Harvey's English works were edited by A. B. Grosart (1884–85); *Ciceronianus* was edited by H. S. Wilson and translated by C. A. Forbes (1945). Autobiographical material appears in *The Letter Book of Gabriel Harvey,* edited by E. J. L. Scott (1884), and Harvey's *Marginalia,* edited by G. C. Moore Smith (1913), which also contains the best biography. (E. H. MR.)

HARVEY, GEORGE BRINTON McCLELLAN (1864–1928), U.S. editor and diplomat, was born in Peacham, Vt., Feb. 16, 1864. At 18 he became a reporter on the *Springfield* (Mass.) *Republican,* and later on the *Chicago News* and the *New York World.* He was insurance commissioner of New Jersey in 1890–91 and managing editor of the *New York World,* 1891–93. In 1899 he purchased the *North American Review,* which he thereafter edited. During 1900–15 he was president of the publishing house of Harper & Bros., and during 1902–13 was editor of *Harper's Weekly.* In 1903 he purchased the *Metropolitan Magazine.*

Harvey was said to have been the first to suggest, in 1906, Woodrow Wilson, then president of Princeton, as a presidential possibility. In the campaign of 1912 he gave Wilson strong support, but after the latter's nomination an estrangement developed. In 1916 Harvey urged the election of Charles E. Hughes, the Republican candidate for president. He was strongly opposed to the League of Nations on the ground that it involved the yielding of national sovereignty. In 1918 he established the *North American Review's War Weekly,* later called *Harvey's Weekly,* which bitterly denounced the Wilson administration. In 1921 he mas appointed ambassador to England by President Harding, a position which he held till Dec. 1923. He was editorial director of the *Washington Post* in 1924–25. He died at Dublin, N.H., Aug. 20, 1928.

HARVEY, SIR JOHN MARTIN (1863–1944), English actor, producer and theatre manager, who came to be associated with his outstanding success as Sydney Carton in *The Only Way* (an adaptation of Charles Dickens' *A Tale of Two Cities),* mas born at Wivenhoe, Essex, on June 22, 1863. He was educated at King's College school, London, and was intended for a naval architect. However, he chose the stage, making his first public appearance at the Court theatre, London, in 1881, while still a boy. He joined Sir Henry Irving's Lyceum company in 1882 and remained there for 14 years. He married Angelita Helena de Silva, who became his leading lady when he entered management.

A man of scholarly refinement, and an actor of power and sensitivity, Harvey maintained the Irving standard and method. His finest performance was as Oedipus Rex in Max Reinhardt's production of that play at Covent Garden theatre, London. in 1912. Martin Harvey was knighted in 1921 and was made an honorary LL.D. of Glasgow university in 1938.

He died on May 14, 1944.

See *The* Autobiography of *J.M.H.* (1933) and M. Willson Disher, *The Last Romantic* (1948). (W. J. M.-P.)

HARVEY, WILLIAM (1578–1657), English physician, the discoverer of the circulation of the blood. was born at Folkestone, Kent. on April 1, 1578. He was educated at Caius college, Cambridge, and then proceeded to Padua to study medicine under Hieronymus Fabricius ab Aquapendente and became doctor of medicine in April 1602. Returning to England, he settled in London. He was admitted (June 1607) fellow of the Royal College of Physicians, and in 1609 obtained the reversion of the post of physician to St. Bartholomew's hospital. and in the same year he succeeded to the post.

In 1616 he began a course of lectures at the College of Physicians in which he first brought forward his views upon the movements of the heart and blood. Meantime his practice increased, and he had the lord chancellor, Francis Bacon, and the earl of Arundel among his patients. He was physician extraordinary to James I and physician in ordinary to Charles I. In 1628 he published the *Exercitatio anatomica de motu cordis et sanguinis in animalibus,* in which he announced his discovery of the circulation of the blood. Between 1629 and 1632 he traveled on the continent, principally in Italy with James Stuart. afterward duke of Richmond. Four years later he accompanied the earl of Arundel on his embassy to the emperor Ferdinand II. He returned to his practice in London at the close of the year 1636, and accompanied Charles I in one of his journeys to Scotland (1639 or 1641), and was in attendance on the king at the battle of Edgehill (Oct. 1642), and then followed Charles I to Oxford.

While with the king at Oxford he was made warden of Merton college, but a year later, in 1646, that city surrendered to Lord Fairfax, and Harvey returned to London. He was now 68 years old, and, having resigned his appointments and relinquished the cares of practice, lived in learned retirement with one or other of his brothers. The work on mhich he had been chiefly engaged at Oxford, and indeed since the publication of his treatise on the circulation in 1628, was an investigation into the subject of generation. Charles I had put the royal deer parks at Windsor and Hampton Court at Harvey's disposal, and had watched his demonstration of the growth of the chick with no less interest than he had watched the movements of the living heart. Harvey had collected a large number of observations, and George Ent succeeded in obtaining the manuscripts, with authority to print them or not. The result was the publication of the *Exercitationes de generatione animalium* (1651).

This was the last of Harvey's labours. He had now reached the age of 73. His theory of the circulation was generally accepted by the most eminent anatomists both in his own country and abroad, and he was known and honoured throughout Europe. In 1654 he nas elected president of the College of Physicians but declined the honour, though he enriched the college with many gifts.

Harvey died on June 3, 1657, and was buried at Hempstead, Essex; in 1883 his remains were placed in the Harvey chapel in the church there.

John Aubrey says: "In person he was not tall, but of the lowest stature; round faced, olivaster complexion, little eyes, round, very black, full of spirits; his hair black as a raven, but quite white 20 years before he died." The best-known portrait of him extant is by Cornelius Jansen in the library of the College of Physicians.

Harvey's Work on the Circulation. — In estimating the character and value of the discovery announced in the *Exercitatio anatomica de motu cordir et sanguinis in animalibus,* it is necessary to bear in mind the previous state of knowledge. Aristotle taught that the blood was elaborated from the food in the liver, thence carried to the heart, and sent through the veins over the body. The Alexandrian physicians Erasistratus and Herophilus taught that, while the veins carried blood from the heart to the members, the arteries carried a subtle kind of air or spirit. Galen discovered that the arteries were not, as their name implies, mere air pipes, but that they contained blood as well as vital air or spirit, and he believed that the nerves arose from the brain and conveyed "animal spirits" to the body. The views of Galen re-

mained current till the 16th century. The physicians of that period had developed certain doctrines concerning the vascular system which may be summarized thus: (1) The blood is not stagnant, but moves in the body. But no one had a conception of a continuous stream returning to its source (a circulation in the true sense of the word) either in the system or in the lungs. If they used the word *circulatio*, as did Andreas Caesalpinus, it was as vaguely as the French policeman cries "*Circulez*." The movements of the blood were in fact thought to be slow and irregular in direction as well as in speed, like the circulation of air in a house, or of a crowd in the streets. (2) They supposed that one kind of blood flowed from the liver to the right ventricle of the heart, and thence to the lungs and the general system by the veins, and that another flowed from the left ventricle to the general system by the arteries. (3) They supposed that the septum of the heart was pervious and allowed blood to pass directly from the right to the left ventricle. (4) They had no conception of the functions of the heart as the motor power of the movement of the blood. They doubted whether its substance was muscular; they supposed its pulsation, like that of the arteries, to be due to expansion of the contained vital spirits.

Of the great anatomists of the 16th century, Andreas Vesalius in 1543 ascertained that the septum between the right and left ventricles is complete, though he could not bring himself to deny the invisible pores which Galen's system demanded. Michael Servetus, in his *Christianismi restitutio* (1553), went somewhat farther, and, from the anatomical fact of the complete septum and the large size of the pulmonary arteries he concluded that there is a communication in the lungs by which blood passes from the pulmonary artery to the pulmonary vein. It seems doubtful whether even Servetus rightly conceived of the entire mass of the blood passing through the pulmonary artery and the lungs. Indeed, a true conception of the lesser circulation as a transference of the whole blood of the right side to the left was impossible until the corresponding transference in the greater or systematic circulation was discovered. Lastly, the system of valves in the veins had been elaborately set forth and illustrated by Harvey's own teacher Fabricius. The way then to Harvey's great work had been paved by the discovery of the valves in the veins, and by that of the lesser circulation, but the significance of the valves mas unsuspected and the fact of even the pulmonary circulation was not generally admitted.

In his treatise Harvey proved (1) that it is the contraction, not the dilatation, of the heart mhich coincides with the pulse, and that the ventricles, as true muscular sacs. squeeze the blood which they contain into the aorta and pulmonary artery; (2) that the pulse is produced by the arteries being filled with blood; (3) that there are no pores in the septum of the heart, so that the whole blood in the right ventricle is sent to the lungs and round by the pulmonary veins to the left ventricle. and also that the whole blood in the left ventricle is again sent into the arteries, round by the smaller veins into the *venae cavae*, and by them to the right ventricle again—thus making a complete circulation; (4) that the blood in the arteries and that in the veins is the same blood; (5) that the action of the right and left sides of the heart, auricles, ventricles and valves, is the same. the mechanism in both being for reception and propulsion of liquid and not of air; (6) that the blood propelled through the arteries to the tissues is not all used, but that most of it runs through into the veins; (7) that there is no to-and-fro undulation in the veins. but a constant stream from the distant parts toward the heart; (8) that the dynamic starting point of the blood is the heart and not the liver.

The method by which Harvey arrived at his solution of the most fundamental and difficult problem in physiology is well worthy of attention. He had not only furnished himself with all the knowledge that books and the instructions of the best anatomists of Italy could give, but, by a long series of dissections, had gained a far more complete knowledge of the comparative anatomy of the heart and vessels than any contemporary had. Thus equipped. he began his investigations into the movements of the heart and blood by seeing their action in living animals. He minutely describes what he saw in dogs, pigs, serpents, frogs and fishes, and even in slugs, oysters, lobsters and insects, in the transparent shrimp, and lastly in the chick while still in the shell. He particularly describes his observations and experiments on the ventricles, the auricles, the arteries and the veins He shows how the arrangement of the vessels in the fetus supports his theory. He adduces facts observed in disease as well as in health to prove the rapidity of the circulation. He explains how the mechanism of the valves in the veins is adapted to favour the flow of the blood to the heart. He estimates the capacity of each ventricle, and reckons the rate at which the whole mass of blood passes through it. He elaborately and clearly demonstrates the effect of obstruction of the bloodstream in arteries or in veins, by the forceps in the case of a snake, by a ligature on the arm of a man, and illustrates his argument by figures. These results can be explained only by the constant circulation of the same blood. Lastly, in the 15th, 16th and 17th chapters of his great work, he adds certain confirmatory evidence as to the effect of position on the circulation, the absorption of animal poisons and of medicines applied externally, the muscular structure of the heart and the necessary working of its valves. The whole treatise, which occupies only 52 pages of print, is a model of accurate observation, patient accumulation of facts, ingenious experimentation, cautious hypothesis and logical deduction.

In one point only was the demonstration of the circulation incomplete. Harvey did not see the capillary channels by which the blood passes from the arteries to the veins. This gap in the circulation was filled 30 years later by the great anatomist Marcello Malpighi, who described the capillary circulation four years after Harvey's death. But the existence of the channels first seen by Malpighi was already clearly pointed to by Harvey's reasoning.

Harvey's Work on Generation.— The *Exercitationes de generatione animalium* is between five and six times as long as the work on circulation, and is followed by excursus *De partu, de uteri membranis, de conceptione;* but, though the fruit of observations as patient and extensive, its value is far inferior. The subject was more abstruse, and was inaccessible to proper investigation without the aid of the microscope. Hieronymus Fabricius, Harvey's master, in his work *De formatione ovi et pulli* (1621), and another pupil of Fabricius, Volcher Coiter of Nürnberg, were among the few in modern times who had preceded Harvey in this study. The 72 chapters which form Harvey's book lack the coordination so conspicuous in the earlier treatise, and some of them seem almost like detached chapters of a system which was never completed or finally revised.

Aristotle had believed that the male parent determined the form of the future embryo. while the female only nourished and nursed the seed. Galen taught that each parent contributes seeds, the union of which produced the young animal. Harvey, after speaking with due honour of Aristotle and Fabricius, begins ab *ovo,* for he says, "almost all animals, even those mhich bring forth their young alive, and man himself, are produced from eggs." This dictum, usually quoted as *omne vivum ex ovo,* was a prevision of genius, and was not proved until K. E. von Baer discovered the mammalian ovum in 1827. Harvey proceeds with a careful anatomical description of the ovary and oviduct of the hen, describes the new-laid egg, and then gives an account of the appearance seen on the successive days of incubation. Commenting on Aristotle and Fabricius, he declares against spontaneous generation, proves that there is no *semen foemineum,* that the chalazas of the hen's eggs are not the *semen galli,* and that both parents contribute to the formation of the egg. He describes accurately the first appearance of the ovarian ova as mere specks, their assumption of yolk and afterward of albumen. He describes two methods of production of the embryo from the ovum: one is metamorphosis, or the direct transformation of pre-existing material, as a worm from an egg, or a butterfly from an aurelia (chrysalis); the other is epigenesis, or development with addition of parts, the true generation observed in all higher animals. Chapters xlvi–l are devoted to the abstruse question of the efficient cause of generation, which, after much discussion of the opinions of Aristotle and of Sennertus, Harvey refers to the action of both parents as the efficient instru-

ments of the first great cause.

He then goes on to describe the order in which the several parts appear in the chick. He states that the fetal heart is the first organ to be seen, and explains that the nutrition of the chick is effected not only by yolk conveyed directly into the midgut, as Aristotle taught, but also by absorption from yolk and white by the umbilical veins; on the fourth day of incubation appear two masses (which he oddly names *vermiculus*), one of which develops into three vesicles, to form the cerebrum, cerebellum and eyes, the other into the breastbone and thorax; on the sixth or seventh day come the viscera; and lastly the feathers and other external parts.

Harvey points out how nearly this order of development in the chick agrees with what he had observed in mammalian and particularly in human embryos. He notes the bifid apex of the fetal heart in man and the equal thickness of the ventricles, the soft cartilages which represent the future bones, the large amount of amniotic fluid and absence of placenta which characterize the fetus in the third month; in the fourth the position of the testes in the abdomen, and the uterus with its Fallopian tubes resembling the bicornuate uterus of the sheep; the large thymus; the caecum, small as in the adult, not forming a second stomach as in the pig, the horse and the hare; the lobulated kidneys, like those of the seal and porpoise, and the large suprarenal veins, not much smaller than those of the kidneys. He failed, however, to trace the connection of the urachus with the bladder. In the following chapters he describes the process of generation in the fallow deer or the roe. Much of Harvey's work on generation was superseded during the next 25 years by that of Malpighi. The remaining writings of Harvey are unimportant.

Harvey as Physician.—Of Harvey as a practising physician very little is known. Aubrey says that "he paid his visits on horseback with a footcloth, his man following on foot, as the fashion then was." He adds, "Though all of his profession would allow him to be an excellent anatomist, I never heard any that admired his therapeutic way. I knew several practitioners that would not have given threepence for one of his bills" (the apothecaries used to collect physicians' prescriptions and sell or publish them to their own profit). "and that a man could hardly tell by his bill what he did aim at." However this may have been, and rational therapeutics was impossible when the foundation stone of physiology had only just been laid, Harvey was an active practitioner, performing such important surgical operations as the removal of a breast, and he turned his obstetric experience to account in his book on generation. Some good practical precepts as to the conduct of labour are quoted by Percivall Willughby (1596–1685). He also took notes of the anatomy of disease, which unfortunately perished with his other manuscripts. He may be regarded as a forerunner of G. B. Morgagni (*q.v.*), for Harvey saw that pathology is but a branch of physiology, and like it must depend on accurate anatomy. The only remaining specimen of his observations in morbid anatomy is his account of the post-mortem examination made by order of the king on the body of the famous Thomas Parr, who died in 1635, at the reputed age of 152. Harvey insists on the value of physiological truths for their own sake, independent of their immediate utility. but he himself provides an interesting example of the practical application of his theory of the circulation, in the cure of a large tumour by tying the arteries which supplied it with blood.

The following is believed to be a complete list of all the known writings of Harvey, published and unpublished: *Exercitatio anatomica de motu cordis et sanguinis in animalibus* (1628); *Exercitatio anatomica de circulatione sanguinis: ad Johannem Riolanum* (1649); *Exercitationes de generatione animalium* (1651); *Anatomia Thomae Parr,* first published in the treatise of John Betts, *De ortu et natura sanguinis* (1669). Letters. to Caspar Horimann of Nürnberg, May 1636; to Schlegel of Hamburg, April 1651; three to Giovanni Nardi of Florence. July 1651, Dec. 1653 and Nov. 1655; two to Morison of Paris, May 1652; two to Horst of Darmstadt, Feb. 1654–55 and July 1655; to Vlackveld of Haarlem, May 1657. His letters to Hoffmann and Schlegel are on the circulation; those to Morison, Horst and Vlackveld refer to the discovery of the lacteals; the two to Nardi are short letters of friendship. All these letters were published by Sir George Ent in his collected works (1687). Of two manuscript letters, one on official business to the secretary, Dorchester. was printed by Aveling, with a facsimile of the crabbed handwriting (*Memorials of Harvey,* 1875), and the other, about a patient, appears in Robert Willis' *Life of Harvey* (1878). *Pralectiones anatomiae universalis* (1616)—manuscript notes of his Lumleian lectures in Latin—are in the British museum library; an autotype reproduction was issued by the College of Physicians in 1886. An account of a second manuscript in the British museum, entitled *Gulielmus Harveius* de *musculis, motu locali,* etc.. was published by Sir G. E. Paget (*Notice of an Unpublished Manuscript of Harvey,* 1850).

The following treatises, or notes toward them, were lost either in the pillaging of Harvey's house, or perhaps in the Great Fire of London, which destroyed the old College of Physicians: *A Treatise on Respiration,* promised and probably at least in part completed (pp. 82, 550, ed. 1766); *Observationes de usu lienis; Observationes de motu locali,* perhaps identical nith the above-mentioned manuscript; *Tractatum physiologicum; Anatomia medicalis* (apparently notes of morbid anatomy); *De generatione insectorum.*

The fine edition of Harvey's works published by the Royal College of Physicians in 1766 was superintended by Mark Akenside; it contains the two treatises, the account of the post-mortem examination of old Parr, and the six letters enumerated above. A translation of this volume by Robert Willis, with Harvey's will, was published by the Sydenham society (1847).

There is a convenient photographic facsimile of the work on the circulation issued by G. illoreton (1894). The standard translation of his collected works is still that of Robert Willis (1847). A convenient reprint of the translation by Willis of the work on the circulation is available (1906).

BIBLIOGRAPHY.—The literature that has arisen on Harvey and his great discovery would fill a library. A bibliography by Geoffrey Keynes was published (1928), and a further account of the works of Harvey on the occasion of the celebration of the tercentenary of the publication of the work on the circulation by the Royal College of Physicians, London (1928). Of later writings on Harvey mention may be made of the biography by D'Arcy Power (1897); the facsimile of Harvey's Paduan diploma issued by the Royal College of Physicians, with pamphlet by J. F. Payne (1908); the volume of *Portraits of Dr. William Harvey* published by the Historical section of the Royal Society of Medicine (1913).

The Harveian oration at the Royal College oi Physicians is devoted to an annual exposition of some part of his work. Among the orations are those by W. Osler, *The Growth of Truth as Illustrated in the Discovery of the Circulation of the Blood* (1906); H. R. Spencer, *William Harvey, Obstetric Physician and Gynaecologist* (1921); A. Chaplin, *Medicine in the Century Before Harvey* (1922); C. Singer, *The Discovery of the Circulation of the Blood* (1922) gives an exposition of the history of this event. (P. H. P.-S.; C. SI.)

HARVEY, a city of Cook county. Ill.. U.S.. is 20 mi. S. of the Chicago loop. The city was from the first both an industrial and residential suburb of Chicago. The area was originally platted as South Lawn by a syndicate of land speculators in 1873. Rapid growth began in 1889 when Turlington W. Harvey, a Chicago capitalist, purchased some of the land. which was then swamp and prairie. The following year he organized the Harvey Land association. The population. negligible when the settlement was incorporated as a village in 1891. had increased to 5.000 by 1895 when Harvey was organized as a city. Engineering. machine-shop and metalworking industries mere attracted there in the 1890s and have since dominated the industrial life of the community. For comparative population figures *see* table in ILLINOIS: *Population.*

(S. L. J.)

HARVEY STEEL PROCESS. Named after the inventor, H. A. Harvey, an American metallurgist, this is a process of hardening the surface of steel, used in the production of armour plate. The essence of the process is that the plate is face-hardened by cementation of its surface. The plate is exposed in a furnace to great heat for a considerable period, about a fortnight, and covered with finely pulverized carbon. The surface of the steel is thus penetrated and carburized to a considerable depth, the front of the plate becoming of a different composition from that of the back. After thus being exposed to cementation, the plate

is withdrawn and cooled slowly to a dull red, when it is suddenly chilled by a water spray. (See IRON AND STEEL; ARMOUR PLATES; METALLURGY.)

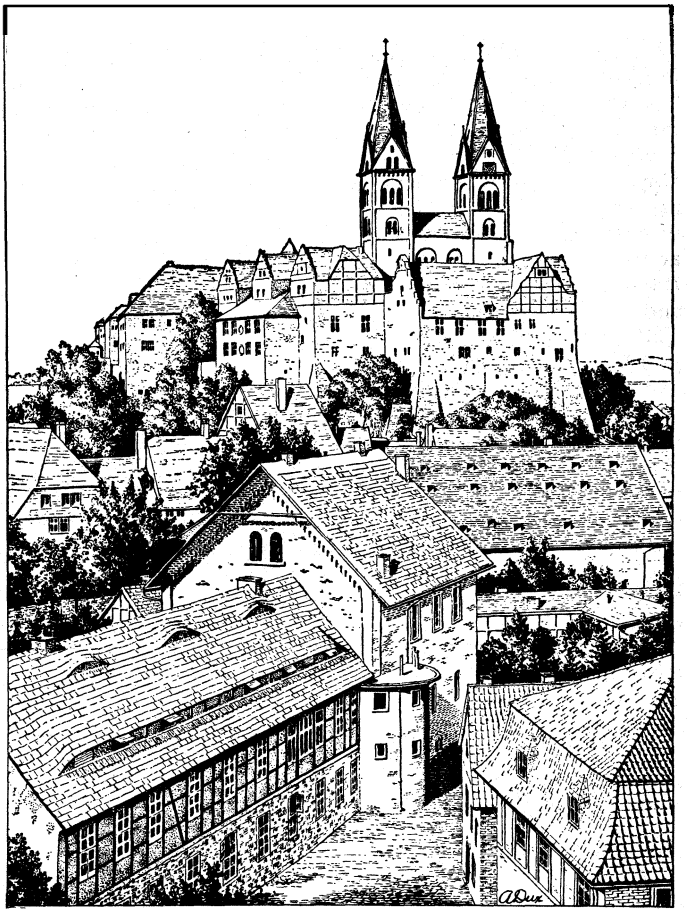
HARWICH, a municipal borough and seaport in the Harwich parliamentary division of Essex, Eng., on the extremity of a small peninsula projecting into the estuary of the Stour and Orwell, 70 mi. N.E. of London by road. Pop. (1951) 14,069. Area 2.4 sq.mi.

Harwich (Herewica, Herewyck) formed part of the manor of Dovercourt. Ring Alfred in 885 defeated 16 Danish ships in the harbour. It became a borough in 1319 by a charter of Edward II. In 1604 James I gave it a charter which provided a new constitution, and from this date began regular parliamentary representation. though two burgesses had attended parliament in 1344. In 1885 the borough was disfranchised. In 1253 Henry III granted to Roger Bigod a market there every Tuesday and a fair on Ascension day and eight days after. James I granted a Friday market and two fairs. The fair and markets died out. Town wall defenses were begun in 1337 and finished after a French raid in 1450. In the 14th century merchants came even from Spain and there was much trade in wheat and wool with Flanders; the passenger traffic appears to have been as important in the 14th century as it is now. In 1578 Sir Martin Frobisher embarked at Harwich on his arctic expedition. Shipbuilding was a large industry in the 17th century. Several Martello towers survive from Napoleonic times.

The town of Harwich occupies an elevated situation, and a wide view is obtained from Beacon hill at the southern end of the esplanade. Many of the streets are ancient and there are several old houses. The nave of All Saints church is of the 12th century and the chancel is of the 14th century. The harbour is one of the best on the east coast of England, and in stormy weather is largely used for shelter; the minimum water alongside Parkeston quay at dead low water is 17 ft. A breakwater and sea wall prevent the blocking of the harbour entrance and encroachments of the sea; and there is another breakwater at Landguard point on the opposite (Suffolk) shore of the estuary. A varied assortment of goods is exported and imports include dairy produce from Denmark, vegetables from Holland and fruit from Italy. Harwich is one of the principal English ports for continental passenger traffic. steamers regularly serving the Hook of Holland, Antwerp and Esbjerg. There are summer services to Zeebrugge, Esbjerg and Goteborg. A train ferry to Zeebrugge was inaugurated in 1924. The continental trains of the Eastern region railway run to Parkeston quay, 1 mi. from Harwich up the Stour, where the passenger steamers start. Besides shipping the chief industries are tailoring, light engineering and fishing. Between the Parkeston quay and Town railway stations is that of Dovercourt (*q.v.*), a popular watering place now united with Harwich. Harwich is an important naval base. A depot of Trinity House, the lighthouse and pilotage authority, was opened in 1953.

HARZBURG, a town of Germany, in the Land of Lower Saxony, situated at the northern foot of the Harz mountains, at the terminus of the railway from Brunswick, 5 mi. E.S.E. from Goslar and 18 mi. S. from Wolfenbiittel. Population 6.198. The town is a spa and possesses brine and carbonated springs. 4 mile and a half south from the town lies the Burgberg, 1,500 ft. above sea level, with remains of an old castle and, according to tradition, formerly an altar to the heathen god Krodo, still to be seen in the Ulrich chapel at Goslar.

HARZ MOUNTAINS, the most northerly mountain-system of Germany, situated between the rivers Weser and Elbe, occupy an area of 784 sq.mi. Their greatest length extends in a south-east and north-west direction for 57 mi. and their maximum breadth is about zo mi. An irregular series of terraced plateaus rises here and there into rounded summits, and is intersected by narrow, deep valleys. The north-western and higher part is Ober or Upper Harz; the south-eastern and more extensive part. Unter or Lower Harz; while the north-west and south-west slopes of the Upper Harz form the Vorharz. The Brocken group, dividing the Upper and Lower Harz, is generally classed with the Upper. The Upper Harz includes the Brocken (3,747 ft.), the Heinrichshohe (3,425 ft.), the Konigsberg (3,376 ft.) and the Wurmberg (3,176 ft.); the Lower Harz, the Josephshohe 'in the Auerberg group and the Viktorshohe in the Ramberg, each 1,887 ft. The Brocken (*q.v.*) is celebrated in legends immortalized in Goethe's *Faust*. While useful in working the numerous mines of the district, at other parts of their course the many streams present most picturesque scenery. The finest valley is the rocky Bodethal, with the Rosstrappe, the Hexentanzplatz, the Baumannshohle and the Bielshohle.



BY COURTESY OF THE GERMAN RAILROAD INFORMATION BUREAU

QUEDLINBURG CASTLE NEAR THE HARZ MOUNTAINS, FOR MANY CENTURIES THE RESIDENCE OF THE ABBESSES OF **QUEDLINBURG**

The Harz is a mass of Palaeozoic rock rising through the Mesozoic strata of north Germany, and bounded on all sides by faults. Slates, schists, quartzites and limestones form the greater part but the Brocken and Viktorshohe are intrusive granite, and diabases and diabase tuffs are interstratified with sediments. Silurian, Devonian and Carboniferous are represented—the Silurian and Devonian forming the greater part of the hills south-east of a line drawn from Lauterberg to Wernigerode, while north-west of this line the Lower Carboniferous predominates. A few patches of Upper Carboniferous on the borders of the hills near Ilfeld, Ballenstedt, etc., are unconformable upon the Devonian. The general strike of the folds, especially in Oberharz is about north-east. The mass belongs to the Hercynian chain of Europe (which derives its name from the Harz), and continues north-eastwards the Ardennes and Eifel. The folding took place at the close of the Palaeozoic; but the faulting to which they owe their present position was probably Tertiary. Metalliferous veins are common, amongst the best-known being the silver-bearing lead veins of Klausthal, which occur in the Culm or Lower Carboniferous.

Owing to its position as the first range which the northerly winds strike after crossing the north German plain, the climate on the summit of the Harz is generally raw and damp, even in summer. In 1895 an observatory was opened on the top of the Brocken, and the results of the first five years (1896–1900) showed a July mean of 50° Fahr., a February mean of 24·7°, and a yearly

mean of 36.6". During the same five years the rainfall averaged 64½ in. annually. But while the hilltop summer is thus ungenial, the summer heat of the lower-lying valleys is greatly tempered and cooled; so that, adding this to the scenery, forests and legendary and romantic associations, the Harz is a favourite summer resort. Among the more popular places of resort are Harzburg, Thale and the Bodethal; Blankenburg, with the Teufelsmauer and the Hermannshohle; Wernigerode, Ilsenburg, Grund, Lauterberg, Hubertusbad, Alexisbad and Suderode. Some places also have mineral springs and baths, pine-needle baths, whey cures, etc. The Harz is penetrated by several railways, among them a mountain railway up the Brocken, opened in 1898.

The northern summits are bare, but the lower slopes of the Upper Harz are rich in pines and firs. Between the forests stretch numerous peat mosses, the spongy reservoirs of which are sources of many small streams. On the Brocken are found one or two arctic and several alpine plants. In the Lower Harz the forests contain a great variety of timber. The beech attains unusual size and beauty, and the walnut tree grows in the eastern districts. The last bear was killed in the Harz in 1705, and the last lynx in 1817, and since then the wolf has become extinct; but deer, foxes, wild cats and badgers are still found.

Mining has been carried on since the middle of the 10th century, especially for rich argentiferous lead, but gold in small quantities, copper, iron, sulphur, alum and arsenic are also found. Klausthal and St. Andreasberg in the Upper Harz are the chief centres. Near the latter the Samson shaft goes down 2,790 ft. or 720 ft. below sea level. For obviating flooding of deep workings, large drainage works have been built. In 1777–99 the Georgsstollen was cut through the mountains from the east of Klausthal westward to Grund, a distance of 4 mi.; the Emst-Auguststollen, no less than 14 mi. in length, was made from the same neighbourhood to Gittelde, at the west side of the Harz, in 1851–64. Marble, granite and gypsum are worked; and vitriol is manufactured. Much wood is exported for building and other purposes, and it is used locally as fuel. The sawdust of numerous mills is collected for use in papermaking. Turf cutting, coarse lacemaking and the breeding of canaries and native songbirds also occupy many of the people. Agriculture is carried on chiefly on the plateaus of the Lower Harz; but there is excellent pasturage both in the north and in the south. In the Lower Harz, as in Switzerland, the cows, which carry bells, are driven up into the heights in early summer, returning to the sheltered regions in late autumn.

Upper and Lower Saxon, Thuringian and Frankish stocks have all contributed to form the present people, and their respective influences are still to be traced in the varieties of dialect. The boundary line between High and Low German passes through the Harz.

The Harz was the last stronghold of paganism in Germany, and to that fact are due its legends and fanciful names.

See G. Braun, *Deutschland* (Berlin, 1926).

HASA (Arabic al-Ḥasā'), the easternmost province of the kingdom of Saudi Arabia, extends S. along the west coast of the Persian gulf, with an average width of 100 to 200 mi. from the frontier of the Kuwait enclave to Jabrin on the north edge of the Empty Quarter. Pop. 150,000. The coast is low and flat, with a deep barrier of sand dunes between it and the hard desert. Along it are the five ports of Jubail, Qatif, 'Uqair (ancient Gerrha), Ras Tannura and al-Khaubar. The fort of Qatīf is a strongly-built structure attributed to the Carmathian prince, Abu-Tāhir. Ras Tannura, a port developed by the California Arabian Standard Oil Co., is the terminus of its 50-mi. pipe line from the Dhahran oil fields. Al-Khaubar, also developed by this company, lies 6 mi. easterly from Dhahran.

About 150 mi. N. lies the main oasis, which gives its name to the province and is famous for its many springs, both hot and cold; its prosperous palm groves producing the excellent *khalās* variety of date; its Shi'a population; its peculiar breed of large white donkeys; and its many settlements, of which the chief are Hufuf (30,000, elevation 600 ft.) and Mubarraz (20,000). The Kiit or fort of Hufuf is attributed to the Carmathians, and its chief architectural feature is the great mosque of Ibrāhīm Pasha, so named after a Turkish governor of the province during the early 19th century. The great market place, or Sūq al-Khamis, is the scene of great activity every Thursday, when a good business is done in the produce of the oasis and the *'abas* (mantles) and leather-work, which are the main features of local industry. 'Ain al-Hārra, near Mubarraz, and Umm-al-Siba' are the most remarkable of the numerous spring-fed pools, from which perennial streams issue for the irrigation of the oasis.

