extremely accurate values of the geoid distances N and the deflections of the vertical components ξ and η at the initial points of the different geodetic systems. As shown in fig. 4. N is the distance between the reference ellipsoid and the geoid at a given point. The tilt of the geoid is given by the angles ξ, the deviation between the plumb line and the perpendicular to the ellipsoid (dotted line) measured in a north-south plane, and η, the deviation measured in an east-west plane (perpendicular to the diagram, fig. 4, and so not shown).

The significance of a common scale is easy to understand. If the length unit obtained by the base line measurements is different in the various countries and on different continents, the computed geodesic lines to be used in the world-wide computations will not be comparable with one another and will cause systematic errors. Because of this fact it is necessary to measure in the different countries, or at least on every continent, one accurate standard base line on which to calibrate the wires or tapes to be used in the measurement of the field base lines. The light-interference method, invented by the Finnish astronomer Y. Väisälä, and put into practice by the Finnish Geodetic institute, supplies the needed standard base lines.

The United Nations' Regional Cartographic Conference for Asia and the Far East in Mussoorie, India, in Feb. 195j, recommended to the governments of the Asian countries "that a few standard base lines in this region should be established by the Vaisala method for assuring the uniform scale in all networks and for calibrating invar tapes and other equipment." The relative accuracy of the standard base lines of Nummela, Fin., and Buenos Aires, Arg., measured by T. J. Kukkamaki (1948) and T. B. Honkasalo (1953) are 1:17,000,000 and 1:9,000,000, or approximately 0.1 in. per 2j mi.

The Geodimeter.—Designed by E. Bergstrand and developed in Sweden, the United States and Germany, this instrument is based on Armand Fizeau's method for measuring the velocity of light. Instead of using a toothed wheel as the modulator and the human eye as the detector, the geodimeter applies a Kerr cell as the modulating unit and a photomultiplier tube as the detecting unit.

To measure distances the transmitter of the geodimeter sends light impulses at a modulating frequency of 10 mc. The impulses are reflected back from a target and are then detected in the photomultiplier tube of the receiver. If the distance between transmitting and target points is an integral amount of quarters of modulated light waves (about 7.5 m.) a special null detector indicates zero, which can be obtained by alternating the modulating frequency to apply a new unit of measurement. If only one frequency is used the distance must be accurate to $\pm$7.5 m. In practice, however, another frequency deviating 1% from the main frequency is used when the distance must be known only to $\pm$750 m. The instrumental accuracy is mainly dependent on the frequency, which is accurate to 1 or 2 parts in 10,000,000. The practical accuracy is a function of the velocity of light waves in *vacuo* and of the propagation anomalies caused by changing atmospheric conditions. These can be determined with an accuracy of about 1:1,000,000.

To measure the exact dimensions of the reference ellipsoid more and longer geodetic yardsticks (*i.e.,* accurately measured arcs in different parts of the world) are imperative. By the latter 19jos. for the most part, only the classic triangulation method had been used for this purpose. On the basis of astronomical observations of latitude and longitude at or near the end points of these yardsticks. we can locate the arcs approximately at the right places on the earth's surface. This astrogeodetic method can be used on the continents. In fact, the mathematicians of the U.S. army map service in 1956 computed new dimensions for the reference ellipsoid on the basis of the long arcs: Tornio, Fin.–Cape Town; Alaska–Chile; one meridian arc and one longitudinal arc in mainland U.S.; and one Eurasian arc, Atlantic coast–Siberia.

V. MODERN ARC MEASURING METHODS

Since the old triangulation method fails completely over the oceans, new methods were needed to connect the continents with one another geodetically. Two modern methods of measuring have been applied: the electronic and the celestial.

Electronic Method.—In the electronic method (Shoran, Hiran, Loran) it is necessary to know only the velocity of light and relatively short triangulation chains for calibrating the equipment which measures the long distances. Lines up to 880 km. have been measured so far with the highest relative accuracy: 1:120.000.

Shoran measurements need two ground stations, A and B, and one or more air-borne stations which carry the transmitting equipment for broadcasting the electromagnetic impulses. The aeroplane flies in loops over approximately the middle of line AB. The Shoran readings give the time which elapses when the impulses travel from the aeroplane to the ground station and back. From this time the distance from station A to aeroplane, as well as the distance from station B to aeroplane, can be computed. The, sum of these distances is different depending on how far the aeroplane is from the vertical plane through the line AB. Every reading gives a single value for the combined distance A-aeroplane-B. These values, reduced to the minimum distance, supply the distance between the ground stations A and B.

Celestial Method.—Four celestial methods have been developed: the rocket–star, solar eclipse, occulation and moon camera.

Rocket–Star.—This is a triangulation method invented and developed by Y. Vaisala in 1946. In this method a rocket is launched in an accurately vertical direction to a certain elevation (*e.g.,* 200 km.) and the neighbouring stars are photographed simultaneously from several observatories or other observation points. By measuring the small angular distances between the images of the stars and the rocket, the direction of the rocket from the observation points can be accurately computed. If the rocket were launched to an elevation of several hundred kilometres it would be possible to find distances across the oceans, and for triangulation on the continents.

The advantage of the rocket–star method lies in the large triangles which can be used.

Solar Eclipse.—This once popular method was developed in 1943 by I. Bonsdorff, director of the Finnish Geodetic institute. It is based on the scheme of the Polish astronomer T. Banachiewic and is used for measuring distances across the oceans. The method is simple although technical difficulties appear. With sound-film techniques photographs are made at two stations, A and B (each on different continents), around the moments when the totality of the eclipse begins and ends. The exact time, *t*, elapsing between the beginning (and end) of the totality at A and B is measured from the film, which also contains the tracks of the time signals and chronometer ticks. The time, t, renders with relatively high accuracy the distance between the stations, if the distance of the moon at the observation time is known accurately. For that purpose at least two solar eclipse stations, B and C, must be located on the same continent and their distance must have been measured by triangulation. The known distance BC gives the distance of the moon, on the basis of which the unknown distance AB across the ocean can be computed. For intercontinental geodetic ties this method was applied during the total solar eclipses in 1945, 1947, 1948, 1954 and 195j. Unfortunately conditions were so capricious —a cloudy sky too often hindered the observations — that only once was it possible to compute the distance across the Atlantic by this method. The accuracy of this tie, according to Kukkamäki's publication, is of the order of 80 m. An essential part of this error was brought about by the irregularity of the moon's topography.

Enthusiasm for this method has waned since total solar eclipses occur rather seldom, and because of the often inconvenient locations of the observation stations, which are determined by the path of the moon's shadow. Also the irregularity of the moon's limb (outline) decreases the accuracy of the observations. and too frequently "heavenly sabotage" destroys the work of the expedition.

Occulation.—In this method the moments during which a star disappears behind the moon's limb and emerges from behind it are observed. As in the solar eclipse method: the distance between the observation points can be computed assuming that the distance of the moon is known. This method also can be applied only relatively seldom, though more frequently than the solar eclipse method.

Moon Camera. — The moon camera method, invented by William Markowitz at the U.S. naval observatory, photographs the moon together with the neighbouring stars from observatories on different continents. The moon camera is so constructed that the moon's limb and the neighbouring stars are held stationary during the exposure of the film. The small angular distances of the distinct points of the moon's limb from the neighbouring stars, measured from the film, give the direction to the moon from the observation points. In theory two complete observations of the moon suffice. Analytically considered, two complete observations give four quantities, and only three unknowns have to be found. Considered geometrically, each observation gives a line of sight along which the station lies. Two lines of sight, well separated in direction, will intersect in a point which locates the station. In practice, the use of the moon in the solution of astronomical and geodetic problems is rather difficult from the standpoints of both computation and observation. What is measured is the displacement of the moon from a calculated position. The moon, however, may be displaced for reasons other than that due to the displacement of the station from the centre of the earth. In order to separate all the unknowns involved numerous observations must be made. Moreover, the moon must be observed over a large portion of its orbit, and at each station it must be observed in different parts of the sky. Before mid-20th century this had not been feasible because of the restrictions involved in determining the position of the moon accurately.

The geocentric co-ordinates of these points can, according to Markowitz, be computed, the geocentric radius R with the accuracy of about 40 m. The variation of R with the latitude and longitude of the observation points gives the general shape of the earth with the mentioned accuracy if a sufficient number of observation points exist. Twenty astronomical observatories of different continents agreed to co-operate during the International Geophysical Year 1957–1958 to apply this method on a world-wide scale.

The three moon methods are similar in that the moon is used as one triangulation point of this celestial triangulation. They help in determining the size and general shape of the earth.

All types of arc measuring methods render the length l of an arc of a great circle of the earth, which is necessary in determining the equatorial radius a.

The flattening f of the reference ellipsoid can be determined also by other astronomical methods utilizing the observed mechanical effects produced by the earth's equatorial protuberance, *i.e.,* by the polar flattening of the earth. This equatorial bulge produces periodic perturbations in the moon's perigee and of the node of its orbit on the ecliptic. The moon in turn acts on the equatorial bulge of the earth and produces the greater part of the slow displacement of the equinoxes known as precession; the sun contributes a fairly large part of the observed precession and the planets the small remainder. From any one of the effects mentioned the flattening of the earth may be deduced. Although there are theoretical difficulties in all of the methods the flattening deduced from the precession is as satisfactory as any; it agrees substantially with the flattening, 1:297, of the international ellipsoid. The flattening deduced by the other lunar methods tends to come out a trifle greater than this. The application of these different methods can reduce the errors in calculating the earth's dimensions.

All these celestial methods require land stations and fail over the open oceans. In addition, they are bound to the existing triangulation chains and to the relatively few astronomical observation points. ,Since the shape of the geoid must be determined point by point, it remained necessary to find a universal method which could be used everywhere in the world. This method will be rendered by physical geodesy.

VI. PHYSICAL GEODESY

There is a difference between geometrical geodesy and physical geodesy. Triangulation, either in the classic or the modern sense, with astronomical observations (*i.e.,* the arc measuring method), is spoken of as geometrical geodesy because it does not consider the structure of the earth's interior. Solely astronomical observations on. and triangulation along. the earth's surface give the size and general shape of the earth even if its structure is unknown. In this respect geometrical geodesy has had considerable success and has supplied reference ellipsoids that are not too diiferent from the actual geoid.

In the classic computations of the dimensions of the reference ellipsoid physical geodesy played an important role. It had been necessary to make the astronomically observed latitude, longitude and azimuth as representative as possible. In other words, in analyzing the astrogeodetic deflection of the vertical components, ξ and η, we must consider not only the effect of the visible topographic features but also the invisible compensating masses of the earth, and thus consider the internal structure of the earth's crust and of the layers under it. J. F. Hayford's ellipsoid, although based entirely on arc measurements made nithin the United States, wàs sufficiently accurate to be adopted in 1924 as the international ellipsoid because he used the topographic-isostatic reduction. *i.e.,* the method of physical geodesy. A similar case was W. A. Heiskanen's derivation of the equator value 978.049 cm. per sec. per sec. of the international gravity formula.

Gravity Anomalies. — The main tool of physical geodesy is, honever, the gravimetric method. The advantage of this method lies in its use of only one quantity, the gravity anomalies. To get the gravity anomalies it is necessary to reduce in some way the observed gravity from the observation point to sea level. Depending on the reduction method used, different values are obtained for sea level gravity g,. Since the earth rotates around its axis and, in addition, is flattened, the g_0 values are smallest at the equator arid increase with latitude. The gravity anomalies seem to have a relation not only to latitude but to longitude as well. Therefore, several scientists have derived gravity formulas assuming that the earth is a triaxial ellipsoid instead of an ellipsoid of revolution; in other words, the equator and the parallel circles are ellipses instead of circles. According to them the long axis of the equator would be close to longitudes 0° and 180°; the short axis close to longitudes +go° and —go°. The difference between the large and small semiaxes of the equator is about 120 m.

The triaxiality of the earth is quite difficult to explain geophysically and even the increasing use of gravimetric methods had not completely proved its existence. It appeared that this problem would best be solved—and in exact form—when the detailed shape of the geoid had been determined gravimetrically. From the geoid map of the world it would be easy to see whether the real geoid is closer to the triaxial ellipsoid or to the ellipsoid of revolution.

The physical basis of physical geodesy lies in the fact that the disturbing masses ***Am*** result in the geoid distances N, the deflection of the vertical components ξ and η, and the gravity anomalies $\Delta g = g_o - y$, where g_o is the observed gravity reduced to sea level and y is obtained from the international gravity formula,

$y = 978.049\ [1 + 0.0052884 \sin^2 + - 0.0000059 \sin^2 2\phi]$ cm./sec^2.

Of these quantities, Δg can be measured, and from it the quantities N, ξ and η can be computed. Figs. 4 and 5 show why the geoid is irregular. Fig. 4 indicates that the mass surplus of the

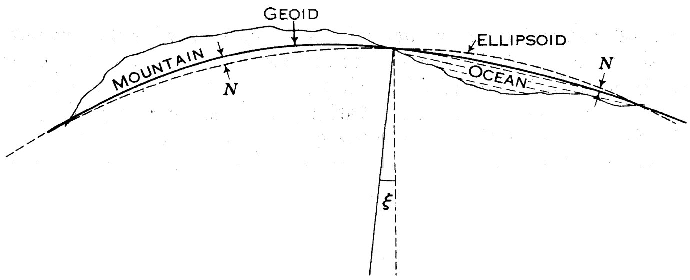

FIG. 4.—THE INFLUENCES OF SURFACE IRREGULARITIES UPON THE SHAPE OF THE GEOID

mountain pulls the plumb line; the mass deficiency of the ocean pushes it toward the mountain. Consequently, the plumb line (solid line) and the normal of the ellipsoid (dotted line) are not the same but make an angle with one another, the deflection of the vertical, ξ. Because the geoid (as an equipotential surface) is always perpendicular to the plumb line, the geoid under the mountains must be above the ellipsoid, and at the oceans it must be below the ellipsoid, if we assume that the mass surplus of the mountains and mass deficiency of the oceans are real and not isostatically compensated. Fig. 5 also shows that the invisible mass anomalies Δm, surplus (++++) or deficiency (− − − −), bring about the gravity anomalies hg, geoid distances N and the deflection com-

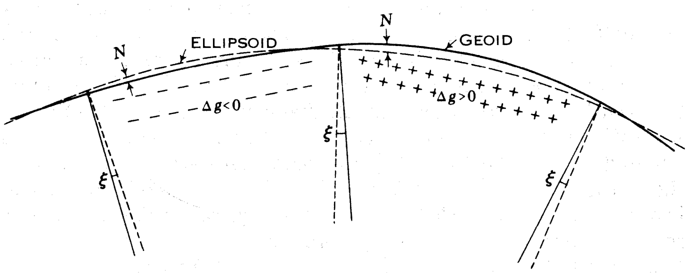

FIG. 5.—THE RELATIONSHIP OF MASS ANOMALIES AND GRAVITY ANOMALIES

ponents ξ and η. In these figures the quantities N and ξ as compared with the size of the earth have been exaggerated greatly to make the picture more clear. In fact, the largest N-values are less than 1:64,000 part of the radius (6,400,000 m.) of the earth, in other words, less than one inch on a sphere of one mile radius.

VII. METHODS AND ACHIEVEMENTS OF PHYSICAL GEODESY

The mathematical basis of physical geodesy is the Stokes' function, as set forth by Sir George Stokes in 1849, and its derivatives, developed by F. A. Vening Meinesz in 1928. The Stokes' function holds that the shape of the geoid can be determined if the gravity anomalies in the neighbourhood of the computation point are known rather well and those around the world are known in broader terms. The Vening Meinesz formulas indicate that in this case the deflection of the vertical components also can be computed.

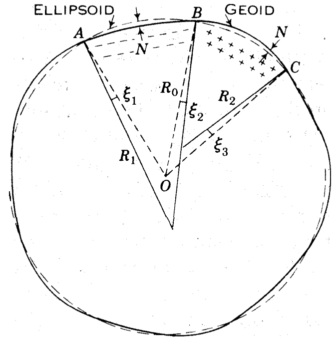

FIG. 6.—THE RELATIONSHIP OF VERTICAL DEFLECTIONS AND DIMENSION OF THE REFERENCE ELLIPSOID

Computations.—Fig. 6 shows how the irregular form of the geoid will interfere in the computation of the radius of curvature of the earth. Because of the warping N of the geoid (solid line) and the deflections of the vertical ξ_1, ξ_2 and ξ_3, it is easy to get wrong dimensions for the earth ellipsoid (dotted line). The arc AB, where the geoid is under the reference ellipsoid, gives too large a radius R_1; arc BC, where the geoid is above the ellipsoid, gives too small a radius R_2; the correct value is R,. Through the isostatic reduction of the astrogeodetic deflections of the vertical the irregularities of the geoid can be "smoothed" and the disturbing effect of the deflections of the vertical on the 'radius R_0 can be reduced and a better result achieved. The whole effect of the quantities ξ_1, ξ_2 and ξ_3, however, can be eliminated only if they are known and considered. Then both arcs dB and BC give the real radius R_0 of the ellipsoid. To put it more mathematically, the curvature of the geoid along the measured arc is obtained instead of the curvature of the mathematical reference ellipsoid as is the case when the deflections of the vertical ξ are not known. The gravimetric method supplies these quantities ξ.

Figs. 7 and 8 explain the limitations of the arc measuring method. Fig. 7 shows that the fictitious geoid distances N_1, N_2 are obtained if the exact dimensions of the reference ellipsoid are not known. Similarly fig. 8 indicates that wrong N-values also result in the case that at the initial point A of the geodetic datum an unsuitable deflection of the vertical ξ_0 has been used. Therefore, we cannot convert the various geodetic systems to a single world system unless we know the real deflections and the geoid distances at the initial points of these systems, or can connect the initial points with one another directly either by triangulation or by some other method.

When the arcs used in the determination of the dimensions of the earth are relatively short as compared with the radius of the earth, the error brought about by the deflections of the vertical at the end points of the arcs used can amount to hundreds of metres. If, for instance, the unknown relative deflection of the vertical at the end points of an arc $\frac{1}{3}$ the radius of the earth is only $4''$, the error in the obtained radius of the earth will be not less than 372 m. If longer measured arcs are available, the error caused by the neglected deflections of the vertical is smaller. If, for instance, in South Africa close to the southern end of the meridian arc Cape Town–Tornio, the ξ-component is $-10''$ and at the northern end, about $+2''$, neglect of these deflections will produce an error in the radius of the earth, computed by aid of this 100° long arc, of about 220 m. if other astrogeodetic points are not used.

As the examples show, in using measured arcs for checking the dimensions of the earth it is necessary not only to know the length of the yardsticks, but also to be able to localize the arcs at the right places on the ellipsoid to be computed. The central angle of the ellipsoid corresponding to the measured arcs must be determined accurately, considering the absolute deflections of the vertical at the end points of the arcs, if the arc is to be converted from geoid to ellipsoid.

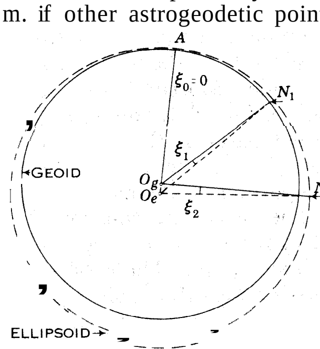

FIG. 7.—THE RELATIONSHIP BE- [illegible] RADIUS [illegible] REFERENCE ELLIPSOID AND THE GEOID DISTANCE N AND DEFLECTIONS ξ

In geodesy two methods have been used for checking the dimensions of the earth ellipsoid: the arc method, as explained earlier. and which comes into consideration if only triangulation chains are availabie; and the area method.

The Area **Method.**—When triangulations with astronomical points cover large areas as in the United States, Europe, the U.S.S.R., or India, use of the area method is preferable. One of the astrogeodetic points of the triangulation will be chosen as the initial point of the geodetic datum For instance, for the triangulation of the United States the initial point is Meades Ranch in Kansas, lat. 39° 13' 26".686; long. 98° 32' 30".506, azimuth to Waldo 75° 28' 14".52. Beginning at this initial point the latitude ϕ, longitude λ and azimuth A are computed geodetically along the chosen reference ellipsoid. The astronomical quantities ϕ', λ' and A' are referred to the geoid, the quantities ϕ, λ and A to the reference ellipsoid used. The differences of these quantities give, at all such triangulation points where astronomical observations are available, the deflections of the vertical components ξ and η, as the following classic formulas show:

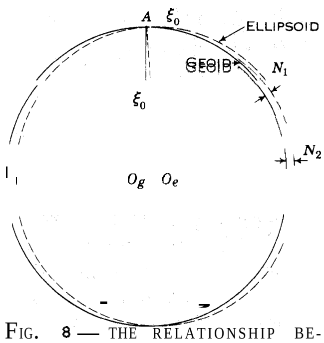

FIG. 8 — THE RELATIONSHIP BETWEEN THE VERTICAL ξ DEFLECTION OF GEOID DISTANCES AT INITIAL POINT

$$\xi = \phi' - \phi$$
$$\eta = (\lambda' - \lambda) \cos \phi$$
$$\eta = (A' - A) \cot \phi.$$

The 7-component can be obtained from the longitude observations as well as from the azimuth observations. If both are available, the point will be called the Laplace point and from the two equations for η the famous Laplace equation is obtained: $(A'-A) = (\lambda'-\lambda) \sin \phi$. Because of the observation errors this equation is not satisfied, but becomes instead the equation: $(A'-A) - (\lambda'-\lambda) \sin \phi = w$. The quantity w of the Laplace equation has nothing to do with deflections of the vertical, but is only the measure of the observation errors. The larger the errors are, the greater is w; $w = 0$ means that the observation error is zero.

If the undulation N_0 at the initial point of the geodetic datum is known or can be guessed then the warping N of the geoid can be computed with the aid of the obtained(- and η-values, along the arc measuring chain, if it has sufficient astronomical points. If this is combined with the gravimetric method the N-values can be interpolated even when only a few astronomical points are available.

In checking the dimensions of the reference ellipsoid based on the arc measurements, the criterion $\Sigma\xi^2 = \min$, or $\Sigma\eta^2 = \min$, or $\Sigma\ (\xi^2+\eta^2) = \min$. has been used depending on whether the arc has been measured in the direction of the meridian, or perpendicular to it, or in some other direction. This method is accurate if the measured arcs are long, but not if they are short, or if the astrogeodetic points used cover an area where the real deflections of the vertical are systematically either negative or positive. For instance, in Europe the criterion $\Sigma\ (\xi^2+\eta^2) = \min$ cannot be used because the average value of ξ in that area is of the order $+5''$ and the average η of the order $+2''$ to $+3''$.

The Gravimetric Method. — The gravimetric method makes it possible to obtain essentially more accurate dimensions for the reference ellipsoid merely by making extremely accurate astronomical observations at or in the neighbourhood of the end points of the measured arc. In addition the deflections of the vertical components ξ_g and η_g at both end points of the arc or close to them can be computed gravimetrically. On the other hand some arbitrary values have been chosen for the astrogeodetic deflection of the vertical components ξ_a and η_a (*e.g.*, zero) at one end (initial) point of the arc and computed along the arc ξ_a and η_a at the other end point. The computed quantities ξ_a, η_a depend on the reference ellipsoid used, while (η_g are nearly independent of it. If the differences $(\xi_g - \eta_a)$ and $(\eta_g - \eta_a)$ at both end points of the arc are nearly equal, the reference ellipsoid used is correct. If there is a difference, say, of 10″, the dimensions of the reference ellipsoid must be corrected so that this difference disappears.

Needless to say, if at, or close to, the end point of every measured arc accurate astronomical observations and the best local gravity survey have been carried out, these can be used for checking the dimensions of the earth. By the least square method the different measured arcs of this kind will give. together, the best possible correction to the equator value of the reference ellipsoid used.

In the area method, of course, the same criterion is used. The astrogeodetic points to be used must be as far as possible from the initial point but not too close to the boundary of the gravimetrically surveyed areas. The detailed gravity field must be available, say, to 500 km. from the computation point to get reliable gravimetric deflections of the vertical.

The deflections of the vertical average less than 5″; the values over 10″ are exceptional. They have been found for the most part in mountainous regions, and in quite a few cases on islands also, and even in lowlands where abnormally light or abnormally heavy disturbing layers are close to the computation point and to the earth's surface. For instance, in flat land in the neighbourhood of Moscow deflections of even 8″ exist. Similarly in south Finland, in the Aland islands, between Finland and Sweden, the deflection is 9″, and close to Columbus, O., also in level land, deflections of 10″ have been found.

Among the largest measured deflections of the vertical are the ξ- and η-values found in the Puerto Rican area (43″, according to D. Rice) and in certain of the British islands in the Pacific (54″, according to William Kaula). The relative deflections of the vertical on the south and north coasts of these islands differ as much as about 50″. When the distance between such stations is only about 50 mi., this distance, if computed from the astronomical co-ordinates, can have an error of 1 mi. or 1:50 of the whole distance. Since it is impossible to determine beforehand where the deflections of the vertical exist, it is impossible to use the astronomical co-ordinates as control points of any maps.

If the gravimetric ξ_g and η_g are known the astronomical quantities ϕ', λ' and A' can be converted to the geodetic quantities ϕ, λ and η from the formulas:

$$\phi = \phi' - \xi_g$$
$$\lambda = \lambda' - \eta_g \sec \phi$$
$$A = A' - \eta_g \tan \phi.$$

The obtained values ϕ, λ and A give the distances and azimuths along the ellipsoid. This is the principle of the astrogravimetric method for determination of the co-ordinates of the control points.

Another example of this principle concerns the western part of the boundary between the United States and Canada, which is the 49th parallel of latitude. For reasons of convenience this parallel was defined astronomically, and the result showed that one bounding station is about 8″ north of where a geodetic determination would have placed it, and another station less than 100 mi. away is about 6" south. The greatest relative error between two adjacent stations is about 7" in a distance of 20 mi., which means an error in the direction from one station to the other, as inferred from the latitudes, of about 35 ft. per mile.

When the quantities N, ξ_g and η_g are known they can be used to: (1) compute the distances along the reference ellipsoid between the astronomic points where ξ_g and η_g have been computed; (2) convert the existing geodetic systems to a single world geodetic system; (3) obtain with greater accuracy the dimensions of the earth; (4) check the accuracy of superlong triangulation, which greatly needs checking, especially where the triangulation chains were measured under difficult conditions, *e.g.*, the chain from Alaska to Chile; (5) reduce the geodetic base lines from the geoid to the ellipsoid; (6) compute the error caused by the deflections of the vertical at the triangulation points which in high mountains can be more than 2"; and (7) draft world maps for the geoid distances N, another set of world maps for the deflection of the vertical component ξ_g and a third set for η_g.

These maps have an exceptionally practical geodetic significance; they are also important for geophysics since there is always a close relation between the N, ξ_g and η_g-values and the internal structure of the earth.

By the 1950s. several areas, including large parts of the United States, Europe, India. Russia, Argentina, Canada and South Africa, had been so well covered by gravity station nets that reliable values, particularly for ξ_g and η_g could be obtained. The enormous progress in this respect was possible because of the folloning: (1) the invention of very fast, accurate gravimeters which can in three minutes measure a gravity value with 20 to 50 times more accuracy than had been possible to get in two days uith pendulum observations; (2) the invention of the Vening Meinesz pendulum apparatus for gravity observations at sea; (3) the invention of the underwater gravimeter for measuring gravity in the shallow shelf areas which cover about 7% of the ocean areas; (4) the interest of the oil companies in carrying out detailed gravity surveys for exploration purposes and universities conducting surveys for scientific purposes.

VIII. MEASURING INSTRUMENTS USED IN GEODESY

For longitude observations in the astronomical part of geodesy the transit instrument has been in general use for a long time. Those used at mid-20th century ordinarily were provided with a self-recording micrometer and were used in conjunction with a chronograph. For latitude determination the same transit, with broken axis, and the zenith telescope (*q.v.*) are used almost universally. For determination of azimuth and triangulation angles, the modern theodolite is used; this instrument is more accurate than the ordinary surveyor's theodolite but does not differ essentially. In addition, accurate chronometers. crystal clocks and radio receivers are needed for measuring the observation time and taking time signals. The accuracy of the astronomical observations. if observations are made on two or three nights at the same point, are of the order 0".1j in latitude and 0".20 in longitude. The standard error of the measurement of one angle in triangulation varies between 0".3 to 2".5 in different countries.

Bars and rods were used earlier for the base line measurements but they were inconvenient. The measurement went slowly and the accuracy was not high regardless of how carefully the observations were made. By mid-20th century bases were measured with tapes or wires made from invar alloy. The coefficient of the temperature expansion of invar is so small (of the order 10^{-7}/°C.) that the temperature need not be determined with high accuracy. The wires and tapes must be calibrated before and after the field work. That can best be done at the standard base lines described earlier.

In principle, the instruments for precise leveling are the same as the usual engineering leveling instruments but are, of course, much more accurate. The development of geodesy as a science closely followed the development of geodetic instruments since as the instruments became handier, more accurate and more rapid, the geodetic observations themselves became more accurate and more convenient.

In modern physical geodesy gravity observations are of basic significance, therefore gravimetric measuring instruments and methods are most important. Gravimetric observations are either absolute or relative. In absolute measurement it is necessary to measure the actual gravity that exists at the observation point. In the relative observation it is necessary to measure only the difference or ratio between the gravity g_0 at the base station and the gravity g at the field stations. When the base station gravity g_0 is known. the difference $(g-g_0)$ or ratio g/g_0 will give the gravity g at the field stations.

Pendulum Apparatus. — Until about 193j the pendulum apparatus was used almost exclusively in gravity observations. Its principle is simple. If the length l and period T of the pendulum can be measured the gravity g can be obtained from the formula

$$T=2\pi\sqrt{l/g}.$$

T is relatively easy to determine, but the measurement of the length of the pendulum l, involves difficulties. In addition the length l varies with temperature and other atmospheric conditions. Therefore, absolute gravity observations at one point take many months and in spite of the utmost care the accuracy is relatively low, rarely more than 3 to 4 mgal. (in geophysics unit g has been named the "gal" [after Galileo]: 1 milligal [mgal.] = 0.001 gal= 0.001 cm./sec./sec.). In relative gravity observations it is necessary to measure only the period T of the pendulum at the base station and the field stations, assuming that l has not changed between the observations. The formula, $g:g_0=T_0^2:T^2$, gives the gravity g if T_0 and T have been measured at the base and field stations and g_0 is known.

Pendulum apparatus needs stable support in order to give the best observational results. In the Netherlands, where the land is not stable. Vening Meinesz, after running into difficulties in his gravity measurements, developed in 1923 a pendulum apparatus that could be used not only there but on the oceans as well. Two pendulums of equal length are allowed to swing in the same vertical plane but in different phase angles. By the use of a certain hypothetical pendulum. the phase of which at any instant is the difference between the phases of the two pendulums at that instant, the disturbing effect of the horizontal acceleration of the support can be eliminated. When the apparatus was supported in gimbals in a submarine 30 to 50 m. below sea level, it was possible to eliminate the effect of the horizontal acceleration of the submarine and so to measure gravity on the open sea. The accuracy of these observations is of the order 2 to 3 mgal. or sufficient for thorough studies of the oceans. particularly since the east-west velocity of the vessel which is not known accurately because of the ocean currents can cause an error (Eotvos effect) of 3 to 4 mgal.

Vening Meinesz measured about 900 stations along different oceans. Later, British. French. Russian. Italian and Spanish scientists continued these observations. However, the greater part of the sea observations between 1945 and 1955 were carried out by Columbia university, New York, under the leadership of W. Maurice Ewing and John Lamar Worzel. More than 4,000 ocean points were observed. Gravity surveys at sea are of basic significance from the geodetic point of view. since without them no application of the Stokes or the Vening Meinesz formulas to geodetic purposes would be possible.

Gravimeters. — Pendulum observations take much time and the results are not very accurate; therefore, various types of gravimeters were devised in the different countries, particularly in the U.S. They are ingenious instruments, working essentially on the principle of the spring balance. and are so accurate that in a few minutes the gravity difference can be read with an accuracy of 0.02 mgal., which is 50 times higher than that obtained earlier by pendulum observations of two days.

As the Vening Meinesz pendulum opened the oceans to gravimetric survey. gravimeters began a new era in the gravity survey of the continents. Oil companies, universities and geodetic institutes around the world were competing to carry out regional and local gravity surveys that by the latter 1950s covered an essential part of the continental surfaces. Gravimeters, however, must be calibrated preferably at the base stations by measuring them several times by an accurate pendulum. Gravimeters considered best for geodetic purposes (Worden, Norgaard gravimeters) have large range (as great as 5,000 mgal.), high accuracy and small weight.

Gravity observations throughout the world can be used for computing geoid distances and deflections of the vertical only if they all refer to the same world gravimetric system, regardless of which system it is. Cntil the latter 1950s all gravity anomalies were computed by the Potsdam system. The absolute gravity observations of this system were done at Pendulum hall. Potsdam, Ger., in 1900–03. The observed gravity value was g = 981,274 gal which, however, according to later observations appeared to be about 15 mgal. too high. Fortunately. the error did no harm since the value is used to obtain gravity differences in the formula, $\Delta g=g-\gamma$. If g is 1j mgal. too large, then γ is also 1j mgal. too large and Δg remains the same.

Gravity values can be best changed to the same system if scientists use the same type of gravimeters and air transportation and carry out gravity observations at national gravity base stations. Such a conversion was made over a ten-year period (1947–57), particularly by the University of Wisconsin group under G. P. Woollard. This group occupied more than 3,000 base stations all over the world and integrated the essential part of the gravity data with the world gravimetric system, in most cases with an accuracy higher than 1 mgal.

IX. ISOSTASY

The mountains, valleys and oceans make it apparent that the earth is not in hydrostatic equilibrium. But the earth is, in broad terms, in isostatic equilibrium in that, beginning from a certain depth in the earth's interior. the surface units are under the same pressure whether they are beneath mountain, lowland or ocean. The depth of the uppermost surfaces is known as the depth of compensation and this type of equilibrium is called isostasy, at the suggestion of the U.S. geologist. C. E. Dutton, in 1889. This isostatic equilibrium is only possible if the mountains are not absolute mass surplus areas nor the oceans absolute mass deficiency areas. In other words, the mean density of the earth's crust must be smaller under the mountains, and larger under the oceans than under the lowlands.

The man who first glimpsed the idea of isostatic equilibrium was Leonardo da Vinci, that many-sided genius of the Renaissance era. Pierre Bouguer and R. J. Boscovich came to the same conclusion much later (18th century). The principle of isostatic equilibrium was, however, developed in a scientific sense in India, where triangulation with astronomical observations was carried out close to the Himalayan mountains before 1850. The difference between latitudes computed geodetically and observed astronomically at the same point was smaller than the mass surplus of the mountains of Asia would indicate. The observed difference of the deflection of the vertical at the Kaliana and Kalianpur stations was only 5″.24 but the value computed from the topographic masses was 15″.88. Therefore, J. H. Pratt in 1854 surmised that the mean density of the crust under the mountains of Asia must be smaller than in the lowlands, to compensate the attraction of the mass of the mountains of Asia to the plumb line direction. The astronomer G. B. Airy came to a similar conclusion in 1855 although he explained the isostatic equilibrium in a different way.

Pratt's isostatic assumption was that mountains rose from the subcrustal area after the manner of fermenting dough. the density of which would be smaller as it rose higher. Airy, on the contrary, reasoned that the high mountains of Asia had sunk in the substratum and would float as timber or icebergs float. The smaller density of the earth's crust under the mountains would, according to Pratt, compensate the effect of the topographic masses and cause the equilibrium. According to Airy the light root formations of the mountains have the same effect.

Pratt contended that if the earth were completely fluid, no mountains or valleys or ocean basins would be possible. But as the earth's crust began to form and gradually grow thicker, contractions and expansions might have taken place in some of its parts which would depress and elevate corresponding areas of the surface. Airy thought that there could be no other support than that afforded by the downward projection of a portion of the earth's light crust into the denser lava; and that this downward projection was of an extent to balance the projection above the lava; in much the same manner, nhen logs float upon the water and the upper surface of one is observed to be higher than that of the others, one assumes that its loner surface lies lower in the water than does that of the other logs.

The isostatic assumptions of Pratt and Airy were completely contradictory; although both were able to explain the discrepancy between the observed and the computed deflections of the vertical and gravity anomalies on the basis of the topography. Both theories have found defenders. The ideas of Pratt were developed in detail by the U.S. scientists. J. F. Hayford and William Bowie. According to them the compensation is complete and local, *i.e.*, every mountain, hill. valley and island is isostatically compensated, however large or small it may be. This assumption was used for practical reasons—to make the mathematical computations as simple as possible. Havford and Boaie computed needed formulas and tables for the topographic isostatic correction of the deflections of the vertical and gravity anomalies corresponding to different values of the depth of compensation, D. Every different value of D renders different gravity anomalies (and deflections of the vertical) at the observation points. When computing different sets of gravity anomalies. corresponding to different values D, it is possible to discuss which D-value is closest to the real structure of the earth's interior. Computations along these lines carried out by different scientists showed that D is close to 100 km. In geodetic computations the value 113.7 km. obtained by Hayford has been used.

From the geophysical point of view, the Pratt-Hayford assumption did not seem suitable; therefore, W. A. Heiskanen made a series of computations (1924, 1931 and 1938) based on Airy's assumption. Heiskanen's method rendered for the normal thickness of the earth's crust an average value close to 30 km.

Of course, according to the Airy-Heiskanen system, the actual thickness. T, of the earth's crust is the function of the topography. The higher the topography. the deeper is the root formation; the deeper the ocean, the thicker is the antiroot of heavy material under the ocean (see fig. 9). The light root formation (density

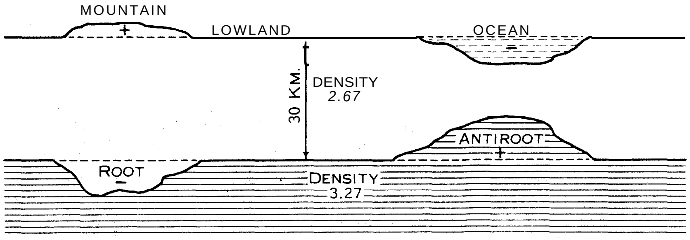

FIG. 9.—THE PRINCIPLE OF ISOSTATIC COMPENSATION

2.67) compensates the mass surplus of the mountains and the heavy antiroot (density 3.27) compensates the mass deficiency of the ocean. Using the density difference 0.6, the real thickness of the earth's crust is j.j km. greater for every kilometre of mountain elevation and 3.7 km. less under the oceans for every kilometre of ocean depth. In this way, the underboundary of the earth's crust. also called the Mohorovicic discontinuity. is in a way an exaggerated mirror picture of the real topography.

For practical reasons it has been assumed in both theories that compensation is complete and local, but in fact, this is not so. Small hills or tiny valleys or islands cannot be in complete isostatic equilibrium. Therefore, Vening Meinesz developed the theory of regional isostatic compensation. This modification of Airy's flotation theory claims that every topographical feature has an isostatic effect not only in the vertical direction under it but in the horizontal direction as well, to as much as 100 or 200 km. horizontal distance R. He computed (1931 and 1940) the needed tables for this regional theory according to different T- (normal thickness of the earth's crust) and R-values. Therefore by the 1950s three different systems—the Pratt-Hayford, the Airy-Heiskanen and the Vening Meinesz—existed for the isostatic study of the earth's structure.

Isostatic studies on the basis of gravity material of different countries, continents and oceans have shown that 85% to 90% of the mass deficiency of the oceans and mass surplus of the high mountains is isostatically compensated. Isostatic equilibrium is the rule. Areas such as small ocean islands, the belts of negative gravity anomalies and the postglacial land uplift regions where the isostatic equilibrium is not complete are exceptions. Since isostatic equilibrium prevails the geoid distances N are rather small. Under the Ieadership of Heiskanen and under the contract of the Cambridge Research center of the U.S. Air Force, the geoid computed in 1951–57 at Ohio State university on the basis of large gravity material of 35 countries revealed that the *N*-values seldom exceed ±50 m. Without the isostatic compensation N would in some cases even exceed 1,000 m., making the geoid studies more difficult. (W. A. Hn.)

X. VARIATION OF LATITUDE

The astronomical latitude of every observation point is variable, caused by a displacement of the axis of rotation in the body of the earth. There is in every body, however irregular in shape, an axis of figure. the axis about which the moment of inertia is a maximum. If for any reason the axis of figure and the axis of rotation do not coincide, the pole of the axis of rotation will describe in the body a closed curve about the pole of the axis figure. For a nearly spherical body like the earth, the axis of rotation will retain in space a nearly invariable direction.

The first general rule of variations for a rigid rotating body was stated (1744) by Leonhard Euler. With Euler's theorems in mind astronomers sought to detect by observation a possible variation in latitude, but succeeded only in reaching the conclusion that if any such existed, it must be small. Finally about 1881. S. C. Chandler undertook a careful study apart from any preconceived theory, basing it both on observations of his own and a study of old records. notably those of Greenwich observatory. At about the same time. the reality of a change in latitude due to a motion of the pole mas proved by simultaneous latitude observations in Berlin, Ger., and Honolulu, Hawaii, places differing in longitude by almost 180°. It was found that an increase in latitude in one occurred simultaneously with an approximately equal decrease at the other. This could not have resulted from local conditions or from incorrect star locations, but must have been due to a motion of the pole of rotation which in approaching one place receded from the other.

Chandler found that the motion of the pole of rotation about the pole of figure required about 14 months. whereas Euler's theory had led astronomers to expect a 10-month period. Simon Newcomb's euplanation. published in 1895, showed that Euler's theory was based on an ideal body absolutely unyielding and unchangeable in shape, a thing unknown in nature. The elastic yielding of the earth and the mobility of the ocean water lengthen the period from 10 months to 14. There is also a motion of the pole of rotation in the body of the earth because the pole of figure itself undergoes a displacement due to seasonal variations in barometric pressure. snow load, etc. The period of these seasonal changes is obviously one year.

The amplitudes of both the annual and the 14-month variations are of the order of magnitude of 0″.1. The quantities sought are small and difficult to measure, but it appears that both components of the polar motion are subject to unpredictable changes. Since the maximum deviation of the pole from its mean position is about 0″.3, which is small in comparison with the usual deflections of the vertical, the reduction of the observed astronomical latitudes to some more or less conventional mean value is not a vital matter in ordinary geodetic work. (It should be noted that the motion of the pole affects longitudes and azimuths also.) The interest of the subject is more on the astronomical and geophysical side.

The International Geodetic association in 1899 organized an International Latitude service with six special latitude observatories. all on parallel 39° 08'; three have remained in continuous operation. The advantage of having them in the same latitude is that all may use the same stars and uncertainties in the star places do not affect the conclusions. The observations may in fact be used to correct the star places.

XI. INTERNATIONAL GEODETIC ORGANIZATIONS

In 1862 the Central European Geodetic association (*Mitteleuropäische Gradmessung*) was organized on the initiative of Gen. Johann Baeyer of Prussia. Its first general conference was held in 1864 with representatives of 13 states or countries, many of them German states later united into the German empire. General conferences at intervals of three years were arranged, with a permanent committee directing the affairs of the organization between conferences. At the next conference (1867) in recognition of a widening scope, the name was changed to European Geodetic association (*Europäische Gradmessung*).

England and the United States were represented at the general conference in 1883 at which matters of world-wide interest, such as a common prime meridian and an international time system, nere discussed. In 1886 the name International Geodetic association *(Internationale Erdmessung)* was chosen to indicate a still wider scope, and a definite international convention was adopted providing for contributions from the member nations. F. R. Helmert, director of the Geodetic institute at Potsdam, Ger., exerted a powerful and beneficent influence on the work of the association. The headquarters, or bureau, of the association remained at Potsdam. The outbreak of World War I prevented the holding of the general conference planned for 1915, leaving that of 1912 in Hamburg the last held by the organization.

In 1919 the International Union of Geodesy and Geophysics was organized at Brussels, Belg., in connection with the newly created International Research council. The International Geodetic and Geophysical union consists of seven semi-independent associations, the largest of which, the International Association of Geodesy, took over the work of the former International Geodetic association. The work of the International Latitude service was taken over jointly by the section of geodesy and the newly formed International Astronomical union, since the subject was of interest to both organizations. The general assembly of the union meets every three years.

On the initiative of I. Bonsdorff the Baltic Geodetic commission was established in 1924 at Helsinki, Fin. It included representatives of eight nations bordering on the Baltic sea and dealt with geodetic problems of common interest to them. The triangulation carried out by this commission around the Baltic sea is extremely accurate, the closure error of this nearly 3,000 km.-long triangulation being only 2.j m. or 1:1,200,000, unparalleled in any earlier studies. (W. D. LA.)

GEOFFREY (1158–1186), duke of Brittany, fourth son of the English king Henry II and his wife Eleanor of Aquitaine, was born on Sept. 23, 1158. In 1167 Henry suggested a marriage between Geoffrey and Constance (d. 1201), daughter and heiress of Conan IV, duke of Brittany (d. 1171). Conan assented to this proposal. Having received the homage of the Breton nobles, Geoffrey joined his brothers, Henry and Richard, who, in alliance with Louis VII of France, were in revolt against their father; but he made his peace in 1174, afterward helping to restore order in Brittany and Normandy. In July 1181 his marriage with Constance was celebrated, and practically the whole of his subsequent life was spent in warfare with his brother Richard. In 1183 he made peace uith his iather, who had come to Richard's assistance; but a fresh struggle soon broke out for the possession of Anjou, and Geoffrey was in Paris treating for aid with Philip Augustus, when he died on Aug. 19, 1186.

GEOFFREY, surnamed MARTEL (1006–1060), count of Anjou, son of the count Fulk Nerra (*q.v.*) and of the countess Hildegarde or Audegarde, was born on Oct. 14, 1006. During his iather's lifetime he mas recognized as suzerain by Fulk l'Oison ("the Gosling"), count of Vendôme, the son of his half-sister Adela. Fulk having revolted, he confiscated the countship, which he did not restore till 1050. On Jan. 1, 1032, he married Agnes, widow of William the Great, duke of Aquitaine, and taking arms against William the Fat, eldest son and successor of William the Great, deieated him and took him prisoner at Mont-Couër (Sept. 20, 1033). He then tried to win recognition as dukes of Aquitaine ior the sons of his wife Agnes by William the Great, who were still minors, but Fulk Nerra promptly took up arms to defend his suzerain William the Fat, irom whom he held the Loudunois and Saintonge in fief against his son. In 1036 Geoffrey Martel had to liberate William the Fat, on payment oi a heavy ransom, but the latter having died in 1038, and the second son of William the Great, Odo, duke of Gascony, having fallen in his turn at the siege of Mauzé (March 10, 1039) Geoffrey made peace with his father, and had his wife's two sons recognized as dukes. He had interfered in the affairs of Maine, though without much result; for having sided against Gervais, bishop of Le Mans, who mas trying to make himself guardian of the young count of Maine, Hugh, he had been beaten and forced to make terms with Gervais in 1038. In 1040 he succeeded his father in Anjou and was able to conquer Touraine (1044) and assert his authority over Maine (*see* ANJOU). He died at Angers on Nov. 14, 1060.

See Louis Halphen, *Le Comté d'Anjou au XIe sidcle* (1906). A summary biography is given by Célestin Port, *Dictionnaive historique, géographique et biographique de Maine-et-Loire* (3 vols., Paris-Angers, 1874–78), vol. ii., pp. 252–253, and a sketch of the wars by Kate Norgate, *England under the Angevin Kings* (2 vols., 1887), vol. i. chs. iii. iv.

GEOFFREY, surnamed PLANTAGENET (PLANTEGENET) (1113–1151), count of Anjou, was the son of Count Fulk the Young and of Eremburge (Arembourg) of La Flèche; he was born on Aug. 24, 1113. He is also called "le bel" or "the handsome," and received the surname of Plantagenet from the habit which he is said to have had of wearing in his cap a sprig of broom (*genêt*). He married (June 2, 1129) Matilda, daughter of Henry I of England, and widow of the emperor Henry V. He died on Sept. 7. 1151. He had three sons: Henry Plantagenet (*see* HEKRY II), Geoffrey and William. *See* also ANJOU.

GEOFFREY OF MONMOUTH (d. 1154), bishop of St. Asaph and creator of the Arthurian legend, was born about the year 1100. In 1129 Geoffrey appears at Oxford among the witnesses of an Oseney charter. A first edition of his *Historia Britonum* was in circulation by the year 1139, although the test which we possess appears to date from 1147. This famous work professes to be a translation from a Celtic source; "a very old book in the British tongue" which Walter, archdeacon of Oxford, had brought from Brittany. There is nothing in the matter or the style of the *Historia* to preclude us irom supposing that Geoffrey drew partly upon confused traditions, partly on his own powers of invention, and to a very slight degree upon the accepted authorities for early British history. The romancer achieved an immediate success. He obtained, about 1140, the archdeaconry of Llandaff "on account of his learning"; and in 1151 was promoted to the see of St. Asaph.

Before his death the *Historia Britonum* had already become a model and a quarry ior poets and chroniclers. The list of imitators begins mith Geoffrey Gaimar, the author of the *Estorie des Engles* (*c.* 1147), and Wace, whose *Roman de Brut* (1155) is partly a translation and partly a free paraphrase of the *Historia*. In the next century the influence of Geoffrey appears in the *Brut* of Layamon, and in the rhyming English chronicle oi Robert of Gloucester. Among later historians who were deceived by the *Historia Britonum* were Higden, Hardyng, Fabyan (1512), Holinshed (1580) and John Milton. Still greater was the influence of Geoffrey upon Warner in *Albion's England* (1586), and Drayton in *Polyolbion* (1613). The *Historia Britonum* provided the material for the earliest English tragedy, *Gorboduc* (1j6j), the *Mirror for Magistrates* (1587), and Shakespeare's *Lear.*

But in the work of expanding and elaborating this theme the successors of Geoffrey went as far beyond him as he had gone beyond Nennius; but he retains the credit due to the founder of a great school. For the development of the tradition *see* ARTHURIAN LEGEND. Of the 12 books into which it is divided only three (Bks. IX, X, XI) are concerned with Arthur. Earlier in the work, however. we have the adventures of Brutus; of his follower Corineus, the vanquisher of the Cornish giant Goemagol (Gogmagog); oi Locrinus and his daughter Sabre (immortalized in Milton's *Comus*); of Bladud the builder of Bath; of Lear and his daughters; of the three pairs of brothers, Ferrex and Porrex, Brennius and Belinus, Elidure and Peridure. The story of Vortigern and Rowena takes its final form in the *Historia Britonum;* and Merlin makes his first appearance in the prelude to the Arthur legend. Besides the *Historia Britonum* Geoffrey is also credited with a *Life of Merlin* composed in Latin verse. The authorship of this work has, however, been disputed, on the ground that the style is superior to that of the *Historia*. A minor composition, the *Prophecies of Merlin,* was written before 1136, and later incorporated with the *Historia,* of which it forms the seventh book. (H. W. C. D.; X.)

GEOFFREY OF PARIS (d. *c.* 1320), French chronicler, was probably the author of the *Chronique métrique de Philippe le Bel,* or *Chronique rimée de Geoffroi de Paris.* This work, which deals with the history of France from 1300 to 1316, contains 7.918 verses. Various short historical poems have also been attributed to Geoffrey, but there is no certain information about either his life or his writings.

GEOFFRIN, MARIE THÉRÈSE, *née* **RODET** (1699–1777), a Frenchwoman who played an interesting part in French literary and artistic life, was born in Paris on June 2, 1699. She married, on July 19, 1713, Pierre François Geoffrin, a rich manufacturer and lieutenant colonel of the national guard, who died in 1750. It was not till 1748, when Mme. Geoffrin was nearly 50, that she became a power in Parisian society and started her two dinners a week, one on Monday for artists, and one on Wednesday for her friends the encyclopaedists and other men oi letters. She received many foreigners of distinction, Hume and Horace Walpole among others. Walpole spent much time in her society before he was finally attached to Mme. de Deffand, and speaks of her in his letters as a model of common sense. She adopted the pose of an old woman earlier than necessary, and her coquetry, if such it can be called, took the form of being mother and mentor to her guests, many of whom were indebted to her generosity ior substantial help. Although her aim appears to have been to have the *Encyclopédie* in conversation and action around her, her advanced views did not prevent her from observing the forms of religion, and she was extremely displeased with any of her iriends who were so rash as to incur open disgrace. A devoted Parisian, Mme. Geoffrin rarely left the city, so that her journey to Poland in 1766 to visit the king, Stanislas Poniatowski, whom she had known in his early days in Paris, was a great event in her life. Mme. Geoffrin died in Paris on Oct. 6, 1777.

GEOFFROY, ÉTIENNE FRANÇOIS (1672–1731), French chemist. whose name is best known in connection with his tables of affinities (*tables des rapports*), which he presented to the French Academy in 1718 and 1720. Born in Paris on Feb. 13, 1672, he was first an apothecary and afterward practised medicine. After studying at Montpellier he accompanied Marshal Tallard on his embassy to London in 1698 and thence traveled to Holland and Italy. Returning to Paris he became professor of chemistry at the Jardin du Roi and of pharmacy and medicine at the Collkge de France, and dean of the faculty of medicine. He died in Paris on Jan. 6. 1731.

The tables of affinities were lists, prepared by collating observations on the actions of substances one upon another, showing the varying degrees of affinity exhibited by analogous bodies for different reagents. and they retained their vogue for the rest of the century, until displaced by the profounder conceptions introduced by C. L. Berthollet. Another of his papers dealt with the delusions of the philosopher's stone. but nevertheless he believed that iron could be artificially formed in the combustion of vegetable matter.

Geoffroy's *Tractatus de materia medica,* published posthumously in 1741, was long celebrated.

His brother CLAUDE JOSEPH, known as Geoffroy the younger (1685–1752), was also an apothecary and chemist who, having a considerable knowledge of botany, devoted himself especially to the study of the essential oils in plants.

GEOFFROY SAINT-HILAIRE. ETIENNE (1772–1844), French naturalist whose law of compensation, or balancing of gron th. had much influence on contemporary thought. was born at Étampes, Seine-et-Oise, on April 15, 1772. He nas originally intended for the church and studied natural philosophy under M. J. Brisson at the Collkge de Navarre in Paris. In 1788 he obtained a canonry of the chapter of Ste. Croix at Étampes, and also a benefice. His preference. however. was for science, so he took up residence at the College du Cardinal Lemoine in Paris, where he studied law and became the pupil and friend of the mineralogist *abbe'* R. J. Haüy. Taking his law degree in 1790, Geoffroy began medical studies under A. F. de Fourcroy at the Jardn du Roi and L. J. RI Daubenton at the College de France. His studies were interrupted in Aug. 1792 when Hauy and all the professors of the Collège du Cardinal Lemoine and of the College de Navarre were arrested by the revolutionists as priests. Geoffroy had some harrowing experiences when he attempted to save the lives of his professors.

At the beginning of the winter of 1792 he returned to his studies in Paris, and in March of the following year Daubenton, through the interest of Bernardin de Saint Pierre, procured him the office of subkeeper and assistant demonstrator of the Cabinet d'Histoire Naturelle du Roi, vacant by the resignation of B. G. E. Lacépède. By a law passed in June 1793, Geoffroy was appointed one of the 12 professors of the newly constituted Muséum National d'Histoire Naturelle. being assigned the chair of zoology. In the same year he began a menagerie there.

In 1794 through the introduction of A. H. Tessier he entered into correspondence with Georges Cuvier. After Cuvier's appointment as assistant at the Muséum d'Histoire Naturelle, he and Geoffroy wrote five memoirs on natural history, one of which, on the classification of mammals, puts forward the idea of the subordination of characters upon which Cuvier based his zoological system.

It mas in a paper entitled "Histoire des Makis, ou singes de Madagascar." written in 1795, that Geoffroy first gave expression to his views on "the unity of organic composition." the influence of which is perceptible in all his subsequent writings; nature, he observes, has only one plan of construction, the same in principle, but varied in its accessory parts.

In 1798 Geoffroy was chosen a member of the great scientific expedition to Egypt, and on the capitulation of Alexandria in Aug. 1801, he took part in resisting the claim made by the British general to the collections of the expedition. Early in Jan. 1802 Geoffroy returned to his usual work in Paris. He was elected a member of the Académie des Sciences in Sept. 1807 In March of the following year the emperor selected him to obtain collections from the museums of Portugal, and in the face of considerable opposition from the British he eventually was successful in retaining the collections permanently for France. In 1809, the year after his return to France, he was made professor of zoology at the Faculty of Sciences at Paris, and from that period devoted himself more exclusively than before to anatomical study. In 1818 he published the first part of his celebrated Philosophie *anatomique,* the second volume of which, published in 1822, and subsequent memoirs account for the formation of monstrosities on the principle of arrest of development, and of the attraction of similar parts.