Before the Wahhabi movement of the 18th century, Hasa was ruled by princes of a dynasty called 'Urair. In due course it was absorbed by the Wahhabi empire and, on the destruction of the latter, it came within the orbit of Turkey. Relapsing again under the Wahhabi rule of Faisal Ibn-Sa'ud, it was reoccupied in 1875 by Midhat Pasha and remained part of the Turkish province of Nejd until 1914, when 'Abd-al-'Aziz Ibn-Sa'ud captured it by a bold *coup-de-main* and ejected the Turkish garrisons from Hufuf, Qatif and 'Uqair. In 1933 the Standard Oil Co. of California acquired an oil concession covering the entire sedimentary area in Saudi Arabia, which included almost all but the westernmost third of the kingdom. In 1936 this concession was shared on an equal basis with the Texas Co. The merger (known as the California Arabian Standard Oil Co.) explored and mapped either by precision triangulation or aerial methods almost the entire area under Ibn-Sa'ud's rule. In 1938, engineers mapped the formerly unexplored east coast line of Hasa. The peninsula of Qatar, closing the Gulf of Bahrein on the south, forms geographically part of Hasa, but is administered semi-independently by its Sheikhly family of Ibn-Thānī under British protection. Its boundary with Hasa was still unsettled during World War II; Ibn-Sa'ud had claims on the whole territory. The area is of importance because of the discovery of oil there. Part of the prosperity of Hasa is due to its share in the pearl fisheries along its coast.

(H. St. J. B. P.; P.K.H.)

HASAN and HUSAIN (or HOSAIN), sons of the fourth Mohammedan caliph 'Ali by his wife Fatima, daughter of Mohammed. On 'Ali's death Hasan was proclaimed caliph; but the strength of Mu'awiya, who had rebelled against 'Ali, was such that he resigned his claim on condition that he should have the disposal of the treasure stored at Kufa, with the revenues of Darabjird. This secret negotiation came to the ears of Hasan's supporters, a mutiny broke out and Hasan was wounded. He retired to Medina where he died about 669. The story that he was poisoned at Mu'awiya's instigation is generally discredited *(see* CALIPHATE). Subsequently his brother Husain revolted against Mu'awiya's successor Yazid, but was defeated and killed at Karbala on Oct. 10, 680. Husain is the hero of the religious drama performed annually *(e.g.,* at Karbala) on the anniversary of his death by the Shi'ites of Persia and India, to whom the family of 'Ali are the only true heirs of Mohammed.

See Sir W. Muir, *The Caliphate,* rev. ed (Edinburgh, 1915); Sir Lewis Pelly, *The Miracle Play* of *Hasan and Hosein* (1879).

HASAN UL-BASRI (Abū Sa'ūd ul-Ḥasan ibn Abī-l-Ḥasan Yassār ul-Baṣrī) (642–728 or 737), Arabian theologian, was born at Medina, the son of a freedman of Zaid ibn Thābit, one of the *Anṣār* (Helpers of the Prophet). He became a teacher of Basra and founded a school there, where among his pupils was Wāṣil ibn 'Atā, the founder of the Mo'tazilites. He himself was a great supporter of orthodoxy and practised ascetism. With him fear is the basis of morality, and sadness the characteristic of his religion. In politics he adhered to the earliest principles of Islam, being strictly opposed to the inherited caliphate of the Omayyads and a believer in the election of the caliph.

His life is given in Nawāwī's *Biographical Dictionary* (ed. F. Wüstenfeld, Göttingen, 1842–47). Cf. R. DOZY, *Essai sur l'histoire de l'islamisme* (1879); A. von Kremer, *Cztlturgeschichtliche Streifzüge* (1873); R. A. Nicholson, *A Literary History of the Arabs* (1907).

HASBEYA, a small Druse town of the Beka', Lebanon, at the foot of Mt. Hermon, 36 mi. W. of Damascus and set in the midst of olives, vines and other fruit trees. Its castle was held by the crusaders but recaptured by the Druses (1171).

In the immediate neighbourhood is the chief sanctuary of the Druses and the place where the founder of the sect dwelt. A large

number of Christians were massacred here in 1860. In the course of the punitive expedition the sacred and secret books of the Druses were discovered. The ground around Hasbeya is volcanic, and there are bitumen pits in the neighbourhood. An identification of the site with the Baal-Gad or Baal-Hermon of the Bible has been suggested. (E. Ro.)

HASDAI IBN SHAPRUT (*c.* 915–970/90), the founder of the new culture of the Jews in Moorish Spain in the 10th century, was born at Jaen and died at Córdoba. He was both physician and minister to Caliph Abd ar-Rahman III in Córdoba. A man of wide learning and culture, he encouraged the settlement of Jewish scholars in Andalusia, and promoted the Jewish renaissance in Europe.

See article in *Jewish Encyclopedia.*

HASDEU or HĂJDEU, **BOGDAN PETRICEICU** (1836–1907), Rumanian philologist, was born at Khotin, Bessarabia, and studied at the University of Kharkov. In 1858 he first settled in Jassy as professor of the high school and librarian. He may be considered as the pioneer in many branches of Rumanian philology and history. At Jassy he started his *Archiva historica a Romaniei* (1865–67), in which a large number of old documents in Slavonic and Rumanian were published for the first time. In 1870 he inaugurated *Columna lui Traian,* the best philological review of the time in Rumania. In his *Cuvente den Bătrâni* (2 vol., 1878–81) he was the first to contribute to the history of apocryphal literature in Rumania. His *Historia critica a Romanilor* (18; 5), though incomplete. marks the beginning of critical investigation into the history of Rumania. Hasdeu edited the ancient Psalter of Coresi of 1577 (*Psaltirea lui Coresi,* 1881). In 1876 he was appointed director of the state archives in Bucharest and in 1878 professor of philology at the University of Bucharest. His works include one drama. *Rasvan şi Vidra.*

After the death of his only child Julia in 1888 Hasdeu became a mystic and a strong believer in spiritualism. He died at Campina on Sept. 7, 1907. (M. G.)

HASDRUBAL, the name of several Carthaginian generals, the most important being:

1. The son-in-law of Hamilcar Barca (*q.v.*), whom he followed in his campaign against the governing aristocracy at Carthage at the close of the First Punic War and in his subsequent wars in Spain. After Hamilcar's death (228 B.C.), Hasdrubal. who succeeded him in the command, extended the new province by diplomacy and consolidated it by the foundation of New Carthage (Cartagena) as its capital and by a treaty with Rome which fixed the frontier on the Ebro. In 221 he was killed by an assassin.

Polybius ii. 1; Livy xxi, 2; Appian, *Hispanica,* 4–8.

2. The second son of Hamilcar Barca. Left in command of Spain when his brother Hannibal went to Italy (218 B.C.). he fought for seven years against Publius Cornelius Scipio and his brother Gnaeus. A defeat on the Ebro in 215 prevented him from joining Hannibal in Italy at a critical moment. but in 211 he completely routed his opponents. He nas subsequently outgeneralled at Baecula bv the younger P. Cornelius Scipio. Nevertheless, by a retreat he evaded Scipio and broke into central Italy (207). He was ultimately defeated on the banks of the Metaurus (*q.v.*), his head being thrown into Hannibal's camp by order of the Roman general C. Claudius Nero.

3. The son of Gisgo. who commanded Carthaginian armies in Spain (214–206 B.C.) and in Africa (205–203).

Polybius x, 34–xi, 3; Livy xxvii, 1–51; Appian, *Bellum Hannibalicum,* ch. lii *sqq.;* C. Lehmann, *Die Angriffe der drei Barkiden auf Italien* (Leipzig, 1905). *See* also PUNIC WARS. (H. H. Sd.)

HASE, CARL BENEDICT (1780–1864), French Hellenist. of German extraction. was born at Sulza near Naumburg on May 11. 1780, and died in Paris on March 21. 1864. He made his way to Paris on foot in 1801. and from being employed to edit Johannes Lydus by Choiseul-Gouffier. devoted himself to Byzantine studies. In addition to various professorships, in 1812 he nas chosen to supervise the studies of Louis Napoleon and his brother. His most important works are the editions of Leo Diaconus and other Byzantine nriters (1819), and of Johannes Lydus. *De ostentis* (1823), *a* masterpiece of textual restoration, the difficulties of which were aggravated by the fact that the manuscript had for a long time been stowed away in a wine barrel in a monastery.

See J. D. Guigniaut, *Notice historique sur la vie et les travaux de Carl Benedict Hase* (186;) ; articles in *Nouvelle Biographie générale* and *Allgemeine deutsche Biographie;* and a collection of autobiographical letters, *Brieje von der Wandetung una aus Paris,* edited by O. Heine (1894), containing a vivid account of Hase's journey, his enthusiastic impressions oi Paris and the hardships of his early life.

HASE, KARL AUGUST VON (1800–1890), German Protestant theologian and church historian, was born at Steinbach, Saxony on Aug. 25, 1800. He studied at Leipzig and Erlangen, and was professor of theology at Jena from 1829 to 1883. He died at Jena on Jan. 3, 1890. Hase's aim was to reconcile modern culture with historical Christianity in a scientific way. His views are presented scientifically in his *Evangelisch-protestantische Dogmatik* (1826; 6th ed., 1870), the value of which "lies partly in the full and judiciously chosen historical materials prefixed to each dogma. and partly in the skill, caution and tact with which the permanent religious significance of various dogmas is discussed" (Otto Pfleiderer).

More popular in style is his *Gnosis oder prot.-evang. Glaubenslehre* (3 vol., 1827–29; 2nd ed., 1869–70). But his reputation rests chiefly on his treatment of church history in his *Kirchengeschichte, Lehrbuch zunächst fur akadenzische Vorlesungen* (1834, 12th ed., 1900).

For his life *see* his *Ideale und Irrtümer* (1872; 5th ed., 1894) and *Annalen meines Lebens* (1891); *R.* Bürkner, *Karl von Hase* (1900). *See* also O. Pfleiderer, *Development of Theology* (1890); *F.* Lichtenberger, *Hist. of German Theology* (1889).

HASHEMITE KINGDOM OF THE JORDAN: *see* JORDAN.

HASHISH or HASHEESH, the Arabic name, meaning literally "dried herb," for the various preparations of the Indian hemp plant *(Cannabis indica),* used as a narcotic or intoxicant in the East. and either smoked, chewed, or drunk *(see* HEMP). From the Arabic hashishin. *i.e.,* "hemp-eaters," comes the English "assassin" (see ASSASSIN).

HASKOVO, Bulgaria: *see* KHASKOVO.

HASLEMERE, an urban district (1933) in the Farnham parliamentary division of Surrey. Eng.. 41 mi. S.W. of London by road. Pop. (1951) 12.003. Area 9.0 sq.mi. It is a residential area near the Sussex border in an elevated valley between the ridges of Hindhead (Gibbet hill. 895 ft.) and Blackdown (918 ft.). These summits are open heath, but their flanks are wooded and deeply scored by steep valleys. of which the most remarkable is the Devil's Punch Bowl. on the west flank of Hindhead. On Blackdown is Aldworth. built for Alfred. Lord Tennyson. Both hill areas are largely National Trust property.

Haslemere was a borough from 1596 until 1831. There is an Educational and Natural History museum founded in 1895 by Sir Jonathan Hutchinson.

HASLER or HASSLER, **HANS LEO (VON)** (1564–1612), German composer. was born at Nürnberg. Ger.. on Oct. 2 j. 1564. He was taught by his father. Isaac Hasler, a musician of some standing in Nürnberg, and afterward became a pupil of Andrea Gabrieli in Venice. Italy. In 1585 he became organist to Octavian Fupger at Augsburg and in 1600 was appointed musical director in that city. He next became organist of the Frauenkirche at Nürnberg (1601) and in 1608 entered the service of Augustus I of Saxony, continuing with his successor John George. He died on June 8, 1612. at Frankfurt, whence he had accompanied John George to the imperial election.

Hasler is considered the greatest German representative of the Venetian school, and he had a deep influence in turning German music toward Italy and away from the Netherlands. A fine contrapuntalist. he wrote church music (masses. motets. psalms, etc.) of great beauty, but his fame rests on the charm of his secular songs. which are essentially German in spirit. One of the melodies in his *Lustgarten neuer teutscher Gesäng,* "Mein G'muth ist mir verwirret" was adapted to the chorale "O Haupt voll Blut und Wunden" and was used by J. S. Bach in his Passion according to St. Matthew.

JACOB HASLER (1569–after 1618), younger brother of Hans Leo, was also an organist and composer. He was organist to Christoph Fugger at Augsburg from 1593, to Count Eitel Fritz of Hohenzollern at Hechingen from 1597, and to the imperial court at Prague from 1602 to 1612. He published organ and church music and also madrigals.

KASPAR HASLER (1562–1618), elder brother of Hans Leo. was organist at the Lorenz-Kirche, Niirnberg, and edited several collections of Italian motets.

HASLINGDEN, a market town and municipal borough (1891) in the Rossendale parliamentary division of Lancashire, Eng., 17 mi. N.N.W. of Manchester by road. Pop. (1951) 14,513. Area 12.8 sq.mi. The old town stood on a slope on the border of the ancient Rossendale forest, but the modern part has extended about its base.

The parish church of St. James (rebuilt 1780) retains a 16th-century tower. Woolen manufactures have largely given place to the making of cotton goods, rubber, footwear, poultry equipment (pedigree poultry are bred), chemicals and engineering; stone is quarried nearby. There is a weekly cattle market. To the northwest is Haslingden moor and Thirteen Stones hill, once an ancient stone circle.

HASSAM, (FREDERICK) CHILDE (1859–1935), U.S. painter and etcher, an important exponent of Impressionism in American art, was born in Dorchester, now part of the city of Boston: Mass., on Oct. 17, 1859 and studied in Boston and Paris. He soon fell under the influence of the Impressionists, and took to painting in a style of his own, in brilliant colour, with effective touches of pure pigment. He settled in New York city on his return from Paris, where he became a member of the group of U.S. Impressionists known as the Ten American Painters. Scenes of New York life remained his favourite subject matter, though he also did New England and rural New York landscapes. Hassam received many medals and awards. He died on Aug. 27, 1935.

HASSAN, a town and district of Mysore, India. The town, 61 mi. N.W. of Mysore city, had a population in 1951 of 24,869. It was founded in the 11th century.

HASSAN DISTRICT divides naturally into the Malnad, or hill country, including some of the highest ranges of the Western Ghats, and the Maidan or plain country, sloping toward the south. The Hemavati, which flows into the Cauvery in the extreme south, is the most important river. The upper slopes of the Western Ghats are clothed with forests, and wild animals abound. Minerals found are gold, magnesite, mica, corundum and asbestos. The soil of the valleys is rich red loam. The area is 2,638 sq.mi. The population in 1951 was 715,135.

The district contains remarkable monuments! such as the colossal Jain image at Sravana Belgola (a monolith 57 ft. high on the summit of a hill) and the great temple at Halebid (*q.v.*). Coffee is extensively cultivated. The Southern railway traverses the northeast of the district, and Hassan has a station on the line from Arsikere to Mysore.

The history of Hassan begins with the Hoysala dynasty, which lasted from the 11th until the 14th century. The capital was at Dwarasamundra (Dorasamudra or Dwaravati-pura), the ruins of which are scattered. around the village of Halebid. The earlier kings professed the Jain faith, but the finest temples were erected to Siva by later monarchs. At their zenith all south India owned their sway.

HASSAN IBN THABIT (*c.* 563–*c.* 674), Arab poet, best known for his poems in defense of Mohammed. He was born in Medina. a member of the tribe of Khazraj. In his youth he traveled to Hira and Damascus, then settled in Medina, where, after the advent of Mohammed, he accepted Islam and became the new religion's first poet, using in his verse many phrases from the Koran. He is said to have lived to be over 110 years old. He was an able satirist. but his poetry is regarded as lacking in distinction. His works were edited by H. Hirschfeld, with introduction (1910).

HASSE, JOHANN ADOLPH (1699–1783), German musical composer, was born at Bergedorf near Hamburg. on March 25. 1699. After singing in a travelling operatic cdmpany and at the court theatre of Brunswick, he made his début as a composer at that theatre with the opera *Antigonus.* Afterward he went to Italy to complete his studies under Porpora, with whom, however, he seems to have disagreed both as a man and as an artist. But he gained the friendship of Alessandro Scarlatti, to whom he owed his first commission for a serenade for two voices, sung by two of the greatest singers of Italy. Farinelli and Signora Tesi. Subsequently his opera *Sesostrato,* written for the Royal opera at Naples in 1726. made his name known all over Italy. He then spent some years in Venice. where he married (1730) the soprano singer Faustina Bordogni (1693–1783) with whom he was invited to Dresden by the splendour-loving elector of Saxony, Augustus II. In 1733 Hasse was invited to London by the aristocratic clique inimical to Handel. But he modestly and wisely declined to become the great master's rival, remaining in London only long enough to superintend the rehearsals for his opera *Artaserse* (first produced at Venice, 1730). Meanwhile Faustina had remained at Dresden, the declared favourite of the public and unfortunately also of the elector; her husband, who remained attached to her was only allowed to see her at long intervals. In 1739, after the death of Augustus II, Hasse settled permanently at Dresden till 1763, when he and his wife retired from court service. Later! however, he went with his family to Vienna: and added several operas to the great number of his works already in existence. His last work for the stage was the opera *Ruggiero* (1771), written for the wedding of Archduke Ferdinand at Milan. On the same occasion a work by Mozart, then 14 years old, was performed. and Hasse observed "this youngster will surpass us all." Hasse died at Venice on Dec. 23. 1783. His compositions, many of which were popular during his lifetime but were soon forgotten, include 120 operas, besides oratorios, cantatas, masses and many instrumental works.

HASSELT, ANDRÉ HENRI CONSTANT VAN (1806–1874), Belgian Romantic poet who exercised a strong influence on French literature in Belgium before the revival inspired by the founding of the literary periodical *La Jeune Belgique* (1881). He was born in Maastricht, Holland, on Jan. 5, 1806, and obtained Belgian nationality in 1833, settling in Brussels, where he was employed at the Bibliotheque de Bourgogne before becoming an inspector of schools. He knew Victor Hugo. Alexandre Dumas and other French Romantic writers, but was also influenced by the German lyric poets. His first book of poems, *Primevères* (1834) was followed by the patriotic *La Belgique* (1842) and by poems on a variety of themes. His chief work, *Les Quatre Incarnations du Christ,* appeared first in 1863, and was augmented in 1867 and re-edited in 1908. He also wrote novels for young people. and a few historical studies. He died in Brussels, Dec. 1, 1874.

In spite of imperfections of form and a declamatory style, Van Hasselt's work remains one of the highest achievements in Belgian poetry during the greater part of the 19th century. Romantic in conception and austerely spiritual, it displays great literary beauty. His chief contribution, however, consists in his introduction into French prosody of rhythms and metrical devices from German poetry, nhich he knew by heart.

Van Hasselt's masterpiece is his epic, *Les Quatre Incarnations du Christ,* in which he presents great historical events as marking the progress of society under the influence of Christianity toward a final establishment of Christ's kingdom upon earth. The poem is admirably constructed and is often extremely moving.

His works were published in ten volumes (1876–77).

See M. Reichert, *Les Sources Allemandes des oeuvres poétiques d'André van Hasselt* (1933). (J.-E.-M.-G. D.)

HASSELT, the capital of the Belgian province of Limburg. Pop. (1955 est.) 33.564. It stands at the junction of several important roads and railways from Maaseyck. Maastricht and Liège. It has many breweries and distilleries, and makes coarse gin called Hasselt spirit. On Aug. 6, 1831, the Dutch troops obtained there their chief success over the Belgian nationalists during the War of Independence. A septennial fete is held on the day of Assumption. Aug. 15, in honour of the Virgin under the name of Virga Jesse. Fir trees and branches are planted in front of the houses. The figure of the giant who is supposed to have once held the

Hazelbosch under his terror is paraded on this occasion as the "lounge man." Originally this celebration was held annually, but in the 18th century it was restricted to once in seven years. Hasselt in the 20th century began to grow as the industrial capital of the new Kempen coalfield.

HASSENPFLUG, HANS DANIEL LUDWIG FRIEDRICH (1794–1862), German statesman, was born at Hanau, Hesse, on Feb. 26, 1794. He studied law at Gottingen, graduated in 1816, and took his seat as Assessor in the judicial chamber of the board of government (*Regierungskollegium*) at Cassel, of which his father Johann Hassenpflug was also a member. He rose rapidly, and in May 1832 was appointed successively minister of justice and of the interior. He now became conspicuous in the constitutional struggles of Germany. He deliberately set to work to reverse the Hessian constitution of 1831. The story of the constitutional deadlock that resulted belongs to the history of Hesse-Cassel and Germany; so far as Hassenpflug himself was concerned, it made him, more even than Metternich, the Mephistopheles of the Reaction to the German people. In the summer of 1837 he was suddenly removed from his post as minister of the interior and he thereupon left the elector's service.

In 1838–39 he was head of the administration of the little principality of Hohenzollern-Sigmaringen, and in 1839–40 civil governor of the grand-duchy of Luxemburg. From 1841 to 1850 he was in the Prussian judicial service. In 1850 he was tried for peculation and convicted; and, though this judgment was reversed on appeal, he left the service of Prussia.

He was now recalled by the elector of Hesse, and immediately threw himself again with zeal into the struggle against the constitution. Finding the opinion of all classes, including the army, solidly against him, he decided to risk all on an alliance with the reviving fortunes of Austria, which was steadily working for the restoration of the status quo overthrown by the revolution of 1848. On his advice the elector seceded from the Northern Union established by Prussia and, on Sept. 13 fled from Hesse with his minister. They went to Frankfort, where the federal diet had been re-established, and on the 21st persuaded the diet to decree armed intervention in Hesse. This decree, carried out by Austrian troops, all but led to war with Prussia, but the unreadiness of the Berlin government led to the triumph of Austria and of Hassenpflug, who at the end of the year was installed at Cassel as minister of finance. He was loathed and despised by all, and disliked even by his master. In November 1853, he was publicly horse-whipped by the count of Isenburg-Wachtersbach, the elector's son-in-law. The count was pronounced insane; but Hassenpflug tendered his resignation. It was not accepted; and it was not till Oct. 16, 1855 that he was finally relieved of his offices. He died at Marburg on Oct. 16, 1862. He lived just long enough to hear of the restoration of the Hesse constitution of 1831 (June 21, 1862), which it had been his life's mission to destroy. Of his publications the most important is Actenstucke, die landstiindischen Anklagen *wider* den *Kurfürstlichen* hessischen *Staatsminister Hassenpflug.* Ein *Beitrag zur* Zeitgeschichte *und zum* neueren deutschen *Staatsrechte,* anonym. (Stuttgart and Tiibingen, 1836.) He was twice married, his first wife being the sister of the brothers Grimm.

See the biography by Wippermann in *Allgemeine* deutsche *Biographie,* with authorities.

HASTINAPUR, an ancient city of India, in the Meerut district of the Uttar Pradesh (formerly United Provinces), lying on the banks of a former bed of the Ganges, 22 mi. N.E. of Meerut. It formed the capital of the great Pandava kingdom, celebrated in the Mahabharata, and probably one of the earliest Aryan settlements outside the Punjab. Tradition points to a group of shapeless mounds as the residence of the Lunar princes of the house of Bharata whose deeds are commemorated in the great national epic. The town was finally swept away by a flood of the Ganges, and the capital was transferred to Kausambi.

HASTINGS, a famous English family. Sir Henry de Hastings (d. 1268), was summoned to parliament as a baron by Simon de Montfort in 1264. Having joined Montfort's party Sir Henry led the Londoners at the battle of Lewes and was taken prisoner at Evesham. He was among those who resisted the king at Kenilworth, and after the issue of the Dictum de Kenilworth he commanded the remnants of the baronial party when they made their last stand in the isle of Ely, submitting to Henry in July 1267.

His son JOHN, BARON HASTINGS (c. 1262–c. 1313), married Isabella (d. 1305), daughter of William de Valence, earl of Pembroke, a half-brother of Henry III. His paternal grandmother, Ada, was a younger daughter of David, earl of Huntingdon, and a niece of the Scottish king, William the Lion; and in 1290 when Margaret, the maid of Norway, died, Hastings came forward, unsuccessfully, as a claimant for the vacant throne. He fought constantly either in France or in Scotland; he led the bishop of Durham's men at the celebrated siege of Carlaverock castle in 1300; and with his brother Edmund he signed the letter which in 1301 the English barons sent to Pope Boniface VIII, repudiating papal interference in the affairs of Scotland; on two occasions he represented the king in Aquitaine.

LAURENCE HASTINGS (1318?–1348), son of John, 3rd baron, was created earl of Pembroke in 1339. (See PEMBROKE, EARLS OF.)

HASTINGS, FRANCIS RAWDON-HASTINGS, 1ST MARQUESS OF (1754–1826), British soldier and governor general of India, born on Dec. g, 1754, was the son of Sir John Rawdon of Moira, County Down, 4th baronet, who was created Baron Rawdon of Moira and afterward earl of Moira, in the Irish peerage. Lord Rawdon, as he was then called, was educated at Harrow and Oxford and joined the army in 1771 as ensign in the 15th foot. His life may be divided into four periods: from 1775 to 1782 he was engaged with much distinction in the American war; from 1783 to 1813 he held various high appointments at home and took an active part in the business of the house of lords; from 1813 to 1823 was the period of his labours in India; after retiring from which, in the last years of his life (1824–26), he was governor of Malta. He was created an English peer, Baron Rawdon, in 1783 and succeeded his father as earl of Moira in 1793.

In 1812 he was appointed governor general of Bengal and commander in chief of the forces in India. He landed at Calcutta and assumed office in succession to Lord Minto in Oct. 1813. One of the chief questions which awaited him was that of relations with the Gurkha state of Nepal. Lord Moira, after travelling through the northern provinces to study the question, declared war against Nepal (Nov. 1814). The enemy's frontier was 600 mi. long, and Lord Moira, who directed the plan of the campaign, resolved to act offensively along the whole line. In 1816 the Gurkhas abandoned the disputed districts, ceded some territory to the British and agreed to receive a British resident. This affair brought Lord Moira the marquessate of Hastings (1817).

He had now to deal with a combination of Maratha powers. In 1816 the Pindaris entered British territory in the Northern Circars, where they destroyed 339 villages. Before the end of 1817 the preparations of Lord Hastings were completed, when the peshwa suddenly broke into war, and the British were opposed at once to the Maratha and Pindari powers, estimated at 200.000 men and 500 guns. Both were utterly shattered in a brief campaign of four months (1817–18). The peshwa's dominions were annexed; and those of Sindhia, Holkar and the raja of Berar lay at the mercy of the governor general and were saved only by his moderation. Thus, 60 years after the battle of Plassey, the supremacy of British power in India was effectively established.

While Lord Hastings' achievements were appreciated in India, the court of directors of the East India company grumbled at his having extended British territory. They also disliked his measures for introducing education among the natives and his encouraging the freedom of the press. In 1819 he obtained the cession by purchase of the island of Singapore. In finance his administration was very successful, as, in spite of his wars, he showed an annual surplus of £2,000,000 sterling. Lord Hastings did not escape unjust detraction. His last years of office were embittered by the discussions on the affairs of the banking-house of W. Palmer and company. Annoyed by the insinuations made against him. he tendered his resignation in 1821, though he did not leave India till the first day of 1823. He was much exhausted by his nine years

of labour in India, and his fortune was gone. In 1824 he received the comparatively small post of governor of Malta. He died on Nov. 28, 1826, leaving a request that his right hand should be cut off and preserved till the death of the marchioness of Hastings and then be interred in her coffin.

Mehta, *Lord Hastings and the Indian States* (Bombay, 1930).

HASTINGS, FRANK ABNEY (1794–1828), British naval officer and philhellene, was son of Lieut. Gen. Sir Charles Hastings, a natural son of Francis Hastings, 10th earl of Huntingdon. He served in the navy from 1805 to 1820. In 1822 he joined the Greek service. For two years he took part in the naval operations in the Gulf of Smyrna and elsewhere. He saw that the light squadrons of the Greeks must in the end be overpowered by the heavier Turkish navy, clumsy as it was; and in 1823 he drew up and presented to Lord Byron an able memorandum which was laid before the Greek government in 1824. This paper contains the germs of the great revolution afterward effected in naval gunnery and tactics. In substance the memorandum advocated the use of steamers in preference to sailing ships, and of direct fire with shells and hot shot, as a more trustworthy means of destroying the Turkish fleet than fire ships.

The application of Hastings' ideas led necessarily to the disuse of sailing ships, and the introduction of armour. Largely by the use of his own money, of which he is said to have spent £7,000, he was able to some extent to carry out his bold plans. In 1824 he came to England to obtain a steamer, and in 1825 he had fitted out a small steamer named the "Karteria" (Perseverance), manned by Englishmen, Swedes and Greeks, and provided with apparatus for the discharge of shell and hot shot. The effect produced by his shells in an attack on the sea line of communication of the Turkish army, then besieging Athens at Oropus and Volo in March and April 1827, proved the truth of his contention. After the defeat of the Greeks round Athens, Hastings, in co-operation with Gen. Sir R. Church (*q.v.*), shifted the scene of the attack to western Greece. There his destruction of a small Turkish squadron at Salona bay in the Gulf of Corinth (Sept. 29, 1827) provoked Ibrahim Pasha into the aggressive movements which led to the destruction of his fleet by the allies at Navarino (*q.v.*) on Oct. 20, 1827. On May 25, 1828, Hastings was wounded in an attack on Anatolikon, and he died in the harbour of Zante on June 1.

See T. Gordon, *History of the Greek Revolution* (1832); G. Finlay, *History of the Greek Revolution* (Edinburgh, 1861).

HASTINGS, WARREN (1732–1818), the first governor general of British India, was born on Dec. 6, 1732, in the hamlet of Churchill, near Daylesford, of an old Oxfordshire family which had fallen into poverty. His mother died a few days after his birth; his father, Pynaston Hastings, drifted away to die obscurely in the West Indies. Young Hastings attended a charity school in his native village until, at eight, he was taken in charge by an uncle, Howard Hastings, who held a post in the customs. After two years at a private school at Newington Butts, he was sent to Westminster, where Edward Thurlow, Lord Shelburne, Elijah Impey and the poets William Cowper and Charles Churchill were among his contemporaries. In 1749 his uncle died, leaving him to the care of a distant kinsman, Creswicke, who sent his ward to seek his fortune as a writer in Bengal.

When Hastings landed at Calcutta in Oct. 1750 the affairs of the East India com'pany were at a low ebb. In southern India French influence was predominant. Bengal, however, was under the able government of Ali Vardi Khan, who peremptorily forbade the foreign settlers at Calcutta and Chandernagore to introduce feuds from Europe. Hastings was placed in charge of an *aurang* or factory in the interior, where his duties would be to superintend the weaving of silk and cotton goods under a system of money advances. In 1753 he was transferred to Cossimbazar, the river port of the native capital of Murshidabad. In 1756 the old nawab died, and was succeeded by his grandson Suraj ud-Daula, a young madman of 19, whose name is indelibly associated with the tragedy of the Black Hole. When Suraj ud-Daula resolved to drive the English out of Bengal, his first step was to occupy the fortified factory at Cossimbazar and to imprison Hastings and his companions. Hastings was soon released at the intercession of the Dutch resident and made use of his position at Murshidabad to open negotiations with the English fugitives at Falta, the site of a Dutch factory near the mouth of the Hooghly. After a while he fled from the Mohammedan court to join the main body of the English at Falta.

When the relieving force arrived from Madras under Col. Robert Clive and Adm. Charles Watson, Hastings enrolled as a volunteer and took part in the action which led to the recovery of Calcutta. Clive appointed him in 1758 resident at the court of Murshidabad. There he first came into collision with the Bengali Brahman, Nuncomar. During his three years of office as resident he served the company well, but his name nowhere occurs in the official lists of those who derived pecuniary profit from the necessities and weakness of the native court. In 1761 he was promoted to be member of council, under the presidency of Henry Vansittart, who had been introduced by Clive from Madras. The period of Vansittart's government has been truly described as "the most revolting page of our [British] Indian history." The administration was left in the hands of the nawab, while a few irresponsible English traders had drawn to themselves all real power. The members of council, the commanders of the troops and the commercial residents plundered on a grand scale. The youngest servant of the company claimed the right of trading on his own account, free from taxation and from local jurisdiction, not only for himself but also for every native subordinate whom he might permit to use his name.

This exemption, threatening the very foundations of the Moslem government, finally led to a rupture with the nawab. Sometimes in conjunction only with Vansittart, sometimes absolutely alone, Hastings protested unceasingly against the policy and practices of his colleagues. On one occasion he was stigmatized in a minute by Stanlake Batson with "having espoused the nawab's cause, and as a hired solicitor defended all his actions, however dishonourable and detrimental to the Company." An altercation ensued. Batson gave him the lie and struck him in the council chamber. When war was actually begun, Hastings officially recorded his previous resolution to resign, in order to repudiate responsibility for measures which he had always opposed. After the decisive victory of Buxar over the allied forces of Bengal and Oudh, he resigned and sailed for England in Nov. 1764.

Fourteen years' residence in Bengal had not made Hastings a rich man, estimated by the opportunities of his position. According to the custom of the time he had augmented his slender salary by private trade. At a later date he was charged by Edmund Burke with having taken up profitable contracts for supplying bullocks for the use of the company's troops. It is admitted that he conducted by means of agents a large business in timber in the Gangetic Sundarbans. When at Falta he had married Mrs. John Buchanan, the widow of an officer. She bore him two children: one of them died in infancy at Murshidabad and was shortly followed by her mother (1759); the other child, a son, was sent to England and died shortly before his father's return. While at home Hastings made the personal acquaintance of Samuel Johnson and Lord Mansfield. In 1766 he was called upon to give evidence before a committee of the house of commons upon the affairs of Bengal.

In the winter of 1768, Hastings received the appointment of second in council at Madras. Among his companions on his voyage round the Cape were the Baron Imhoff, a speculative portrait painter, and his wife Maria, a lady of some personal attractions and great social charm, who was destined henceforth to be Hastings' lifelong companion. At Madras he won the good will of his employers by devoting himself to the improvement of their manufacturing business; and he kept his hands clean from the prevalent taint of pecuniary transactions with the nawab of the Carnatic. He drew up a scheme for the construction of a pier

at Madras, to avoid the dangers of landing through the surf, and instructed his brother-in-law in England to obtain estimates from the engineers James Brindley and John Smeaton.

In 1772 he was nominated to the second place in council in Bengal with a promise of the reversion of the governorship when John Cartier should retire. The second governorship of Clive was marked by the transfer of the *diwani* or financial administration from the Mogul emperor to the company and by the enforcement of stringent regulations against the besetting sin of peculation. But Clive was followed by two inefficient successors; and in 1770 occurred the most terrible Indian famine on record, which is credibly estimated to have swept away one-third of the population. In April 1772 Warren Hastings took his seat as president of the council at Fort William. His first care was to effect a radical reform in the system of government. Clive's plan of governing through the agency of the native court had proved a failure. The directors were determined "to stand forth as *diwan* and take upon themselves by their own servants the entire management of the revenues." All the officers of administration were transferred from Murshidabad to Calcutta, which Hastings boasted he would make the first city in Asia.

This reform involved the ruin of many native reputations and brought Hastings for a second time into collision with Nuncomar. At the same time a settlement of the land revenue on leases for five years was begun, and the police and military systems of the country were placed upon a new footing. Hastings was a man of immense industry, with an insatiable appetite for detail. The whole of this large series of reforms was conducted under his own personal supervision. As a measure of economy, the stipend paid to the titular nawab of Bengal, who was then a minor, was reduced by one-half—to 16 *lakhs* a year (about £160,000). Thomas Macaulay imputes this reduction to Hastings as a characteristic act of financial immorality; but it had been expressly enjoined by the court of directors, in a dispatch dated six months before Hastings took up office. His bargains with Shuja ud-Daula, the nawab wazir of Oudh, stand on a different basis.

The Marathas had got possession of the person of the Mogul emperor, Shah Alam, from whom Clive obtained the grant of the *diwani* of Bengal, Bihar and Orissa in 1765 and to whom he assigned for the upkeep of his dignity and expenses the districts of Kora and Allahabad and a tribute of £325,000.

With the emperor in their camp, the Marathas were threatening the province of Oudh. Hastings, as a deliberate measure of policy, withheld the tribute due to the emperor and resold Allahabad and Kora to the wazir of Oudh. The Marathas retreated, and danger for the time was dissipated by the death of their principal leader. The wazir now determined to satisfy an old quarrel against the adjoining tribe of Rohillas, who had established themselves for some generations in a fertile tract west of Oudh. They were not so much the occupiers of the soil as a dominant caste of warriors and freebooters. But in those troubled days their title was as good as any to be found in India. After some hesitation, Hastings allowed the company's troops to be used to further the designs of his Oudh ally, in consideration of a payment to the Bengal treasury. The Rohillas were defeated. Some of them fled the country, and so far as possible Hastings obtained terms for those who remained. The fighting, no doubt, on the part of the wazir was conducted with all the savagery of oriental warfare; but there is no evidence that it was a war of extermination.

Meanwhile the Regulating act, passed by Lord North's ministry in 1773, changed the constitution of the Bengal government. The council was reduced to four members with a governor general, with certain indefinite powers of control over the presidencies of Madras and Bombay. Hastings was named in the act as governor general for a term of five years. The council consisted of Gen. Sir John Clavering and Col. George Monson, two third-rate politicians of considerable parliamentary influence; Philip Francis (*q.v.*), then known only as an able permanent official; and Richard Barwell, of the Bengal civil service. At the same time a supreme court of judicature was appointed, composed of a chief and three puisne judges, to exercise an indeterminate jurisdiction at Calcutta. The chief justice was Sir Elijah Impey, already mentioned as a schoolfellow of Hastings at Westminster. The tendency of the Regulating act was to establish for the first time the influence of the crown, or rather of parliament, in Indian affairs. The new members of council disembarked at Calcutta on Oct. 19, 1774; and on the following day commenced the long feud which scarcely terminated 21 years later with the acquittal of Warren Hastings by the house of lords. Taking advantage of an ambiguous clause in their commission, the majority of the council (for Barwell uniformly sided with Hastings) reviewed the recent measures of the governor general. All that he had done they condemned; all that they could they reversed. Hastings was reduced to the position of a cipher at their meetings. They listened to detailed allegations of corruption brought against him by Nuncomar.

Hastings disdained to reply and referred his accuser to the supreme court. The majority of the council, in their executive capacity, resolved that the governor general had been guilty of peculation and ordered him to refund. A few days later Nuncomar was thrown into prison on a charge of forgery preferred by a private prosecutor, tried before the supreme court sitting in bar, found guilty by a jury of Englishmen and sentenced to be hanged. Hastings always maintained that he did not cause the charge to be instituted, and the legality of Nuncomar's trial is thoroughly proved by Sir James Stephen. The majority of the council abandoned their supporter, who was executed in due course. He had forwarded a petition for reprieve to the council, which Clavering took care should not be presented in time and which was subsequently burned by the common hangman on the motion of Francis. Meanwhile, Hastings had sent an agent to England with a general authority to place his resignation in the hands of the company under certain conditions. The resignation was promptly accepted, and one of the directors was appointed to the vacancy. But in the meantime Colonel Monson had died, and Hastings was thus restored, by virtue of his casting vote, to the supreme management of affairs. He refused to ratify his resignation; and when Clavering attempted to seize the governor generalship, he obtained an opinion from the judges of the supreme court in his favour. Hastings was never again subjected to gross insult, and his general policy prevailed.

A crisis was now approaching in foreign affairs. Bengal was prosperous and free from external enemies on every quarter. But the government of Bombay had hurried on a rupture with the Maratha confederacy at a time when France was on the point of declaring war against England and when England was faced with revolt in America. Hastings shouldered the whole responsibility of military affairs. The French settlements in India were promptly occupied. On the part of Bombay, the Maratha war was conducted with procrastination and disgrace. But Hastings avenged the capitulation of Wargaon by the complete success of his own plan of operations. Thomas Goddard with a Bengal army marched across India and achieved almost without a blow the conquest of Gujarat. William Popham stormed the rock fortress of Gwalior, then deemed impregnable and the key of central India; and by this feat held in check Sindhia, the most formidable of the Maratha chiefs. The Bhonsla Maratha rajah of Nagpur, whose dominions bordered on Bengal, was won over by the diplomacy of an emissary of Hastings.

But while these events were taking place, a new source of embarrassment had arisen at Calcutta. The supreme court assumed a jurisdiction of first instance over the entire province of Bengal. The English common law was arbitrarily extended to an alien system of society. *Zamindars*, or government renters, were arrested on mesne process; the sanctity of the *zenana* was violated by the sheriff's officer; the deepest feelings of the people and the entire fabric of revenue administration were alike disregarded. On this point the entire council acted in harmony. Hastings and Francis went joint bail for imprisoned natives of distinction. At last, after the dispute between the judges and the executive threatened to become a trial of armed force, Hastings set it at rest by a characteristic stroke of policy. A new judicial office was created in the name of the company, to which Impey was appointed. The understanding between Hastings and Francis was

for a short period extended to genera1 policy. Francis received patronage for his friends, while Hastings was to be unimpeded in the control of foreign affairs. But a difference of interpretation arose. Hastings recorded in an officialminute that he had found Francis' private and public conduct to be "void of truth and honour." They met as duellists. Francis fell wounded and soon afterward returned to England.

The Maratha war was not yet terminated when a more formidable danger threatened the English in India. The Madras authorities had irritated beyond endurance the two greatest Mussulman powers in the peninsula, the nizam of the Deccan and Hyder Ali, the usurper of Mysore, who began to negotiate an alliance with the Marathas. A second time the genius of Hastings saved the situation. On the arrival of the news that Hyder had descended from the highlands of Mysore, cut to pieces the only British army in the field and swept the Carnatic up to the gates of Madras, he adopted a daring policy. He signed a blank treaty of peace with the Marathas, who were still in arms, reversed the action of the Madras goyernment toward the nizam and concentrated all the resources of Bengal against Hyder Ali. Sir Eyre Coote was sent by sea to Madras with all the troops and treasure available; and reinforcements marched southward under Col. Thomas Pearse along the coast line of Orissa. The landing of Coote preserved Madras from destruction, though the war lasted through many campaigns and terminated only with the death of Hyder. Pearse's detachment was decimated by an epidemic of cholera (perhaps the first mention of this disease by name in Indian history) ; but the survivors penetrated to Madras, held Bhonsla and the nizam in check and corroborated the lesson taught by Goddard — that the company's sepoys could march anywhere, when boldly led.

Hastings had to provide the ways and means for this exhausting war. He reformed the collection of the land tax, and the government monopolies of opium and salt were placed upon a remunerative basis. Pressing demands were met by loans and in at least one case from the private purse of the governor general. Hastings' fertile mind at once turned to the hoards of the native princes and zamindars. Chait Singh, the zamindar of Benares, who had grown rich under British protection, lay under suspicion of disloyalty. The wazir of Oudh had fallen into arrears for the maintenance of the company's garrison posted in his dominions, and his administration was in disorder. In his case the ancestral hoards were under the control of his mother, the begum of Oudh, into whose hands they had passed when Hastings was powerless in council.

Hastings decided to go to Oudh and Benares to enforce administrative and financial reforms. When he reached Benares and presented his demands, the rajah rose in insurrection, and the governor general barely escaped with his life. But Popham rallied a force for his defense. The insurgents were defeated, Chait Singh took to flight. and an augmented revenue demand was imposed upon his successor. The wazir of Oudh consented to everything demanded of him. The begum was charged with having abetted Chait Singh in his rebellion, and after severe pressure applied to herself and her attendant eunuchs, was deprived of her treasure and of her rich jagir lands. But Hastings appears to have been uneasy about the incidents of this expedition and to have anticipated censure in England. He therefore procured documentary evidence of the rebellious intentions of the rajah and begum, to the validity of which Impey obligingly lent his extrajudicial sanction.

The remainder of Hastings' term of office in India was passed in comparative tranquillity. But in England the long struggle between the company and the ministers of the crown for supreme control of Indian affairs and the attendant patronage reached its climax. The success of Hastings' administration alone postponed the solution. His original term of five years would have expired in 1778; but it was annually prolonged by special act of parliament until his voluntary resignation. Indian affairs formed the hinge on which party politics turned. On one occasion Henry Dundas carried a motion in the house of commons, censuring Hastings and demanding his recall. The directors of the company were disposed to agree; but in the court of proprietors Hastings always possessed a sufficient majority. Charles Fox's India bill led to the downfall of the coalition ministry in 1783. The act which William Pitt carried in 1784 introduced a new constitution, in which Hastings felt that he had no place. In Feb. 1785 he sailed from Calcutta, after a dignified ceremony of resignation and amid enthusiastic farewells from all classes.

On his arrival in England, after a second absence of 16 years, he was well received. Pitt had never taken a side against him, while Thurlow was his pronounced friend. But Francis, whom he had discomfited in the council chamber at Calcutta, was more than his match in the parliamentary arena. Burke had taken the subject races of India under the protection of his eloquence. Francis, who had been the early friend of Burke, supplied him with the animus against Hastings and with the knowledge of detail which he might otherwise have lacked. The Whig party followed Burke's lead. Dundas, Pitt's favourite subordinate, had already committed himself by his earlier resolution of censure; and Pitt was induced by motives which are still obscure to incline the ministerial majority to the same side. To meet the oratory of Burke and Richard Sheridan and Fox, Hastings wrote an elaborate minute with which he wearied the ears of the house for two successive nights; and he subsidized a swarm of pamphleteers. The impeachment was decided upon in 1786, but the actual trial did not commence until 1788. For seven long years Hastings was upon his defense on the charge of "high crimes and misdemeanours." During this anxious period he bore himself with characteristic dignity.

At last, in 1795, the house of lords gave a verdict of not guilty on all charges laid against him; and he left the bar at which he had so frequently appeared with his reputation clear, but ruined in fortune. The wealth he brought back from India was swallowed up in the expenses of his trial. He forwarded a petition to Pitt praying that he might be reimbursed his costs from the public funds. This petition, of course, was rejected. At last, when he was reduced to actual destitution, it was arranged that the East India company should grant him an annuity of £4,000 for a term of years, with £90,000 paid down in advance. This annuity expired before his death; and he was compelled to make more than one fresh appeal to the bounty of the company, which was never withheld. Shortly before his acquittal he had fulfilled the dream of his childhood by buying back the ancestral manor of Daylesford, where the remainder of his life was passed in honourable retirement. In 1813 he was called on to give evidence upon Indian affairs before the two houses of parliament, which received him with exceptional marks of respect; and Oxford university conferred on him the honorary degree of D.C.L. In 1814 he was sworn to the privy council. He died on Aug. 22, 1818, in his 86th year, and lies buried behind the chancel of the parish church, which he had recently restored at his own charges.

In physical appearance, Hastings "looked like a great man, and not like a bad man." The body was wholly subjugated to the mind. A frame naturally slight had been further attenuated by rigorous habits of temperance and thus rendered proof against the diseases of the tropics. Against his private character not even calumny has breathed a reproach. As brother, as husband and as friend, his affections were as steadfast as they were warm. A classical education and the instincts of family pride saved him from the greed and the vulgar display which marked the typical "nabob." Concerning his second marriage, it suffices to say that the Baroness Imhoff was nearly 40 years of age, with a family of grown-up children, when the law of her native land allowed her to become Mrs. Hastings. She survived her husband, who cherished toward her to the last the sentiments of a lover. Her children he adopted as his own; and it was chiefly for her sake that he desired the peerage which was twice held out to him.

Hastings' public career will probably never cease to be a subject of controversy. He was the scapegoat upon whose head parliament laid the accumulated sins, real and imaginary, of the East India company. If the acquisition of the Indian empire can be supported on ethical grounds, Hastings needs no defense. No one who reads his private correspondence will admit that even

his least defensible acts were dictated by dishonourable motives. On certain of his public measures no difference of opinion can arise. He was the first to attempt to open a trade route with Tibet and to organize a survey of Bengal and of the eastern seas. He persuaded the *pundits* of Bengal to disclose the treasures of Sanskrit to European scholars. He founded the Madrasa or college for Mohammedan education at Calcutta, primarily out of his own funds: and he projected the foundation of an Indian institute in England. The Bengal Asiatic society was established under his auspices, though he yielded the post of president to Sir William Jones. No Englishman ever understood the Indian character so well as Hastings; none ever devoted himself more heartily to the promotion of every scheme. great and small. that could advance the prosperity of India. Indians and Anglo-Indians alike venerated his name, the former as their first beneficent administrator. the latter as the most able and most enlightened of their own class. If Clive's sword conquered the Indian empire. it was the brain of Hastings that planned the system of civil administration and his genius that saved the empire in a dark hour.

(J. S. Co.; X.)

HASTINGS, WILLIAM, BARON (*c.* 1430–1483), a son of Sir Leonard Hastings (d. 1455). was master of the mint and chamberlain of the royal household under Edward IV. Crested a baron in 1461. he married Catherine, daughter of Richard Neville, earl of Salisbury. He was faithful to Edward IV during the king's exile in the n-inter of 1470–71. After the king's return Hastings fought for him at Barnet and at Tewkesbury, thereafter retaining Edward'~confidence for the remainder of the reign despite the hostility of the queen and her kinsmen. He was made captain of Calais in 1471 and was with Edward IV when he met Louis XI of France at Picquigny in 147j, on which occasion he received gifts from Louis and from Charles the Bold of Burgundy. After Edward IV's death Hastings refused to ally himself with Richard, duke of Gloucester, afterward King Richard III. During a meeting of the council on June 13, 1483, he was seized and at once put to death. This dramatic incident is related by Sir Thomas More in his *History of Richard III,* and was worked by Shakespeare into his play *Richard III.*

HASTINGS, a municipal, county and parliamentary borough and seaside town of Sussex, Eng., one of the Cinque Ports, 64 mi. S.S.E. of London by road. Pop. (1951) 65,522. Area 11.4 sq.mi. Hastings stands where an outlier of the chalk downs reaches the coast. and the shore line is backed by cliffs. Two converging valleys running seaward contain much of the town. which has spread up the steep slopes as well as westward along the shore at the foot of the cliffs, and since 1872 the borough has included the town of St. Leonards, built (1828) by James Burton, father of the more famous Decimus. At the eastward end of the foreshore is the old fishing village. Hastings has some light industries. but its main occupation is catering for visitors who, because of its genial climate and sandy beaches, are attracted the year round. Romantically placed on the cliff overlooking the old town are the ruins of Hastings castle, and below it are the remains of a harbour begun in 1893 but never finished.

Rock shelters on Castle hill and numerous flint implements suggest an extensive early population: and there are earthworks and a promontory camp probably of the early Iron Age or Romano-British date. In 700, the name tells us, it was the residence of the Haestingas tribe (*i.e.,* "Haesta's people"). Hastings was not a Roman settlement, but it mas a place of some importance in the Anglo-Saxon period. In the reign of Aethelstan (928) it was important enough to have a mint. The battle of Bastings (*see* below) in 1066 was fought near the present Battle abbey, about 6 mi. N. After the Conquest, William I made the earthworks of the castle and by 1086 Hastings had given its name to the rape (*q.v.*) of Sussex in which it lay. The town at that time had a harbour and a market. but although it became the chief town of the Cinque Ports (*q.v.*) it was not mentioned in *Domesday Book.* Its charter shows. however, that it had greater liberties than Dover in return for the same services. It was represented in the parliament of 1265 and was incorporated by Elizabeth I in a charter of 1588.

The fragments of the castle stand on the brink of the West cliff, together with the ruins, excavated in 1824, of the castle chapel, a transitional Norman structure 110 ft. long, with a nave, chancel and aisles. Besides the chapel there was formerly a college, both being under the control of a dean and secular canons. The deanery was held by Thomas Becket. and one of the canonries by William of Wykeham. Titus Oates, whose father was rector of the parish, was baptized in 1649 in the church of All Saints, a 15th-century Perpendicular building. The parish church of St. Clement replaced (about 1380) an earlier structure which in turn had replaced a church washed away by the sea. (X.)

The Battle of Hastings (1066).—The battle of Hastings (Oct. 14, 1066) between Harold, king of England, and William, duke of Normandy. was "one of those battles which at rare intervals have decided the fate of nations" (Sir F. M. Stenton, *Anglo-Saxon England,* Oxford University Press). By 1066 William controlled, directly or by alliance. every harbour from the Scheldt to Brest; his wife's father, Baldwin of Flanders. was regent of France. and the count of Anjou, his only other dangerous neighbour, was distracted by rebellion. With a solemn papal blessing and the emperor's approval, William prepared to enforce his claim to the English crown. He persuaded the Norman barons to promise support. and recruited thousands of volunteers from Brittany, Maine, France, Flanders, Spain and Italy, mostly adventurers attracted by prospects of conquest. The organization of supplies and transport for this miscellaneous host of about 5,000 knights, and the imposition of disciplined Norman cohesion upon them, were probably William's supreme military achievements.

Harold mobilized his fleet and army in May, repelled his outlawed brother Tostig's raids on the south and east coasts. and concentrated his large fleet off Spithead and his militia along the Hampshire, Sussex and Kentish coasts. Ready to move early in August, William's transports were kept in port by north winds for eight weeks, first in the Dives estuary until Sept. 12, then at St. Valéry-sur-Somme. Meanwhile the English militia, short of supplies after four months' fruitless waiting, lost morale and on Sept. 8 were dismissed; the ships were brought back to the Thames, many being lost en route. The channel was thus left open, and the best chance of destroying William's army was lost. At this moment Harald III Hardrada, king of Norway, another claimant of the English crown. supported by Tostig, entered the Humber with 300 ships, defeating the forces of Edwin, earl of Mercia, and his brother Morcar, earl of Northumbria, in a heavy battle at Gate Fulford, outside York (Sept. 20). This battle crippled Hardrada's forces, but also left the two earls incapable of raising another army that year. King Harold, hearing of this invasion, left London immediately with his housecarls and such thegns and shire militia as he could muster, and by forced marches surprised the invaders at Stamfordbridge on Sept. 25, utterly destroying them and killing Karald and Tostig.

On Sept. 27 the wind changed, and after nightfall William crossed the channel unopposed and disembarked quietly at Pevensey next morning. He quickly transferred his forces to Hastings, built a castle and began to explore and ravage the neighbourhood, determined not to lose touch with his ships until he had defeated Harold's main army. Harold, at Pork, learned on about Oct. 2 of William's landing. summoned all thegns and shire militia to follow, and set off by forced marches, gathering reinforcements as he went. and by Oct. 13 he was approaching Hastings with about 7.000 men, including his housecarls. some thegns and shire levies and many half-armed. untrained peasants. He had mobilized barely half of England's trained soldiers, yet he advanced against

William instead of making William come to meet him in a chosen defensive position. a bad strategical decision probably explained by his eagerness to defend his own men and lands. which William. was hnrrying, and to thrust the Normans back into the sea.

William, warned of Harold's approach. determined to force battle immediately. At dawn on Oct. 14 he advanced. sighting Harold's army on the ridge 10 mi. N.W. of Hastings. William arrayed his army for attack, his archers and crossbowmen in the front line. his heavy infantry in the second, his knights in three divisions in the rear. Normans in the centre, Bretons and French on left and right respectively. The English. lacking archers and cavalry (though they used horses for movement from place to place) could not hamper these manoeuvres, but prepared to resist. Their position was not wholly favourable; William's advance was unexpected, and Harold had to fight where he stood or retreat. He placed himself. his housecarls and his other trained troops around his standard at the summit of the ridge (where the high altar of Battle abbey was later placed), grouping his other men along the crest for about 400 yd. westward and about 200 yd. eastward, at which points the slope became steep enough to protect both flanks. The front was too small: some men, finding no fighting room. withdrew: the rest. in too close order, made a perfect target for arrows. In front the easy slope (jo ft. in 400 yd.) allowed William's knights an open approach, against which Harold relied on the close "shield wall" formation of his trained troops to hurl back and dishearten the enemy. The idea that Harold prepared a palisade is incorrect; but the disparity of English and Norman equipment and tactics was smaller than is often supposed. The heavily armoured knight, riding a powerful charger and holding couched a heavy thrusting lance, was still 100 years away: Norman armour was flimsy, the horses light and unprotected. and the knights, using javelins: maces and swords. had to engage hand to hand, where the great two-handed English battle-axes would work terrible havoc. Harold's hopes depended on keeping his line unbroken. his casualties light, and so exhausting and demoralizing the Normans.

William's archers opened at close range. inflicting many casualties but suffering heavily from the English slings and spears; William therefore threw in his cavalry. which was so badly mauled by the English battle-axes that it panicked and fled. William himself checked and turned them. counterattacking a large body of Englishmen who had broken ranks in pursuit. William pressed his cavalry charges throughout the day. interspersing them with flights of arrows. an'd annihilating considerable numbers of Englishmen whom he drew from their positions by two feigned flights. The defense. hard-pressed. depleted and tiring. was worn down and slowly outnumbered: Harold's brothers. Gyrth and Leofwine. fell, and late in the afternoon a chance arrow killed Harold. The leaderless English fought on till dusk and then broke: a last rally in the gloom caused the Normans further casualties and endangered William himself. But as darkness fell the English scattered, leaving William the winner of one of the most daring gambles in history. (R. F. T.)

HASTINGS, a town in the North Island of New Zealand. in the Hawke's Bay province, 12 mi. S. of Napier by rail. Pop. (1961) 23.383. It is the centre of a rich agricultural. pastoral and fruit-growing district. Hastings was formerly known as Heretaunga and is named after Warren Hastings (*q.v.*).

HASTINGS, a city in Nebraska, U.S., about 90 mi. W. of Lincoln, is the seat of Adams county. It was founded in 1872 as the western terminus of the St. Joseph and Denver railroad on Walter Micklen's homestead and named after a surveyor who graded the final section of the railroad into the village. It was incorporated in 1874.

Located in irrigated farm land it is a wholesale and distributing. centre with large grain storage facilities. Its industries include the manufacture of agricultural implements, irrigation equipment. air conditioning machinery. sheet metal and millwork and the processing of food. A natural gas company has its regional headquarters there. Water and electricity plants are municipally on ned

Educational institutions include Hastings college (Presbyterian), founded in 1882; Mary Lanning School of Nursing: and Immaculate Conception monastery. The House of Yesterday. a municipal museum. emphasizes the Great Plains in its historical. geological and biological collections: the J. M. McDonald planetarium is operated in conjunction with the museum. Good Samaritan Village (Lutheran) offers low cost housing and nursing care for the aged. Hastings State hospital and Mary Lanning hospital also serve the community. A nearby artificial lake provides facilities for water sports. For comparative population figures *see* table in *NEBRASKA:* Population. (R. S. V. M.)

HAT: *see* HAT MANUFACTURE; HEADDRESS.

HATAY, the southernmost *il* (province) of Turkey. on the Mediterranean coast. is bounded west by the Gulf of Iskenderun (Alexandretta). south and east by Syrian territory. Pop. (1960) 441,198. Area 2.139 sq.mi. Formerly part of the Turkish empire, coextensive with the former sanjak of Alexandretta. Hatay came under French mandatory control after World War I but. after a period from Jan. 1937 as a separate entity under Syrian responsibility. it was returned to Turkey by a Turko-French agreement in June 1939. Between the Amanus mountains or Nur Daglari (6.000 ft.) in the west and the rim of the Syrian plateau on the eastern border is a large plain watered by the Asi (Orontes) river. partly occupied by a shallow lake. Climate and agriculture are typically Mediterranean. Main roads connect Hatay with Syria and with the rest of Turkey. The chief towns are Xntioch (Antakya), the capital, and Iskenderun. See also TURKEY: *History.* (N. TU.; S. ER.; E. TU.)

HATCHMENT or ACHIEVEMENT, in heraldry, the setting out of armorial bearings. with all that belongs to them: shield, helm and crest, supporters and motto or word. The term "hatchment" is now usually applied to armorial bearings enclosed in a black lozenge-shaped frame suspended against the wall of a deceased person's house. It remains for from 6 to 12 months, when it is removed to the parish church. This custom is falling into disuse, though a hatchment was shown in a London street in 1928. It is usual to hang the hatchment of a head of a house at Oxford and Cambridge universities over the entrance to his lodge or residence.

If for a bachelor, the hatchment has a black ground: if for a single woman, her arms are represented upon a lozenge. bordered with knotted ribbons, also on a black ground. If the hatchment is for a married man. his arms upon a shield impale those of his surviving wife; or if she is an heiress they are placed upon a scutcheon or pretence, and crest and other appendages are added. The dexter half of the ground is black. the sinister white. For a wife whose husband is alive the same arrangement is used, but only the sinister ground is black. For a widower the same is used as for a married man, but the whole ground is black; for a widow the husband's arms are given with her own, but upon a lozenge. with ribbons. without crest or appendages, and the whole ground is black. When there have been two wives or two husbands the ground is divided into three parts per pale, and the division behind the arms of the survivor is white. It is thus easy to discern from the hatchment the sex, condition and quality and possibly the name of the deceased. In Scottish hatchments it is not unusual to place the arms of the father and mother of the deceased in the two lateral angles of the lozenge.

HATFIELD, a town in Hertfordshire, Eng.. 20 mi. N. of Hyde Park corner. London, on the Great North road. Pop. (1951) 13,834. The church of St. Etheldreda contains an Early English round arch; the chancel and transepts are also of the 13th century. In the Salisbury chapel (1618) are monuments to Robert Cecil, 1st earl of Salisbury. and Robert Cecil, the 3rd marquess. Hatfield house stands close to the site of a palace of the bishops of Ely erected in the 11th century; hence the true name of the town, Bishop's Hatfield. Of the red brick palace, built round a large quadrangle, only one side remains. and it contains the banqueting hall, used as a restaurant for visitors. After the Dissolution Henry VIII kept the palace mainly as a residence for his children. and it was there that Elizabeth I received the news of her accession. James I exchanged Hatfield in 160; for Theobalds, near Cheshunt, an estate of the 1st earl of Salisbury. who immediately pulled down three sides of the old palace to build the present

Hatfield house. which remained in the Cecil family thereafter. It is built in the shape of an E. Large gardens were laid out by James I and altered through the centuries. The west wing of the house was severely damaged by fire in 1835 when the eccentric widow of the 1st marquess of Salisbury was burned. The 3rd marquess installed electric lighting in 1881. During World War II it was used as a hospital. Hatfield house is rich in portraits of and by well-known persons. among which are three of Elizabeth I.

When Hatfield New Town (to cover 3.7 sq.mi. between the Barnet bypass and Hatfield park) was designated in 1948. there was already enough industry in the district to employ nearly all its 25,000 inhabitants. The chief works are those of the de Havilland Aircraft company. Others include engineering, cardboard boxes, etc. In 1952 a technical college was opened.

HATHERLEY, WILLIAM PAGE WOOD, 1ST BARON, (1801–1881), lord chancellor of Great Britain. was born in London on Nov. 29. 1801. The son of Sir Matthew Wood, a London alderman and lord mayor who became famous for befriending Queen Caroline and braving George IV. he was educated at Winchester, Geneva university and at Trinity college. Cambridge. of which he became a fellow in 1824. He entered Lincoln's Inn. and was called to the bar in 1823. He practised as an equity draftsman and before parliamentary committees. In 1845 he became Q.C., and in 1847 became M.P. for the city of Oxford. In 1849 he 77-35 appointed vice-chancellor of the county palatine of Lancaster. and was solicitor general in 1851–52. When the Liberal party returned to power in 1853, he was raised to the bench as a vice-chancellor.

In 1868 he was made a lord justice of appeal. but before the end of the year was selected by Gladstone to be lord chancellor. He retired in 1872. but sat occasionally as a law lord. He died in London on July 10, 1881.

HATHQR, Egyptian goddess. was originally a personification of the sky. as the meaning of her name; "Castle of (the sky-god) Horus." shows. In the sun temples built by six kings of the 5th dynasty (c. 2560–2450 B.C.) near Memphis, Egy., her worship was. therefore. associated with that of another sun-god. Ra of Heliopolis. In the old centre of her cult, at Dendera, in upper Egypt. however. she was considered as the wife of Horus and as the goddess of festivity. dance and love.

From Dendera her worship spread elsewhere, and she was consequently identified with a number of local tree. lion and cow goddesses. as at Deir el-Bahri (Dayr al-Bahri). There. however. owing to the proximity of the necropolis of Thehes. she became "Lady of the West" and patroness of the region of the dead. quite contrary to her earlier nature. The Greeks identified Hathor with their Aphrodite. (J. CY.)

HAT MANUFACTURE. The hat. a covering for the head worn by both sexes, is distinguished from the cap or bonnet by the possession of a brim. The history of the hat as part of the apparel of both sexes. with the various changes in shape which it has undergone, is treated in the article HEADDRESS.

At the present day the hat trade is divided into four sections. The first is concerned with the manufacture of hats made from fur: the second. with those made from wool. The productions from these two sections are known as fur felt hats and wool felt hats respectively. The third section engages itself in the manufacture of hats made from materials plaited or woven from straw or vegetable products of a fibrous nature such as palm leaf. hemp, bamboo, rush, etc. This section is known as the straw hat section of the industry (see STRAW). The fourth has to do with hats made from silk plush and is termed silk hatting.

Fur Felt Hats.—The manufacture of fur felt hats under modern conditions entails a series of processes in which highly skilled labour must be employed. The furs used in the industry are coney (rabbit), hare, muskrat, nutria and beaver. The three latter are aquatic and before they can be utilised, have to be washed thoroughly in a strong solution of whale oil soap and water to remove the scum and dirt with which the fur fibres are encrusted. Hare and coney do not require this preliminary washing. All long coarse guard hairs are plucked from the skin, leaving only the smooth soft fur.

After plucking, the remaining fur is treated with a solution of nitrate of mercury; process known as *carroting*, its object being to open out the minute branches or *barbs* with which each fur fibre is covered. Carroted skins are fed into a machine which cuts the hide into short shreds, the fur fibre emerges on an endless belt, the hide, now denuded of fur and useless for hat manufacturing purposes being discarded. Fur fibre having been sorted according to its quality value, now undergoes an operation known as *blowing* by which the fibres are fed into a machine whose mechanism contains numerous revolving cylinders bearing .thousands of steel teeth or pickers. The action of this machine separates from the individual fur fibres the *kemp* or colouring matter useless for hat manufacturing purposes, and the *down* of the fibre the portion from which fur felt hats are made.

The accumulation of millions of fur fibres into a *hood* from which a finished hat is made is known as *forming;* this, as having reference to the manufacture of fur felt hats, is the process by which fur fibres are knit closely together to form a fabric which shall have the requisite configuration, thickness, homogeneity and stability. For this purpose, a quantity of fur, varying according to the weight and dimensions of hood that is to be made, is fed into a machine and projected into a chamber containing a minutely perforated copper cone. This cone revolves, and to its damp outer side are drawn by suction the myriads of mist-like fur particles; thus the cone rapidly becomes covered with a film of fur. The cone, with its coating of fur, is wrapper1 round with flannel and, protected further with a metal cover, is immersed in hot water after which the formed hood is removed from the cone.

Each fur fibre has a number of minute branches or barbs and when a mass of such fibres is subjected to heat, moisture and motion with the addition of pressure, the fibres become firmly interlocked. Repetitions of this treatment result in fur felt the shape of which is relatively much the same as that of the original mass, but decreased in size through the working together of fibres and the consequent shrinkage. It is usual to form the hat body or "hood" (the unit which. after many processes, finally emerges as a completed hat) as a cone about 29 in. in height and about 20 in. in diameter. As the hood is handled, not as a cone but in the flat, the diameter of the cone is not considered in the terminology. Thus, the size of the hood above mentioned would be referred to as 29×31, the latter figure being the width of the flat hood across the corners at the base.