When, in 1830, Geoffroy proceeded to apply to the invertebrates his views as to the unity of animal composition, he found a vigorous opponent in Georges Cuvier, and the discussion between them. continued up to the time of the death of the latter. soon attracted the attention of scientists throughout Europe. Geoffroy, a synthesist, contended, in accordance with his theory of unity of plan in organic composition, that all animals are formed of the same elements, in the same number, and with the same connections; homologous parts. however they differ in form and size, must remain associated in the same invariable order. He held that if one organ takes on an excess of development, it is at the expense of some other part; and he maintained that. since nature takes no sudden leaps, even organs that are superfluous in any given species, if they have played an important part in other species of the same family, are retained as rudiments testifying to the permanence of the general plan of creation. It was his conviction that, owing to the conditions of life, the same forms had not been perpetuated since the origin of all things, although it was not his belief that existing species are becoming modified. Cuvier. who was an analytical observer of facts, admitted only the prevalence of "laws of coexistence" or "harmony" in animal organs, and maintained the absolute invariability of species. which he declared had been created with a regard to the circumstances in which they were placed, each organ contrived with a view to the function it had to fulfill, thus putting, in Geoffroy's consideration, the effect for the cause.

In July 1840 Geoffroy became blind. He resigned his chair at the museum in 1841, and died at Paris on June 19, 1844.

Geoffroy wrote: *Catalogue drs mammifères du Muséum National d'Histoire Naturelle* (1813), not quite completed; *Philosophie anatomique,* vol. i, *Des organes respiratoires* (1818), and vol. ii, *Des monstruosités humaines* (1822) ; *Sur le principe de l'unité de composition organique* (1828) ; *Principes de philosophie zoologique* (1830) ; *Notions synthétiques, historiques et physiologiques de philosophie naturrlle* (1838), and other works; also part of the *Description dr l'Égypte par la commission des sciences* (1821–30) ; and, with *Frédéric Cuvier* (1773–1838), a younger brother of G. Cuvier. *Histoire naturelle des mammifères,* 4 vol. (1820–42).

See *Vie, travaux, et doctrine scientifique d'Étienne Geoffroy Saint-Hilaire, par son fils M. Isidore Geoffroy Saint-Hilaire* (1847), to which is appended a list of Geoffroy's works.

GEOFFROY SAINT-HILAIRE, ISIDORE (1805–1861). French zoologist. distinguished for his work on anatomical abnormalities in man and animals: was a son of the preceding, born on Dec. 16. 1805. at the Jardin des Plantes, Paris, where he spent most of his life.

In 1824 he joined his father at the Muséum d'Histoire Naturelle as assistant naturalist and after taking his M.D. in 1829 taught zoology at the Athénée from 1830 to 1833, The end of his first year's course was interrupted by the outbreak of the July revolution, with fighting close to the Jardin des Plantes in the street that bears his family name. He was elected a member of the Académie des Sciences, Paris, in 1833. and in 1837 acted as deputy for his father at the Faculté des Sciences, Paris; the following year he was sent to Bordeaux to organize a similar faculty there. Subsequently he became successively inspector of the Academy of Paris (1840); professor at the museum (1841) ; a member of ihe royal council for public instruction (1845); and in 1850 professor of zoology in the Faculty of Sciences. Paris.

He took an active interest in general natural history, teratology and applied zoology, and wrote numerous memoirs in various scientific publications.

Geoffroy Saint-Hilaire died in Paris on Nov. 10, 1861.

His more important works include *Histoire générale et particulière des anomalies dr l'organisation chez l'homme et les animaux,* 3 vol. (1832); *Essais de zoologie générale* (1840); *Vie . . . d'Étienne Geoffroy Saint-Hilairr* (1847); and *Histoire naturelle générale des règnes organiques,* 3 vol. (1854–60).

See also *R.* Knox, *Great Artists and Great Anatomists* (1852).

(EN. HE.)

GEOGRAPHY (ARTICLES ON). The nature of geography as a discipline is discussed in GEOGRAPHY. which surveys the history of geographical exploration; the geographical theories of the ancients; the work of such pioneers of scientific geography as Humboldt and Ritter; the fields of professional specialization that have won general recognition, and the deviant theories. As GEOGRAPHY explains. the scope of the subject is so broad that it touches on many topics that constitute the core of other disciplines. Many articles written by specialists in these separate areas of study thus have implications of a geographic nature.

In the articles on continents and their subdivisions. the degree of detail increases as the size of the area diminishes. For example. EUROPE in its section on physical geography lists the Paris basin as one of the natural areas; a section of FRANCE is devoted to the geography of the Paris basin; PARIS gives additional detail; and there are two brief articles on SEINE, one referring to the political subdivision of northern France to which Paris belongs, the other referring to the Seine river, which forms a natural highway in Paris.

The geographical areas of a general nature to which articles are devoted include ARCTIC, THE; ANTARCTICA; PACIFIC ISLANDS; MELANESIA; POLYNESIA; etc. Articles on various oceans. mountains, rivers, lakes, marshes, grasslands, etc., offer additional perspectives.

The article NATURAL RESOURCES gives a world survey, in terms of natural regions, of vegetation, soil, animal products: water supply and minerals. This broad picture is supplemented by separate articles on major raw materials and industries. For example, the fishing industry, discussed in a subdivision of NATURAL RESOURCES, is represented also by the article FISHERIES. Regional distribution of basic materials is analyzed in the articles on the continents as well as in such articles as PETROLEUM; IRON AND STEEL; WHEAT; COTTON; FORESTS AND FORESTRY, etc. COMMERCE. HISTORY OF, analyzes, largely in historical terms, the relationship between factors of geography and commerce. TRADE, INTERNATIONAL emphasizes contemporary problems and data.

ZOOGEOGRAPHY divides the world into zoological regions and traces, in text and maps, the spread of animals throughout the world in the course of the evolutionary process.

Population geography is discussed in the articles on nations, states, cities, etc.. and in POPULATION. In the fields of urban and settlement geography, articles of special interest are URBAN SOCIOLOGY; CITY PLANNING; REGIONAL PLANNING.

Among the articles that may be of interest to the student of military geography. in addition to the articles on wars. battles and campaigns, are MOUNTAIN WARFARE; INTELLIGENCE, MILITARY AND GOVERNMENTAL; STRATEGY.

MAP surveys the history and techniques of map making, from the flat world of the ancients to the various types of cartographical projection now in use. The reader interested in modern maps of distribution will find examples in such articles as: TRADE. INTERNATIONAL; FOOD SUPPLY OF THE WORLD; CLIMATE AND CLIMATOLOGY: OCEAN AND OCEANOGRAPHY; TIDES; TROPICAL STORM.

Among the articles on various aspects of political geography are SPHERES OF INFLUENCE; MONROE DOCTRINE. THE; LAND REFORMS.

GEOPOLITICS describes an application of political geography that is generally regarded by geographers as pseudoscientific. but has had a powerful impact on the contemporary world.

The science of ecology, which investigates the relationship of plants. animals and human beings to their environment. has made significant contributions to geography. These are discussed in ECOLOGY, ANIMAL; POPULATION ECOLOGY; a section of PLANTS AND PLANT SCIENCE; and sections on human ecology in SOCIOLOGY and ANTHROPOLOGY.

The relationship between geography and ethnology in various areas of the world is discussed in RACES OF MANKIND. A historical perspective on this subject is presented in MIGRATION, which traces the origin of the connection between various racial groups and the lands with which they are now identified.

GEOGRAPHY is that field of learning in which the characteristics of particular places on the earth's surface are examined. It is concerned with the arrangement oi things and with the associations of things that distinguish one area from another. It is concerned with the connections and movements between areas. The face of the earth is made up of many different kinds of features. each the momentary result of an ongoing process. A process is a sequence of changes. systematically related as in a chain of cause and efiect. There are physical and chemical processes developing the forms of the land surface, the shapes of the ocean basins. the differing characteristics of water and climate. There are biotic processes by which plants and animals spread over the earth in complex areal relation to the physical features and to each other. And there are economic, social and political processes by which mankind occupies the world's lands.

As a result of all these processes the face of the earth is marked off into distinctive areas: geography seeks to interpret the significance of likenesses and differences among places in terms of causes and consequences.

In ancient and mediaeval times geographers could do no more than identify and describe the features that gave distinctive character to different countries. Writers of geography. to be sure, speculated regarding cause and effect processes. sometimes with amazing insight. They made the first attempts to measure things and to place them on maps. During the great age of exploration which began about 1500. the methods of mapping were greatly developed: the, continental outlines were plotted with ever-increasing accuracy; the rivers appeared in more and more detail; the positions of mountain ranges were established by survey rather than guesswork. Furnished with all these new data. geographers about the middle of the 18th century started to define broadly homogeneous regions in terms of physical make-up. or in what were conceived to he the major characteristic associations of plants and animals, or in terms of the economic life, or in terms of the political organization of national territories.

As man's understanding of the world increased, more and more attention was given to systematic studies; that is, to those features that were systematically related to each other because they were the result of a single process. Geography has sometimes been called the mother of sciences, since many fields of learning that started with observations of the actual face of the earth turned to the study of specific processes wherever they might be located. These new disciplines were defined by the subjects they investigated. Some of the processes at work on the surface of the earth, notably the physical and chemical ones, were reproduced under laboratory conditions where they could be examined in isolation from the environments of particular places. From these studies there resulted a great increase in the understanding of cause and effect relations. and numerous fundamental principles were formulated to describe the ideal or theoretical sequences of change. In a similar way the biotic processes were examined under controlled conditions. and such important concepts were developed as those of evolution and natural selection. The social sciences, too, have sought to understand the theoretical sequences of economic. social and political change as these sequences were presumed to go on when isolated from the disturbing circumstances of actual places. Since the so-called cultural processes could not be isolated in laboratories, they were isolated symbolically by such phrases as "other things being equal."

Modern geography starts with the understandings provided by the systematic sciences. Unlike these other fields, geography cannot be defined by its subject matter. for anything that is unevenly distributed over the surface of the earth can be examined profitably by geographical methods. Rather geography is a point of view. a system of procedures. It makes three kinds of contribution to understanding: (1) it extends the findings of the systematic sciences by observing the differences between the theoretical operation of a process and the actual operation as modified by the conditions of the total environment of a particular place; (2) it provides a method of testing the validity of concepts developed by the systematic sciences; and (3) it provides a realistic analysis of the conditions of particular places and so aids in the clarification of the issues involved in all kinds of policy decisions.

Obviously a large amount of geographic work is done by persons not identified professionally as geographers. Scholars in the various systematic fields do not fail to concern themselves with the applications of their theoretical understandings to the study of conditions in particular situations, and such applications usually involve geographic work. When an economist examines the economic conditions of a country and prescribes remedial measures designed to provide for more production. he is involved in part with the geographic point of view. When a businessman studies the advantages or disadvantages of a specific location for his factory or his retail store, or when he plans for the more efficient operation of a system of transportation or of a marketing organization. he is working in part with geographic data.

Professional geographers can offer certain concepts and methods derived from experience in the analysis of the significance of areal differences on the earth. They play a role similar to that of the proiessional historian. Many persons who are not historians write accounts of the sequences of events that are called history: but such persons would be severely criticized if they failed to make expert use of historical method. Professional geographers encourage nongeographers to apply geographic concepts and to make use of acceptable geographic method. but they condemn the inexpert use of concepts or method. Uniortunately much work of a geographic nature is done by scholars in other fields. by businessmen and engineers, in a way that reveals an ignorance of the concepts of modern geography and that makes crude and imprecise use of geographic method. (PE. J.)

PROGRESS OF GEOGRAPHIC EXPLORATION

Exploration, in one form or another. has always been a major concern of geography. Geographic exploration was started long before the beginning of recorded history. As early as it n-as possible to communicate ideas or experiences. some of these ideas must have been concerned with the nature of the face of the earth, the human habitat. Even if the purpose was to describe the characteristics and arrangement of hunting grounds, or the strange things observed in distant lands, the result was geography of a sort. At first the chief effort was to gather and present facts about places: later the effort was organized around systems of facts, groups of facts related to single processes. Geography was concerned also with the perfecting of methods for selecting and measuring facts. The first phases of this work have been completed: no part of the earth today can be said to be completely unknonn; in no part of a map can the cartographer safely draw pictures of Martian monsters or spouting whales. But knowledge of places is a relati e matter. There are vast areas of the earth that are not mapped precisely, and the characteristics of many areas are not sufficiently well known to provide a basis for making practical application of geography. The new exploration is no longer concerned nith continental outlines; rather it is concerned with filling in those outlines with precise detail relevant to the economic, social, political or military problems nith which mankind is faced.

MEDITERRANEAN REGION

Geographic exploration, in so far as its record has been handed down as a part of the stream of occidental culture, had its beginnings in the Mediterranean. Even the names Europe, Asia and Africa were first applied to the three shores of the eastern Mediterranean. later to be extended as the geographic horizons were widened.

Egyptians and Phoenicians. — The Egyptians had explored and conquered large tracts of land before the 14th century B.C., both southward up the Nile and northeastward to the borders of Assyria; but the first seagoing explorers seem to have been the Phoenicians. who made Sidon a commercial port as early as 1400 B.C. and later raised Tyre to equal fame. The merchant adventurers of Tyre and Sidon explored the whole coast of the hlediterranean. founding the colony of Carthage before 800 B.C. They and other colonizers on the shores of the Iberian peninsula sailed northward along the Atlantic coast, probably trading with Cornwall for tin, and to the south. going far along the west coast of Airica. They certainly reached the Azores, because Carthaginian coins of the 4th century B.C. have been found on the island of Corvo. With the support of Egypt they traded also on the Red sea. reaching lands yielding gold and ivory: probably on the coast of Africa or Arabia. It is probable that they also reached India from the Red sea. Herodotus heard in Egypt that in the days of Ring Kicho (600 B.C.) a Phoenician fleet. sent from the Red sea southward along the African coast, had returned to Egypt by the Pillars of Hercules. Herodotus was the earliest of the Greek travellers to give a full and trustworthy narrative of his peregrinations in Asia as far as Persia, in Egypt and North Africa, on the Black sea coasts as far as the Caucasus, and in Italy (c. 464–447 B.C.).

Greeks. — The maritime trade of the Greek city-states and their colonies became more important than that of the Phoenicians soon after the jth century B.C. Greek ships sailed beyond the Mediterranean, opening up the Black sea on the east and the borders of the Atlantic on the west. Massilia (on the site of the modern Marseilles) was a colony of Greeks from Phocaea, and thence a voyage of great importance was made by Pytheas about 330 B.C. His own narrative is lost and the facts have to be gathered from references by Strabo 300 years later to criticisms of the voyage in lost books of the Greek geographers. Pytheas was probably the first navigator to fix the position of the lands he reached by crude astronomical observations, and he seems to have been a keen observer of places and people. He coasted the Bay of Biscay and the east of Britain as far as Orkney, where he heard a report of Thule, a more northern land, and a confused hint of the arctic region. On a later voyage he coasted along the east side of the North sea and probably entered the Baltic. During the same years the conquests of Alexander the Great opened to the Greek world a knowledge of the continent of Asia as far as the northern plain of India, and his general Kearchus conducted a fleet from the mouth of the Indus to the Persian gulf. This was the first voyage in the Indian ocean to be described in a manner comparable with the record of the land journey of Xenophon a century earlier, when. after the death of Cyrus, he led the 10,000 from Mesopotamia across the plateau of Armenia to the Black sea. In the following centuries the Ptolemies, Greek kings of Egypt, encouraged exploration, and about 115 B.C. Eudoxus of Cyzicus under their auspices explored the Arabian sea; he planned to circumnavigate Africa but could not get support for so daring a project.

Romans. — The rise and extension of the Roman empire involved scouting expeditions before and surveys after the conquest of each province of the lands bordering on the Mzditerranean in Europe, Asia and Africa. Conquering generals described the tribes they subdued and the regions they occupied, and Julius Caesar won renown as a writer no less than as a fighter. Each province of the empire was bound to Rome by the causeways mhich still form the skeleton of the road map of Europe. Pliny and Seneca say that Nero (about A.D. 60) sent two centurions to follow up the Nile from Egypt, and they were stopped by great marshes, probably those of the Sudan. about 19° N. The practical advantages of discovery appealed to the Roman mentality more powerfully than did the abstract theories mhich fascinated the Greeks; for example. Hippalus. who, about A.D. 79, learned from the Arabs of the regular seasonal changes of the monsoons. made these winds serve him as the means of establishing a trade route between the Red sea and India across the open ocean, whereas earlier navigators had had to hug the coast. Trade along this route continued to develop, and a century later Pausanias makes it appear that direct communication had even been opened up with China. In the time of Justinian (483–565) two Nestorian monks made the journey from Constantinople overland to China and on their return introduced the first silkworms into the Mediterranean lands.

After the fall of the Roman empire and the incursion of barbarians from the north, a wave of Arab domination surged over the Asiatic and African provinces and swept far into the southern peninsulas of Europe. The geographical learning of the Greeks and Romans enshrined in the writings of Ptolemy of Alexandria (*fl.* A.D. 150) passed to the Arabs and was forgotten in Christian Europe! where the conception of the globe degenerated to that of a flat disk with Jerusalem at the centre. The Arabs trading with India. China and the east coast of Africa acquired a sound knowledge of the Indian ocean and a fair idea of the interior of Africa before the year 1000. Among the well-known geographical writers of this period were Abu Zaid, Masudi, Istakhri and Idrisi.

NORSEMEN

Meanwhile the Norsemen from the fiords of Scandinavia were harrying the coasts of northern Europe and even making their way into the Mediterranean. Othar of Helgeland discovered the North cape and, rounding it, proceeded as far as the White sea in the middle of the 9th century. Later he visited the court of Alfred the Great, and it was the English king who first reduced to writing the discoveries of the earliest polar explorer and introduced to literature the midnight sun of the arctic summer. Late in the 9th century Iceland was colonized from Norway, and in 982 Eric the Red. sailing westward, discovered Greenland; soon afterward his son Leif Ericsson, sailing thence to the southwest, came on a new land; which he named Vinland, and was thus the first European to reach America.

ASIAN AND AFRICAN LAND JOURNEYS

The domination of central Asia from the Caspian to the Pacific by the Mongol emperors made very long overland journeys practicable at the close of the middle ages. and Venetian merchants had thus established contact with China before Marco Polo set out in 1271 for Cambaluc (approximate site of modern Peking), the capital of Kublai Khan. The story of his 17 years' sojourn in the far east and of his journeyings by land and sea in central Asia, China, the Malay archipelago and India was the greatest work on travel of the middle ages, and for the first time it made the venerable civilization and the rich products of the orient familiar to the people of Europe. Many of his statements were derided by contemporaries. but his substantial veracity and remarkable powers of observation have been vindicated by modern travellers and students. Missionaries, whose activity increased as that of the crusaders diminished, pushed far afield in Asia, and their records contain some grains of geographical value among a vast quantity of superstitious and ignorant chaff. One only need be mentioned here, Friar Odoric of Pordenone. who. early in the 14th century, visited India, the Malay archipelago. China and Tibet, where he was the first European to enter Lhasa, not yet a forbidden city. A Moslem contemporary. Ibn Batuta. was the greatest of the Arabian travellers who left accounts of their journeys. Between 1325 and 1355 he explored Arabia and Persia and spent eight years in the service of the Mogul ruler of Delhi. going on to China and the Malay archipelago. He also visited the East African coast as far south as Mombasa and Kilwa and crossed the desert from the Red sea to Syene on the Nile; finally he explored West Africa by land, reaching Timbuktu and the Niger.

Many travellers in the early part of the 15th century made notable journeys throughout the mainland of Asia and the eastern archipelago, impelled by the growing demand for the silks, spices and other valuable products of the tropics. From Spain Ruy Gonzalez de Clavijo journeyed to the court of Timur at Samarkand: from Italy Nicolo de' Conti later in the century spent 25 years in the far east, reaching China, Java and Sumatra.

OPENING OF THE OCEANS

Long voyages out of sight of land began in the 15th century after the use of the magnetic compass had become general. As early as the 13th century portolano charts had been prepared to guide navigators from port to port. and they were quite accurate with regard to the Mediterranean coasts. But whereas latitude could be measured with fair accuracy by the use of the astrolabe. the measurement of longitude remained a matter of guesswork. The first voyages into the open oceans originated in Portugal and Spain.

Portuguese.— A large amount of geographical data was collected in Portugal by Prince Henry the Navigator, and under his auspices the earliest great voyages were undertaken. The first objective of the Portuguese was the exploration of the African coast, with the hope that eventually a nay would be found to reach India by sea. The Azores. 800 mi. out in the open Atlantic. were rediscovered and settled in 1432, while successive expeditions stimulated by the prnce crept by degrees along the Sahara coast to the fertile lands beyond; in 1462, after his death, they reached Sierra Leone and a few years later explored the whole Guinea coast. Then discovery became rapid. In 1481 the equator was crossed, in 1482 Diogo Cam passed the mouth of the Congo. and in 1488 Bartholomeu Diaz de Novaes. by a splendid effort, fetched a wide sweep far out of sight of land and reached Mossel bay. In returning he saw the southern point of Africa and named the Cape of Storms. This was the greatest landmark in the history of exploration. The King of Portugal, seeing the wealth of the Indies within his grasp. changed the name to Cape of Good Hope, and Vasco da Gama (*q.v.*) realized the hope in 1498 by sailing round the cape to the Arab port of Mombasa, whence with the aid of local pilots he reached India and fulfilled the dream of ages. Luis de Camoens. uho himself made the voyage half a century later, celebrated the achievement in his epic poem, the *Lusiads*.

Spanish.—Paolo del Pozzo Toscanelli as early as 1474 had pointed out from Ptolemy's maps that the east coast of Asia might be reached more easily by sailing due west than by going south and then east and north. Christopher Columbus, a native of Genoa who had much experience of navigating the Atlantic and had sailed to Iceland, became possessed with the idea of making this voyage. He spent many years in the endeavour to find a patron, and in 1492 had almost persuaded the king of England and the king of Spain to embark on the enterprise; the king of England hesitated the longer, and Columbus with Spanish ships made an easy passage from the Azores to the islands which he named the West Indies. Following a suggestion of the pope. a meridian line running north and south through the middle of the Atlantic was fixed by treaty between Spain and Portugal, the former country agreeing to restrict exploration to the western hemisphere so marked out and the latter country to the eastern hemisphere. Columbus, after other voyages to the West Indies. died in 1 jo6 in the belief that he had reached the islands off the coast of Asia.

The merchants of Bristol had often sent their ships several weeks' sail to the westward into the Atlantic in search of legendary islands; in 1497 John Cabot. no doubt inspired by the success of Columbus. persevered until he found the coast of Labrador and Newfoundland, thus repeating the old Norse discovery of North America and. though the quest was not then pursued. pegging out a claim to England's oldest colony. The companions of Columbus continued to cruise among the West Indies and quickly traced out the shores of the Spanish Main to the south. and the limits of the Caribbean sea to west and north. In 1513 Vasco Nuñez de Balboa caught the first glimpse of an inaccessible ocean to the west from "a peak in Darien" and recognized that Asia was still far off. In 1500 Vicente Pinzón. sent from Spain to explore the coast southward from the Orinoco. first sighted land near Pernambuco and, following it northward round Cape São Roque, discovered the mouth of the Amazon. His shipmate Amerigo Vespucci. a clever man who took part in several voyages of discovery, described this voyage, and by a curious chance his Christian name in its latinized form was attached forever to the continents of America. By making a westward sweep in a voyage to the Cape of Good Hope, Pedro Alvares Cabral lit on the coast of Brazil in the sarne year. The Spaniards. realizing that America was a solid obstacle between Europe and Asia. pushed forward to discover a passage to the south. In 1515 Juan Diaz de Solís reached the Rio de la Plata, which seemed to offer a way through. Five years later Ferdinand Magellan showed that it was only an estuary, and, proceeding southward. he found and passed through the tortuous strait which bears his name, so piercing the harrier of America. Persevering in face of every difficulty which could befall an explorer; he pushed on across the incredible breadth of the Pacific. Although he met his death in the Philippine Islands in 1521, his ship the "Vittoria" under Juan Sebastian del Cano with a handful of survivors returned to Spain in 1j22 by the Cape of Good Hope after the first circumnavigation. Among his rewards Del Cano received the world as his crest with the proud motto *Primus circumdedisti* me.

Voyages by Other Europeans.— The Spanish and Portuguese between them soon completed the rough outlines of Africa and the two Americas. But the 16th century saw their maritime power challenged by the enterprise of France. England and the Netherlands, whose sailors disregarded alike papal bulls and private agreements between Spain and Portugal. These other Europeans established their claim to a share in the new world and in the sea routes to the east. French fishermen following in the track of Cabot early began to frequent the Grand Banks of Newfoundland. and the king of France in 1524 sent out Giovanni da Verrazano, a Florentine. who explored the coast of North America between the lands discovered by Cabot in the north and by the Spaniards in the south. He found no way through, and ten years later a French expedition under Jacques Cartier set out to search the Gulf of St. Lawrence for a way to the far east. In a second voyage in 1535 Cartier ascended the St. Lawrence to the present site of Montreal and, although only the name of Lachine Rapids remains of this attempt to reach China that way, he spent two years in the effort to start the French colony of Canada.

Queen Elizabeth I saw a wave of enthusiasm for discovery sweep over England, rousing sailors. soldiers. merchants. parsons, philosophers. poets and politicians to vie with each other in promoting expeditions overseas for the glory of their country and their own fame and profit. The gallants of the court were ever ready to command the expeditions for which the shrewd City merchants found the means. while quiet scholars like Richard Hakluyt promoted the work by recording the great deeds of earlier as well as contemporary adventurers. Hakluyt's *Principal Navigations,* first published in 1589, is to this day delightful reading. and. supplemented by *Hakluytus Posthumus or Purchas His Pilgrimes,* published in 162;. forms the only record of many great expeditions. On the continent similar compilations such as those of the Italian Gian Battista Ramusio (1583–1613) and the splendidly illustrated Dutch volumes of Theodorus de Bry (1590–1634) played a similar stimulating part. In England as elsewhere at first the object was to find a westward route to the far east. Richard Chancellor tried for a northeast passage, and though he got no farther than the White sea he went on by land to Moscow and opened up direct trade with Russia, leading to the formation of the Muscovy company, the first of many chartered companies for exploration and trade. In 1576 Martin Frobisher made a spirited attempt to find a northwest passage to China and reached the coast of Labrador at its northern extremity. John Davis, one of the greatest arctic explorers of all time, took up the quest in 1585, and in successive years he navigated the broad strait which bears his name to 72° N., finding open sea to the northward and hope of an ultimate passage westward. Francis Drake, setting out to trace a route from the other side, made the second circumnavigation of the world in 1577–80. He passed the Strait of Magellan, after which he was blown southward to 56° S., and satisfied himself that the Atlantic and Pacific oceans met south of Tierra del Fuego. Drake proceeded northward and explored the Pacific coast of North America to 48° in vain search of a passage to the east. Eventually he returned by the Philippines and the Cape of Good Hope. Thomas Cavendish repeated this voyage in 1586–88, adding to the confidence with which long voyages were undertaken, and Richard Hawkins, though less fortunate, again showed the British flag in the Pacific before the end of the century.

Walter Raleigh, Humphrey Gilbert and many more took part in exploring the North American Atlantic coast, and in 1600 Queen Elizabeth I granted a charter to the East India company, which initiated direct trade with India and prepared the way for the British empire in the east. Spanish exploration from the Pacific ports of Spain's American possessions was renewed, partly no doubt in order to anticipate English discoveries. In 1567 Alvaro de Mendaña de Neyra, sailing from Callao, crossed the Pacific and discovered the Solomon Islands. Pedro Sarmiento de Gamboa in 1579 went south from Callao and surveyed the Strait of Magellan with a view to fortifying it and so holding for the Spaniards what they then supposed to be the only entry to the Pacific. The Dutch made many attempts to find a northern passage to China in the last decade of the 16th century. Willem Barents, after discovering Spitsbergen, was wrecked on the north coast of Novaya Zemlya, and after wintering there made a heroic journey by boat along the coast, on which he died; his crew returned safely in 1597.

In the 17th century the search for a northern passage to the far east still went on. The work of Davis was followed by that of Henry Hudson, who in 1607 reached a latitude of 81° N. in the Spitsbergen region; in 1610 he discovered the inland sea now known as Hudson bay. William Baffin came later, reaching about 77° 45′ N. in 1616 and naming Smith sound to the north of the great bay called after him at the end of Davis strait. A charter for the Hudson's Bay company was granted in 1670.

SEARCH FOR THE SOUTHLAND

A belief in a southern continent surrounding the pole and extending into middle and even low latitudes had found expression on maps since the time of the early Greek geographers. Magellan believed that Tierra del Fuego was a part of this great land mass. Many explorers were drawn by the magnet of this illusion into the unknown parts of the great oceans. Pedro Fernández de Quiños and Luis Vaes de Torres were sent out in 1605 by the viceroy of Peru to take possession of the supposed southern continent; on reaching the New Hebrides Quiños believed he had gained his goal and took possession with great ceremony of "Australia del Espiritu Santo," the first appearance of the name "Australia" on the map. In returning Torres passed through the strait which bears his name, discovering the northern end of Australia and exploring part of the coast of New Guinea.

The great period of Dutch voyages began with the formation of the Dutch East India company in 1602, though Dutch merchant adventurers, sailing by the Cape of Good Hope, were active on the coast of Japan by 1600 and soon after were successful rivals to the Portuguese already established in India and the Malay archipelago. The company in 1614 determined to find a way into the Pacific south of the Strait of Magellan and sent out Jacob Lemaire in the "Eendracht" and Willem Schouten in the "Hoorn." These ships passed south of Tierra del Fuego, proving that it was not part of a southern continent, named Staten Land (not recognizing it as an island) and saw and named Cape Horn on Jan. 29, 1616. Lemaire and Schouten crossed the Pacific, sailed along the north coast of New Guinea and reached the Moluccas. Other Dutch mariners working from the north discovered the west coast of Australia, still supposed to be a projection of a vast southern continent, Dirk Hartog reaching 26° S. on that coast in 1616. Anthony van Diemen, governor of the Netherlands Indies, resolved in 1642 to explore the coast of the southern continent and sent Abel Janszoon Tasman to carry out the task. Tasman's voyage was the greatest contribution to exploration since Magellan. He sailed westward across the Indian ocean to Mauritius, then in a great sweep southward and eastward he came on high land which he named after Van Diemen, though it is now known as Tasmania. Sailing farther east he came on the west coast of another lofty land which he named Staten Land, believing it to be part of the southern continent continuous with Schouten's Staten Land off South America. It was really New Zealand. He sailed on to the Fiji Islands and returned along the north coast of New Britain and New Guinea to Batavia. In 1644 he went out again with three ships, when he explored in some detail the south coast of New Guinea and the north and west coasts of Australia, which he called New Holland. In 1699 William Dampier, a noted buccaneer in his early days, made an important voyage on H.M.S. "Roebuck" along the west and north of Australia and the north of New Guinea, rediscovering and naming New Britain. His voyages were remarkable for his extraordinarily keen observations of natural phenomena; in some respects he was the pioneer of scientific exploration. The Dutchman Jacob Roggeveen in 1721 and the Frenchman J. B. C. Bouvet de Lozier in 1739 set out expressly to discover and annex the southland, and the latter took an ice-clad islet of the South Atlantic to be part of it.

EXPLORATION OF THE PACIFIC

By the middle of the 18th century the methods of navigation had greatly improved, and the introduction of the quadrant gave new precision to determinations of latitude. The great bugbear of long voyages was scurvy, supposed to be an inevitable result of life on board the small craft of those days and often fatal to the larger part of the crew. In the second half of the 18th century scientific geographers in Europe secured a more systematic system of exploration in which adventure, though still encountered, was subordinated to research. Already in the first year of the century the astronomer Edmund Halley had been sent in command of a British warship to the South Atlantic in order to study the variation of the compass. In 1764 John Byron was sent on a circumnavigation voyage for discovery. On his return a larger expedition was dispatched under Samuel Wallis and Philip Carteret; it was absent from 1766 to 1769, discovering Tahiti and many other islands in the Pacific. A French expedition under L. A. de Bougainville followed, and for half a century there was keen rivalry between France and Great Britain in the Pacific.

Voyages of Cook and Others.—A new era in exploration, which raised British maritime enterprise to a unique place in the eyes of the world, was introduced with the three great voyages of James Cook. The first of these voyages, from 1768 to 1771, was undertaken in part to observe the transit of Venus of 1769 from a suitable place in the Pacific. This mission was carried out, and much more was accomplished. Many island groups in the Pacific were discovered, New Zealand was identified as separate from the southland, and much of the east coast of Australia was surveyed with amazing accuracy. It was on Cook's second voyage of 1772 to 1775 that the chronometer was first used, which for the first time permitted the accurate determination of longitude. Cook sailed far to the south of the Antarctic circle and proved beyond doubt that habitable land did not exist to the south of the known continents. Perhaps the greatest result of this voyage, however, was the proof that scurvy was preventable by proper diet. The third voyage, started in 1776, had the objective of seeking a northern passage from the Pacific to the Atlantic. Cook surveyed the northern part of the Pacific coast of North America and, after passing through Bering strait, pushed northward to 70° N., where he was stopped by ice. In these three voyages Cook not only had sailed completely around the world, but had covered more than 140° of latitude. On retiring to Hawaii for the winter Cook mas killed by natives in 1779, but Edward Clarke, his second in command spent another season in the effort to penetrate the Arctic ocean from Bering strait; he returned to England in 1780.

Cook's voyage around the antarctic continent was supplemented by a great Russian expedition under Fabian von Bellingshausen in 1819–21, and by a group of hardy American and British sealers in the first third of the 19th century, chief among them James Weddell, who in 1823 reached 74° 15' S in the sea named after him. and John Biscoe, who in 1831–32 made a complete circumnavigation, discovering the most southerly land so far known.

Port Jackson, the present Sydney. was founded as the first settlement in Australia in 1788, and the coasts were explored by such daring boat travellers as Matthew Flinders and George Bass, the latter proving that Tasmania was an island in 1798. Cook was followed on the west coast of North America in 1792–94 by George Vancouver. who extended northward from Cape Mendocino the work of Spanish explorers and made exact surveys along the coast. The French expedition of J. F. de Galaup, comte de la Pérouse, in two ships spent the years 1785 to 1788 in crossing and recrossing the widest part of the Pacific; the expedition never returned, and many efforts were made to discover its fate. the most extensive being that made by J. A. Bruni d'Entrecasteaux in 1791–93.

COMPLETING THE CONTINENTAL OUTLINES

The 18th century saw the completion of the great task of outlining the continental shores. Even those of the Arctic sea had been traced out by Russian travellers such as Vitus Bering (by birth a Dane), Simon Dezhneff and T. Chelyuskin, whose name remains on the most northerly cape of the old world. The Spaniards had made known the broad lines of the geography of South America, Central America and the southern part of North America, the central and northern portions of which had been penetrated in all directions by French and British pioneers. The interior of Australia remained totally unknown, as were the arctic regions north of 80° N. and the antarctic south of the polar circle. In the old world Asia had been traversed in all directions, although large areas remained unvisited between the trade routes and the tracks of explorers. China was mapped by Jesuit missionaries in the early years of the century, and the accurate mapping of India was under way before its close. Africa was the least known of the continents. and the French geographer J. B. B. d'Anville, despairing of reconciling the conflicting accounts drawn from tradition and the stories of Arab traders, who had undoubtedly penetrated far into the interior. swept the map clear of all features which had not been seen by European travellers and left a blank of "unexplored territory" within the coast line from Morocco and Abyssinia on the north to Cape Colony and Natal on the south. James Bruce explored the Blue Nile from its source in Abyssinia to its junction with the White Nile, and before his death a strong effort was made in England by the founding of the African association, which enabled John Ledyard to make a great journey across the Sudan from east to west and Mungo Park to trace much of the course of the Niger. Scientific geography was powerfully advanced by the measurement of arcs of the meridian near Quito on the equator by a French commission under C. M. de la Condamine in 1735–43 and another in Lapland under P. L. M. de Maupertuis in 1736.

THE ARCTIC

Only a few outstanding expeditions to the arctic in the 19th and 20th centuries can be mentioned among the hundreds that carried out important work in that area. Sir John Ross in 1818 reached the mouth of Smith sound beyond Baffin bay, and. seeking a northwest passage, his nephew James Clark Ross reached the north magnetic pole on Boothia peninsula in 1831. Sir John Franklin set out in 1845. lured by the fatal fascination of the passage, and when he failed to return there began the rush of arctic exploration known as the Franklin search. Out of much that was weak, foolish and incompetent in direction there arose in execution heroes and geniuses such as Sir Francis Leopold M'Clintock, who developed the method of man-hauled sledging and stood out among those who explored the coasts and channels of the arctic archipelago. Americans vied with British in the search, and a high place must be given to Elisha Rent Kane. who in 1853 pushed through Smith sound. some of his parties reaching 80° N. In 1873 Karl Weyprecht and Julius Payer on an Austrian expedition discovered Franz Josef Land. In 1875 the last of the old-fashioned British naval polar expeditions in two ships with hundreds of men was sent out under Sir George Nares to reach the north pole. It failed to get through Smith sound but Albert H. Markham in a sledge journey pushed on to 83° 20′ N. In 1878 Baron N. A. E. Nordenskiold in the Swedish ship "Vega" made the long-sought northeast passage along the coast of Siberia and circumnavigated Europe and Asia. In 1882 a series of circumpolar stations for scientific observations was set up by international agreement; the honour of occupying the most northerly point fell to the United States expedition under A. W. Greely, and from his base J. B Lockwood got to 83° 24′ N. Fridtjof Nansen in 1888 crossed the interior of Greenland for the first time. and by travelling on skis and inventing new devices for camping and cooking revolutionized polar travel Five years later by a still more daring and original plan he drifted in the "Fram" across the Arctic sea and got to 86° 14′ N. In 1903–06 Roald Amundsen, another Norwegian in the "Gjoa" was the first to carry a ship through the half-forgotten northnest passage. Invaluable work was done by American. Italian, British and especially Danish explorers, including Mylius Erichsen, Knud Rasmussen and Lauge Knoch in northern Greenland. Robert E. Peary, who had been engaged in polar exploration since 1885, was the first to reach the north pole in 1909. During the 1920s the first air flights to the pole were made. In 1926 Richard E. Byrd flew to the pole from Spitsbergen and returned rhere. A few days later Roald Amundsen and Lincoln Ellsworth with the ltalian pilot Umberto Nobile flew in the dirigible "Norge" from Spitsbergen across the pole to Alaska. After World War II numerous weather stations were established permanently in the arctic regions. and flights to the vicinity of the pole occurred frequently. (See also ARCTIC REGIONS.)

ANTARCTIC EXPLORATION

The antarctic regions were explored for the last time by sailing ships by three expeditions In the period between 1838 and 1843. It seems probable that the first to sight the coast of the antarctic continent was an expedition under the command of the U.S. naval officer Charles Wilkes, in 1840. A French expedition under J. S. C. Dumont d'Urville also sighted land at about the same time in the sector south of Australia. A year later a British expedition under James Clark Ross discovered the south-running coast of Victoria Land. with its tno great volcanoes, Erebus and Terror, and the great ice barrier that bears his name. The antarctic seas remained largely unvisited, except for a souihward dash by the "Challenger" in 1874, until Scottish and Norwegian whalers went in search of new whaling grounds in 1892–95. Scientific expeditions equipped mainly by private enterprise, under the inspiration of the International Geographical congress of 1895, went out from Belgium under Adrien de Gerlache in 1897. spending the antarctic night for the first time drifting in the pack ice south of South America; and from London under C. E. Borchgrevink in the "Southern Cross," spending the winter upon the antarctic continent for the first time in 1898–99. These were succeeded by four simultaneous and purely scientific expeditions in 1901–04. The British national expedition in the "Discovery," under Robert F. Scott of the royal navy, initiated antarctic sledging, taking advantage of Nansen's methods, and penetrated far into the frozen continent. The German expedition under Erich von Drygalski in the "Gauss," the Swedish expedition under Otto Nordenskjold in the "Antarctic" and the private Scottish national expedition under W. S. Bruce in the "Scotia" were all commanded by men of science and did much valuable scientific work.

In 1907–09 Ernest H. Shackleton in a private expedition in the "Nimrod" succeeded, by the innovation of using ponies for transport. in getting to within 97 geographical miles of the south pole and turned only because his provisions were exhausted, while other parties climbed Mt. Erebus and reached the magnetic pole. On Jan. 18. 1912. Scott in the great "Terra Nova" expedition succeeded in reaching the pole by Shackleton's route only to find that he had been anticipated by a month (Dec. 14, 1911) by Roald Amundsen, who had made a dash on skis with dog sledges from a more easterly base. Meanwhile an Australian expedition under Douglas Mawson. with J. K. Davis in command of the "Aurora," explored a great stretch of coast from George V Coast to Queen Mary Coast and penetrated far into the icy interior.

After the addition of air flights and air photography to the techniques of exploration, the antarctic continent was revisited and its character became better known. Among the numerous expeditions sent out for scientific purposes after 1920, the three expeditions under the command of Richard E. Byrd were especially important. The basic purpose was to gather climatic data, to increase the knowledge of antarctic geology and to complete the mapping of the coast line. The first expedition of 1928–30 was followed by a second in 1933–35. A vast amount of meteorological data mas gathered, and the coast-line mapping mas considerably advanced. A third expedition in 1939–41 established two bases on opposite sides of the continent and carried out numerous exploratory flights back and forth between these bases. The British Graham Land expedition of 1934–37 also brought back important new maps and observations. *(See* also ANTARCTIC REGIONS.)

INNER ASIA

In Asia three great areas remained practically unexplored well into the 19th century. These were Arabia, the mountains and tablelands north and east of India and the deserts of central Asia beyond them. The northern half of Arabia was traversed in many directions by European travellers, prominent among them W. G. Palgrave in the middle of the century. followed by Charles Doughty, Wilfrid Scarven Blunt, C. Huber, Gertrude Bell and T. E. Lawrence. To the north of India the great effort was to penetrate the Himalayas and explore Tibet. Most of the work was done by officers of the survey of India, such as George Everest, Sir Richard and Henry Strachey and H. H. Godwin-Austen. Private explorers also had their part: foremost among them were the French missionaries Évariste Huc and Joseph Gabet, who reached Lhasa irom China in an expedition of 1844–46; the great botanist Joseph D Hooker, who explored Sikkim in 1848–49; mountaineers, including the three brothers Hermann, Adolf and Robert von Schlagintueit in 1854–57, W. M. (later Baron) Conway. Douglas Freshfield, the duke of the Abruzzi, F. de Filippi, William Hunter Workman and Fanny Bullock Workman. Finally the many attempts to climb the world's highest mountain, Mt. Everest, culminated in the successful British expedition under John Hunt in 1953.

In central Asia north of the great plateau Russian travellers visited the khanates of Bokhara and Samarkand, and many scientific expeditions ranged the vast spaces. Chief among them were those oi Nikolai Prjevalsky, who between 1870 and 1885 traversed nearly the whole breadth of the continent and defined the great system of internal drainage and its mountain rampart. His work was supplemented and extended by many of his countrymen and in a high degree by the Swedish scholar Sven Hedin from 1894 onward. Francis Younghusband and other British officers made great journeys in the deserts of Gobi and Takla Makan. and the remains of ancient cities attracted the archaeological survey of India, for which Xurel Stein made important journeys. Of great significance in the history of Cnited States geography was the expedition of 1903 to central Asia under the leadership of Raphael Pumpelly, in which such outstanding scholars as William Morris Davis and Ellsworth Huntington took part.

AFRICA

Africa had been left at the end of the 18th century with the map of its interior a blank, the lower course of the Nile, the middle of the Niger and the mouths of the Congo and Zambezi remaining as openings to the mysteries of the interior. The Niger was traced to its mouth at an early date. and between 1822 and 1827 Dixon Denham and Hugh Clapperton made difficult journeys in the Sahara and Sudan and discovered Lake Chad for the African association. In 1849 David Livingstone, the greatest of all African travellers, began his missionary journeys from Cape Colony and explored the Kalahari desert, discovering the salt Lake Ngami. Convinced that mission work was of little use until the continent was opened up, he spent the rest of his life in settling the puzzling hydrography of central Africa. He traced the course of the Zambezi by 1855. Later he pushed his way northward, discovering Lake Nyasa and exploring Lake Tanganyika, and at the time of his death in 1873 he was intently following the northward-flowing Lualaba in the hope that it would prove to be the ultimate source of the Nile. The Nile problem, under the encouragement of the Royal Geographical society, attracted many scientific and adventurous explorers. Richard Burton and J. H. Speke in 1858 discovered the vast Victoria Nyanza (Lake Victoria) on the high plateau under the equator, collecting the headwaters which issued from it as the White Nile; and pushing southward they reached Lake Tanganyika in the great rift which cleaves Africa from north to south. In 1864 Samuel Baker, exploring the Sudan, discovered the Albert Nyanza, another feeder of the Nile. Details of the geography of the Sudan were worked out by scientific men such as Gerhard Rohlfs, Georg Schweinfurth and Wilhelm Junker between 1860 and 1875. H. M. Stanley, a newspaper correspondent who had been sent out by the New York Herald to "find Livingstone" in 1871, found also that he himself was a born explorer, and in a magnificent journey lasting from 1874 to 1877 he crossed Africa from east to west, proving that Livingstone's Lualaba ran not to the Nile but to the Congo and following that huge equatorial river to the sea. The formation of the Congo Free State under the king of the Belgians led to the rapid exploration of the Congo basin, largely by Belgian officers, and the launching of a German colonial policy in 1884 brought many German explorers and men of science into eastern and western Africa. In the extension of spheres of influence most of the geographical problems of the once dark continent were solved before the end of the century, French officers (Gen. Louis Lyautey prominent among them) completing our knowledge of the western Sahara and Sudan.

AUSTRALIA

Australia was almost completely explored by white settlers under their own governments within the 19th century. Matthew Flinders was the first to sail round Australia, the coast of which he laid down in 1801–03. The eastern mountain chain shut off the first settlers in New South Wales from the west. but when the range was crossed rivers were found flowing inland and a vague theory of a great inland sea attracted explorers. John Oxley traced part of the Lachlan river in 1816, the fine pastures of the Darling Downs were discovered in 1827, and the Murray river was followed to the sea in 1829–30. The search for new pastures was the main motive for discovery until after 1850, when prospective new gold fields became a rival lure. The formation of the Saan River Settlement in 1834 and of Adelaide in 1836 gave new points of attack on the interior, and in 1840 E. J. Eyre travelled on foot round the shore of the Great Australian Bight which separated them. In 1844 Ludwig Leichhardt made a splendid journey of 3.000 mi. across tropical Australia from east to west, including the southern shore of the Gulf of Carpentaria, and in the following year Charles Sturt, leaving the east coast farther south, penetrated to the very centre of the continent. John McDouall Stuart succeeded in crossing the continent from south to north in 1862 after two abortive attempts. and his route was afterward followed by an overland telegraph line. In 1861 Robert O'Hara Burke and William John Wills crossed the continent with the aid of camels but perished on the return, a calamity which drew many expeditions into the wilderness to learn their fate. From 1874 for more than 30 years Western Australia was the scene of exploration in search of pasture arid of gold, beginning with the journeys of John Forrest, A. C. and F. J. Gregory, P. E. Warburton and

Ernest Giles and culminating in the great 5.000-mi. march of David Carnegie in 1895. Journeys of pure scientific research were also made, foremost among them those of Baldwin Spencer.

(H. R. Mı.; P. E. J.)

THE AMERICAS

The geographic exploration of the Americas. which resulted in the filling in of the continental outlines with information about the rivers, the mountains, the climate and vegetation and the native peoples. was for the most part carried out by missionaries, gold seekers, fur trappers and adventurers. In any case. they were mostly persons who did not write books. As a result the history of geographic exploration usually omits reference to the Americas. Yet the *bandeiras* of Brazil. those bands of explorers that visited the remotest parts of the interior of South America during the 16th and 17th centuries. and the Spanish expeditions that pushed out from the chief centres of colonial settlement into the unknown. seeking Indians to Christianize or gold to carry back home or good land to settle on—all these were also explorers who gradually reduced the areas on maps that had to be labelled "unknown." Francisco de Orellana, the Spaniard who was the first European to travel the length of the Amazon, deserves as much of a place among the world's explorers as is accorded to the discoverers of the Nile sources. In North America. the first Europeans to push across the great interior were Spanish missionaries in the southwest and French missionaries and fur trappers in the east and north. There were many pioneers from the English colonies along the eastern seaboard who pushed westward. Some of these, such as Daniel Boone, are well known, but there were many others whose names are not recorded.

After the United States had acquired a vast territory west of the Mississippi as a result of the Louisiana Purchase of 1803, a number of exploring parties and surveys were dispatched to report on conditions in the area between the settled part of the country and the Pacific coast. Some of these expeditions were sent out by the army. some by such civilian agencies of the government as the geographical and geological survey. One of the earliest of these was the expedition headed by Meriwether Lewis and William Clark, which reached the mouth of the Columbia river in 1805. Other exploring parties were headed by Zebulon Pike. John C. Frémont and Stephen H. Long. In 1878 John Wesley Powell. who in 1869 had been the first European to descend the Colorado river through the Grand canyon. published a report on the arid region of western United States, the result of many years of painstaking geographical work. He was perhaps the last of the explorers and also the first of the field men who undertook to prepare inventories of the quality and potential uses of the land.

DEVELOPMENT OF GEOGRAPHIC CONCEPTS

During all the centuries when geography mas chiefly concerned with the exploration of unknown areas and nith the plotting of continental outlines, geography as a field of scholarship was developing slowly. Attention was directed at first to the nature of the observable features that gave distinctive character to particular countries. From the Greeks on, however geographers hdve been seeking for more precise ways of measuring things and for plotting them on maps Over the centuries many concepts regarding the purposes and methods of geography have been formulated, tested. reformulated or abandoned.

Geographic Ideas of the Greeks.—The stream of geographic ideas that permeates the western norld had its origin in the writings of the early Greeks. The Homeric poems include a strange mixture of fact and fancy concerning the lands and peoples of the Aegean area However, it is Thales of, Miletus (640–546 B C.) who is commonly recognized as the first Greek geographer. During a visit to Egypt Thales became acquainted with the practices of abstract geometry as developed in that country for the measurement of land and he introduced the geometry of lines to Greek thought. His disciple Anaximander (611–*c.* 547 B C.) made a map of the world based on iriformation obtained from sailors in Miletus.

One of the fundamental problems with which the Greek geographers wrestled was the form and size of the earth. Before the time of Homer (goo B.C.) the earth had been conceived as a flat disk surrounded by the river Oceanus. Anaximander offered the concept of the earth as a cylindrical mass suspended in a spherical universe. It was Aristotle. however, nho first demonstrated the sphericity of the earth by noting: (1) that all matter tended to fall together toward a common centre; (2) that the earth threw a circular shadow on the moon during an eclipse: and (3) that as one travelled from north to south familiar stars disappeared and new ones came above the horizon.

Eratosthenes of Alexandria (c. 276–*c.* 194 B.C.) calculated the circumference of the earth. He learned of a deep well located at Syene (now Aswan) in Egypt nhich was completely illuminated by the sun at the summer solstice. Assuming this place to be on the tropic. and assuming Alexandria to be directly north of Syene, he measured the zenith distance of the sun at the latter place at the solstice. Reckoning the distance between the two places to be about 500 geographical miles, he arrived at a figure for the whole circumference of the earth which was remarkably close to the figure which is known to be correct.

The Greek geographers. like most of the Greek philosophers, were great believers in the concept of symmetry Herodotus (c. 484–425 B.C.), who was both a geographer and a historian. held to the view that the inhabitable lands were not circular, but were longer from east to west than they were broad from north to south. from which is derived the modern designation of longitude and latitude. He followed the principle of symmetry to fill in the arrangement of lands and the courses of rivers beyond the limits reached by explorers. He insisted that the Nile must flow from nest to east before turning north in order to balance the Danube. nhich flows from west to east before turning south. He also named the three continents that border the eastern Mediterranean: on the northern side. Europe; on the eastern side. Asia; and on the southern side, Africa. The geographical and historical ideas that Herodotus accumulated nere derived from the critical examination of a vast number of documents and also from extensive and arduous travels and field observations.

The first geographer to divide the surface of the earth into zones based on latitude (known as *klimata*) was Parmenides (c. 450 B.C). He conceived of a torrid zone nhich mas too hot to be inhabitable. two frigid zones that were too cold, and two intermediate temperate zones which constituted the inhabitable earth. Aristotle developed the idea of zones of climate and defined the temperate zone as extending from the tropics to the polar circle. Purely on the basis of theory he assumed the existence of a south-temperate zone corresponding to the known world of the Greeks. He, too, believed that the torrid zone was too hot to be inhabitable and that people who lived too close to the equator had been burned black by the sun.

The word "geography" was probably first used by Eratosthenes. The writing of geography, under whatever name. was greatly stimulated by the expansion of Greek culture, partly through the establishment of colonies of Greeks around the coasts of the Mediterranean and the Black sea. and partly through the conquests of Alexander the Great. who extended Greek horizons eastward to India.

Ideas of the Romans.—Unlike the Greeks, the Romans were primarily concerned with practical questions. The first of the encyclopaedic descriptive works dealing with the geography of countries came from the Roman geographers. The one whose works are best known is Strabo (c. 64 B.C.–A.D. 20). His 17 volumes describing the whole of the known world, and supported in considerable part by his own field observations. are like a handbook for the guidance of military commanders or public administrators. This work set a pattern for encyclopaedic geographic writing nhich has been followed ever since.

Claudius Ptolemaeus, known as Ptolemy. was a mathematician, astronomer and geographer who lived in Alexandria between A D. 127 and 141 or 151. In his great work on geography (c. 150–160) he brought together the results of Greek geographical learning. He attempted to provide the data on latitude and longitude by which maps might be constructed, but unfortunately he discarded the estimate of the earth's circumference made by Eratosthenes in favour of a much less accurate one offered by another Greek geographer. He adopted a suggestion of Hipparchus that the equator be divided into 360 parts (later known as degrees). Ptolemy recognized the difference between treatments of the world as a whole. of parts of the world or regions. and of localities; for these different kinds of writings he used the terms "geography." the treatment of the world as a whole; "chorography," the treatment of parts of the earth; and "topography," the treatment of small localities in detail.

Moslem Geographers. — The dark age of geography began before the fall of the Roman empire. It resulted in part from the completion of Roman conquests and in part from the rise of Christianity. A narrow interpretation of the scriptures led certain ecclesiastics to deny the sphericity of the earth and any of the geographical concepts based on it. Greek science gave way to widespread ignorance and bigotry.

Many of the Greek writings, and especially the works of Ptolemy, were translated into Arabic and tested by new observations over a wide area. Such travelling merchants as Ibn Haukal in the 10th century. and Ibn Batuta in the 14th century journeyed far beyond the limits reached by the Greeks. Ibn Batuta (1304–78) went far to the south along the east coast of Africa to a place nearly 10° S. of the equator. He found the temperatures on the equator more moderate than those farther to the north. The idea of uninhabitable torrid zones which appears in the book by Aristotle was thrown in doubt. Yet so simple and persuasive is the idea that the world's climates can be properly grouped in just three zones and that these zones have some effect on the way people live in them that even in the mid-20th century it was still being taught in the schools. This oversimplification has been the cause of much obscurity regarding the relation of man to climate.

The Moslem scholars did much not only to preserve and criticize Greek learning but also to add new kno ledge and new concepts of their own. The works in historical geography of Al-Biruni, Al-Baladhuri and especially of Ibn Khaldun (1332–1406) reach new standards in accuracy of observation and in interpretation of the relations of people to the land. It is apparent, too, that the Moslem geographers had started to formulate ideas concerning the uplift of mountains by folding and the erosion of slopes by running water, and also of the great amounts of time which these processes require. Such advanced ideas were developed by field men. by great travellers; for example. Ibn Batuta. during 30 years of travel. is estimated to have covered 75,000 mi., ranging as far east as India and the Malay archipelago. The Moslems, however, contributed nothing to the progress of cartography.

Revival of 16th–18th Centuries. — While the Moslem geographers were making their contributions to the development of geographic thought. the geographic horizons in Christian Europe remained narrow. Roger Bacon. writing in the 13th century and generally credited with originating the modern scientific method, described Ethiopia in terms which Ptolemy would have considered naïve and careless and which were based on information as much as 1.joo years old. Geographic horizons were reopened in Europe first as a result of the crusades and then of the discoveries of the Portuguese and Spanish expeditions.

The revival of geographic thought is recorded in the works of several scholars during the 16th. 17th and 18th centuries. The first of these was Petrus Apianus (Peter Bienewitz), whose book published in 1524 went back to Ptolemy for its inspiration. Gerardus Mercator (Gerhard Kremer) (1512–94) was a student of Apianus and later established a geographical institute at Louvain. where he worked on the development of his well-known projection. Sebastian Münster in 1544 published a descriptive book that followed the example of Strabo. But not until Philip Cluwer (1580–1623) and Bernhardus Varenius (Bernhard Varen) (1622–50) wrote their monumental geographical treatises was the revival of geographic learning well started. Varenius divided the field into general geography (dealing with the earth as a whole) and special geography (dealing with parts of the earth on a chorographic or topographic scale). His early death at the age of 28 prevented him from undertaking his proposed work on special geography, but a century later his general geography was still the accepted standard authority. In 1625 Nathanael Carpenter published the first geographical work in English. in which he showed a remarkable degree of scientific objectivity in his interpretations of observed phenomena. He foreshadowed the point of view of geographers of later centuries by focusing attention on the areal relationships of things on the surface of the earth. In 1686 Edmund Halley produced the first mind chart and presented his theory of the trade winds which related them to the distribution of heat on the earth. In the second half of the 18th century and the early 19th century there was a large amount of geographical writing. bringing together a vast number of new observations concerning physical geography. Some of this was summarized in the works of Philippe Buache (1756), the first geographer to make use of contour lines (1737), and in writings by Torbern Bergman (1766) and J. R. Foster (1783). At the same time Jedidiah Morse of Charlestown. Mass., published his compendium of geography (1789); in Britain John Pinkerton's *Modern Geography* appeared in 1802; and on the continent Conrad Malte-Brun started the publication of the first *Géographie universelle* in 1810. This was the period in which there was a wave of new scientific writing, including works by such masters as J. B. de Lamarck. P. S. de Laplace, A. G. Werner, James Hutton, Charles Lyell, Georges Cuvier. William Smith, J. F. Blumenbach and others. This was the intellectual environment in which Immanuel Kant lived.

Kant.—Kant. the great German master of logical thought. gave geography its place in the over-all framework of organized, objective knowledge (science). For a number of years after 1765 he lectured at the Cniversity of Königsberg on physical geography, and these lectures were subsequently published. It is possible, according to Kant, to classify all knowledge gained from observation in either of two ways: a classification of things perceived in accordance with some logical system. a logical classification; or a classification of things perceived in terms of the time and space where they occur, a physical classification. From the former method a systematic classification of nature is gained, as when plants or animals are placed in a system of species and genera regardless of where they occur. From the latter a geographic description of nature is gained, as when the plants and animals that occur together in the same area are identified. Description according to time is history; description according to place is geography. History is a report of phenomena that follow one another; geography is a report of phenomena that are beside one another. Geography and history together fill up the entire circumference of our perceptions. This is essentially the concept of the place of geography among the sciences that has guided the main stream of geographic thought since Kant.

Kant regarded physical geography as the summary of nature, the basis not only of history but also of "all other possible geographies." Of the latter he enumerates five: (1) mathematical geography. the measurement of the form, size and movements of the earth and its place in the solar system; (2) moral geography (in the sense of mores), an account of the different customs and characteristics of mankind; (3) political geography. the study of areas according to their governmental organization; (4) commercial geography, dealing with trade in surplus products of countries; and (j) theological geography, the study of the distribution of religions.

Humboldt and Ritter.—Until the latter part of the 18th century there mere essentially two main purposes of geographic study: there was the study of the shape and size of the earth, represented by Ptolemy and Apianus-Mercator; and there was the compilation of informative descriptions of countries and regions, represented by Strabo and Miinster. Kant provided a place in the broad framework of geography for both. Since Rant the mathematical tradition has been carried on by the cartographers, on the borderline between geography and geodesy; the tradition of descriptive writings about places has become the main stream of geographic work.

With Alexander von Humboldt (1769–1859) and Karl Ritter (1779–1859), however, the nature of the main stream itself was changed. When Strabo was writing, and even when Münster was reviving the descriptive tradition, geographers were seeking to identify the phenomena and the associations of phenomena that gave distinctive character to particular places. Understanding of process had not advanced far enough to permit a recognition of phenomena that were systematically related to each other in that they had been produced by the same process. The purpose of descriptive writing had been an essentially practical one: that of providing geographically organized information either for the use of military commanders or public administrators or as a basis for the understanding of history. No scientific principle (that is, no concept of systematically related phenomena) guided the selection of what information to include, what classifications of phenomena to adopt. Such writings have been described as encyclopaedic in that the information included was not necessarily tied together by its relevance to a problem.

By the beginning of the 19th century the systematic sciences, each discipline being devoted to the examination of a particular process (as defined in the introduction to this article), had so far advanced the understanding oi physical and chemical processes that no longer could such knowledge be disregarded in the study of particular places. Since the beginning of the 19th century the selection of phenomena to include in a study of the physical aspects of geography and the definition of categories of phenomena to be included in a system of classification have been guided by systematic knowledge of the processes involved. This advance in geographic theory was the result of the work of numerous geographers in the late 18th century who made the first applications of the new knowledge; yet it remained for two men to make the first effective use of these ideas and so to stand out as giants in the development of geographic thought.

It is remarkable that geography all over the world should owe so great a debt to two scholars — Humboldt and Ritter—who worked at the same time, both in Germany, and both for 30 years in the same city, Berlin. They were in many ways quite different in their backgrounds and in their approach to the common subject. Humboldt began his education with the purpose of becoming a diplomat, but stimulating contacts with teachers of science developed the passion and capacity for careful, direct field observations of natural phenomena. During his early 20s he travelled in England and in 1795 he made a geological and botanical tour of Switzerland and Italy. Then for five years (1799–1804) he travelled in South and Central America, amassing a vast amount of recorded and measured data regarding the countries he visited. Later, in 1829, at the age of 60, Humboldt travelled info central Asia. For most of the later years of his life, however, he was engaged in the writing of his great works: the account of his travels in America and his description of the physical geography of the earth in the *Kosmos*. He lived alternately in Paris and Berlin.

Humboldt's great contributions to geographic procedure were two. First, he applied his knowledge of physical and biological processes to the systematic classification and comparative description of the phenomena he and others had observed; second, he devised methods of measuring the phenomena he observed. For example, in his field studies of tropical mountains in America he measured the temperature at different elevations and for the first time showed temperature differences on a map by drawing lines to connect points of equal temperature (isotherms). He made use of census data where they were available, but in the absence of such data he carefully checked estimates of the population of various regions and countries of America. The step from qualitative, encyclopaedic description to quantitative, systematic description was a major one in the history of geography.

Karl Ritter was Humboldt's junior by ten years. He always regarded Humboldt as his master and in many ways based his geographical writings on the ideas of the elder scholar. Perhaps no man had a broader background of preparation for geographic study than did Ritter. He was taught by men who insisted that knowledge of the world could be gained only by the direct observation of nature. Like Humboldt, Ritter was a persistent and careful field observer; unlike Humboldt, he never made long journeys to distant places, but rather confined his field observations to Europe. He received a fine training in the natural sciences, and he was also a student of history and theology. In many of his writings he was more historian than geographer, and opposition to his ideas that developed after his death arose in part from the accusation that he had made geography a handmaiden of history. He wrote what has come to be known as geographical history (a geographical interpretation of history) rather than historical geography (the reconstruction of past geographies and the tracing of geographical changes through time). Ritter emphasized the importance of comparative studies of different parts of the world and the danger of drawing conclusions or formulating generalizations on the basis of knowledge of one area alone. In his studies he always attempted to show how things existed together in the same areas in mutual interrelationship. He thought of geography as a kind of physiology and comparative anatomy of the features of the earth's surface. Yet his deeply religious attitude led him to adopt a strongly teleological point of view. His monumental work, ***Die Erdkunde im Verhiiltnis zur Natur und zur Geschichte des Menschen*** (2 vol., Berlin, 1817–18; 2nd ed., 1822–59), covered only Asia and a part of Africa.

Ritter also made two contributions to geographic method. First, he insisted that one should proceed from observation to observation, not from opinion to hypothesis to observation. He was among the first, for example, to show that Buache's idea of continuous mountain systems separating the drainage basins of the great rivers was contrary to observed facts. In gathering together impressive arrays of data from the reports of others, Ritter's purpose was to let these data speak for themselves in bringing out the coherent relations among things. He was the first to provide a system of subdivisions of the continents based on surface features as a framework for his detailed regional descriptions. Second, Ritter's approach was regional rather than systematic; that is, he focused his attention on particular places and on the phenomena unsystematically associated there rather than on systematically related phenomena wherever they might occur. Yet Ritter himself acknowledged that without the systematic studies of Humboldt his own work could never have been carried out.

GEOGRAPHY AFTER HUMBOLDT AND RITTER

Humboldt and Ritter had gathered together the geographical ideas of the past, and from their writings there emerged a new and unified concept of the nature of geography. The main stream of geographic scholarship since Humboldt and Ritter has been devoted to an understanding of the significance of likenesses and differences from place to place on the earth and of the meaning of the associations and interconnections among phenomena in particular places. Armchair geography, based on the spinning of elaborate theories in advance of precise observation, is no longer acceptable; in contrast geography has become essentially an out-of-door subject, based in large measure on the direct observation of phenomena in the field. One technical problem has been the method of recording such direct observations. At first such data were recorded only in the form of notes (written or sketched) ; since 1915 the recording of field data on maps in the field has became standard practice, and since about 1930 the recording of observations on vertical air photographs has given a new precision to geographical study that it never could have possessed before.

The idea that Humboldt represented a systematic or topical approach to geographic study in contrast with Ritter's regional approach has been overemphasized by some geographers. Clearly both these scholars used both approaches, perhaps with varying emphasis. The modern concept does not recognize the topical and the regional approach as different aspects of geography, but rather recognizes the need for combining them.

In the period since the middle of the 19th century chorographic study (that is, study of areal differentiation and its meaning) has been moving steadily away from the encyclopaedic description of the Strabo-Münster tradition toward an organization of material relevant to a specified purpose or objective. Modern geographic writing starts with a problem and applies the geographic method to the search for answers or for clarification of the issues involved in the formulation of policy.

Meanwhile, however, a number of deviations from the main stream of geographic scholarship have appeared. One such deviation conceived of geography as a science of relationships, specifically those between man and his physical environment. Another conceived of geography as devoted solely to the interpretation of the visible features of the landscape. Still another and widely popular deviation identified geography with geopolitics. Others, such as the identification of geography with geophysics! need not be discussed in this article since they have few if any adherents in the modern period.

THE MAIN STREAM: GEOGRAPHY AS CHOROGRAPHIC SCIENCE

Chorographic science is that aspect of learning which treats of the areal arrangements and associations of things on the face of the earth and seeks to understand the causes and consequences of such areal differentiation. As already stated. geography cannot be defined by its subject matter, for anything that is unevenly distributed over the earth can be examined by the methods of geographic study. The continued development of the chorographic approach has led to greater and greater attention to procedures for selecting features to be studied and for rejecting other features as irrelevant. It hss also led to great increase in precision of field observation. Both these developments were adumbrated in the writings of Humboldt and Ritter.

Clearly the main stream of geographic scholarship was defined in Germany by two late 19th- and early 20th-century figures. These were Ferdinand von Richthofen and Alfred Hettner. In the modern period the geographers whose contributions have been of the utmost importance, and who have set forth their philosophical ideas regarding the content of geography, are too numerous to permit mention of more than a few. The ideas of Richthofen and Hettner and of many others were discussed and critically analyzed in English in the monumental work of Richard Hartshorne, ***The Nature of Geography*** (1939).

French Tradition of **Regional Studies.**—No country has contributed more to the development of geography than France. In proportion to the size of the country and the financial resources of its universities the quantity and quality of French geographic work has been outstanding. But France has achieved this status largely during the 20th century.

During most of the 19th century geography was widely taught and geographic writings were in demand. The first chair of geography was established at the Sorbonne in 1809, and in 1821 one of the oldest geographical societies in the world was established at Paris. Rut the geographical writings of that century were in the encyclopaedic tradition and the teaching was aimed chiefly at a geographic interpretation of history. Two comprehensive series were published under the title *Géographie universelle:* the 8-volume series (1810–29) by Conrad Malte-Brun, and the 19-volume series (1875–94) by Elisée Reclus. The series by Reclus represented in its day the most scholarly kind of descriptive geography; yet it represented no conceptual advance over the work of Ritter, since the genetic approach had not yet been applied to the study of population.

French geography was raised to a new level of accomplishment by the great master Paul Vidal de la Blache (1845–1918). In 1899 Vidal de la Blache set the new tone for French geographical studies in his inaugural address at the Sorbonne. He expressed himself as opposed to any strict determinism with regard to the relation of human activities to the physical environment; rather he recognized man as the active agent, operating in a setting that offered both possibilities and obstacles to man's wishes. But he was convinced that the way to go forward in geographical studies was to focus attention on relatively small areas in which to examine in detail the areal differentiation resulting from physical and human processes. Vidal's influence was great, and most of the French geographers after his time were either his pupils or pupils oi his pupils.

Perhaps Vidal's greatest disciple was Jean Brunhes (1869–1930), whose *Human Geography* is a widely read book in English as well as in the originai French.

The French geographers who developed under the influence of Vidal showed a remarkable unity of purpose and achieved a high standard oi performance. The French regional monographs, some dealing with parts of France, others dealing with other parts of the world, are a famous and distinctive part of geographic literature. Vidal was responsible for formulating the original plans for another great *Géographie universelle,* and after his death the direction of the project was carried on by his successor Lucien Gallois. The first of these volumes to appear were the ones on Great Britain and the Netherlands by Albert Demangeon (1927). The whole series was completed in 1946–48 with the publication of the three volumes on France by Emmanuel de Martonne and Demangeon. No finer books bringing together material on the geography of the whole world had ever been published.

Although all the volumes are of a high standard of accuracy and of literary quality, the outstanding volumes by De Martonne and Demangeon on *La France,* by De Martonne on *Europe Centrale,* by Henri Baulig on *Amérique Septentrionale* and by Pierre Denis on *Amérique du Sud* should be given special mention. In these the regional descriptions are given focus through the inspired identification of central themes around which the descriptive material is organized.

The French regional tradition was passed, also, to workers in other countries. In Germany Friedrich Ratzel initiated a series of regional monographs dealing with different parts of Germany under the general title of *Forschungen zur deutschen Landeskunde.* The Pan American Institute of Geography and History, a specialized agency of the Organization of American States, undertook to plan and co-ordinate the preparation of a series of volumes dealing with the countries of the western hemisphere. Brazilian geographers were especially active in the writing of regional monographs in the French tradition. They were stimulated, in part, by the presence of several outstanding French scholars, notably Pierre Deffontaines and Pierre Monbeig. The Brazilians were also influenced by the German-American geographer Leo Waibel and by several geographers irom the United States who introduced techniques of field mapping and resource inventory.

The French and German chorographic tradition was extended, also, to other parts of the world, where a number of outstanding scholars made contributions to geographic thought. Major geographic work has been done in Australia, New Zealand and South Africa, in Italy, Czechoslovakia, Poland and the Russian S.F.S.R. The Russians were especially important during the 19th century for introducing new concepts in the study of soil geography. Geographical work has also been important in China, Japan and India.

20th-Century Developments.— By the middle of the 20th century the chorographic tradition had been notably advanced by new concepts regarding the focus of geographic objectives and by new techniques of observation and analysis. These changes had their roots in the 19th century, but appeared strongly after World War I. France, Germany, Great Britain and the United States shared in the return to the main stream of geography.

In the first place the need for a central theme or problem around which to organize geographic material became more widely recognized. The encyclopaedic coverage of areas was recognized as important; but it became more and more clearly demonstrated that even an encyclopaedia must be written for a specific purpose or to fill a specific kind of need. This involves, then, a certain amount of selection in the kinds of data to be treated. If the encyclopaedia is to provide background information for the planning of a military campaign, this determines the kind of information required. If the encyclopaedia is to be used as a reference work in schools or colleges, a different selection is required. But there are also many kinds oi questions concerning origins and antecedents that may be asked regarding the geographic ieatures oi an area, and these questions are problems which in turn provide a means for distinguishing betw-een relevant and irrelevant items. Or there may be an economic, social or political situation which needs to be changed or remedied, and this also provides a problem around which to organize the materials and analyses of geography. By mid-20th century leaders in professional geography were critical of research undertakings not specifically directed toward stated ends.

This trend away irom the uncritically encyclopaedic kind of writing gave additional emphasis to direct field observation, again in the tradition of Humboldt. Direct field observation must of necessity be carried out in small areas, ior the range of human vision on the curved surface of the earth is small. When the features of the earth are mapped on small-scale maps they must be highly generalized, as when a pattern of specific fields and farms is generalized into a kind of agricultural region. But the agricultural region cannot be seen directly, for it is too big; the details that make it up are the specific features of human settlement, the specific slopes and soils, and these must be mapped on large-scale maps. Geographers still use the adjective "topographic" to define that scale of field mapping which permits the plotting of specific fields and farms or specific blocks and even buildings in a city; a topographic map is one with a scale large enough to permit such specific features to be mapped.

Topographic studies, using the word in this sense, were common in Great Britain even during the 19th century. As early as 1895 Hugh Robert Mill wrote an essay in which he described in detail the characteristics of a small part of Sussex. He urged similar treatment for the area of each of the sheets of the British topographic maps (inch to the mile scale). The numerous essays brought together under the editorship of Alan Grant Ogilvie in 1928 (*Great Britain: Essays in Regional Geography*) dealt with specific kinds of problems or features in relatively small areas. In few of these studies, however, were the physical, biotic and human features of an area treated with the same degree of detail. It was commoner to treat the physical characteristics of an area in detail and then to sketch in the human aspects superficially.

The development of geographic thought and method were greatly advanced when geographers in the United States first developed the procedures ior treating all the relevant features of a small agricultural area with the same degree of detail. One of the first geographers to insist on the need for such balance was Wellington D. Jones. With Carl O. Sauer he published an outline for the detailed field study of an agricultural area in 1915. In the summer of 1915 graduate students at The University of Chicago were ofiered the first field course in which such a balanced approach was taught. Shortly thereafter Sauer made field study a basic part of graduate training at the University of Michigan, Ann Arbor. Thereafter it became standard procedure to examine geographic problems in the field in small areas.

Surveys and Inventories.— In the period since 1920 the methods of detailed field study have been applied, with increasing success, to the practical problems of land planning. By mid-20th century it was widely appreciated that an inventory of land quality and existing land use was an essential basis for formulating land-use policy. The first survey with the purpose of providing such background information was the Michigan Land Economic survey undertaken during the 1920s and 1930s to tell the policy makers what actually existed in the cutover lands of the northern part of the state. During the 1930s similar field methods were used by geographers to survey the area of the Tennessee Valley authority. There, for the first time in connection with a large survey, mapping was done on air photographs.

At this same time, L. Dudley Stamp introduced the idea of the detailed field survey to Great Britain. In 1930 the British Land Utilisation survey was started with the objective of recording on maps of suitable scale the facts of land use and land quality for every acre of England, Scotland and Wales. The survey was carried out by unpaid volunteers from the universities, colleges and schools under the guidance of professional geographers, using maps of a scale of 1:10,560 (six inches to the mile). This survey proved of inestimable value during World War II, when Britain was forced to make use of every available acre of land for agricultural production. It is not too much to say that the survey was a most important factor in helping Britain to survive the war years. It also provided the material for Stamp's book *The Land of Britain: Its Use and Misuse.*

Two other surveys made use of geographic field methods for resource inventory and land-use mapping as a basis ior the formulation of public policy. One was the Puerto Rico Rural Land Classification program (1948–52), done for the government oi Puerto Rico, in which the island was mapped on a scale of 1:10,000. From these maps effective plans for the better use of the limited agricultural base were drawn up. Another survey was directed broadly at the resources of tropical Africa under the direction of George H. T. Kimble. It was widely recognized that at mid-20th century there were not enough adequately trained field men to carry on surveys fast enough, even in the world's critical areas. Geographers and others were seeking to perfect the methods of resource inventory through the interpretation of air photographs with a minimum of direct field contact. In this development professional geographers in the universities were handicapped by lack of financial support; meanwhile government apencies and private organizations were in some cases proceeding without the benefit of the experience gathered by the geographic profession over centuries of field study.

Spatial Interchange.— The study of the movements and communications that connect one area with another has long been an essential aspect of chorographic work. To treat areal differentiation as a purely static phenomenon is insufficient. During the 19th century, especially in Germany and France, there was much interest in transportation as a geographic phenomenon. The study of spatial interchange deals not only with the volumes of movement but also with the facilities, such as railroad equipment, or the capacities of ports and ships to move different kinds of goods. At mid-20th century a tendency had appeared to apply mathematical iormulas from the field of physics to the description of the volume and velocity of movements in relation to the factors of location and distance.

DEVIANTS FROM THE MAIN STREAM

During the 19th and 20th centuries there were a number of deviant developments in the field of geography. Some of these died out early; for example, the proposal that geography should concern itself wholly with geophysics, abandoning studies oi human geography as "unscientific." Other deviants were proposed by individual scholars but attracted iew followers; for example, that geography should be defined as human ecology, a field already claimed if not developed by sociology. Among the various deviant currents that have appeared, three may be given special attention: (1) geography as the science of relationships; (2) geography as the study of landscape; and (3) geography as geopolitics.

Science of Relationships.— The idea of defining geography as the study of relationships appeared during the second half of the 19th century. At that time the understanding of the physical and biotic processes at work on the earth had been much iarther advanced than the understanding of the economic, social and political processes. Few geographers have at any time thought of their field as covering only the physical and biotic aspects of the earth or of omitting study of the human or cultural aspects; yet the concepts of causal relationship as developed in 19th-century physical geography and biogeography were quite out of harmony with those oi human geography. The theory of evolution applied to the changes in plants and animals had a tremendous influence on the intellectual world. It was reflected in physical geography, especially, by attempts to define ideal sequences of change, such as the cycle of youth, maturity and old age of land forms. These attempts were notably successful. William Morris Davis, professor of geography at Harvard university, was an outstanding leader in this development.

But when the new concepts appeared in physical geography and biogeography, no similar principles were immediately forthcoming to organize the treatment of man and his works. It was in this situation that an attempt was made to relate the human aspects of geography to the better-understood physical aspects and to define geography as the study of the interrelationships between man and his physical environment.

In Germany, Friedrich Ratzel attempted to bring the treatment of man into line with the treatment of physical features. In the first volume of his *Anthropogeographie* (1882 and 1899), he organized his material in terms of the natural conditions of the earth, in relation to which he examined various cultural ieatures. In the second volume (1891 and 1912) he did the opposite, organizing his material in terms of human culture, in relation to which he examined the physical features of the earth. Ratzel, however, was thoroughly in sympathy with the tradition of Humboldt and Ritter; he never lost sight of the need for direct observation of all relevant elements of a situation. Thus in his classic volume on *Deutschland* he pointed out that two physically similar areas, the Black Forest and the Vosges mountains, had developed in quite different ways because of the differences in economy and historical tradition.

Some of Ratzel's disciples were not so careful to observe all the relevant interrelated phenomena. Especially those who were trained chiefly in physical geography insisted that a geographic analysis must show a relationship that crossed the border between physical and human phenomena, thus neglecting the relationships on the same side of the border. Few geographers ever subscribed to such extreme forms of environmental determinism as suggested by the historian H. T. Buckle and others; but many went forth deliberately to seek examples of environmental influence on human activities, and many remained blind to contrary evidence. As a result geography was divided into physical geography (a well-developed field of science) and human geography (a relatively superficial treatment of man's relations to the physical earth). The adjective "geographic" came to refer to the physical character of an area. Thus a "geographic factor" was some condition of the physical environment to which human activities were to be related as "responses" or "adjustments."

Geography as the science of relationships persisted longer in the English-speaking world than elsewhere. It found few adherents in Germany, where Alfred Hettner was developing the ideas associated with the main stream of geography. It was effectively attacked by the French geographers under the leadership of Paul Vidal de la Blache. But it was given persuasive support in the United States by such scholars as William Morris Davis, Ellen C. Semple, Wallace W. Atwood. Ellsworth Huntington, Robert DeCourcy Ward and R. H. Whitbeck. Yet this approach to geographic study proved to be a dead end. As Griffith Taylor, an eloquent supporter of the ideas of environmental determinism, wrote, such relationships between man and his environment are nowhere more clearly seen than when one looks at the world as a whole. Yet when one looks at the world as a whole all the aspects of the iace of the earth, physical as well as human, are highly generalized. Only when the earth is examined in topographic detail—that is, on maps large enough to permit the plotting of specific ieatures of human occupance—can generalization be kept to such limits that results can be checked. At mid-20th century detailed field studies had yet to demonstrate through proper historical and comparative methods the validity of the concept of environmental determinism. Modern geographers, on the contrary, insist on the principle that the significance to man of the features of the physical earth is a function of the attitudes, objectives and technical abilities of man himself. In other words, the physical and biotic environment has different meaning for different persons; and further, geography examines the relationships not only between man and the physical or biotic aspects of the environment but also between man and the variety of cultural ieatures resulting from economic, social and political processes. Only thus can the relative significance of areal differences be weighed and evaluated. Geography can no longer be divided neatly into physical and human geography, and a geographic factor is any factor of location or areal association that is relevant to a problem.

Study of Landscape.— The idea that geography should be restricted to an examination of the visible character of the landscape appeared as another deviant in 19th-century Germany, especially in the works of Otto Schliiter. In the United States this approach to geography was introduced by Carl O. Sauer in a paper entitled "The Morphology of Landscape" (1925). The immediate popularity of this point oi view among the younger geographers of that period represented a reaction against the idea that geography was restricted to a study of the relationships between man and his physical environment. Sauer's paper shows the results of experience in detailed field mapping and field study, the influence of ideas irom German geographic literature and the challenge of concepts presented by the rapidly developing field of anthropology. Sauer was concerned with the significance to man of the physical and biotic conditions of a small area or site, and also with man's transformation of the site. Perhaps it was the iollowers of Sauer rather than Sauer himseli who tried to restrict geographic attention to form and structure alone to the neglect of function—in other words, to the anatomy of the visible landscape rather than to its physiology.

As in other attempts to provide a limited definition of the field of geography, this proved to be a dead end. Geography, according to the concepts developed by Kant and restated by Sauer, is one aspect (along with history) oi the whole range oi perception; Sauer called it a "nai'vely-given sector of reality." Geography, then, is not subject to definition or limitation; geography is not what geographers do, for much work in this sector of reality is done by persons who are not professional geographers and who are not especially competent in the use of geographic methods.

Geopolitics.— Another deviant from the main stream of geographic science is that known by the popular term "geopolitics." The great popularity of geopolitics as a practical field oi study in which human geography and applied political science are used for the examination of certain problems in international relations had its great development as a result of World War II. Karl Haushoier, a German geographer, was credited with the iormulation of ideas that had a profound effect on the strategic policy of Adoli Hitler. Whether Haushoier's ideas had the greater influence on Hitler or Hitler's on Haushoier has not been established. The iact is, however, that the German school of geopolitics was used to provide a pseudoscientific rationalization of Nazi policy. In the United States and Great Britain another school of geopolitics was developed which sought to go back to H. J. Mackinder and A. T. Mahan rather than to Haushoier.

Geopolitics, as distinguished irom political geography, combines the concepts and techniques of a variety oi disciplines ior the purpose oi iormulating strategic policy in international relations. But strategic policy as formulated by the leaders of any one state has the basic purpose of advancing the interests of that state; every state has a somewhat different set of purposes and these are oiten in conflict with the purposes of other states. Geopolitics, then, is an applied field which would seem inevitably to be divided into as many schools as there are independent states. Geography may be used, along with other disciplines, in working out the plans of geopolitics; but geography is not the same as geopolitics, nor is geopolitics a field of scholarship by itself. *(See* also GEOPOLITICS.)

GEOGRAPHY IN THE 20TH CENTURY

Two outstanding books were published in the United States discussing the field of geography. One by Richard Hartshorne, *The Nature of Geography* (1939), reviewed the main course of geographic thought and the various deviants that had irom time to time become important. It was a historical work, with emphasis on the ideas formulated by the Germans. It presented the chorographic viewpoint in its many aspects and as developed over many centuries. The other book involved the work oi more than 100 proiessional geographers; *American Geography, Inventory and Prospect* (1954), edited by Preston E. James and Clarence F. Jones, brought together the experience of hali a century in the formulation of the concepts of geography and in the development of acceptable procedures of geographic research.

Geography is recognized as a single discipline, unified not by its subject matter but rather by its point of view and its method. The point of view is defined in terms of the regional concept: the method of all geographic study is the regional method. The term "region," however, is defined somewhat differently irom the definition given in the dictionary. Popularly the word "region" denotes a relatively large area having some general quality of homogeneity but with boundaries not precisely defined. In *American Geography, Inventory and Prospect* a region is an area of any size that is homogeneous in terms of specific criteria and that is distinguished from bordering areas by a particular kind of association of areally related ieatures. The old distinction between topical (or systematic) geography and regional geography is not considered valid. Topical geography is defined as the study oi a particular group of features produced by one kind of process wherever these ieatures may occur in the world (Varenius' general geography); regional geography is defined as the study oi all kinds of features as they occur in particular areas (Varenius' special geography). At mid-20th century, however, it was recognized that in so iar as all regions had to be defined in terms of specific criteria the approach to regions had to be a topical one; and since the study of any topic involves the definition of homogeneous areas, all topical study had to make use of the regional method.

The new concept of the region stemmed irom experience in detailed field studies. It is clear that no two points on the iace of the earth are identical. On the other hand, if the complexity of the iace of the earth is to be brought within manageable limits for the purpose oi examining the causes and consequences of areal differentiation, to examine each spot separately would deieat the endeavour. Geographers must always generalize; they must define categories of phenomena that are meaningiul in that they are associated in area with other phenomena; they must seek associations of phenomena, defined as regions, that are significant in that they are related to a particular process or group of processes. In all science as iormulated by Kant there are two kinds of generalizations: one that deals with the classification of phenomena into categories of greater or lesser degree oi generalization; and another that describes the ideal operation of a process, or a chain of cause and effect relations. Geography traditionally deals with the former; but modern geography classifies phenomena on the basis oi systematic knowledge of process.

Conceived in this way the region is a device for illuminating the factors of a problem which otherwise would be less clearly understood. It is not an objective fact; rather it is an intellectual concept. A region is justified if it illuminates the elements of a problem; it is not justified ii it obscures these elements. There is no such thing as a "true region'!; there are, in iact, as many regional systems as there are problems worth studying by geographic method.

The regions which a geographer defines and observes on the iace of the earth are plotted at a reduced scale on maps. With modern methods of field observation, including air photography, geographers can achieve a degree of precision never before possible; maps can be even more exact than statistics, only the iorm of precision is geometric rather than arithmetic. When a homogeneous area is defined and plotted on a map, its outline is matched against the outlines of other kinds of phenomena. Oi course every phenomenon has some kind of areal relationship to every other phenomenon on earth, but some relationships are accordant and some discordant. Accordant areal relations are found by matching maps and noting where regional outlines coincide or correspond. This is the regional method.

Two kinds of concepts are developed by the application of geographic procedures. One concept has to do with the make-up of regions. Since the phenomena on the face of the earth are the result of such a variety of processes, ii significant regional systems are to be developed it would seem that either the broader, more highly generalized multiple-feature regions must be careiully analyzed to bring out their components, or else the broader regions must be built up by the matching of maps of numerous very small single-ieature regions. A topographic study is now defined as a study carried out on maps of sufficiently large scale to permit the plotting of the specific ieatures of the human occupance—large enough, that is, to show specific fields on a farm. When the map scale is too small to permit the plotting of specific ieatures, so that these ieatures must be generalized in categories of greater areal spread, the study is defined as chorographic. The whole Ptolemaic system in which geography is defined as that scale which deals with the world as a whole is no longer commonly in use. The adjective "geographic" refers to patterns of areal differences on the earth and to the regional systems that are used to reveal them.

The other kind oi concept developed by modern geographic study is that of causal relationships, as distinguished from areal relationships which are revealed by the regional method. Even when two phenomena occupy exactly the same space (that is, their outlines coincide) this does not demonstrate a causal connection between them. A causal connection can be demonstrated only by tracing the operation of a process through time. Coincident areal relations may indicate a probability of some kind of causal connection; but to prove that such a connection exists, the nature of the process or processes that have produced the observed phenomena must be described.

This means that geography cannot be strictly contemporary. All geographic study must be approached historically if it is to be complete. Historical geography is understood to be concerned with the recreation of past geographies and with geographical changes through time. A full understanding of contemporary geographic phenomena requires the full perspective of past geographies, ior the operation of any one process at a particular place and time is to a certain extent modified by the total environment with which the process is involved. The systematic sciences work to unravel all these disturbing connections with the environment and to describe the ideal operation of the process in isolation; geography seeks to put the process back in its earthly setting and to see its connections both in space and time.

SUBDIVISIONS OF GEOGRAPHY

Obviously no one scholar could become thoroughly competent in all branches of so broad a field. In the first place, a considerable amount of geographic work is actually done by persons who are not professional geographers. In the second place, those who hope to become professional geographers must select a group of topical fields and certain areas of the world in which they intend to specialize. There are as many topical fields, at least potentially, as there are kinds of processes acting to differentiate one part of the earth irom another. The following brief outline of topical fields is not definitive.

Population geography is a field that was still inadequately developed in the 1950s. The mapping of the distribution of people, as J. Brunhes pointed out, is one of the primary tasks of geographic study. The data, on which maps must be based, are numbers of persons, summed up in enumeration areas. But the enumeration areas are usually too large or include arbitrary segments of a national territory that obscure the facts of population distribution. Population geography also includes the study of the movements of people and of such population characteristics as age and sex structure, ethnic composition, religious and linguistic groupings and a variety of other matters. The geographer's contribution consists of finding ways to portray more effectively the patterns of distribution on maps and to analyze more effectively the areal relations of population to other ieatures.

Settlement geography is closely related to population geography in that one of the methods oi locating persons within enumeration areas is to observe the distribution of houses. Settlement geography, however, goes beyond this to study all the iacilities men build in the process of occupying an area: the iorms and functions of buildings, the road and property patterns and the groupings of these things. Much has been done with settlement patterns since August Meitzen in 189; examined the settlements of eastern Germany. Studies of the rural habitation in France and oi house types in the United States have brought to light important relationships not only of houses to building materials but of houses to cultural traditions.

Urban geography includes the urban part of settlement geography, but goes beyond the problems commonly considered in rural areas. Cities are examined not only in terms oi their patterns oi arrangement, their internal structure and the arrangement of functional areas within them, but also in terms oi the services they perform and of the movements of goods and persons that are involved. Urban geography provides an essential background for city planning.

Political geography iocuses attention on politically organized areas or political regions. The purpose is to show how the effective administration of a political area is related to the geographic arrangement of the various parts of the state—the capital city, the industrial core, the areas of concentrated settlement, the boundaries, the dependent areas and the sources of raw materials. It is recognized that any successful state operates on the basis of a "state-idea"; that is, a body of principles or traditions which can command the loyal support oi a considerable majority of the people. Where the state-idea is poorly developed, or where different state-ideas are held in different parts of the national territory, the effective iunctioning of the state is imperilled. The arrangement of these nonmaterial aspects of the political life, examined in relation to material aspects such as those enumerated above, offers many problems and opportunities.

Economic geography is a much-developed part of geography, especially in Great Britain and the United States. So much attention has been given to the study of the significance of likenesses and differences among places in terms of economic processes that economic geography can no longer be considered as a field of specialization of itseli. Among the more important subdivisions of economic geography are: (1) the study of resources and the inventory and evaluation of the resource base of an area; (2) the geography of mining and minerals; (3) the geography oi agriculture and land utilization; (4) the geography of manufacturing industry, involving the principles of industrial location and the factors in industrial site selection; (j) the geography of transportation, involving not only the movements of goods from place to place but also analysis of the arrangement of iacilities such as railroads, docks, airfields or shipping lines; (6) marketing geography, or the application of geographic methods to the analysis oi actual and potential markets, including sales territories, salesmen's routes and all the numerous factors involved in estimating the potential sales of a given site. There are many other topical specialties within the general field of economic geography that might be mentioned, such as the geographic study of recreation, or the geographic study of service occupations, or any number of other ways of making a living.

Physical geography is a subdivision of the whole field of geography which, like economic geography, is too broad to be cultivated as a whole. In each of the topical specialties dealing with physical processes on the earth there have been many important contributions during the 19th and 20th centuries, and in each of these specialties, concerned with areal differentiation, there are close connections with the bordering systematic fields in which study oi process is the primary aim. Physical geography is divided into a number of specialties, of which the more important are: (1) climatology, closely connected with synoptic meteorology; (2) geomorphology, closely connected with various aspects of geology; (3) the geographic study of soils, closely connected with studies in agronomy and related subjects; (4) the geographic study of water on the land, closely connected with hydrology; (5) the geographic study of the oceans, a vast potential field of geographic study only little developed, since most of the work in oceanography has been done irom the point of view of physical or biological science. Of these topical fields some have been better developed than others by geographers. Much has been done in climatology, especially in the construction oi broad regional systems such as those formulated by A. J. Herbertson, Emmanuel de Martonne, W. Koppen and C. W. Thornthwaite. At the beginning of the 20th century in Great Britain and the United States most oi the scholars w-ho called themselves geographers were specialists in geomorphology. the study oi land forms. In the United States the geographic profession mas established by such notable masters as William Morris Davis. Rollin D. Salisbury and Wallace W. Atwood. Davis' formulation of the cycle of land iorm development from youth through maturity to old age stimulated much attention to suriace ieatures in America and in Europe and the application of similar ideas to other topical fields. Davis' concepts were challenged by Walter Penck, with the result that by mid-20th century a new and stronger geomorpbology was emerging from the co-ordination oi the ideas of two quite different approaches: one (Davis') through the study oi erosion along valley lines, the other (Penck's) through the study oi the development of slopes. In the study of soils, Curtis F. Marbut introduced the concepts developed by the Russian scientists of the 19th century and combined them with an application of the cycle idea oi Davis. Geographers made great advances in the whole theory of classification oi phenomena on the earth's surface through the study of soils.

Biogeography is still another subdivision oi geography. Especially in the study of vegetation have geographers made important contributions. To be sure, the 19th-century "life-zone" ideas of C. H. Merriam proved to be too highly generalized to throw much light on the actual arrangements of plants and animals. Yet the classification of vegetation and the preparation of maps of vegetation suitable for geographic uses have been notably advanced,. especially by such scholars as F. Shreve, Homer L. Shantz, H. M. Raup, J. W. Harshberger, F. E. Egler and A. W. Küchler. There has been some application of geographic method, also. to the study of animal geography or zoogeography. In the general field oi biogeography there is also the topical branch known as medical geography, which deals with the geographic arrangement oi diseases and with the factors relevant to the incidence and spread of disease. Notable in this development have been the studies carried on by Jacques M. May at the American Geographical society. During World War II, also, there was a considerable advance in physiological climatology, a field in which the effect of climate on the healthy human being is examined. As a result of experimental studies of human activity under controlled conditions of temperature and humidity, much new light was thrown on human behaviour. The older. and stimulating but not always provable suggestions of Ellsworth Huntington regarding climate and man were greatly modified by the new knowledge gained irom controlled experiment. A practical result of these studies was the development of new kinds of clothing and new kinds of houses.

Military geography was a field especially developed during World War II. All aspects of geographic study were applied to military problems. In no field is precise geographic knowledge regarding particular places more essential than in the field of military planning, whether tactical or strategic.

Techniques of geographic study have also been given much attention, especially since 1920, when the detailed field study of small areas began to bring in striking results. Geographic information is derived irom iour kinds of sources: (1) documents, including not only written records, but also maps, photographs and statistics; (2) vertical air photographs; (3) direct observation in the field; and (4) the interview of iniormants. Geographic data once brought together are analyzed: (1) by expository methods, using word symbols; (2) by statistical methods, using mathematical symbols; (3) by cartographic methods, using map symbols; and (4) by the interpretation of air photographs. Most geographic studies require competence in all these methods oi gathering and analyzing data. There has been a considerable amount of experimentation, especially in the Gnited States, with the methods of field study in small areas. The methods of recording direct observations in uritten notes, in field sketches, with ground photography and on maps have all been made vastly more effective. After World War I vertical air photography began to play a more and more important role as a geographic technique, and during the 1940s and 1950s the development of new cameras, new film and better planes made this entirely new source oi information one of prime importance. It is much less costly and also much more accurate to derite maps of homogeneous areas irom the interpretation of air photographs than it ever could be from ground observation alone However, the interpretation of the photographs requires a certain irreducible minimum of ground work; and the study of all the nonvisible features of an area that cannot be photographed demands actual examination in the field. Air photography raises geographic study to a new level of exactness.

Cartography.—Cartography is a field which overlaps between geography and geodesy. The traditional interest in mathematical geography, as carried iorward by Ptolemy and Apianus, is now to be found among the geographic cartographers, who are still experimenting with new projections, valuable for specific purposes. The actual field construction of detailed maps, once a laborious job carried out with measuring tape and plane table, during the 1940s was greatly speeded and rendered less costly through the application of air photography to photogrammetry. Most topographic maps after mid-20th century were made by the methods of photogrammetry. Most of the world had been covered at least once by vertical air photographs. The use of such photographs for purposes of map construction involves quite different techniques than does the use of the photographs to bring out the geographic patterns of areal likenesses and differences. Geographic cartography was also enormously advanced during World War II when many new kinds oi maps, using different colours or different black-and-white symbols, were tried out. This field included also the construction of detailed terrain models, oi which one notable example was the model of the United States at the Babson institute in Wellesley, Mass., made under the direction of Wallace W. Atwood, Jr. As a result of the war new map libraries made their appearance, and the whole new field of map intelligence (the collection of information about map series and the evaluation of maps for different purposes) was developed. Cartography, which is recognized as an essential part of geographic study and which at one time constituted a major interest among geographers, in the mid-20th century was brought back to its proper position as a major geographic interest. GEOGRAPHY, SOCIETIES OF. *More than* 150 *organizations* have primary interests in geography *and the related* fields *of exploration and travel.* Most *are centred in and serve individual* cities and their environs. Many are regional, more than 20 are national in scope and 3 are international. They differ greatly in *membership.* status *and objectives.*

The predecessor of modern geographical societies is commonly considered to be the Association for Promoting the Discovery of the Interior Parts of Africa (1788). In 1805 the Palestine association was founded in London, and these two organizations were merged into the Royal Geographical society, which originated at London in 1830 and was incorporated by royal charter in 1859. Meanwhile the Société de Géographes was founded at Paris in 1821 and the Gesellschaft für Erdkunde at Berlin in 1828. Gradually other societies came into existence, in Mexico (1839), in Russia (1845) and in the United States (1851). During the latter half of the 19th century the number of geographical societies increased rapidly, and their growth in membership was accelerated during the first half of the 20th century, especially following World Wars I and II.

Of the various types of geographical societies, the most numerous are semiscientific-semisocial organizations composed of merchants, military personnel, government employees, teachers and laymen interested in geography and travel. Among the better known in this category are the National Geographic society (Washington, D.C.), the Canadian Geographical society (Otta a), and local societies in Berlin, Rome, Paris, Philadelphia and Chicago. They maintain libraries and map collections, sponsor lectures and publish periodicals of mixed popular and professional interest.

Other organizations such as the Alpine club (England). Explorers club (U.S.) and Hakluyt society (England) are concerned primarily with organizing expeditions and publishing accounts of exploration and travel in little-known areas.

Some societies, such as the Royal Geographical society (London), have partial support from government sources. Others. such as the American Geographical society (New York city), supplement their income from dues by soliciting gifts, obtaining foundation grants and operating under research contracts. They have employed professional staffs, enlarged their research facilities and produced journals of high scholarly value, among them the *Geographical Journal* and the *Geographzcal Review*. In addition. they sponsor popular lectures, scientific expeditions and publication of reports, monographs and books.

Societies for teachers of geography, such as the National Council for Geographic Education (U.S.) and the Geographical association (England), are dedicated to the improvement of the techniques and scope of geographical education. College and university professors divide their support between the educational societies and the strictly professional associations whose members are formally trained and employed as geographers. Examples of such associations, fundamentally concerned with basic research in geography and its application for the advancement of the profession, are the Association of American Geographers, the Institute of British Geographers, the Association de Géographes Français and the Zentralverband der Deutschen Geographen. Their journals are devoted almost exclusively to the results of original research, although some also publish news journals in addition to scholarly periodicals and monographs.

Somewhat more limited in scope but equally professional in character are geographical institutes, usually associated with university departments, or specialized divisions of large associations and scientific bodies such as the Geography and Map division of the Special Libraries association (U.S.), Section E of the American Academy for the Advancement of Science, Section E of the British Association for the Advancement of Science, the Division of Earth Sciences in the National Academy of Sciences–National Research Council (U.S.), and the Institut Geografii Academiia Nauk (U.S.S.R.). Government agencies which are primarily geographic, such as the Institut Géographique National (France), the Conselho Nacional de Geografia (Brazil) and the Geographic branch, department of mines and technical surveys (Canada), often support research projects in institutes and societies.

Some of the national, regional and even local geographical societies have members in foreign countries, but only three are organized on an international basis. International meetings of geographical societies date back to the Congrès International pour les Progrès des Sciences Géographiques at Antwerp, Belg , in 1871. Subsequent congresses were held at London (189j), Geneva (1908) and Rome (1913). In 1922 the International Geographical union was created at Brussels. Member countries are affiliated through their academies of science or their principal geographical organizations. The headquarters of the union changes with the election of new secretaries at general assemblies, usually held every four years. Research and organizational work of the union is carried out by more than a score of commissions. International geographical congresses, held under the auspices of the union, are attended by official delegations from member countries and by individual geographers who present and discuss research papers.

The Pan American Institute of Geography and History was created as an organ of the Organization of American States in 1928. The headquarters is in Mexico City, and 21 American republics are members. The institute is composed of three commissions on cartography, geography and history, which meet independently at consultations about every two years and jointly at general assemblies every four years. Between assemblies the business of the institute is carried on by a directing council consisting of one official delegate from the government of each member state.

The International Society of Geographical Pathology originated at Geneva in 1931. It is composed of national committees and of individual members concerned with the geographical distribution of diseases.

GEOLOGICAL SURVEY (U.S.), a bureau of the U.S. department of the interior. was established by act of congress on March 3, 1879, following recommendations of the National Academy of Sciences, to classify the public lands and to examine the geologic structure, mineral resources and products of the national domain. Additional duties assigned since then require the bureau to supervise mineral lease development and to collect, publish and distribute data concerning the physical features and mineral and water resources of the United States, its territories and possessions. Responsibility for the performance of these functions is distributed among the topographic. geologic, conservation and water resources divisions.

Topographic Division.—This division is responsible for delineating the physical features of the United States as quadrangles of the National Topographic Map series. These multipurpose three-dimensional maps provide basic information for mineral and water resources studies, engineering projects, national defense and industrial and community planning. By the second half of the 20th century the geological survey had published about 20,000 different topographic quadrangle maps. However, many of these maps needed revision or remapping for publication at a larger scale. so that about 40% of the country was covered by maps that had been prepared at a scale and with a basic accuracy adequate for modern needs. The map information office was established by bureau of the budget directive in 1946 as the central source for map information in the U.S. government to answer inquiries and fill requests for maps, aerial photos and related data. During a single year, more than 3,000,000 maps were sold or distributed.

Geologic Division.—The geologic division maps and studies the surface and bedrock geology of the United States and appraises its mineral and mineral fuel resources, and conducts research in geology, geophysics, geochemistry and allied earth science disciplines with special emphasis on their application to discovery and development of natural resources. The work also includes geologic mapping and research to obtain basic data for engineering construction planning, for military geology, for soils surveys and for advancing the science of geology. The results of investigations have been published in bulletins, professional papers, circulars, and geologic and related map series, in reports printed by co-operative agencies and in trade and technical journals.

Conservation Division.—This division supervises the development of certain minerals under leases on federal and Indian lands according to the applicable federal laws and examines and classifies federal lands as to mineral and water-power values. In this way the proper development and use of resources on these lands is assured. Early in the second half of the 20th century the value of mineral production on such lands supervised by the geological survey had exceeded $840,000,000 annually, enriching the United States treasury, reclamation fund, Indian beneficiaries and the various states by more than $98,000,000 in annual royalties.

Water Resources Division. — The water resources division investigates and describes the quantity, distribution, chemical and physical quality, sediment content, availability and uses of water. Reports published by scientists and engineers of the division provide essential background knowledge for use by the public, by industry and agriculture and by government agencies responsible for water conservation. development and use.

Additional information on the work of the geological survey as reflected in the director's *Annual Report;* index maps of each state and of Hanaii and Puerto Rico showing areas covered by survey topographic mapping; and a list of publications of the U.S. geological survey with latest supplement are available to the public free upon request. *See* also GOVERNMENT DEPARTMENTS: *United States*. (H. B. N.)

GEOLOGY (ARTICLES ON). The basic simplicity of geology has been obscured by the giant proportions in which it works — particularly its time scale, in which the whole of recorded history figures as a mere tick of the clock. However, natural processes on so great a scale as, for example, the movement of a continental ice cap, the uplift of a submerged land mass or the formation of the sedimentary rock known as coal. can hardly fail to leave traces. Some of these were observed in antiquity, but, since they failed to fit in with any pattern of accepted theory, they were dismissed as inscrutable whims of nature. The survey article GEOLOGY summarizes the history of the reduction of these processes to terms of cause and effect, and gives an over-all view of modern earth science.

Individual articles are devoted to the major subdivisions of geology and of geological time. GEOCHRONOLOGY discusses the methods by which the age of the earth's crust as a whole and of various rock strata have been estimated. PALAEONTOLOGY explains how fossils are used as keys to the sequence of the sedimentary deposits that encased them in the processes of petrification; it reaches about 500,000,000 years into the past, to fossils of the earliest animals known to have been equipped uith bony structures or shells. PALAEOBOTANY traces plant fossils as far back as about 1,500,000,000 years — almost half the estimated age of the earth's crust.

These articles, and sections in the articles on geological epochs, describe forms of life that may seem grotesque but that were adapted to their environment before the occurrence of geological events that involved changes in climate and other factors. Each of these articles includes a survey of a phase of organic evolution. For example, CRETACEOUS SYSTEM tells of "the time of the great dying" of the dinosaurs; the article on the ensuing epoch. EOCENE AND PALEOCENE, reviews the evidence of the rapid advance of mammals from crude and miniature forms to their position of dominance in the animal world. Another example of the articles on geological time units is PLEISTOCENE EPOCH, dealing with the stretch of time in which a large part of the earth's surface was subject to alternate periods of glaciation and interglacially mild climate. It includes a summary of the geological history of man, as written in the strata of this comparatively recent epoch. This subject is developed more fully in MAN, EVOLUTION OF, which links the findings of geology with those of biology and anthropology.

The imprints left on the earth's crust by such geological agents as water, wind and glaciation, and the methods of recognizing these traces, are described in the article which deals with the source of 85% to 90% of the world's mineral wealth—SEDIMENTARY ROCKS. This is supplemented by WIND EROSION AND DEPOSITION. In PETROLOGY the emphasis is on igneous rocks; metamorphic rocks are dealt with in METAMORPHISM. Among other articles closely linked to this subject are MINERALOGY; ORE DEPOSITS: and SOIL. Individual articles are devoted to important rocks and minerals, such as CONGLOMERATE; SANDSTONE; SCHIST; IRON; COPPER; etc.. and the gems.

Sections of descriptive geology are included in each of the articles on continents, nations and other major geographical units. The basic principles of stratigraphical geology. by which the order of origin of rock strata can be determined in spite of forces that have upset and entangled them, are discussed in STRATIFICATION and STRATIGRAPHY. GEOPHYSICS is devoted to the science that studies the earth as a body of matter subject to the laws of dynamics. gravitation, etc.; the practical applications of some of these theories are treated in GEOPHYSICAL PROSPECTING. The methods by which the size, shape and internal structure of the earth are determined are discussed in GEODESY.

Continents, mountains and oceans. like bodies constructed on a smaller scale, rise and fall in response to variations in their weight and in the strength of counterbalancing forces, although adjustment to a change such as the melting of an ice cap is a process measured in many thousands of years. The workings of this principle are explained in ISOSTASY. Various manifestations of it are discussed in GEODESY; EARTH; and EARTHQUAKES.

VOLCANISM discusses the geophysical background of volcanic eruptions. TIDES deals with the effects of gravitational pull on the earth's crust and its atmosphere as well as on its waters. GEOCHEMISTRY explores the process of geochemical evolution that prepared the way for organic evolution.

In COSMOGONY, the Brobdingnagian proportions of geology shrink to those of Lilliput. Linking geophysics and geochemistry with astronomy, this science traces the common origin of the chemical elements of our earth and those of millions of planetary siblings in its galactic family.

GEOLOGY, the study or science of the earth, is a broad and diverse subject with many subdivisions and several closely allied fields. Geologists are concerned primarily with rocks that form the outer part of the solid earth; but an understanding of these materials, and of changes that have occurred and are now going on in their compositions and arrangements. involves principles and techniques of physics and chemistry. Geophysics and geochemistry, both important and fast growing scientific disciplines, are a logical outgrowth of this overlap in interest which extends beyond the visible rocky shell to deeper zones of the earth. Biology also plays an essential role in the study of rocks. great masses of which show profound effects of biologic processes and contain clear records of animals and plants that lived in past ages. Paleontology, the study of this fossil evidence, is an essential part of geology: and the aid of organic chemistry is required for study of the interactions among rock materials and organic substances.

Air and water are major agents in geologic processes; but the atmosphere is the special realm of another science, meteorology, and study of the earth's waters is shared by hydrology and oceanography, two fields closely associated with geology. Inquiries into the origin and formative stages of the earth have developed the special subject cosmogony. which is related to astronomy. Geodesy supplies basic information on the form of the earth, on precise geographic locations and on values of gravity. Physical geography. concerned with surface features of the globe and giving large attention to maps, likewise has close kinship with geology as another in the group of subjects to which the term geoscience has been applied.

Geology has developed several main branches which for a brief survey may be classified as follows: (1) physical geology, including mineralogy, the systematic study of minerals; petrology, the study of rocks, their physical and chemical properties and modes of origin; geomorphology, the study of land forms and processes of their development; sedimentation, the origin and deposition of modern sediments; structural geology, a study of the geometry of rock masses, with emphasis on crustal deformation; economic geology, the study of valuable mineral deposits; and (2) historical geology, including stratigraphy, the systematic study of bedded rocks and their relations in time; paleontology, the study of fossils and their location in the total sequence of bedded rocks; and mapping of bedrock units defined by physical characteristics and geologic age. This classification does not list specifically a number of important subjects that receive attention below. Moreover. like most brief classifications this one appears to draw sharp boundaries that are not real. For example, stratigraphy is part of the study of sediments, a subject that has both physical and historical aspects. Actually a rigid separation of all geology into physical and historical facets does not bear close analysis. Nearly all geologic study seeks to determine an order of events, and a main objective of the science is to work out the full history of the earth and its inhabitants.

For a guide to the various articles dealing with the science of geology *see* GEOLOGY (ARTICLES ON), above. *See* also articles on: the various branches of science referred to, as BIOLOGY; METEOROLOGY; etc.; geologic processes, as EROSION OF LAND; METAMORPHISM; etc.; rock bodies, as BATHOLITH; SILL; etc.; eras, systems, periods and epochs, as CENOZOIC ERA; CARBONIFEROUS SYSTEM AND PERIOD; PLEISTOCENE EPOCH; rocks and minerals, as GRANITE; CONGLOMERATE; CASSITERITE; CLAY AND CLAY MINERALS; etc.; and CRYSTALLOGRAPHY; MINERALOGY; PETROLOGY. The plates accompanying this article illustrate many of the processes and formations discussed.

For proper perspective an explanation of geology starts with a summary description of the entire earth and its major physical features. The development of human knowledge and concepts regarding the earth is summarized in a final section of this article.