After a hood has been formed, the fabric has little cohesion and has to be hardened or shrunk, the object being to interlock or knit together the individual hair fibres so closely that they become inseparable. In the hardening operation, the formed hoods, saturated with water, are stacked together in lots of six to ten. rolled up in a wet cloth and manipulated by hand. Some shrinkage occurs. During this process, the operator must he careful not to tear the hood or treat the delicate fabric so roughly as to cause a "shove" or other damage.

The universal method is to divide the hardening process into four successive shrinking operations known as *(a) hardening, (b) starting, (c) planking, (d) second or final planking.*

These operations are not closely defined, and the extent to which each is carried varies with different manufacturers and with special requirements. To indicate the progressive steps, a hood 29 in.×31 in. (height 29 in., width across base 31 in.) after hardening will be considered as an example and the following table will show the approximate relative dimensions:

Operation	Dimensions inches
A. After hardening	29 × 31
B. „ starting	18 × 24
C. „ planking	11 × 16½
D. „ second planking	10¼ × 15¾

Briefly the following is a description of operations B., C. and D.

Starting is a shrinking operation employing an open kettle of boiling water and a machine with three deeply corrugated revolving rollers. The operator takes four to six hoods. wets them in boiling water, piles them one on the other, rolls them up, wraps

a canvas cloth round them and tosses the bundle between the rollers of the machine. After a time, the bundle is taken out, unwrapped, unrolled and the hats immersed in boiling water. Each hood is then subjected to hand manipulation. The same hoods are then stacked up again, this time however, their relative positions are changed. They are rolled up again but the rolling is started from another corner or side, the canvas is wrapped on and the bundle tossed between the rollers. These operations are repeated until the operator finds that the shrinking has been carried far enough.

Planking is an operation similar to "starting" employing a three-roller machine over an open hot water bath. The pressure used is somewhat greater, more manipulation is performed and the hoods are put through the machine a greater number of times.

Second planking is another shrinking operation employing similar equipment but requiring still greater pressure and increased manipulation.

The operations by which fur fibre is converted into a fur felt hood comprise what is known as the wet side of hat manufacturing: the processes by which the hood is converted into a finished hat being termed the dry side of the industry. In this regard no general methods are adopted. so much depending on the particular shape or style of headwear it is purposed to produce. Usually, before a hood is converted into a hat, a certain amount of stiffening or proofing is applied In this operation the hooa is treated with a solution composed of shellac and methylated spirit. The hood after this application is placed in a hot oven or kiln the spirit in the solution tending to slightly open the "pores" of the fabric, the heat whilst evaporating the spirit, driving the shellac into the opened "pores" and there solidifying The object of this process is to weld the fur fibres so closely together that they cannot be separated during subsequent operations.

The operation of *blocking* or *shaping* is that whereby the hood is converted into its ultimate shape. As a rule. the hood is saturated with dry steam and whilst in this condition pulled over a wooden block the shape of the hat to be produced The dry steam softens the shellac or "proofing" in the hood allowing the whole to become malleable The wooden block with its felt covering is now allowed to dry and in drying the shellac again hardens, thus once more tightening up the fur fibres so that the whole fabric has moulded itself to the configuration of the block on which it has been placed. When quite dry, the hood, now converted into a definite shape, is removed from the block and can be regarded as a hat, the trimming of which is merely a matter of fashion requirements.

Wool Felt Hats.—In the manufacture of these articles the wool used is technically known as *noils*, being the short fibre separated by *stapling* from the *tops* or longer wool fibres used in the weaving of cloth The *noil* is carded through a machine carrying a number of cylinders clothed with wire card. This has a cleaning and strengthening effect and the wool noil emerges in a continuous web rather like a lace curtain. This web is wrapped round a double cone which is cut through the middle giving two half cones of carded wool known technically as *formes*.

A forme varies in size and in weight according to the type of hat for which it is intended, but before it can be made into a hat it has to be reduced to a hood, as in fur felt hat production. This process known as hardening is conducted by means of steam and rotary rubbing, the action serving to shrink and consolidate the wool, the final hardening being obtained by means of machine rolling whilst the formes are immersed in boiling water. The forme. having been reduced to a hood, is thoroughly dried.

In the shrinking processes, various surface inequalities become apparent on the hood and in order to remove the same and get a perfectly even face to the fabric and to obtain a degree of lustre the hoods are passed through a machine containing a wheel or bob coated with fine sand paper and revolving at a high speed. This is termed pouncing or buffing.

Wool felt hat production from the hood stage proceeds very closely on the lines adopted in the manufacture of fur felt hats.

The operation of dyeing both fur and wool hats is conducted whilst they are in the hood stage and prior to their being stiffened or proofed.

The continent of Europe supplies approximately 90% of the world's fur and wool hoods for hat manufacturing.

Silk Hats.—The silk hat was invented in Florence about 1760, but it was not until the beginning of the 19th century that it was worn to any extent.

A silk hat consists of a light stiff body covered with a plush of silk, the manufacture of which in a brilliant glossy condition is the most important element in the industry. Originally the bodies were made of felt and various other materials, but now calico is chiefly used. The calico is first stiffened with a varnish of shellac, and then cut into pieces sufficient for crown, side and brim. The side-piece is wound round a wooden hat block, its edges are joined by hot ironing, and the crown-piece is put on and similarly attached to the side. The brim, consisting of three thicknesses of calico cemented together, is now slipped over and brought to its position, and thereafter a second side-piece and another crown are cemented on. The whole of the body, thus prepared, now receives a coat of size; subsequently it is varnished, and thus made ready for the operation of covering. In covering this body, the under brim, generally of merino, is first attached, then the upper brim, and lastly the crown and side sewn together are drawn over. All these by hot ironing and stretching are drawn smooth and tight, and as the varnish of the body softens with the heat, body and cover adhere all over to each other without wrinkle or pucker. Dressing and polishing by means of damping, brushing and ironing come next, after which the hat is "velured" in a revolving machine by the application of haircloth and velvet velures, which cleans the nap and gives it a smooth and glossy surface. The brim has only then to be bound, the linings inserted, and the brim finally curled, when the hat is ready for use.

HATSHEPSET or **HATASU** (*fl.* 1500 B.C.), Egyptian queen, daughter of Thotmes I., sister and queen of the short-reigned Thotmes II., after whose death she secured the crown in spite of opposition from the future Thotmes III., who was the son either of Thotmes I. or of Thotmes II. She acquired fame by her magnificent terrace-temple at Dēr el-Bahri and by her obelisks at Thebes, the expenses of which were partly met by the treasure-hunting expeditions which she sent to South Arabia. The long military inactivity of her reign, during which State affairs were in the hands of her partisans, shook Egyptian power in Asia. In 1841 her tomb was discovered on a cliff behind the Valley of the King's Tomb. Her successor, Thotmes III., had her name and figure cut off from the sculptures in her temple and treated the remains of her partisans in a similar manner.

See *Cambridge Ancient Hi-tory,* vol. ii (1924).

HATTIESBURG, a city of southeastern Mississippi, U.S.. and the seat of Forrest county, is located on the Leaf and Bowie rivers. 65 mi. from the Gulf of Mexico and about 85 mi. S.E. of Jackson. The town was founded in 1881 by Capt. William Harris Hardy. Confederate soldier, statesman and engineer, and named for his wife. It was incorporated in 1884. Early settlers were attracted to the area by the large acreage of virgin pine timberland n-hich constituted the major source of wealth for many years. Adequately served by an excellent system of highways and railways, and also by a trade area consisting of ten surrounding counties. Hattiesburg is referred to locally as the "Hub of South Mississippi." Industrial plants produce timber products and building materials and a variety of other items. including metal goods, clothing, fertilizers, mattresses. food products, naval stores and boilers.

Hattiesburg is known for its medical and recreational facilities. as well as for its culture and hospitality. It is the seat of Mississippi Southern college (1910), a state institution; and William Carey college (1906), owned and operated by the Mississippi Baptist convention. Camp Shelby. a U.S. army training centre. is nearby. For comparatix-e population figures *see* table in MISSISSIPPI: *Population.* (J. T. D.)

HATTO I (850?–913), archbishop of Mainz, belonged to a Swabian family. and was probably educated at the monastery of Reichenau. of n-hich he became abhot in 888. The German king Arnulf appointed him archbishop of Mainz in 891. He presided

over the synod of Tribur in 895. accompanied the king to Italy in 854 and 895, and in 899, when Arnulf died, became regent of Germany, and guardian of the young king, Louis the Child. He compelled Zwentibold, king of Lorraine, an illegitimate son of Arnulf, to recognize Louis. In 896 he secured for himself the abbey of Ellwangen and in 898 that of Lorsch. He assisted the Franconian family of the Conradines in its feud with the Babenbergs, and was accused of betraying Adalbert, count of Babenberg, to death. He retained his influence during the whole of the reign of Louis, and on the king's death in 911 helped to secure the election of Conrad; duke of Franconia, to the vacant throne. When trouble arose between Conrad and Henry. duke of Saxony, afterward King Henry the Fowler. the attitude of Conrad was ascribed by the Saxons to the influence of Hatto, who wished to prevent Henry from securing authority in Thuringia, where the see of Mainz had extensive possessions. He was accused of complicity in a plot to murder Duke Henry. who in turn ravaged the archiepiscopal lands in Saxony and Thuringia. He died on May 1j, 913. Stories of cruelty and treachery gathered round his name.

HATTON, SIR CHRISTOPHER (1540–1591), lord chancellor of England, was a son of William Hatton of Holdenby, Northamptonshire. He was educated at St. Mary hall. Oxford; admitted to the Inner Temple in May 1560; and enrolled as one of the queen's gentleman pensioners in 1564. A handsome and accomplished man and a good dancer, he soon became a prime favourite of Elizabeth I. In 1572 he was made captain of her bodyguard; in Nov. 1577 vice-chamberlain of her household and a privy councillor; and in December of the same year a knight. Regularly elected to parliament from 1571, he soon became a leading government spokesman in the house of commons. In foreign affairs he sided with the earl of Leicester and Sir Francis Walsingham rather than with the more cautious Lord Burghley. He was a promoter of Sir Francis Drake's great voyage (1577–80), and Drake renamed his flagship "Golden Hind" in honour of Hatton, whose cognizance was "a hind statant Or." At this time Hatton though not himself in favour of the queen's proposed marriage to Francis, duke of Alençon, was active in the prosecution of the Puritan John Stubbe for printing a violent pamphlet against it. Later he took a prominent part in the examinations of various Catholic plotters. notably William Parry (1585) and Anthony Babington(1586). He was a commissioner lor the trial of Mary, queen of Scots, at Fotheringay and afterward advised William Davison (*q.v.*) to dispatch the warrant for her execution. He strongly supported archbishop John Whitgift's efforts to discipline the Puritans, and this may well explain his appointment as lord chancellor in 1587. He lacked any great knowledge of the law, but seems to have been a sensible and businesslike chancellor. In 1588 he was made knight of the garter and chancellor of Oxford university. He died in London on Nov. 20, 1591, and was buried in St. Paul's cathedral. His name is perpetuated in Hatton garden, part of Ely place. Holborn. of which Elizabeth forced the bishop of Ely to grant him the virtual freehold. Hatton also built the magnificent Holdenby (or Holmby) house in Northamptonshire. He wrote the fourth act of a tragedy. *Tancred and Gismund*, and was a patron of men of letters such as Thomas Churchyard. John Dee and Barnaby Rich. Edmund Spenser addressed a sonnet to him. and William Byrd a musical work, and his death occasioned several panegyrics in both prose and verse.

See E. St. J. Rrooks, *Sir Christopher Hatton* (London, 1946); Sir N. H. Nicholas, *Life aad Times of Sir C. Hatton* (London, 1847).

(R. B. WM.)

HATTON, JOHN LIPTROT (1809–1886), English musical composer, was born at Liverpool on Oct. 12, 1809. He was virtually a self-taught musician, and found his way to London as a member of Macready's company at Drury Lane in 1832. Ten years after this he was appointed conductor at the same theatre for a series of English operas, and in 1843 his own first operetta, *Queen of the Thames*, was given with success. He had a successful career in Austria and the United States, and from about 1853 was engaged at the Princess's theatre to provide and conduct the music for Charles Kean's Shakespearean revivals. Hatton excelled in the lyrical forms of music, and won popularity by such songs as "To Anthea," "Good-bye, Sweetheart," and "Simon the Cellarer," the first of which may be called a classic in its own way. He died at Margate on Sept. 20, 1886.

HATZFELDT, MELCHIOR (1593–1658), **COUNT OF GLEICHEN** and Imperialist general, was born on Oct. 10, 1593 at Krottorf, Hesse. He served with the Imperialist army in the Thirty Years' War, was defeated by the Swedes, led by Bauer, at Wittstock (1636), and in the following year assisted at the relief of Leipzig. From 1639 to 1643 he led the campaigns in Restphalia and the Rhine lands. In 1644 he raised a new army in Bohemia; but in 1645, owing to his defeat at the battle of Jankau, in which he was made prisoner by Torstensson, he was succeeded in his command by Gallas. He retired in 1646. The war in Poland in 1657 brought him from his retirement. He led an army of 16,000 men to the help of the king of Poland against the Swedes, and captured Cracow. He then advanced against Thorn, but his health failed, and he surrendered the command to Montecucculi. He died on Jan. g, 1658 at Powitzka, near Traehenberg.

See J. Krebs, *Aus dem Leben des kaiserl. Feldmarschalls Grafen Melchior von Hatzfeldt* (1910).

HATZIDAKIS (CHATZIDAKIS), GEORGE N. (1848–1941), the first and greatest linguist of modern Greece, who was eminent in studies of ancient, medieval and modern Greek. and the initiator of the *Historical Lexicon of the Greek Langztage*, was born at Myrthio. Crete. on Nov 12, 1848. After his classical studies in Athens (1873–77), he devoted himself to comparative linguistics in Germany (1877-81). He obtained his Ph D. degree in Athens (1883) and taught linguistics there (1885-1923) and in Salonica (1926–28). Hatzidakis was among the first members of the Academy of Athens (1926). and an honorary member of five other European academies. Between 1881 and 1935 he wrote 9 books and nearly 600 other works, mostly on medieval and modern Greek, especially on the origin of its dialects from the *Koinē* (except *Tsakonian*). Adhering to the idea of Greek bilingualism, however. he failed to sense the rise of the new common Greek language even in Athens from *c* 1835; he supported the lost cause of the puristic language *(kathareuousa)* against the popular language as a literary and educational vehicle Among his norks are: *Einleitung in die nezrgriechisclze Grammatik* (1892) and *Medieval and Modern Greek* (1905–7), both aggregates of previously published articles. He died in Athens on June 26, 1941.

See *Orbis:* 4,574–576 (1955). (D J. G.)

HAUCH, JOHANNES CARSTEN (1790–1872), Danish poet, dramatist and novelist, whose works expressed his high moral seriousness and tragic philosophy, was born in Frederikshald. Norway, on May 12. 1790. As a student, he was strongly attracted by romanticism; but after early and unsuccessful literary attempts he turned to natural sciences, particularly zoology. He took his doctorate in 1821and then studied in Paris and Italy. In 1825 he had a foot amputated and shortly afterward attempted suicide. He emerged from the spiritual crisis which followed with a renewed desire to write. On his return to Denmark. he was successively lecturer in natural sciences at Soro, professor of Scandinavian literature at Kiel (1846–48) and. following his friend Adam Oehlenschlager. professor of aesthetics at Copenhagen from 1851 until his death in Rome on March 4, 1872.

Hauch was by nature gloomy and brooding, but also of exceptional rectitude and nobility: his works have a tragic quality and express high moral ideals and a belief in universal justice. As a dramatist he modeled himself upon Shakespeare and Oehlenschlager and wrote a number of historical tragedies about men of destiny: *Bajazet, Tiberius* and *Gregor den Syvende* (Pope Gregory 1-11) (all 1828); and great Danish figures: *Svend Grathe* (1841) and *Marsk Stig* (1850). Later, his historical novels exerted donsiderable influence. they include *Vilhelm Zabern* (1834); *Guldmageren* ("The Alchemist." 1836), *En polsk Familie* (1835) and *Robert Fulton* (1853). But his greatest success was as a poet, particularly as a writer of odes. One of his most important poetic works was the ballad-cycle *Valdemar Atterdag* (1861).

Hauch's collected poems were published, 2 vol. (1891); his collected novels, 7 vol. (1873–74); his plays, 3 vol. (1852–59); his essays and reflections upon aesthetics, 3 vol. (1855–69). *See* also G. Brandes, "Car-

sten Hauch," in Brandes' *Samlede Skrifter,* vol. i (1899); K. Ronning, J. C. *Hauch* (1890). (*S. M* K)

HAUCK, ALBERT (1845–1918), German theologian, was born at Hassertrudingen, M.-Franken, on Dec. 9, 1845, and studied at the universities of Erlangen and of Berlin. He took orders, and from 1875–8 was pastor at Frankenheim. Hauck was professor of theology at Erlangen (1882–89), and at Leipzig (1889–98), and then for a year rector of the university. He died on April 7, 1918. His most important work is *Kirchengeschichte Deutschlands* (j vols. 1887–1911; 5th ed 1920). He edited the 3rd edition of the *Realencyclopadie* of Protestant theology (24 vols. 1896–1913).

HAUER, FRANZ, RITTER VON (182 2–1899), Austrian geologist, born in Vienna on Jan. 30, 1822, was son of Joseph von Hauer (1778–1863), who was equally distinguished as a high Austrian official and authority on finance and as a palaeontologist. In 1886 Franz Hauer became superintendent of the imperial natural history museum in Vienna. Among his special geological works are those on the Cephalopoda of the Triassic and Jurassic formations of Alpine regions (1855–1856). His most important general work was that of the *Geological Map of Austro-Hungary,* in twelve sheets (186 7–1871; 4th ed , 1884, including Bosnia and Montenegro). He died on March 20, 1899.

PUBLICATIONS.—*Beiträge zur Paläontolographie von Österreich* (1858–59); *Die Geologie und ihre Anwendung auf die Kenntnis der Bodenbeschaffenheit drr österr.-ungar. Monarchie* (1875; ed. 2, 1878). See *Memoir* by Dr. *E.* Tietze; *Jahrbuch der* K. *K. geolog. Reichsanstalt* (1899, reprinted 1900, with portrait).

HAUFF, WILHELM (1802–1827), German poet and novelist, was born at Stuttgart on Nov. 29, 1802, and educated at the Klosterschule at Blaubeuren, and the university of Tubingen. For the children of the Wiirttemberg minister of war, von Hügel, to whom he acted as tutor, he wrote his *Märchen,* which he published in his *Märchenalmanach auf das Jahr 1826.* To the same period belong his *Mitteilungen aus den Memoiren des Satan* (1826) and *Der Mann im Monde* (1825). The latter, a parody of the novels of H. Clauren (pseudonym of K. G. S. Heun) was published under Clauren's name, and Hauff was mulcted in damages. Nevertheless he went on to write a *Kontroverspredigt über* H. *Clauren und den Mann im Monde* (1826). His historical romance *Lichtenstein* (1826), treating of the reign of duke Ulrich of Swabia, was one of the early imitations of Walter Scott. His other works include the charming *Bettlerin vom Pont des Arts; Phantasien im Bremer Ratskeller* (1827); and some short poems which have passed into *Volkslieder,* among them *Morgenrot, Morgenrot, leuchtest mir zum frühen Tod;* and *Steh' ich in finstrer Mitternacht.* Hauff died prematurely on Nov. 18, 1827. The freshness and originality of Hauff's talent, his inventiveness and his genial humour have made him a minor classic.

See his *Samtliche Werke,* ed. *G.* Schwab (3 vols., 1830-34; 5 vols., 18th ed, 1882); ed. F. Bobertag (1891–97); and a selection by M. Mendheim (3 vols., 1891). These and later editions contain biographical material.

HAUG, MARTIN (1827–1876), German orientalist, was born at Ostdorf near Balingen, Wiirttemberg, on Jan. 30, 1827. He studied oriental languages, especially Sanskrit, at Tübingen and Gottingen, and in 1854 settled as *Privatdozent* at Bonn. In 1856 he removed to Heidelberg, where he assisted Bunsen in his literary work; and in 1859 he went out to India, where he became superintendent of Sanskrit studies and professor of Sanskrit in Poona. The result of his researches into Zend literature was a volume of *Essays on the sacred language, writings and religion of the Parsees* (Bombay, 1862). Having returned to Stuttgart in 1866, he was called to Munich as professor of Sanskrit and comparative philology in 1868. He died on June 3, 1876.

HAUGE, HANS NIELSEN (1771–1824), Norwegian preacher, was born in the parish of Thuno, Norway, on April 3, 1771, the son of a peasant. In his twenty-sixth year, believing himself to be divinely commissioned, he began to preach, calling people to repentance and attacking rationalism. In 1804 he was arrested, and only released from prison in 1814. He died at Breddwill, near Christiania, on March 29, 1824. His pietistic adherents, who did not formally break with the church, but placed great stress on the evangelical doctrines of faith and grace, were called *Haugianer* or *Leser* (*i.e.,* Readers).

See C. Bang, *Hans Nielsen Hauge og hans Samtid* (Christiania; 2nd ed., 1875); O. Rost, *Nogle Bemaerkninger om Hans Nielsen Hauge og hans Retning* (1883).

HAUGESUND, a seaport of Norway in Rogaland *fylke* (county), on the west coast, 34 mi. N. by W. of Stavanger. Pop. (1950) 18,747. It is an important fishing centre, particularly for herrings which form the chief export. Macketel and lobsters are also important. The principal imports are coal and salt. There are factories for woollen goods and margarine, and a small shipbuilding industry. The town is difficult of access by land. Haugesund is the reputed death-place of Harald Haarfager, to whom an obelisk of red'granite was erected in 1872 on the thousandth anniversary of his victory at the Hafsfjord (near Stavanger) whereby he won the sovereignty of Norway. The memorial stands 1¼ mi. N. of the town, on the Haraldshaug.

HAUGHTON, WILLIAM (c. 1575–1605), English playwright whom Henslowe's *Diary* shows to have collaborated in plays for the Admiral's company from 1597 to 1602. Philip Henslowe first mentions "yonge Horton" on Nov. 5, 1597, and on March 10, 1600. he lent him ten shillings "to release him out of the Clink." With Thomas Dekker and Henry Chettle, Haughton wrote *The Pleasant Comodie of Patient Grissill* (1603), and he collaborated with many other playwrights including John Day and Richard Hathway. *English-Men For my Money* (1616) is ascribed to his sole authorship.

For a list of Haughton's lost and doubtful plays, *see* E. K. Chambers, *The Elizabethan Stage,* vol. iii (1923). *See* also *English-Men For my Money,* ed. by *A.* C. Baugh (1917); W. J. Lawrence, "Englishmen for my Money," *Review of English Studies, I* (1925).

HAUGWITZ, CHRISTIAN AUGUST HEINRICH KURT, COUNT VON, FRCIHERR VON KRAPPITZ (1752–1832), Prussian statesman, was born on June 11, 1752, at Peucke near Öls. In 1791 he was elected by the Silesian estates general director of the province. At the invitation of Frederick William II. he entered the Prussian service, became ambassador at Vienna in 1792 and a member of the cabinet at Berlin.

Haugwitz, who had attended the young emperor Francis II. at his coronation and been present at the conferences held at Mainz to consider the attitude of the German powers towards the Revolution, was at first opposed to intervention in France, but eventually entered on the negotiations for the subsidy treaty between Great Britain and Prussia, and Great Britain and Holland, signed at The Hague on April 19, 1794. Haugwitz, however, was not the man to direct a strong and aggressive policy; and in October the denunciation by Great Britain of The Hague treaty broke the last tie that bound Prussia to the Coalition. The separate treaty with France, signed at Basle on April 5, 1795, was mainly due to the influence of Haugwitz.

No guarantee of the retention of the Rhine provinces of the Empire had been inserted in the Basle treaty; but Haugwitz and the king hoped to preserve them by establishing the armed neutrality of North Germany and securing its recognition by the French republic. This policy was rendered futile by the victories of Napoleon Bonaparte and the virtual conquest of South Germany by the French. Haugwitz recognized this fact, and in vain urged Frederick William III. to join the new Coalition in 1798. When the king refused his urgent advice to demand the evacuation of Hanover by the French in 1803, he offered to resign, and in Aug. 1804 he was replaced by Hardenberg. In his retirement Haugwitz was still consulted, and used his influence against Hardenberg's policy of a *rapprochement* with France. He was recalled, as Hardenberg's colleague in the foreign office, in 1805. He pursued a vacillating policy, and was definitely worsted by Napoleon. The ultimatum he was to have conveyed to the French emperor was never delivered. Instead he signed the treaties of Schonbrunn (Dec. 15, 1805) and Paris (Feb. 15, 1806), which gave Hanover to Prussia in return for Ansbach, Cleves and Neuchbtel. The Prussian ultimatum to Napoleon was eventually forced upon him, and with the battle of Jena (Oct. 14), his political career came to an end.

The last eleven years of his life were spent in Italy, and he died in Venice on Feb. 9, 1832. During his retirement in Italy he wrote memoirs in justification of his policy, a fragment of which dealing with the episode of the treaty of Schonbrunn was published at Jena in 1837.

See L. von Ranke, *Hardenberg u. d. Gesch. des preuss. Staates* (Leipzig, 1879–81), note on Haugwitz's memoirs in vol. ii.; *Denkwürdigkeiten des Staatskanzlers Fürsten von Hardenberg,* ed. Ranke (5 vols., Leipzig, 1877).

HAUPT, MORITZ (1808–1874), German philologist, was born at Zittau, in Lusatia, on July 27, 1808. On the close of his university course at Leipzig (1830) he studied Greek, Latin, German, Old French, Provençal and Bohemian. In Sept. 1837 he "habilitated" at Leipzig as *Privatdozent,* and his first lectures, dealing with such diverse subjects as Catullus and the *Nibelungenlied,* indicated the twofold direction of his labours. He became professor extraordinarius (1841) and then professor ordinarius (1843) of German language and literature. But, having taken part in 1849 with Otto Jahn and Theodor Mommsen in a political agitation for the maintenance of the imperial constitution, Haupt was deprived of his professorship by a decree of April 22, 1851. Two years later, however, he was called to succeed his friend Lachmann at Berlin, and became a member of the Berlin academy. He died on Feb. 5, 1874.

Haupt edited texts of Ovid, Catullus, Tibullus, Propertius, Horace and Virgil. As early as 1836, with Hoffmann von Fallersleben, he started the *Altdeutsche Blatter,* which in 1841 gave place to the *Zeitschrift für deutsches Altertum,* of which he continued editor till his death. Hartmann von Aue's *Erec* (1839) and his *Lieder, Buchlein* and *Der arme Heinrich* (1842), Rudolf von Ems's *Guter Gerhard* (1840) and Conrad von Würzburg's *Engelhard* (1844) are the principal German works which he edited. Three volumes of his *Opuscula* were published at Leipzig (1875–77).

See Kirchhoff, "Gedächtnisrede," in *Abhandl. der Königl. Akad. der Wissenschaften zu Berlin* (1875); Otto Belger, *Moritz Haupt als Lehrer* (1879); Sandys, *Hist. Class. Sclzol.* iii. (1908).

HAUPTMANN, GERHART (1862–1946), German author, was born in Obersalzbrunn, Silesia, on Nov. 15, 1862, the son of an innkeeper. He was educated locally and in Breslau, and was at first intended for a farmer. His instincts were, however, always artistic. In 1880–81 he spent two years at the Breslau school of art, followed by a year's study at Jena university. He then travelled in France, Spain and Italy and in 1884 established himself in Rome as a sculptor. Obliged by reasons of health to return to Germany. he lived in Dresden, Berlin (where he had thoughts of going on the stage) and Erkner, near Berlin, later settling at Schreiberhau, Silesia. He died June 8, 1946.

A man of great versatility and exceptionally wide artistic sympathies, Hauptmann hesitated long before choosing literature as his means of expression. His earliest work was *Promethidenlos* (1885). In 1889 he began the series of dramas which set him at a bound at the head of the German dramatic writers of his time. Hauptmann's first drama, *Vor Sonnenaufgang* (1889), appeared at a moment when the cultivated German public read nothing but Scandinavian, French and Russian authors, and German writers, to gain a hearing, were obliged to adopt foreign pseudonyms. Hauptmann's genius forced German attention back to its native authors. He was at heart always rather a romanticist than a naturalist, but circumstances forced him to begin as a naturalist. *Vor Sonnenaufgang* aroused a storm of criticism similar to that encountered by Ibsen and Strindberg, by whose side he took his place. He persevered, however, with a series of dramas depicting the life of the working classes or the poverty-stricken middle classes until, by 1910, German naturalism was fully established. These naturalist dramas include *Einsanze Menschen* (1891), *Fuhrmann Henschel* (1898), *Gabriel Schillings Flucht* (1912), and most notably *Die Weber* (1892), a social drama on the grand scale, representing the rise, outbreak, development and failure of a miniature revolution, and perhaps Hauptmann's greatest work. These dramas had created the type of German naturalism; but in Hauptmann exact and conscientious observation was mellowed by his great sensibility and feeling for beauty and genuine poetic gift. His romantic tendencies found play as early as 1892 in the somewhat fantastic *Hanneles Himmelfahrt,* while *Die Versunkene Glocke* (1896) and *Und Pippa Tanzt* (1906) are fairy pieces in a rather vague symbolic style. Hauptmann's insight, intellectual honesty and earnest purpose maintained him in the position which he had won as the foremost and most representative German writer. His later plays, however, the best of which was perhaps *Der Weisse Heiland* (1919), met with less appreciation than his earlier work. The subjective vision which now permeated his work perhaps hardly replaced his earlier peculiar gift for reproducing the life of others. Hauptmann's narrative work is less famous than his dramatic, but he produced two stories almost perfect in form and content: *Der Narr in Christo Emanuel Quint* (1910) and *Der Ketzer von Soana* (1918), as well as one of the most famous of German novels in *Atlantis* (1912). Hauptmann's verse, though dignified and sincere, lacks warmth.

See C. Holl, *Gerhart Hauptmann,* etc. (1913); W. Bonsels, *Das junge Deutschland und der grosse Krieg, aus Anlass des Briefwechsels Romain Rollands mit G. Hauptmann uber den Krieg und die Kultur* (1914); A. Esprey, *G. Hauptmann und wir Deutschen* (1916); J. H. Marschan, *Das Mitleid bei G. Hauptmann,* bib. (1919); Paul Fechter, *Gerlzart Hauptmann* (1922); P. Schlenther, G. *Hauptmann* (1922).

HAUPTMANN, MORITZ (1792–1868), German musical composer and writer, was born at Dresden, on Oct. 13, 1792, and studied music under Scholz, Lanska, Grosse and Morlacchi, the rival of Weber. Afterwards he completed his education as a violinist and composer under Spohr, and till 1820 held various appointments in private families, varying his musical occupations with mathematical and other studies bearing chiefly on acoustics and kindred subjects. For a time also Hauptmann was employed as an architect, but all other pursuits gave place to music, and a tragic grand opera, *Mathilde,* dates from 1826. In 1822 he entered the orchestra of Cassel, again under Spohr's direction, and taught composition and musical theory to Ferdinand David, Burgmuller, Kiel and others. His compositions at this time chiefly consisted of motets, masses, cantatas and songs. In 1842 Hauptmann became cantor at the Thomas-school of Leipzig where one of his predecessors had been J. S. Bach, and professor at the conservatoire. Here his unique gift as a teacher developed, and was acknowledged by a crowd of enthusiastic pupils, among whom were Joachim, von Biilow, Sullivan and Cowen. He was, as already indicated, a mathematician and a philosopher as well as a musician, and brought his studies in philosophy to bear on music. His most important publication was *Die Natur der Harmonik und Metrik* (1853, Eng. trans. *The Nature of Harmony and Metric,* 1888), a standard work. He died on Jan. 3, 1868.

Amongst his vocal compositions — by far the most important portion of his work — may be mentioned two masses, choral songs for mixed voices (*Op.* 32, 47), and numerous part songs, which remain in the repertory of most German choirs.

See a selection from the two German volumes of his letters to Hauser, Spohr and others, *Letters of a Leipzig Cantor* (1892).

HAUREAU (JEAN), BARTHELEMY (1812–1896), French historian, was born in Paris. He was a deputy to the National Assembly of 1848; contact with the revolution gradually cooled his old ardour. He became director of the ms. department of the Bibliothbque Nationale but resigned after the *coup d'état* of 1851, and refused to accept any administrative post until after the fall of the empire. He was director of the national printing press from 1870 to 1881, and in 1893 became director of the Fondation Thiers. He died on April 29, 1896.

Hauréau devoted his life to the religious, philosophical and more particularly the literary history of the middle ages. From the time of his appointment to the Bibliothèque Nationale up to the last days of his life he made abstracts of all the mediaeval Latin writings (many anonymous or of doubtful attribution) relating to philosophy, theology, grammar, canon law and poetry, carefully noting on cards the first words of each passage. After his death this index of *incipits,* arranged alphabetically, was pre-

sented to the Académie des Inscriptions, and a copy was placed in the ms. department of the Bibliothèque Nationale.