Following are the main divisions of this article:

I. GENERAL VIEW OF THE EARTH

Geodetic studies have determined that the earth has the form of an oblate spheroid with polar radius about 21.6 km. (13.4 mi.) shorter than the equatorial radius. The circumference following the equator measures a little over 40,000 km. (about 24,900 mi.). Relief features of the surface. large from the human viewpoint, are relatively small; Mt. Everest, with its summit nearly 9,000 m. (29,028 ft.) above sea level. would appear to scale on a globe with a diameter of 40 cm. (16 in.) as a projection only 0.3 mm. (0.012 in.) high. The visible part of the earth consists of three spherical envelopes: atmosphere, hydrosphere and lithosphere. Though gases of the atmosphere extend outward in detectable quantity many hundreds of miles, fully three-fourths of the gaseous matter, by weight, is in a zone 15 km. (about 9 mi.) thick directly above the earth's surface. The great bulk of water making the hydrosphere is in the interconnecting ocean basins covering nearly 71% of the earth's surface; but water is widely distributed on the lands also. in streams and lakes and as ground water filling openings in soil and bedrock. The lithosphere is the solid outer part of the earth.

Information on sea floors is building up rapidly through use of echo sounding and other recently perfected methods of study. Greatest depths of the oceans exceed 10,800 m. (more than 35,000 ft.). If all surface irregularities could be leveled off. the sea would be universal with a depth of almost 2.5 km. (about 1.5 mi.). The continental surfaces vary widely in height and configuration; Asia, the highest and most rugged, has average height about 1,000 m. (3,200 ft.) above the sea. All continents have mountainous belts, some youthful and rugged. others old and subdued. The topography of ocean floors, like that of continents, varies from wide planar areas to high and steep mountain ranges, some of which project above the sea as island chains whereas others are wholly submerged. with shoal water over the highest portions. Recent oceanographic studies reveal that ocean floors generally are as uneven as continental surfaces. Conspicuous among major mountain belts rising from deep waters are those forming the islands of Indonesia in the Pacific. and the Antilles in the Atlantic. Many islands have been built up on ocean floors by volcanic eruptions; examples are the Hawaiian Islands in a deep part of the Pacific and Ascension and St. Helena in mid-Atlantic. Some other islands, such as Great Britain and Ireland, are merely parts of continental areas cut off by shallow channels from their mainlands Many more such islands would be formed if sea level should rise about 100 ft., as would result if there were an increase in temperature sufficient to melt the ice caps that cover much of Antarctica and Greenland.

II. PHYSICAL GEOLOGY

A. MINERALOGY AND PETROLOGY

As these subjects are treated at length in separate articles, only a summary of their employment in general geology is appropriate here. Minerals are the basic units in the composition of most rocks. and therefore they are in a real sense the geologist's alphabet. Many hundreds of distinct mineral species are recognized, but comparatively few are important in the kinds of rocks that are abundant in the outer part of the earth. Thus a few related minerals known as the feldspars, together with quartz, are the essential ingredients in granite and its near relatives; and limestones, widely distributed on all continents, consist largely of the one mineral calcite. Many rocks have a more complex mineralogy, and in some the mineral particles are so minute they can be identified only through highly specialized techniques. For example. several clay minerals important in rocks known as shales or claystones cannot be resolved by the most powerful optical microscopes.

Under exceptional conditions mineral substances grow into nearly perfect crystals that have distinctive external forms. Silicon dioxide forms clear crystals of quartz that are hexagonal prisms with terminations shaped as pyramids; iron sulfide forms perfect cubes of pyrite, the faces marked with parallel lines. But when a substance crystallizes in bulk, crowding of grains growing from neighbouring centres prevents formation of recognizable crystals, though each mineral is formed with its peculiar internal atomic structure. Modern laboratories have varied and highly effective devices for working out the mineral content of rock materials. Standard equipment is the petrographic microscope, constructed for viewing thin sections of rock that are ground uniformly to about .001 in. thick. No matter how fine the grain, so long as the rock is crystalline its essential minerals can be determined by their peculiar optical properties as revealed in transmitted light under high magnification. Opaque minerals, such as those with a high content of metallic elements, require a different technique that uses reflected light from polished surfaces; this kind of microscopic analysis has particular application to metallic ore minerals. Another device exposes mineral grains to X-rays which, on emerging, outline on a photographic film a pattern that represents the atomic structure peculiar to a given mineral species. Substances such as the clays are made up of particles so minute they are submicroscopic in relation to ordinary petrographic microscopes: but these particles become clearly visible under the electron microscope, which gives images with diameters enlarged by a factor of tens of thousands. The several clay minerals are identified also by a technique known as thermoanalysis which takes advantage of pronounced differences in thermal properties. The instrument used in the analysis automatically draws a graph that is recognized as peculiar to a given mineral composition.

Analytical chemistry plays a major role in the study of minerals and rocks. An exact quantitative analysis is a valuable supplement to other techniques, and for many specimens the chemical examination plays a major role. Rocks with glassy texture have no atomic organization and therefore give no response to microscopic study. Natural glasses are common in rocks of volcanic origin. In many such specimens small mineral grains scattered through a glassy groundmass can be recognized under a microscope, giving information to supplement the chemical study; but the quantitative analysis is of first importance. Thousands of such analyses made by reliable laboratories are on record for comparative study. Comparing the composition of a glassy specimen with compositions of crystalline rocks whose minerals are known will give much essential information.

Spectroscopic study of rock specimens is an important recent development, and a complex instrument known as the mass spectrometer is used in an increasing number of petrographic laboratories This device detects the presence of elements in extremely small quantities; it also isolates and measures quantitatively the several isotopes of elements such as lead and carbon. The mass spectrograph is indispensable in analyses used for determining ages of minerals on the basis of progressive atomic changes in such elements as uranium and thorium. See also MASS SPECTROSCOPY.

1. The Earth's Crust.—The term crust, which geologists commonly apply to the outer part of the solid earth, is inherited from a speculative concept, once widely held, that our globe was once a molten mass nhich slowly cooled and solidified from the surface downward, and that the major part of the volume is still molten, below a comparatively thin shell of solid rock. This latter view is now untenable. whether or not the earth passed through a molten stage; hut, as explained later. we are convinced that an outer part of the earth, no more than a few tens of kilometres thick, differs in physical properties from deeper zones (see GEOCHEMISTRY; EARTHQUAKES), though the change is not marked by passage from solid to fluid materials. It is convenient, therefore, to keep the term crust for the distinctive outer zone.

The rocks of the earth's crust are exposed to view only on continents and islands. which comprise about 30% of the earth's surface. The known rocks are divisible into three main groups: igneous rocks, which have solidified from molten matter called magma: sedimentary rocks. those made up of fragments derived from pre-existing rocks. of materials precipitated from solution or of organic products: and metamorphic rocks. which have been derived from either igneous or sedimentary rocks under conditions that caused changes in composition. texture and internal structure.

2. Igneous Rocks.—The igneous rocks are formed as either extrusive or intrusive masses. Extrusive rocks are products of volcanic action; they appear at the surface as molten lavas which spread in sheets and harden, or they are made up of fragments, large and small, blown from vents by violent gaseous explosions. Intrusive rocks have formed by slow cooling of molten masses below the earth's surface; many such bodies are now exposed to view because long continued erosion has removed the older rock cover. Some of these bodies doubtless were reservoirs that supplied volcanoes in the past.

The grain size or texture of igneous rocks is closely related to the mode of origin. Lavas generally are fine grained, even glassy, because rapid loss of heat, with resulting solidification, allowed little or no opportunity for mineral grains to grow. But the same kind of magma, under a cover of solid rock thousands of feet thick, has lost heat very slowly; accordingly the grains have had, from the human point of view. long ages for growth, and the resultant rock is coarse grained. Examples are ordinary granites, in which all grains of the essential minerals can be distinguished with the unaided eye. A rock with similar chemical composition that formed in a lava flow may have a uniform appearance. with no distinguishable grains; but magnification up to 50 or 100 times under a petrographic microscope may reveal a texture and mineral composition strikingly like that of the granite. Such a rock. known as rhyolite, is said to have aphanitic (*i.e.,* invisible) texture.

In a general way the textures of igneous rocks vary according to the depth at which the bodies were formed. Deep-seated (abyssal or plutonic) bodies are coarse grained; intrusive bodies that cooled at shallower depths (hypabyssal masses) generally have medium to fine grains; and extrusive rocks are fine grained to glassy. There are, however, some complexities in this general rule. Many sheets of rhyolitic lava have large and well-formed crystals of feldspar and quartz isolated in an aphanitic groundmass; the rock is called rhyolite porphyry, and the crystals are phenocrysts. Presumably these formed in a quiescent magma body underground, part of which was erupted in a volcanic outbreak, whereupon the magma enclosing the crystals cooled quickly to form rock with fine grain. Porphyritic texture is common also in bodies of intrusive rock, of both the shallow- and deep-zone types; in such rocks the groundmass has visible grains which are much smaller than the enclosed phenocrysts. The contrasting grain size in all porphyries suggests an abrupt change in physical-chemical conditions while the parent bodies were forming.

Exposed intrusive bodies are most numerous in great mountain zones for two reasons: (1) the mountain belts have been zones of major deformation, and abundant evidence indicates that igneous action is favoured by crustal disturbance; and (2) great uplifts in mountain belts have set the stage for erosion to the depths at which plutonic masses have formed. Logically the best displays of large intrusive bodies are found not in youthful chains such as the Alps, but in much older mountain units—for example, the Riesengebirge of Germany—where the deep cores have been exposed by erosion through long ages.

Bodies of intrusive rock are classified according to their locations. sizes and shapes. The general term pluton is used for any large intrusive body. An abyssal mass of major size is appropriately called a batholith (literally "deep stone"). Commonly, such a body is exposed over an area measuring hundreds or even thousands of square miles; the Coast range batholith of British Columbia is more than 1,000 mi. long. These large bodies are not simple units with uniform structure and texture; they are complex assemblages of crosscutting and intertnined masses that indicate a long and varied history of development, with recurrent episodes. The major batholiths commonly are elongate parallel to the associated mountain belts. Intrusive bodies formed at shallow or intermediate depths have varied sizes and forms; most common are dikes, which are tabular, elongate bodies that cut across the enclosing rocks. and sills, generally similar in form to dikes but emplaced parallel to pre-existing layers of sedimentary or volcanic rocks. Sizes of both dikes and sills have a wide range. Some measure only a few feet in greatest dimension of exposure; but in northern England the Cleveland dike, essentially vertical, is traced more than 100 mi. and the Whin sill, nearly horizontal, extends fully 80 mi., with an average thickness about 90 ft.

Knowledge of intrusive igneous bodies has been built up slowly by comparative studies, some in regions where erosion has brought to light only the masses that developed at shallow depths, others in profoundly eroded belts where "only the bones of the extinct mountains" can be seen. Eeneath growing mountain chains around the Pacific ocean igneous intrusive action is doubtless now in progress, though beyond the range of direct observation. Study of extrusive activity and the resulting rocks is more favourable. Active volcanic centres are widely distributed. and some of these are under continuous observation. The behaviour of Vesuvius and other Mediterranean volcanoes has been watched through many centuries; and well-equipped scientific stations have been in operation for some decades at a number of active centres. Study of active volcanoes is supplemented by observations made on great volumes of older volcanic products which, because they accumulated on the earth's surface, are much more accessible than the intrusive bodies which have come into view only through chance exposure by erosion.

Volcanic materials are erupted through openings of two general types — central vents and long fissures. Around a central vent, which is essentially a great vertical pipe, products of eruption are built up to form a cone which may grow into a high mountain with a crater at its top; well-known examples are Vesuvius in Italy, Mayon in the Philippine Islands and Fujiyama in Japan. Two kinds of products issue from a vent: fragments known as ash and cinders, which are blasted violently upward by gaseous explosions; and lava or liquid rock, which commonly breaks through the side of the cone and spreads beyond its base. In a fissure eruption, lava wells upward and pours outward along an opening miles or even tens of miles in length. An eruption of this kind was observed in Iceland in 1783, Ancient outpourings of molten rock, in part along great fissures, built up widespread lava fields to form plateaus thousands of square miles in area; outstanding examples are in the Deccan region of India, the Columbia plateau of northwestern United States and the Paraná basin of South America. Commonly the outflow along a fissure has become obstructed except at a few favoured points where central eruptions have built up cones along a nearly straight line. The Hawaiian Islands, each constructed by long continued volcanic eruptions, are arranged along a line that probably represents a great zone of weakness in the floor of the, Pacific ocean.

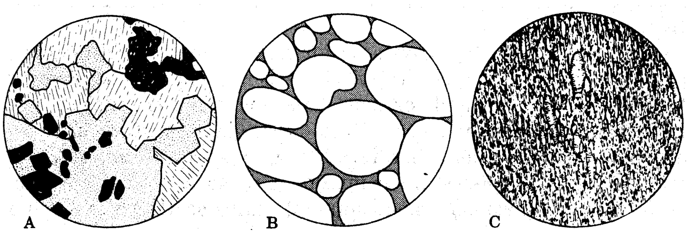
Old volcanic rocks, exposed haphazardly and without relation to vents from which they issued, are distinguished from intrusive rocks by several criteria. Quantities of gas escape freely from molten lava, and in late stages of cooling the gas, expanding under compression in the stiffening fluid, forms rounded openings or vesicles in the upper part of a flow. These vesicles, many of which in old flows have been filled with minerals deposited from solution, serve to distinguish the flow from a sill which may be similar in general form. Moreover, most assemblages of volcanic rocks contain an abundance of distinctive fragmental products of explosive action and associated glassy materials.

In volcanic rocks the chemical composition, matching that of known intrusive bodies, ranges between wide limits. Silica, the most distinctive ingredient, varies from about 40% to more than 75%. The high-silica rocks are generally light coloured and their excess of silica is expressed in abundant grains of quartz. Low-silica rocks range in colour from gray to brown and nearly black; they are rich in minerals containing iron and magnesium. Intermediate types are numerous, representing a complete gradation between the low-silica and high-silica rocks. Granite and its near relatives in chemical and mineral composition are commonly grouped as granitic rocks; they are predominant in the continents. Basalt, accepted as typical of the low-silica rocks, appears to be predominant in ocean floors. Basaltic flows that have built up wide plateaus in several continents have remarkably uniform composition. According to a favoured concept these lavas have risen from a zone of dark, heavy rock that extends continuously from the ocean floors beneath the granitic rocks in all the continents.

Igneous rocks yield minerals that are important economically, others that have large scientific value. The most reliable determinations of age are obtained by analysis of certain minerals, notably those containing uranium, that have been sealed in igneous bodies since their formation. From these analyses the oldest igneous masses are known to be more than 2,000,000,000 years old. Such quantitative determinations are in accord with much qualitative evidence in the geologic record, all testifying to the vast length of geologic time.

3. Sedimentary Rocks. — Rock materials exposed to air and moisture are subject to continual change, both physical and chemical. Bedrock is broken into pieces, large and small, which are moved by running water and other agents to lower ground and spread in sheets over lake bottoms, flood plains and sea floors. Dissolved matter is carried to seas and other water bodies and some of it is precipitated either chemically or by the action of organisms. The deposited material becomes compacted and in time much of it is cemented into firm rock. Generally the process of deposition is not continuous but sporadic, and sheets of material representing separate episodes come to form distinct layers of rock. As a result the sedimentary rocks are stratified; the individual layers are beds or strata.

Large parts of every continental mass are covered with sedimentary rocks that represent deposits formed during many periods of the earth's history. In part these bedded rocks are nearly



FROM LONGWELL AND FLINT, "INTRODUCTION TO PHYSICAL GEOLOGY"

FIG. 1. — TEXTURES OF ROCKS MAGNIFIED ABOUT 8 TIMES. (A) DIORITE (CRYSTALLINE IGNEOUS ROCK); (B) SANDSTONE; (C) PHYLLITE (METAMORPHOSED SHALE)

horizontal, as they were originally; but in large areas, particularly in mountain belts, they show various degrees of deformation. The principal kinds of sedimentary rocks are conglomerate, sandstone, siltstone, shale, limestone and dolomite.

Conglomerate, made up of fragments derived from older rocks, more or less rounded by wear and ranging in size from boulders (diameters 25 cm or more) down to pebbles (minimal diameters 2 mm.); interstices generally are filled with sediments of finer grain, more or less firmly cemented.

Sandstone, consisting of sand grains (diameters 2 to $\frac{1}{16}$ mm.), predominantly quartz. Interstices generally hold still finer particles and cementing material.

Siltstone, consisting chiefly of silt particles (diameters $\frac{1}{16}$ to $\frac{1}{256}$ mm) more or less well cemented.

Shale, consisting chiefly of clay arranged in thin layers or laminae. If lamination is lacking, the term claystone is appropriate.

Limestone, made up of mineral grains consisting chiefly of the mineral calcite. Commonly has numerous fragments of shells, microscopic or larger, from marine animals.

Dolomite, similar to limestone, but has a high content of magnesium.

Although the kinds of rock listed above are most important quantitatively, many others are recognized, some of large practical value. Among these are beds of common salt, gypsum, phosphate and iron oxide. Coal, in extensive beds, has developed from plant materials accumulated in swampy areas and later buried under large thicknesses of ordinary sediments.

4. Metamorphic Rocks. — Metamorphism means literally transformation, and logically the term might be applied to any profound change. In geology the meaning is restricted; it does not include the decay of rock materials exposed to the weather, nor the fusion of rocks by igneous processes. Metamorphic rocks have been developed from earlier igneous and sedimentary rocks by heat and pressure, at some depth and most effectively in the great mountain zones. Resultant changes are in texture, in mineral composition and in structural features of the rock. Survival of some characteristics of the original rock indicates that fusion has not played an essential part in the change.

Two general kinds of metamorphic effects are recognized: (1) dynamic metamorphism resulting from strong compression, perhaps aided by some increase in temperature from friction; and (2) thermal metamorphism caused by high temperature in rocks adjacent to intrusive igneous bodies. Effects are accentuated through introduction of elements by fluids that move from a molten mass into the surrounding rock. Susceptibility of different rocks to either type of metamorphism varies greatly. Thus in part of the Appalachian mountain belt in Pennsylvania, coal in strongly crumpled beds was changed to anthracite, a type of coal from which nearly all volatile matter has been expelled; but the shale beds adjacent to this coal are unchanged except for the crumpling. By contrast, in a more strongly deformed belt in

Rhode Island coal has been changed into graphite, and in the enclosing shale beds shearing has developed thin cleavage plates lined with flakes of mica. Near an intrusive igneous mass in South Africa shale was altered to hornfels. a hard metamorphic rock studded with crystals of minerals that grew during the period of high temperature. Beds of sandstone alongside the altered shale are unchanged except for firmer cementation of the quartz grains.

Extreme metamorphism in some mountain zones has resulted from combined dynamic and thermal effects. Fluids rising from deep-seated plutons have combined with rock material in deformed sedimentary rocks, and the resultant product is indistinguishable from granite that has crystallized from magma. To some extent: therefore, granitic rocks may be a product of metamorphic as well as igneous processes.

Many of the metamorphic rocks consist of flaky minerals. such as mica and chlorite, set in parallel arrangement. These minerals cause the rock to split into thin sheets, and the rocks are said to be foliated (fig. 1[C]).

The commonest kinds of foliated metamorphic rock are slate, phyllite, schist and gneiss. Marble and quartzite are nonfoliated metamorphic rocks.

Slate, a rock with remarkably plane cleavage cutting across folded beds of the original rock and dividing it into thin plates. Surfaces of the plates are lustrous, but no minerals are distinguishable without high magnification.

Phyllite, an exceptionally lustrous rock representing a higher stage of metamorphism than slate. The cleavage plates commonly are wrinkled or sharply bent.

Schist, a well-foliated rock in which the flaky minerals, usually mica or chlorite, are plainly visible. Quartz is abundant, and many schists are studded with garnets.

Gneiss, a coarse-grained rock with imperfect foliation. Granite gneiss is a strongly banded rock with the mineral composition of granite.

Marble, recrystallized limestone, wholly granular. Dolomite marble is recrystallized dolomite. Either rock may be studded with minerals formed irom impurities.

Quartzite, iormed from quartz sandstone by complete filling of all spaces between grains with quartz.

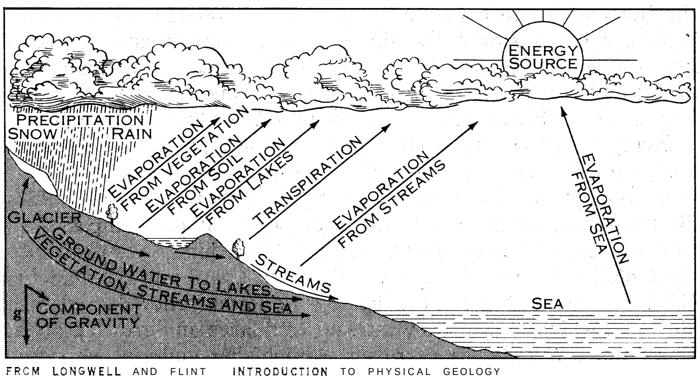
B. Geomorphology

Land forms are features of slow but continuous development. Wide distribution on the lands of sedimentary rocks that had their origin in former seas suggests clearly that the present mountains, plateaus and other landscape features owe their beginning to widespread uplift. Evidence that these features are being steadily modified is compelling. though parts of this evidence become clear only with special study. Engineers charged with the problem of controlling the flow and checking channels for navigation in large streams supply convincing quantitative data. Even casual observers of the Colorado river in the Grand canyon of Arizona are impressed with the amount of visible sediment in the stream, especially at flood stage. Measurements show that the river carries past a given point an average of 11,000 tons per hour, or nearly 100,000,000 tons per year. This annual load, most of it brought from the Rocky mountains and the high plateau country, has over a long period built an immense delta at the head of the Gulf of California. Many other great rivers, such as the Mississippi, the Amazon. the Niger, the Nile. the Ganges and the Hwang-ho. are carrying vast quantities of rock matter from continents to seas, as indicated by their large and growing deltas. Countless smaller streams that flow directly into the sea swell the total mass of transported sediment, much of which does not go into construction of deltas but is spread widely on sea floors by action of waves and currents. Moreover the water flowing into the seas carries a great total load that is invisible, dissolved from rocks on the lands.

The ultimate forces responsible for wearing down land masses are solar energy and gravity. Heat from the sun evaporates sea water; and. using the atmosphere as its agent. the solar heat causes circulation of water vapour, part of which is precipitated as rain and snow on the lands. The water returns toward the sea. much of it by circuitous routes (fig. 2). This continuous movement of water between sea and land is the hydrologic cycle. which performs a vast amount of work. Water and air react with rock materials, changing them chemically and breaking them into small pieces; this complex action is weathering. Running water moves the loose rock debris and in the process causes further breakup of bedrock. At high altitudes and in polar regions snow is compacted into masses of ice, which move slowly downslope as glaciers and add their energy to that of running water in wearing down the land. Water makes its way underground and slowly moves seaward, dissolving rock material as it goes. Winds and waves join the attack on the lands. All these activities are included in the composite process of erosion, which sculptures the continents in great detail and tends to reduce them toward sea level. Thus gravity, aided by solar energy, strives to establish equilibrium by leveling out all irregularities on the earth's surface. At the present rate of erosion. which is reasonably well known, the continents would be worn to sea level within a small fraction of the time that has elapsed since life on the lands began. This suggests strongly that the work of erosion is opposed by another process; and there is abundant evidence that the lands have been elevated repeatedly, on a large scale. Therefore the landscapes of today represent a stage in the conflict between two sets of forces: one set strives to reduce continents to featureless plains; the other set. within the earth. rejuvenates the lands by forming mountain chains and broad upwarps. The processes of uplift are given special attention in a later section. Weathering and erosion merit further discussion here.

1. Weathering.— Blocks of stone in walls of very old buildings are discoloured, many have irregular surfaces from spalling and some are visibly crumbling. Bedrock in the hills has been exposed to weather vastly longer and shows much greater change unless it is situated where running water or some other agent carries away the products of decay as they are formed. Such a situation is a nearly vertical cliff with a stream near its base; but as a rule even there blocks of rock, fallen from the cliff and in various stages of decay, form great heaps of slide-rock. Nearly level fields back from the cliff normally have a cover of soil which, as shown by careful study, was produced by decay of the underlying bedrock. Commonly the blanket of soil is several feet or even tens of feet thick; and an artificial shaft penetrating it reveals a gradation from soil downward through decayed rock into unaltered bedrock.

Changes in rock through weathering are partly mechanical, partly chemical. In regions that have cold seasons an effective mechanical agent is frost wedging. Water penetrates crevices in rock, and expansion in freezing, repeated time after time. displaces grains and even large blocks. Growing roots of plants produce similar effects, but rooted plants can grow only where chem-



FROM LONGWELL AND FLINT INTRODUCTION TO PHYSICAL GEOLOGY

FIG 2 — THE HYDROLOGIC CYCLE POWERED BY SOLAR HEAT AND GRAVITY

ical action has made food available to them. The most effective chemical reagent is water that carries in solution carbon dioxide, a gas universally present in the air in minute quantities. Rain carries some of the gas to the ground. and hence much of the water that comes in contact with rocks is a weak solution of carbonic acid, which reacts slowly with some of the minerals. Feldspars. the chief minerals in granitic rock. eventually yield clay which is the basic material in ordinary soils. Clay is a complex mixture of silicate minerals, in themselves a large field for study. Potassium carbonate, another product of weathered feldspar, is a nourishing food for plants. Once a soil with a plant cover is started the chemical breakdown of underlying bedrock is accelerated because decaying plant tissues supply carbonic acid to percolating water. Soils are best developed under warm, humid climates, which favour plant growth and the accompanying chemical decay of bedrock. In arctic and desert lands chemical weathering is weak, plants are few, soils are generally poor and nearly unaltered bedrock is exposed over large areas. (See SOIL EROSION AND CONSERVATION.)

Large daily variations in temperature, especially pronounced in deserts, were once credited with effective breaking of exposed bedrock. According to this concept expansion from heating during the day, followed by contraction from rapid cooling at night, would explain the separation of thin slabs from large blocks of rock at the surface. This view has been discredited by careful experiments with use of an electric heating and cooling device equipped with automatic control. Thousands of alternations between temperatures considerably higher and lower than those measured in deserts have failed to produce in samples of rock any fractures detectable even under high magnification. Study of thin shells that separate from rock exposed to the weather reveals as a common cause of the separation the slow development of clay minerals, which involves an increase in volume. The outer surface of exposed rock dries rapidly after wetting; but moisture that penetrates into minor crevices stays until some decay is started, and the resultant swelling causes flakes to spall off. Separation of successive thin shells from massive rock such as granite is called exfoliation. This is a common form of weathering in regions that have moderate rainfall.

2. Erosion by Running Water. — Rain water falling on a sloping field that has been freshly plowed may wash away quantities of soil. No area of ground is perfectly even, and the water, controlled by gravity, becomes concentrated along local sags in the surface of the field, where stream channels are developed. If the rainfall is of short duration only a few nearly parallel channels may develop, separated by wide, ungullied areas; but if hard rainfall is prolonged, or if the field is left undisturbed through successive rains, channels tributary to those first formed start and grow longer headward; these tributaries in turn become branched, and the process continues until the entire surface is covered with a network of steep-walled gullies. As water continues to flow the gullies are in general continuously deepened. But cutting down of a main channel may be checked where it crosses from the plowed area into a meadow protected by sod; this channel cannot then carry away all the sediment delivered into it by tributary gullies, and the excess material is deposited at the bottom of the main stream to form a widening alluvial flat. With continued growth the alluvial deposit may extend backward into the lower reaches of tributaries, thus decreasing their gradients and limiting their power to cut down and to carry sediment. Gullies in the higher parts of the slope retain their vigour longest.

Every land area with abundant or moderate precipitation has an integrated drainage system. In the Alps, a mountain mass that was uplifted late in geologic history, a network of deep valleys directs the drainage toward the four points of the compass into four principal streams: northward into the Rhine; westward into the Rhône; southward into the Po; and eastward into the Danube. Each of these major streams has a wide lower valley floored with alluvium which extends downstream to a large and growing delta. Upstream the valley is narrower, with higher and steeper sides; and in the mountains each large tributary is a deep gorge, many with nearly vertical sides. The gradient of the stream bed near the delta is only a few inches per mile; upstream it steepens progressively, and many of the mountain tributaries are raging torrents with stretches of rapids and some vertical falls. Such a stream is actively deepening its valley, though it is floored with bedrock. The swift water is armed with sediment ranging in size from sand grains to coarse rubble; scrubbing of this material over the stream bed breaks and wears the particles themselves, but the constant abrasion also wears the bedrock floor. Moreover much of the bedrock is divided into blocks by intersecting joints, and many such blocks are loosened and dislodged by the force of the swift stream to become part of the abrading load.

Study of numerous stream valleys in various stages of growth reveals a general progression in development of form, both longitudinally and in cross section. Nearly all large rivers flow into the sea, and sea level limits the depth to which they can cut. In any segment of a valley that is far above sea level the energy of the stream is used mainly in cutting down to establish a graded profile, an ideal slope on which the stream can transport its load of sediment without either cutting or depositing. The large rivers that receive drainage from the western Alps are essentially at grade in their lower courses; but in the high mountain country the profiles are excessively steep, downcutting is active and valleys are deep and narrow. When the profile in a considerable segment of a valley approaches the graded form the stream, deflected from one side to the other, erodes laterally to make the valley floor much wider than the stream channel. This tendency to cut laterally is of course present at earlier stages in valley development; but so long as active downcutting continues the stream is not at a given level long enough for lateral erosion to be effective. After a wide, flat floor is developed the stream at high flood stage spreads beyond its normal channel and deposits sediment to form a flood plain, which grows in width as the widening of the valley continues. On a well-developed flood plain the sluggish stream, diverted laterally by small obstacles, characteristically develops a sequence of wide, looping bends, or meanders, many of which impinge against the valley sides.

Deepening of a valley does not end abruptly with the formation of a flood plain. Slow downcutting continues; and with lateral shifting of the stream, remnants of earlier valley floors may be preserved as terraces. Commonly these terraces are at different heights on opposite sides of a valley, each being the only remaining part of a former floor. On the other hand some paired terraces, well above the present stream, suggest recent rejuvenation of the stream by uplift of the land or by lowering of sea level. Such terraces in the Mississippi valley probably indicate downcutting by the stream caused by subtraction of water from the seas in formation of the present icecaps of the polar regions; the river has regraded its valley to the lower sea level.

Lateral cutting by mature streams has been an important factor in the planing down of wide land masses. But the general lowering of a land surface is begun as soon as the surface is occupied by a network of functional stream channels. Streams in the Alps, aided by glaciers, have removed the vast quantity of rock material that once occupied the vacant spaces of the present valleys. Moreover, the divides between adjacent valleys are being reduced slowly as material is eroded from the opposed slopes.

Some wide and high continental areas are not fully covered with stream channels because of deficient rainfall. Permanent streams that cross the Colorado plateau in western United States receive most of their water supply in the Rocky mountains to the east and north; and valleys cut into the plateau by these streams are deep, steep-walled canyons that have few large tributaries. Erosion is proceeding far more rapidly in the Alps than in the Colorado plateau. Many arid regions have no drainage to the sea; examples are the Dead sea basin, areas in central and western Australia and the Great basin of western United States. The Dead sea depression is far below sea level and is being filled slowly with sediments brought in chiefly by the Jordan river, which has its source in mountains to the north. The Great basin, like other regions with interior drainage, receives many streams, some from mountain blocks within its area, others from bordering highlands. Sediments eroded from the high areas are filling the many separate depressions. The tendency is for some depressions, as they are filled, to spill over into lower areas; ultimately the entire region will be reduced nearly to a featureless plain well above sea level unless crustal movements or a change in climate may interrupt the present trend.

3. Erosion by Mass Movements. — Transport of rock debris on land surfaces is not confined to channels of active streams. On every slope a component of gravity exerts a pull which results in large-scale migration of soil, broken rock and even large masses of bedrock. Abrupt landslides are the most familiar and spectacular example of such movement. Every year large numbers of slides occur in mountainous country—the Alps, the Himalayas, the Rocky mountains and other belts of steep topography; the sliding masses range in volume from a few square yards to a cubic mile or more. Some large slides, starting without any warning and moving at high speed, have overwhelmed towns and caused other catastrophes. Commonly a sliding mass blocks a large stream to form a lake, thus complicating the routine of erosive action. In a region subject to strong earthquakes, a sharp shock often has started a number of landslides involving masses that probably were nearing the point of release.

Chronic landslides, which move slowly and intermittently on steep slopes, are more common than the catastrophic kind. Masses of soil and broken rock move partly by slow flowage, partly by slipping over a firmer basement. In cold seasons such masses may be frozen and practically stationary; thawing in spring causes saturation with water and renewed flowage or sliding on a lubricated base. Differential movement creates a hummocky surface; forest trees growing on the slope are tilted at various angles and locally they are uprooted. Chronic slides represent all gradations between regular landsliding and imperceptibly slow downslope movement known as creep, which operates on every slope covered with loose, weathered material. Even soil covered with close-knit sod creeps downslope, as indicated by slow but persistent tilting of poles, gravestones and other objects set into the ground on hillsides.

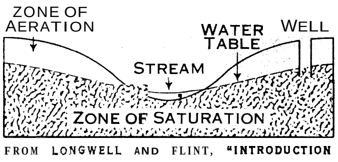
The several forms of mass movement on land surfaces are comprised under the general term mass wasting. All such movements tend to bring loose rock material within reach of streams. which continue the transport to lower ground or to the sea. In high country the cutting of deep valleys by streams creates steep slopes on which mass movements are especially effective. Thus stream erosion and mass wasting co-operate in the wearing down of land masses.

4. Erosion **by** Ground Water.—Of the average annual precipitation on all land areas about 25% runs off directly down slopes into stream channels; a considerable part evaporates; the remainder, half or more of the total, sinks into the ground where it brings about many physical and chemical changes. The weathering processes produce soluble substances which are carried by percolating ground water, some to be deposited in open spaces in bedrock, more to be delivered to streams and carried eventually to the sea. A considerable fraction of the total load carried by rivers is invisible, in dissolved form. One common ingredient, usually in small amount, is sodium chloride, familiar as common salt; another is calcium carbonate, an important part of which is derived from limestone bedrock, another part from decomposed feldspar minerals. Ordinary limestone and dolomite underlie great areas of every continent. Under humid climates with warm seasons the ground water, charged with carbon dioxide supplied mainly by vegetation, dissolves vast quantities of these carbonate rocks. In Yugoslavia, Kentucky and many other large areas the subsurface solution has had profound effects on topography. Roofs of caverns have collapsed to form large numbers of steep-walled sinks; streams, large and small, have been drawn into a network of caverns, leaving dry valleys formed at an earlier stage. Remnants of collapsed cavern roofs known as natural bridges are a common feature. A landscape dominated by the effects of ground-water solution is said to have karst topography, from a region in Yugoslavia where such effects are prominent.

Whether or not the bedrock of a region is highly soluble, ground water plays a major part in weathering and erosion. It provides the perennial supply for stream flow; immediate surface runoff causes flash floods, whereas the trickling of water from soil and from openings in bedrock continues at a nearly uniform rate. After a period of rainfall the water settles along openings to the water table, a more or less definite surface, higher under hills than under lowlands, at the top of the zone of permanent saturation; wells sunk below this depth are assured a steady flow (fig. 3). Above the water table is a zone of varied thickness known as the zone of aeration because air enters openings after water from the surface settles to the zone of permanent saturation. Weathering is active in the zone of aeration, where air is in contact with rock materials that usually are wet with water bearing carbonic acid from plants. Freezing and thawing of shallow ground water, together with its lubricating effect in soil, plays an essential part in movement by creep.

Thus ground water has a major role in weathering and in mass wasting and is the chief agent in delivering to streams vast quantities of dissolved mineral matter. Masses of dripstone formed in many caverns represent local and incidental deposition from the dissolved load in transit.

5. Erosion **by** Glacier Ice.—In some high mountains and in large parts of the arctic regions snowfall exceeds melting. Accumulating snow becomes compressed into ice; and on reaching a critical thickness masses of ice move under their own weight by solid flow; such a moving mass is a glacier. In the Alps, the Himalayas, the Coast range of British Columbia and many other mountain chains the high valleys are filled with glaciers, some of them tens of miles long. Movement of a glacier down its valley is too slow to be seen directly; but accurate instrumental measurements record speeds ranging from a few inches to several tens of feet per day. At temperate latitudes the lower end of a glacier is at fairly high altitude determined by the balance between rates of movement and of melting. Some glaciers in northwestern Canada flow directly into the sea. Greenland and Antarctica have enormous icecaps in which flowage is radially outward; great masses become separated from the margins and drift away as icebergs.

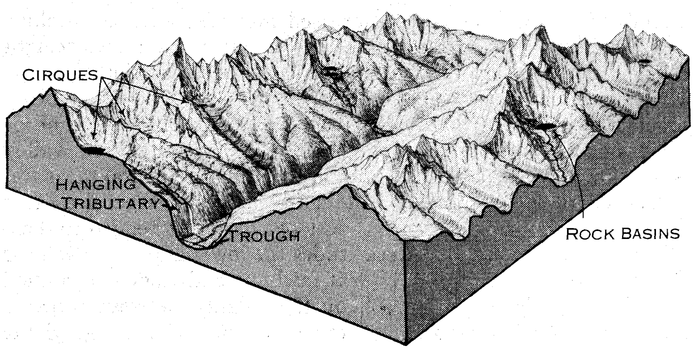


FROM LONGWELL AND FLINT, "INTRODUCTION TO PHYSICAL GEOLOGY

FIG 3 — DIAGRAM OF GROUND-WATER ZONES

Information about glaciers as erosive agents comes from study of active glaciers supplemented by observations in valleys from which glacier ice has almost or entirely vanished. At the lower end of a vigorous valley glacier a ridge, or complex group of ridges, extends across the valley. This end moraine is made up chiefly of coarse rubble containing many blocks of rock with one or more faces smoothed and scratched. Similar blocks are frozen in the ice exposed at the glacier front; evidently the morainal ridge was built up slowly by accumulation of rubble as the ice released it by melting along a front that has varied little in position through a long period. Water in streams of meltwater issuing from the glacier is gray-white and has been called glacier milk; it carries in suspension quantities of silt-size particles made of fresh rock ground up by abrasion as the lower surface of the glacier, armed with blocks of rock, grinds over the valley floor. Moraines on top of the glacier are formed of rubble gathered from the valley walls partly as a result of lateral grinding action by the moving ice.

The features of a valley recently cleared of glacier ice testify to vigorous erosive action. Areas of bedrock on the floor are polished and marked with grooves and scratches generally parallel to the axis of the valley. Rugged surfaces, both on the walls and on the floor, represent forcible removal of blocks bounded by joints. The cross section of the valley suggests a wide U in contrast to the V form of a mountain valley fashioned by a stream. Lateral erosion by the moving ice caused widening by removing not only the points of spurs that normally jut into a main valley between tributaries, but also considerable parts of the tributary valleys. Walls of the glaciated valley are remarkably steep and straight and are marked by numerous high falls from tributary streams that would normally join the main stream at grade but now are in hanging valleys (fig. 4). The head of the ice-freed valley has the form of a wide semicircular amphitheatre (cirque), caused by continual plucking action as ice forming in the snow field became part of the moving glacier. At a divide from which two or mofe glaciers moved in different directions, the growing cirques have partly intersected to form a sharp, jagged ridge. The Matterhorn is a pyramid-shaped mass that has survived destruction between cirques slowly growing together; and numerous similar peaks in the high Swiss Alps testify to the magnitude of erosion by glaciation of that mountain mass. Although the number of glaciers now in the Alps exceeds 1,200, formerly there were many more; and the existing glaciers were much longer than now, as indicated by the glaciated forms of valleys and the abundance of characteristic glacial deposits extending many miles below the present terminal moraines. Long and careful study in the Alps has determined that the valleys were fashioned by stream erosion; onset of a cooler world climate brought development of glaciers that reached to a low level in all Alpine valleys; and increased temperatures have reduced the glaciers to their present status. This general history applies to high mountain valleys in both the northern and southern hemispheres.



FROM LONGWELL AND FLINT, "INTRODUCTION TO PHYSICAL GEOLOGY"

FIG. 4.— FEATURES IN GLACIATED MOUNTAINS

The deep, steep-walled fiords in Norway, British Columbia, New Zealand and some other lands are valleys fashioned by glaciers and now occupied by the sea.

Study of modern glaciers has brought realization that at the time of maximum glaciation in the Alps great ice sheets covered wide areas of continents within the temperate zones. In Europe an icecap extended from the Arctic ocean to central Germany, and the British Isles were covered with ice, in North America all of Canada and the northern part of the United States were glaciated. Much of the soil was removed from the glaciated areas, and the bedrock was polished, grooved and locally eroded by plucking action. Wide belts marginal to the ice sheets were mantled with characteristic glacial deposits, including the unassorted and unstratified till deposited under the ice and in end moraines, and the stratified drift laid down by meltwater flowing from the icecaps during stages of their growth and decay.

6. Erosion by Waves.—The assault on shore areas by storm waves can be observed at margins of large lakes; and effects of sea waves on open coasts are much more pronounced. Historical records show that wave erosion has made appreciable inroads in some coastal areas; for example, along a 30-mi. stretch of the Yorkshire coast in eastern England waves have cut inland $2\frac{1}{2}$ to 3 mi. since the Roman occupation, sweeping away the sites of many villages. On the other hand some stretches of British and other coasts have been extended seaward through deposition by currents, waves and streams. Whether wave work is effective in reducing a land area depends on exposure of a shore to prevailing storm winds, kind of bedrock, depth of water near shore, location and direction of currents, relation to streams that carry large volumes of sediment and other variables. So long as sea level remains constant the extent to which wave erosion can advance inland is limited. Wave motion extends to a moderate depth known as wave base, and in the lower part of the layer of agitated water there is little energy. As storm waves plane inland. energy is absorbed by friction on the wave-cut platform. Hence with each advance the ability to erode decreases and the eroded surface slopes upward to an intersection with sea level. If sea level rises slowly. as it did while the great ice sheets of the past were melting, the extent to which waves can plane inland is increased. Northern lands that have been elevated since the ice vanished (see below) have conspicuous wave-cut surfaces on resistant bedrock, terminating inland against unmistakable sea cliffs and remnants of beaches.

Like streams, waves require tools for effective cutting. Blocks dislodged from cliffs by direct impact of the water are then used for abrasion, together with rock fragments brought from the land by streams and shifted along shore by currents. High cliffs commonly are undercut by wave action, and eventually the overhanging parts collapse, to be broken up completely. Some more resistant parts of the bedrock are bypassed temporarily and stand above water as isolated stacks.

7. Erosion in Arid **Regions.**—No sharp demarcation can be made between climates classed as arid and humid; but by a common definition, regions with less than 25 cm. (10 in.) average annual precipitation are arid. In these regions the surface of the ground is dry much of the time, there is little or no protective vegetation and strong winds are an effective eroding agent. Coarse particles swept along the ground have sandblast action, wearing and polishing facets on loose stones and on bedrock. Window glass exposed to such storms quickly becomes frosted, and unprotected wooden telephone poles are within a short time worn through near the base. Finer particles are carried away in great quantities and to large distances; during and following strong windstorms in the deserts of north Africa, appreciable amounts of dust settle on decks of ships in the Mediterranean and even in countries of southern Europe. In grazing and farming regions classed as semiarid, strong winds carry away vast quantities of soil, particularly during periods of exceptional drought. During the early 1930s a wide belt east of the Rocky mountains in the United States lost much valuable topsoil in windstorms known as black blizzards, which carried dust as far east as the Atlantic seaboard.

Although abrasion by wind-blown sand is important locally, the chief work of the wind is in transportation of rock materials broken up by other agents. In contrast to running water, wind carries quantities of sediment from lower to higher ground. (See also DESERT; DUNES; WIND EROSION AND DEPOSITION.)

8. **Net** Results of Erosive Processes.—Each of the eroding agents—surface water. ground water, glacier ice, wave action and wind—is fashioning distinctive landscape features. These land forms are ephemeral, slowly but constantly changing, and the tendency is toward gradual lowering of the lands. The ideal result if erosion on lands continued without interruption would be reduction of every continent to a low, featureless surface, or peneplain; and by wave action such surfaces might eventually be brought below sea level. Profound effects of erosion are widespread. Very old mountain chains have been brought to low or moderate altitudes; examples are the Caledonian chains of Scandinavia and Britain, the mountains of eastern Australia and the Appalachian belt of eastern North America. Still older chains have been entirely destroyed and only their roots remain as evidence ***(see*** below). In each continent wide surfaces that bevel indiscriminately across resistant and weak bedrock represent close approaches to peneplains; but these surfaces have been uplifted and are now being dissected by streams. The forces causing uplift have been persistent, and erosion keeps refashioning land forms that never are brought to completion.

C. PRINCIPLES OF SEDIMENTATION

An understanding of sedimentary rocks is all-important in geology, and sediments now being deposited provide the essential key. The sedimentary processes are a vast and complex subject for study; kinds of materials are numerous, they are worked on by several kinds of agents, the environments of deposition are diverse and many of them hidden from direct view. Many investigators are devoting their attention to problems of sedimentation not only by systematic field observations but also in special laboratories equipped with devices for mechanical and chemical analyses. Attack on difficult aspects of the study is made increasingly effective by co-operative pooling of information won by workers in a number of disciplines: for example, soil scientists; engineers concerned with problems of flood control, reclamation and water-power development; well drillers interested in kinds of material encountered by their tools; companies laying transoceanic cables; and biologists studying the various habitats of organisms that live in swamps. on lake bottoms or at different depths on the sea floor.

On the basis of environment of deposition sediments are broadly assigned to the three categories: terrestrial, those laid down on the lands; marine, those deposited on sea floors though they may have come from the lands; and mixed terrestrial-marine, those deposited in transitional environments such as deltas, marine estuaries and areas bet een high and low tide. In each major group the sediments are further described as clastic (consisting of rock fragments) and chemical (formed either as inorganic precipitates or at least in part through the agency of organisms). Further classifications recognize the particular environments of deposition on land or in the sea, and the several agents that emplace the sediments.

1. Terrestrial Sediments.—Running water is the chief agent for transporting and sorting clastic sediments on land, and vast deposits are accumulating in stream valleys. Bars of sand and gravel in stream channels are a familiar example; but such features are ephemeral, shifting with successive floods. Far more important are deposits on flood plains. Maximum loads are carried by a stream at flood stage; in large floods the sediment-laden water spreads beyond the channel, velocity of flow is much decreased and a layer of sediment, chiefly sand, silt and clay, is spread over the nearly level plain. In a major valley, such as that of the Amazon, the Mississippi or the Hwang-ho, flood waters cover a belt tens of miles wide; over much of the area the water, nearly stationary, is present for days or even weeks until the finest clay particles may settle out. Although flood-plain sediments are chiefly fine grained, gravel and coarse sand included locally may represent lateral migration of the channel in the growth and shifting of meanders. Tributaries that enter from hilly country commonly mix coarse deposits with finer sediments of the main valley.

In general the grain size of sediments along a large stream valley decreases steadily downstream. Abundant gravel in headwater areas has angular fragments, many of boulder size. These become smoothed and reduced in diameter by abrasion in transport; careful measurements show a constant increase in average roundness and decrease in average size of grain with distance of travel. The prospective goal of these stream-borne particles is the sea; but there are long delays for quantities of sediment spread over a flood plain. A stream in its slow lateral migration across its valley eventually cuts into these temporary deposits and carries them farther; but they are subject to the chance of redeposition on the wider plain farther downstream. Moreover below a critical point along the course of every major stream the flood plain is steadily building up. burying older deposits to increasing depth, because the stream must adjust its grade to increasing length as the delta grows seaward. The Mississippi river once entered the sea far north of its present mouth; it has deposited flood-plain sediments hundreds of feet thick to maintain a slope of a few inches per mile as the delta front migrates southward.

The profiles of many streams are interrupted by lakes in their paths. Thus the Rhône river floas into the Lake of Geneva, in Switzerland, deposits its suspended load and flows out a clear stream. Eventually the lake will be filled with sediment into which the river will then cut to establish a normal grade. Deposits in lakes generally are coarse grained near the margins, progressively finer grained inward, though preponderant contributions by a large stream make the pattern asymmetric. Known lakes represent various stages in filling by sedimentation; and some old lake deposits have been well exposed to view by erosion. Chemical deposition of calcium carbonate and other mineral substances occurs in the interior parts of some lake basins, especially those in lands with deficient rainfall. In humid regions lakes in the last stages of filling with sediments become swamps in which accumulating plant materials may form beds of peat like those common in Ireland, Scotland and many other lands. Formation of peat, an early stage in the development of coal, has required accumulation of the plant substances in swampy basins protected from detrital sediments. followed by complex biochemical changes.

Lakes and swamps, nith their peculiar kinds of sedimentary accumulations. are especially numerous in the wide continental areas that were covered with glacier ice in the recent past. The unassorted deposits (till) formed by the ice and the stratified drift laid down by meltwater from the icecaps are described briefly above in connection with erosion by glaciers. Other types of unstratified rock waste that are widespread on the lands are the materials moving by creep, landsliding and other forms of mass wasting; and residual material on low, flat areas where intensive weathering is in progress but there is no appreciable movement. In some tropical countries the deeply weathered residuum has a pronounced red colour from concentration of ferric oxide (*see* LATERITE).

Distinctive fine-grained sediment accumulated by wind action is called loess. In wide areas of China such material, wholly unstratified, is spread over hilly country without regard for topography. The grains are of silt size or smaller, in large part unweathered and with angular shape.

Apparently this material was carried by winds from the arid regions of central Asia. Similar loess in many parts of the Rhine and Mississippi valleys may have had its source on barren plains formed by fine sediments washed from melting icecaps. Another common kind of wind deposit is dune sand, abundant in arid regions but widespread also near sandy shores of seas and large lakes, where a constant supply of sand is provided by the action of waves and currents.

2. Mixed **Terrestrial-Marine** Deposits.—Great deltas provide the most imposing visible exhibits of waste products moved from lands to seas. Exposed surfaces of the Ganges-Brahmaputra and Nile deltas measure about 80,000 $km.^2$ (50,000 sq.mi.) each; that of the Hwang-ho is much larger; and if to these is added the surface areas of deltas of the Amazon, Orinoco, Mississippi, Colorado, Yukon, Indus, Volga, Po, Rhône, Rhine and other comparable streams, the total is over 1,000,000 $km.^2$ (600,000 sq.mi.). As all large delta surfaces slope gently outward underwater, areas at the bases of marine deltas combine to make a total several times that of the exposed delta plains. Rates at which several great deltas are growing seaward are estimated from frequent measurement of sediments delivered by their streams and from repeated checks on positions of shore lines. The amount of sediment added to the Mississippi delta averages about 2,000,000 tons per day. Locally the exposed surface has grown seaward several miles within 50 years; but in situations exposed to storm waves the shore line has been cut back. Precise geodetic work has determined that in much of its area the delta is subsiding at rates of two or three metres per century, a movement that is partly or wholly compensated by continued upbuilding. Data from deep wells drilled for oil, supplemented by geophysical studies, indicate that at a maximum the total thickness of the deltaic deposits exceeds 11,000 m. (36,000 ft.); presumably, therefore, crustal subsidence has proceeded as the delta grew.

Streams in crossing their deltas branch into distributary channels which diverge outward in a fanlike pattern. Because of imperfect drainage there are swampy areas and even lakes between adjacent distributaries. Sediments in large deltas are predominantly fine grained; in the Mississippi delta the percentage of clay is high and generally the largest grains are of coarse-sand size, though scattered small pebbles are reported. In parts of the deposit, sand, silt and clay are mingled in complex fashion because at flood stage the muddy water of the stream mixes with sea nater and salt causes flocculation of the clay, which in sinking carries coarser particles with it. Moreover the distributaries continually change their courses. carrying sand and silt into swampy areas to be mixed with clay and decaying vegetable matter. With outward growth of the delta plain, stream deposits of continental type come to overlie marine sediments; later subsidence or a rise in sea level may result in marine deposition over the continental beds. This constant interplay makes deltaic sediments extremely complex.

Most small streams that enter the sea cannot build deltas because waves and currents sweep away the sediments as fast as they are delivered. In some situations areas between the limits of high and low tides—the littoral zone—acquire a mixture of continental and marine deposits. Along some coasts strong waves breaking on a sandy bottom heap the sand into an offshore bar which may grow into an extensive barrier island. Long lagoons protected by such barriers accumulate sediments from the land, as well as sediments brought in by waves during exceptional storms. Another environment for mixture of land and sea deposits is provided by estuaries in which the water changes from salt to fresh with the rise and fall of the tides.

3. Marine Sediments. — Marine basins occupy much more than half the earth's surface. and their situations lower than the lands have made them the receptacles of sediments through long ages. Sediments washed from the lands are continually being spread over sea floors, supplementing vast deposits of directly marine origin. These processes are for the most part concealed from direct human observation. Effective and rapidly improving methods of studying marine sedimentation belong in the field of oceanography (see OCEAN AND OCEANOGRAPHY), but their value in geology justifies a brief summary here. The techniques most essential in geologic study of sea floors are those for determining depths and for bottom sampling. Until well into the 20th century both these operations were slow and inaccurate and the resulting scattered observations gave little basis for reliable conclusions. The development of equipment for echo sounding made it possible to obtain an accurate continuous profile of the floor beneath a vessel moving at its normal speed. Until the second half of the 20th century devices used for collecting bottom samples penetrated to very shallow depths and either mixed the sediments indiscriminately or caused distortion and compaction of individual layers. Coring cylinders were developed that have recovered cores up to 23 m. (75 ft.) long in which the layers of sediment are essentially undisturbed. Large numbers of such samples, taken at various depths and representing a wide range in distance from land, are studied in laboratories to determine the physical and chemical compositions of the sediments, thickness and arrangement of layers, content of organic remains and other significant facts.

Marine sediments commonly are classified according to their depth below sea level, and also according to their origin. Three depth zones are recognized in the first classification: the shallow or neritic zone, the deep or bathyal zone and the very deep or abyssal zone. These subdivisions are in general those recognized on a profile from a continental margin into an ocean basin. Continents and large islands are bordered by comparatively shallow water on a shelf which slopes gently outward to a depth ranging from 100 to 200 m. (325 to 650 ft.); sediments of this shelf are classed as neritic. At the outer edge of the shelf the slope steepens appreciably on the continental slope, which extends to the deep ocean floor; sediments of this slope are bathyal, and those of the ocean floor are abyssal. A classification according to source of sediments is as follows:

- I. Derived from lands and contributed by
  - A Streams
  - B. Wave erosion of coasts
  - C. Winds
  - D. Floating ice
- II. Formed in the sea by:
  - A. Shells and skeletons of marine animals and plants
  - B Chemical precipitation
- III. Fragmental material erupted by volcanoes
- IV Paiticles ot meteorites from outside the earth

As the shelf seas border continents and islands, a large part of the neritic sediments is made up of clastic materials derived from the lands. Generally these materials become well sorted according to size; waves agitate the sediments near shore and currents separate fine particles from coarse and carry them to depths below wave action. In a simple system the coarse materials, spread out near shore, would grade seaward into silt and clay. Actually the movements of sea water are extremely complex because of coastal irregularities, varied directions of storm winds. uneven bottom topography, proximity of great ocean currents and other variables. Accordingly the coarse sediments are carried out much farther in some places than in others. Moreover sea level has not remained fixed and on the gently sloping shelf a moderate shift in the water level results in a large shift of the shore line. During the glacial ages when vast quantities of water were locked up in ice sheets on lands sea level was as much as 90 m. (300 ft.) lower than at present. As the level shifted gradually, downward and upward nith growth and wasting of icecaps, shore lines migrated tens of miles on the wide shelves. As a result coarse clastic sediments were deposited far out at times of maximum glaciation, to be covered with fine-grained deposits when waning glacier ice restored the higher sea level.

Great quantities of land-derived clastic sediments are spread beyond the shelves onto the continental slopes and parts of the deep ocean floors. Recent geophysical work has determined that thick deposits lie on these floors at the bases of the slopes; probably much of this material is carried out by sliding of loose, water-saturated sediments on the unstable sloping surfaces. Transatlantic cables have been broken by such sliding masses; and studies indicate that swift currents generated by the sliding carry loads of clay, silt and sand far out on the ocean floors. These currents move along the bottom because the exceptional loads of sediments make them turbidity currents, much heavier than the clear water above.

Of the sediments with marine origin an overwhelming percentage is contributed by animals and plants, for the most part small floating or swimming forms, many of them microscopic or nearly so. In tropical and temperate zones the surface waters teem with myriads of these organisms, some of which form shells of calcium carbonate (commonly called lime), others of silica, extracted from sea water. The discarded shells settle to the ocean floors and slowly build a deposit over wide areas. In warm regions the calcareous shells are predominant, and great expanses of the ocean floors are covered with calcareous ooze. This deposit is absent from the deeper parts of ocean basins, however, because the cold water at great depth, containing much carbon dioxide, dissolves the slowly settling flakes of calcium carbonate. Siliceous ooze, much less soluble, covers large areas in deep oceans; but in wide tracts the siliceous particles are mingled with fine clay, probably supplied by winds carrying dust from lands or from volcanic eruptions. Through oxidation the clay has acquired a distinctive red colour. The red-clay deposits in deep oceans contain more particles of meteorites than are found elsewhere. probably because accumulation of the clay is so slow the meteoritic materials are relatively concentrated and conditions on the ocean floors protect these materials from rapid chemical decay.

Some cores brought up from deep ocean floors, far from land, consist chiefly of clastic materials, including fairly coarse sand, with only a thin cover of ooze or of red clay. Probably the clastic sediments were derived by sliding from a continental slope and carried far out by turbidity currents.

Marine organisms are abundant over the continental shelves, but generally the organic materials are masked by clastic sediments that accumulate more rapidly in most parts of the neritic zone. But there are notable exceptions to this general rule. Along some low coasts that are protected from sediment-laden currents the shells of mollusks and other large shelled animals accumulate in widespread layers. In coastal belts of southern Florida and the Bahama Islands such accumulations are being cemented rapidly into firm rock. On shelves in the tropical zone corals and other reef-forming animals are building immense calcareous deposits, many of them near coasts. Calcareous ooze also is forming on some shelf areas from which clastic sediments are diverted. Precipitation of lime around coasts of some low-latitude islands is explained as the result of oversaturation on loss of carbon dioxide through increase of temperature or lowering of pressure.

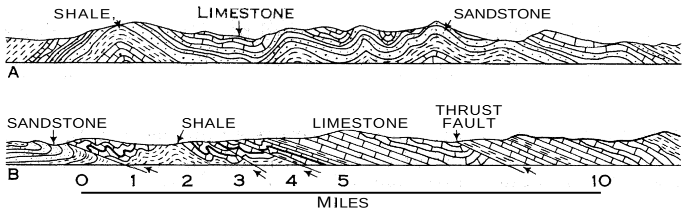
The neritic sediments are of particular interest in geology, because in large part the marine sedimentary rocks now exposed on land have features that indicate their origin in the shelf zone. Some rocks exposed in mountain belts, however, have characteris; tics peculiar to sediments in deeper parts of the oceans.

4. Conversion of Sediments to Sedimentary Rocks. — Cementation and compaction convert deposits of loose clastic sediments and soft oozes into firm rocks. some of them as strong as granite. Layers of clay and line silt become compacted more and more under the weight of overlying beds, and much water in the original mud is expelled. Calcareous ooze loses excess water in the same way, and slow crystallization of the carbonate minerals produces firm limestone and dolomite. Water moving through pores between sand grains and pebbles in the coarser clastic layers slowly deposits dissolved mineral matter, such as calcium carbonate, .which binds the particles together; layers of sand become sandstone, those made of larger particles—pebbles to boulders—become conglomerate. In the change from loose sediment to strong rock many distinctive features are preserved: tracks of animals made on muddy surfaces; forms of ripples molded in loose sand beneath oscillating waves; cracks formed on muddy surfaces from drying; and, particularly important, shells and bones of animals and tissues and impressions of plants which give reliable information on the environments under which the sediments were laid down.

D. Structural Geology

Geometric study of rocks recognizes primary structures—those acquired in the genesis of a rock mass—and secondary structures that result from later deformation. Familiarity with primary features is essential for effective study of deformed masses. The many significant features in sedimentary rocks make them especially valuable for detecting and evaluating later changes in form. Of outstanding importance is the nearly horizontal attitude of true sedimentary beds when they are deposited; such beds that now have steep attitudes clearly record later distortion. In many belts of strong disturbance the beds have been overturned, even completely inverted. as shown by positions of animal tracks, plant roots, mud cracks and other features that mark tops of sedimentary layers. Volcanic rocks also have distinctive features, such as vesicles in the upper parts of lava sheets, which give them value in structural studies.

Such studies may result in purely factual descriptions of de-



BY COURTESY OF U.S. GEOLOGICAL SURVEY

FIG. 5.— (A) FOLDED MARINE STRATA IN WESTERN VIRGINIA: (B) STRATA IN SOUTHWESTERN VIRGINIA. FOLDED AND SLICED BY THRUST FAULTS

formed rocks; but a broad view of the subject considers possible causes of deformation, and inquires into the structure of entire continents and of the earth as a whole.

1. Evidence **of** Crustal **Movements.**—Within historic time abrupt and large-scale displacements of bedrock have occurred. In 1899 part of the Alaskan coast was raised instantaneously as much as 14.5 m. (47 ft.) ; the movement was attended by a major earthquake. Other extensive breaks in bedrock. coinciding with earthquakes, have been recorded in Chile. California, Japan, Italy and many other lands. Movements of another kind, slow and affecting wide areas, are revealed in evidence partly historic and partly older. Marks made at high tide level along the Norwegian coast more than a century ago are now several feet above the reach of tides. Uplift of Scandinavia has been long continued, as shown by a succession of wide benches bearing marks of shore lines, the highest about 27j m. (goo ft.) above present sea level. Evidence of similar broad uplift is conspicuous in Newfoundland. and in Canada along the St. Lawrence river and around Hudson bay. **A** movement of this kind. involving gradual bending of a wide surface, is known as crustal warping. Ancient warping at many dates is recorded in broad bending, both upward and downward, of sedimentary beds; the structural evidence remains though the land surface that must have been deformed has been destroyed by erosion.

In addition to broad warps, the principal kinds of structural features that record deformation are folds, joints, faults, cleavage and unconformities.

Folds occur in a more or less regular sequence of upbends or anticlines and downbends or synclines. In major mountain chains folding has affected belts tens of miles wide and hundreds of miles long; individual folds are continuous for tens of miles and the largest measure several miles between crests of adjacent anticlines. Folds of smaller scale are superimposed on the sides or limbs of the major folds. The general pattern may be imitated in miniature by placing a stack of cloths or of thin paper sheets on a table and compressing from opposite edges. Folding can occur only in layered rocks and is best developed in thick sections of sedimentary beds, although some volcanic rocks consisting of lava flows and beds of volcanic ash also are strongly folded. This **kind** of deformation inditates large-scale compression.

Joints, or breaks along which no perceptible movement has occurred, are present in nearly all large exposures of bedrock. Only in exceptional places can quarrymen find good stone sufficiently free from joints to provide perfect monoliths 50 to 100 ft. long. In igneous rocks many joints have formed by contraction on cooling. Joints cutting rocks of all kinds probably have resulted from stresses set up by warping, folding and other deformation.

Faults are breaks in bedrock along which displacement has occurred parallel to the fractures. Abrupt slips on active faults cause earthquakes; such movements on a given fault may occur at intervals of years or tens of years to relieve stresses that build up slowly. Dimensions of faults range from inches to hundreds of miles, and amounts of displacement vary widely. The San Andreas fault in California on which movement caused the earthquake of 1906 can be traced at the surface nearly 1,000 km. (600 mi.) ; displacement in 1906 was horizontal, as much as 21 ft.—roads and fences were sharply offset to that extent. Earlier movements account for a total displacement of many miles. On some other faults the displacement has been chiefly vertical. producing a high cliff or scarp. Most faults are inclined, some steeply, others at a low angle. **If** displacement is relatively downward on the side toward which the break is inclined, the fault is called normal; if that side has moved relatively upward, the fault is reverse. Reverse faults with low angles of inclination and large displacement are called thrust faults, or simply thrusts. Such faults commonly are associated with folds in mountain belts. The great majority of known faults are dead—that is, movement on them apparently ceased long ago.

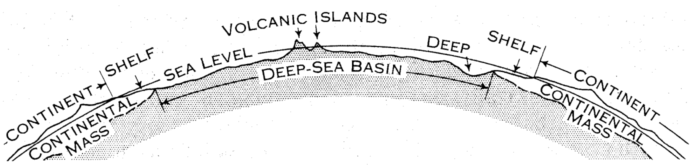
Cleavage has been developed in many large masses of rock under high compressive stress. In nearly all large mountain belts shale in closely folded beds has been transformed into slate. Cleavage, cutting sharply across the original bedding, divides the slate into thin plates with remarkably plane surfaces. In many zones of extreme deformation the slate has passed into lustrous phyllite, or even into mica schist, in which the cleavage surfaces commonly are much crumpled.

Many old crustal movements are recorded by interruptions in sequences of sedimentary beds. For example in the walls of the Grand canyon of Arizona a thick section of beds containing fossils of marine animals is almost horizontal; but the base of the section rests on the edges of tilted older beds, some of which also yield marine fossils. **A** general succession of events is clearly indicated: the older beds were deposited on a sea floor; they were deformed, lifted above the sea and partly destroyed by erosion; the region later subsided. a new section of marine beds was laid down and the present land was formed by widespread uplift but with little deformation of the younger beds. The two sequences of beds are unconformable. and because of the angular divergence they are said to be separated by an angular unconformity. Many unconformities represent interruptions in sedimentation by broad warping movements that left the older beds essentially horizontal; successive sequences of beds then have no perceptible angular divergence, though the surface separating them may represent a long history of erosion.

Discordant contacts between masses of rock result also from large-scale faulting and from igneous intrusion; but the term unconformity is applied only to a relation that involves erosion and deposition of layered rocks, either sedimentary or volcanic in origin.

2. Mountain Structure.— Kinds and structure of rock masses exposed in mountain lands are highly varied; but in every great mountain belt exceptionally thick sedimentary sections have been deformed by folding and faulting. Erosion has truncated folds over wide areas and exposed complete sections of the beds, which have maximum total thicknesses as great as 10 to 13 km. (6 to 8 mi.). The beds. consisting of conglomerate. sandstone. shale and limestone. are largely of marine origin as shown by included fossils. and in considerable part the sediments resemble modern deposits in shallow water and at moderate depths: therefore the basins of deposition must have subsided slowly while the sediments accumulated. In many places the marine beds intertongue laterally with coarse littoral and deltaic deposits. As this relationship extends through large thicknesses, the lands that supplied the clastic sediments must have been rising while the sedimentary basins mere sinking. Therefore the site of a mountain belt was a zone of disturbance for a long time before the mountains were formed. Lavas and other volcanic materials commonly are included with sediments in parts of the section.

Generally the zone of subsidence and sedimentation marking the early stages of mountain history was situated near the margin of a continental mass. hluch of the clastic sediment, however, has



FROM LONGWELL AND FLINT, "INTRODUCTION TO PHYSICAL GEOLOGY"

FIG. 6.— MAJORFEATURES OF RELIEF ON A SEGMENT OF THE EARTH, WITH VERTICAL SCALE EXAGGERATED ABOUT 8 TIMES

come from land on the seaward side. as shown by the direction of gradation from coarse to fine materials. Thus in parts of the Appalachian mountains coarse-grained sediments grade westward through shale to limestone. The land that supplied pebbles, sand. and silt lay east of the present coast, and perhaps consisted of islands in a chain similar to the present island arcs of the Caribbean region and many parts of the Pacific basin. Modern island arcs are in zones of volcanic activity. with products similar to volcanic rocks found in the deformed sections of mountain belts. The areas of thick sedimentary sections vary in width but generally are no wider than the mountain belt. In the Appalachian mountains the total section of beds is six to eight times as thick as the section of the same age in the wide Mississippi valley region directly to the west. Therefore before deformation occurred the base of the thick section curved gently downward in the form of a broad trough, the result of slow subsidence as the sediments accumulated. Because of this troughlike form the area of thick sediments is called a geosyncline—a downbending of global scale —and the long period of sedimentary accumulation before the development of mountain structure is referred to as the geosynclinal stage.

Deformation of a large belt to form mountain structure is called orogeny, literally the genesis of mountains. In a general way orogeny has follon-ed the geosynclinal stage; but the history has been complex in every great mountain unit. Within parts of the Appalachian belt angular unconformities record repeated deformation, erosion that beveled the resulting folds and faults. then continued subsidence and sedimentation. But a final paroxysm of deformation ended the geosynclinal stage, mountainous topography became the rule and later history has been a contest between erosion and renewed uplift. Apparently the Alps and related mountain units. which are much younger than the Appalachians and Crals, are in an early stage of their history following deformation of the geosynclinal deposits. Erosion has proceeded far enough to reveal spectacular effects of folding and faulting. Great folds, overturned toward the north, have repeated the beds in complex fashion; further repetition has resulted from low-angle thrust faults on which great slices of the deformed rock, piled one above another. have been moved many miles northward. Similar structure is found in older mountain belts. where erosion has exposed also great masses of metamorphic rock and large intrusive bodies of granitic rock emplaced during the orogeny,

Sites of the oldest great mountain units are in present lowlands, and are recognized in elongate belts of contorted and faulted sedimentary rocks, much metamorphosed, partly engulfed in large granitic batholiths. Such "roots" of mountains are conspicuous in parts of Canada, Fennoscandia. Siberia, central Africa and Brazil, in areas that through long ages have been above sea level, subject to weathering and erosion. .Other well-known mountain belts. forming a sequence from old to comparatively young, have generally similar structure and the heights of the belts increase with decreasing age; examples representing four dates in a long span of time are the northwest Highlands of Scotland. the Xppalachian chain, the Rocky mountains and the Alps. Some island arcs in the Pacific basin and in the Caribbean region appear to be mountain units now growing. Therefore orogeny has been continuous or recurrent through much of geologic time. The cause and the mechanism of orogeny and of broad warping movements that repeatedly have lifted and depressed continental areas are matters of much interest and active study; but the subject is too involved and speculative for treatment here. Some physical principles involved in the history of persistent mountain uplifts merit brief attention.

3. Balance in the Earth's Crust.--Old mountain units such as the Appalachian chain, the ranges of South Africa, and the Rocky mountains of Colorado have been brought to subdued relief by erosion but have regained much of the lost altitude by repeated upwarping. This behaviour is generally similar to that of an iceberg \\-hich. though its emerged portion is subject to continuous melting. maintains much of its height by buoyant rise of the greater mass under water. The comparison is a reminder that rocks exposed in the continents are on the average appreciably less dense than the basaltic rocks common in the ocean floors. Though wide continental surfaces have been submerged repeatedly. the resulting seas have been shallow; all known evidence indicates that continents and deep ocean floors never have exchanged places. Therefore a favoured concept regards the continents as the upper surfaces of crustal plates with comparatively low density that are buoyed up on a subcrust of higher density; high mountain chains logically represent thickened parts of the continental plates (fig. 6). This concept is strongly supported by geophysical data related to the study of earthquakes. Elastic waves traveling from an earthquake centre or from the location of a large artificial explosion move at higher speeds through basaltic rocks than through the granitic rocks common in continental masses. Instrumental records of these waves at many stations indicate that the average thickness of continental plates is 25 to 40 km. and that beneath a high mountain unit such as the Alps the thickness is 60 km. or more. Thus the large irregularities of the earth's surface are not haphazard but are controlled by gravity; the general state of balance between segments of the crust that differ in density is called isostasy (equal standing).

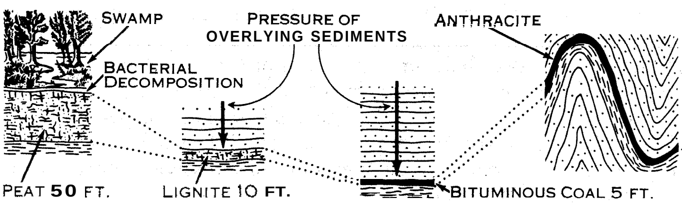
The concept of isostatic balance is in accord with the behaviour of areas that were covered with icecaps during the great Ice Age, or Pleistocene epoch. Since the ice disappeared the glaciated areas have been warped upward, as shown by elevated shore lines; in Scandinavia and Canada the highest marine terraces are hundreds of feet above sea level and probably much more uplift occurred while the wasting ice kept the sea from contact with the land. Presumably the icecaps, many thousands of feet thick, disturbed the isostatic balance and caused downwarping; this may have involved slow flowage of rock materials: at great depth. outward from the loaded areas. Wasting of the ice has brought readjustment and rise of land surfaces toward preglacial levels.

E. Economic Geology

The minerals on uhich our civilization is heavily dependent are obtained from the earth's crust and therefore have a prominent place in the study and practice of geology Although the term mineral ordinarily suggests solid substances water also is a mineral resource of primary importance. A major part of the water supply developed for private, public and industrial use is obtained directly or indirectly from underground sources; even streams and lakes used in systems of nater supply receive their steady replenishment from ground water. Therefore some knowledge of the kinds and structure of local bedrock is essential in plans for developing, conserving and insuring the sanitary quality of an adequate water supply, particularly for a large community. Many wide areas on the flanks of highlands are favoured with artesian conditions.

The solid economic minerals are grouped in two general categories: metallic and nonmetallic. Deposits of metallic minerals—those from which are extracted common metals such as iron, copper, zinc and lead, and many that are less common—are extremely diverse in their occurrence and origin. Many large masses of metalliferous ore are connected, directly or indirectly, nith bodies of igneous rock. Masses that apparently separated directly out of molten magmas are illustrated by the magnetic iron ores at Kiruna, Swed. Some metallic ores were formed at contacts of igneous bodies with older rocks; others by hydrothermal action that extended from the bodies of magma far out into the adjacent older rock; still others in veins built up by crystallization from solutions that migrated outward from magmas along joints and faults in older rocks. Imuortant metalliferous deuosits of sedimentary origin include the Clinton iron-ore beds that are widespread in the Appalachian region, and the iron ranges of the Lake Superior region. The latter deposits, the largest and richest bodies of hematite discovered by the second half of the 20th century, were enriched by circulating waters which dissolved silica and other substances, leaving a residue with a high content of iron oxide. Many other bodies of metalliferous ores! varied in origin, have been enriched by dissolving of mineral matter in the zone of aeration and redeposition below the water table. Another type of concentration has been performed by running water on the surface; the lighter rock materials have been washed away, and heavy substances such as gold, platinum and tin oxide have accumulated in placer deposits. (For further information on metalliferous deposits *see* the articles MINING, METAL; ORE DEPOSITS; and articles on various metals and metallic ores.)

Of outstanding importance among nonmetallic deposits are the mineral fuels—coal: petroleum and natural gas—which are rich in solar energy locked up in chemical compounds by plants and animals of past ages. Coal originated in vast swamps; plant materials, accumulated in large thickness, were compressed under the weight of sediments deposited over them, and slow chemical changes with attendant loss of gas have resulted in fuels of several grades from peat to anthracite (fig. 7). Petroleum is a product of slow chemical change in organic material, much of it contributed by small marine plants and animals to sediments as they accumulated on sea floors. Oil and gas generated in the source beds have migrated into adjacent porous layers, where generally water has forced the lighter fluids into various kinds of traps, sealed by beds of shale or other impervious rock (fig. 8). Occurrence of some



FROM LONGWELL AND FLINT, "INTRODUCTION TO PHYSICAL GEOLOGY"

FIG. 7.— CONVERSION OF PLANT MATTER INTO PEAT AND THREE GRADES OF COAL

extensive gas deposits free from oil is explained by escape of the more mobile gas from an earlier common trap to a location under more impervious rock. Exceptionally the migrating oil and gas have come to rest in volcanic rocks, or even in metamorphic rocks that have some porosity; but nearly all oil and gas pools of commercial value are in sedimentary rocks. Geologic principles and information are important aids in the search for new producing localities and a large majority of trained geologists find employment in the petroleum industry. Geophysical principles and techniques for finding favourable structures also are employed extensively in the continuing search for oil. Many important discoveries have been made by drilling to depths considered impractical in earlier exploration; some producing wells are as deep as 6,000 m. (20,000 ft.). (For further information *see* GEOPHYSICAL PROSPECTING; COAL AND COAL MINING; PETROLEUM; GAS INDUSTRY.)

Other nonmetallic deposits include a large number of mineral concentrates, some of which originated as chemical precipitates in seas and lakes; prominent among these are gypsum and common salt.

Economic development of deposits in the earth's crust applies

principles of geology to practical ends. On the other hand, information revealed in mining operations and in the world-wide search for petroleum has contributed much to the growth of geologic science.

III. HISTORICAL GEOLOGY

A major part of the legible history of the earth is read from sedimentary rocks, which record an order of events, changing environments, developments in animal and plant life and effects of crustal movements. Important supplements to the record are found (1) in volcanic rocks, which in many places are interlayered with and grade into sedimentary deposits; (2) in relations of intrusive igneous bodies to older and younger rocks; and, (3) in surfaces resulting from erosion, some of them exhibited in present landscapes, others in large part buried under sedimentary or volcanic accumulations. The high lights of known earth history, viewed in human perspective, make a lively record of a vacillating contest between sea and land; the development, rise and wasting away of great mountain systems; the waxing, waning and shifting of volcanic belts; and above all the miracle of evolving life in seas and on lands, leading to modern floras and faunas and the rise of man. Relative dates through a vast lapse of time are clearly indicated in the stratigraphic record and reliable absolute dates are becoming available from geochemical studies of critical isotopes.

The comprehensive study of stratified rocks is stratigraphy. The study of fossilized plants and animals with regard to their distribution in time is paleontology. These two disciplines are complementary and in geologic practice they are inseparable. In the interest of clear explanation they are here introduced separately, though fossils are discussed only in their relation to stratified rocks.

A. STRATIGRAPHY

Study of sedimentary rocks begins logically with consideration of materials that make up the various rock types. This aspect of the subject, sedimentary petrography, is outlined briefly under *Mineralogy and Petrology,* above, though only the commonest kinds of rock are listed. In a descriptive study it becomes clear that the key to an understanding of sedimentary rocks is supplied by the many kinds of sediments now accumulating; this aspect of the subject is discussed above under *Principles of Sedimentation.* The third step in the study considers the over-all relations of the stratified rocks in space and time and the history recorded in them; this broad view of the subject is stratigraphy. A fundamental principle in the study, known as the law of superposition, is that in a sequence of layered rocks as they were laid down, any layer is older than the layer next above it. This seems elementary for rocks that have not been disturbed; but commonly in mountain zones very thick sections of strata have been overturned, even completely inverted. and can be correctly understood only through criteria that indicate tops of beds and thus establish the sequence of deposition. Another requirement for useful interpretation of strata is recognition of physical conditions under which they were laid down. Again comparison is made with sediments now being deposited. Close matching of the diverse kinds of modern sediments with materials in sedimentary rocks representing an immense span of time gives strong support to the uniformitarian principle, which states that processes now acting on the earth have operated continuously and rather uniformly through long ages. This principle. resting on world-wide inductive studies, is one of the most fundamental in geology.

1. Sedimentary Facie% — Sedimentslaid down by a stream on its flood plain are readily distinguished from the unassorted till in the end moraine of a glacier. Each environment of sedimentary deposition puts its stamp on the deposits, and the distinctive marks are preserved in the consolidated sediments. Thus we distinguish marine from terrestrial strata, partly by inherent physical differences and partly by contained fossils. But marine beds are of many kinds: near-shore or littoral deposits of sand and gravel grade outward into muds, which in turn may grade into limy ooze; along many coasts the sand heaped up by breaking waves to form barrier islands grades shoreward into muds rich in black carbonaceous matter from decaying plants. Each distinctive type of sedimentary deposit is a facies (from the Latin for "face"). The term is used flexibly, in relation to broad as well as more specific distinctions in stratified rocks. A littoral facies, representing deposition between high and low tide, differs broadly from a distinctly marine neritic facies deposited below the lowest tides; but within the littoral zone a lagunal facies, common behind the great offshore bars of the Carolina coast, is very different from a sand-beach facies that is widely developed along the Florida coasts. Moreover the great differences in physical conditions are reflected in kinds of animals and plants living in the diverse environments. In many sections of sedimentary rocks beds of sandstone are seen to grade laterally into and interfinger with beds of shale. Clearly the two types of deposit were formed at the same time; but fossil shells and other remains of animals in the two kinds of rock are very different, indicating that in the past different environments were suited to different forms of life, as is true today. Thus a given biofacies as represented by an assemblage of fossils may be recognized as in harmony with a lithofacies represented by rocks in which the fossils occur.

2. Broad Stratigraphic Patterns. — Sedimentary deposits of past ages, as of the present, are endlessly complex; but from detailed studies in all continents a few outstanding patterns emerge. Each continent has at least one wide lowland that has been repeatedly invaded by seas and is now mantled with marine strata, little deformed and with small or moderate total thickness. These areas are known as stable platforms; examples are the central part of European Russia. central Siberia. a large part of the Sahara, central and southern Brazil, the central United States and Canada, northern and northwestern Australia. On each of these wide regions the encroaching seas left nearly level beds of limestone, shale and clean quartz sandstone. Erosion following withdrawals of seas made irregular surfaces on which the next succeeding strata were laid down unconformably but without angular discordance. The total deposit on each platform averages at most a few thousands of feet thick but represents a long span of time. Along one margin of each platform, however, deposits of the same general age are much thicker, more varied in character and strongly deformed. Thus the strata of the Russian platform thicken eastward into the Ural mountains. and the little-deformed beds that are widely exposed in the Mississippi valley pass into the folded, faulted and far thicker sections of the Appalachian mountains. These deformed belts went through eventful geosynclinal histories that culminated in mountain-making disturbances.

On the broad platforms the distinctive stratigraphic units can be traced widely and their relations to each other are generally clear. In the geosynclinal belts the relations are more complex because conditions of sedimentation were locally turbulent and deformation has broken the continuity of beds. Many stratigraphic problems in these disturbed belts would be insoluble without the aid of paleontology. which plays a major role in the study and practical use of stratified rocks.

B. Paleontology and the Scale of Time

Paleontology, in its own right a broad science dealing with the remains of animals and plants preserved in rocks. is treated at length in another article Its critical importance in geology arises from the use of fossils as time markers in stratified rocks. Near the start of the 19th century independent workers in England and in France discovered that units of sedimentary rocks can be traced over wide areas by means of distinctive fossils in each unit. In England these classical studies involved marine limestones replete with well-preserved shells of clams. cephalopods and other

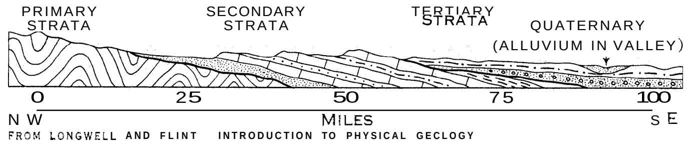

FIG. 9. — DIAGRAMMATIC SECTION ACROSS PART OF WALES AND SOUTHERN ENGLAND TO SHOW GENERAL RELATIONSHIP OF FOUR DISTINCT GROUPS OF SEDIMENTARY ROCKS

invertebrates. representing orders and some families common in present-day seas but strikingly different from any known species or genera now living. Moreover some of the fossil species were found only in single beds or a few successive beds; and those ranging through somewhat greater thicknesses were seen to be replaced in higher beds by different species. Such changes seem commonplace under present concepts of evolution; but the discoverers accepted the facts merely as a rule of thumb to aid in classifying and mapping the thick sections of sedimentary rocks. Within a few decades the work of field classification had progressed widely in Britain and continental Europe and was under way in North America and other continents. The pioneering stages of the study made most rapid strides in Britain. and accordingly many of the widely accepted terms used in stratigraphic classification are of British origin. In its general structure the southern part of Great Britain is rather ideal for an over-all view of the stratigraphic sequence; the bedrock is tilted downward to the southeast and long continued erosion has exposed the strata in general sequence, with progressively older units toward the northwest (fig. 9). (See also PALAEOSTOLOGY .)

The early work on fossil-bearing strata was done northwest of London in the central part of England, where the structure is simple and fossils are fairly abundant. Farther northwest the beds are much folded and faulted, and fossils are scarce in some thick units. Pioneer workers recognized that the deformed strata in western England and in Wales are much older than the beds with simpler structure farther east; and in a first crude classification the deformed rocks of the western sector were designated Primary, the next-younger series Secondary. The pioneers saw. furthermore, that a distinctive thick sequence in southeast England overlies the Secondary sequence and generally has been less tilted; this third major group was called Tertiary. In more recent years the latest deposits of the region, largely unconsolidated alluvium above the Tertiary rocks. were grouped under the designation Quaternary. But meanwhile research on the older fossil-bearing rocks found that the assemblages of fossil forms are progressively more primitive downward in the total sequence, and three eras were recognized. with names based on the comparative biologic records. The Primary rocks were assigned to the Paleozoic (ancient-life) era; the Secondary rocks to the Mesozoic (medieval-life) era; and all younger rocks to the Cenozoic (recent-life) era.

The contagion of stratigraphic research spread widely; large areas in France. Switzerland and Germany were studied and mapped, and subdivisions of the eras gradually took form. In Britain the Paleozoic era was first divided into five periods, each represented by a system of rocks deposited during the time interval. The two oldest of the Paleozoic periods and corresponding systems, named Cambrian and Silurian. had their types in deformed rocks of Wales and the names are of Welsh derivation; the third. Devonian. was named for a section of the rocks in Devonshire; the fourth mas called Carboniferous because the section includes widespread beds of coal; the fifth is not well represented in Britain, and

Bottom right: Fossil fish on a slab of shale formed in a lake during Eocene time. Southwestern Wyoming its name. Permian, is based on a section in the province of Perm in European Russia. Continued research showed the need for some revisions of the scheme for Paleozoic subdivisions. The Silurian system as first defined was disproportionately complex, and the terms Lower and Cpper Silurian came into use. Eventually Ordovician. another term derived from Wales, was substituted for Lower Silurian, and this usage has met general approval. Likewise Carboniferous was split into Loner and Upper divisions, a usage still followed in many countries though in the United States, and generally in North America. corresponding terms are Mississippian and Pennsylvanian. Thus the Paleozoic era has come to have seven recognized subdivisions; each represented by a thick system of strata.

The section of rocks representing the Mesozoic era. less formidable than the Paleozoic section. was divided into the three systems. Triassic, Jurassic and Cretaceous, each representing a period bearing the same name. The term Triassic comes from Germany, where the system is tripartite with a marine unit separating two nonmarine units. The name Jurassic recognizes a prominent development of marine strata in the Jura mountains of France and Snitzerland. Cretaceous, from the Latin *creta,* "chalk," mas first applied to the extensive deposits of chalk forming the prominent white cliffs on both sides of the English channel; eventually the name was applied to the entire thick sequence of strata between the Jurassic beds and those classed as Cenozoic. The Cretaceous is one of the greatest geologic systems, represented by thick marine beds in all continents.

The Cenozoic era in which we live is commonly divided into two periods to which the old terms Tertiary and Quaternary are applied. As in human history. the records in the latest geologic periods are best preserved; accordingly each Cenozoic period is divided into epochs. represented by series of deposits in ahich fossils of species now living increase steadily in number from the oldest epoch to the youngest.

1. Records Earlier Than Paleozoic. — Every continent has wide exposures of rocks older than Paleozoic; generally the Cambrian beds, the oldest of the Paleozoic, are unconformable on the older rocks, nhich in large part are much metamorphosed and intruded by igneous bodies. No basis has been found for systematic classification of these older rocks, which generally are lumped together as Pre-Cambrian. In many places thick sections of unmetamorphosed sedimentary rock are unconformable below Cambrian beds. but nowhere in these Pre-Cambrian sections have any distinctive fossils been found by continued and exhaustive search. Life existed before Cambrian time, but apparently the living forms were simple and without hard parts, such as shell, bone or woody tissue. that could be readily fossilized. The most abundant Pre-Cambrian fossils are deposits of calcareous algae. primitive microscopic plants that gron- in moldlike masses and precipitate from sea water calcium carbonate to build up characteristic globular structures with fine lamination. Trails and burrows of wormlike creatures are found in the Pre-Cambrian Beltian rocks of Montana, objects resembling sponge spicules and an impression suggesting a jelly fish are reported from beds below the Cambrian in the Grand canyon, and abundant carbon. some of it'metamorphosed to graphite, is disseminated through Pre-Cambrian beds in all continents. Geochemical tests of the carbon in rocks of Finland give evidence considered conclusive that the carbon is the residue of organic matter. Apparently life was abundant, at least in the later part of Pre-Cambrian time, but few if any forms had developed the ability to secrete mineral matter for protective parts.

Physical processes operated in Pre-Cambrian just as in later time. The sedimentary rocks. where they have escaped metamorphism, resemble in all respects the deposits of sediments now forming. Marine, deltaic and terrestrial facies are clearly distinguished. Crustal movements were similar to those of later eras; thick sedimentary sections were intensely deformed, metamorphosed, intruded and in part engulfed by igneous bodies. Several successive mountain belts, all eroded to low relief, are recognized in Canada: Finland and other areas with wide exposures of Pre-Cambrian rocks. Dating by radioactive minerals collected in those old mountain zones shows that four-fifths or more of the earth's history had elapsed at the start of the Cambrian period.

2. Logic of the Time Chart. — Boundaries between successive eras. periods and epochs are of course not rigidly fixed. Time runs continuously; we subdivide it. for convenience only. into hours and months, into medieval and modern parts of human history and into geologic periods. If the subdivisions of the time chart had been designed in south Africa instead of Europe, doubtless there would be material differences. Rock exposures are restricted to continents, which have had varied histories of submergence. emergence and orogeny. If the Paleozoic periods had been based solely on evidence found in Great Britain, the limited section there now classed as Permian might have been included with the Carboniferous. In some areas consecutive systems are conveniently separated by unconformities that record uplift and erosion: elsewhere, even on the same continent, rocks of these systems have no sensible physical boundaries and are distinguished only by fossil criteria in comparison with sections taken as standard. Correlation of strata from one continent to another rests in most cases on fossil evidence, which is most trustworthy where sizeable groups of fossil forms are available. Floating forms. like some of the tiny foraminifera. are particularly good time markers as a given species had a brief span of life and became widely distributed by ocean currents. One of the most reliable fossils for correlation in Ordovician rocks was the graptolite, a distinctive floating animal. In later geologic time, species of fishes and other swimming forms were distributed more rapidly than bottom-dwelling animals. Most species of animals have been short lived in a geologic sense?and occurrence of several identical species in widely separated fossil faunas indicates nearly contemporaneous formation of the enclosing rocks.

3. Developments in Life Through Geologic Time. — In the Cambrian period the seas were populated with invertebrate animals of many kinds, all comparatively small and strikingly different from forms now living. though all major groups were represented. The dominant animal was the trilobite. a swimming arthropod. Primitive plants lived in the seas, but apparently the lands were without plants or animals. Primitive fishes appeared in Ordovician time, and in the Silurian period lowly plants and animals made a beginning on land. In Devonian time amphibious animals developed, and the first recorded forests were made up

Geologic Column and Scale of Time

(Ages increase from top downward, as in a sequence of sedimentary rocks)

System and Period	Series and Epoch	Distinctive Records of Life	1000 Years*
		CENOZOIC ERA	
Quaternary	Recent	Modern man	*11*
			>44
	Pleistocene	Early man	1,000
Tertiary	Pliocene	Large carnivores	
	Miocene	Whales, apes, grazing forms	(21,000)
	Oligocene	Large browsing mammals	
	Eocene	Rise of flowering plants	(58,000)
	Paleocene	First placental mammals	70,000
		MESOZOIC ERA	
Cretaceous		Extinction of dinosaurs, floras with modern aspects	130,000
Jurassic		Dinosaurs' zenith, primitive birds, first small mammals.	160,000
Triassic		Appearance of dinosaurs	200,000
		PALEOZOIC ERA	
Permian		Conifers abundant, reptiles developed	(230,000) 235,000
Carboniferous			
Upper (Pennsylvanian)		First reptiles, great coal forests	260,000
Lower (Mississippian)		Sharks abundant	285,000
Devonian		Amphibians appeared, fishes abundant	320,000
Silurian		Earliest land plants and animals	350,000
			(380,000)
Ordovician		First primitive fishes	400,000
Cambrian		Large faunas of marine invertebrates	(440,000) 500,000
		PRE-CAMBRIAN TIME	
		Plants and animals with soft tissues, few fossils	(620,000)
No known basis for systematic division			(1,420,000) (1,800,000) (2,680,000) (3,310,000) 3,500,000-4,000,000

*Italicized figures are from radiocarbon analyses; figures in parentheses are reliable values from radioactive minerals found in rocks that belong in time divisions indicated; plain figures give estimated dates at start of corresponding time units.

of primitive scale trees and large ferns. From that time on the land plants evolved rapidly, and the widespread coal beds of Carboniferous (Pennsylvanian) time are a product of lush forest growth. The first fossils of small reptiles are found in Pennsylvanian beds, and the Permian record shows rapid development of larger reptilian forms. The Mesozoic era was the age of reptiles; dinosaurs appeared in the Triassic period, developed to huge size through Jurassic time, and became extinct before the era ended. Fossils of small mammals are found in Jurassic rocks. and primitive birds with teeth appeared during that period. Forest trees with modern aspect flourished in late Mesozoic time and evolved profusely through the Cenozoic. The Cenozoic era is the age of mammals; many large forms became extinct during the era, and others — notably the horse, elephant, camel and several carnivores — reached their zenith in Quaternary time. The development of man began late in the Tertiary period and proceeded rapidly through the Great Ice Age (Pleistocene epoch).

4. Absolute Dates. — The oldest known fossils of fishes are in Ordovician rocks; mammals first appeared late in the Triassic period; orogeny in the Alpine belt began near the start of the Cenozoic era. These statements give relative dates, but how long ago in years did the events occur? Methods have been developed that can give the answer provided suitable materials can be found in critical places. Radioactive elements, notably uranium and thorium, emit helium gas at a uniform rate. and the end product of disintegration is an isotope of lead. If a uranium mineral taken from fresh granite is analyzed precisely, the ratio between the uranium and its lead isotope uill give the length of time since the granite crystallized. As many as six methods of age determination that involve the element lead are in use. Another method uses the elements potassium and argon; still another, preferred for dating the older Pre-Cambrian rocks, is based on strontium-rubidium ratios. Large numbers of determinations have been made, most of them on minerals in igneous rocks. One rare occurrence of a uranium mineral in a marine sedimentary formation exposed in Sweden dates that formation exactly. The ages of most sedimentary beds can be only approximated by dating igneous bodies older and younger than the beds.

Sample values that fit into the time scale are shown in the time chart. Many granitic bodies cutting Pre-Cambrian rocks have supplied exceptionally good material for analyses. and in the research there is particular interest in exploring the earliest available record of the earth's history. As the studies continue the early frontier is pushed steadily back; within a few years the oldest determined dates increased from a little more than 2,000,000,000 to well over 3,000,000,000 years. These values of course apply to local parts of the crust and are minimal for the age of the earth itself.

Because rates of radioactive disintegration are very slow the methods based on these rates are not suitable for determining dates late in the Cenozoic era. A technique was developed making use of the carbon isotope C^{14}, known as radiocarbon, small amounts of which are present in the carbon dioxide of the atmosphere. Growing tissues of plants and animals incorporate carbon, and durable tissues such as wood retain measurable quantities of radiocarbon long after death of the organism, though the activity of this isotope declines at a known rate. Analyses of carefully selected materials give reliable ages up to about 40.000 years. This method is used for dating events late in the Pleistocene epoch, involving the declining stages of the great ice sheets and some activities of prehistoric man. (See also GEOCHRONOLOGY.)

C. Geologic Mapping

Programs of geologic study and mapping under way in nearly all countries rest on many practical considerations such as soil conservation. water supply. flood control. development of hydroelectric poner, location and recovery of economic mineral deposits. Government bureaus as well as commercial and scientific organizations are active in these geologic programs. In some European countries mapping of the surface geology has been completed to reasonably large scales. though many important details remain for further study. Geologic maps nith scale six inches to the mile are available for a large part of Great Britain; but in all continents great areas are still unexplored geologically or have been mapped only in reconnaissance fashion. Preparation of good topographic base maps is a preliminary to satisfactory geologic study of an area. On such a base the geologist plots boundaries of the important bedrock units which on the completed map are shown with distinguishing patterns or colours. Accurate mapping and description of a complex area usually requires co-operative efforts of students with specialized qualifications; for example, petrologists to study the igneous and metamorphic rocks and paleontologists to identify critical fossils in sedimentary strata. A large organization such as a government geological survey has personnel with diversified training, laboratories equipped for varied analyses and special equipment for use in the field. A development highly useful to field geologists is a wide coverage of air photographs, both vertical and oblique, which serve as a guide in field study and also help in making accurate locations on maps. Many details of bedrock that are obscure on the ground, especially in wooded country, are shown with remarkable clarity on vertical photographs. A technique known as photogeology uses photographs for constructing preliminary geologic maps, which are then checked and corrected by geologists working on the ground.

A completed geologic map identifies the lithology and so far as possible the geologic age of each important unit of bedrock; it represents also important structural details such as directions and degrees of inclination of strata. locations of faults and axial traces of folds. Ordinarily the map is supplemented by vertical sections on which structural features seen at the surface are projected to limited depth, thus helping users of the map to visualize the underground relations. The amount of detail shown on map and sections of course depends on the scale. Small-scale maps may represent the sedimentary rocks merely according to the period and system to which they belong; *e.g.,* Cambrian, Jurassic, Tertiary. But generally each distinct lithologic unit large enough to be shown clearly to the scale of the map is represented. A mappable unit is a formation; ordinarily it consists dominantly of one kind of rock — conglomerate, sandstone, shale, limestone, et~. — and represents an episode in the sedimentary history of the region. One geologic period may be represented on a given map by several prominent formations, each with distinctive physical characteristics and with critical fossils that assign it to a lower, middle or upper position in the parent system.

Thorough study and mapping of the bedrock in a wide region provides a basis for reconstructing physical conditions as they changed from epoch to epoch and period to period of geologic time. Marine strata with distinctive lithologies and fossils reveal the distributions of former seas on modern lands. Margins of those seas are indicated by lateral gradation of marine sediments into littoral or deltaic facies. Advance of a sea across a wide lowland is evident in continuous overlap of littoral and terrestrial sediments by marine deposits; overlap in the reverse order is evidence of a retreating shore line. Emergence of a land for considerable time resulted in erosion, evident in an unconformity at the base of any younger deposits. Fossil records in beds above and below a surface of unconformity may indicate emergence of the land through a short interval or during geologic periods.

Paleogeographic maps are constructed to show the distribution of seas, lands and mountain systems at given geologic dates. Such maps cannot be accurate in every detail, but they show with assurance the major geographic elements and a series of such maps is helpful in tracing the evolution of continents from early Paleozoic time to the present. Some maps show, in addition to geographic outlines. the distribution of rock masses and of major structural elements. such as belts of folding. at given geologic dates; these maps are properly called paleogeologic maps. Such constructions help appreciably in reading the history uritten in rocks of the earth's crust, the chief objective of geologic study.

IV. DEVELOPMENT OF THE SCIENCE

A number of ancient scholars did remarkably accurate reasoning about some aspects of geology, but their individual efforts led to no sustained progress. In the 5th century B.C. the Greek philosopher Herodotus deduced from deposits on the flood plain of the

Nile that "Egypt is the gift of the river"; and from the large number of fossil shells and beds of salt in Egypt that much of the present land had once been under the sea. A century later Aristotle voiced the same conclusion. and offered as an explanation of earthquakes and volcanism the violent escape of winds pent up nithin the earth. These ideas have at least the merit that they attribute such phenomena to natural instead of supernatural causes. Another Grecian philosopher who had the correct scientific attitude was Eratosthenes. who in the 3rd century B C. announced a first approximation of the earth's circumference and correctly cited the abundance of sea shells on land as proof of earlier extensions of the sea. Similar ideas were voiced by Strabo and other Roman scholars. But these brilliant early views did not rest on a solid foundation of detailed inductive study, and they were all but forgotten in the prolonged intellectual hibernation of the middle ages. The world was not yet ready for these advanced ideas. All the fundamentals had to be rediscovered during the intellectual surge that began with the Renaissance. Additional information will be found in biographical entries on persons referred to below.

A. Formative Stage

Leonardo da Vinci, the Italian engineer and artist (1452–1519), was an outstanding representative of the formative stage in geologic science. His views are well reasoned and clearly expressed, they concern a wide range of natural phenomena, and they are based on original observations. He saw evidence that salt is being carried irom lands to the sea, and concluded that "the sea would be more salt in our times than it has been at any time previously.'? He observed that muddy water flowing into marshy ground emerges clear, and reasoned that the sediment would in time change the marsh into dry ground. Marine shells in bedrock iar from the sea and at high altitudes claimed his special attention. In his time a favourite doctrine, dating back to the ancient philosopher Theophrastus (4th century B.C.), held that fossils are merely imitative iorms produced by a "plastic force" in the earth. But Da Vinci observed that fossil shells include representatives of several major groups of living marine animals; that individual shells exhibit all minute details, such as muscle scars, found in shells of living iorms; and that the rock matrix enclosing iossils consists of sedimentary material identical in all respects with deposits now accumulating. He saw no escape from the conclusion that the layers in which the fossils occur represent deposits on an old sea floor. A tenacious doctrine, of his day and later, recognized that fossil shells are indeed the remains of organisms that once lived, but held they were deposited in their present positions during the Noachian flood. Da Vinci exposed the fallacy of this comiortable view by pointing out the shells are not related to the surface of the land but lie in many superposed layers that are consolidated and extend underground, beneath the mountains.

Da Vinci's scientific powers were far in advance of his day; but the spirit of original research that he typifies reappeared at intervals and in different lands, and finally became dominant in geology nearly three centuries aiter his notes were written. Georgius Agricola (1494–1jj5), a German who studied medicine in Italy, saw evidence that mineral veins had been deposited by rising solutions and on returning to the mining community of Joachimsthal, Bohemia, he made a systematic study of ore deposits as a basis for his published works, *De re metallica*. In the following two centuries several able men were concerned with the earth's interior, and speculations in cosmogony became popular. Descartes (1596–16jo) published a classical diagram showing the earth with layered structure based on the postulate of an earlier molten stage. A curious feature of the diagram is the representation of vast water bodies in the earth's crust, in keeping with biblical statements about "waters under the Earth"; presumably this common concept arose from attempts to explain the source of springs, the steady flow of streams and the origin of volcanic vapors. Principles oi ground-water circulation mere not firmly established until the 19th century, although John Ray (1627–1705), an English scientist nearly contemporary with Descartes, published a remarkably accurate treatise on the mechanism of springs. Descartes recognized that great dislocations of the crust had been required to produce the steep inclinations of strata in mountain regions. Though his representation of these movements appears crude irom present viewpoints, at least his interpretation of inclined strata was much more astute than that taught in A. G. Werner's school of mining and geology at Freiberg, Ger., more than a century later.

In spite of difficulties in communication, during the 17th century scholars in several countries of Europe developed geological ideas that were remarkably alike in their modern aspect. The English physicist Robert Hooke (1635–1703) analyzed and discarded the popular doctrine that fossils were "sports of Nature." He demonstrated convincingly that shells in sedimentary rocks are remains of marine organisms, and expressed his conviction that Great Britain and Ireland were uplifted from former positions on the sea floor. At almost exactly the same time Nicolaus Steno (1638–86), a brilliant Dane who spent much oi his life in Italy, was drawing similar conclusions from his observations in lands bordering the Mediterranean. Steno represents the high-water mark in the development of geologic thought in his century. He went far in the study and description of minerals; he understood clearly the meaning oi fossils and the implication of crustal movements given by beds containing marine shells in high mountains; he saw in ancient stratified rocks the analogues of sedimentary deposits then iorming (thus he was a pioneer in stating fundamentals of stratigraphy); and he recognized that running water had been the chiei agent in sculpturing landscapes.

B. 18th-Century Advances

In the 18th century there were increasing signs of maturity and co-ordination in thinking about the earth. Reliance on new field observation rather than time-honoured speculation was coming to be a basic concept. Improved evaluation of evidence was becoming possible through developments in physics, chemistry and biology. Comprehension of the real significance of sedimentary rocks was slowly dawning. French mineralogist Jacques Guettard (1715–86) observed that definite bands of these rocks, each with its own peculiarities, are disposed in a roughly concentric pattern in the Paris basin of France; with patient labour through a large part of his career he traced outcrops of these formations, which he called mineral hands, and delineated them on maps. These may be considered the first true geologic maps, though apparently they were constructed without real appreciation of the sequence in iormations and were not accompanied by sections to show the geologic structure. In connection with his field work—in which he was assisted for a time by the chemist Lavoisier—Guettard collected hundreds of fossils which he made accurate drawings of and described. So iar as we know, however, it did not occur to him that certain fossils characterized each of his mineral bands, or that the fossils mere arranged in a sequence according to age.

Guettard found another problem in the course of field work ior his map in the Auvergne region of central France, which has one of the most superb exhibits of volcanic rocks. Though he had not seen an active volcano, Guettard had read descriptions of Vesuvius and had seen specimens of its dark lava. With this background he recognized the fresh cinder cones and flows oi ropy basalt that are common in the Auvergne landscapes. He identified also older flows, weathered and considerably eroded but still traceable to vents from which they issued. But still he failed to grasp the full implication of the widespread basaltic rocks in central France. Vast quantities of the basalt, older than the cinder cones and forming extensive plateaus, cannot be connected with any visible vents. This older basalt is in nearly horizontal sheets, some of them interbedded with layers of shale. and sandstone that contain marine fossils. In accord with an interpretation common in his day Guettard concluded that basalt was formed primarily by deposition irom aqueous solution; and that local fusion of the primary rock by subterranean combustion of coal was responsible for the cones and lava flows in Auvergne. Fortunately another French scientist, Nicholas Desmarest (1725–181j), closely followed Guettard in study of the region and compared features there with those in volcanic areas of Italy from Padua in the north to Naples in the south. By this comparative study he demonstrated that all the Auvergne basalt is of igneous origin. But Desmarest also made an error that appears glaring from the present point of view. He found that granitic rocks form the basement beneath the basalts of Auvergne, and suggested that the basalt resulted from fusion of the granite. Analytic chemistry of rocks had not pro'gressed far enough to guide him in this aspect of his problem. Not until much later mas it demonstrated that granite and basalt are at opposite poles in a great series of igneous rocks.

Some co-ordination of efforts in geologic research had begun in the 18th century, but one of the major controversies in the history of the science also raged in that period. The school led by A. G. Werner (1750–1817), known as the Neptunists, maintained that nearly all rocks were formed as precipitates from the water of a primitive universal ocean which held in solution great quantities of mineral matter. According to this theory the first precipitate from this ocean crystallized as granite, which thus was the oldest of the rocks in the visible part of the crust; later precipitates formed gneiss, slate, basalt, porphyry and syenite, all of which were classed with granite as Primitive rocks, with world-wide distribution. Later the level of the ocean was lowered (by what mechanism is not made clear), and Transition rocks, including limestone and certain kinds of sandstone, were precipitated. Wherever these deposits were laid down against slopes of emerging mountains, the resulting layers were steeply inclined. As the waters continued to subside, rocks called the *Flötz* ("flat," in contrast to the tilted Transition beds) were deposited at lower altitudes. As Werner soon came to recognize basalt in rocks as young as *Flötz,* his theory provided for recurrent precipitation of basalt. This Wernerian theory, which now seems preposterous, was widely accepted ior several decades; the author was a magnetic teacher, and students from many lands flocked to his classrooms. 'The first geologic map of the eastern United States, published in 1809 by William Maclure, represents the rocks in fcur classes that are essentially Werner's, although Secondary is used instead of *Flötz*.

Geologists in the school opposed to the Neptunists were known as Plutonists because they regarded granite, basalt and rocks of several other kinds as igneous or plutonic in origin. Desmarest belonged to this school, but the real leader mas James Hutton (1726–97) of Edinburgh, whose influence in shaping geologic thought grew as Werner's declined. Hutton spent much of his life making field observations and building inductive concepts which he checked by discussions with acquaintances. The contributions he made to correct understanding of igneous rocks is large; but his outstanding achievement was iormulation oi the uniformitarian principle, which states that natural agents now at work on and within the earth have operated with general uniformity through immensely long periods of time. This principle, accepted as a basic tenet in geologic thought, is diametrically opposed to the doctrine of catastrophism commonly held in Hutton's day, according to which every major feature such as a mountain chain or a deep chasm was formed abruptly, by catastrophic iorces. This roncept was taken for granted during centuries dominated by teaching that only a few thousands of years had elapsed since the earth was created Hutton, reasoning inductively from a wealth oi evidence, concluded that the earth dates from the remote past; he could see "no vestige of a beginning—no prospect oi an end." He recognized that erosion, which is fashioning the valleys oi present landscapes, must have destroyed generations of mountains, and that in the beveled edges oi iolded strata we view "the ruins oi an older world"

Two Germans of the 18th century, J. G. Lehmann and G C. Fuchsel, held advanced views on the meaning oi sedimentary rocks Both realized that the older strata were iormed by water action, and that they must have been nearly horizontal at the time of deposition like their modern representatives These two workers reasoned correctly that strata now steeply inclined indicate large-scale deformation—a view that contrasts favourably with Werner's concept of the Transition rorkc.

C. Strides in the 19th Century

The next great advance in geologic thought and method started with discoveries made independently in England and France near the year 1800. William Smith, a surveyor working on canals in central England, observed that in strata now classified as Jurassic anv limited group of beds had the same assemblage of fossil forms, in whatever part oi England he found it. Higher and lower distinctive units could be recognized in the same way. Using this relationship as a guide, he constructed first a table of stratigraphic units (1799) and later a complete geologic map of England, Wales and part of Scotland, accompanied by a section showing the general structure. About the same time Georges Cuvier and Alesandre Brongniart, two French zoologists well trained in comparative anatomy, worked together in Guettard's old field, the Paris basin; there they found that "fossils are generally the same in corresponding beds, and present tolerably marked differences in species from one group of beds to another." By use of this principle they separated the Tertiary strata of north-central France into natural units, arranged these in chronologic sequence and described them (1808). Three years later they represented the distribution of these units and their structural relations by a geologic map and section.

Discovery oi a vital scientific principle generally is followed by phenomenal progress in research. At the start of the 19th century geology was ripe for the practical application oi paleontology, and the succeeding decades witnessed an amazing development of the science. Christian Leopold von Bucb, one of Werner's ablest students, brought out a geologic map of all Germany in 1824; Élie de Beaumont began a similar map of France; an improved map of England and Wales, and maps of Scotland and Ireland, were published within 20 years. During this period the chart of geologic time divisions and systems of rocks was worked out, geological surveys were established in countries of Europe, and work begun in other continents demonstrated that the stratigraphic principle of Smith and Cuvier has world-wide application. Geology had progressed from a field of large speculation to a science building solidly on factual data. The vast field of paleontology continued its development as an ally of stratigraphy, and doubtless the vista into the past revealed by the study of fossils made some contribution to biological researches on which were based the concept of evolution set forth by Darwin in 1859. At least the reverse effect was dynamic; the doctrine of evolution changed paleontology irom a rule-oi-thumb technique, as practised by some of its devotees, into a science with a firm philosophic foundation. The development of vertebrate paleontology, largely after Darwin's concept was announced, contributed a great store oi favourable evidence.

All aspects of physical geology made great progress in the 19th century. Techniques for studying minerals and rocks were steadily improved; as an example, H. C. Sorby's development of thin-section equipment (*see* Petrology) was a major aid in the systematic analysis and classification of rock materials, leading to fundamental research on problems of their genesis. Swiss students cited evidence that the Alpine glaciers were once much more extensive, and Agassiz went on to demonstrate that Pleistocene icecaps covered great areas in northern Europe and North America. Study of the structure in mountain belts focused attention on the geosynclinal stage in mountain history, first pointed out by James Hall of New York and elaborated by J. D. Dana. Analysis oi the complex structure of the Swiss Alps, begun by Arnold Escher von der Linth, was continued by Albert Heim and others. Charles Lapworth, B. N. Peach and John Horne made their classic study in the northwest Highlands of Scotland. The systematic study of land iorms was advanced and stimulated by the explorations of J. W. Powell and G. K. Gilbert in the Colorado plateau, a region with exceptional exposures oi bedrock with comparatively simple structure. This briei list of distinguished workers and achievements could be amplified many times without recording the full century of accomplishment in geology, which included unspectacular but useful exploration and mapping of large areas in several continents, an appreciable start toward the eventual goal—thorough geologic study of all land areas.