See notice by Paul Meyer prefixed to vol. xxxiii. of the *Histoire littéraire de la France.*

HAUSA, a Negro people found chiefly in northern Nigeria and the region immediately to the north in French West Africa. They number approximately 5,537,000 and constitute the single most numerous ethnic group in northern Nigeria. The Hausa have a sense of ethnic unity based on common language, similarity of customs and a tradition of common origin. According to a widely known legend, a man named Bayajida, having fled from Baghdad, his place of origin, arrived ultimately in Daura, at present a minor Hausa kingdom in the north. There. as a reward for his valour in killing a snake in the town well which was terrorizing the local population, he married the queen. His son. Bawo, is the reputed progenito'r of six sons who founded the Hausa states of Gobir, Katsina. Kano, Zaria, Biram and Rano, which, together with Daura itself, form the original seven Hausa states. In addition, the states of Zanfara, Kebbi. Nupe, Gwari. Yauri, Bauchi and Kororofa are traditionally called the "illegitimate seven," since they arose out of the assimilation of populations of non-Hausa origin. A reckoning based on the Kano Chronicle, a main source of indigenous history, would place the beginning of the rule of Bagauda, the first king of Kano and the grandson of Bayajida, in A.D. 999.

The early rulers of the Hausa states were pagans. Islam was introduced in the latter part of the 14th century by a delegation of learned hioslems from the Negro kingdom of Mali, at the bend of the Niger in the Sudanese Republic. It gradually spread among the Hausa, profoundly influencing their traditional beliefs and customs. A small minority of pagan Hausa, generally called Maguzawa. persists in some rural areas.

With the destruction of the vast Songhai empire with its capital at Timbuktu at the end of the 16th century, the important trans-Saharan caravan trade largely moved eastward to the Hausa cities of Katsina and Kano, which became flourishing centres of trade and Moslem culture.

Fulani and British Rule.—At the beginning of the 19th century the Fulani (*q.v.*), a largely pastoral people, originally from Senegal. who had settled in considerable numbers in Hausa country and were thoroughly Islamic, waged a holy war against the native Hausa rulers who mere accused of religious laxity. Under the leadership of Usuman dan Fodio, the Fulani succeeded in conquering virtually all of the Hausa states and establishing an empire with its capital at Sokoto. After the death of the founder. the empire was divided and administered from two theoretically equal centres, Sokoto for the east and Gwando for the west. The individual states under their emirs, however, retained considerable autonomy, conducting independent wars and slave expeditions and even engaging in internecine warfare. The Fulani empire was on the verge of dissolution at the time of the advent of the British under the leadership of Lord Lugard in 1907. Under British administration the Fulani continued as the ruling class. The policy of indirect rule, by which indigenous political forms were as far as possible preserved and adapted to modern conditions, was first formulated by Lord Lugard in northern Nigeria as the result of his contact with the highly organized Hausa emirates and subsequently applied in other British territories in Africa. Slave-raiding and the legal status of slavery were abolished under British rule.

Political and Economic Organization.— In the pre-British period, the Hausa states were organized on a feudal basis, the emir being surrounded by a number of titled officeholders who held as fiefs various villages from which their agents collected taxes. In addition to the Fulani nobility and the free Hausa farmers and artisans there were large numbers of slaves obtained in warfare and slave-trading, some of whom were individually owned, in which case they were treated as members of the household. Others worked on the estates of the officeholders or of the king. A few royal slaves held important positions of authority. The children of those born in slavery held a special position and might not be sold.

The economy rested on the intensive cultivation of sorghum, maize, millet and other food plants. The principles of crop rotation and mixed farming based on the use of manure from the Fulani cattle were utilized; the plow was unknown. The existence of part-time specialists in leather, metalwork, weaving, dyeing and other crafts, professional traders, the use of cowrie shell currency and permanent markets in the larger cities, all testified to the vigour of the Hausa economy.

The chief political and commercial centres were large walled cities with mud-brick architecture, whose style and construction mere probably borrowed from the Negro Moslem centres of the Niger bend and ultimately from North Africa.

Language and Literature.— The Hausa language belongs to the Chad group of Hamito-Semitic languages (see AFRICAN LANGUAGES). As a result of Islamic influence, numerous Arabic words have been borrowed, particularly in the spheres of religion and technology. The number of people who speak Hausa as a second language is difficult to estimate, but is considerable, and the language has become the general lingua franca in northern Nigeria, where it enjoys official status. Many Fulani speak it as a mother tongue.

Hausa is traditionally written in an orthography based on the Arabic alphabet, and an indigenous literature both in poetry and prose exists. The poetry employs quantitative metres of Arabic origin. The Moslem literati, however, more often use Arabic in their nritings, which thus holds a position analogous to that of Latin in Europe in the middle ages. After the establishment of the British protectorate, an orthography based on the Latin alphabet came into widespread use and by the middle of the 20th century appeared likely to displace the older system. The standard literary dialect nas that of the important commercial centre of Kano, the largest Hausa city. Dialect differences were considerable, that of Sokoto and the northwest being, in general, the most divergent from the standard form. These differences, however. were not sufficiently serious to interfere with mutual intelligibility.

(J. G.)

HAUSER, KASPAR (*c.* 1812–1833), a German youth whose origin is surrounded with mystery. The first record of him is in May 1828, when he appeared in h'iirnberg, dressed as a peasant, and with a helpless and bewildered air that attracted attention. In his possession was found a letter purporting to be nritten by a labourer, stating that the boy was given into his custody on Oct. 7, 1812, and that according to agreement he had instructed him in reading, writing and the Christian religion, but had kept him in close confinement. With this letter was enclosed another purporting to be written by the boy's mother, stating that he was born on April 30, 1812, that his name was Kaspar, and that his father, an ex-cavalry officer in the 6th regiment at h'iirnberg, was dead. For some time the lad was detained at Nurnberg as a vagrant; Daumer then undertook his guardianship and the charge of his education. Earl Stanhope became interested in his history, and sent him in 1832 to Ansbach to be educated. He became clerk in the office of Feuerbach, president of the court of appeal; and his strange history was almost forgotten when interest in it was revived by his death as the result of a wound received on Dec. 14, 1833. Whether the wound was self-inflicted or whether, as he alleged, it was dealt by a stranger, is unknown. Kaspar Hauser's story has been used by Jakob Wassermann in a novel (1908) and by Kurt Martens in a play (1904).

The theory of Daumer and Feuerbach and other pamphleteers (see E. E. Evans, *Story of Kaspar Hauser From* Authentic Rec*ords,* 1892) mas that the youth was the crown prince of Baden, the legitimate son of the grand duke Charles of Baden, and that he had been kidnapped at Karlsruhe in Oct. 1812 by emissaries of the countess of Hochberg (morganatic wife of the grand duke) in order to secure the succession to her offspring; but this theory was ansnered in 1875 by the publication in the Augsburg *Allgemeine Zeitung* of the official record of the baptism, post-mortem

examination and burial of the heir supposed to have been kidnapped. See *Kaspar Hauser und sein badisclzes Prinzentum* (1876). The evidence was analyzed by Andrew Lang in his *Historical Mysteries* (1904), with results unfavourable to the "romantic" version of the story. Lang's view was that possibly Kaspar was a sort of "ambulatory automatist," an instance of a phenomenon, known by other cases to students of psychical abnormalities, of which the characteristics are a mania for straying away and the persistence of delusions as to identity; but he inclines to regard Kaspar as simply a "humbug." The "authentic records" purporting to confirm the kidnapping story Lang stigmatizes as "worthless and impudent rubbish."

HAUSHOFER, KARL (1869–1946), German political geographer and popularizer of geopolitics (*q.v.*), a theory of organic national development, was born in Munich on Aug. 27, 1869. The son of a professor at the University of Munich, he followed a military career until the end of World War I, attaining the rank of general. He acquired his first taste of the world-wide problems of political geography during an extended stay in Japan (1908–10). He was fascinated by Japan's expansionist ambition to become the leading power of Asia, and several of his books, including his most ambitious study in political geography, *Geopolitik des Pazifischen Ozeans* (1924), dealt with the role of Japan in 20th-century politics. In 1924 Haushofer founded the *Zeitschrift für Geopolitik,* which greatly influenced the new elite of Germany in the 1920s and '30s, augmented by Haushofer's teachings at the Institute of Geopolitics which he directed at the University of Munich. Compounded of sound observations and hazy theories, Haushofer's concept of the dominant role of the vast spaces was based upon Friedrich Ratzel's theories of space and nation and Rudolf Kjellén's conception of the state as a biological organism; his vision of the future role of Russia led him to adopt wholeheartedly the "heartland" idea of Sir Halford J. Mackinder (*q.v.*).

Haushofer's influence was considerable in military circles, but his impact upon the Nazi leadership was probably less significant than was assumed during World War II when the German pseudo science of geopolitics was identified in the United States with the Nazi doctrine of world domination. During the war Haushofer continued his efforts to justify the drives of Germany and Japan for world power, although his cultural background and his marriage to a woman of Jewish extraction must have made this task increasingly distasteful to him. When, after Germany's collapse, he was investigated as an alleged war criminal, he and his wife ended their lives, March 13, 1946.

His son Xlbrecht, who held a chair in geopolitics in the University of Berlin, had been executed as a resistance fighter against the Hitler regime. (H. W. WT.)

HAUSSER, LUDWIG (1818–1867), German historian, who played an active part in the movement for German unity, was born at Kleebourg, Alsace, on Oct. 26, 1818. He became professor in Heidelberg in 1850 and was a member of the Baden parliament. A moderate liberal, he was a passionate supporter of Prussia's leadership and opposed the inclusion of Austria in the German confederation. Hausser was a founder of the newspapers *Deutsche Zeitung* (1847) and of the *Süddeutsche Zeitung* (1862) and won the enthusiasm of many students for German unification. His chief work is *Dezctsche Gesclziclzte vom Tode Friedrichs der Grosse bis zur Gründung des deutschen Bundes* (4 vol., 1854–57). He died at Heidelberg on March 19, 1867.

See E. Marcks, *Ludwig Hausser und die politische Geschichtsschreibung in Heidelberg* (1903).

HAUSSMANN, GEQRGES EUGENE, BARON (1809–1891), French financier: whose name is associated with the rebuilding of Paris, was born in that city on March 27, 1809. of a Protestant family, German in origin. He mas educated at the Collhge Henri IV, and subsequently studied law, attending simultaneously the classes at the Paris conservatoire of music, for he was a good musician. He became *sous-préfet* of Nérac in 1830. and advanced rapidly in the civil service until in 1853 he was chosen by Persigny prefect of the Seine in succession to Jean Jacques Berger. who hesitated to incur the vast expenses of the imperial schemes for the embellishment of Paris.

Haussmann laid out the Bois de Boulogne, and made extensive improvements in the smaller parks. The gardens of the Luxembourg palace were cut down to allow of the formation of new streets, and the Boulevard de Sebastopol, the southern half of which is now the Boulevard St. Michel, was driven through a populous district. A new water supply, a gigantic system of seners, new bridges. the opera and other public buildings, the inclusion of outlying districts — these were among the new prefect's achievements, accomplished by the aid of a bold handling of the public funds which called forth Jules Ferry's indictment, *Les Comptes fantastiques de Haussmann,* in 1867. A loan of 250 million francs was sanctioned for the city of Paris in 1865, and another of 260 million in 1869. These sums represented only part of his financial schemes, which led to his dismissal by the government of Émile Ollivier. After the fall of the Empire he spent about a year abroad, but he re-entered public life in 1877, when he became Bonapartist deputy for Ajaccio.

Haussmann died in Paris on Jan. 11, 1891. He had been made senator in 1857, member of the Academy of Fine Arts in 1867, and grand cross of the Legion of Honour in 1862. His name is preserved in the Boulevard Haussmann. His later years were occupied with the preparation of his *Mémoires* (3 vol., 1890–1893). *See* also PARIS.

HAUSSONVILLE, JOSEPH OTHENIN BERNARD DE CLERON, COMTE D' (1809–1884), French politician and historian, was born in Paris on May 27, 1809. the son of Charles Louis Bernard de Cléron, comte d'Haussonville (1770–1846), chamberlain at the court of Napoleon. After holding various diplomatic posts, he was elected to the chamber of deputies in 1842, and became a life senator in 1878. In the senate he defended the religious associations against the anticlericals. He died in Paris on May 28, 1884.

His wife, Louise (1818–82), daughter of Duc Victor de Broglie, published *Robert Emmett* (1858) and other books.

His son GABRIEL PAUL OTHENIN DE CLÉRON was born at Gurcy-le-Châtel (Seine-et-Marne) on Sept. 21, 1843. In 1891. as representative of the Comte de Paris in France. he tried to strengthen the Orleanist party, but their prospects were dashed in 1894 by the death of the comte de Paris. D'Haussonville died in Paris on Sept. 1, 1924.

His works include: *Etudes biographiques et littéraires* (2 series, 1879 and 1888); *Le Comte de Paris, souvenirs personnels* (1895); *Souvenirs sur [illegible] de Maintenon,* with *G.* Hanotaux, 3 vol. (1903–04); *Ombres françaises et visions anglaises* (1914).

HAUTE-GARONNE, a frontier *département* of southwestern France, formed in 1790 from portions of the provinces of Languedoc (Toulousain and Lauraguais) and Gascony (Comminges and Nébouzan). Pop. (1954) 525,669. Area 2.458 sq.mi. It is bounded north by the *département* of Tarn-et-Garonne. east by Tarn. southeast by Aude and Aribge, south by Spain and west by Gers and Hautes-Pyrénées. Quaternary and Tertiary deposits occupy the centre of the *département.* Toward the south the land rises gradually to the Pyrenees, which on the Spanish border exceed 10,000 ft. Two passes, the Port d'Oô and the Port de Vénasque. exceed 9.800 and 7,900 ft. respectively. The Garonne flows in a northerly direction and receives the Pique, the Salat, the Louge. the Ariège, the Touch and the Save. Except in the mountains the climate is mild, the mean annual temperature being rather higher than at Paris. The rainfall. which averages 24 in. at Toulouse, exceeds 40 in. in the mountains; and sudden inundations of the Garonne cause much damage. Thick forests of oak, fir and pine furnish timber for shipbuilding. Wheat, maize and other grains are the principal crops. and there is generally a surplus for export. Market gardening flourishes around Toulouse. Vineyards are extensive, though the wine is of medium quality; and chestnuts, apples and peaches are grown. Cattle and sheep are reared and co-operative dairies are numerous in the mountains; but deforestation has tended to reduce the area of pastureland, the soil. unretained by tree roots, having been gradually washed away. Haute-Garonne has deposits of zinc and lead. and saltworkings; there is an ancient marbleworking industry at St. Béat. The mineral springs of Bagnhres-de-Luchon, Encausse, Bar-

bazan and Salies-du-Salat are well known. Manufactures include iron and copper goods. woolen, cotton and linen goods, leather, paper. boots and shoes, and tobacco. The main line of the Southern railway from Bordeaux to Cette passes through Toulouse The Canal du Midi traverses the *département* for 32 mi and the lateral canal of the Garonne for 1j mi. The Garonne is navigable below its confluence with the Salat. There are three *arrondissements*—Toulouse, Muret and St. Gaudens—subdivided into 39 cantons and 589 communes. Toulouse is the seat of a court of appeal and of an archbishop, the headquarters of the 17th army corps and the centre of an academy; and St. Gaudens, Bagnères-de-Luchon and St. Bertrand-de-Comminges are important. St. Aventin, Montsaunks and Vénerque possess old churches in the romanesque style. The choir of St. Just at Valcabrkre dates from the 8th or 9th century and part of the nave from the 11th century. There are ruins of a Cistercian abbey at Bonnefont near St. Martory. Gallo-Roman remains have been discovered at Martres. Near Revel is the reservoir of St. Ferréol, constructed for the Canal du Midi in the 17th century.

HAUTE-LOIRE, a *département* of central France. formed in 1790 of Velay and portions of Vivarais and Gkvaudan, three districts formerly belonging to the old province of Languedoc, of a portion of Forez formerly belonging to Lyonnais, and a portion of lower Auvergne. Pop. (1954) 215,57j. Area 1,931 sq.mi. It is bounded north by Puy-de-DBme and Loire, east by Loire and Ardèche, south by Ardèche and Lozkre and west by Lozère and Cantal. Forming a portion of the Plateau Central, it is traversed from north to south by four mountain ranges. Its highest point, the Mont Mézenc (5,755 ft.), in the southeast, belongs to the mountains of Vivarais, nhich are continued along the eastern border by the Boutikres chain. The Lignon divides the Boutikres from the Massif du Mégal, which is separated by the Loire from the mountains of Velay, a granitic range overlaid with volcanic rocks. The Margeride mountains run along the western border. The Loire waters the eastern half of the *département*. The Allier, which joins it at Nevers, traverses the western portion. The chief affluents of the Loire within the *département* are the Borne on the left, joining it near Le Puy, and the Lignon, on the right. The winters are long and rigorous. Rye, oats, barley and wheat are cultivated, and aromatic and medicinal plants are abundant on the plateaus. Lentils. peas, mangel-wurzels and other forage and potatoes are also groan. Horned cattle belong principally to the Mézenc breed; goats are numerous The woods yield pine, fir, oak and beech. Lacemaking and coal mining (around Brassac and Langeac) are main industries. There are also mines of antimony and stone quarries. Silk milling. caoutchouc making, papermaking, glass blowing and wood sawing are also carried on. The principal imports are flour, brandy, wine, livestock. lace-thread and agricultural implements. Exports include fat stock, wool, aromatic plants. coal, lace. The *département* is served chiefly by the Paris-Lyon-Mkditerranee railway. There are three *arrondissements*—Le Puy, Yssingeaux and Brioude—with 29 cantons and 267 communes.

Haute-Loire forms the diocese of Le Puy in the ecclesiastical province of Bourges, and belongs to the academie (educational division) of Clermont-Ferrand. Its court of appeal is at Riom. The churches of Chamalikres. St. Paulien and Sainte-Marie-des-Chazes are romanesque in style; Le Monastier preserves the church, in part romanesque, and the buildings of the abbey to which it owes its origin. Arlempdes and Bouzols (near Coubon) have the ruins of large feudal châteaus. The rocky plateau overlooking Polignac is occupied by the ruins of the stronghold of the ancient family of Polignac, including a square donjon of the 14th century. Interesting Gallo-Roman remains have been found on the site.

HAUTE-MARNE, a *de'partement* of northeastern France, made up of districts belonging to the former province of Champagne (Bassigny, Perthois, Vallage), with smaller portions of Lorraine and Burgundy. and some fragments of Franche-Comté. Area 2,416 sq mi. Pop. (1954) 197,147. It is bounded northeast by Meuse, east by Vosges, southeast by Haute-Saône south and southwest by Côte d'Or, west by Aube and northwest by Marne. Its greatest elevation (1,693 ft.) is in the plateau of Langres between the sources of the Marne and those of the Aube; the watershed between the Rhône and the Seine and Meuse, formed by the plateau of Langres continued northeast by the Monts Faucilles. has an average height of 1,500 or 1,600 ft. To the north is Bassigny (the *paybas* or low country, as distinguished from the highlands), a district characterized by monotonous flats of little fertility and extensive wooded tracts. The principal river of the *département* is the Marne. It receives on the right the Rognon, and on the left the Blaise. The western portion is watered by the Aube and its tributary the Aujon, both of which have their sources on the plateau of Langres. The Meuse rises in the Monts Faucilles, and has a course of 31 mi. within the *département*. The Apance, the Amance, the Salon and the Vingeanne are tributaries of the Saône. The mean temperature is 51° F., nearly that of Paris; the rainfall is slightly less than the average for France.

Agriculture is carried on by small proprietors. The chief crops are wheat and oats; potatoes, lucerne and mangel-wurzels are next in importance. Horse and cattle raising flourish in Bassigny. The white wine of Soyers is notable. The *de'partement* is rich in iron and building stone is quarried. The warm springs of Bourbonne-les-Bains are among the earliest known and most frequented in France. Industrial establishments include blast furnaces, foundries, forges, plate-rolling works and shops for nail making and smith's work of various descriptions. St. Dizier is the chief centre of manufacture and distribution. The cutlery trade is important at Nogent-en-Bassigny and in the neighbourhood of Langres. Val d'Osne is well known for its metalwork. Flour-milling, glovemaking (at Chaumont), basketmaking and tanning are also carried on. The principal import is coal. while manufactured goods, iron! stone, wood and cereals are exported. The line of the Eastern railway from Paris to Belfort passes through Chaumont and Langres. The canal from the Marne to the Saône and that of the Haute-Marne together cover 99 mi.; there is a canal 14 mi. long from St. Dizier to Wassy. There are three *arrondissenzents* (Chaumont! Saint-Dizier and Langres), with 28 cantons and 550 communes. Chaumont is the capital. The *département* forms the diocese of Langres; it belongs to the 7th military region and to the educational circumscription (académie) of Dijon, where also is its court of appeal. At Montier-en-Der the remains of a 7th-century abbey include a church with nave and aisles of the 10th, and choir of the 13th century. Wassy, the scene of the massacre of Protestants in 1562, has a church largely of the romanesque period. Vignory has a church of the 11th century. Joinville, a metallurgical centre, preserves a château in the Renaissance style. Pailly. near Langres, has a late 16th-century château.

HAUTES-ALPES, a *département* in southeast France, formed in 1790 out of the southeastern portion of the old province of Dauphiné, together with a small part of north Provence. It is bounded north by the *de'partement* of Savoie, east by Italy and south and southeast by the *département* of the Basses-Alpes, south by the last-named *département,* and west by the *départements* of the Drôme and of the Isère. Its area is 2,179 sq.mi. Pop. (1954) 85,067. It is very mountainous and includes the Pelvoux mass of primary rocks rising to a height of 12,973 ft. in the north, the high line of the Cothian alps 12,609 ft. in the east: and the Papillon mountains of Mesozoic rocks in the south. The *de'parternent* consists of the basins of the upper Durance (with tributaries, Guisane, Gyronde and Guil), of the upper Drac, leading to Grenoble, and of the Buech. The *département* is divided into two *arrondissements* (Gap and Briançon), 24 cantons and 184 communes. There are no large industries and commerce is almost wholly local. The prolonged winter greatly hinders agricultural development, while the pastoral region has been greatly damaged and forests destroyed by the ravages of Provençal sheep, vast flocks of which are driven up there in the summer as the pastures are leased out to a large extent and but little utilized by the inhabitants. It now forms the diocese of Gap (this see is first certainly mentioned in the 6th century) in the ecclesiastical province of Aix-en-Provence; in 1791 there was annexed to it the archiepiscopal see of Embrun, which was then suppressed. There are 114 mi. of railway in the *de'partement.* This includes the main

line from Briançon past Gap toward Grenoble. About 16½ mi. west of Gap is the important railway junction of Veynes. from which branch off lines to Grenoble, to Valence by Die and Livron, and to Sisteron for Marseilles. The chief town is Gap; Briançon and Embrun are the other towns.

HAUTE-SAÔNE, a *de'partement* of eastern France, formed in 1790 from the northern part of Franche Comté. It is traversed by the river Sabne, bounded north by the *département* of the Vosges, east by the territory of Belfort and the *de'partement* of Haut-Rhin, south by Doubs and Jura and west by Côte-d'Or and Haute-Marne. Pop. (1954) 209,303; area, 2,075 sq.mi. The *département* is the upper basin of the Saône from the Ballon de Servance (3,986 ft.) in the northeast to its confluence with the Ognon in the southwest, and it also includes the right side of the lower Ognon valley extending over to the left side in the upper part of that valley toward Belfort. The sandstones and granite of the southern Vosges give place to limestones framing the two valleys at a level of 800 to 1.000 ft., and the water that soaks through these limestones emerges as springs feeding the streams in the valleys zoo ft. lower down. The northeastern districts are cold, due in part to the coldness of the soil, and have an annual rainfall ranging from 36 to 48 in. Toward the southwest the climate becomes more temperate. At Vesoul and Gray the rainfall reaches only 24 in. per annum.

Half of the area of Haute-Sabne is arable land, growing wheat, oats, meslin, rye and potatoes. The vine flourishes mainly in the *arrondissement* of Gray; tobacco is grown. Apples, plums and cherries (from which the kirsch, for which the *de'partement* is famous, is distilled) are the chief fruits. The woods which cover a quarter of the *de'partement* are composed mainly of firs in the Vosges and of oak, beech, hornbeam and aspen elsewhere. Horses and horned cattle thrive on the river pastures. Mines of coal (at Ronchamp) and rock salt (at Gouhenans) and stone quarries are worked. The hot springs of Luxeuil-les-Bains are the most famous of Haute-Saône. There are ironworking establishments, copper foundries, engineering works, steel foundries and factories at Plancher-les-Mines and elsewhere for producing ironmongery, nails, pins, files, saws, screws, shot, chains, agricultural implements, locks, spinning machinery, edge tools; there are also glassworks, potteries and brick and tileworks, cotton factories. of which Héricourt (pop. in 1954, 6,233) is the chief centre, paper mills, printworks, fulling mills, hosiery factories and straw-hat factories, as well as sugar works, distilleries, dye works, sawmills, starchworks, chemical works at Gouhenans, oil mills. tanyards and flour mills. The *de'partement* exports wheat, cattle, cheese, butter, iron. cotton cloth, wood, pottery, kirschwasser, plaster, leather, glass, etc. The Sabne provides a navigable channel of about 70 mi.. which is connected with the Moselle and the Meuse at Corre by the Canal de l'Est along the valley of the Coney. Gray is the chief emporium of the water-borne trade of the Saône. Haute-Saône is served chiefly by the Eastern railway. There are two *arrondissements*— *Vesoul* and Lure—comprising 28 cantons, 583 communes; Haute-Saône is in the district of the 7th army corps (Besançon), and in its legal, ecclesiastical and educational relations depends on Besançon.

Vesoul, the capital of the *de'partement,* Gray, Lure and Luxeuil are the principal towns. The Roman ruins and mosaics which may be seen at Membrey, the church (13th and 15th centuries) and abbey buildings in and around Faverney (10th, 13th and 14th centuries), in the *arrondissement* of Vesoul, are of antiquarian interest.

HAUTE-SAVOIE, a frontier *dkpartement* of France, formed in 1860 of the old provinces of the Genevois, the Chablais and the Faucigny, previously the northern portion of the duchy of Savoy neutralized in 1815. It is bounded north by the canton and Lake of Geneva, east by the Swiss canton of the Valais, south by Italy and the *dkpartement* of Savoie, and west by the *dkpartenzent* of the Ain. Pop. (1954) 293,852. Area, 1,775 sq.mi. It slopes from the Mont Blanc (15,771 ft.) chain on the southeast down to the lake and canton of Geneva and the Rhbne (945 ft.) on the west. It is drained by many streams, chief of which are the Arve and the Fier, feeders of the Rhône; the Fier forms the lake of Annecy. The climate varies considerably with the altitude; the maximum rainfall is in May and June. The tourist industry is highly important, especially at Charnonix. Cattle and poultry are reared, and Gruykre cheeses and honey are made. There are chalybeate springs at Évian and Amphion, and at St. Gervais and elsewhere. Anthracite and asphalt mines are numerous, as well as stone quarries. There is much trade in pine and other wood from mountain forests. Cotton is manufactured at Annecy; Cluses is the centre of the clockmaking industry; and there is a well-known bell foundry at Annecy-le-Vieux. The *département* is divided into four *arrondissements* (Annecy, the principal town, Bonneville, Saint-Julien-on-Genevois and Thonon-les-Bains), 28 cantons and 315 communes. It forms the diocese of Annecy in the province of Chambéry, is in the district of the 14th army corps (Lyons) and in the Académie (educational division) of Chambéry, where is its court of appeal. Thonon (the old capital of the Chablais) is the chief town on the south shore of the Lake of Geneva and, after Annecy, the largest place in the *de'partement.*

HAUTES-PYRÉNÉES, a *de'partement* of southwestern France, on the Spanish frontier, formed in 1790, half of it being taken from Bigorre and the remainder from Armagnac, Nébouzan, Astarac and Quatre Vallées, districts of the province of Gascony. Pop. (1954) 203,544. Area, 1,751 sq.mi. Hautes-Pyrénées is bounded south by Spain, west by the *de'partement* of Basses-Pyrénées, north by Gers and east by Haute-Garonne. The south of the *département,* comprising two-thirds of its area, is occupied by the central Pyrenees composed of Paleozoic rocks with Mesozoic rocks on the northward facing slopes. The ancient volcanic rocks stand out as the highest peaks, some exceeding 10,000 ft., the Vignemale (10,820 ft.) being the highest in the French Pyrenees. The imposing cirques (Cirques de Troumouse, Gavarnie and Estaubé), with glaciers and waterfalls, and the pleasant valleys attract many tourists. The north of the *de'pautement* has plains and undulating hills clothed with cornfields, vineyards and meadows. To the northeast, the cold and wind-swept plateau of Lannemezan (about 2,000 ft.) with Miocene and glacial deposits, presents a striking contrast to the plain below. The Adour and its tributary, the Gave de Pau, and the Neste, an affluent of the Garonne, drain the *de'partement.* The sources of the second and third lie close together in the Cirque of Gavarnie. An important section of the Pyrenees, which carries the Massif Néouvielle and the Pic du Midi de Bigorre runs northward between these two valleys. The Adour descends from the Pic du Midi through the Campan valley and leaves the mountains at Bagnkres and then divides into a multitude of channels, notably the Canal d'Alaric (36 mi. long), to irrigate the rich plain of Tarbes. Beyond Hautes-Pyrénées it receives the Arros, which flows through the *dkpartenzent* from south to north-northwest; on the left it receives the Gave de Pau; it is navigable in the lower stretches. The Gave de Pau, larger than the upper Adour, after passing Argelks. a well-known centre for excursions, and Lourdes, leaves the mountains. The Neste is important as furnishing the plateau of Lannemezan with a canal, the Canal de la Neste, the waters of which are partly used for irrigation and partly for supplying the streams that rise there and are dried up in summer—the Gers and the Bai'se, affluents of the Garonne. The climate of Hautes-Pyrénées, cold on the highlands, gives, on the plains, hot summers, fine autumns, mild winters and rainy springs. On the plateau of Lannemezan, summers are dry and scorching, winters very severe. The average annual rainfall at Tarbes, in the north, is about 34 in.; at the higher altitudes it is much greater. The mean annual temperature at Tarbes is 59° F.

Hautes-Pyrénées is agricultural in the plains, pastoral in the highlands. The more important cereals are wheat and maize, chiefly in the Adour valley and the northern part of the *département,* which is much used for the feeding of pigs and poultry, especially geese; rye, oats and barley are grown in the mountain districts. The wines of Madiran and Peyrigukre are well known, and chestnut trees and fruit trees are grown on the lower slopes. Horse breeding is important around Tarbes and Bagnères-de-Bigorre, and there is a famous stud at Tarbes. The horse of the region has Arab, English and Navarrese blood and is well fitted

for saddle and harness. Cattle raising is important; the milch cows of Lourdes and the oxen of Tarbes and the valley of the Aure are highly esteemed. Sheep and goats are also reared. The forests, which occur chiefly in the highlands, are mainly coniferous and still contain wild animals (bears, wolves, etc.). There are at Campan and Sarrancolin quarries of fine marble, which is sawed and worked at Bagnkres. There is a group of slate quarries at Labasskre and an important slate works at Tarbes. Deposits of lignite, lead, manganese and zinc are found. The principal mineral springs in the valley of the Gave de Pau are Cauterets (hot springs containing sulfur and sodium), St. Sauveur (springs with sulfur and sodium) and Barkges (hot springs with sulfur and sodium), and in the valley of the Adour Bagnkres (hot or cold springs containing calcium sulfates, iron, sulfur and sodium) and Capvern near Lannemezan (springs containing calcium sulfates).

The *département* has flour mills and sawmills, a large military arsenal at Tarbes, paper mills, tanneries and manufactories of agricultural implements and looms. The spinning and weaving of wool are carried on chiefly at Bagnkres-de-Bigorre.

Of the passes *(ports)* into Spain, even the chief, Gavarnie (7,398 ft.), is not accessible to carriages. The Southern railway main line, from Bayonne to Toulouse, traverses the *département*. There are three *arrondissements*, Tarbes, Argelks-Gazost and Bagnkres-de-Bigorre, 26 cantons and 480 communes. Tarbes is the capital of Hautes-Pyrénées, which is attached to the appeal court of Pau and forms part of the region of the 18th army corps (Bordeaux). There are bishops at Tarbes and Lourdes, under the archbishop of Auch. The *département* is in the académie (educational division) of Toulouse. Tarbes, Lourdes, Bagnères-de-Bigorre and Luz-St. Sauveur are the principal towns. St. Savin, in the valley of the Gave de Pau, and Sarrancolin have interesting romanesque churches. The church of Maubourguet was built by the Templars in the 12th century.

HAUTE-VIENNE, a *département* of central France, formed in 1790 of Haut-Limousin and of portions of Marche, Poitou and Berry. Pop. (1954) 324,429. Area, 2,145 sq.mi. It is bounded north by Indre, east by Creuse, southeast by Corrkze, southwest by Dordogne, west by Charente and northwest by Vienne. The highest altitude (3,130 ft.) is in the extreme southeast and belongs to the treeless but well-watered plateau of Millevaches, formed of granite, gneiss and mica. From that point the *département* slopes toward the west, southwest and north. To the northwest of the Millevaches are the Ambazac and Blond Hills, and the mountains of Limousin are on the south. The Vienne traverses the *département* from east to west, forming in its upper course the basin of Limoges, passing Eymoutiers, St. Léonard, Limoges and St. Junien, and receiving most of its tributaries from the south. The altitude, inland position and cold soils of Haute-Vienne and the northern exposure of its valleys make the winters long and severe; but the climate is milder in the west and northwest. The annual rainfall often reaches 36 or 37 in, and even more in the mountains. Rye, wheat, buckwheat and oats are the cereals most grown, but the chestnut still forms the staple food of large numbers. Potatoes, walnuts and cider apples are cultivated. Good breeds of horned cattle and sheep are reared in the valleys and find a ready market in Paris. Horses for remount purposes are also raised. The quarries furnish granite and large quantities of kaolin, which is both exported and used in the porcelain morks of the *département*. Limoges is a centre of the porcelain industry and has important liqueur distilleries. Agricultural implements and hats are other industrial products, and there are breweries, dye morks, tanneries, iron foundries and printing works. Wine and alcohol for liqueur-manufacture, coal, raw materials for textile industries, hops, skins and various manufactured articles are among the imports.