D. Progress in the 20th Century

During the 20th century geology has advanced at an accelerating pace; it has assured foundations, it is aided by growth of kindred sciences and it has the advantage of constantly improving techniques. The discovery of radioactivity and the rapid advances in knowledge of atomic structure have revolutionized some aspects of geologic research. B. B. Boltwood's suggestion in 1905 that lead might be the final disintegration product of uranium started developments in methods for determining ages of minerals. Several independent methods, giving results that can he checked one against another, lead to confident values. X-ray equipment, the mass spectrometer, devices for thermoanalysis and the electron microscope are used for accurate analyses that mould have seemed magical to workers in the 19th century. Geophysicists, using seismic, gravimetric and magnetic equipment, detect important structural elements in the crust. The survey of ocean floors (*see* Ocean and Oceanography), a highly important field in geologic research, is bringing radical changes in some traditional concepts.

GEOLOGY, SOCIETIES OF. This article listing selected geological societies in the world also lists geological surveys in various countries. 'The surveys are agencies of government departments, though in the U.S.S.R. there is a ministry of geology. Societies are free associations of geologists, but in Communist countries they are under government supervision. In some countries there is only a geological survey and no society; in some others there is a society but no survey. The Geological Society of London, founded in 1807, is the oldest association of its kind in the world. The first International Geological congress took place in Paris in 1878, and sessions have been held at intervals ever since. In Britain also was founded the first government geological survey as a result of Charles Lyell's recommendation in 1835. This example was followed by Austria-Hungary (1849), Norway and Sweden (1858) and Italy (1868). In the U.S., the first systematic surveying was started in New York in 1824. The Massachusetts survey of 1830 was imitated by other states, until these schemes were taken over by the U.S. Geological survey in 1879.

Africa.— Egypt has a geological survey which has published reports since 1900; South Africa's survey publishes reports (1910) and its society produces transactions (1896). Surveys in other territories produce similar publications, the Belgian Congo since 1945, French Equatorial Africa (1943), French West Africa (bulletin, 1938; also reports! 1946), Ghana (1925; also memoir since 1929), Kenya (1933), Nigeria (1921), Algeria (publications in six series, since 1885), Mozambique (1937), Federation of Rhodesia and Nyasaland (1917).

Asia.— China has a survey (bulletin and memoirs, 1919) and an institute of geology (bulletin, 1956); India a survey (bulletin, 1950; memoirs, 1856) and a society (journal, 1926); Pakistan a survey (records, 1950); Japan a survey (with reports, 1922; also bulletin, 1950) and a society (journal, 1894); the Philippines also has a society (publishing since 1947).

Australasia and **Oceania.**—In Australia there is a bureau issuing a bulletin (1932) and reports (1948) and a society issuing a journal (1953). New Zealand has a survey which produces reports

(1907) and memoirs (1928).

Europe.—Societies and surveys are to be found in most countries. In Austria there is a geological union with a yearbook (1850) and a society with reports (1908); in Belgium a royal geological society with annals (1874) and memoirs (1898); in Czechoslovakia an institute with bulletin (1921) and transactions (1929). Denmark has a survey (with four series of publications, 1890) and a society (transactions, 1894); France has a survey publishing a bulletin (1889) and memoirs (1893), and a society (bulletin, 1830; memoirs, 1833); the German Federal Republic has an institute (yearbook, 1880) and a society (reports, 1955), and the German Democratic Republic has a service with transactions (1872). In Hungary, the survey publishes annals (1872) and the society journals (1871); Italy's national service and society bring out bulletins (1870, 1882); Norway's survey publishes reports (1891) and its society publishes a journal (1905). Poland has a state institute with a bulletin (1920) and a society with a yearbook (1921); Rumania an institute (annual reports, 1907; also memoirs, 1924); Spain an institute (bulletin, 1874; memoirs, 1873); Sweden a survey, (reports and bulletin 1868) and a society (proceedings 1872); Switzerland a commission (reports, 1899) and a society (notes, 1888); Turkey an institute (publications in five series, 1936) and a society (bulletin. 1947). The United Kingdom's survey produces reports (1896), special reports on mineral resources (1915) and a bulletin (1939); its society publishes transactions (1811), proceedings (1834), a journal (1845) and memoirs (1958). The U.S.S.R. has a ministry of geology and an institute which publishes transactions (1938) and journal (1939).

North America.—The Canadian survey and association publish reports (1904) and proceedings (1947) respectively. Mexico has an institute (bulletin, 1895; and annals 1917) and a society (bulletin, 1905). The United States survey publishes bulletins (1883), water-supply papers (1896), professional papers (1902) and monographs (1890). The Geological Society of America publishes bulletins (1889) and memoirs (1934).

South America.—Argentine's survey publishes a bulletin (1913) and annals (1947), and its society a review (1926). Brazil and Colombia each have a survey with bulletins (1920, 1932). In Peru there is a survey (bulletin, 1945) and a society (bulletin. 1925) and in Venezuela a survey (bulletin, 1951).

GEOMAGNETISM

GEOMAGNETISM (or TERRESTRIAL MAGNETISM) is the natural magnetism of the earth and its atmosphere.

The marvelous property of the magnetism of the earth and its materials has stirred man's imagination since the time of the ancients, when magnetized rocks (loadstones) created wonder and awe as a magical manifestation. Magnets were also an early industrial product of the smithy's forge, since they were made by hammering a piece of steel over an anvil while this steel gradually cooled in the geomagnetic field.

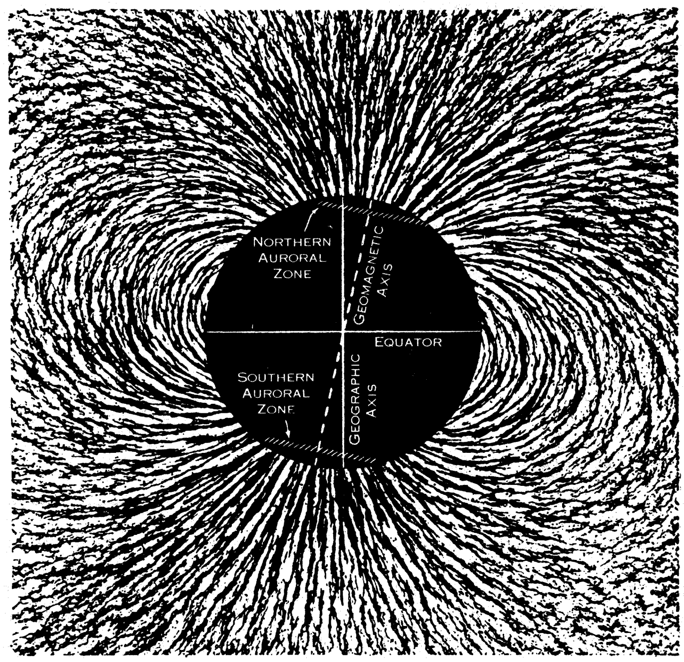
The geomagnetic field is the familiar influence which directs the compass needle. (See COMPASS.) The compass was used for the navigation of ships in quite early times. During the period 1200 to 1600 it gradually became clear that the compass needle directed by the geomagnetic field does not in general point true north, nor does it point to the north magnetic pole. instead it attempts to set itself parallel to the lines of force of the field. These facts and their understanding evolved slowly, according to Crichton Mitchell. but were firmly established by the time of the appearance of the first book on terrestrial magnetism in 1600. This book *De magnete*, by Sir William Gilbert, physician to Queen Elizabeth I is famous because it was also one of the first modern scientific treatises nritten on any subject.

The geomagnetic field also bends the rays of the aurora, and changes in the field are accompanied by changes in the quality of radio transmission.

Since the mid-1930s new techniques available for the study of rock or fossil magnetism have renewed interest in geomagnetism. It has been shown that rocks today still retain some of the magnetism acquired at the time of their formation, perhaps several hundred million years ago. The new data thus made available assist in reconstructing the history of the earth. It is argued that some of these data show how the continents drifted and rotated relative to one another, and relative to the earth's axis of rotation during many millions of years. Lava beds laid down one above the other sometimes show alternating directions of magnetization downward or upward. indicating possible great changes in the geomagnetic field during periods as short as 500 000 years. It has even been suggested on this basis that the earth's magnetic field sometimes reverses itself.

The geomagnetic field may be distorted over mineralized areas, and over oil- or gas-bearing geological structures. This distortion can be measured from low-flying aircraft. The information obtained helps locate new natural resources.

Gilbert showed that geomagnetism arose mainly from inside the earth, and the great German mathematician K. F. Gauss was able to prove this mathematically over 200 years later, about 1830. The character of this field is such as might be expected if it arose mainly from a short, powerful magnet near the earth's centre. The axis of this theoretical magnet is inclined to the earth's axis of rotation, and penetrates the earth's surface at about latitude 78.6° N.. and longitude 289.9° E. in the northern hemisphere, and at latitude 78.6" S., longitude 109.9° E. in the southern hemisphere. These points are called geomagnetic poles, and these theoretical poles, of importance to scientists in studies of the aurora and cosmic rays, should be carefully distinguished from the magnetic poles located by compass or other measurements made on polar expeditions. Because of irregularities in the earth's magnetism the actually ob-



FROM "TERRESTRIAL MAGNETISM AND ELECTRICITY," BY J. A. FLEMING (MCGRAW-HILL BOOK COMPANY, INC., 1939)

FIG. 1.— IDEALIZED MODEL OF EARTH AND ITS MAGNETIC FIELD SHOWING ZONES WHERE AURORAL DISPLAYS ARE MOST FREQUENT

served magnetic poles are located 1,000 mi. or more away from the theoretical geomagnetic poles.

The magnetic compass needle tends to align itself vertically at the observed magnetic pole. so that the magnetic pole is a region where the compass loses its directive force. The north magnetic pole in 1948 was at about latitude 73.0° N.. longitude 260.0° E., on Prince of Wales Island. North America, and was moving northwest at about 5 mi. per year. The south magnetic pole in 1945 was estimated to be near latitude 68.2" S., longitude 145.4° E., near the coast of Antarctica.

At the north magnetic pole the magnetic force is about 0.59 centimetre-gram-second (c.g.s.) unit. Magnetic force has been demonstrated by almost every schoolboy causing a compass needle to move by the action of a steel pocketknife. At the pole this force is directed downward toward the earth's centre. At the south magnetic pole the force is about 0.71 c.g.s. and is directed away from the earth's centre. At the magnetic equator, very roughly about halfway between the magnetic poles. the magnetic force is directed approximately northward. and is roughly half of the polar values, though varying from about 0.30 to 0.40 c.g.s.

The north-seeking end of a compass magnet tends to align itself in the general direction of the north magnetic pole. Local effects caused by magnetic rocks and other irregularities in the earth's magnetism usually are responsible for the fact that the compass direction varies somewhat from magnetic north

The iron or magnetite content of rocks is highly variable and

FIG. 2.— WORLD MAP OF MAGNETIC DECLINATION (D); LINES CONNECT POINTS OF EQUAL VARIATION OF COMPASS FROM GEOGRAPHIC NORTH. 1955

may produce local distortions of the geomagnetic field called magnetic anomalies. Changes in electric currents flowing deep within the earth produce geomagnetic secular or long-term variations, changing the direction and force of the geomagnetic field slowly over the centuries. Secular changes in direction of the compass as great as 30° in 400 years have been recorded. Small changes of compass direction of the order one-fifth of a degree daily in low latitudes also occur, due to electric currents flowing in the ionosphere (*q.v.*). These currents acquire their energy from variable winds produced by the heating action of the sun, and from the lunar and solar tides in the upper atmosphere (see ATMOSPHERE). Magnetic storms, which are irregular changes in magnetic field, sometimes appear on a world-wide scale. They occasionally disrupt radio programs and communications. and are associated to some degree with actively changing sunspots or flares on the sun.

Elements of the Geomagnetic Field.—The magnetic elements comprise D, declination (or variation of the compass), the angle between the direction of an ideal compass and true north, measured positively from north around by east; H, horizontal intensity, the maximum strength of the magnetic force in the horizontal plane; Z, vertical intensity, strength of the force in the geographic vertical; F, total intensity, maximum strength of the force, regardless of direction; I, inclination or dip, angle between direction of field and the horizontal plane; X, strength of the force toward geographic north; and Y, strength of the force toward geographic east. X, Y and Z are vectors, since they have both scalar magnitude and direction. H and F are scalars, and D and I are angles. X is reckoned positive when directed toward the north; Y and D when directed toward the east; and Z and I when directed downward. Also $Y/X = \tan D$; $Y/H = \sin D$; $X^2 + Y^2 + Z^2 = F^2$; etc. The elements usually measured are D, I and H, but possibly D, I and F aboard aircraft or nonmagnetic ships.

Declination (D) is measured by noting the deviation from true north of a magnetic needle suspended by a fine fibre. The direction of true north is obtained from observation of the sun to a precision of 0.1′ or less. using observatory or field type instruments.

Horizontal Intensity (H) is measured by means of a magnetometer (see MAGNETOMETER) in units of length, mass and time (centimetre-gram-second units). The magnet used for D (see above) may be set in motion and its oscillation timed, and then used to deflect another magnet from a known distance. The period of oscillation $T = 2\pi\sqrt{K/MH}$, where K is the moment of inertia of the oscillating system, M its magnetic moment and H the horizontal intensity. When deflecting. the angle of deflection, u, is given by $\sin u = 2M/Hr^3$ in which r is the distance between the two magnets. This gives two equations for solving for M and H, and H is expressed in terms of length, mass and time. Laboratory tests determine necessary small corrections so that H is measured fairly readily to about 0.0001 c.g.s. unit or better. The customary unit is the gamma= 10^{-5} c.g.s. unit.

Inclination (I) is measured with an earth inductor (inclinometer) consisting of a coil of wire rotatable about its transverse axis and connected through a commutator to a sensitive galvanometer. The earth inductor is mounted with its axis of rotation in the magnetic meridian, and is rotated. It is then tilted in this meridian into the direction of dip. in which case no deflection of the galvanometer is noted. The angle of tilt, measured downward from the horizontal plane, is the inclination.

Observation Stations.—At about 100 special stations called magnetic observatories measurements are made as described above. Additional measurements may involve accurately mounted and standardized coils in which components of the geomagnetic field may be neutralized and measured. Total intensity F can be measured using a nuclear magnetic-resonance magnetometer. The magnetic moments of the protons in a material precess about a magnetic field F with an angular frequency $\omega = \gamma_p F$, where γ_p, the gyromagnetic ratio of the proton. is equal to 2.67528 ($\pm$ 0.00006) $\times 10^4$ sec^{-1} per gauss. A coil carrying a surge of current jolts the protons in the material and the frequency of precession is picked up as a signal in the same or associated coil winding to measure the field F. This type of instrument is preferred for measurements made in motion, such as aboard satellites of the International Geophysical year.

At magnetic observatories. widely scattered over the earth, though greatly concentrated in Europe, photographic records of time variations in D, H and *Z* are obtained by means of magnetic variometers. These are calibrated about once a week by means of magnetometers. The D-variometer consists of a magnet usually suspended by a vertical quartz fibre with negligible torsional restraint. The H-variometer is similar, but uses a vertical fibre ahich can be twisted so that the magnet is perpendicular to the magnetic meridian. In the vertical or *Z*-variometer the magnet is balanced against gravity about a horizontal fibre. or consists of a weighted magnet free to rotate on knife edges about a horizontal axis. Electromagnetic versions of these instruments also exist. Portable observatories in highly compact form measure D, H and Z aith accuracy comparable to the permanent observatory type.

Special magnetic survey instruments have been designed and used aboard nonmagnetic survey ships like the "Carnegie," a famous sailing ship destroyed in 1929, and the present day nonmagnetic ship, the "Zarya," used by the U.S.S.R. Special devices have also been developed to facilitate the search for minerals by magnetic methods of geophysical prospecting. These devices note changes in the magnetic field with distance over the earth's surface both at the ground and in aircraft aloft. Extensive surveys by air have been made over both continental and ocean areas.

The geomagnetic field, as part of our natural environment, has been measured at intervals of from 5 to 20 years at some 2,000 stations. called repeat stations. About 80,000 observations of declination (D) have been made at many thousands of points. Probably several million closely spaced observations of other components of the field have been made in connection nith geophysical exploration.

Studies of geomagnetism, as a global phenomenon, are facilitated also by special years in which magnetic observatories are operated at additional and usually less accessible locations, such as in the polar regions. Thus a small network of about 12 stations was added temporarily in 1882–1883, the first International Polar year, many more in 1932–1933 during the second International Polar year and over 100 additional stations during the International Geophysical year, 1957–58.

The Earth's Main Magnetic Field. — Contour lines drawn on maps of the world are prepared at five or ten year intervals by Great Britain, the United States and the Soviet Union, to indicate points of equal magnetic declination, horizontal intensity, vertical intensity. inclination or dip and total intensity. By far the greater part of the magnetic field can be interpreted as due to a short strong magnet at the earth's centre, directed from the north to the south geomagnetic pole. This magnet is tilted at an angle of about 11.5° to the earth's axis of rotation. so that it lies along the geomagnetic axis intersecting the earth's surface in northwest Greenland. in the meridian 69° W. of Greenwich. The approximation to the earth's surface magnetic field, using the same magnet can be improved by moving the magnet, parallel to itself, toward a point determined to be at about 6.5° N. latitude and 162° E. longitude in 1922. It is known that this eccentric dipole has been drifting slowly westward since 1830. This has sometimes been regarded as indicating that the earth's central metallic core. of radius about 2,900 km., does not rotate as fast as does the surface of the earth. In fact, some irregularities in the rotation of the

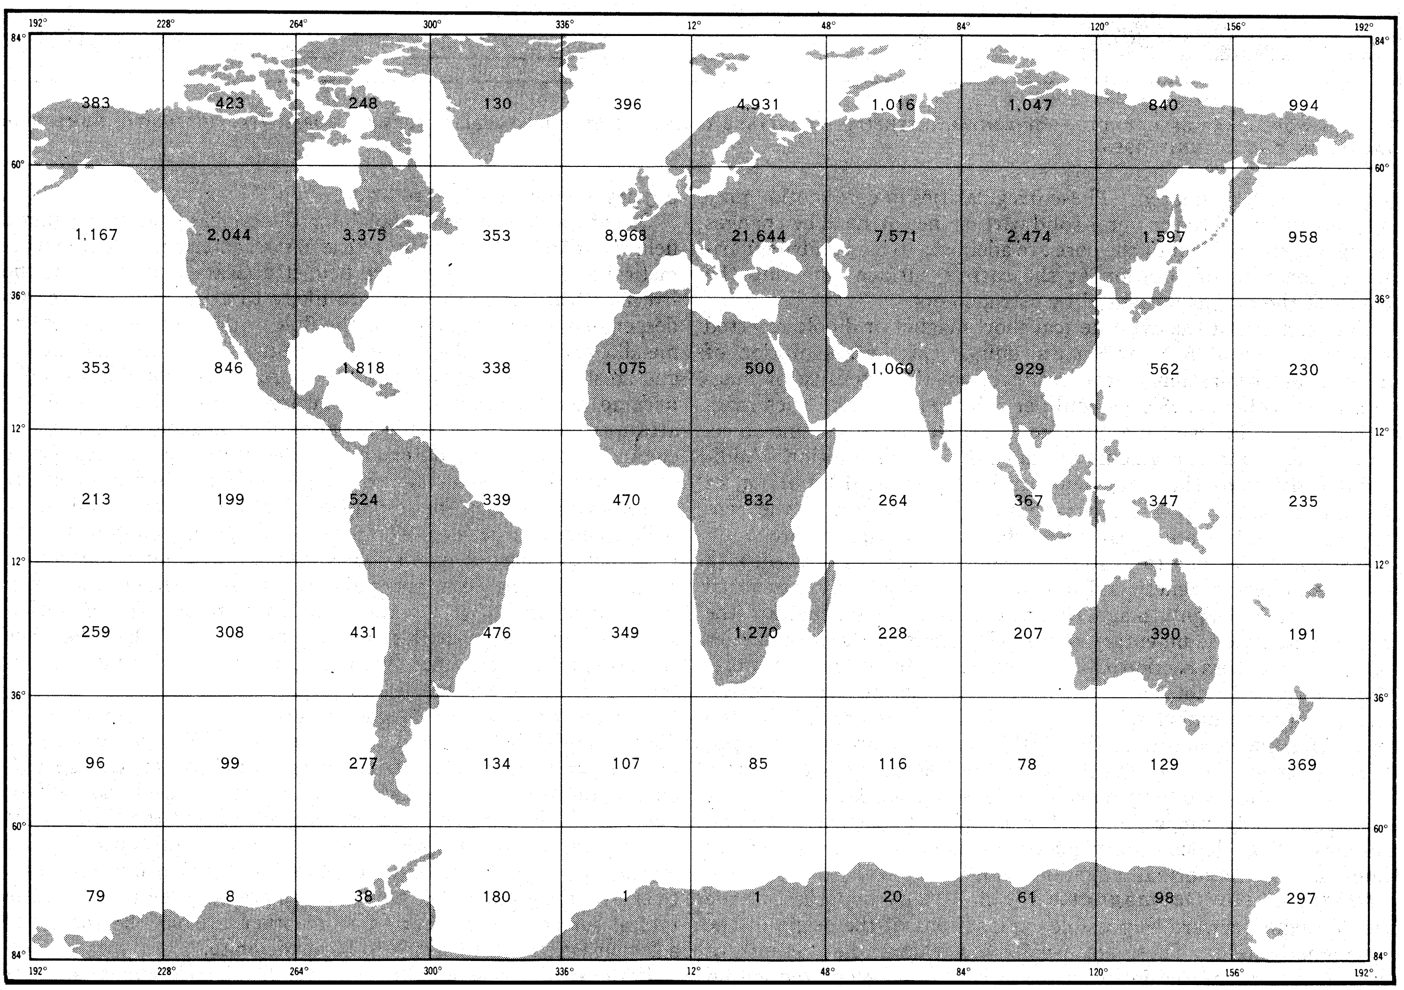

FIG. 3.— WORLD MAP SHOWING APPROXIMATE NUMBER OF OBSERVATIONS OF MAGNETIC DECLINATION TO 1955

FIG. 4.—WORLD MAP OF MAGNETIC HORIZONTAL INTENSITY (H); LINES CONNECT POINTS OF EQUAL VALUES OF HORIZONTAL INTENSITY, NUMERICAL VALUES IN C.-G.-S. UNIT, 1955

core have been estimated. These irregularities in core motion may be communicated to the outer solid part of the earth. The changes in angular momentum of the core are adequate to explain irregularities in the rate of rotation at the earth's surface, affecting the length of the day as measured by astronomers.

The strength of the hypothetical short magnet or dipole referred to above is about 8×10^{25} c.g.s. units. On the assumption of uniform magnetization of the entire earth, the intensity of magnetization is about 0.08 c.g s. unit per cubic centimetre. Such magnetization would result if a saturated steel magnet of volume 80 cc. were imbedded in every cubic metre of the earth's interior. Additional features of the main field can be represented by about 12 radially directed dipoles, each about $\frac{1}{80}$ the strength of the central dipole. and located near the surface of the earth's core.

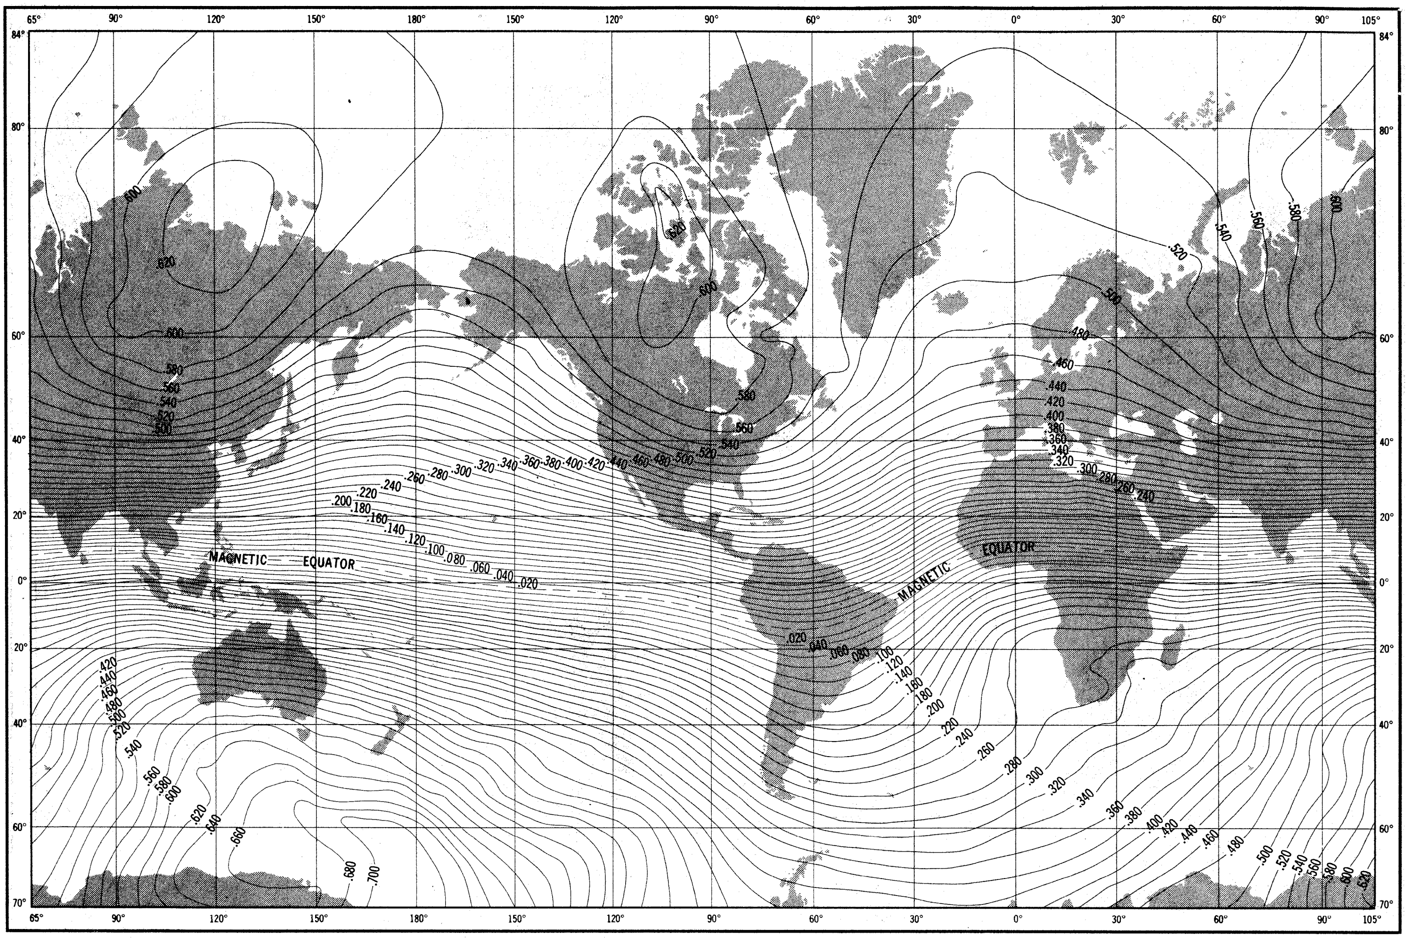
The anomalies due to crustal rocks are usually associated with deposits of ferromagnetic substances. Anomalies are also caused when relatively highly magnetic igneous extrusions penetrate the weakly magnetic sedimentary rocks. The scale of these anomalies may range in cross section from a few metres to 100 km. or more. They are usually not shown on world maps because they are too small, and the number of magnetic observations are usually too few. This fine structure of the earth's surface is about as complicated as the surface topography to which it is usually not related. Local anomalies due to igneous intrusions or irregularities in basement rocks may range from a few hundred to several thousand gammas. Near deposits of magnetic ore values may rise to several times that of the normal magnetic field.

Origin of the **Geomagnetic** Field.—illany hypotheses have been brought fonvard as possible explanations of the origin of the geomagnetic field. These are usually based upon the presence of ferromagnetic material in rocks, electric currents generated within the earth's interior or very tentative suggestions related to the physics of large bodies in rotation.

One of the difficulties of explaining the origin of the geomagnetic field is our lack of knowledge of the earth's interior. From mathematical analysis of the surface field it appears that many of the irregular features of the field are likely to arise from sources no deeper than the outer layers of the fluid within the earth's central metallic core. According to one prevailing set of ideas the mantle and crust surrounding the core are more or less solid and cannot undergo rapid changes within a century or two. For this reason attempts are made to assign the cause of geomagnetism mainly to energy changes in the outer half of the central core. Elaborate calculations have been made showing that if the fluid motions are of suitable type a magnetic field originally quite small might be built up into a large one. The process is fundamentally similar to that in an ordinary dynamo. Heat necessary to move the fluid is supposed to come from the radioactivity of uranium and other metals, and about 1% of the concentration of these materials known to exist in the earth's crust might suffice. It has also been suggested many times that thermoelectric currents might arise, at the junction between mantle and core.

The theory of a ferromagnetic earth. originally proposed by Sir William Gilbert in 1600, seems defective because only a thin outer layer of the earth, about 20 km. thick or so, can be cool enough to be magnetic. Below 20 km. or so the rocks will be nonmagnetic because the temperature will exceed the Curie point of temperature (of the order 400° C. for some substances). The amount of magnetic materials required in this thin crust in order to explain the geomagnetic field is much greater than that found in typical surface rocks. For this and other reasons the theory of a ferromagnetic earth seems to be inadequate.

If the earth's magnetic field is due to electric currents, these have to be more or less continuously generated and maintained.



BY COURTESY OF U.S. HYDROGRAPHIC OFFICE

FIG. 5.— WORLD MAP OF VERTICAL INTENSITY (Z); LINES CONNECT POINTS OF EQUAL VALUES OF VERTICAL INTENSITY. NUMERICAL VALUES IN C.-G.-S. UNIT. 1955

Otherwise once created they would decay to insignificance in the earth's core within a few tens of thousands of years.

Hence it appears that while a part of the earth's magnetization arises from ferromagnetic materials in the earth's crust, it seems likely that the larger part is caused by electric currents flowing near and within the earth's central core, as a consequence of the fluid motions and thermal changes taking place.

Secular Variation.— The geomagnetic field changes continuously with time. The field components may increase or decrease locally. a little each year for a few hundred years. For instance, from 1600 to 1800 the declination in London changed from 11° E. to 24° W.

Horizontal intensity in South Africa decreased about 6,000 gammas from 1843 to 1943, or by an amount almost equal to half the present value of the geomagnetic field there today. Substantial changes with time also occur in other areas, often on a continental or greater scale.

Changes of this kind are too localized to be explained only by motions of the magnetic poles of the earth. and are most simply explained as due to localized changes nithin the earth's interior.

The central dipole term since about 1830 has also been gradually decreasing at a rate of about $\frac{1}{2,000}$ annually. When the surface field of the central dipole is subtracted from the observed surface magnetic field a residual magnetic field is indicated. The pattern of the residual field somewhat resembles that for secular change in general character. This is because the additions year by year of the secular change build up or greatly modify the residual field. Both main and residual field patterns could arise from sources near the surface of the earth's central core. Since secular change in some components of field may be greater than 100 gammas increase or decrease in one year. it Is clear that a substantial residual field can be built up in a few hundred years, if the rate of change is maintained. One possible explanation is that the permanent magnetic field in the fluid core is linked to and participates in the motion of the electrically conducting fluid. This could give rise to a residual magnetic field undergoing continuous change in the core. the magnetic field at the surface of the core being able to penetrate the rigid mantle above so that it is observable at the earth's surface.

Secular Variation in the Geologic Past.— Ferromagnetic particles of rock are loosened by weathering and carried in rivers to the ocean, where they are aligned magnetically parallel to the geomagnetic field as they settle to the bottom. As time goes on the layer thickens and the particles become sedimentary rock. Under special and favourable circumstances the direction of the geomagnetic field millions of years in the past may be determined by laboratory experiments on specimens of the rock. Annual bottom layers or varves may also develop, sometimes in glacial lakes, and from them the direction of the geomagnetic field tens of thousands of years ago may sometimes be estimated. A cooled lava bed may also indicate the direction of the geomagnetic field millions of years ago.

If one accepts the results of this fossil magnetism (and many arguments have been urged favouring such acceptance, as well as many to the contrary) it appears that the geomagnetic field has undergone quite substantial changes in the past. According to some of these measurements the magnetic poles have usually remained not far removed from the earth's axis of rotation. In times earlier than 100,000,000 years ago there is some suggestive evidence of motion of the magnetic poles almost to the equator, which has caused some to speculate that the continents may have drifted and rotated relative to the axis of rotation. There are also indications from the directions of magnetization observed in ancient successive lava flows that the geomagnetic field may even

FIG 6.— WORLDMAP OF SECULAR VARIATION IN VERTICAL INTENSITY. 1889–1955; LINES CONNECT POINTS OF EQUAL CHANGE PER ANNUM. NUMERICAL VALUES IN C.-G.-S. UNIT TIMES 10^{-5}

have reversed at intervals of some hundreds of thousands of years. Independent checks of these conclusions have been hard to find, so that the conclusions though exciting are highly tentative. In any event, the results based upon fossil magnetism provide considerable material for interpreting the remote as well as the immediate past of the earth.

The Solar and Lunar Daily Magnetic Variations.— Besides the large and slowly appearing secular changes there are smaller more rapidly appearing changes during intervals as short as a day or less. Of special interest is the change associated with the position of the sun throughout the day. known as the solar daily magnetic variation, and a somewhat smaller similar effect associated n·ith the position of the moon, known as the lunar magnetic variation. On successive days these variations are usually similar. since the phenomena show regular and typical features. The variations depend mainly on local time, and upon latitude and longitude. The variations also show local features related to the earth's main magnetic field. There is also an important dependence on season related to the position of the sun.

The solar daily variation appears to be caused by two major electric current circulations flowing mainly in the sunlit portion of the upper atmosphere, clockwise in the southern hemisphere (as viewed from outside the atmosphere! and counterclockwise in the northern, moving about the earth n·ith the sun so that their centres remain about 15° longitude ahead of the noon meridian and at about 40° of latitude from the equators. On the dark side weaker and reversed vortices can be designated. These current circulations induce weaker current systems within the earth which may contribute as much as 40% to the horizontal component of the solar daily variation at ground level. In the northern hemisphere these currents produce an increase in the eastward component (Y) of the magnetic field (amounting to more than jo gammas) in the forenoon in middle latitudes and a decrease in the afternoon. The northward component (X) increases to a maximum (of somewhat higher magnitude) just before noon at the equator. undergoes little change in middle latitudes and decreases to a minimum just before noon in high latitudes. The vertical component (Z) shows little change near the equator and in high latitudes but sinks to a minimum just before noon in middle latitudes. In the southern hemisphere these variations are antisymmetric in Y and Z and symmetric in X.

In the northern summer the solar daily variation in the northern hemisphere is about 50% larger in amplitude than the yearly average. this condition being repeated in the southern hemisphere about six months later. At the equinoxes the amplitude is about the same in both northern and southern hemispheres. There frequently appear day-to-day differences which may be as great as 100% in amplitude at any given station and as much as several hours in phase. The amplitude also varies with sunspot cycle and may be as much as 60% greater at sunspot maximum than at sunspot minimum. No connections between fluctuations in the variation field and weather have ever been demonstrated because weather is primarily a local phenomenon and fluctuations in the magnetic variation are more widely manifested.

The solar daily variation also shows irregularities which depend upon regional anomalies of the earth's main field. Because of induced currents diiferences can probably be detected between effects noted over the oceans as compared with less highly electrically conducting land areas. In addition there are effects related to the position of the magnetic equator and to the general lack of symmetry of the geomagnetic field about the earth's axis of rotation.

The lunar daily magnetic variation is also due to electric current circuits within the ionosphere. These circuits migrate about the earth with the apparent motion of the moon, together with their induced current systems flowing within the earth. Instead of the four current circulations noted for the solar daily magnetic variation. eight are noted in the lunar case. of average strength about $\frac{1}{20}$ that of the solar variations. However, the strength of current flow in the current circuits for the lunar variation is greatest on the sunlit side of the earth.

Magnetic Storms.— Strong and erratic variations in geomagnetism known as magnetic storms may last for from a few hours up to several days. During very great storms the compass direction may change by a degree or more in direction and by as much as 2.000 gammas in intensity in middle latitudes; in the polar regions fluctuations in compass direction may be much greater nith changes in horizontal intensity as great as 5,000 gammas in areas beneath intense auroral displays.

Magnetic storms often start suddenly, simultaneous to within a minute or even some seconds over the entire earth. They often start soon after the onset of active solar changes, such as those related to actively changing sunspots. Marked ionospheric storms also occur at times of magnetic storms, and may seriously disrupt radio communications. Polar aurora migrate to lower latitudes and have even been seen from equatorial locations such as India and Samoa. A storm may discharge energy at the rate of more than 2,000,000,000 horsepower for a period of from one to several

FIG 7 — SOLAR DIURNAL VARIATION OF EARTH'S MAGNETISM IN NORTH COMPONENT, *X*, EAST COMPONENT. *Y*, VERTICAL INTENSITY, *Z*, AND INCLINATION, *I*, FOR VARIOUS LATITUDES, WORLD-WIDE AVERAGE FOR SUNSPOT MINIMUM YEAR

hours. Field changes at the rate of 10 to 20 gammas per second have been observed. Telegraphic and telephonic communication over long lines is often interrupted. Under extreme conditions electric power lines have become overloaded, and power transformers burned out by the electric currents produced in transmission lines by the magnetic field changes.

Field of Magnetic Storms.—Magnetic field changes minute by minute are recorded photographically as magnetograms at magnetic observatories. During magnetic storms the field changes with time are particularly irregular, complex and erratic. In spite of this. certain main systematic features are noted when departures in field from normal are averaged at a number of stations, grouped in various latitude belts around the earth.

Data averaged for many storms according to time, beginning with the time of sudden commencement of a storm, provide estimates of the storm-time variation in various geographical belts. The same data averaged according to local time give an apparent diurnal effect. This daily variation varies in amplitude with storm time, more or less in unison with the average storm-time variation. The average storm shows an increase in horizontal magnetic intensity during the initial phase of the storm, followed by a much larger diminution to a minimum in about 24 hours. This minimum

is called the main or negative phase of the storm. There is then usually a slow recovery to a normal value in the course of a day or two. In the vertical intensity (Z) the changes are smaller, and reversed in sign in low and middle latitudes. The average changes in declination (D) are usually smaller and more localized.

The daily variation of disturbance is associated with opposed current circulations. In the northern hemisphere during storms an electrojet (electric current, limited laterally) is directed westward, centred near an early morning hour meridian, near the auroral zone at 60°–70° north latitude. Another electrojet is similarly centred in south latitude. Roughly diametrically opposite at the other side of the polar cap a weaker eastward directed electrojet may be in evidence. along the auroral zone. Electric currents circulate within the ionosphere completing their current circuits in low latitudes and across the polar caps. The height of current near the auroral zone has been found to be near the 100 km. level; and this has been confirmed directly by rocket by J. A. Van Allen during the International Geophysical year, 1957–58. The height of the storm-time currents may be partly at the same level. and is the subject of further investigation. It is clear from associations with cosmic rays that some substantial electric currents flow at very high levels, and beyond the atmosphere. Some very intense storms have current patterns enduring for only a few hours, and it seems to be established that the very great magnetic storms tend to go through their initial, main and recovery phases more rapidly.

Other Forms of Magnetic Disturbance.— In addition to the daily variations and magnetic storms geomagnetic phenomena include sudden commencements. bays, pulsations and solar-flare effects on the geomagnetic field known as crochets.

Sudden commencements appear more or less simultaneously over the entire earth, within one minute or less. The sudden commencement consists mainly of an abrupt increase of horizontal intensity of from several to several hundred gammas, effects usually being largest in equatorial and especially in the polar regions. Examination of some cases from the Polar year, 1932–33, have shown that the effect can be traced or associated with a polar electrojet, at least in part. In equatorial regions, as in the solar daily magnetic variation, an added electrojet at the magnetic equator is sometimes noted on the sunlit side of the earth. In many cases the polar effects are predominant, and in others there may be a preliminary reversed impulse. In some locations, such as the magnetic equator, the average amplitude of sudden commencements is closely related to the amplitude of the solar daily variation. In some cases, at least, polar electrojets seem to provide a fairly localized current distribution during sudden commencements.

Other electrojets appear in the polar regions near or along the auroral zone, where they grow to maximum strength in about an hour and then decay. These current sources produce an intensification of the geomagnetic field lasting a few hours and called magnetic bays. They are often accompanied by local blackout of radio communications, and sometimes but not always appear fairly closely linked with auroral displays.

The geomagnetic field also undergoes sinusoidal or nearly sinusoidal pulsations. Those of higher frequency, of the order several thousand cycles per second, originate in lightning discharges, and are propagated from northern to southern hemisphere, or vice versa, via the lines of force of the geomagnetic field, usually being several earth radii above the earth at the highest point in the plane of the magnetic equator. They are reflected successively from northern to southern hemisphere, each time they reach ground level, with some reduction in frequency following each reflection. They show a diurnal variation in frequency of occurrence according to universal or Greenwich time, and are believed associated with the world-wide distribution of thunderstorms. When heard as an auditory signal on radio earphones the pitch is reduced after each transmission and return from the opposite hemisphere. For this reason they have been called whistlers. They provide a means of study of regions several earth radii above the earth.

Other pulsations of much lower frequency occur with periods of some seconds to several minutes. The trains of signals may last for minutes or for hours. In some cases these are world nide and may be manifestations of hydromagnetic naves. In others they appear to correspond to locally intense fluctuations in the intensity or distribution of strongly localized sources such as the electrojets along the auroral zone; in fact. they sometimes precede the appearance of the electrojets of magnetic bays. and depend upon local time. Other pulsations are more frequent at certain hours of universal time, and therefore conditions favouring their occurrence may depend upon the orientation of the terrestrial dipole to the sun.

During solar flares the increased solar radiation augments the electric conductivity of the region in which electric currents producing the solar and lunar daily magnetic variations flow. The resulting pulse in magnetic field, due to strengthening of the current systems lasts from some minutes to several hours and is called a crochet. It is accompanied by sudden ionospheric changes and by the fade-out of radio communications at some frequencies. Since crochets near the magnetic equator appear to be larger when the solar daily magnetic variation is larger they provide statistical evidence of day-to-day fluctuations in upper air winds, on the basis of the dynamo theory.

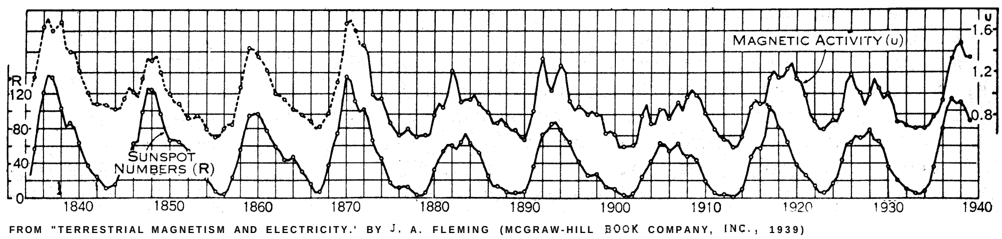
Mathematical Analysis of the Field.—Mathematical analysis has shown conclusively that the major part of the magnetic field is due to causes within the earth. It may be assumed that the components of the magnetic field may be expressed to a sufficient degree of accuracy as the appropriate derivatives of a magnetic potential expressed in terms of a spherical harmonic series *(see* SPHERICAL HARMONICS) of the form

$$V=a\sum_{n=0}^{\infty}\sum_{m=0}^{n}[(a/r)^{n+1}(I^m_{n,c}\cos m\lambda+I^m_{n,s}\sin m\lambda)\\ +(r/a)^n(E^m_{n,c}\cos m\lambda+E^m_{n,s}\sin m\lambda)]P^m_n$$

a being the radius of the earth; P^m_n, the associated Legendrian of degree n and order m; the I's and E's. the coefficients of the particular harmonics; and r and λ, with θ, the spherical co-ordinates, radius, longitude and polar distance, respectively. In this expression the portion containing a/r (and including the coefficients I) satisfy Laplace's equation everywhere outside the sphere $r=a$ and hence must be due to magnetic origins within that sphere. The portion containing r/a (and including the coefficients E) satisfy Laplace's equation everywhere inside the sphere $r=a$ and hence must be due to magnetic origins outside that sphere.

The magnetic elements most frequently used in mathematical analysis, evaluated at the earth's surface where $r=a$, are given by

$$X=(1/a)\partial V/a\partial\theta=\sum_{n=0}^{\infty}\sum_{m=0}^{n}[(I^m_{n,c}+E^m_{n,c})\cos m\lambda+\\ (I^m_{n,s}+E^m_{n,s})\sin m\lambda]\partial P^m_n/\partial\theta$$



FROM "TERRESTRIAL MAGNETISM AND ELECTRICITY," BY J. A. FLEMING (MCGRAW-HILL BOOK COMPANY, INC., 1939)

FIG. 11.— VARIATION IN SEMIANNUAL MEAN VALUES OF MAGNETIC ACTIVITY (UPPER CURVE) COMPARED WITH CORRESPONDING VARIATIONS IN SUNSPOTS (LOWER CURVE), 1835–1940

$$Y=-(1/a\sin\theta)\partial V/\partial\lambda=-\sum_{n=0}^{\infty}\sum_{m=0}^{n}[-m(I^m_{n,c}+E^m_{n,c})\sin m\lambda+m(I^m_{n,s}+E^m_{n,s})\cos m\lambda]P^m_n/\sin\theta$$

$$Z=\partial V/\partial r=\sum_{n=0}^{\infty}\sum_{m=0}^{n}\{[-(n+1)I^m_{n,c}+nE^m_{n,c}]\cos m\lambda+[-(n+1)I^m_{n,s}+nE^m_{n,s}]\sin m\lambda\}P^m_n$$

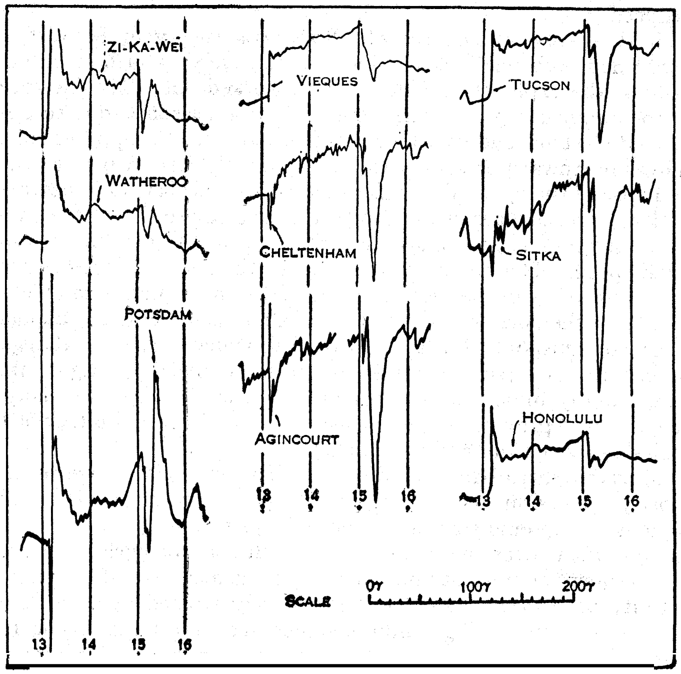
The sums of the coefficients $I^m_{n,c}+E^m_{n,c}$ and $I^m_{n,s}+E^m_{n,s}$ may be obtained by fitting either the observed values of X or of Y by least squares or some other method. If the field is derivable from a potential the values obtained from either the X or the Y data should be identical. Similarly the values of the differences $-(n+1)I^m_{n,c}$ and $-(n+1)I^m_{n,s}+nE^m_{n,s}$ may be obtained from the observations of Z. Thus, by an analysis of the observations of X or Y and of Z, a means is afforded for separating the field into portions due to internal and external causes by solution of simultaneous equations involving the above-mentioned sums and differences.

Gauss concluded from an analysis of the data available in 1835 that the main field was predominantly, if not entirely of internal origin. Later analyses by A. Schmidt (1885), L. A. Bauer (1922) and F. Dyson and H. Furner (1922) showed an external field amounting to several per cent of the internal field although the latter investigators attributed the results to uncertainties in the observations. Assumption that the external field is purely a mathematical fiction would require the admission of errors in the magnetic data amounting to about 1° in inclination and consistent with regard to sign. Since external magnetic fields are definitely present in the diurnal variation and magnetic disturbance fields (*see* following sections) there is no reason to doubt they may be present in the permanent field as well. However, considerable uncertainty must be attached to the assigned magnitudes of the external field. E. H. Vestine and I. Lange in their analysis of the main field for 1945 found an external part of less than 1% of the whole as did H. F. Finch and B. R. Leaton in 1957.

In the more recent analyses differences appear in the values of the coefficients, accordingly as they were determined from the observations of X or of Y, which appear to be too large to be attributed to errors of observation. But if the earth's field is derivable from a potential the two sets of coefficients should agree to within the accuracy of the observations. This discrepancy is sometimes interpreted as indicating the presence of a nonpotential field, that is one in which curl $H\neq O$. Such a field might be due to vertical electric currents flowing between the earth's surface and outer space. Magnitudes of these hypothetical currents are about 0.2 amperes per square kilometre at their maxima, 10^4 times as great as the normal atmospheric electric currents (*see* ELECTRICITY, ATMOSPHERIC). Great irregularity exists in the distribution of these currents; in some regions they are directed upward and in others downward. Their existence has not been verified by other physical observations. Present thought is inclined to regard them as mathematical results arising in attempting to fit faulty data to a rigid mathematical frame; in fact, there is a trend among magnetic cartographers to adjust their maps so that curl H = O, thus implicitly denying existence of the so-called nonpotential field, a procedure used in the U.S. hydrographic office charts for 1945.

Other applications have been made of potential analyses to the solar and lunar daily magnetic variations by many writers. Since the number of stations is not great enough to describe the details of the dependence of the solar daily variation upon longitude. dependence upon local time is assumed. The time variations at the available stations are expressed in amplitude and phase by Fourier series. The coefficients found are then conveniently expressed in spherical harmonics as in the case of the earth's main field, using least square methods for obtaining the best fit.

It was found that both the solar and lunar daily variations originate mainly above the earth, with a minor portion, about one-third originating within the earth. The latter is ascribed to induced earth currents, and its time phase and amplitude used in conjunction with the observed external part derived from the spherical harmonic analysis has yielded estimates of the electric conductivity deep within the earth's interior. At about 250 km. depth this comes out



FROM "TERRESTRIAL MAGNETISM AND ELECTRICITY," BY J. A. FLEMING (MCGRAW-HILL BOOK COMPANY INC 1939)

FIG. 12.— PHOTOGRAPHIC RECORDS OF SUDDEN COMMENCEMENT OF GREAT WORLD-WIDE MAGNETIC STORM AT 13 HOURS 09 MINUTES GREENWICH MEAN TIME, MAY 13, 1921; VERTICAL LINES SHOW HOUR MARKS

to about 4×10^{-13} electromagnetic unit. There is an increase with depth, as inferred from similar studies of storm data, so that values are reached as great as 10^{-11}, near 1,000 km. depth, and about as conducting as sea water. This is much higher than the electric conductivity of surface rock, which is as low as 10^{-16}, and much lower than copper, which is 6.1×10^{-4} electromagnetic unit.

The first satisfactory explanation of the solar daily variations was offered by Balfour Stewart in his article in the *Encyclopædia Britannica* in 1878, which was a classic in geomagnetism. His ideas have been elaborated further by A. Schuster in 1889 and 1908, and by S. Chapman in 1919, and it appears now certain that upper air winds produce the solar and lunar magnetic variations. These are partly a consequence of solar heating, and of tidal action (*see* METEOROLOGY; TIDES). These winds move electrically-conducting air across the lines of force of the geomagnetic field, thereby generating currents producing the daily variations. In a narrow belt above the magnetic equator the motion of the ions and electrons is such that the transmission of current is more efficient, thereby giving rise to an electrojet directed from west to east, centred near the 11 A.M. meridian. By firing a rocket carrying a magnetometer through this current layer, the height of the overhead current layer, near the equator, has been found to be around 95 km.

At the magnetic equator the day-to-day differences in the solar daily variation are shown to depend mainly upon the size of the electrical driving forces in the E-region, and not upon day-to-day differences in electric conductivity. This is because these driving forces are shown to lift the ions upward in unison in higher ionized regions known as the F-region as predicted by the dynamo theory. The day-to-day variability of these generating winds does not seem to vary much with sunspot cycle. A similar but smaller effect of this kind is noted in the E-region itself.

The height of the current layer responsible for the lunar daily variation is not established, but may be near the same level as for the solar case, which is the E-region. The upper more extensive F-region is less suited ordinarily to the generation of electric currents because the geomagnetic field there is able to seriously restrict the flow of current across this field. In the denser E-region the electric current carriers collide so frequently with the gas constituents that continuous effects of the geomagnetic field are much reduced.

It thus appears that the old *Britannica* theory of Stewart is confirmed both qualitatively and quantitatively, though some details of the explanation remain to be worked out. The increase in the amplitude of the variations with local season is due to improved electric conductivity in the ionosphere as the apparent sun moves northward or southward. and probably also in part to the response of the upper air winds to the associated changes in heating action. The changes in amplitude from one day to the next, sometimes as great as 100%, are mainly due to day-to-day changes in wind speed. The dominant influence of the sun is attested since the correlation of the yearly mean of the noon minus midnight values of the solar daily variation is about 0.99 with the annual means of sunspots. For this reason the magnetic changes, though of interest as a part of our environment in their own right, are continuously monitored as an index of solar activity. Actually, they seem to provide a direct measure of the X-ray and ultraviolet emission by the sun and its corona.

Magnetic disturbance manifests itself over a wide range in intensity; the term magnetic storm designates the more disturbed periods. Magnetic storms are more frequent and intense around or somewhat after the maximum of each sunspot cycle, and are less frequent at sunspot minimum. Various measures of magnetic activity have been devised and extensively studied because they are useful in predicting conditions affecting radio transmission to great distances. For instance, use is made of an international magnetic character figure C. C is 0. 1, or 2 according to whether or not the photographic record or magnetogram for the day is magnetically quiet, slightly disturbed or greatly disturbed, and becomes the international figure when averaged for many stations. A more quantitative measure is the u-measure based on successive day-to-day differences in horizontal intensity averaged for equatorial stations. A third measure is the K-index, introduced by J. Bartels in which one of a series of numbers from one to nine is given to each three-hour interval of each day at each participating magnetic observatory, according to the departure of any element from smooth undisturbed conditions. A fourth measure is the Q-index, rather similar to the K-index, except for being based upon ranges observed during 15-minute intervals. It is found that K-indices from 0 to 4 show little or no correlation with sunspots, whereas larger K-indices are correlated.

Magnetic disturbance is more marked at the equinoxes, the value being about 30% higher than at the solstices. Storms also tend to recur every 27 days, a consequence of the solar rotation period. Some sequences have persisted for as many as 17 solar rotations.

In 1896 K. Birkeland proposed that magnetic storms and aurora were caused by solar particles penetrating the earth's atmosphere. C. Stormer computed many paths of such solar particles in the earth's neighbourhood. Chapman and Ferraro calculated the magnetic effects of solar streams near the earth, as affected by their motion and interaction with the geomagnetic field. They concluded that the earth's magnetic field would carve out a hollow in the advancing solar stream.

Electric currents induced in the face of the advancing stream would provide geomagnetic effects, during the initial phase of a magnetic storm. Later a current ring formed from the solar stream at a distance of several earth radii, might contribute during the main and recovery phases of the storm.

It seems to be generally agreed that particles in motion along the geomagnetic field contribute to the aurora and polar disturbances. The polar electrojets show that electrically polarized gases appear in the auroral regions, but the manner in which this electric driving force is generated is obscure. However, it seems likely that positively and negatively charged particles are maintained in a slightly separated state along both a vertical and horizontal direction, in the low ionosphere. The electric field produced can contribute substantially to the production of electric currents throughout the ionosphere during storms, and serve to raise, lower and otherwise transport the higher ionosphere, as

well as contribute to the motion and shifting of auroral rays. Differential penetration of incoming particles, accompanied by X-rays penetrating levels of only a few tens of kilometres is undoubtedly important near the auroral zone, and possibly elsewhere as well; as a very simple partial theory of storms and disturbance the vertical polarization can produce surges of storm-time type, and horizontal polarization can produce many changes in the form of bays or of the diurnally varying type. In addition, there appear to be fields of storm-time variation type originating in regions beyond the atmosphere.

There may also be dynamo effects associated with winds in auroral regions, due to heat transport from solar streams and the hot solar corona enveloping the earth.