The *département* is served by the Orléans railway. It is divided into the *arrondissements* of Limoges, Bellac and Rochechouart (29 cantons and 206 communes), and belongs to the académie (educational division) of Poitiers and the ecclesiastical province of Bourges. Limoges, the capital, is the seat of a bishopric and of a court of appeal and the headquarters of the 12th army corps. The other principal towns are St. Yrieix and St. Junien. Solignac, St. Léonard and Le Dorat have fine romanesque churches. There are important remains of the château of Chalusset (S.S.E. of Limoges), and the château of Rochechouart dates from the 13th, 15th and 16th centuries.

HAUT-RHIN, *de'partement* of France. formed after the Revolution in 1790 from the southern portion of Alsace, and incorporated in 1870 nith the German empire; it was resuscitated by the Treaty of Versailles in 1918, when Alsace-Lorraine became French once more. It is bounded north by Bas-Rhin, east by the *land* of Baden-Wurttemberg, south by Switzerland, southwest by the territory of Belfort and west by the Vosges. Pop. (1954) 509,647. Area, 1,354 sq.mi.

The *département* occupies the southern portion of the Rhine trough. The Vosges and Black Forest are the remains of a Hercynian block, rifted, apparently, at some stage in the uprise of the Alps, with the result that the deep Rhine trough from Basle northnard was formed. Loess deposits occur in the south and along the foot of the Vosges and give good soil with layers useful for the manufacture of bricks. Haut-Rhin is one of the most fertile parts in central Europe. The hills are richly wooded, chiefly with fir, beech and oak. The agricultural products are corn, potatoes, flax, grapes and other fruit. Cotton spinning and weaving is the most important industry centred in Mulhouse, Colmar, Guebwiller and the Vosges valleys.

Other industries are the manufacture of woolen and silk goods, chemicals, paints, machinery, pottery, bricks, tiles and paper. Potash is produced near Mulhouse, and also lime. Haut-Rhin is also important for its wine.

Haut-Rhin is at a disadvantage as regards commerce, owing to its isolation from the rest of France and the fact that the Rhine, its main outlet, has its mouth outside France. The Rhine is navigable for small vessels as far as Basle, but the *de'partement* is served by the Ill; the Rhine-Rhône canal is another outlet. This *de'partement* and Bas-Rhin, however, gain from the fact that they are in the French customs boundary, and thus have French markets open to their industrial products.

Colmar is the capital of the *de'partenzent*, which includes six *arrondissements* (Colmar, Altkirch, Guebwiller, Mulhouse, Ribeauville, and Thann), 26 cantons, and 386 communes. It is under the académie of Strasbourg. Colmar is the seat of Superior Regional Tribunal. It is the bishopric of Strasbourg. The other important towns are Mulhouse, Guebwiller and Altkirch. Most of the towns are situated on the Ill; there are no important towns on the Rhine south of Strasbourg, owing to its marshy banks. The *département* is served by rail from Basle via Mulhouse and Colmar to Strasbourg.

HAUY, RENÉ JUST (1743–1822), French mineralogist one of the founders of the science of crystallography, was born at St. Just, Oise, on Feb. 28, 1743. An accident directed his attention to crystallography. Happening to let a specimen of calcite fall, he was led by examination of the fragments to make experiments which resulted in the statement of the geometrical law of crystallization according to which the secondary faces on a crystal are related to the primitive form, or cleavage nucleus, by a law of whole numbers, and the angles between them can be arrived at by mathematical calculation. Hauy's name is also known for the observations he made in pyroelectricity. the property of certain crystals, *e.g.,* tourmaline (*q.v.*), of developing electric charges on heating or cooling. In 1802, under Napoleon, he became professor of mineralogy at the museum of natural history, but was deprived of his appointment at the Restoration. He died in Paris on June 3, 1822.

Among his numerous works may be mentioned *Traite' de minkralogie* (4 vol., 1801); *Tableau comparatif des rksultats de la cristallographie, et de l'analyse chimique, relativement à la classification des minéraux* (1809); *Traite' des caractères physiques des pierres précieuses* (1817); and *Traite' de cristallographie* (2 vol., 1822). He also contributed papers to various scientific journals.

HAVANA (LA HABANA), a province in middle western Cuba, between Pinar del Rio and Matanzas provinces. Although the smallest province in area (3,174 sq.mi.), including the Isle of Pines,

it is densely populated (1961 est.. 1.858.112) because of the great concentration in and near the city of Havana. It consists mostly of hilly belts near the northern coast and in the centre. and a gently sloping plain in the south bordered by a swampy coast of mangrove forests. The northern coast is high and is characterized by an abundance of terraces: sandy beaches and the beautiful Bay of Havana.

The fertile soils of the province, especially in the Red plain of the south, yield considerable quantities of sugar cane. excellent quality cigar-wrapper tobacco. fruits, vegetables and milk for the urban market of Havana. Güines. in the southeastern section of the province, has been traditionally the supplier of agricultural products for Havana, using irrigation facilities of the Mayabeque river. The province has excellent communications. including a good network of modern highways, railways and airways. Many industrial plants are located around as well as in Havana.

(D. R. D.)

HAVANA (LA HABANA) capital, commercial metropolis and major port of the republic of Cuba. the largest city of the West Indies and one of the leading tropical cities in the new world, lies on the northern coast of the island, toward the western end. Its location on one of the fine harbours of the hemisphere made it commercially and militarily important from colonial times and is a major factor in accounting for its steady growth in population from 235.931 in 1899 to 897.042 (est.) in 1961. Other factors in its growth have been its salubrious climate, picturesque location and. before the advent to power of Fidel Castro in 1959, gay entertainment which made it a mecca for tourists. The mean annual temperature varies only about 10 degrees. averaging 76" F. Rain falls throughout the year. the wet season being from May to November.

The city has three sections: the old city; the new, closely settled subdivisions; and the suburbs. Old Havana is located on the peninsula between the harbour channel and the bay; the newer section of Vedado extends along the coast to the Almendares river; a little farther out are the residential and industrial suburbs of Guanabacoa and Marianao. The aspect of Havana from the sea is picturesque. Although the country clubs and many of the fashionable residential suburbs along the coast were expropriated by the Castro government, from a physical standpoint the view remains no less impressive. On the left of the entrance to the harbour rises the Morro castle and lighthouse. On the right La Punta fortress appears and beyond it the Prado. or Paseo de Martí. the main avenue leading to the heart of the city'. Lining the Prado are buildings constructed of West Indian white coral limestone.

The entrance-strait to the harbour, about 300 yd. wide and 1.750 yd. long, leads to the inner harbour. which lies east and south of the city. The water front in the older sections is lined with wharves and docks. There are three distinct arms of the inner bay, called respectively. Ensenada de Marimalena, Guanabacoa bay and the Ensenada de Atarés.

Streets and Buildings.— From well out toward the western suburbs. the Llalecon, or sea wall, a wide boulevard which skirts the sea and city, furnishes a colourful foreground which is extended along inside the harbour (on reclaimed ground which covers the shallows of the harbour entrance) and creates wide parks and valuable commercial lands. The Malecón merges at the Prado into the Avenida del Puerto. which, with a width varying from 50 to 125 ft., connects this outer drive to the old narrow streets of the business section. This entrance to the old business thoroughfares: Calles O'Reilly and Obispo, and Calle de Oficios eased much or' the old downtown congestion. Most of the old streets of Havana, originally laid out to furnish shade along their narrow drives and walks and to carry only a few dozen Cuban coaches (*quitrines* or *volantas*) were converted into one-way streets to accommodate motor vehicles. thus giving a more ordered control of the traffic problem.

Many public buildings were built along the Malecón and the Avenida del Puerto, including the Capitania, or office of the captain of the port. The newer section has also a number of hne parks. notably the Parque del Maine, with its monument by Felix Cabarrocas dedicated to the U.S. battleship "Maine," which was blown up in Havana harbour on Feb. 15, 1898. In 1960, in an angry gesture against the United States. Fidel Castro had the eagle atop the monument removed by a wrecking crane, resulting in the partial destruction of the main shaft of the monument as well. The announced intention was to replace the eagle with the "dove of peace." The Presidential palace, the residence of the chief executive, is at the head of the Avenida de las Misiones, a wide thoroughfare; this avenue leads from Xvenida del Puerto inland and was designed to be lined for its short length with the embassies and legations of foreign governments.

Historic *Landmarks.*—Of the older landmarks! one of the most important is the old palace of the Spanish governors, now the city

AUTHENTICATED NEWS

hall and office of the Ayuntamiento or city government; this fine old pile stands on the site of the original parish church on the eastern side of the Plaza de Xrmas. the old centre of the colonial city. The palace was erected in 1773–92 and remodeled in 1835 and 1851. It was the scene of the surrender by the Spaniards of the sovereignty of the island to the United States at the close of the Spanish-American War and the scene, too. of the transfer of its sovereignty from the United States to the first president of Cuba. Tomás Estrada Palma. on May 20. 1902.

Havana was once the most strongly fortified city in Spanish America and many of its old forts built to withstand attacks irom pirates are still standing. The most precious of these old historical landmarks is the ancient stronghold. La Fuerza. or more properly, El Castillo de la Real Fuerza. begun in 1565 and completed in 1583. standing on the site of the yet older fortress built by order of Hernando de Soto in 1533, but destroyed by the French pirate Jacques de Sores. The later fortress was the home of the governors general and the citadel and refuge of the populace in times of danger from 1581 until the middle of the 18th century. Crowning the old watchtower of La Fuerza is a weather vane formed in the shape of an Indian maiden, called "La Habana." The two 16th-century fortresses. Morro castle or El Castillo de los Tres Reyes del Morro (castle of the three kings of the headland) and La Punta, on either side of the harbour entrance, are perhaps the best-known Cuban landmarks. La Cabaña, behind and above Morro castle is the largest fort in Havana and was completed in 1771.

Another old building (restored and used by the senate) is of elaborate 13th-century Spanish baroque architecture. The old city also contains the post office (the church of San Francisco), begun in 1575 and rebuilt in 1731–37; also the old municipal jail, a typical Spanish fortress on the Prado, and the Castillo del Principe, now the penitentiary. In this section also is the National library, the Llaestranza, formerly the navy yard and the headquarters of the artillery. The old city abounds in ancient private residences. Before the Castro revolution many of them had been acquired by the government and patriotic societies in order to restore and preserve them.

Many of the public buildings were formerly churches, and in-

deed churches of the colonial epoch are still among the most interesting and carefully preserved relics of the older days. The convent of Santa Clara, built in 1644, was bought by the government at a substantial price in 1928 and converted into the ministry of public works; in the large patio of this old building are still preserved the first houses and streets built in Havana, which were enclosed in the old church and monastery by its builders in the 17th century. The cathedral is the most noteworthy, architecturally. of the city's churches; it was originally the Jesuit church, erected between 1656 and 1724, although the interior decorations date only from 1790–1820. One of the tombs of Columbus is marked there; the remains of the discoverer were removed, according to certain claimants, from Santo Domingo (Dominican Republic) in 1796, and lay there until carried to Spain in 1898. *(See* COLUMBUS.)

Parks and Suburbs. — Havana has been famous since the days of the Spaniards for its parks and drives. The harbour's edge on the east is traversed in part by the old Paseo or Alameda de Paula, originally laid out in 1772, and by the Avenida del Puerto, the latter a portion of the elaborate modern reconstruction of Havana (including the opening of the Avenida de las Misiones and the beautification of the Prado), designed and carried out under Carlos Manuel de Céspedes while minister of public works under Pres. Gerardo Machado. The Malecbn or sea-wall drive, extended around the harbour entrance as the Avenida del Puerto, traverses the edge of the city along the sea for several miles, a beautiful drive and promenade. The Prado, rechristened the Paseo de Martí in honour of the "Apostle of Cuban independence," follows the line of the old city wall. The lower Prado is lined nith residences and clubs, but the so-called upper Prado leads to the Parque Central on one side of which was built the pretentious and costly capitol, begun by Pres. José Miguel Gomez about 1910 and completed under Pres. Gerardo Machado in 1929. The Prado continues to the Plaza de la Fraternidad, formerly Parque de Colón or Campo de Marte curving in its course and furnishing a highway into the heart of the old city, although its formal climax is the Parque de Colón where stand handsome monuments to José Martí and other Cubans notable in history and science. This park is surrounded by handsome offices, hotels and clubs, among them the more elaborate and costly Centro Asturiano, one of the two large Spanish clubs, the other being the Casino Español. In this section were some of the handsomely equipped hotels that made Havana an important winter resort.

From Plaza de la Fraternidad, the Avenida de Simbn Bolivar, formerly Calzada de la Reina, reaches the Paseo de Carlos III and the Paseo de Tacón, passing westward through the city to the botanical gardens and the Quinta de los Molinos to the old citadel of El Principe, begun in 1774 and finished 20 years later. Los Molinos was once the summer palace of the Spanish governors general and adjoins the gardens of the university. Near El Principe is the Colón cemetery, with many historic monuments and mausoleums. Another famous promenade and drive is the Avenida de Menocal, at the west end of the new city; the Cerro, in the southwest, is a residence quarter.

Suburban growth in Havana was rapid and extensive. The whole territory now tributary to the capital covers a large area. On the south and west the city is surrounded by a range of hills, with the conspicuous fortifications of Castillo del Principe on the west. Lower down on the hills are the suburbs of Vedado, Jesus del Monte and Luyanó; besides these, Puentes Grandes, old Marianao and Guanabacoa are populous suburbs.

Education. — In the upheaval of revolution and the establishment of the Castro regime, the Universidad de La Habana — the national university established in 1728 — suffered catastrophic damage. Shorn of its traditional autonomy and made subservient to the regime, two-thirds of its faculty were forced out and most of them went into exile. The Catholic university in the suburb of Marianao was closed, as were the once excellent secondary schools previously maintained under Protestant, Catholic and nonsectarian auspices. All private schools were outlawed.

Although it was the avowed aim of Castro's 26th of July movement to extend educational facilities to 'all Cubans, it was not known in the early 1960s to what degree that objective had been fulfilled. The content of instruction in the schools was being changed to support the political orientation of the Castro regime.

Among the libraries are those of the Sociedad Económica de Amigos del País founded in 1793, and the Biblioteca Nacional (National library). The only newspapers allowed by the Castro government were those under strict government control-Revolution, *Hoy* and a few others. The venerable and internationally respected *Diario de la Marina,* established in 1838, and all other private newspapers were suppressed.

Population and Health. — Havana had 51.307 people in 1791; 96,304 in 1811; 94,023 in 1817; 184.508 in 1841; 235,981 in 1899, the year following independence; 360,517 in 1919; 432,353 in 1925; 542,522 in 1931; 659,883 in 1943; and 785,455 in 1953, while the suburbs aggregated another 432,219. The population is mainly native-born and predominantly Afro-European. The European element is, of course, primarily Iberian and representative chiefly of northern and northwestern Spain. The knowledge of English became widespread in Havana because of the impact of American tourists and the advent of motion pictures, radio and television.

The workers' residence portion of the city is congested, and before the U.S. occupation *(see* CUBA: *History),* health conditions were notoriously bad and deaths from epidemics, including periodic scourges of yellow fever, rose to high figures. One of the worst of the yellow-fever epidemics broke out in 1900, immediately following the War of Independence, and concomitant with a heavy immigration from Spain. Stringent sanitary regulations failed to stop the epidemic until a commission of U.S. army surgeons led by Walter Reed *(q.v.)* definitely established in a series of experiments that the fever was transmitted by the mosquito known as *Stegomyia fasciata,* later classified as the *Aedes aegypti.* Immediately after Reed's findings (which corroborated a discarded hypothesis of Dr. Carlos J. Finlay, the noted Cuban physician and biologist) were announced, the campaign against the disease began. Maj. William C. Gorgas *(q.v.),* later the sanitary officer who cleaned up the Panama Canal Zone, led the fight that practically exterminated the mosquitoes of Havana and ended yellow-fever epidemics.

Havana became one of the most carefully protected ports in the world, so far as sanitary measures were concerned, and its death rate was reduced to normal proportions. Changes in the water system, with additions of new reservoirs, brought the excellent water from the hills into the capital and the fetid Havana of the colonial period became a memory only.

Transportation and Communication. — Havana is the hub of Cuba's transportation system. In its earlier history the commercial and military importance of Havana was derived from its location on its fine natural harbour, which is completely protected and accessible to ships of almost any draft. It was linked by coastwise navigation with various ports of the Caribbean.

To the importance of water transportation must be added the fact that Havana is the terminus for the chief railways and is therefore linked with all the major communities of the island. The coming of the automobile created new problems as well as new opportunities in transportation. The elongated shape of Cuba made highway communication difficult and costly until the completion of the paved central highway. Havana, quite naturally, is the focal point on this highway which feeds its heavy traffic into the city from both east and west. Havana is also the terminus of airlines; the airport serving both domestic and international airlines is about 8 mi. from the centre of the city at Rancho Boyeros.

Commerce and Industry. — About three-quarters of the imports and a large portion of the exports of the island pass through Havana, which is a world shipping centre.

The principal industrial activity is based on sugar and its by-products. Next to sugar, tobacco is probably the most important product, and Havana cigars are considered by general opinion to be the finest in the world. There are also textile mills, meat-packing plants, chemical factories and perfume plants.

History. — Havana was founded in 1514 as San Cristbbal de la Habana by Diego Velásquez de León on an unhealthful site proba-

bly where the town of Batabano now stands. but was early removed to its present location and rapidly assumed an increasing importance in the Spanish colonies of the new world and was used as a base for Spanish exploring expeditions. In 1634 its important strategic position was recognized by a royal decree declaring it to be the *Llave del Nuevo Mundo y Antemural de las Indias Occidentales* ("Key of the New World and Bulwark of the West Indies"), and the arms of the modern city carry the symbolic key.

The town was the object of numerous attacks by English. French and Dutch pirates. In 1537 it was sacked and burned, in 1555 it was plundered by French buccaneers and in 1586 Sir Francis Drake threatened it; but in 1589 Philip II of Spain ordered the erection of La Punta and the Morro castle, the ancient defenses, and the residence of the governor of the island was removed from Santiago de Cuba to Havana, which gained the rank of a city in 1592.

The estimated population of the city was about 3.000 by 1600 but had doubled by 1655, when many Spaniards fled there from Jamaica after the capture of that island by the English. During the 17th century Havana became the port of rendezvous of the east-bound fleets of Spanish galleons and was thus the object of many attacks by the English, Dutch and French. The port was blockaded four times by the Dutch in the first half of the 17th century and in 1671 the city walls were begun, being completed in 1702.

The European wars of the 17th and 18th centuries were marked by various incidents in local history. After the end of the War of the Spanish Succession (1713) came a period of comparative prosperity in slave-trading and general commerce. The creation, in 1740, of a monopolistic trading-company was an event of importance in the history of the island. English squadrons threatened the city several times in the first half of the 18th century. but it was not until 1762 that an investment, made by Adm. Sir George Pocock and the earl of Albermarle, was successful. The siege lasted from June to August and was attended by heavy losses on both sides. The British commznders wrung great sums from the church and the city as prize of war and price of good order. By the treaty of Feb. 10, 1763, at the close of the Seven Years' War, Havana was restored to Spain in exchange for the Floridas.

The English turned over the control of the city on July 6. Their occupation greatly stimulated trade, and from it dates the modern history of the city and of the island. The gradual removal of obstacles from the commerce of the island from 1766 to 1818 particularly benefited Havana. At the end of the 18th century the city was one of the seven or eight great commercial centres of the world, and in the first quarter of the 19th century was a rival, in population and in trade, of Rio de Janeiro, Buenos Aires and New York.

In general, the history of Havana under the Spaniards, and since independence, has been the history of Cuba. Various pirate raids, the slave traffic in the 18th and 19th centuries, filibustering expeditions in the 19th century, the war between Spain and the United States in 1898–99 and tension between the U.S. and Castro governments all had direct bearing on the history of Havana and the city suffered and triumphed with them.

The overthrow of the Batista government by Fidel Castro in Jan. 1959 brought profound and drastic changes in the life of Havana—and Cuba. Foreign-owned land. sugar factories. ranches. corporations and banks were an immediate target for expropriation or, indeed. confiscation. Property of wealthy Cubans. particularly those who were considered supporters of Batista. was likewise taken over by the government.

There followed also the development of close commercial and trade relations with the Soviet Union and other "iron curtain" countries. Meanwhile, continued hostility toward the United States by Castro led to the cancellation of the traditional sugar purchases by the United States. This was a major source of foreign exchange for Cuba. since the isiand for many years had been allowed a quota in the United States market of about one-third of the U.S. total consumption and for which a premium price was paid. The loss of that market was partially replaced by purchases by the Communist governments on a barter basis. but it was a severe blow to the economy of the island.

Equally severe was the impact of the revolution and its violent aftermath upon the tourist traffic. Tourism had long been of great importance to Havana. and during the 1950s it vastly increased. New luxury hotels and gambling casinos were constructed largely by U.S. capital. The estimated value to Cuba of tourism in 1958—the last year before Castro—was about $60.000.000. Castro at first made a strong effort to attract tourists after he rose to po er. and he employed an American advertising firm to promote his campaign Rut the news from Havana of unrest, coupled with the stream of government anti-United States propaganda. discouraged prospective visitors. Soon the cruise ships were canceling stops at Havana. and U.S. citizens began to look elsewhere for their vacations. Finally, on Jan. 3, 1961, came the official break in diplomatic relations between the United States and Cuba and. on Jan. 16. an announcement by the C.S. department of state that all Cnited States citizens desiring to visit Cuba must obtain passports specifically endorsed for such travel. Tourism from the United States thereafter was negligible.

See CUBA: *History.* (W. THO.; C. E. MC.; L. NN.)

HAVANT AND WATERLOO, an urban district (1932) in the Portsmouth, Langstone parliamentary division of the county of Hampshire. Eng ; Havant is 11 mi. S.E. of Portsmouth by road. Pop. (1961) 74.564. Area 18.9 sq.mi. It includes Waterlooville, much of the Forest of Bere, and Hayling Island. joined to the mainland by road and rail bridges, where a priory of the abbey of Jumièges was submerged by the sea in 1325. A Roman villa' was found at Langstone and *Havehunte* is mentioned in *Domesday Book.* Of medieval Havant. largely burned down in 1760, the 12th-century church of St. Faith survives. Many great documents were of Havant parchment, famous for 1,000 years, until it ceased to be made in 1936. Products include electronic equipment. sheet metal, gloves and coachwork; but agriculture and catering for yachtsmen and visitors are also important.

HAVASUPAI, abbreviated to Supai, a group of Indians speaking a Yuman (*q.v.*) language who live on a small reservation on Cataract creek in the western edge of Grand Canyon National park. Ariz. In 1776, Father Garces, their first European visitor. found them scattered over canyon and plateau east of the Walapai from whom they can hardly be distinguished. Their indifferent agriculture supplemented by the natural resources of some 4.000 sq.mi. provided a relative abundance for this group of 300. Men hunted game with bow and arrow. clubs, snares and traps. Women made twined baskets to harvest wild seeds and for transportation, storage and cooking. Red ochre. mined for face paint. was still widely traded in the second half of the 20th century. The Havasupai camped in brush shelters or. in minter. in dirt-covered conical wooden huts. Wherever in the canyon there was level land, and springs made irrigation possible, they planted corn, beans, squash and sunflowers for food and cotton for tinder. There they gathered in late summer for sports, games and gambling. A head chief and a council offered prayers and advice. After a feast and circle dance for visitors they stored the harvest in caves and moved back to the plateau.

They had medicine men, or shamans. to control weather, game, snakes and disease. Only rich men had two wives. Warfare was insignificant. After death the body and all personal property were burned. Sons of the Havasupai inherited agricultural land if they could use it.

About 1870 manufactured goods replaced pottery and skin clothing. and decorated coiled basketry was developed for trade. In the 20th century they raised peaches. alfalfa, horses and cattle, but the reservation (518 ac.) was inadequate when it was established in 1882 and the fields periodically eroded.

See Leslie Spier, "Havasupai Ethnography," American Museum of Natural History *Anthropological Papers,* vol. 29, part iii (1928) ; Joseph Wampler, *Havasu Canyon* (1959). (A. F. W.)

HAVEL, a river of former Prussia. Ger. rising at a height of 223 ft. on the Mecklenburg plateau. 7 mi. N.W. of Neu-Strelitz. and after threading several lakes flowing south as far as Spandau. From there it curves southnest, past Potsdam and Brandenburg, traversing another chain of lakes. and finally continues northwest until it joins the Elbe from the right several miles above Wittenberg after a total course of 213 mi, and a total fall of only 158 ft.

Its banks are mostly marshy or sandy, and the stream is navigable from the Mecklenburg lakes downward. Several canals connect it with other rivers. Area of river basin, 9,372 sq.mi.

HAVELBERG, a town in the former *Land* of Brandenburg, now in the district of Magdeburg, Ger., on the Havel just above its junction with the Elbe. Population (1950) 6,900. Havelberg was formerly a strong fortress and changed hands frequently during the Thirty Years' War. The town was incorporated in 1875, and is built partly on an island in the Havel, and partly on hills on the right bank of the river, on one of which is the Romanesque cathedral dating from the 12th century.

HAVELOCK, SIR HENRY (1795–1857), British soldier, one of the heroes of the Indian Mutiny, the second of four brothers (all of whom entered the army), was born at Ford hall, Bishop-Wearmouth, Sunderland, on April 5, 1795, the son of a wealthy shipbuilder. Educated at Charterhouse school, he entered the Middle Temple in 1813, studying under Chitty, the eminent special pleader. But in 1815 he took a commission in the 95th rifle brigade, procured for him by the interest of his brother William. In 1823, having exchanged into the 21st and then into the 13th light infantry, he followed his brothers William and Charles to India, first qualifying himself in Hindustani under John Gilchrist, a celebrated orientalist.

At the close of 23 years' service he was still a lieutenant, and it was not until 1838 that, after three years' adjutancy of his regiment, he became captain. Before this, however, he had held several staff appointments, notably that of deputy assistant adjutant-general of the forces in Burma till the peace of Yandabu, of which he, with Lumsden and Knox, procured the ratifications at Ava from the "Golden Foot." who bestowed on him the "gold leaf" insignia of Burmese nobility. In 1828 he published at Serampore *Campaigns in Ava,* and in 1829 he married Hannah Shepherd, daughter of Joshua Marshman. About the same time he became a Baptist, being baptized by John Mack at Serampore. During the first Afghan war he was present as aide-de-camp to Sir Willoughby Cotton at the capture of Ghazni, on July 23, 1839, and at the occupation of Kabul. After a short absence in Bengal to secure the publication of his *Memoirs of the Afghan Campaign,* he returned to Kabul in charge of recruits, and became interpreter to General Elphinstone. In 1840, being attached to Sir Robert Sale's force, he took part in the Khurd-Kabul fight, in the celebrated passage of the defiles of the Ghilzais (1841) and in the fighting from Tezeen to Jalalabad. Here, after many months' siege, his column in a sortie *en masse* defeated Akbar Khan on April 7, 1842. He was now made deputy adjutant-general of the infantry division in Kabul, and in September he assisted at Jagdalak, at Tezeen, and at the release of the British prisoners at Kabul, besides taking a prominent part at Istaliff. He also served in the Mahratta and Sikh campaigns of 1843 and 1845. After two years spent in England he became (1854), quartermaster-general, then full colonel, and lastly adjutant-general of the troops in India.

In 1857 he was selected by Sir James Outram to command a division in the Persian campaign. Peace with Persia set him free just as the Mutiny broke out; and he commanded a column "to quell disturbances in Allahabad, to support Lawrence at Lucknow and Wheeler at Cawnpore, to disperse and utterly destroy all mutineers and insurgents." At this time Lady Canning wrote of him in her diary: "General Havelock is not in fashion, but all the same we believe that he will do well. No doubt he is fussy and tiresome, but his little old stiff figure looks as active and fit for use as if he were made of steel." Havelock proved himself the man for the occasion. At Fatehpur, on July 12, at Aong and Pandoobridge on the 1 jth, at Cawnpore on the 16th, at Unao on the 29th, at Busherutgunge on the 29th and again on Aug. 5, at Boorhya on Aug. 12, and at Bithur on the 16th he defeated overwhelming forces. Twice he advanced for the relief of Lucknow, but twice prudence forbade a reckless exposure of troops wasted by battle and disease in the almost impracticable task. Reinforcements arriving at last under Outram, he crowned his successes on Sept. 25, 1857 by the capture of Lucknow. There he died on Nov. 24, 1857, of dysentery, brought on by the anxieties and fatigues connected with his victorious march and with the subsequent blockade of the British troops. He received a K.C.B. Other honours, a major-generalship and a baronetcy, he did not live to receive; they were conferred on his heir.

See J. C. Marshman, *Life of Havelock* (1860); A. Forbes, *Havelock* (English Men of Action Series, 1890); F. M. Holmes, *Four Heroes of India* (1892); G. B. Smith, *Heroes of the Nineteenth Century* (1901); L. J. Trotter, *The Bayard of India* (1903).

HAVELOK THE DANE, an Anglo-Danish romance. The hero. under the name of Cuheran or Cuaran, was a scullion-jongleur at the court of Edelsi (Alsi) or Godric, king of Lincoln and Lindsey. At the same court was brought up Argentille or Goldborough, the orphan daughter of Adelbrict, the Danish king of Norfolk, and his wife Orwain, Edelsi's sister; and Edelsi, to humiliate his ward, married her to the scullion Cuaran. But, inspired by a vision, Cuaran and Goldborough set out for Grimsby, where Cuaran learned that Grim. his supposed father, was dead. His foster-sister, moreover: told him that his real name was Havelok: that he was the son of Gunter (or Birkabeyn), king of Denmark, and had been rescued by Grim, who though a poor fisherman was a noble in his own country, when Gunter perished by treason. The hero then wins back his own and Goldborough's kingdoms, punishing traitors and rewarding the faithful. The story exists in two French versions: as an interpolation between GeffreiGaimar's *Brut* and his *Estorie des Engles* (*c.* 1150) and in the Anglo-Norman *Lai d'Havelok* (12th century). The English *Havelok* (c. 1300) is written in a Lincolnshire dialect and embodies abundant local tradition. The name of Havelok (Habloc, Abloec, Abloyc) is said to correspond in Welsh to Anlaf or Olaf. The close similarity between the Havelok saga and the story of Hamlet (Amlethus), as told by Saxo Grammaticus, was pointed out long ago by Scandinavian scholars (*see* HAMLET). Part of the Havelok legend lingers in local tradition. Havelok destroyed his enemies in Denmark by casting down great stones upon them from the top of a tower, and Grim is said to have kicked three of the turrets from the church tower in his efforts to destroy the enemy's ships. John Weever (*Antient Funerall Monuments,* p. 749, 1631) says that Grimsby merchants were free from toll in Elsinore through the interest of Havelok, the Danish prince; and the common seal of the town of Grimsby represents Grim, with "Habloc" on his right hand and Goldborough on his left.

The unique English ms. of *Havelok* (Mss. Laud Misc. 108) in the Bodleian was edited for the Roxburghe club by Sir F. Madden in 1828. This edition contains the two French versions. There are subsequent editions by W. W. Skeat (1868) for the E. E. Text Society, by F. Holthausen (1901), and by W. W. Skeat and K. Sisam (1915); and a modern English version by Miss E. Hickey (1902). Gaimar's text and the French *lai* are edited by Sir T. D. Hardy and C. F. Martin in *Rerum Brit. med. aev. scriptores,* vol. i. (1888). *See* also the account of the saga by H. L. Ward (*Cat. of Romances,* i. 423–446); for the identification of Havelok with hnlaf Curan *see* G. Storm, *Englische Studien,* iii. 533 (1880), a reprint of an earlier article; E. K. Putnam, *The Lambeth Version of Havelok* (Baltimore, 1900).

HAVENSTEIN, RUDOLF (1857–1923), German financier, was born at Meswitz on March 10, 1857, the son of an official in the Prussian judicial department. He studied at Heidelberg and Berlin and entered the judicial service, transferring in 1890 to the Ministry of Finance. He became president of the Prussian State bank in 1900, and in 1908 succeeded Koch as president of the Reichsbank, the affairs of which he conducted during the critical war and post-war periods. He was blamed for giving excessive credits after the war and thus conducing to the deterioration of the currency. He died in Berlin on Nov. 20, 1923.

HAVERFIELD (BALGUY), EVELINA (1867–1920), English war hospital worker, daughter of the 3rd Baron Abinger, was born on Aug. 9, 1867. She married Major Haverfield, R.A., in 1887, and *en secondes noces* General Balguy in 1899. She collected abandoned troop horses on the veldt during the Boer War and nursed them back to good condition. She was among the first London suffragists to be sentenced to imprisonment and organized a branch of the Women's Social and Political Union. She joined the Women's Emergency Corps in August 1914, founded and organized the Women's Volunteer Reserve, and was commandant-

in-chief of the Women's Reserve Ambulance (Green Cross) Corps. She gave heroic service to the Serbian wounded during the war. and returned to Serbia in 1919 to establish an orphanage for Serbian children She succumbed to pneumonia, brought on by fatigue and exposure, on March 21, 1920, at Baiyna-Bachta.

HAVERFIELD, FRANCIS JOHN (1860–1919), English historian and archaeologist, was born at Shipston-on-Stour on Nov 8, 1860. Educated at Winchester and New college, Oxford, he became a tutor at Christ Church in 1891, and Camden professor of ancient history in 1907. Haverfield was an authority on the history and antiquities of Roman Britain, and was entrusted by Mommsen with the editing of the British section of the *Corpus Inscriptionum.* He died at Oxford on Sept. 1, 1919. Amongst his publications were *The Romanization of Roman Britain* (1905, 4th ed. 1923), *Ancient Town Planning* (1913), and many monographs on Roman history.

For a bibliography of his works see ***The Journal*** of Roman ***Studies,*** vol. viii.

HAVERFORD, a residential village in eastern Pennsylvania, U.S., 9 mi. N.W. of Philadelphia, is situated in Haverford township, Delaware county, and in Lower Merion township, Montgomery county. The community was founded by Welsh settlers in the 1680s. It is the site of Haverford college for men, with an enrollment of about 450, founded by the Quaker Society of Friends in 1833. and one of the leading small colleges of the eastern United States. The income from a large trust fund permits employment of a distinguished faculty and the furnishing of board and lodging for students at less than cost. (R. F. WE.)

HAVERFORDWEST, chief town of Pembrokeshire, South Wales, a municipal borough and a county of itself, in the Pembroke parliamentary division, 7 mi. N.N.E. of Milford Haven. Pop. (1961) 8.872. Area 2.2 sq.mi. Situated at the highest navigable point on the Western Cleddau, where the river is also bridgeable, it is a focus of routes from St. David's, Fishguard, Cardigan, Carmarthen, Pembroke and Milford Haven. Haverfordwest is a market town, with traces of its medieval walls and fortifications, and streets that are steep because the houses cluster round the castle on a hillock. Large numbers of Flemings were permitted by Henry I to settle in the hundred of Roose or Rhos in the years 1106–08. 1111 and 1156. The castle, though first mentioned in 1214, is believed to have been built in 1120 by Gilbert de Clare, first earl of Pembroke, to keep an important road to Ireland open and to protect the English and Flemish colonists. It was garrisoned for the king in the Civil War but was captured by parliament in 1644–45 and afterward partly demolished. The church of St. Mary has beautiful 13th-century arches in the chancel, a carved 15th-century oak ceiling and many interesting memorials. The church of St. Thomas has a 15th-century tower, and St. Martin's dates from the 14th century. By the river are ruins of an Augustinian priory founded by Robert de Hmlford *c.* 1200. The earliest charter known is one from Henry II. During the palatinate the town was granted a lord lieutenant, being the only British town to be so favoured. In 1536 Haverfordwest was declared to be a town and county of itself and was further empowered to send representatives to parliament. It remained prosperous through maritime commerce during the 17th and 18th centuries, but with the rise of Milford Haven and the coming of the railways its trade declined. The town came to rely on the marketing of agricultural produce, but still retained an importance out of proportion to its modern significance. A special feature of such towns is the large number of charities which, in Haverfordwest, include John Perrot's bequest (1579) for the improvement of the town and Tasker's charity school founded in 1684. The people of Haverfordwest, like those in the surrounding districts in the southern part of the county of Pembroke, are almost entirely English-speaking.

HAVERHILL, a market town and urban district in the Bury St. Edmunds parliamentary division of West Suffolk, Eng., 19 mi. S.W. of Bury St. Edmunds by road. Pop. (1961) 5.446. Haverhill means "barley hill." The Perpendicular church of St, Mary was restored after a great fire in the town in 1665. There are manufactures of clothing and matting. brushes and twines; a considerable agricultural trade; corn mills; and ironworks.

HAVERHILL, a manufacturing city of Essex county in the lower Merrimack river valley of northeastern Massachusetts, U S., 35 mi. N. of Boston.

It was founded by the Rev. John Ward, who named the settlement after his native Haverhill in Suffolk. Eng. Haverhill was the home of Hannah Dustin, the redoubtable woman who was captured by the Indians in 1697 and managed several days later to slay ten of her abductors and escape. John Greenleaf Whittier (*q.v.*), the New England poet, was born there but lived most of his life in nearby Amesbury. Haverhill was incorporated as a town in f645 and as a city in 1869.

The village was originally agricultural until the growth of leather tanning and shipbuilding after 1795. and later shoe manufacturing and hatmaking became the dominant industries.

The city grew rapidly as the factories attracted many Italians, French Canadians. Greeks and other immigrants, but the total population has steadily decreased since reaching its peak of 53,884 in 1920, after uhich time Haverhill felt the decline of manufacturing common to Merrimack valley towns. Many workers commute to nearby cities, while new industries have been sought. Apart from leather and shoes, coin-operated machines, paper boxboard and electric coils are produced.

Bradford, a small part of the city south of the Merrimack river, was annexed in 1897 and is the seat of Bradford Junior college, founded 1803, one of the oldest upper schools for girls in New England. For comparative population figures *see* table in MASSACHUSETTS: *Population.* (G. K. L.)

HAVRE, LE, the second seaport of France and capital of an *crrondissement* in the *département* of Seine-Maritime, on the estuary of the Seine. 143 mi. W.N.W. of Paris and 55 mi. W. of Rouen. Pop. (1954) 137.175. Until 1516 Le Havre was only a fishing village possessing a chapel dedicated to Notre-Dame-de-Grâce, to which it owes the name. Le Havre (harbour) de Grbce, given to it by Francis I when he began the construction of its harbour.

The town in 1562 was delivered over to the keeping of Queen Elizabeth I by Louis I, prince of Condé. leader of the Huguenots, but the English were expelled in 1563 by Charles IX and his mother, Catherine de Medici. in person. Defenses and harbour works were continued by Richelieu and completed by Vauban. The English bombarded it in 1694, 1759, 1794 and 1795. It was a port of considerable importance as early as 1572 and dispatched vessels to the whale and cod fishing at Spitsbergen and Newfoundland. In 1672 it became the entrepôt of the French East India company and afterward of the Senegal and Guinea companies.

Napoleon I raised the city to a war harbour of the first rank, and under Napoleon III works begun by Louis XVI were completed. During World War I Great Britain and the U.S. used Le Havre as a base and point of landing for troops and stores. Also after the fall of Antwerp and Ostend the Belgian government was transferred there and housed in the Hôtel des Régales at St. Adresse. After the Armistice in Nov. 1918, Le Havre formed one of the U.S. embarkation points.

During World War II the city suffered severe damage. It was captured by the Germans in June 1940 and liberated in Sept. 1944. Le Havre was the target of over 170 bombings, which leveled nearly three-quarters of the city. Reconstruction began immediately after the cessation of hostilities.

The greater part of the town stands on a level strip of ground but on the north rises an eminence, la Côte, the richer quarter. The central point of the town is the Place de l'Hôtel de Ville in which are the public gardens. The church of Notre Dame. dating from the 16th and 17th centuries, is a mixture of late Gothic and Renaissance styles of architecture but the tower is older. The carved oak organ case was the gift of Cardinal Richelieu. The chief buildings of Le Havre, including the *hôtel de ville,* the law courts and the exchange, are all of modern erection.

The museum was totally destroyed during World War II, but its collection of antiquities and paintings had been evacuated. Le Havre is the seat of a subprefect, and a tribunal of first instance, a tribunal of commerce, a board of trade arbitrators, a tri-

bunal of maritime commerce, a chamber of commerce and a branch of the Bank of France. There are 14 basins (the oldest of which dates back to 1669) with more than 8 mi. of quays. A program of port improvements included a large graving dock and wharfage in tidal basin, a floating dock and pontoons, a basin for large oil tankers and reservoirs in the outer harbour, and a wharf and mole for goods storage in the north part of the port. A petroleum pipeline to Paris was built.

The chief docks are the Bassin Bellot and the Bassin de l'Eure. In the latter the mail steamers of the Compagnie Générale Transatlantique are berthed; and the Tancarville canal, by which river boats unable to attempt the estuary of the Seine can make the port direct, enters the harbour by this basin. The port, which is an important point of emigration, has regular steam communication with New York city and with many of the other chief ports of Europe, North, South and Central America, the West Indies and Africa.

Le Havre is the great French port for cotton' and coffee and also imports copper and other metals? wool, rum! foreign wines, oilseeds and dyewoods. Its industries are rope making, timber for building, wire drawing! machinery making, flour milling, oils, dye extracting from woods, spinning and weaving, toy and chemical manufacture.

HAWAII, nicknamed the "Aloha state." was the 50th state to be admitted (in 1959) to the Cnited States. Geographically Hawaii (the Hawaiian or Sandwich Islands) is a chain of islands near the centre of the North Pacific ocean, 1,578 mi. from E.S.E. to W.N.W. between 18° 55′ and 28° 25′ N. and 154° 48' and 178° 25' W. It consists of the islands ceded by the republic of Hawaii to the U.S. in 1898 and made a territory by congress in 1900, and hence excludes the small coral island, Midway, which was acquired by the U.S. in 1859. Several other small islands are not included in the state. The capital is Honolulu (*q.v.*).

Hawaii. with a total area of 6.424 sq.mi., 9 sq.mi. of which are inland water, ranks 47th among the states in land area. The state tree is the kukui or candlenut (*Aleurites Moluccana*) and the state flower is the red hibiscus. The Hawaiian goose. or *nene*, is the state bird (unofficial). The state flag consists of a field with eight horizontal stripes. from the top down of white, red and blue. A rectangular area containing a device resembling the British union jack extends half way down the hoist. (Although Hawaii was never under British rule. an English sea captain in the 1790s is said to have presented King Kamehameha I with a British jack which he used and whose design was incorporated into the present flag of Hawaii, officially adopted in 1845.) The state motto is *Ua mau* ke eu o ka *aina i ka pono* ("the life of the land is perpetuated in righteousness"). The state song is *Hawaii Ponoi* ("Hawaii's Own"), written by King Kalakaua.

In addition to the cross references to related articles given under the various headings of this article see OCEANIA; PACIFIC ISLANDS; POLYNESIA. See also UNITED STATES (OF AMERICA).

Following are the main divisions of this article:

I. GEOGRAPHY

A. PHYSICAL FEATURES

Hawaii, comprising both volcanic and coral islands built up from depths of 15,000 to 18,000 ft., is the northernmost of the Central Pacific island groups. It has the largest area (6.424 sq.mi.) and greatest altitude (13.784 ft.). It is also the most isolated of important land areas.

The nearest important groups to the south are Samoa, 2.263 nautical miles. and Tahiti. 2.390 nautical miles. To the north. Unalaska in the Aleutian Islands is 2,106 mi., and to the west. Guam is 3.337 mi. The distances in nautical miles from Honolulu to principal ports of the Pacific are: San Francisco. 2,100; Los Angeles, 2.226; Seattle. 2.409; Sitka, 2.395; Yokohama, 3,445; Sydney. 4.424; Panama. 4.665; Manila. 4.778; Hong Kong, 4.961: Valparaiso, 5.916. Cape Horn is 6.488 mi.

The large. high islands, Hawaii (4.021 sq.mi. land area), Maui (728), Molokai (259), Lanai (141), Kahoolawe (45), Oahu (595), Kauai (551) and Niihau (72), together with their near-by small islands, form the east-southeast fourth or about 375 mi. of the chain, extending to 22° 14' N. and 160° 15′ W.

The islands of the remainder of the chain are so small that their total area is only 3 sq.mi., and yet they afford a rich field for the naturalist. Those in the west half of this part of the chain are coral (mostly sand) islands; those in the other half, forming a transition link with the large inhabited islands, are lava rock. The islands of the entire chain apparently were formed beginning at the westerly and finishing at the easterly end, where there are still active volcanoes.

1. Westerly Islands. — The small westerly islands are remains of larger islands which have mostly eroded. The lava rock islands rest on more or less extensive banks lying at small depths, and the coral ones are sand islands or islets on the rims of large atolls. Those of lava rock are Nihoa or Bird (903 ft. high), Necker Island (276), French Frigate shoals (a rock 120 ft. high and 16 sand islets) and Gardner pinnacles (170); the coral ones, 10–14 ft. high! are Laysan Island, Lisianski Island, Pearl and Hermes reef (12 islets), Midway (Sand Island and Eastern Island) and Kure, or Ocean, Island (Green Island and two islets). None is inhabited except the station at Midway. The Hawaiians anciently visited Nihoa and Necker, not only for fish but also to obtain materials for their famous featherwork. The waters abound in fish and turtles. The islands are most noted, however, for their bird life, and in 1909 all of them, except Midway, were created by the national government into the Hawaiian Islands Bird reservation, to protect them from Japanese poachers who, for the feathers, killed 300,000 birds in one season. Collectively, the islands form the largest and most numerous bird colony in the world. Of the many varieties of sea birds, some are not found elsewhere.

2. Hawaii. — The "Big Island," as it is called, which contains two-thirds of the area of the group, is roughly triangular in shape, with sides of 90, 75 and 60 mi.; it consists of five volcanic mountains about 20 mi. apart, connected by saddles 3,000–7,000 ft.

high, formed by overlapping lava flows. Being the newest island, and still in the making by volcanic action. little of its 297 mi. of coast is bordered by coral reefs, and there has been little erosion except along the 60 mi. of the northeast coast from the principal harbour, Hilo, to the north end of the island. There, on the windward side of the older mountains, copious rains and ocean waves and currents have created valleys and cliffs increasing northward in depth and height and culminating in the Waipio and Waimanu valleys, which are several thousand feet deep and recede from coastal cliffs 1,500 ft. high. Throughout the rest of the island there is not a stream except at times of unusual rain—partly because of the porosity of the rocks and soils and, on the leeward side, partly because of insufficiency of rain.

The Kohala mountain or range (5,505 ft.), the oldest, its windward side deeply eroded. its top a water sponge, its leeward side dry, with the higher slopes covered with cinder cones. forms the north angle of the island. Next, southeasterly, is Mauna Kea ("White mountain," so-called from the frequent snow on its summit). This is the highest mountain of the group and one of the highest island mountains in the world (13,784 ft.).

Southwesterly from Mauna Kea is Hualalai (8,251 ft.), whose summit, like that of Mauna Kea, has no great crater and is covered with cinder cones, but, unlike Mauna Kea, has many small pit craters. Its only flow in historic times was in 1801.

Further south is Mauna Loa, "Long mountain," twin of and 104 ft. lower than Mauna Kea. It is an immense lava dome, not only the largest volcano, but the largest mountain in the world in cubic content; it discharges more lava than any other volcano. On the summit is an elongated caldera ("caldron"). Mokuaweoweo (3.7 sq.mi.). Eruptions within it occurred in historic times in 1849, 1865, 1903 and 1914; four others were partly on the adjacent rift zones, usually on two lines running northeast and southwest from the summit. Principal flows of the 19th and 20th centuries were in 1843, 1852, 1855–56 (lasting 16 months), 1859 (33 mi. long, 1 mi. wide in places). 1868, 1877 (submarine), 1880–81, 1887, 1899, 1907, 1916, 1919, 1926, 1935–36 (bombed to divert its course), 1942 and 1950 (the most voluminous flow in recorded history: 615,000 cu.yd. in three weeks). In 1955 a violent outbreak in the Puna district south of Hilo lasted for three months and destroyed two villages.

Lastly and easternmost is Kilauea, with the largest and most spectacular of all active craters, an oval pit 4.14 sq.mi. in area, with walls now 500 ft. high—1,000 ft. a century ago. Although an independent volcano and older than Mauna Loa. Kilauea is merely a hole in the side of the latter at an elevation of 4,090 ft.; it is reached by car in an hour, over 30 mi. of concrete road through tropical forests from Hilo.

Kilauea was continuously active for more than 100 years previous to 1924. Most of its activity has been confined to the fire pit of Halemaumau, 3,000 by 3,500 ft. and 470 ft. deep. Operating in cycles, the lava rises until it overflows and breaks through some subterranean passage and drains out. only to begin the cycle again. Just before the last dropout, in 1924, the lake of boiling molten lava covered about 50 ac. In 1954 a spectacular but short-lived eruption flowed on the floor of Kilauea as well as in the fire pit, Halemaumau. The only two explosive eruptions of historic times have occurred at Kilauea, in 1790 and 1924; the former destroyed a portion of a Hawaiian army. Since that time, almost no loss of human life has been caused by volcanoes in Hawaii.

In 1911 a volcanic observatory was established at Kilauea, and in 1916 the national government created the Hawaii National park. consisting of the Kilauea and Mauna Loa sections (245 sq.mi. together) on Hawaii and the Haleakala section (26 sq.mi.) on Maui (see below), to which was added in 1927 a strip (72 sq.mi.) connecting the first two sections. In the Kilauea section, besides the volcano, there is much of interest, such as numerous other pit craters, sulfur banks, pumice beds, lava tubes, tree molds, stalactites, tropical forests and birds and sulfur-steam baths.

Earthquakes have been numerous and tidal waves occasional in Hawaii. On April 1, 1946, the entire Hawaiian chain was struck by a seismic sea wave. Two hundred persons were killed and 1,300 rendered homeless. Damage to public and private property was $24,000,000. The waterfront area of the city of Hilo was wiped out. Since that time a seismographic warning system has been put in operation to alert residents when waves are expected.

3. Maui, Molokai, Lanai, Kahoolawe and Molokini (the last two uninhabited), probably once a single island, are now separated by channels 6 to 10 mi. wide and 250 to 600 ft. deep. They are separated from Hawaii by a channel 26 mi. wide and 6,192 ft. deep and from Oahu by one 23 mi wide and 2,244 ft. deep.

Maui, shaped like the head and bust of a woman, consists of two mountains (East and West Maui) connected by a low isthmus 6 mi. wide. One of these mountains, Haleakala ("House of the Sun," 10.02 j ft.), has on its summit the largest of all extinct craters, 20 mi. around and 2,720 ft. deep; on its floor of 19 sq.mi. are 16 reddish cinder cones 400 to 900 ft. high. The view from the summit is the grandest in the territory. The windward side, a succession of gorges, rich in waterfalls and verdure. supplies the water for the irrigation of the arid isthmus. It is traversed by a scenic drive. The other mountain, whose highest peak is Puu Kukui (5.788 ft.), being much older, is marked by deep radiating canyons such as the beautiful Iao or Wailuku valley (4,000 ft. deep).

Molokai likewise consists of two mountains, Mauna Loa peak (1,415 ft.) at the west end and Kamakou (4,970 ft.) at the east end, connected by a saddle 400 ft. high, both cut off by erosion on the windward side, so that the island, which is 40 mi. long, is narrow and of fairly even width. about 7 mi. The windward side, one of the most scenic coasts of tlie group. is a precipice. 500 to 4.000 ft. high, sheer from the ocean, the highest part of which is deeply indented by magnificent valleys. On a low peninsula, projecting from the base of the precipice and near its centre, is the site of the leper settlement of Kalawao, which is virtually empty because of the advance of treatment methods.

Lanai (3,370 ft.) and Kahoolawe (1,491 ft.) are single mountains, with cliffs on their southerly coasts exposed to the ocean, their northerly coasts being protected by Maui and Molokai. A pineapple company, having acquired Lanai, constructed a harbour on the south coast and a model village, Lanai City. in the centre of an extensive interior plateau, which has been placed in cultivation. Kahoolawe is uninhabited and for some years has been used as a target area by U.S. armed forces. Molokini is a small, crescent-shaped, barren, rocky island, 160 ft. high, between East Maui and Kahoolawe.

4. Oahu, which is roughly diamond shaped, was once two immense volcanoes; erosion has made of it two rugged, parallel mountain ranges. One range, Koolau (Puu Konahuanui. 3,105 ft.), is twice as long as and older than the other, Waianae (Kaala, 4,025 ft.); the two are connected by a saddle 800–1,200 ft. high. There are many small, recent tuff, ash and lava cone craters, mostly coastal, especially in and about Honolulu. such as Diamond Head and Punchbowl. This island, though third in size and fifth in height. is important agriculturally. It contains the state capital, Honolulu, the landlocked Pearl Harbor (see HONOLULU), Diamond Head and Waikiki beach. The picturesque sites of this island are easily accessible; the most noted panoramic view is that of the windward side at the Pali (precipice), the only traversable pass (1,200 ft.), 6 mi. up a beautiful valley back of Honolulu.

5. Kauai, separated from Oahu by a channel 63 mi. wide and 11,232 ft. deep, is roughly circular in form, about 25 mi. across, and consists mainly of one mountain (Waialeale, 5,080 ft.), with marginal lowlands except on the northwest. It is the oldest, most weathered and most verdant of the larger islands, abounding in rivers and waterfalls. Its chief scenic attractions are Waimea canyon (3,000 ft. deep) in the southwest, comparable in vivid colouration and forms to the Grand canyon of the Colorado; the spacious Hanalei valley in the north; and the Napali coast of precipices, 4,000 ft. high, on the northwest.

6. Niihau, separated from Kauai by a channel 15 mi. wide and 3,300 ft. deep, is a small island 17 by 6 mi.; it is privately owned and is operated as a sheep ranch. Lehua Island and Kaula, uninhabited, are crescent-shaped remains of tuff cones, respectively ½ mi. N. and 23 mi. S.W. of Niihau.

B. Climate

The chief determinants of the climate are the prevailing northeast trade winds from over cool ocean currents and the remarkable heights and contours of the land areas. The result is a climate cooler than elsewhere in the same latitude, equable temperatures, abundant sunshine and absence of tropical storms. Mauna Loa on Hawaii and Haleakala on Maui form such barriers to the trade winds that their leeward slopes have regular land and sea breezes. At times, especially in winter, a kona, or southerly wind, brings mugginess and local downpours. The windward slopes are cooler than the leeward, and the temperature falls about 1° F. for each 300 ft. of altitude. The year-round average temperature in the lowlands is about 75° F. There is no distinctly rainy or dry season, but usually more rain falls in winter than in summer. There is wide variation in temperature, rainfall and wind for neighbouring localities.

The record high temperature for the territory was 100° F. at Pahala, Hawaii, in April 1931. Except for the top of Mauna Loa, the record low of 18° was reached at Haleakala crater in May 1941. The mean annual temperature at the federal building at Honolulu is 75.2°, with a record maximum of 88° and a record minimum of 57°. Usually there is snow on Mauna Kea and Mauna Loa and sometimes on Haleakala. The summit of the island of Kauai has perhaps the greatest average rainfall in the world, 468 in., reaching 624 in. during the year ending in July 1948. The greatest precipitation measured in the islands during a 24-hour period was in the lowlands of Kauai, in Jan. 1956, when more than 46 in. fell. As little as 4 in. a year has been found in the Kona region of Hawaii. At the federal building in Honolulu on leeward Oahu, the average annual rainfall is 24 in., with a record range of from 43.5 to 11.7 in. Four miles distant, at 1,028 ft. in the lee of the mountain ridge, the average is 155 in. The record rainfall for Honolulu in a 24-hour period came in March 1958, with a downpour of more than 18 in.

C. Vegetation

The isolation of Hawaii, its division into islands, the barriers of deep canyons and high precipices and the wide variations in rainfall, temperature, wind, barometric pressure and geologic age of different localities have evolved a flora that not only is exceptionally extensive in the area, but ranks first in the world in percentage of endemic genera and species. There are about 900 species of flowering plants (more than 300 being trees), 140 ferns and also many hundred mosses, lichens, fungi and algae. Attractive forests of tall tree ferns are hung with vines such as the luxuriant ie and the fragrant *mazle,* both used as garlands or *leis.* The unique silversword plant is found in Hawaii National park. The forests are tropical and only a few shed their leaves seasonally.

Six botanical regions or zones are commonly treated more or less separately: strand, lowland, lower forest, middle forest, mountain bog and upper forest, with subdivisions of dry and wet, windward and leeward, etc.. each having in large measure its distinct flora. but with considerable overlapping. Above 11,000 ft. there is almost no vegetation.

Hundreds of species have been introduced into the islands since their discovery by Europeans and about 25 were introduced anciently by the Hawaiians. Among the ancient introductions are the coconut; breadfruit; ohia or Malay apple (*Jambosa malaccensis*); taro (*Colocasia antiquorum*), used for making a paste (poi), the principal food of the Hawaiians; sweet potato; yam; banana; pia or arrowroot (*Tacca pinnatifida);* sugar cane; gourd; kava and ti (*Piper methysticum* and *Cordyline terminalis*). roots used for making drinks; olona (*Touchardia latifolia*), yielding exceedingly strong and durable fibre for fish nets, etc.; *wauke* (*Broussonetia papyrifera*), fibre used for making kapa or paper cloth; *kukui* or candlenut (*Aleurites moluccana*), useful for candles. oil, dyes, paint, gum, food and medicine; milo (*Thespesia populnea*) and kou (*Cordia subcordata*), now almost extinct, and *kamanz* (*Calophyllum znophyllum*), all three yielding beautiful wood valued for making calabashes and other dishes; hau (*Pariti tiliaceum*), useful for making outriggers and rope and training over arbours for shade; *noni* (*Morinda citrifolia*), useful for dyes; and perhaps ginger, Among the more common later introductions are the avocado or alligator pear, mango. pineapple, orange and other citrus fruits. papaya, guava, coffee, grape, fig. poha or Cape gooseberry, litchi, mulberry, tamarind, date, passion fruits, cherimoya, custard apple and macadamia or Australian nut.

D. Animal Life

Isolation and wide variations in local conditions have had much the same effect, though in lesser degree, on the fauna as on the flora, resulting in a high percentage of native species and extreme localization. There is only one certainly indigenous land mammal, a small bat. Dogs, hogs and perhaps rats and mice were introduced anciently by the Hawaiians, and many domestic mammals have been brought in since Captain Cook's discovery; some very early, as goats and English pigs by Cook in 1778, cattle and sheep by George Vancouver in 1793 and horses by R. J. Cleveland in 1803. Axis deer *(Cervus axis)* were introduced in 1867 and the mongoose in 1883, to destroy rats.

There were about 125 species of birds, resident and migrant, of which perhaps a score are now extinct. On the inhabited islands the native birds are disappointingly few, as their habitats are mostly in the forests and on the heights. Most prized for featherwork were the yellow feathers of the now extinct mamo *(Drepanis pacifica)* and nearly extinct o-o *(Moho nobilis)*; the vermilion of the iiwi (*Vestiaria coccirzea)*; and the crimson of the apapane *(Hinzatione sanguinea)*. Very common are the brown *elepaio* (*Chasiempis sandwicensis*); the green and yellow *amakihi (Clzlorodrepanis* spp.); and the *ou (Psittirostra psittacea)*, the best Hawaiian songster. A wild goose, *nene (Bernicia sandwicensis)*, confines itself to dry areas on the island of Hawaii. The birds most commonly seen on the lower and more open areas are introductions. Chickens were anciently introduced by the natives, and later importations include, besides domestic fowls, the skylark: cardinals, Chinese thrush, myna, turtledove, pigeon, linnet, blue-cheeked parrot, ricebird, English sparrow, pheasant, quail and California partridge.

The only native land reptiles are seven species of small skinks and geckos, commonly called lizards. There are no snakes. Frogs and toads are introductions, including *Bujo marinus,* imported in 1932 to control insects. Although there are several thousand species of indigenous insects, mostly endemic, they are not troublesome or destructive. The noxious forms, which are mostly introductions, include the sugar-cane leafhopper and borer, rice borer, Mediterranean fruit fly, Asiatic fruit fly, melon fly, Japanese beetle, horn fly, cutworms, army worms, termites, fleas and mosquitoes. Perhaps no animal group has contributed more light on the subject of evolution than the joo species of land and freshwater shells of Hawaii, especially the beautiful tree shells (*Achatinella).* The exceptionally rich marine animal life includes more than 650 species of fish, many of which are fantastic in shape and colour. Among introduced fishes are trout, carp, black bass, catfish, goldfish and top minnows.

E. Geographical Regions

The territory of Hawaii was divided into five counties by the territorial legislature in 1905 and these revisions were retained when the territory became a state in 1959. These are county of Oahu (superseded in 1909 by city and county of Honolulu); county of Maui (including islands of Maui, Molokai—except Kalawao—, Lanai, and Kahoolawe), with county seat at Wailuku; county of Hawaii, with county seat at Hilo; county of Kauai (including the island of Niihau), with county seat at Lihue; and county of Kalawao, the peninsula on Molokai. (For area of city and county of Honolulu, *see* Honolulu.)

II. THE PEOPLE

Hawaii is often called the melting pot of the Pacific, because its population is a mixture of many ancestral stocks who are slowly welding a neo-Hawaiian type combining features from not only Caucasian, European groups but from those of the Pacific islands and the far east as well (see History, below).

The descendants of the Polynesians who came to the islands 1,000 years ago are called Hawaiians. They have bronze skin, large dark eyes, heavy features and dark-brown or black hair that may be straight or wavy. The population of about 300.000 found by the discoverers in 1778 shrank until at the beginning of the second half of the 20th century there were only about 12.000 full-blooded Hawaiians in Hawaii—slightly more than 2% of the population. There were, however, about 80.000 part-Hawaiians, and together the Hawaiians and part-Hawaiians formed the fastest expanding racial group.

People of many other stocks came to the islands or were brought to work on the sugar plantations (see *Population*, below). Most of these folk, enjoying the opportunities provided in Hawaii, successively left the ranks of unskilled labour, and those of Chinese. Japanese, Korean and Filipino ancestry entered all walks of life, including the professions and finance.

TABLE I.—Population by Racial Groups

Race	1950		1940	
	Number	%	Number	%
Hawaiian	86,091	17.2	64,310	
Caucasian	114,793	23.0	103,791	24.5
Chinese	32,376	6.5	28,774	6.8
Filipino	61,071	12.2	52,569	12.4
Japanese	184,611	36.9	157,905	37.3
Others	20,852	4.2	15,981	3.8
Total	499,794	100.0	423,330	100.0

After 1950 racial data were not kept because the intermixture of groups made it impossible to list individuals even according to race of father. The oriental component was steadily declining in proportion; the Caucasian group had grown in the first half of the 20th century and the trend was not altered after World War I. Intermarriage of racial groups is very common in Hanaii, and many of the finest physical specimens are of half a dozen stocks. In a schoolroom in the islands, the children may be of 50 different combinations of racial ancestries. There is no segregation in the islands of any kind, and no housing area where there is a barrier to home ownership. Anyone who stirs up racial antagonisms is severely criticized, and Hawaiian or oriental blood is frequently a political asset in the state.

The daily life of the people may vary from the metropolitan existence of Honolulu to the sheltered seclusion of Niihau, an island where Hawaiians speak their own language and do not have telephones, automobiles, motion pictures or liquor stores.

1. Languages.—English is spoken by almost everyone in Hawaii. Hawaiian is one of the two official languages of the government, but except for a number of loan words used daily by the inhabitants, one has to go to some trouble to hear Hawaiian spoken. Many other languages may be heard on the streets, and radio programs in Japanese and several Filipino dialects are popular.

2. Religion.—All the great religions of the world are represented in Hawaii. In 1819 a royal decree ordered the Hawaiians to give up their paganism, and the field was open to the Congregationalist missionaries who arrived from New England in 1820. Roman Catholic missionaries came first in 1827, and Mormons in 1850. (See also History, below.) Religious tolerance as well as racial tolerance is a part of island life. There are more than 150 churches on Oahu alone. The Roman Catholic and Buddhist religions were the leading faiths in Ha aii at mid-20th century.

3. Customs and Culture.—The spirit of hospitality represented by the welcoming Hawaiian word *aloha* has continued through history to make the stranger feel at home in those islands. Easy informality is found in the customary dress of 20th-century Hawaii. Outside of business offices, people of all races wear both traditional and modern versions of Hawaiian garments. The women at home relax in a *muumuu*, modeled on the Mother Hubbard gowns made for the natives by missionary women. A fitted *muumuu* with a train is called a *holoku*. Men wear *aloha* shirfs all year round; these are patterned sport shirts. usually worn with the tail outside the trousers. Flowers are a favourite expression of affection, and on many occasions a lei, or wreath, is presented. A lei may be formed of flowers or of seeds, coral, shells. nuts, or pieces of ivory, and may be worn not only around the neck but on the head or around a hat.

Foods enjoyed in the islands are as varied as the many nationalities and races represented there. Most people eat foods similar to those consumed in mainland United States. but special dishes of the orient and the Pacific islands are popular. At a *luau* or Hawaiian feast, one might eat poi, a starchy paste made from the pounded root of the taro plant; *laulau*, a steamed package of chopped taro leaf mixed uith fish and pork or chicken; salmon and tomato; *haupia*, a coconut pudding; limu. an edible seaweed; steamed yams, breadfruit and bananas; and pineapples, papayas and mangoes. The main dish is usually a whole roasted pig, cooked by preheated stones in an underground oven or imu.

The mild climate makes Hawaii a recreational paradise all year round. Hotels and vacation resorts provide comfort for visitors on the five largest islands. Water sports are particularly popular, and the ocean temperature varies little from summer to winter.

During the winter months there is skiing on the slopes of Mauna Kea. In addition to the usual U.S. holidays others are celebrated. These include Chinese New Year's, in January or February; Cherry Blossom festival. in the spring; Lei day, on May 1; Kamehameha day. June 11; and Aloha week, in October or November.

Arts and crafts are popular in Hawaii, reflecting the skill of the ancient Hawaiians in such forms as featherwork. wood carving and mat weaving. examples of which may be seen at the Bishop museum in Honolulu.

Early Hawaiian music mas a chant accompanied by simple instruments. Enjoyment in singing hymns introduced by the missionaries led to the development of vocal music, so that today Hawaiian music is heard round the world. The words to the most famous Hawaiian song, "Aloha Oe" ("Love to Thee"), were composed by Queen Liliuokalani. The ukulele was not native to the islands but was developed from a small guitar brought by Portuguese labourers in the latter 19th century. The steel guitar was invented in 1895. The Royal Hawaiian band. formed in 1872, still gives concerts in Honolulu. The Honolulu Symphony orchestra was founded in 1900.