During the International Geophysical year (*q.v.*) measurements made by earth satellites and lunar probes showed that the earth was encircled or ringed by radiation belts. An intense equatorial belt about 2,000 km. above the earth is caused by high-energy radiation from space. An outer belt, mainly of energetic electrons is of greatest strength at about 6 earth-radii. The electrons and protons in these belts undergo spiraling motions along the lines of force of the geomagnetic field, itself believed to be distorted at times by clouds of hot solar gases exerting a dragging action upon the field lines. The electrons and protons also drift across the field, and around the earth, and may penetrate into polar regions at times. An explosion of an atomic bomb in the ionosphere confirmed this conclusion. Solar gases also may compress or drag terrestrial field lines to produce an accelerating action upon protons and electrons. This may cause them to leave the radiation belts and penetrate into auroral regions, especially at about the observed local midnight. *See* also MAGNETISM; METEOROLOGY.

GEOMETRES, JOHN (JOHN KYRIOTES) (fl. 10th century), Byzantine poet, official and bishop is known for his short poems in classical metre. He held the post of protospatharios ("officer commanding the guards") at the Byzantine court, and later was ordained priest, finally becoming metropolitan of Melitene in eastern Asia Minor. His poems, on both contemporary politics and religious subjects, are distinguished by considerable charm and appreciation of natural beauty. His prose works, largely unpublished, include a life of the Virgin Mary, consisting of a series of sermons for her feast days, and an encomium of the apple.

GEOMETRIC PERIOD, in architecture. the earlier of the two sections into which the Decorated period (*q.v.*) of English Gothic (see GOTHIC ARCHITECTURE) is usually divided, comprising roughly, the last half of the 13th century.

GEOMETRIC SOLIDS: see SOLIDS, GEOMETRIC.

GEOMETRIES, FINITE. The incidence axioms of projective geometry require that every line contain at least three points. If the number of points on one line is a finite number, say $n+1$, then every other line contains the same number of points and we say that the geometry is of order n. If the geometry is of dimension three or higher, then from the basic theory of projective geometry, it is Desarguesian and may be represented by co-ordinates from a division ring D. In a geometry of order n, the division ring contains exactly n elements. By a well-known theorem of J. H. M. Wedderburn, D must be a finite field, $GF(p^r)$, where $n = p^r$, p being a prime. In the k-dimensional geometry over $GF(p^r)$, designated as $PG(k,p^r)$, a point has a homogeneous representation $(\lambda x_0, \lambda x_1, \ldots, \lambda x_k)$ where $x_0, \ldots, x_k$ are fixed elements of $GF(p^r)$, not all zero, and λ ranges over all nonzero elements of $GF(p^r)$. The points whose co-ordinates satisfy a linear equation

$$c_0x_0 + c_1x_1 + \ldots + c_kx_k = 0$$

where the equation is not identically zero, form a subspace of $k-1$ dimensions; those satisfying m independent linear equations form a subspace of $k-m$ dimensions. (See ALGEBRAS [LINEAR]).

Finite projective planes include the Desarguesian planes $PG(2,p^r)$ but there are also a number of types of non-Desarguesian finite planes. All known planes are of prime power order. These include planes described by O. Veblen and Wedderburn in a paper written in 1907. In these planes there is a system of co-ordinates V with n elements. In V there is an addition $a+b$ and a multiplication ab satisfying the following conditions:

- $V1$. Addition is an Abelian group with a zero element 0;
- $V2$. $(a+b)m = am + bm$;
- $V3$. If $a \neq 0$, equations $ax = b$ and $xa = c$ have unique solutions for x;
- $V4$. There is a unit 1 such that $1b = b1 = b$ for every b;
- $V5$. If $r \neq s$, then $xr = xs + t$ has a unique solution for x.

From V we may construct a plane a whose points consist of $n+1$ infinite points designated as (m), m running over the n elements of V and a further point (∞) and also n^2 finite points (x,y) with x and y running over all elements of V. The lines are: L_∞ containing the $n+1$ infinite points; for each c of V a line containing (∞) and all points (x,y) with $x = c$; for each m and b of V a line containing (m) and all points (x,y) whose co-ordinates satisfy $y = xm + b$. The above conditions imply that $n = p^r$, p a prime, since multiplication induces automorphisms on the additive group permuting all nonzero elements transitively. A nearfield is the special case of a Veblen-Wedderburn system in which multiplication forms a group. The fields $GF(p^r)$ are of course special cases of nearfields. Replacement of the distributive law $V2$, $(a+b)m = am + bm$, by the other distributive law $V2'$, $m(a+b) = ma + mb$, gives the family of planes dual to the Veblen-Wedderburn planes.

The plane of order 2 (known as the Fano plane) contains seven points. If the points are represented appropriately by the numerals 1, 2, 3, 4, 5, 6, 7 then the lines are given as the columns of the following array:

$$\begin{array}{ccccccc} 1 & 2 & 3 & 4 & 5 & 6 & 7 \\ 2 & 3 & 4 & 5 & 6 & 7 & 1 \\ 4 & 5 & 6 & 7 & 1 & 2 & 3 \end{array}$$

This is the Desarguesian plane and may be co-ordinatized by $GF(2)$ the field of the residues 0 and 1 modulo 2. Here we may take $1 = (\infty)$ $2 = (0)$, $4 = (1)$ $3 = (0,0)$, $5 = (1,0)$ $6 = (1,1)$ $7 = (0,1)$. The line $y = x + 1$, for example, contains the points 4, 5 and 7. It will be noticed that, permuting the points 1, . . . , 7 cyclically in this order, the lines are also permuted cyclically. This permutation is, therefore, a collineation. This is an instance of a general theorem proved by J. Singer, namely, that every $PG(k,p^r)$ possesses a cyclic collineation of order $(q^{k+1}-1)/(q-1)$, $q = p^r$, permuting points and hyperplanes regularly.

A nearfield of order 9 exists whose elements are of the form $au + b$, a, $b \in GF(3)$, *i.e.*, a, b residues modulo 3. Addition is given by the rule $(a_1u + b_1) + (a_2u + b_2) = (a_1 + a_2)u + (b_1 + b_2)$. The multiplication of the eight nonzero elements is the quaternion group and is determined by the rules $(au+b)c = c(au+b) = acu + bc$, $c \in GF(3)$, $(au+b)^2 = -1$, $a \neq 0$ together with the distributive law $V2$. This yields by the rules above the Veblen-Wedderburn plane (and with the opposite distributive law $V2'$, also the dual plane). This plane and its dual are distinct and are non-Desarguesian.

There is known one other non-Desarguesian plane of order nine, which is self-dual. This mas given originally by Veblen and Wedderburn in their 1907 paper and in 1957 Hughes found an infinite family of finite planes including this one. The 91 points are A_i, B_i, C_i, D_i, E_i, F_i, G_i, $i = 0, 1, \ldots, 12$ modulo 13. Seven representative lines are:

L_0	A_0	A_1	A_3	A_9	B_0	C_0	D_0	E_0	F_0	G_0
M_0	A_0	B_1	B_8	D_3	D_{11}	E_2	E_5	E_6	G_7	G_9
N_0	A_0	C_1	C_8	E_7	E_9	F_3	F_{11}	G_2	G_5	G_6

R_0	A_0	B_7	B_9	D_1	D_8	F_2	F_5	F_6	G_3	G_{11}
S_0	A_0	B_2	B_5	B_6	C_3	C_{11}	E_1	E_8	F_7	F_9
T_0	A_0	C_7	C_9	D_2	D_5	D_6	E_3	E_{11}	F_1	F_8
U_0	A_0	B_3	B_{11}	C_2	C_5	C_6	D_7	D_9	G_1	G_8

The rest of the 91 lines are given by adding 1, . . . , 12 modulo 13 to the subscripts of both points and lines.

The most striking result known on finite planes, without any further hypothesis, was found by R. H. Bruck and H. J. Ryser in 1949. This asserts that if $n = 1, 2 (\text{mod } 4)$, there cannot be a plane of order n unless n can be expressed as a sum of two integral squares, $n = u^2 + v^2$. In particular no plane of order 6, 14, 21, 22 exists and infinitely many other orders are excluded by this rule. In 1956 A. M. Gleason proved that a finite plane, in uhich every set of four points not on a line lies in a Fano subplane, is necessarily Desarguesian. T. G. Ostrom and A. O. Wagner have shown that if the collineation group of a finite plane is doubly transitive on points, the plane is necessarily Desarguesian.

GEOMETRY, one of the three principal branches of mathematics (the other two being algebra and analysis), may be described as the branch which deals with the properties of space. Its most elementary part is known to every schoolboy under the name of plane and solid geometry, the former dealing with the properties of figures in a plane, the latter nith the properties of figures in space (of three dimensions). These two subjects form. however, only a small part of geometry as the term is now understood.

The present article attempts, first, to describe briefly these two elementary topics in geometry, and secondly, to give the reader some conception of the content of geometry as a whole with references to other articles where more detailed information on the various topics may be found.

The first section of this article, a general survey of the field of geometry, covers subjects such as Greek geometry, construction problems, spaces of more than three dimensions, imaginary elements, differential geometry, projective geometry, inversion geometry, topology and primitive elements of space.

'The section on the history of geometry discusses ancient empirical and demonstrative geometries. developments during medieval times and the Renaissance. the invention of analytic geometry, modern synthetic geometry and the foundations of geometry.

The final section deals with the subject of non-Euclidean geometry

GENERAL SURVEY

Like most other branches of knowledge, geometry arose originally in response to man's practical needs. The word "geometry" (Gr. $\gamma\eta$, earth and $\mu\epsilon\tau\rho o\nu$, measure) means "earth measurement."

Indeed, the subject seems to have had its birth in ancient Egypt. where the periodic inundations of the Nile made the surveying of the land for the re-establishment of boundary lines a necessity. This early empirical geometry consisted merely of a number of crude rules for the mensuration of various simple geometric figures; for the laying out of angles, especially right angles, etc. (See below for details as to history.)

The ancient Greeks developed this crude beginning into the science which is now studied in the schools under the name of demonstrative geometry, the plane and solid geometry already mentioned. This form of geometry depends on the observation that the propositions of geometry are logically inter-related; *i.e.*, that, if certain propositions are granted, certain others can be proved as logical consequences of those assumed. This suggests the possibility of arranging all the propositions in a sequence such that every proposition in the list, after a certain one, is a logical consequence of some or ail the propositions that precede it. The first comprehensive and systematic attempt to exhibit the propositions of geometry in such a sequence, which has come down to us, is one of the most famous works in all literature, the *Elements* of Euclid (*q.v.*) of Alexandria (*c.* 300 B.C.). This work consists of 13 books, the first six and the last three of which are devoted to plane and solid geometry respectively. More or less literal translations of this ancient work were used to within a generation ago as textbooks in the public schools of England. The textbooks of the present time in all countries are adaptations of Euclid's Elements designed to meet the pedagogical needs of young pupils; they may claim pedagogical advantages, but at the sacrifice of some logical rigour and comprehensiveness.

The *Foundations of* Geometry.—If the propositions of geometry have been arranged in a strictly logical sequence, as above indicated, it is evident that a certain number at the beginning of the list are not logical consequences of the preceding ones. The first proposition is, of course, not a logical consequence of a preceding one; nor is it likely that the second is a logical consequence of the first. The question then, naturally, arises as to the logical status of these unproved propositions on which all the others depend. Moreover, these propositions involve certain terms, such as point, straight line, circle, etc. What meaning attaches to such terms? A definition defines a term in terms of certain others, the meaning of which is supposed known. In order to avoid defining in a circle some terms must remain undefined. The foundations of geometry must then consist, from the purely logical point of view, of a set of undefined terms and a set of unproved propositions concerning them, such that every new term can be defined in terms of the undefined, and such that every new proposition can be proved a consequence of the unproved. The unproved propositions are usually called axioms (*q.v.*) or postulates. Are these to be regarded as self-evident truths? Are they imposed on our minds a *priori,* as Kant (q *v.*) taught, and is it impossible to think logically without granting them? Or are they, in accordance with the teaching of John Stuart Mill (*q.v.*) of experimental origin? Do the undefined terms denote primitive notions, the meaning of which is clear without definition to everybody? Prevailing opinion regards a geometric theorem as true beyond possibility of doubt by a reasonable being. Will a critical inspection bear out this opinion? The answer is in the negative. Indeed, Bertrand Russell has said: "Mathematics may be defined as the science in which we never know what we are talking about nor whether what we say is true." ("Recent work on the Principles of Mathematics," *The International Monthly,* 1901.) Many a reader. in looking back on his school days, may heartily agree with this definition. Modern work on the foundations has shown that Kant was wrong and that Mill was only partly right. Logically considered, the axioms and postulates are mere assumptions. A certain writer has considered the dethroning of the "self-evident" as analogous to the change from an absolute monarchy to a democracy. The "self-evident truth," which ruled by the Divine right of the alleged inconceivability of the opposite, has been replaced by the "assumption," which is elected for its qualifications to serve (the reference is obviously to an ideal democracy).

Greek Geometry.—The more elementary part of Greek geometry is too well known to warrant a detailed exposition here. The reader will recall with pleasure or pain, but without difficulty, the theorems on the equality or congruence (to use the more modern term) of triangles, on parallel lines, on the circle, on the measurement of angles by various circular arcs, on the similarity of triangles and other figures, on regular polygons, on proportion, on perimeters and areas, etc , in plane geometry; and the various properties of planes and lines, dihedral, trihedral, and polyhedral angles, the mensuration of pyramids, prisms, cones, cylinders, and the sphere, etc., in solid geometry.

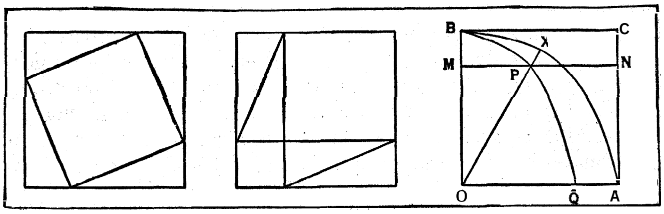

FIG. 1 FIG. 2

Among the high spots of this material we may mention the famous so called Pythagorean proposition (the square on the hypotenuse of a right triangle is equal to the sum of the squares on the other two sides) of which many proofs have been published. Among them the visual proofsare of special interest, one of which is reproduced herewith. A mere comparison of the two drawings in fig. 1 establishes the theorem. The theorem is of interest also for the problems to which it gave rise. Even in ancient times the problem of finding right triangles with integral sides, *i.e.*, to find three whole numbers x, y, and z, such that $x^2+y^2=z^2$, engaged the attention of mathematicians and was completely solved by them. The generalization to the solution in whole numbers of the equation $x^n+y^n=z^n$ is still one of the unsolved problems in the theory of numbers (see NUMBERS, THEORY OF), no solutions existing for any value of n greater than two and less than 100. Certain other famous problems deserve mention on account of their influence on the development of geometry and of mathematics in general.

The Duplication of the *Cube*.—The Athenians, so the story goes, appealed to the oracle at Delos to know how to stay the plague which visited their city in 430 B.C. The oracle replied that they must double in size the altar of Apollo without changing its shape. The altar being in the form of a cube, the problem was to find the size of a cube whose volume was twice that of a given cube. In modern notation, if a is the side of the given cube, the problem is to construct x such that $x^3=2a^3$. It must be remembered that, to the Greeks, "construct" meant construct with *ruler* and compasses only. With this limitation on the means to be employed the problem is now known to be impossible. But the attempts to solve it led to the invention of numerous new curves (*see* CURVES; CURVES, SPECIAL) and was a powerful stimulus to mathematicians through many centuries.

The Trisection of an Angle.—TO construct the bisector of any angle is one of the easiest problems in plane geometry. It was inevitable that a construction for dividing any angle into three (or more) equal parts should be sought. Again, if the construction is to apply to any angle (certain special angles such as a right angle are, of course, readily trisected) and if ruler and compasses only may be used, the problem is impossible; *i.e.*, there is no such construction. Many new curves, however, have been invented for the purpose of solution. Among these we may mention the curve that was later known as the *quadratrix*, because it furnished a solution also for the problem of squaring the circle (see below). In fig. 2 OX rotates at a uniform rate through one right angle from the position OB to the position OA, in the same time that the line MN, always parallel to OA, moves at a uniform rate from the position BC to the position OA. The intersection P of the line OX and MN then traces the curve in question. The use of this curve in trisecting an angle is almost trivially simple Let XOB be the angle to be trisected. Divide BM into three equal parts and draw lines through the points of division parallel to OA. These lines meet the quadratrix in points which if joined to O yield the required trisectors.

The Squaring of the *Circle*.—This problem, perhaps the most famous one of all, consists in constructing a square equal in area to the area of a given circle. It, too, is impossible if ruler and compasses are the only instruments permitted. The use of the quadratrix in the solution of this problem depends on the following relation. In the preceding figure it may be proved that the length of the quadrant BXA satisfies the following proportion:

$$\frac{BXA}{OA}=\frac{OA}{OQ}.$$

This makes it possible to construct a line equal in length to the circumference of the circle, from which a square equal in area to that of the circle is easily constructed. In spite of the fact that the solution of these problems by means of ruler and compasses alone has been known to be impossible for over 100 years, angle-trisecters and circle-squarers continue to appear. The best that can be said of these deluded individuals is that their enthusiasm has outstripped their scholarship. A later section of this article is devoted to the modern aspect of construction problems, and another section to developments arising from Euclid's parallel postulate.

The Conic Sections.—Partly under the stimulation of the problems just mentioned, the ancient Greeks investigated a class of curves known as the conic sections (*q.v.*), or more briefly the conics, and developed a large number of their properties. These curves arise as the plane sections of a right circular cone and have three distinct forms, the ellipse, the parabola, and the hyperbola. They have played a fundamentally important rôle in the development, not only of pure mathematics, but also in the applications. The reader may find further information in the article referred to (see also PROJECTIVE GEOMETRY). Suffice it to say that, had the conic sections not been previously studied, Kepler could not have discovered his famous laws concerning the motion of the planets, nor would we to-day have the benefit of searchlights with their parabolic reflectors. With the work of Apollonius on conics and the work of Archimedes on certain spirals and his remarkable determination of certain areas—he succeeded in finding the areas of an ellipse and of a parabolic segment—we reach the limits of ancient Greek geometry. No essential progress was made in this subject for over 1,000 years. We may, however, at this point say a few words about a more modern development, which is largely in the spirit of ancient geometry.

The Geometry of the Triangle and Circle.—This development relates to a detailed study of the triangle (*q.v.*) and circle (*q.v.*). It consists largely of the discovery of numerous points and lines connected with a triangle or circle and the discussion of their properties. Some of the latter are very remarkable. As an example, we may mention the nine-point circle related to a triangle, so-called because it passes through (a) the three midpoints of the sides, (b) the feet of the perpendiculars drawn from the vertices to the opposite sides, and (c) the mid-points of the lines joining the intersection of the three altitudes to the three vertices. This circle is tangent to the inscribed circle of the triangle, and also to the three circles which are each tangent to one side and the other two sides produced.

Descartes and the Invention of Analytic Geometry.—A new stimulus came to the development of geometry by the introduction through Descartes (1637, *q.v.*) of the so-called analytic methods. By representing a point in a plane by means of two numbers (co-ordinates), giving the distance and direction of the point from two intersecting lines (axes) of the plane, it was found possible to translate any geometric situation into an algebraic situation, whereby the powerful methods of algebra became available as a means of geometric investigation. The resulting analytic geometry (*q.v.*) is distinguished from the older or synthetic geometry by its method rather than by its content. Analytic and synthetic geometry do not then constitute two different branches of geometry; they denote, rather, two distinct methods of studying geometry. There seems to be no need, therefore, to give further details as to this method at this point; the reader should consult the article just mentioned. We may, however, try to characterize briefly the effect on the development of geometry of the introduction of these new methods.

In the first place, it provided a systematic plan for further progress A curve in the plane is represented by an equation in the variable co-ordinates (x, y) of a point on the curve. The straight lines are represented by equations of the first degree. Equations of the second degree turn out to represent the conic sections (*see* above). It was therefore natural to study next the curves represented by equations of the third degree (cubic curves); then those of the fourth degree (quartic curves); and so on. It was possible even to develop a general theory of curves of degree n. Some curves, such as the quadratrix previously mentioned. lead to equations that are not algebraic but transcendental (see EQUATIONS, THEORY OF). Similar remarks apply to the geometry of space (of three dimensions). A point in space is represented by three co-ordinates (x, y, z); an equation in these three variables represents a surface; and surfaces may then be classified according to their degree (those of the first degree being the planes), and then systematically studied.

Construction Problems. — In the second place, and closely related to the preceding, the new method gave a means of classifying the construction problems inherited from the ancients, as well as new ones. A construction problem, when formulated analytically, is found to be equivalent to the solution of an equation or to that of a system of simultaneous equations. A construction with ruler and compasses is possible only when the corresponding equations can be solved by means of the rational operations (addition, subtraction, multiplication, division) and the extraction of square roots. The equations underlying the problem of duplicating the cube and that of trisecting an angle cannot be solved without introducing irrational operations of higher order than square roots (in both these cases cube roots suffice). These problems are, therefore, impossible with ruler and compasses, as previously stated. Another problem that had a great influence on the development of algebra was that of constructing a regular polygon of a given number of sides. The ancient Greeks were able, with ruler and compasses, to construct regular polygons of three, four, five, six, eight, ten, . . . , sides; but failed in their attempts to construct one of seven sides. The determination of those values of n for which a regular polygon of n sides can be constructed with ruler and compasses led to a detailed study of the so-called cyclotomic equations, $x^n - 1 = 0$. As a result it was shown that the problem is possible only when n has the form $n = 2^k p_1 p_2 p_3 \ldots$, where each p represents a prime number of the form $2^{2^T}+1$. Since seven is not of this form, the problem is impossible when $n = 7$. It will be noted that the first prime of the required form greater than 5 is 17; the next 257. The general result given is due to K. F. Gauss (1796) (*q.v.*).

Spaces of More Than Three Dimensions. — In the third place the analytic formulation of geometry led naturally, almost inevitably, to a vast extension of the domain of geometry. Since the points of a plane could be represented by pairs of co-ordinates (x, y). the points of a space of three dimensions by triples (x, y, z) of co-ordinates, the question arises as to the geometric interpretation of a set of four independent co-ordinates (x, y, z, u) of a set of five, . . .; in general, of a set of n such co-ordinates. This led to the conception of a space of four, five, . . . , or in general of n dimensions. The precise formulation of the idea of dimension (q *v.*), as here used, need not concern us at this place. We may note, however, that the notion of a space of four or more dimensions is not, as is generally supposed, necessarily beyond our powers of concrete representation. True, a space of points of more than three dimensions is an abstract generalization to visualize which is beyond the present po ers of our imagination. But, if we use other elements than points with which to build our space, no such difficulty arises. Thus the totality of straight lines in ordinary space (of three dimensions) is four-dimensional; *i.e.*, constitutes a four-dimensional space (of lines). The totality of all spheres in ordinary space is a four-dimensional space of spheres. The corresponding geometries (line geometry and sphere geometry, see below) are just as concrete as the ordinary point geometries in the plane or in ordinary space. Nevertheless, point spaces of more than three dimensions are the ones usually thought of when n-dimensional spaces are being considered. Strangely enough, they find a large part of their interest in the field of applied mathematics. The four dimensional space-time manifold of Einstein-Minkowski is one that has recently aroused considerable popular interest in connection with the theory of relativity (*q.v.*). In the field of applied mathematics the conception of a space of more than three dimensions is generally of value in that it makes possible the application of geometric language to a problem that is essentially analytic. This language is of great convenience and is often suggestive of the relations sought. As an example we may cite the dynamical theory of gases. Suppose a gas consists of a (very large) number, N, of molecules. The dynamical condition of each of these molecules is represented by six co-ordinates, three to specify its position in space and three more to give the three components of its velocity. To describe completely the state of the gas at any instant $6N$ co-ordinates would be necessary. Jeans, in his *Dynamical* Theory of Gases, says: "We can suppose this dynamical system represented in a generalized space of $6N$ dimensions." A space of $6N$ dimensions, where N is the number of molecules in a certain volume of a gas! After this, it will cause no surprise to learn that spaces of an infinite number of dimensions have also been defined and their properties investigated. Indeed, there are several different kinds of such spaces. Before leaving this topic, it should perhaps be noted that, while we have chosen to introduce the concept of an n-dimensional space on an analytic basis, the same can be done equally well on a purely synthetic basis.

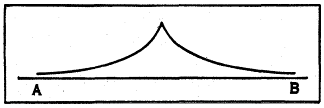

FIG. 3

Imaginary Elements. — In the fourth place, the introduction of analytic methods led to the conception of imaginary points, lines, etc., a conception which proved very fruitful. Not only did it make possible a greater generality in the statement of theorems and give a deeper insight into geometric relations, as, for example, the characterization of a circle as any conic which passes through certain two imaginary points at infinity, but it also opened up a new field of enquiry. A complex variable $x = x' + ix''$ ($i^2 = -1$) depends on two real variables x', x''. A complex line has then two real dimensions; a complex plane of points (x, y), where x and y each depend on two real variables, is a space of four real dimensions. The discussions of the one-dimensional loci on the complex line, and the one-, two-, and three-dimensional spreads in the complex plane constitutes a new world for the geometer to explore.

Finally, we should mention the fact that the introduction of the analytic method contributed largely to the idea of the unity of mathematics. There have been several instances in the preceding paragraphs not merely illustrating the possibility of regarding every geometric situation from an analytic point of view, which is, of course, the very essence of analytic geometry, but also exemplifying the fact that analytic situations may be given a geometric interpretation. It becomes increasingly difficult to distinguish analysis from geometry; these two branches of mathematics appear rather as different aspects of the same thing.

Differential Geometry. — The introduction of the differential and integral calculus (Newton and Leibniz, *qq.v.*) only a half century after the introduction of analytic geometry, greatly increased the power of the latter. The application of the fundamental ideas of the calculus to geometry introduced many new and valuable concepts. The resulting discipline is known as differential geometry (*q.v.*). Among the more elementary concepts referred to we may cite, by way of example, the curvature of a plane curve. The curvature at a point on a curve is a number which measures the sharpness of bending at that point. More precisely, if the curve is thought of as traced by a point moving with uniform speed along the curve, and this speed is taken as unity, the curvature at a point is proportional to the rate at which the tangent to the curve is turning at the instant when the moving point is at the given point. The curvature of a straight line is zero, the curvature of a circle is the same at every point and is equal to the reciprocal of the radius of the circle. This conception leads to a very beautiful theorem in the general theory of surfaces. The line drawn through a point on a surface perpendicular to the tangent plane at that point is called the normal to the surface. Let us consider the plane curves obtained as sections of our surface by planes passing through this normal — the so-called normal sections. Each of these plane curves has a curvature at the point. Among all these normal sections there will, in general, be one for which the curvature is a maximum, and'one for which the curvature is a minimum. (The exception is when all the curvatures are the same, in which case the surface is a plane or a sphere, or the point is some sort of exceptional point. We shall consider only "general" points, *i.e.,* points that are not exceptional.) The theorem referred to states that these two normal sections are always at right angles to each other. (The theorem is true, as stated, for all respectable surfaces other than planes or spheres; the exceptions may be disregarded in a survey of this kind.) Further, this theorem makes possible the definition of the so-called total curvature of a surface at a point as the product of the maximum and minimum curvatures of the normal sections just referred to. The investigation of surfaces of constant total curvature leads to the result that the only such surfaces are the plane whose total curvature at every point is zero; the sphere whose total curvature at every point is a positive constant (equal to the reciprocal of the radius squared); and the so-called pseudo-sphere whose total curvature at every point is a negative constant. (A negative total curvature indicates a saddle-shaped surface.) The pseudo-sphere is obtained by revolving about the line ***AB*** the curve (known as the tractrix) in fig. 3. These surfaces of constant curvature are of interest in connection with non-Euclidean geometry. ***(See*** below.)

Projective Geometry.— Early in the 17th century Desargues (1593–1662) proved the theorem that, if the vertices of two triangles lie on three lines meeting in a point, then their sides meet in three points lying on a line (see fig. 4). This theorem, it will be observed, has nothing to do with measurement, while the theorems of the older geometry are metric. Such theorems occur singly in the 17th century; they were not recognized as forming part of a new kind of geometry until about the beginning of the 19th century, when the so-called projective geometry *(q.v.)* was developed as a self-contained body of doctrine. If we take a photograph of a straight railroad track, with equally spaced ties, the parallel lines of the track appear in the photograph as converging, the equal distances between the ties appear unequal in the photograph, getting shorter and shorter as they recede in the picture. The right angles between the ties and the track appear as acute angles. If the landscape contains a circular pond it appears in the photograph as an ellipse. And yet the picture represents the scene; something of the actual relationships of the scene must be preserved, even though distances and angles are distorted, and parallel lines are no longer parallel. The properties of the scene that are preserved in the photograph, *i.e.,* the properties that are unchanged ("invariant" is the technical term), under the transformation produced by taking the photograph, are the properties studied by projective geometry. If the mechanism of this transformation is analysed, it is readily seen to consist of the following: Given any plane geometric figure (we confine ourselves to plane figures for the sake of simplicity), let O be any point not in the plane of the figure and think of straight lines drawn from O to every point of the figure. Let this set of lines be cut by any other plane not passing through O. This plane section of the lines through O gives a new figure in the cutting plane which is said to have been obtained from the original figure by the process of projection and section. It will be noted that in the case of our photograph the original scene is our first figure, the photographic plate is the cutting plane, while the point O is the point in the camera in which the light rays from the scene converge. Corresponding to every point of the original figure there is by this process determined a definite point in the new figure; corresponding to every straight line in the original there is a straight line in the new; if a point P in the original lies on a line l, the corresponding point P' in the new figure will lie on the line l' corresponding to l. A projective transformation consists of such a transformation by projection and section or of the result of a sequence of any number of such projections and sections. A projective transformation then transforms points into points, and straight lines into straight lines, and preserves the property of the incidence of points and lines. It does not preserve distances or angles; the latter, therefore, have no place in projective geometry as such. Its nature is to some extent characterized by calling it the geometry of position (*Geometrie* der *Lage*). It is, as to structure, a very simple geometry and an extraordinarily symmetric one. Further details must be sought in the article referred to above. Projective geometry, moreover, furnishes a scientific basis for descriptive geometry *(q.v.)* which is a branch of applied rather than of pure geometry.

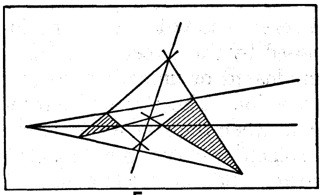

FIG. 4

The set of all projective transformations (in a plane or in space) form what is known as a group of *transformations* by virtue of the fact that the result of performing any two of the operations of the set in succession is equivalent to a third transformation of the set. Projective geometry is characterized completely by the fact that it studies those properties of figures which are invariant under the group of all projective transformations. Similarly, the set of all rigid motions in space form a group (see GROUPS). Ordinary elementary metric Euclidean geometry is then the geometry which studies those properties of figures that remain invariant under the group of all such motions. These are special cases of a fundamental principle, first enunciated by Felix Klein in 1872, to the effect that corresponding to every group of transformations in space there is a geometry consisting of those properties of space which are invariant under the given group. This principle provides at once a general classification of geometries; it also provides a systematic method of procedure in studying geometry as a whole, by the systematic investigation of all possible groups of transformations. In this project Sophus Lie *(q.v.)* laid the foundations in his theory of continuous groups. The group of motions just referred to is a sub-group of the general projective groups; other sub-groups are equivalent to the non-Euclidean (hyperbolic or elliptic) displacements; so that ordinary Euclidean and the two forms of non-Euclidean geometry are all implicitly contained in projective geometry, from which they are obtained by specialization. Furthermore, non-projective transformations may be defined by means of the projective, so that Arthur Cayley *(q.v.)* was led to exclaim: "Projective geometry is all geometry."

Inversion Geometry.—Among other geometries that have received extensive study, and in which the point is still the primary element of space, we may mention the inversion geometry in which the fundamental transformations are the so-called inversions with respect to a circle (plane inversion geometry), or with respect to a sphere (inversion geometry in space), or with respect to a hyper-sphere (in spaces of more than three dimensions).

Topology.—The set of all possible continuous transformations, *i.e.,* roughly speaking, the set of all twistings, bendings, stretchings or contractions without tearing anything apart, also form a group. The corresponding geometry is known as analysis situs. It must consider, by what has been said, those properties of figures that remain invariant under any continuous transformation whatever. Are there such properties? A simple closed curve in a plane divides the plane into two regions, an inside and an outside. This is a theorem of analysis situs. A surface may be either one-sided or two-sided (a simple one-sided surface may be obtained by taking a strip of paper and fastening together the two ends, having previously turned one of the ends over through an angle of 180°; see fig. 5) and this property is invariant under any continuous transformation. If a map is drawn on any simple closed surface, say a sphere, by any set of intersecting lines on the surface dividing the surface into a set of regions (countries), and if the number of regions is denoted by r, the number of sides (the portions of the lines between two points of intersection) by s and the number of vertices (the points of intersection of the lines) by v, then the relation $v+r=s+1$ always holds. This, too, is a theorem of analysis situs (due to L. Euler, *q.v.*). It has been stated that, given any such map, four different colours are sufficient to colour the countries in such a way that no two countries with a boundary line in common shall have

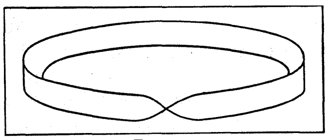

FIG. 5

the same colour. The proof of this apparently simple theorem, however, presents serious difficulties; it is still one of the unsolved problems of analysis situs.

Primitive Elements of Space.—We have hitherto assumed the point as the primitive element of space, except that once or twice we have hinted at the fact that this is not essential. In fact, the idea that some other geometric entity might be used as the primitive element, immediately opens up a new and vast field of geometric investigation. If, for example, we think of ordinary space as made up of all the straight lines in it, and study the properties of these lines and of systems of these lines, we enter the field of line geometry (*q.v.*), which, as has been said, is four-dimensional. If the sphere is taken as the primitive element of space, we obtain the so-called sphere geometry, and so on.

There are other aspects of geometry which it might be thought desirable to include in this general survey. For example, some may seek here a reference to such matters as curves without tangents, or to the so-called "crinkly" or surface-filling curves. But these are essentially problems of higher analysis in geometric garb. Others may look in vain for a discussion of the very important concept of elements at infinity in the various geometries; such a discussion will be found in the articles devoted to the geometries in question. Enough has been said, it is hoped, to give the reader some notion of the scope of geometry as a whole, and some idea of its fundamental conceptions and of the type of problem with which it deals.

BIBLIOGRAPHY.—Any one of the numerous school texts on plane or solid geometry will serve to refresh the reader's memory on these subjects. The standard edition of Euclid's *Elements* in English, is that by T. L. Heath in 3 vols. (Cambridge, 1908). For bibliographies of the various branches of geometry the reader should consult the articles referred to in this article. On certain special topics the following may be helpful: J. W. Young, *The Fundamental Concepts of Algebra and Geometry* (New York, 1911), for brief discussions of non-Euclidean geometry, construction problems, foundations of geometry, *n*-dimensional space, etc. This book presupposes no mathematical preparation beyond elementary algebra and geometry. Somewhat more mathematics is presupposed in *Monographs on Topics of Modern Mathematics*, edit. by J. W. A. Young (New York, 1911). It contains chapters on *The Foundations of Geometry* by O. Veblen; *Modern Pure Geometry* by T. F. Holgate; *Non-euclidean Geometry*, by F. S. Woods; *Constructions With Ruler and Compasses*, by L. E. Dickson. For imaginary elements in geometry *see* J. L. Coolidge, *Geometry in the Complex Domain* (Oxford, 1924). (J. W. Y.)

HISTORY OF GEOMETRY

The history of geometry may be considered under separate heads as follows: Ancient empirical geometry, ancient demonstrative geometry, sporadic developments during mediaeval times and the Renaissance, analytical geometry, modern synthetic geometry and, finally, the foundations of geometry.

Ancient Empirical Geometry.—Early Babylonian records disclose the use in auguries of triangles, quadrangles and parallel lines; drawings of Babylonian carriages indicate the division of a circumference into four and six equal parts. For angular measurement the circumference was divided into 360 equal parts or degrees, each degree into 60 minutes, and each minute into 60 seconds. Like the Hebrews (I. Kings vii. 23), the Babylonians took $\pi = 3$. One tablet reveals the approximate computation of the diagonal of a rectangle, expressed in the sexagesimal notation. More attention to geometry was given in Egypt. Greek writers state that land surveying was practised in Egypt because frequent overflows of the Nile obliterated landmarks. More reliable information is obtained from papyri and from inscriptions on the walls of temples. The Ahmes papyrus written about 1550 B.C. or, according to others, about 1700 B.C., is the most important ancient mathematical manuscript known. In this more stress is laid upon arithmetic and algebra than upon geometry. Ahmes calculates the areas of squares and rectangles; he approximates the area of an isosceles triangle by multiplying the slanting side by half the base, and of an isosceles trapezoid by multiplying half the sum of the two bases by the slant height. Remarkable is the rule for finding the area of a circle: From the diameter subtract one-ninth of it, and square the remainder. This rule implies that π nearly equals 3·16. Examples on the measurement of pyramids in Ahmes are of doubtful interpretation, but in another nearly contemporaneous papyrus (see *Ancient Egypt*, 1917), a calculation is given yielding the exact volume of the frustum of a rectangular pyramid—an astounding achievement in early Egyptian times.

The Greek geometry of Thales and his school, about the 7th century B.C., was only just emerging from the empirical stage; it dealt with such cases as the equality of vertical angles, the equality of the base angles of an isosceles triangle and the bisection of a circle by a diameter. This was a geometry of lines; Egyptian geometry was mainly one of areas and volumes. Thales's measurements of the heights of the pyramids by their shadows and of the distance of ships at sea presupposes the use of similar triangles.

Ancient Demonstrative Geometry.—The transition from empirical to rigorous demonstrative geometry was necessarily very slow. The discovery by the Pythagoreans in Italy of the existence of incommensurable magnitudes (such as the side and diagonal of a square) marks a long step toward reasoned conclusions. The story of the slaughter of a hecatomb of oxen in celebration of the discovery of a proof of the "Pythagorean theorem" of the right triangle is probably a myth, but it indicates a high appreciation of an intellectual achievement in pure geometry. Another indication of progress was the proposing, by the Sophists of Athens, of the three famous problems of construction—the squaring of the circle, the trisection of any given angle, and the duplication of a cube. These are now known to be impossible under the restrictions imposed by the Greeks—the use of a pair of compasses and an ungraduated or unmarked ruler in a finite number of steps of construction. The Greeks themselves found solutions of these problems when the above restrictions were abandoned. Hippias of Elis invented a curve, the "quadratrix," by which angles could be trisected and the circle could be squared. But the drawing of the quadratrix involved theoretically an infinite number of steps. Hippocrates of Chios, evidently hoping eventually to achieve the quadrature of the circle, successfully "squared" certain lunes and thus furnished the earliest example of a curvilinear area for which under the Greek restrictions an exactly equal area could be constructed in a plane which was bounded by straight lines. The duplication of the cube which, algebraically expressed, means constructing $X = \sqrt[3]{2S}$, where S is the side of a given cube, was solved "mechanically" by the aid of the conchoid of Nicomedes and by other means. Progress in giving definitions of fundamental concepts like "point," "line," "surface" and in giving explicit expression to axioms, was made by Plato and his pupils. The theory of proportion as related to magnitudes was developed by Eudoxus and Theaetetus. Eudoxus is credited also with the "method of exhaustion" which is not the same as the modern theory of limits, even though it involves the concept of a variable and a constant. The procedure as found in Euclid's *Elements*, bk. xii., Prop. 2, involves a part of our modern process of showing that a constant is the limit of a variable, but the Greeks did not actually pass, as we do, from the variable to its limit, but resorted, instead, to a process of *reductio ad absurdum*.

A most interesting phase in the development of the Greek philosophy of mathematics is seen in Zeno of Elea's arguments on motion. As explained in Aristotle's *Physics*, Zeno tried to prove that motion is impossible. Swift-footed Achilles could not catch a tortoise, the arrow in its flight is at any moment at rest, etc. For centuries Zeno was branded as a paralogist, but such recent writers as Paul Tannery and Bertrand Russell (*Principles of Mathematics*, 1903) advance the view that Zeno was misunderstood and that his arguments were sound and involved profound questions which have been successfully resolved only by the theory of the continuum as developed in recent mathematics. The paradoxes of Zeno, as well as Antiphon's attempt to square the circle by inscribing a series of regular polygons of an increasingly greater number of sides, the ultimate polygon coinciding with the circle, convinced Greek mathematicians that a clear and logical science of geometry could not be attained, except by eliminating the seemingly mystic concepts of infinity and of fixed infinitesimals. And thus we find Euclid excluding the infinitely little from his *Elements* by a definition (bk. v., def. 4): "Magnitudes are said to have a ratio to one another, when the less can be multiplied so as to exceed the other"; if the less were infinitely small, any finite multiple of it would still be infinitely small and could not satisfy this definition. Likewise, Archimedes, in the preface to his *Quadrature of the Parabola,* gives a postulate which he attributes to Eudoxus: If a and b are magnitudes, such that $a< b$, it shall be possible to find a finite number n, such that $na>b$. Thus in the classical writings of Euclid, Archimedes, and Apollonius of Perga, the infinitely small is carefully avoided.

Euclid was the author of several works, the most important of which is his *Elements,* written between 330 and 320 B.C. It contained 13 books, of which the first six and the last three were devoted to geometry (plane and solid), the seventh, eighth and ninth to arithmetic, and the tenth to irrationals. The proof of the theorem of Pythagoras on the right triangle is the only part of the geometry which Greek commentators definitely ascribe to Euclid. The geometrical theorems and the methods of proof (the method of exhaustion and the definition of proportion of magnitudes) appear to be due to earlier investigators. The great achievement of Euclid was the arrangement of the material handed down to him into a coherent, logical system. He ranks as a great systematizer. It is one of the marvels in the history of mathematics that the *Elements,* written in the 4th century B.C., should have established and maintained itself as a text-book in geometry for over 2,000 years. In England it was the authorized text down to the opening of the present century.

Euclid eschewed all practical applications of geometry. This attitude was abandoned by Archimedes who found the relation, $3\frac{1}{7}>\pi>3\frac{10}{71}$, needed in computing the area of a circle, and who discovered theorems on the areas of the surface of a sphere and of a cylinder, as well as on the volumes of a sphere and cylinder.

Besides the development of ordinary elementary geometry, the Greeks must be credited with the study of the conic sections (the ellipse, parabola, and hyperbola). The beginnings were made in the time of Plato; the culmination was reached in the work called the *Conic Sections,* written by Apollonius of Perga.

With Euclid, Archimedes and Apollonius, geometry reached the highest development during ancient times. Later Greek writers discovered certain curves (the conchoid of Nicomedes and the cissoid of Diocles); Pappus reached certain theorems and view points which were more fully developed in modern times. But these were the afterglow following the sunset of Greek geometry.

Mediaeval Times and the Renaissance.—The Hindus of this period did not excel in geometry. Their creative work is limited to theorems on the area and diagonals of a quadrilateral inscribed in a circle, theorems developed mainly by Brahmagupta (c. 628). The outstanding Arabic achievement was the geometric solution of cubic equations, by the method of intersecting conics, a process which had been foreshadowed by Archimedes. The fullest Arabic exposition of this topic was given by the poet Omar Khayyam. In Europe creative work began with Johann Kepler, who made use of the concepts of infinitely small and infinitely great quantities, which Euclid and Archimedes had carefully avoided in their classical writings. Kepler looked upon a circle as a polygon having an infinite number of sides, and upon a sphere as consisting of an infinite number of pyramids. He arrived at the areas and volumes of figures generated by curves revolving about a line as axis. The Italian, Bonaventura Cavalieri, a pupil of Galileo, developed the *Geometry of Indivisibles,* and succeeded in solving many of the problems on volumes which had been proposed by Kepler for solution. Researches which foreshadowed the great achievements of a more modern period are found in the work of Evangelista Torricelli, Vincenzo Viviani, Gilles P. de Roberval, and especially of Gérard Desargues and Blaise Pascal on modern synthetic geometry.

The Invention of Analytic Geometry.—Analytic geometry was created by two Frenchmen, René Descartes and Pierre de Fermat. The chief credit is rightly awarded to Descartes, who promptly published his results in his La *ge'ome'trie,* 1637; Fermat's treatise *Ad locos planos et solidos isagoge* appeared posthumously in 1679. The two main ideas involved in analytical geometry are the location of points in a figure by the use of co-ordinates and the algebraic representation of a curve or surface by an equation involving two or three variables. Of these only the latter was new in the 17th century; co-ordinate representation was practised in ancient times by Apollonius and others. Descartes's La *ge'ome'trie* does not contain a systematic development of analytical geometry in the manner found in modern texts. The method must be constructed from isolated statements occurring in different parts of the treatise. Nevertheless, it is a work of genius occupying a conspicuous place in the history of geometry. The words "abscissa" and "ordinate" were not due to Descartes. In the technical sense of analytical geometry they were first used by Leibniz in 1692, in the *Acta Eruditorum.* An important example solved by Descartes in his *La ge'ome'trie* was the "Problem of Pappus": Given several straight lines in a plane find the locus of a point such that the perpendicular drawn from the point to the given lines, shall satisfy the condition that the product of certain of them shall be in a given ratio to the product of the others. This problem afforded an excellent example of the power of the analytical method, a power which Boltzmann more recently described by saying that the formula appears at times cleverer than the man who invented it.

The cultivators of analytical geometry in the 18th century were Jean Paul de Gua de Malves, Gabriel Cramer, Leonhard Euler and, in general, the mathematicians who developed the differential and integral calculus. Thus Newton in 1704 published a classification of cubic curves. The calculus offered a general and expeditious method of finding tangents at any point of a continuous curve having derivatives.

During the 19th century, new principles were introduced into analytic geometry which afforded greater power and generality to the science. Thus the principle of duality was applied by Julius Plücker to equations of lines and curves. The duality consisted in a double interpretation of one and the same equation so that $ux+vy+1=0$, for example, could be interpreted as having two variables x, y representing co-ordinates of points, u and v being constants, or the equation could be interpreted as having two variables u, v representing lines, x and y being constants. In the first case the equation represents a straight line, in the second case, a point. By this duality, one and the same process would yield two theorems. But for the full analytic application of duality, Augustus F. Möbius and Plucker found it necessary to abandon the ordinary Cartesian co-ordinates and to introduce the more general homogeneous co-ordinates. Plucker studied the singularities of plane curves and developed four equations (the "Plucker equations") expressing the relations between the number of double points, double tangents, stationary points, and stationary tangents of a curve of a given degree and class. The discovery of these relations Arthur Cayley considered "the most important one beyond all comparison in the entire subject of modern geometry."

Etienne Bobillier and Plucker introduced an "abridged notation." J. J. Sylvester and Otto Hesse showed how processes of elimination could be simplified by the use of determinants. Particularly prominent in elaborating the higher fields of the science were Alfred Clebsch, Henri Halphen, and Jean Gaston Darboux. Curves and surfaces of higher order afford fields of never-ending research. *(See* CURVE; CURVES, SPECIAL.)

Modern Synthetic Geometry.—This was cultivated in the 19th century simultaneously with analytic geometry. The two movements occupied the same field of study, but differed in method of exposition. Rivalry existed between the followers of the two methods, which was usually but not always friendly. The continual direct viewing of figures as existing in space adds exceptional charm to the study of synthetic geometry, but the equation of the analytic method may outrun thought itself and constitutes a powerful tool in research. Jean Victor Poncelet and others used both the synthetic and the analytic methods; Jakob Steiner used only the former, Plucker only the latter. Modern synthetic geometry was first cultivated by Gaspard Monge, L. N. M. Carnot, and J. V. Poncelet in France, and by Mobius and Steiner in Germany and Switzerland, and was developed to still higher perfection by Michel Chasles in France and von Staudt in Germany. Monge in 1795 was the first to stress the "descriptive geometry" used in engineering. The principle of duality was advanced by J. D. Gergonne and Poncelet for the study of descriptive properties without reference to the analytic processes elaborated by Plücker. The use of the anharmonic or cross ratio was stressed by Steiner and Chasles.

The Foundations of Geometry.—The parallel postulate of Euclid (according to which two lines in a plane meet if the sum of the two interior angles on the same side of a transversal is less than two right angles) seemed unsatisfactory even to some of the ancient mathematicians. Proofs of it were attempted on the assumption of the other Euclidean axioms, but were always found invalid. After many failures, certain investigators tried to build up a geometry in which the postulate does not hold, in which, in other words, the angle sum in question may be less than two right angles and yet the lines may not meet, no matter how far they are produced. The result was a non-Euclidean geometry, perfectly consistent with its assumptions, developed independently by the Russian, Nicolai I. Lobachevski (1829) and the Hungarian mathematician, János Bolyai (1834). So novel were these creations that they failed to secure general attention for many years. With reference to the assumptions about parallel lines, there are now recognized three principal geometties—the "parabolic" or Euclidean based on Euclid's parallel postulate, the "hyperbolic" or Lobachevskian based on the denial of that postulate, and the "elliptic" or Riemannian geometry in which parallel lines do not exist at all. Felix Klein considered two forms of "elliptic" geometry. Two-dimensional geometric figures in the first of these geometries are visualized when drawn in a plane; those in the second geometry are partly visualized on a saddle-shaped surface like the pseudosphere; those in the third geometry are visualized on a sphere. Recently, these geometries have assumed importance in cosmological speculations. According to Albert Einstein, the universe is finite and its geometry is "elliptic."

The question of the number of dimensions has agitated mathematicians and philosophers since the time of the Greeks. The first to assume definitely the existence of a fourth dimension of space was the Platonist, Henry More, of Cambridge, England, a contemporary of Isaac Newton. But not till the 19th century did mathematicians enter upon an extensive study of geometries of higher dimensions. As a rule it was not claimed that these higher dimensions had real existence in our physical space; they were ideal creations of the human mind. However, as early as the 18th century, D'Alembert and Lagrange looked upon time, which appeared as a fourth variable in mechanics, as a fourth dimension. This idea was developed in more recent time by Hermann Minkowski and Einstein in a manner leading to a fourth dimensional world, a "fusion of geometry and physics." Said Minkowski (1908): "Nobody has ever noticed a place except at a time, or a time except at a place."

The foundations of geometry are the last part of the geometric structure to be firmly established. Italian and German mathematicians (Giuseppe Peano, 1880; Moritz Pasch, 1882; Mario Pieri, 1899) were the first to enter upon a minute study of independent, consistent and complete sets of axioms enabling the different geometries to be built up without borrowing anything from intuition. It was recognized that Euclid, who for centuries had been admired for the rigour of his demonstrations, does depend here and there upon facts not deduced from the axioms but obtained from visual inspection of the figures. Thus, in Euclid's Elements, in the very first proposition, it is assumed without proof that two circles drawn in the figure intersect each other. The study of the foundations of different geometries was continued in Germany, by David Hilbert, in France by Henri Poincaré and in the United States mainly by Oswald Veblen.

NON-EUCLIDEAN GEOMETRY

The various metrical geometries are concerned with the properties of the various types of congruence-groups, which are defined in the study of the axioms of geometry and of their immediate consequences. But this point of view of the subject is the outcome of recent research, and historically the subject has a different origin. Non-Euclidean geometry arose from the discussion, extending from the Greek period to the present day, of the various assumptions which are implicit in the traditional Euclidean system of geometry. In the course of these investigations it became evident that metrical geometries, each internally consistent but inconsistent in many respects with each other and with the Euclidean system, could be developed. A short historical sketch will explain this origin of the subject, and describe the famous and interesting progress of thought on the subject.

History.—In 1621 Sir Henry Savile called attention to the existence of two blemishes (duo *naevi*) in geometry, namely, the theory of parallels and the theory of proportion. In both respects the work of later scholars has given rise to important branches of mathematics, while at the same time showing that Euclid is in these respects more free from blemish than had been previously credible. It was from endeavours to improve the theory of parallels that non-Euclidean geometry arose; and though it has now acquired a far wider scope, its historical origin remains instructive and interesting. Euclid's "axiom of parallels" appears as Postulate V. to the first book of his Elements, and is stated thus, "And that, if a straight line falling on two straight lines make the angles, internal and on the same side, less than two right angles, the two straight lines, being produced indefinitely, meet on the side on which are the angles less than two right angles."

To Euclid's successors this axiom had signally failed to appear self-evident, and had failed equally to appear indemonstrable. Without the use of the postulate its converse is proved in Euclid's 17th proposition, and it was hoped that by further efforts the postulate itself could be also proved. The first step consisted in the discovery of equivalent axioms. Christopher Clavius in 1574 deduced the axiom from the assumption that a line whose points are all equidistant from a straight line is itself straight. John Wallis in 1663 showed that the postulate follows from the possibility of similar triangles on different scales. Girolamo Saccheri (1733) showed that it is sufficient to have a single triangle, the sum of whose angles is two right angles. Other equivalent forms may be obtained, but none shows any essential superiority to Euclid's. Indeed plausibility, which is chiefly aimed at, becomes a positive demerit where it conceals a real assumption.

Saccheri.—A new method, which, though it failed to lead to the desired goal, proved in the end immensely fruitful, was invented by Saccheri, in a work entitled Euclides ab *omni* naevo *vindicatus* (Milan, 1733). If the postulate of parallels is involved in Euclid's other assumptions, contradictions must emerge when it is denied while the others are maintained. This led Saccheri to attempt a reductio ad *absurdum,* in which he mistakenly believed himself to have succeeded. What is interesting, however, is not his fallacious conclusion, but the non-Euclidean results which he obtains in the process. Saccheri distinguishes three hypotheses (corresponding to what are now known as Euclidean or parabolic, elliptic and hyperbolic geometry), and proves that some one of the three must be universally true. His three hypotheses are thus obtained: equal perpendiculars *AC, BD* are drawn from a straight line AB, and *CD* are joined. It is shown that the angles *ACD,* BDC are equal. The first hypothesis is that these are both right angles; the second, that they are both obtuse; and the third, that they are both acute. Many of the results afterwards obtained by Lobachevski and Bolyai are here developed. Saccheri fails to be the founder of non-Euclidean geometry only because he does not perceive the possible truth of his non-Euclidean hypotheses.

Lambert.—Some advance is made by Johann Heinrich Lambert in his Theorie der *Parallellinien* (written 1766; posthumously published 1786). Though he still believed in the necessary truth of Euclidean geometry, he confessed that, in all his attempted proofs, something remained undemonstrated. He deals with the same three hypotheses as Saccheri, showing that the second holds on a sphere, while the third would hold on a sphere of purely imaginary radius. The second hypothesis he succeeds in condemning, since, like all who preceded Bernhard Riemann, he is unable to conceive of the straight line as finite and closed. But the third hypothesis, which is the same as Lobachevski's, is not even professedly refuted.

Three Periods of non-Euclidean Geometry.—Non-Euclidean geometry proper begins with Karl Friedrich Gauss. The advance which he made was rather philosophical than mathematical. It was he (probably) who first recognized that the postulate of parallels is possibly false, and should be empirically tested by measuring the angles of large triangles. 'The history of non-Euclidean geometry has been aptly divided by Felix Klein into three very distinct periods. The first—which contains only Gauss, Lobachevski and Bolyai—is characterized by its synthetic method and by its close relation to Euclid. The attempt at indirect proof of the disputed postulate would seem to have been the source of these three men's discoveries; but when the postulate had been denied, they found that the results, so far from showing contradictions, were just as self-consistent as Euclid. They inferred that the postulate, if true at all, can only be proved by observations and measurements. Only one kind of non-Euclidean space is known to them, namely, that which is now called hyperbolic. The second period is analytical, and is characterized by a close relation to the theory of surfaces. It begins with Riemann's inaugural dissertation, which regards space as a particular case of a manifold (see MANIFOLDS); but the characteristic standpoint of the period is chiefly emphasized by Eugenio Beltrami. The conception of measure of curvature is extended by Riemann from surfaces to spaces, and a new kind of space, finite but unbounded (corresponding to the second hypothesis of Saccheri and Lambert), is shown to be possible. As opposed to the second period, which is purely metrical, the third period is essentially projective in its method. It begins with Arthur Cayley, who showed that metrical properties are projective properties relative to a certain fundamental quadric, and that different geometries arise according as this quadric is real, imaginary or degenerate. Klein, to whom the development of Cayley's work is due, showed further that there are two forms of Riemann's space, called by him the elliptic and the spherical. Finally, it has been shown by Sophus Lie, that if figures are to be freely movable throughout all space in ∞^6 ways, no other three-dimensional spaces than the above four are possible.

Gauss—Gauss published nothing on the theory of parallels, and it was not generally known until after his death that he had interested himself in that theory from a very early date. In 1799 he announces that Euclidean geometry would follow from the assumption that a triangle can be drawn greater than any given triangle. Though unwilling to assume this, we find him in 1804 still hoping to prove the postulate of parallels. In 1830 he announces his conviction that geometry is not an a *priori* science; in the following year he explains that non-Euclidean geometry is free from contradictions, and that, in this system, the angles of a triangle diminish without limit when all the sides are increased. He also gives for the circumference of a circle of radius r the formula $\pi k(e^{r/k}-e^{-r/k})$, where k is a constant depending upon the nature of the space. In 1832, in reply to the receipt of Bolyai's Appendix, he gives an elegant proof that the amount by which the sum of the angles of a triangle falls short of two right angles is proportional to the area of the triangle. From these and a few other remarks it appears that Gauss possessed the foundations of hyperbolic geometry, which he was probably the first to regard as perhaps true. It is not known with certainty whether he influenced Lobachevski and Bolyai, but the evidence we possess is against such a view.

Lobachevski.—The first to publish a non-Euclidean geometry was Nicholas Lobachevski, professor of mathematics in the new university of Razan. In the place of the disputed postulate he puts the following: "All straight lines which, in a plane, radiate from a given point, can, with respect to any other straight line in the same plane, be divided into two classes, the intersecting and the non-intersecting. The boundary line of the one and the other class is called *parallel* to the given *line*." It follows that there are two parallels to the given line through any point, each meeting the line at infinity, like a Euclidean parallel. Hence a line has two distinct points at infinity, and not one only as in ordinary geometry. The two parallels to a line through a point make equal acute angles with the perpendicular to the line through the point. If p be the length of the perpendicular, either of these angles is denoted by $\Pi(p)$. The determination of $\Pi(p)$ is the chief problem; it appears finally that, with a suitable choice of the unit of length,

$$\tan\tfrac{1}{2}\,\Pi(p)=e^{-p}.$$

Before obtaining this result it is shown that spherical trigonometry is unchanged, and that the normals to a circle or a sphere still pass through its centre. When the radius of the circle or sphere becomes infinite all these normals become parallel, but the circle or sphere does not become a straight line or plane. It becomes what Lobachevski calls a limit-line or limit-surface. The geometry on such a surface is shown to be Euclidean, limit-lines replacing Euclidean straight lines. It is, in fact, a surface of zero measure of curvature. By the help of these propositions Lobachevski obtains the above value of $\Pi(p)$, and thence the solution of triangles. He points out that his formulae result from those of spherical trigonometry by substituting ia, ib, ic, for the sides a, b, c.

Bolyai.—John Bolyai, a Hungarian, obtained results closely corresponding to those of Lobachevski. These he published in an appendix to a work by his father, entitled Appendix Scientiam *spatii* absolute veram *exhibens:* a veritate aut falsitate Axiomatis *XI.* Euclidei (a *priori* haud unquam decidenda) independentem: *adjecta* ad *casum falsitatis,* quadratura circuli geometrica. This work was published in 1831, but its conception dates from 1823. It reveals a profounder appreciation of the importance of the new ideas, but otherwise differs little from Lobachevski's. Both men point out that Euclidean geometry is a limiting case of their own more general system, that the geometry of very small spaces is always approximately Euclidean, that no a *priori* grounds exist for a decision, and that observation can only give an approximate answer. Bolyai gives also, as his title indicates, a geometrical construction, in hyperbolic space, for the quadrature of the circle, and shows that the area of the greatest possible triangle, which has all its sides parallel and all its angles zero, is πi^2, where i is what we should now call the space-constant.

Riemann.—The works of Lobachevski and Bolyai, though known and valued by Gauss, remained obscure and ineffective until, in 1866, they were translated into French by J. Hoiiel. But at this time Riemann's dissertation, *Über* die Hypothesen, *welche* der Geometrie *zu* Grunde liegen, was already about to be published. In this work Riemann, without any knowledge of his predecessors in the same field, inaugurated a far more profound discussion, based on a far more general standpoint; and by its (posthumous) publication in 1867 the attention of mathematicians and philosophers was at last secured.

Riemann's work contains two fundamental conceptions, that of a manifold and that of the *measure* of' *curvature* of a continuous manifold possessed of what he calls flatness in the smallest parts.

There are four points in which this profound and epoch-making work is open to criticism or development—(I) the idea of a manifold requires more precise determination; (2) the introduction of coordinates is entirely unexplained and the requisite presuppositions are unanalysed; (3) the assumption that ds is the square root of a quadratic function of dx_1, dx_2, . . . is arbitrary; (4) the idea of superposition, or congruence, is not adequately analysed. The modern solution of these difficulties is properly considered in connection with the general subject of the axioms of geometry.

Helmholtz.—The publication of Riemann's dissertation was closely followed by two works of Hermann von Helmholtz, again undertaken in ignorance of the work of predecessors. In these a proof is attempted that ds must be a rational integral quadratic function of the increments of the coordinates. This proof has since been show? by Lie to stand in need of correction. Helmholtz's remaining works on the subject are of almost exclusively philosophical interest.

Beltrami.—The only other writer of importance in the second period is Eugenio Beltrami, by whom Riemann's work was brought into connection with that of Lobachevski and Bolyai. As he gave a convenient Euclidean interpretation of hyperbolic plane geometry, his results will be stated at length. The *Saggio* shows that Lobachevski's plane geometry holds in Euclidean geometry on surfaces of constant negative curvature, straight lines being replaced by geodesics. Such surfaces are capable of a conformal representation on a plane, by which geodesics are represented by straight lines (see ANALYSIS, COMPLEX). Hence if we take, as coordinates on the surface, the coordinates of corresponding points on the plane, the geodesics must have linear equations.

Transition to the Projective Method.—The *Saggio* gives a Euclidean interpretation confined to two dimensions. But a consideration of the auxiliary plane suggests a different interpretation, which may be extended to any number of dimensions. If, instead of referring to the pseudosphere, we merely define distance and angle, in the Euclidean plane, as those functions of the coordinates which gave us distance and angle on the pseudosphere, we find that the geometry of our plane has become Lobachevski's. All the points of the limiting circle are now at infinity, and points beyond it are imaginary. If we give our circle an imaginary radius the geometry on the plane become elliptic. Replacing the circle by a sphere, we obtain an analogous representation for three dimensions. Instead of a circle or sphere we may take any conic or quadric. With this definition, if the fundamental quadric be $\Sigma xx=0$, and if $\Sigma xx'$ be the polar form of Σxx, the distance ρ between x and x' is given by the projective formula

$$\cos(p/k)=\Sigma xx'/\{\Sigma xx\cdot\Sigma x'x'\}^{\frac{1}{2}}.$$

That this formula is projective is rendered evident by observing that $e^{-2ip/k}$ is the anharmonic ratio of the range consisting of the two points and the intersections of the line joining them with the fundamental quadric. With this we are brought to the third or projective period. The method of this period is due to Cayley; its application to previous non-Euclidean geometry is due to Klein. The projective method contains a generalization of discoveries already made by Laguerre in 1853 as regards Euclidean geometry. The arbitrariness of this procedure of deriving metrical geometry from the properties of conics is removed by Lie's theory of congruence. We then arrive at the stage of thought which finds its expression in the modern treatment of the axioms of geometry.

The Two Kinds of Elliptic Space.—The projective method leads to a discrimination, first made by Klein, of two varieties of Riemann's space; Klein calls these elliptic and spherical. They are also called the polar and antipodal forms of elliptic space. The latter names will here be used. The difference is strictly analogous to that between the diameters and the points of a sphere. In the polar form two straight lines in a plane always intersect in one and only one point; in the antipodal form they intersect always in two points, which are antipodes. The antipodal form may be called a "quasi-geometry." Similarly in the antipodal form two diameters always determine a plane, but two points on a sphere do not determine a great circle when they are antipodes, and two great circles always intersect in two points. Again, a plane does not form a boundary among lines through a point: we can pass from any one such line to any other without passing through the plane. But a great circle does divide the surface of a sphere. So, in the polar form, a complete straight line does not divide a plane, and a plane does not divide space, and does not, like a Euclidean plane, have two sides. But, in the antipodal form, a plane is, in these respects, like a Euclidean plane.

Finally, it is of interest to note that, though it is theoretically possible to prove, by scientific methods, that our geometry is non-Euclidean, it is wholly impossible to prove by such methods that it is accurately Euclidean. For the unavoidable errors of observation must always leave a slight margin in our measurements. A triangle might be found whose angles were certainly greater, or certainly less, than two right angles; but to prove them *exactly* equal to right angles must always be beyond our powers. If, therefore, any man cherishes a hope of proving the exact truth of Euclid. such a hope must be based, not upon scientific, but upon philosophical considerations.

GEOPHYSICAL PROSPECTING (GEOPHYSICAL EXPLORATION, APPLIED GEOPHYSICS) is the application of the principles of physics to the study of subsurface geology, particularly as related to exploration for ore, oil and gas deposits. Geophysical exploration is used for other purposes, including (1) the location of ground water supplies; (2) the determination of thickness and type of soil; (3) the kinds of rock and their depths and surface configurations; (4) the in situ determination of the physical and dynamic properties of soils and rocks; (5) the thickness of ice at sea and on the polar ice caps; (6) the depth of water in oceans and lakes and the nature and thickness of bottom sediments; and (7) the structure and composition of the earth's crust.

The techniques of measurement employed are based on the fundamental principles of those fields of physics represented by gravity, magnetism, electricity, light, sound, heat and radioactivity. The measurements are usually conducted at ground level: but may be made in bore holes or in underground mine workings. In water-covered areas the instruments are either placed on bottom or suspended in the water, and some of the measurements can be made from aircraft.

The success of all geophysical methods depends upon there being a contrast between the physical properties of the material being investigated or sought and those of the surrounding material. The properties exploited are magnetic susceptibility, density, elasticity, electrical conductivity. thermal conductivity and radioactivity. If a substance, such as oil, does not in itself provide a marked enough difference from its surroundings to be detected, then it frequently can be located indirectly through an association with some stratigraphic or structural geologic condition (anticline, fault, buried valley, etc.) which can be geophysically mapped. In the case of disseminated ore minerals where there is no well-defined lode of material, indirect location may be achieved through being able to map the subsurface extent of the host rock, such as an intrusive or associated buried structure. (*See* GEOLOGY.)

METHODS

In accordance with the physical properties of geologic materials that can be utilized for measurements, the methods of applied geophysics can be subdivided into gravitational, magnetic, seismic, electrical, electromagnetic, geothermal and radioactive methods. In nearly all cases the results obtained must be interpreted geologically. Hence, the analysis of the results plays just as important a role in the successful use of geophysical studies as does the choice of measurement used and the care with which the measurements are made.

From the standpoint of interpretation geophysical methods can be subdivided into two groups: (1) methods without depth control; and (2) methods having depth control. In the first group the measurements incorporate spontaneous effects from many sources, both local and distant, over which the observer has no control. For example. a gravity measurement is affected by the change in earth radius with latitude and the earth's rotation, the elevation of the site relative to sea level, the local topography, the thickness of the earth's crust. the configuration of the underlying crystalline rock complex and the density of the intervening rocks, as well as by any abnormal mass variation that might be associated with a mineral deposit. Therefore, the successful interpretation of gravity data depends on: (1) the accuracy with which the effects

	Method		Field	Geologic Application	
Spontaneous Action	I. Gravitational	A. Torsion balance B. Pendulum C. Gravimeter	Oil, mining, geodesy	Anticlinal structures; buried ridges, salt domes; faults, intrusions; ore; bodies; reefs; major structural trends	No depth control
Spontaneous Action	II. Magnetic		Oil, mining	Anticlinal structures; buried ridges; intrusions; faults; iron, pyrrhotite; and associated sulfide ores; gold placers	No depth control
Spontaneous Action	III. Electrical	A. Self-potential	Mining	Sulfide ore bodies	No depth control
Reaction to energizing fields	III. Electrical	B. Galvanic application of primary energy 1. Potential distribution of secondary field, measured a. Equipotential line methods b. Resistivity c. Potential drop ratio	Mining, civil engineering, oil	General stratigraphic and structural conditions; bedrock depth on dam sites; ground water; oil structures; sulfide ore bodies; highway problems; electrical logging	Control of depth of penetration
Reaction to energizing fields	III. Electrical	2. Electromagnetic field, measured	Mining	Iron formation; sulfide ore bodies	Control of depth of penetration
Reaction to energizing fields	III. Electrical	C. Inductive application of primary energy	Oil, mining	Faults; anticlinal, etc., structures; sulfide ore bodies	Control of depth of penetration
Reaction to energizing fields	IV. Seismic	A. Refraction	Oil, civil engineering, crustal structure	Salt domes; anticlinal, etc., structures; faults; foundation and highway problems; ground water; marine sediments	Control of depth of penetration
Reaction to energizing fields	IV. Seismic	B. Reflection	Oil	Low-dip structures; buried ridges; faults; reefs	Control of depth of penetration

SUMMARY OF THE FOUR MAJOR GEOPHYSICAL PROSPECTING METHODS

of known controls related to position and elevation are evaluated; (2) the accuracy with which the residual obtained is subdivided into contributions from regional controls of unknown magnitude related to variations in crustal thickness, basement rock lithology, etc., and those of local origin; and (3) how well knowledge of geologic factors concerning structure or modes of ore deposition can be applied in deducing the significance of the final residual, particularly as to whether this residual represents the effect of a shallow, thin body or a deeper, thicker or more concentrated body. With so many variables it is not possible to make a quantitative analysis leading to an unambiguous solution. In the last stages the interpretation always depends upon the geologic knowledge of the interpreter and his success through trial calculations in finding a reasonable geological model whose gravity effect matches that observed. This in itself, however, is no guarantee that the interpretation is correct. It is a possible interpretation that may even be probable but never unique. The above limitations also apply to the interpretations of magnetic, electrical self-potential, thermal and radioactive measurements.

In the second group of measurements (those with depth control), energy (seismic or electric) is introduced into the ground and variations in transmissibility with distance are observed and interpreted in terms of geologic quantities. The depth of investigation with these techniques is governed by the spacing between the transmitting and reception points. It is thus possible to separate shallow effects from those having a deep origin. By the application of suitable physical theory, depths to geologic horizons having marked differences in transmissibility can be computed on a quantitative basis and the physical nature of these horizons deduced. The accuracy, ease of interpretation and applicability of all methods falling into this group are not the same, and there are conditions, both natural and economic, under which the measurements of the first group are preferable for exploration studies despite their inherent limitations.

In each group (gravity, magnetic, seismic, etc.) there are subdivisions related to variations in technique, instrumentation or quantities measured. A summary of methods and their geologic applications is given in the Table. Details on some of the methods with special reference to rock properties, instruments and interpretation procedures are given in the following sections.

Gravity Methods.— Gravity methods are based upon the measurement of physical quantities related to the gravitational field which in turn are affected by differences in densities and disposition of underlying geologic bodies.

The density values of a few minerals for which gravity prospecting has been done are: Pyrite, 4.9–5.2; pyrrhotite, 4.5–4.7; galena, 7.4–7.6; barite, 4.3–4.5; magnetite, 4.9–5.2; lignite, 1.1–1.2. Concentrations of economic value of these minerals occur in rock materials usually having a density varying from 2.6–2.8 gm/cc. In oil and gas exploration, where there is no direct density control associated with the material being sought, exploration is based on the mapping of geologic structures to determine situations that might localize the material being sought. In such cases the significant density values are: Salt, 2.1–2.2; igneous rocks, 2.5–3.0; sedimentary rocks, 1.6–2.8. The last value increases with depth due to consolidation and geologic age and as a result structural deformation associated with faults and folding can be detected. Compaction of sediments over ridges or knolls on the underlying crystalline rock surface also leads to a local increase in mass, as does the development of calcareous cap rock over the heads of intrusive salt columns. In the later situation the high density value may be superimposed upon a broader low value related to the deficiency in mass associated with the salt column as a whole. In the early days of gravity prospecting both the Eötvös torsion balance for determining gravity gradient and pendulum apparatus were extensively employed, but these have been supplanted by spring balance systems (gravimeters). The latter can be read in a matter of minutes in contrast to the several hours required for obtaining readings with the earlier instruments. While gravimeters vary in design those in common use consist essentially of a weighted boom that pivots about a hinge point. The boom is linked to a spring system so that the unit is essentially unstable and hence very sensitive to slight variations in gravitational attraction. Deflections of the boom from a central "null" position are measured by observing the change in the tension in the spring system required to bring the boom back to that position. Readings are obtained from a graduated dial on the head of the instrument which is attached to the spring system through a screw. (Gravimeters therefore do not read the force of gravity directly, and only indicate differences in gravitational attraction.) There must be an accurate calibration of the screw, reading dial and spring response for the readings to have gravitational significance. Two methods of calibration are employed: (1) a series of comparative readings is taken between sites for which the change in gravity is known from pendulum measurements; or (2) the instrument is tilted through a known angle and readings are taken for simulated changes in gravity (calculated on the basis that tilting results in an apparent decrease in gravity which varies as the cosine of the angle of tilt).

Relative gravity measurements using a pendulum can be used as a calibration standard, since these are free from side effects so long as the physical dimensions of the pendulum and environment of oscillation remain constant. The only factor having significance then is the change in a period of the pendulum in moving from one site to another.

For discussion of the design, construction, sensitivity and uses of pendulums and gravimeters see GRAVITATION: The *Measurement* of Gravitational Forces: *Measurement* of the *Intensity* of Gravity.

By placing gravimeters on bottom in shallow water areas in watertight housings with automatic leveling and electronic recording, it is possible to carry out gravimeter surveys in inundated areas as well as on land. Special gravimeters have been developed for use in submarines and on gyrostabilized platforms on surface ships! and it has been demonstrated that these instruments can be used in aircraft.

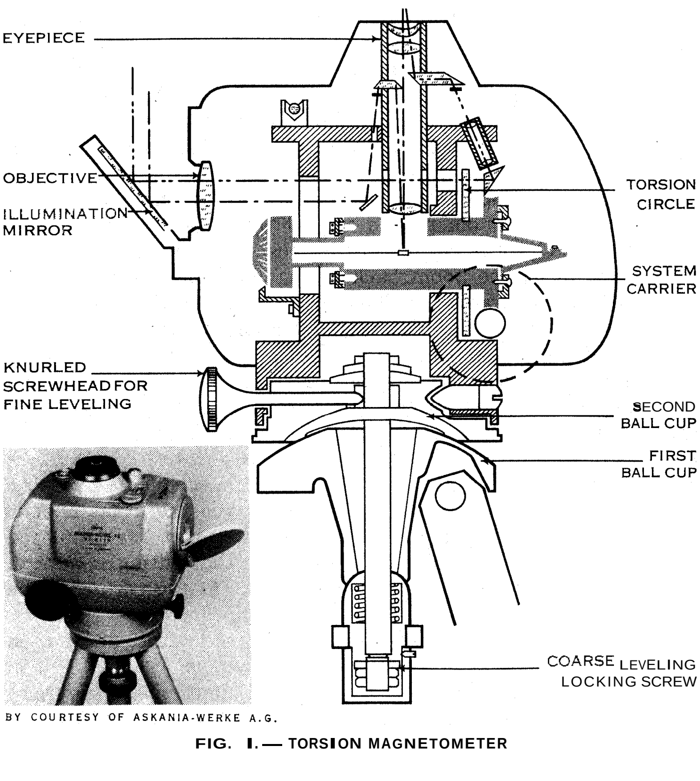
With the high sensitivity of modern gravimeters, changes in the length of the springs with time (drift) must be corrected for, as well as the fluctuation in gravity due to the tidal pull of the sun and the moon. The former can be evaluated only by a systematic series of repeat measurements at control bases; the latter can be calculated from suitable tables or determined empirically by direct observation with a stationary instrument. The final observed gravity values are then corrected for latitude, elevation, terrain, etc., to obtain residuals (anomalies), as discussed previously before they can be utilized for evaluating subsurface geologic conditions. In oil prospecting, observations usually are made at one-mile intervals; in mineral prospecting, observations may be required at intervals of 100 ft.

Magnetic Methods. — Magnetic methods are based upon measuring the magnetic effects produced by varying concentrations of ferromagnetic minerals. Of these, magnetite is the most common mineral and has the greatest magnetic susceptibility, pyrrhotite being appreciably less susceptible and the other common iron minerals are but weakly magnetic.

Instruments used for magnetic prospecting vary from the simple mining compass used in the 17th century to sensitive airborne magnetic units permitting intensity variations to be measured with an accuracy greater than $\frac{1}{10,000}$ part of the earth's field. It is possible to measure any angular or intensity component, but total intensity and vertical intensity anomalies can be most easily interpreted.

One of the most widely used magnetic instruments is the Schmidt vertical magnetometer. It consists of a pair of blade magnets balanced horizontally on a quartz knife edge.

The balance is oriented at right angles to the magnetic meridian



BY COURTESY OF ASKANIA-WERKE A.G.

FIG. 1.— TORSION MAGNETOMETER

and the deflection from the horizontal observed. Thus, magnetic vertical intensity is compared with gravity (assumed to be constant); the deflections of the system are read on an autocollimation telescope (see COLLIMATOR).

Instrument readings are converted into gammas (10^{-5} gauss units) using a calibration factor established by placing the system in a Helmholtz coil and then observing deflections for known electric currents in the coil. The torsion fibre magnetometer (see fig. 1) is another type vertical component instrument that has a greater operating range than the Schmidt type instrument It also has an advantage in that it is easier and quicker to read. The instrument values are referred to a base, corrected for temperature and diurnal variation (see GEOMAGNETISM), and corrected for the normal geographic variation of the earth's magnetic field. Since the end of World War II continuous-recording magnetic instruments have been used. These can be divided into magnetic saturation induction, earth inductor and free proton precession instruments. The magnetic saturation induction instrument has been most widely used. While designs vary, the instrument basically consists of a highly permeable magnetic core of permalloy, mumetal or the like, two opposed identical primary windings, a surrounding secondary winding and an external neutralizing coil. The action of a saturation induction element depends on the core, which becomes completely saturated in magnetic fields of only a few gauss. The core is in the form of a long wire or strip to prevent demagnetizing effect and a primary coil is wound on it; weak currents in the primary carry the core to saturation, and for each cycle of current in the primary the core goes through a so-called saturation or hysteresis cycle. The saturation induction unit measures the change in external magnetic field along the core's length axis. The unit is oriented vertically to record changes on the earth's vertical component. In this position it is subject to an error of 250 γ per degree error in level in the magnetic meridian plane and 16 γ per degree error in level perpendicular to the meridian plane. Aligned along the earth's total intensity vector the error is approximately 16 γ per degree off orientation. The unit, therefore, can best be used to measure changes in total intensity. Recording is done graphically. using a continuous chart recorder. The scale sensitivity of the resultant magnetogram can be varied by means of a selector switch and set to give a full-scale deflection on the record chart equal to 50, 100, 200. 1,500, or 5,000 gammas. The value of the base line of the record chart can also be changed in steps varying from 50 to 5,000 gammas. When used in aerial prospecting. the detector element is usually housed in a streamlined "bird" which is towed behind and beneath the plane on a cable about 100 ft. long, thus eliminating the magnetic effect of the plane. Wing tip and spar installations of the sensing head have also been successfully used.

As elevation is critical with such measurements, several methods have been used to determine the position of the plane in space. On land surveys a gyroscopically stabilized, continuous-strip camera is used together with a recording radio altimeter. The three records are co-ordinated by an electrical system and marked and numbered simultaneously by a keying device. Another method for use over water or other unmapped areas involves the use of Shoran (short range navigation) a radio navigation aid. With this system the distance from two ground stations is measured electronically and is constantly recorded and co-ordinated with the total magnetic intensity chart. Knowing the position of the ground stations, it is then possible to locate the traverse lines without maps or other information.

The Varian nuclear precession magnetometer is another continuous recording magnetic instrument which measures the earth's total magnetic field by observing the free precession (progressive movement) frequency of the protons in a sample of water. Spinning protons in a sample of water tend to orient their axes parallel to any magnetic field that is present. If the protons are reoriented by a strong magnetic field at right angles to the earth's field and the inducing field is then caused to decay quickly, the protons start to precess around axes parallel to the earth's field. They start in phase and a small electromagnetic force (e.m.f.) is induced in a coil placed near the sample. The frequency of this e.m.f. is proportional to the field causing the precession and inversely proportional to the angular momentum. If this precession frequency is accurately measured, it is possible to determine the total field to an accuracy of 2 gammas.

The interpretation of magnetic measurements is subject to the same fundamental drawbacks mentioned in connection with gravity measurements as regards the contrast in physical properties present, depth of origin and integrated contributions from many sources, plus effects related to permanent versus induced magnetization from the earth's magnetic field, changes in strength and direction of the earth's field with location and the cancelling effect related to proximity of opposite induced poles at the boundaries of finite geologic bodies. Despite the difficulties of interpretation, the method has proved valuable in exploration for magnetic mineral deposits, in the determination of geologic structural trends and in estimating the probable depth of the crystalline rock floor beneath sedimentary rock areas. *(See* also MAGNETISM: *Measurement of Magnetic Quantities.)*

Seismic Methods. — Seismic methods are based on determinations of the time interval that elapses between the initiation of a sound wave from detonation of a dynamite charge or other artificial shock and the arrival of the vibration impulses at a series of seismic detectors (geophones). *(See* also SEISMOGRAPH.) The arrivals are amplified and recorded along with time marks (.01 sec. intervals) on a moving photographic paper strip by the use of galvanometers to give a seismogram, or are first recorded on magnetic tape that can be played back and recorded as above for various filter systems. The latter system thus permits greater scope for analytical studies than is possible with the conventional seismogram. Seismic wave propagation is analogous to that defined by optical theory for the refraction and the reflection of light *(see* REFRACTION). The depths and media reached by seismic waves depend on the distance between shot point and receiving points.

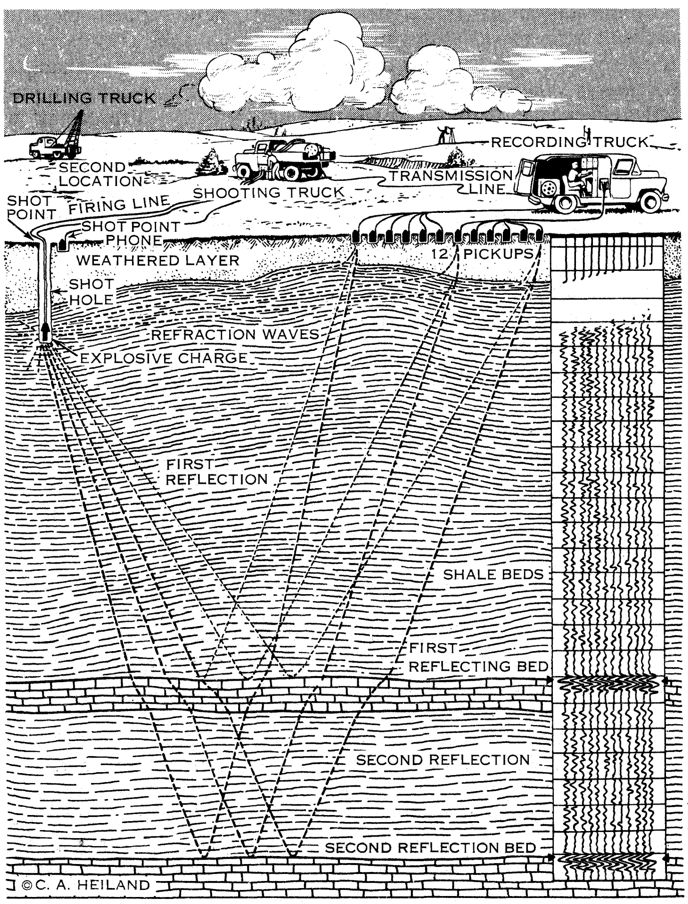


FIG. 2.— SEISMIC REFLECTION METHOD FOR GEOPHYSICAL PROSPECTING
Field equipment is shown above, seismic wave paths below and a seismogram at the right

The first impulses or "breaks" in a seismogram *(see* fig. 2) are caused by waves which have traveled via the quickest path between the shot point and any receiving point. At short distances this is usually also the shortest path, but beyond a certain distance it is quicker for a refracted pulse to travel via a longer path involving underlying layers having a higher velocity. From a plot of travel time as a function of surface distance, data are obtained for determining both the velocity of the material and number of layers present. From the distances at which changes in velocity are indicated the depth of each layer can be computed. The method depends upon (1) the velocity within each of the layers penetrated at depth being greater than that in the layers above; (2) the layers are bounded by plane surfaces; and (3) the material within each layer is essentially homogeneous Under the conditions which are commonly encountered in areas having sedimentary deposits other than limestone. these conditions are commonly satisfied. As discussed under *Gravity Methods,* above, in general the deeper, older formations as a result of higher compression have a higher density and also a higher seismic velocity than the overlying material *(see* also EARTH: *Origin, Composition* and ***Age;*** EARTHQUAKE). As the velocity values determined from the travel-time plot are governed by the slope of the underlying surfaces as well as the nature of the material itself, being greater than normal when receiving up slope and less than normal when receiving down slope, it is customary to record in opposite directions over the same surface area. Observed differences in velocity define not only the direction of slope of the rock surfaces, but also provide information for computing the degree of slope present. Where conditions of downward refraction are encountered in the sedimentary column. as is obtained when a high velocity limestone is underlain by a lower velocity sandstone, there may be no direct evidence in the arrivals of this condition and the calculated values for the depth of any horizons below the limestone will be seriously in error. For what might be termed "normal" conditions (increase in velocity with depth) the error in depths determined is usually less than 10% with this method.

For purely qualitative studies for locating marked horizontal discontinuities in transmissibility, such as are occasioned by intrusive bodies or faults of large displacement, the technique of "fan shooting." a variation of refraction shooting, is employed. Here the apparent velocities along several azimuths from a shot point are recorded. Any velocity abnormalities on one or more azimuths will thus give a bearing on disturbed structure. Cross fan recordings across the area will further define the nature and position of the structural abnormality.

Reflection impulses depend upon the reflection of seismic waves from media of greater elasticity at depth. Their time of arrival depends on the average velocity between surface and reflecting surface and the distance between the shot point and receiving points. *(See* SOUND: Sound *Measurements.)* In essence the method depends upon determining the time for an echo. As in the refraction method, a travel-time graph is plotted. Because of the geometry of the travel path a parabolic plot is obtained. The degree of symmetry of the plot about a central axis defined by the shot point with recording on cross axes portrays the degree of inclination of the buried reflecting horizons. As the travel times for reflected waves are markedly influenced by the low velocity of the near-surface material lying above water table, a correction for the so-called "weathering layer" is important in all reflection studies. This correction can be determined empirically by a short refraction measurement to determine both the velocity and thickness of this layer. The average velocity that is used in computing reflection depths is best determined from velocity measurements in bore holes. Where such control cannot be obtained a value can be derived from a plot of the square of the travel time as a function of the square of the distance. The slope of the resulting graph gives a value that defines the square of the average velocity. Where there is good velocity information and reflecting horizons, the reflection method has been found to have an accuracy of about 1% in depicting subsurface structure.

Because the surface distance required for a reflection measurement is so much less than that required for a refraction measurement in exploring to any depth, there are many advantages to be gained from using the method: (1) The short spread of instruments required eliminates the problem of getting permission to work over several tracts of land; (2) permits "spot" determination of depths rather than average values over an area as is the case in deep refraction studies; (3) requires small charges of explosives and even allows mechanical methods to be employed as a source of energy; (4) permits rapid observations, since a minimum amount of observational data is required. In general, therefore, the reflection method is employed for all deep exploration work. Resolution at depths shallower than 200 ft. is usually not possible because the time interval between the first refraction arrival and the first reflection arrival at these depths is so short that there is not time enough to damp out the first motion sufficiently for the reflection arrival to be recognized.

The refraction method is therefore commonly used for shallow engineering studies, and has also been found to be useful in deep exploration in certain areas where good reflections can not be obtained and for studies of crustal structure at depths of 10 to 50 km.

Electrical Methods. — With the exception of the self-potential method, electrical prospecting methods depend upon differences in electrical conductivity between the geological bodies under study and the surrounding rocks. Metallic minerals, particularly the sulfides, range in resistivity from 1.0 to several ohm-cm.; consolidated sediments of low water content average about 10^4 ohm-cm.; igneous rocks range from 10^4 to 10^6 ohm-cm. and saturated unconsolidated sediments, from 10^2 to 10^4 ohm-cm. The resistivity of the latter depends largely on the amount and electrolytic nature (salinity) of the included water.

The self-potential method makes use of the fact that most metallic sulfide minerals are easily oxidized by downward-percolating ground water. Because of the surface oxidation of such ore bodies the elements of a simple chemical battery are established and a spontaneous electric current flows down through the ore body and back to the surface through thk surrounding water-saturated ground, which acts as the electrolyte. It is possible to locate these localized electrical fields and hence ore bodies by mapping points of equal electrical potential at the surface using non-polarizing electrodes and a sensitive ammeter, or a milliammeter, or by measuring potential differences between successive profile stakes forming a grid over an area using a potentiometer.

In all other electrical methods, electrical energy is supplied to the ground either galvanically or inductively. Direct current or alternating current of low frequency is usually used. In the equipotential-line method, power is supplied to two points or line electrodes; the equipotential lines are traced by two search electrodes connected through an audio-amplifier with headphones in the output; one of the probes is held stationary and the other is moved until the sound disappears. The presence of a good conductor is indicated by the spreading of the equipotential lines and a poor conductor, by the drawing together of the equipotential lines (*see* fig. 3). Interpretation is largely qualitative and empirical.

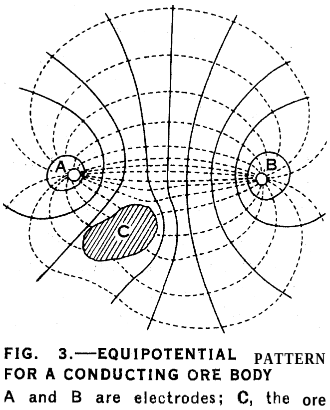

FIG. 3.—EQUIPOTENTIAL PATTERN FOR A CONDUCTING ORE BODY
A and B are electrodes; C, the ore body. Solid lines indicate equipotential; dashed lines, current flow

A potential method that is used extensively is known as the "resistivity" method. Four evenly spaced electrodes are driven into the ground; the external pair is supplied with current from batteries or an alternating current source that is read on a milliammeter, while the internal pair is connected to a potentiometer to determine the voltage difference between them (fig. 4). To avoid polarization effects, nonpolarizing potential electrodes can be used, or a commutator inserted in the circuit so that the current through the ground changes in direction every half cycle but retains the same direction through the instrument. The ratio of

FIG. 4.— ELECTRICAL RESISTIVITY METHOD

voltage and current, multiplied by a factor depending on electrode spacing, gives the true resistivity for homogeneous ground, or the so-called "apparent resistivity" for nonhomogeneous ground. The depth of effective penetration is about one third the distance between the two outer electrodes. If the electrode arrangement is moved over the ground with constant spacing, variation of resistivity in a horizontal direction to a fixed depth is obtained. This method is quite useful for determining the presence of any horizontal discontinuities, such as, for example, rock rising near the surface along the line of a proposed highway. By keeping the centre of the electrode arrangement fixed and expanding the spacing of the electrodes about this centre point changes in resistivity with depth can be determined and their depth deduced. This method has been extensively used in subsurface engineering studies as, for example, in the determination of the depth to bedrock beneath river bottom alluvium.

Interpretation of resistivity results is handicapped by the marked effects of variations in soil moisture and the chemistry of the interstitial water as well as by vertical and horizontal changes in lithology; the potential differences measured represent accumulative effects from the entire section penetrated. Interpretation techniques employed include the matching of plots of apparent resistivity as a function of electrode spacing against theoretical "type" curves, the location of inflection points, breaks. changes in slope of logarithmic plots of the results, accumulative resistivity value plots and other methods of a somewhat more quantitative nature. Best results in the use of resistivity values for determining depths have been obtained where it has been possible to use well data to establish local empirical correlations between the resistivity plots and geologic depth data.

A special application of electrical methods is in the study of subsurface stratigraphy by measuring the potential differences between the surface and an electrode lowered in a bore hole and by also measuring variations in electrical resistivity with depth. Both measurements must be carried out before a hole is cased. The procedure is known as electrical logging. The potential log gives a measure of porosity and permeability since the measurements are markedly affected by the ability of the drilling fluid to penetrate the formations and the contrasts in electrolytic properties of the formational fluid and the drilling fluid. The resistivity measurements define the position of formational boundaries and the physical character of the lithology. Three resistivity logs usually are taken: one having shallow penetration is used for defining the location of formational boundaries and the other two, having intermediate and deep penetration, are used for determining the extent the drilling fluid has penetrated into the formations and the true resistivity of the formation present. The various measurements taken in conjunction provide a valuable tool for not only studying conditions in a given well but also for carrying out correlation studies between wells and thus defining geologic structure and horizontal changes in lithology.

Electromagnetic Methods. — The electromagnetic methods are based upon the fact that an alternating magnetic field will cause an electric current to flow in conducting material. Since most metallic minerals are good electrical conductors the method is best suited for their exploration. Measurements are carried out by connecting a source of alternating current to a coil of uire which acts as a source for a magnetic field similar to that which would be produced by a short magnet located on the axis of the coil. The magnetic field of the coil alternates in intensity in the same manner that the coil current alternates. A receiving system consisting of a second (search) coil connected to a voltmeter is mounted so as to be free to rotate about a horizonal axis. If the receiving coil is mounted so as to rotate on an axis perpendicular to that of the induced magnetic field then induced voltage will vary from a maximum when the plane of the coil is perpendicular to that of the applied field and to zero nhen the plane of the coil is parallel to that of the applied field. These are the conditions if no conductor is present. If a conductor is present the induced current in the conductor sets up a secondary magnetic field that distorts the primary field. That is, the inphase portion of the secondary field combines with that of the primary to give a resultant value that is not horizontal except directly over the conductor. The voltmeter is used only as a null detector to determine when the receiver coil is parallel to the resultant field. By using an inclinometer to record the angle of the moving search coil when in the null position, the location of a conductor can be determined as the crossover (inflection) point on a profile across the body.

Another variation of this method is to have both the receiver and transmitting coils in the horizontal plane. In this arrangement the voltage developed over nonconducting ground is a function of the construction of the coils which are usually moved across the ground with a constant separation. The presence of a conductor is indicated by changes in the voltage values from the normal values for this configuration. When both coils are outside but adjacent to a conductor the secondary field generated by the induced current in the conductor adds to the normal field and gives an increase in voltage values. When the coils straddle the conductor the secondary field opposes the primary field. giving a decrease in voltage. The conductor is therefore marked by a voltage minimum. Effective depth penetration is about one half the coil separation. The method is also adaptable for airborne operations. Here the transmitting coil is mounted on the plane fuselage and the search coil is trailed in a "bird" on a joo ft. cable.

Radioactive Methods.—In the disintegration of radioactive minerals three spontaneous emissions take place, the ejection of an electron (beta ray), a helium nucleus (alpha ray) and short-nave length electromagnetic radiations (gamma rays) (see RADIOACTIVITY, NATURAL). Radioactive measurements are based upon the detection of these natural radioactive emissions, primarily the gamma rays. The gamma rays correspond to X-rays and have sufficient penetrating power to pass through rock material several feet thick as uell as through iron several inches in thickness; it is this property which is utilized in prospecting for radioactive minerals and in radioactive logging in the underground study of oil fields.

The instruments used in radioactive exploration are the Geiger counter and the scintillometer. The gamma rays ionize the medium through which they pass by colliding with nuclear electrons and knocking them out of their orbits thus leaving the atoms ionized. The Geiger counter is a discharge tube which records the presence of gamma rays by the ionization they produce in a gas in the tube. The gas used is a mixture of argon and some polyatomic vapour. In the centre of the tube is a wire (anode) with an enclosing cylindrical tube serving as a cathode. A difference in potential (about 1.000 v.) is maintained between the anode and the cathode. When the gas is sufficiently ionized by gamma rays passing through the chamber a discharge occurs which is amplified and heard as a click. The number of clicks per minute, which is a measure of the gamma-ray radiation present, is usually indicated on a dial on the counter. Because of cosmic rays in the atmosphere there is a background count which varies with the efficiency of the instrument.

The scintillometer is a gamma-ray detection instrument whose operation depends upon the fact that certain crystal elements emit a flash of light upon absorbing gamma rays. This flash is picked up by a photo multiplier tube and amplified and a visual reading of the emission rate obtained. This instrument is almost 100 times more sensitive than the Geiger counter. Because of the efficiency of this instrument in indicating the presence of gamma rays it is possible to differentiate emanation from different mineral sources on the basis of the energy levels associated with the source elements. Scintillometer as well as Geiger counter measurements can be carried out both from a moving surface vehicle and from low-flying aircraft.

In addition to prospecting for radioactive minerals the radioactive method is extensively applied in bore hole studies of subsurface stratigraphy. Different sedimentary rocks are naturally characterized by different concentrations of radioactive material. The shales and volcanic ash give the highest gamma-ray count and the limestones the lowest. In addition to the natural gamma-ray log the same technique of measurement is used to determine neutron absorption with a neutron source lowered ahead of a gamma-ray detector. Neutrons are absorbed by hydrogen compounds and as a result a low return indicates the presence of porous formations or those with chemically-combined water, as clay and shale. Such ambiguity, however, can be resolved when the neutron log is combined with the gamma-ray log for interpretation.

From the preceding discussion it is clear that geophysical exploration techniques can not be applied indiscriminately. A knowledge of the geologic parameters likely to be associated with the mineral or subsurface condition being studied is essential both in choosing the method to be applied and in interpreting the results obtained.

For further discussion of geologic principles and concepts used in this article see GEOCHEMISTRY; GEOLOGY. See also ORE DEPOSITS; PETROLEUM.

GEOPHYSICAL YEAR, INTERNATIONAL: see INTERNATIONAL GEOPHYSICAL YEAR.

GEOPHYSICS, the study of the earth, using the research methods of physics. The areas of interest range from the earth's deep interior where matter is at several thousand degrees centigrade and 1,500,000 atm. pressure, through the crust with its ocean basins and bewildering inhomogeneities, to the tenuous upper atmosphere. The problems are analogous to those of astronomy, in that the subject studied is seldom under direct observation and handling, forcing conclusions to be drawn primarily by the mathematical and physical interpretation of physical measurements. For discussion of the scientific study of the chemistry of the earth see GEOCHEMISTRY.

For the convenience of classification, geophysics may be divided into the following somewhat overlapping branches. geodesy, the study and theory of the earth s figure, including gravity; seismology, the study of the earth's interior layering, lateral variation, density and other physical properties by means of the reflection and refraction of elastic uaves; hydrology, the study of the movements and circulation of water in the uppermost rocks and surface channels of the earth; oceanography, the study of ocean basins, both bottom sediments and current motions; meteorology, the study of the motion and properties of the lower, primarily weather formative atmosphere; upper air physics and cosmic ray research, the study of the electrical and physical properties of the outer fringe of atmosphere and the particle bombardment of the earth from space; terrestrial electricity (geoelectricity), the study of the charge distribution and movement of currents in the atmosphere and earth; terrestrial magnetism (geomagnetism), the study of the source, figure and changes of the earth's magnetic field and the response of matter to it; and volcanology, the study of the origin and properties of volcanoes. In addition, the dating of meteorites and crustal rocks by means of analysis of their radioactive components, as well as the branch of astronomy dealing with the rotational and translational motion of the earth may be included.

For details on these branches of geophysics, *see* the articles on: ATMOSPHERE; CLIMATE AND CLIMATOLOGY; COSMOGONY; EARTH; EARTHQUAKES; ELECTRICITY, ATMOSPHERIC; GEOCHRONOLOGY; GEODESY; GEOMAGNETISM; HYDROGRAPHY; METEOROLOGY; OCEAN AND OCEANOGRAPHY; PLANET; RADIOACTIVITY, ARTIFICIAL; RADIOACTIVITY, NATURAL; SEISMOMETER; SOUND; TIDES: *Bodily Tides;* VOLCANISM; VOLCANO.

The techniques of geophysics include measurements of gravity, direction and intensity of the earth's magnetic field, electrical potential gradients, movements of fluids and motions of the solid surface, both rapid fluctuations as from earthquakes and long-term events due to gradual shifts relative to sea level. Measurements of the above properties over a period of years permit a determination of properties in the earth's interior. Much laboratory work is also done. The properties of matter are studied under extreme temperatures and pressures. Models of various features of the earth are constructed and tested to ascertain their response to given variation in physical parameters.

The primary international geophysical organization is the International Union of Geodesy and Geophysics formed in Brussels in 1919. The union consists of seven international associations: geodesy, seismology and physics of the earth's interior. meteorology, geomagnetism and aeronomy, physical oceanography, hydrology, and volcanology. Meetings are held every three years. Interrupted during World War II, they were started again in 1948. The United States affiliate of the International union is the American Geophysical union with offices in Washington, D.C.

Many universities throughout the world offer courses in the various branches of geophysics. Since geophysical methods of investigation are primarily mathematical and physical, and in addition demand a knowledge of geology, geophysics is taught chiefly at the post-graduate level. Those who wish to enter this specialty should start their mathematical training at the earliest possible time. Reviews in the various topics of geophysics appear yearly in *Advances in Geophysics*, the initial volume of which appeared in 1955.

Since geophysics deals with world-wide phenomena, the need for international co-operation is great. This has led to three International Geophysical years, in 1882–83, 1932–33 and 1957–58, the first two being termed International Polar years. The main purpose of these events is to obtain physical measurements simultaneously over large portions of the earth and to inaugurate projects which demand international participation. *See* also INTERNATIONAL GEOPHYSICAL YEAR. (J. C. JN.)

GEOPOLITICS. The term "geopolitics" was coined shortly before World War I, spread throughout central Europe between the two wars and came into world-wide use with World War II.

Meaning. — There is no universally accepted definition of the word. It is frequently and loosely used as an alternate term for "political geography," a legitimate child of human geography. The use of the term "geopolitics" is therefore not necessarily indicative of its true meaning, and careful analysis is needed in order to distinguish between an objective study of politico-geographical factors and power-political speculations in the realm of geopolitics. Anyone might rightly guess it to be a portmanteau word combining "geography" and "politics," and wrongly conclude that it is an alternate name for "political geography," one of the oldest branches of earth science. Actually, it is almost never used in this broad sense.

All the usual meanings of "geopolitics" relate to the utilization of geography in the service of national governments. Within this delimitation the term is employed in three senses: (1) As used by some special students of the subject, and sometimes by publicists and editorial writers, the word refers to the power position of the nations, insofar as their power is conditioned by nature. (2) A few careful writers make the term a synonym for "applied political geography," as distinct from the history, principles and theory of political geography. In this usage it is akin to other applied sciences, in that it treats of universally applicable conditions — the natural environments of governments — and reaches conclusions through objective and impartial study. (3) A far larger number of writers and speakers use geopolitics loosely to designate national policy as affected by the natural environment. Nearly always a single country is considered with reference to the rest of the world, and a single aspect of its position is likely to be stressed — generally either national security or foreign policy. This is the layman's commonest usage.

The momentous meaning of geopolitics is very like that last described, but is restricted to conscious special pleading to promote the interests of a particular government or to sway its national policy. This is the sole meaning of the term in central Europe, where originated both the name and the restricted definition. This narrow but indubitable geopolitics was best exemplified in the German movement between World Wars I and II which popularized the name.

It was not scientific geography and has frequently been called a pseudo science. Such geopolitics uses forms and methods of geography but its proponents assume that the natural environment determines the actions oi political groups, and many geopoliticians lack adequate understanding of earth conditions.

It would be fallacious, however. to look upon geopolitical doctrine and ideology as something exclusively rooted in central European or German soil. Not only did it spread to countries which, like Italy. Spain or Japan. sympathized with the expansionist ambitions of Germany, but it must also be remembered that the U.S. creed of "manifest destiny" between 1830 and 1860 was based on the kind of argumentation typical of geopolitics.

Origin. — The name was coined and defined by Rudolf Kjellén, a Swedish political scientist. professor at the University of Uppsala and member of the Swedish parliament. He made "Geopolitik" one of the five co-ordinate aspects of a theoretical system of government. the others being "Ekonomopolitik," "Demo-politik," "Socio-politik" and "Krato-politik." This system he called "The State as an Organism" (*Staten som Lifsform*, definitive edition, 1916).

Kjellén had been profoundly impressed by the work of natural scientists, and especially imbued with the political geography expounded by the German geographer. Friedrich Ratzel, who had been trained in the "new" biology of the middle 19th century. Geography, like all the scientific disciplines. was affected by the evolutionary view of the universe. Ratzel restated much of the theory of geography in the light of evolution and natural selection. In particular, he was the first to publish a survey of political geography analyzed as a systematic branch of the subject. In this work Ratzel compared the state to an organism, but he was careful to point out that he was using simile and metaphor.

Kjellén saw in Ratzel's treatise on political geography the logical bridge between natural science and political science. He apparently believed he was incorporating Ratzel's concepts of political geography into his own systematic treatise on the state. The name "geopolitics," which he applied to the geographic section, may well have suggested itself to his mind as the parallel form to Socio-politik and the rest of his subdivisions.

In adapting Ratzel's work, he subtly metamorphosed it. Untrained in the rigorous discipline of natural science, he disregarded Ratzel's cautions and declared flatly that the state *is* an organism, and hence endowed with biological qualities: viz., growth and decay, and differentiation of members and organs. The importance he attached to this interpretation of his source appears in the title of his book. The *State as an Organism.*

If the state is an organism. it has powers of action independent of and superior to the human groups or individuals who constitute it. This view coincides with ideas expressed a century earlier by the pre-Darwinian German philosophers Johann Fichte, Georg Hegel and Friedrich von Schlegel. One effect of Kjellén's construction was therefore to clothe German political philosophy of an earlier day with the new garment of evolutionary natural science. In an epoch when natural science was conceded by public opinion to have almost the authority of Revelation. Kjellén's claim for geopolitics handed a powerful weapon to any state disposed to use it for propaganda and as a mold for national policy. In Germany, and subsequently in Japan and Italy, the opportunity was not missed.

Kjellén's treatise was translated into German in 1917, and so at the end of World War I in 1918 lay ready to hand as a lever for rebuilding the defeated German state into a great power. It was seized upon by certain geographers. political scientists and publicists. who pushed it to the forefront of German attention, and kept it there during the 20 critical years between the two world wars.

This group was led by Karl Haushofer (1869–1946), who made himself the incarnation of geopolitics. As an officer of the Bavarian army. his career included much service on the general staff. Before World War I. he embraced the opportunity to carry his study of geography far beyond the considerable training given to all German army officers. Field studies in the orient led to the degree of Ph.D. at the University of Munich, with a dissertation on the political and military geography of the Japanese empire as it was in the first decade of the 20th century.

On his retirement from the army in 1919 he made his mission in life the regeneration of the German state by the aid of geography. He took over Kjellén's organismal theory of the state, and adopted "geopolitics" as the name for the brand of geography to which he thereafter devoted himself tirelessly. His geopolitics was compounded of facts about the earth, theories of government and items of German history.

From these sources he distilled a powerful propaganda, which strongly appealed to almost every sort of German. It was given coherence and direction by the assumption that the German state, which had been continuously growing for centuries, was an organism that must continue to spread over more and more territory until it conquered and absorbed the whole earth.

Methods and Manner. — Haushofer's first platform was in the University of Munich, where he lectured on geopolitics from 1919 — after the Nazis came to power in 1933 as professor of geopolitics. There he drew together a group of disciples who included a number of journalists who were instrumental in giving geopolitics wide publicity.

In 1924 he extended the range of his influence by launching the monthly *Journal of Geopolitics (Zeitschrift fur Geopolitik)*, of which he became and remained editor in chief. and by a long lead the chief contributor. It carried occasional articles intended to influence public opinion in those foreign countries particularly sympathetic to the German way of life, or intimately bound to Germany by economic ties. It was supplemented by a steady stream of books. Here. too, Haushofer led his devoted associates in volume of output. *(See* the bibliography for the most important books of the geopoliticians.) Nearly all writers on the subject adhered to their master's views, to the extent of copying his obscure style, often even for a German reader, and cloudy terminology.

Haushofer compounded willful ambiguity with a mystical philosophy at variance with the assumed scientific character of geopolitics. The compulsion to synthesize ideas into a universal view (*Weltanschauung*, "world outlook") is a trait common to German intellectuals, and Haushofer was no exception. His *Weltanschauung* was founded on theories of space. Thereby it retained the form of geography, but its content included extensions of geographical space into the realm of the mystical. The drive that made it a practical philosophy was political, springing from the ambition of German nationalists to dominate other peoples. The theory and the practice were welded into a national policy that was framed by the nature of central Europe. rooted in 800 years of German territorial expansion, rationalized by powerful German philosophers of the 19th century, reanimated by the biological (organismal) concept of the state and clothed in the creed of German "racial" superiority.

When the real meaning of the geopoliticians can be discerned, their world proves to be a product of environmental determinism, but chauvinistically German, disclosing a pitiless attitude toward non-German society that startles the foreigner. This attitude can be read most clearly in established writers whose manner has remained lucid, while their matter has turned geopolitical. A book by an old-line geographer. become a geopolitician, created a minor international incident when it was published in an English translation in 1934 (Ewald Banse, *Raum und Volk im Weltkriege*, 1932). For an account of the incident see the British and American editions: *Germany, Prepare for War!* (1934) and *Germany Prepares for War* (1941).

A favourite literary device of the geopoliticians was the slogan. One of the terms they adopted from Ratzel. *Lebensraum* ("living space"), has found its way into the English language. Each catchword or phrase refers to the earth, or some part of it, and most of them state or imply a political association with the earth; *e.g.*, boundary consciousness, space policy. Some two-score of these slogans were hammered into the consciousness of the German nation by unceasing repetition.

An important instrument of the geopoliticians was the map, which they used constantly and in novel ways. As geographers they well understood the impressiveness of the map and the ease with which it can be read if simple and neat. Treating it as a "weapon," they published hundreds of maps and pictographs. So far as possible, they restricted each map to a single theme, drawn to show the third dimension, and labeled succinctly. They stretched representation beyond existing facts to include aspirations, such as territorial goals. They justified omissions, and even falsifications. The *Zeitschrift fur Geopolitik* is the principal source of these maps. Reproductions of typical samples of maps and of symbols commonly used are to be found in Derwent Whittlesey, *German Strategy of World Conquest.*

Political Significance. — By gaining the widest possible publicity, the geopoliticians sought ceaselessly to win the German public to their program of national political regeneration. and to spur sympathizers in foreign countries to work for acceptance of German plans abroad. Educational propaganda was one of the two roads to the goal of German supremacy that they never lost sight of.

The other road was laid out to reach directly as many responsible officials of the government as possible, and to aid the state to regain its position as a great power through existing or newly created governmental agencies.

Haushofer made contact with Adolf Hitler very early — during the months of 1923–24 when the future *Fuhrer* of Germany was in prison near Munich. That enforced retreat was spent in writing *Mein Kampf*, reportedly with Rudolf Hess as amanuensis. Hess had become an early disciple of Haushofer's. It is due to these influences that geopolitics can be credited with a number of the ideas that appear in *Mein Kampf*, especially in the sections on foreign affairs.

Haushofer's long and reputable connection with the army general staff gave him personal access to the men who in the 1920s were undertaking to rebuild *sub rosa* the German military power. The general staff needed no persuasion as to the importance of geography in tactics and in strictly military strategy. The geopoliticians showed the necessity of a comprehensive and thorough knowledge of world geography for successful prosecution of the political strategy (sometimes called grand strategy) which is an essential component of total war. This they named "geo-strategy" (*Wehr-geopolitik*).

In theory a branch of geopolitics, geo-strategy was the resilient core of the larger subject. Haushofer espoused geopolitics as a means of "renovating" Germany and he viewed a state of war as the normal condition of mankind. Geo-strategy treated warfare as total, embracing the entire populations and resources of the contesting states. It recognized the psychological effects of the geography of the war theatre on fighting forces. It helped to make Germany the first country to realize that air power could take a position alongside sea power and land power. It may fairly be said that geo-strategy was the main theme of the geopoliticians and that geopolitics paved the way for modern concepts of total war.