Performances of various forms of hula may be seen in Hawaii, but it is increasingly difficult to find exhibitions of the ancient hula, the sacred dance and chant of prediscovery Hawaii.

The literature of Hawaii both in Hanaiian and English is extensive and still groning. Ancient types, drawn from native memories, include legends, folk tales, epics of heroes and chants. The missionaries early reduced the Hawaiian language to a Roman alphabet, established printing presses and translated many works into both Hanaiian and English. Both the Bible and the Book of Mormon were translated into Hawaiian, along with textbooks and literary works. Many accounts of voyagers. mission workers and travelers are highly readable. Writers associated with the islands include Herman Melville, Mark Twain, Robert Louis Stevenson. Charles Warren Stoddard. Jack London and Genevieve Taggard. A number of 20th-century novelists and other writers have added to the shelf of works using Hawaii as a setting.

III. HISTORY

A. History Before Discovery

Polynesia was probably the last habitable area to be occupied by man. The Polynesians, although of similar features, language, customs, religion and traditions. are not a pure race. They are supposed to be mainly of Caucasian origin, with infusions of other bloods. and to have come from Asia by way of the Malay peninsula and Java, and thence from island to island by various routes in their migrations eastward. northward and southward. and to have reached Hawaii, probably from Tahiti, about A.D. 750, or earlier, in huge sailing canoes. Until about 1300, some Hawaiians voyaged back and forth to Tahiti, more than 2,000 mi. to the south. During this period many chiefs, who intermarried with Hawaiian reigning families, and priests came to Hawaii; both classes became powerful and the severity of taboos and frequency of human sacrifices increased. Then followed a long period of isolation, the last centuries of which were full of wars and rebellions — the result of pressure of population, rapacity of the nobility and dynastic ambitions and jealousies.

Feudalism grew up much as it did in medieval Europe and from much the same causes. The unit of land, the *ahupuaa,* usually extended from the shore to the mountain top, with rights in the adjoining sea waters, so that the occupants had the means of supplying all their wants — the sea for fish, the littoral for coconuts, the valley for taro, their principal food, the lower slopes for sweet potatoes, yams and bananas and the mountain for wood.

The next subdivision was called the *ili,* either subservient to the *ahupuaa* or independent. Within these were small areas: *kuleanas,* occupied by the common people, who also had certain rights of fishery, water and mountain products. Besides open sea fisheries, there were stone-walled fish ponds, some now 1,000 years old, built semicircularly from the shore. Taro was raised in terraces flooded by conduits from streams. Elaborate systems of water rights were evolved. A conqueror or a successor king often redistributed the lands.

The Hawaiians were a brown race, with straight or wavy black hair, attractive features, large and of fine physique, like the New Zealand Maoris, whose dialect resembled theirs. The ruling classes tended to inbreed. Polygyny and polyandry were practised, especially among the chiefs. Rank descended mainly through the mother.

The language is soft and musical, vowels and liquids predominating. There are only 12 letters, the vowels and *h,* k, *l, m, n, p* and *w, l* and *r* and k and *t* being very similar, and, as each syllable consists of only a vowel or a consonant followed by a vowel, there are only 40 syllables to make the more than 20,000 words. The Hawaiians were fond of oratory, poetry, history, storytelling, chants, riddles, conundrums and proverbs, and paid much attention to the proper use and pronunciation of words. Without writing, knowledge of all sorts was preserved and taught to successive generations by persons specially trained for the purpose.

Without metals, pottery or beasts of burden, the people made implements, weapons and utensils of stone, wood, shell, teeth and bone, and great skill was displayed in arts and industries. The featherwork (capes, robes, helmets, *leis,* kahilis) has not been excelled. Houses were of wood frames and thatched, with stone floors covered with mats. Food was cooked in holes in the ground, imus, by means of hot stones, but many foods, including fish. were often eaten raw. Many of the best foods were taboo to women. Men usually wore only a *malo* or girdle and women a skirt of kapa or paper cloth or leaves or fibre, though both sometimes wore mantles thrown over the shoulders. Canoes were outrigger or double, sometimes 100 ft. long. The men have hardly been surpassed as sailors. fishermen or swimmers. They were skillful navigators, knowing stars, winds and currents. Their year began on Nov. 20 and consisted of 12 lunar months with occasionally an intercalary month They had remarkable knowledge of animals and plants and mere great warriors, using spears, javelins, clubs and slings, but no shields or bows. the latter being small and used only for shooting rats and mice for sport.

They excelled in athletics, in which there were frequent contests, even between champions of different islands, in surfboarding on the crests of waves, swimming, wrestling, boxing, spear throwing (at each other), coasting down permanently prepared courses while standing on narrow sleds, bowling, foot racing, etc. Surfing has become a favourite sport for others as well as Hawaiians. They gambled much and made narcotic and fermented drinks of the awa (kava) and ti roots! but not distilled liquors. They were fond of music: vocal and instrumental, and had percussion, string and wind instruments, including a nose flute but no mouth flute. The ukulele is of Portuguese origin, developed and popularized by the Hawaiians. Their dances were largely the hula of many varieties, the better forms of which have become popular with others. They loved flowers, which they wore much in *leis* or wreaths about necks and hats. This has become customary with non-Hawaiians, especially on arrivals and departures of steamers and airplanes and on May day. They tattooed little. Their proverbially courteous, generous, hospitable spirit has affected the remainder of the population.

There were four principal gods, Kane, Kanaloa, Ku and Lono, and innumerable lesser gods and tutelary deities. Animals, plants, places. professions, families, all objects and forces had their gods or spirits. Temples of stone and idols of wood abounded and hardly anything was undertaken without religious ceremonies. On important occasions there were human sacrifices. There was a vague belief in a future state. Priests and sorcerers were potent. There were cities of refuge to which one might flee and be safe. Cannibalism was unknown but infanticide was prevalent. The political and religious systems were closely interwoven.

During the last period before the discovery, although there were occasional bright intervals and notwithstanding that there was much that was praiseworthy, the nobility and priesthood became more and more tyrannical, the common people more and more oppressed; the laws, chief among which were the intricate and oppressive taboos, bore heavily upon the masses, especially the women, and their administration became largely a matter of arbitrariness and favouritism. (See also Oceania; Pacific Islands; Polynesia.)

B. History After Discovery

Foreigners other than Polynesians who may have arrived in Hawaii as castaways prior to 1778 did not return to the civilized world. Capt. James Cook (*q.v.*), the English navigator, is regarded as the discoverer. He named the group the Sandwich Islands after his patron, the earl of Sandwich. Cook first landed at Waimea, Kauai Island. on Jan. 20. 1778. The natives thought him the god Lono. On his return the next year, he was killed, after a period of friendly relations with the natives, on Feb. 14, 1779, in an affray at Kealakekua bay, Hawaii, where a monument to him now stands.

Then followed a period of contact with premissionary whites (1778–1820), a period of political consolidation and religious disintegration. Kamehameha I, the most striking figure in Hawaiian history, came to the throne of one of the then four kingdoms in 1782 and, equipping himself better than his foes with vessels, firearms and foreign and native aids, succeeded by 1795 in conquering all the islands except Kauai and Niihau, and in

securing these two by cession in 1810. Having effected consolidation, he organized the government. checked oppression. encouraged industry and suppressed crime. until, as it was said, "the old, men and women, and little children could sleep safely in the highways." He thwarted Russian designs upon the island (1815–16) and eliminated Spanish pirates (1818). It was in this period that the sandalwood trade developed. In 1804 an epidemic, probably cholera, destroyed much of the population.

A new period opened after the accession of Kamehameha II (Liholihoj in 1819 and the arrival of the first company of missionaries from New England on March 31, 1820. Fourteen other companies followed during the next 3j years, in all more than 1jo men and women—ministers, teachers, physicians, printers, farmers and businessmen. They introduced the church, the school and the press. The Hawaiians were most eager to learn. By Jan. 7, 1822, the missionaries had learned the language, reduced it to writing and begun printing the first textbook. Two months later the first printed law was issued. By 1840. 50 books had been printed. In 1834 two Hawaiian newspapers were published. An English newspaper: founded in 1843, is still published. The Sew Testament was completed in 1832, the Old in 1839, the dictionary in 1865. Of great assistance was William Ellis. English missionary in Tahiti, who visited Hawaii in 1822. While Christianity soon came to be regarded as the national religion and churches were well attended everywhere, little interest was taken in it as a personal matter until 1829, when there were 18; church members, of whom 117 joined that year.

Interest culminated in the great revival of a decade later! which added one-fifth of the population to church membership. The first convert (1823) was Keopuolani, head queen of Kamehameha, mother of the next two kings and highest chief by blood in the nation. Indeed the chiefs, especially the females, led in embracing and supporting the new religion and learning. Kaahumanu, Kamehameha's favourite queen. was converted in 1825 and was thereafter known as the "New Kaahumanu," as strong for good as she had theretofore been haughty and cruel. Of the ten who joined the church in 1826. nine mere chiefs, including Kalanimoku, known as the "Iron Cable." Kamehameha I had appointed Kaahumanu to be his *kuhina nui,* or premier. with power almost equal to that of the king. She acted as regent when the king and queen visited England in 1824. and, they having died there she continued as regent until her death (1832). Kalanimoku had been prime minister and treasurer to Kamehameha I and continued as such under Kaahumanu until his death in 1827.

The first score or so of years after the arrival of the missionaries was a crucial period, not so much because of the opposition of the Hawaiians as because of the opposition of whites. This opposition came, most dangerously, from British, French and U.S. consuls and naval officers. They opposed the laws against licentiousness and drunkenness, slandered the missionaries, made unjust claims against the government, insisted that they were not subject to Hawaiian laws, attacked with arms the homes of missionaries and chiefs and aimed at the overthrow of the government. The British consul claimed that the islands had become British territory.

1. Growth of Government. — This period was not without bright spots in helpful foreign influences both from residents and from such visitors as Lord Byron of the Royal Navy, cousin of the poet, who brought back the bodies of the king and queen in 1825, and Capt. Thomas ap Catesby Jones (1826) and Captain W. B. Finch (1829) of the U.S. navy, the former of whom negotiated the first treaty entered into by Hawaii. Whaling had become active in 1820 and the sugar industry in 1835.

The first Roman Catholic missionaries arrived in 1827, as part of a French settlement scheme. The priests mere resented by the Hawaiian chiefs not only as colonizers but for religious reasons, because by this time Protestantism had virtually become the state religion. During the next decade, attempts to set up Catholicism were resisted and some native converts were punished. But in 1840 the cornerstone of a Catholic church was laid in Honolulu and from that time dates the expansion of membership which made Catholicism the most numerous Christian denomination in the islands *(see* also *The People: Religion,* above).

The first mission of the Mormon sect arrived in 1850 from the California gold diggings. Almost at the outset this group learned the Hawaiian language and appointed native converts to various church offices. The Book of Mormon was printed in Hawaiian in 1854. The Mormons continued to be active in mission work, their success being symbolized by their temple, a landmark at Laie on the island of Oahu.

Because of increasing complications with foreigners, growth in liberal and humane sentiments on the part of the chiefs and realization of their natural rights by the common people. a conviction arose of the need of a better defined and more advanced form of government as a condition of peace, progress and independence. After vain attempts to secure teachers of the science of government from New England, the missionaries were induced to detach one of their number, William Richards (1793–1847), U.S. Congregational clergyman, to the service of the Hawaiian government, in 1838. He gave valuable advice to the government as did two other missionaries, G. P. Judd and R. Armstrong, similarly detached later. After hearing a course of lectures on government (1839) delivered to the king. chiefs and leading commoners, Kamehameha III promulgated the Declaration of Rights, called Hawaii's Magna Carta, June 7, 1839, the Edict of Toleration, June 17, 1839, and the first constitution, Oct. 8, 1840. This first written constitution for Hawaii contained several innovations: including a representative body of legislators elected by the people. It also set up a supreme court. The first compilation of laws was published in 1842 and in that year Richards obtained recognition of Hawaiian independence by the United States, which was formalized by U.S. secretary of state Daniel Webster in July 1843; Richards later obtained recognition by Great Britain and France.

Contrary to the usual course of history, in Hawaii democratization evolved from the top downward rather than from the bottom upward.

But troubles with foreigners were not at an end. French naval officers in 1839, 1842, 1849 and 1851 made unjust demands. the first and third times accompanied by force. A British naval officer took possession in 1843 and held it until the flag was restored by higher authority. After the ceremonies, the king, addressing his people on the means of preserving independence, used the expression *"Ua mau ke ea o ka* ***aina*** *i ka pono"* ("The life of the land is perpetuated by righteousness"), which became Hawaii's official motto.

Further troubles with foreigners, and especially the outrageous French demands of 1849 and 1851, led to diplomatic missions and, in the latter year, a secret proclamation putting the islands under the protection of the United States. The French: having learned this, retracted and the United States declined the protectorate, but, as a result of further troubles and dangers, within and without, including threatened filibustering from California and the "manifest destiny" sentiment awakened in the United States by the acquisition of the Oregon territory and California, negotiations were opened in 1854 for annexation to the United States. They were terminated by the death of the king. The troublesome foreign representatives were removed and fairer treaties entered into.

2. New Codes.—An able lawyer: John Ricord. was appointed attorney general in 1844 and made a famous report to the legislature of 1845, as a result of which he was requested to draft comprehensive organic acts, which were enacted in 1846–47. W. L. Lee was appointed chief justice in 1846. He was chief drafter of the penal code of 1850 and the more modern constitution of 1852 and chief compiler of the civil code of 1859. Most important of these reforms, perhaps. was the Great *Mahele,* or division of lands. which provided a basis for modern land titles in the islands. Action was taken in 1845 and subsequent years by which the old feudal tenures were changed to allodial (absolutely independent), and the interests of government, crown, chiefs and common people were severed and all claims adjudicated by a board of which Lee was chairman. R. C. Wyllie, a Scot, was minister of foreign affairs 1845–65. For able and untiring service, Lee, Wyllie and Ricord are among the outstanding personages in Hawaiian history.

A tower of strength was Kekuanaoa (father of Kamehamehas IV and V), governor and judge of Oahu. The long and fruitful reign of the liberal-minded Kamehameha III ended on Dec. 15, 1854. Hawaii had become a civilized and Christianized country with constitutional government, highly creditable legislative, executive and judicial branches, secure personal and property rights, allodial tenures, modern industries, the respect of other nations and assured independence.

The next two kings. high-minded, educated and traveled. Kamehameha IV (1854–63) and V (1863–72), were slightly reactionary and pro-British. The former and his consort. Queen Emma. are remembered for founding the Queen's hospital (1860) and introducing (1862) the Episcopal Church. The U.S. board of missions (Congregational), which had sent out workers since 1820, deeming Hawaii qualified to graduate from the field of Christian missions, in 1863 transferred its work to the Hawaiian board. Kamehameha V, after calling and dismissing a constitutional convention, himself promulgated a new constitution (1864).

With his death ended the beneficent Kamehameha dynasty. and after the brief reign (1873–74) of 'the liberal, popular, pro-American Lunalilo, elected against Kalakaua, came the decidedly reactionary reign (1874–91) of the latter, elected as pro-American against Queen Emma as pro-British. At first Kalakaua ruled fairly well and was largely instrumental in bringing about the Reciprocity treaty with the United States (1876). The treaty was terminable after seven years on one year's notice. An extension for a like term was obtained in 1887 but only by giving the United States the exclusive right to enter Pearl Harbor and maintain a naval coaling and repair station there.

3. Reaction and Annexation.— There was ever-increasing endeavour by the king to restore the ancient order nith its customs and ideas of absolutism and divine right, accompanied by extravagance. corruption. personal interference in politics and fomentation of race feeling, until he was compelled to promulgate (1887) a new constitution providing for responsible ministerial government and other guarantees. The struggle continued. however, not only until the end of his reign (1891), during which there was an armed insurrection (1889) by the opposition, but even more hotly during the reign of his sister, Liliuokalani. She had rare qualities as a poet and musical composer and mas interested in welfare work; however, it was deemed necessary to depose her (Jan. 17. 1893) and set up a provisional government, with annexation to the United States as its aim.

This failed for the time being, and a republic was established. July 4, 1894 It continued. disturbed only by an unsuccessful insurrection in 1895. until annexation was accepted by joint resolution of congress in 1898, and further until the territory was established. June 14, 1900.

4. Hawaii, **U.S.**—In 1900 the people of Hawaii, now American citizens. began striving to earn an honoured place in the nation. Population trebled under U.S. administration. The islands slowly won a niche in the national economy, producing sugar and pineapple products for mainland consumption. In turn. Hawaii as a customer for mainland goods was yearly paying about $400,000,000 for these goods by mid-20th century. The third source of income in Hawaii was the growing tourist industry, which met the demand for a romantic vacation spot.

Politically, the islanders slowly won maturity in self-government and began the uphill task of earning statehood. The first legislative session under territorial status was dominated by a quarrelsome Home Rule party, but newly formed Republican and Democratic parties on the national pattern soon began competing to supply the needs of citizenship.

Hawaii was converted during this period into the westernmost bastion of American defense. Garrison troops were stationed on Oahu as early as 1898. Schofield barracks, first occupied in 1909, grew to be the largest permanent army post under the flag. The great naval base at Pearl Harbor was authorized by congress in 1908 and construction and maintenance thereafter made the U.S. government one of Hawaii's biggest employers.

Hawaii saw no hostile action in World War I but its people contributed their share in the conflict. Almost 1,000 men served in the U.S. army or navy, and many others did their bit in the Red Cross or other organization in Europe or Siberia.

In the 20th century, large shipping lines grew up to meet the need for Pacific passenger and freight service. The first cargo to pass through the Panama canal was a bargeload of Hawaiian sugar. The air age likewise arrived in Hawaiian skies. and caused the Honolulu International airport to become the busiest landing field in the entire Pacific. Military aviation started in the islands in 1917. The first flight between California and Oahu was completed by two army lieutenants in 1927. Air passenger service began among the islands in 1929, as well as air freight deliveries. In 1936, regular transpacific clipper flights were started, connecting the U.S. with the orient.

As early as 1903 the territorial legislature had petitioned congress for admission as a state, and many subsequent sessions made the same request without avail. Charges of colonialism and paternalism arose, and fear of carpetbagger rule by nonresidents of the islands was also rife In 1924 congress passed a law extending to Hawaii the benefits of appropriations for general welfare in the states. but Hawaii was still subject to all taxes imposed on the states. and the cry of "taxation without representation!" nas often heard. The Jones-Costigan sugar control act of 1934 clearly discriminated against the rights of sugar producers in Hawaii. Territorial delegate Samuel W. King introduced a statehood bill in congress in 1935 and succeeded in getting the house committee on territories to send a subcommittee to visit Hawaii—the first of many such congressional investigations. When a plebiscite on the question "Do you favour statehood?" was held in 1940, despite fears of Japan the people voted 67% in favour (see *Campaign for* Statelzood, below).

5. World War 11.—On Dec. 7, 1941, the Japanese. while still talking peace in Tokyo and Washington, made a surprise air and submarine attack on Pearl Harbor and the army and navy airfields of Hawaii. Casualties numbered over 3.000, including more than 2,300 killed. The battleship "Arizona." target ship "Utah," destroyers "Cassin." "Downes" and "Shaw" (later salvaged) and the mine layer "Oglala" were lost. The battleship "Oklahoma" also capsized, and other ships were severely damaged Many planes were destroyed or damaged on the ground, and much other damage was done. No fuel depots were destroyed. Some bombs fell on Honolulu; civilian casualties totaled over 100, including 49 dead, but material damage was slight. The Japanese lost 41 planes and 3 submarines. (See also WORLD WAR II.) But a bigger result was the unification of the U.S. people for the nar. The slogan "Remember Pearl Harbor" became reminiscent of "Remember the Maine." The attack marked the extension of World War II to the Pacific and between Japan and the United States, which was joined at once by Great Britain, the Netherlands and China. U.S officers and men individually and collectively exhibited great heroism and resourcefulness during the attack Japanese submarines later briefly shelled Hilo (Hawaii), Nawiliwili (Kauai) and, twice, Kahului (Maui), without casualties and with negligible damage.

The people of Hawaii earned a proud war record, at home and on various world fronts. Memorable is the achievement of the A J.A. (Americans of Japanese Ancestry) volunteers who served at Anzio and Cassino in Italy in the 100th infantry battalion, later incorporated into the 442nd regimental combat team. Many men from Hamaii also served as interpreters in the island-hopping campaigns against Japan.

Martial Law.—The governor of Hawaii issued a proclamation suspending the privilege of the writ of habeas corpus and declaring martial law A military government was set up to exercise executive, judicial and legislative functions. Provost courts, under martial law, supplanted district or police courts throughout the territory.

During the early months of 1942 military precautions were continued. Among them were black-out restrictions mhich provided that only persons on official business could be on the streets. highways, beaches or parks on foot or in vehicles between 6 o'clock P.M. and 6 A.M. Hundreds of thousands of individuals were fingerprinted and an extensive immunization program of the whole population against smallpox and typhoid was completed. The civilian

population was supplied with gas masks.

By the following year the danger of invasion or concentrated air attack had apparently passed, and the management of civil affairs was restored to the civil authorities in March 1943. Martial law remained in effect, however, and the writ of habeas corpus continued to be suspended. Members of the bar association of Hawaii strongly opposed the practice of trying civilians in provost courts. In Oct. 1944 Pres. Franklin D. Roosevelt announced the suspension of martial law and the restoration of habeas corpus. Military authority was restricted thereafter to delense measures in the islands. The U.S. supreme court held in 1946 that the military courts which were set up under martial law during the war period had no power to try civilians.

6. Campaign for Statehood. — After the close of World War II Hawaii renewed its efforts to obtain admission to the sisterhood of states. In 1946 Harry Truman became the first president to urge congress to grant statehood to Hawaii, but a house bill passed in 1947 did not pass the senate. In the spring of 1950 Hawaii drafted a state constitution to submit to the congress for ratification. This constitution was prepared at a convention of 63 delegates elected from all the islands and mas ratified by the voters in the general election held Nov. 7, 1950.

An enabling act for statehood passed the house in March 1950, for a second time, by a majority of 262 to 110, but four days after the senate committee reported favourably, the Korean war broke out and action was deferred. In the last few weeks of the special session toward the end of 1950, opponents of the bills to grant statehood to both Hawaii and Alaska were able to prevent a vote. In 1952, similar bills for the first time reached the senate floor, but a vote of 45 to 44 sent the Alaska bill back to committee and the Democratic leadership decided not to bring up the Hawaii bill. In 1954 a statehood bill passed the senate for the first time but no final action was taken to combine house and senate versions.

The expectation that Hawaii might always send Republicans to congress was upset when in Feb. 1955, the legislature convened for the first time in the history of the territory with a majority of Democrats in both the senate and the house of representatives. In 1956 a Democrat, John A. Burns, was elected as Hawaii's nonvoting delegate to congress; he was re-elected two years later.

In Nov. 1955, Gov. Samuel W. King, in his capacity as president of the 1950 constitutional convention, called the delegates of that body together to act on the reapportionment provision of the proposed state constitution. The convention passed a resolution reaffirming its desire for statehood and requesting the congress meanwhile to permit reapportionment of the legislature as provided by the state constitution. Congress approved in 1956, and in 1958 the first election was carried out under the new plan, which provided for 25 senators and 51 representatives.

In 1957, statehood failed to pass the congress for the 22nd time since 1903. In 1958, as a result of an active effort, Alaska was granted statehood and in 1959 Hawaii's long campaign met with success when Hawaii became the 50th state.

The enabling act was passed by the U.S. senate on March 11, 1959, by a vote of 76 to 15 and by the house of representatives on the following day by 323 to 89. President Eisenhower signed the act on March 18. Citizens voted for statehood in a plebescite on June 27. *(See* also HONOLULU; PACIFIC ISLANDS.)

IV. POPULATION

The population of Hawaii, according to the 1960 federal census was 632,772, exclusive of armed forces personnel. About half the population lived in the capital, Honolulu, a busy, modern city with 294,179 inhabitants. The second city was Hilo (25,996) on the island of Hawaii. The remaining centres mere small towns or villages, or else part of the Honolulu metropolitan area. Urban population was 69%, rural 31%; density was 98.5 per square mile.

TABLE *11.— Hawaii: Places of 5,000 or More Population (1960 census)**

Place	Population				
	1960	1950	1940	1920†	1900†
Total state	632,772	499,794	423,330	255,912	154,001

Lualualei-Maili	5,045	—‡	—§	—	—
Wahiawa	15,512	8,369	5,420	—	—
Waianae-Makaha	6,844	—	—	—	—
Wailuku	6,969	7,424	7,319	—	—

*Populations are reported as constituted at date of each census.
†Returns unavailable for 1920 and 1900 for towns and villages.
‡Not separately returned in 1950.
§Not separately returned in 1940.

From the discovery of the island (1778) the population changed from extreme homogeneity to extreme heterogeneity because of the decrease of Hawaiians during the first century and immigration of others during the next century (see *The People,* above). At the time of the discovery the population probably did not exceed 300,000. Their decrease. attributable to many causes, was rapid, but latterly continued at a diminishing rate. The Hawaiians seemed destined to disappear more through intermarriage with other races than through excess of deaths. The part-Hawaiians increased more rapidly than the pure Hawaiians decreased.

1. .Characteristics. — In 1823 the missionaries estimated the Hawaiians at 142,050. The first census (1832) showed a total population of 130,313, including the few foreigners. The census of 1872 showed a low ebb in the total, 56,897 (51,531 Hawaiians and part-Hawaiians, or 90.5% of the total). That of 1878, just after the reciprocity treaty with the United States began to stimulate the sugar industry and immigration, showed a total population of 57,985, comprising 47,508 Hawaiians and part-Hawaiians (81.9% of the total) and 10,477 of other races.

The census of 1900, the first taken after Hawaii became a territory, showed a total population of 154.001, comprising 37,656 Hawaiians and part-Hawaiians (24.4% of the total) and 116,345 others, including 28,819 Caucasians, 5,767 Chinese and 61,111 Japanese. In 1920 the total population of the territory was 255,912, of which number 41,750, or 16.3%, were Hawaiians and part-Hawaiians. In 1930 the population was 368,336, of which number 50,860, or 13.8%, were Hawaiians and part-Hawaiians. This census represents the smallest recorded percentage of Hawaiians and part-Hawaiians taken together. In 1940 there were 64,310 Hawaiians and part-Hawaiians, forming 15.2% of the total of 423,330. In 1950 there mere 12,245 Hawaiians and 73,846 part-Hawaiians, forming 17.2% of the total population of 499,794.

The growth of the population of the territory up to 1930 was rather rapid, with a 43.9% increase registered in the decade ending in 1930. The increase between 1930 and 1940 was only 14.9%, between 1940 and 1950 it was 18.0% and between 1950 and 1960 was 26.6%.

The number of males per 100 females reached its highest point,

at 223.3, in 1900 and an equal proportion between the sexes was not reached until 1930 The population of Hawaii is predominantly youthful; in 1950, 40% of the residents were under the age of 21.

2. Immigration. — Polynesians from the South Sea Islands were introduced into Hawaii between 1859 and 1885, but the total was less than 2.500 and they proved disappointing both as labourers and prospective citizens, so that most of them nere returned to their homes. Nonoriental immigration was encouraged, principally Portuguese. In the latter part of the 19th century. after the reciprocity treaty increased the need for plantation workers, about 11,000 Portuguese were brought from Madeira and the Azores in 1878–90 and 337 more in 1899. They proved to be industrious, thrifty and law abiding. They brought their families and most of them remained and multiplied. In 1906–13, more than 5.000 more were introduced. many from Portugal itself. Other groups were brought — mainland Americans Norwegians, Germans, Galicians. Russians. Poles. Spaniards from Málaga and Italians. In 1900–01 about 5,000 Puerto Ricans were brought in, and contrary to first expectations, most of them developed well and increased to more than 9,500 by 1950. About 100 Negroes and their families were brought in 1901 and about 500 Hindus (1908–11), most of whom soon left.

To solve the problem of finding a source of willing plantation labour, it was early decided that groups from Asia should be introduced. The Chinese came first (1852–67); then, opposition having arisen, 148 Japanese were brought in 1868. The Japanese government objected, however. and the Chinese continued to come in growing numbers until restrictive measures nere applied by the Hawaiian government in 1883 and attention again turned to Japan. Japanese came in large numbers—65,034 during 1885–99, of nhom almost 20,000 came in the last year. fearing that such immigration might be prohibited. Upon annexation, the United States laws on Chinese exclusion were extended to Hawaii. After the gentlemen's agreement of 1907 with Japan, arrivals were chiefly women. and a rapid increase continued through births. Opposition on the mainland led to Japanese exclusion in 1924. Koreans to the number of 7,859 came in 1903–05, but there were only 4,533 in 1910, 4,950 in 1920 and 7,030 in 1950.

Finally. largely because of the enactment of federal laws prohibiting assisted immigration from foreign countries. the sugar companies turned to Filipinos as the only available labour source. beginning in 1906, and, although many nent on to the mainland, their number grew to 21,031 in 1920 and 63,052 in 1930; they numbered 61.062 in 1950 and constituted the largest racial element on the sugar plantations.

All the various national groups brought into Hawaii prospered. The Puerto Ricans remained United States citizens after arrival. Nearly all the Portuguese became citizens, and after World War II many Filipinos and Chinese took out citizenship papers under laws favouring such action. The Hawaiian-born children of all alien residents are citizens at birth.

See U.S. Bureau of the Census, *Reports. See* also bibliography under *The People,* above.

V. ADMINISTRATION AND SOCIAL CONDITIONS

1. Government. — From 1900 to 1959 the Hawaiian Islands were a territory, an integral part, not a possession, of the United States. governed under an organic act. effective from June 14, 1900. Having been previously an independent sovereignty. Hawaii was the most highly organized territory created by congress and the only one to which was given the administration and revenue of its public lands. The federal officers were a delegate to congress, elected for two years. who could introduce bills and debate but not vote, two judges of a federal district court and a U.S. attorney and marshal, appointed for six years by the president with the consent of the federal senate, and various officials of the treasury, post office, agriculture, commerce and interior departments. The territorial legislature met for a 60-day term every two years. In 1959 the first session was held under a reapportionment act which provided for 51 members of the house of representatives, elected for two years, and 25 members of the senate. nith 12 or 13 elected each two years for four-year terms. This plan anticipated a similar scheme of representation under the state constitution which was ratified by the people of Hawaii in 1950 and went into effect in 1959.

This constitution required that to be eligible for the state senate a candidate must be 30 years old, a resident of the state for not less than three years and a qualified voter of the senatorial district from which he seeks to be elected. A candidate for the house of representatives must be at least 25, a resident of the state for three years and a qualified voter of the representative district.

Regular sessions of the legislature are held annually. starting on the third Wednesday in February. Regular sessions in odd-numbered years are known as general sessions and run for 60 days; regular sessions in even-numbered years are knonn as budget sessions. Budget sessions and special sessions are limited to 30 days, but the governor may extend any session for not more than 30 days

Under the constitution the governor and the lieutenant governor are elected by the voters for four-year terms. All executive and administrative offices and bureaus are allocated by law among not more than 20 principal departments. each headed by a single executive who is appointed by the governor with the advice and consent of the senate The terms of these executives expire at the end of the governor's term.

Local Government.—Under the state constitution the legislature "shall create counties and may create other political subdivisions within the state. and provide for the government thereof." Each political subdivision has the poner to frame and adopt a charter for its own self-government. The taxing power is reserved to the state except so much thereof as may be delegated by the legislature to the various subdivisions.

Qualifications of Voters.—Qualifications for voting include citizenship, registration, residence of one year in the state, age of 20 years and ability to speak, read and write the English or Hawaiian language. Voters do not lose residence through absence in the service of the United States or while engaged in navigation or studying at any institution of learning. The legislature provides for registration and for absentee voting General elections are held on the first Tuesday after the first Monday in November in all even-numbered years.

During territorial rule direct primaries mere adopted in 1913 and women's suffrage in 1920. Political parties are the Republican and Democratic. Until 1955 the Republicans predominated, but in that year, for the first time in history, the territorial legislature convened with a majority of Democrats in both house and senate. Since that time the Democrats have been the preponderant party and since 1956 the delegate to congress has been a Democrat. During the general election of 1958 the registered voters numbered 175,221, of whom more than 88% voted, usual in Hawaii but much higher than in most other places.

2. Taxation. — The tax structure under territorial rule comprised an elaborate system of taxes which included every major type of tax found in the other states and several others not in general use. Among the latter was a general excise (gross income) tax of $3\frac{1}{2}\%$ levied against almost all business activities. In 1957 the territorial income tax law was revised to make payments more closely comparable to the system used by the federal government. The rate on homes occupied by owners was lower than that on real estate in most states. The net assessed valuation of real property at the time statehood was achieved in 1959 was more than $1,085,000,000. All federal taxes, including individual income and corporate income taxes, were applicable in the territory and continued to be in the state. The funded debt of the state at any time was set at $60,000,000.

3. Living Conditions. — The cost of living in Hawaii is slightly higher than that of the mainland United States because most of the goods used by the people must come by ship from other places. Per capita personal income when Hawaii was admitted to the union was about $1,700. Wage scales were about the same as on the mainland. Approximately 200.000 persons were employed. The average weekly wage was about $60 for industrial workers covered

by employment insurance. Payroll for all industries was more than $711,000,000. The sugar plantation companies paid wages of more than $58,000,000 to an average number of full-time equivalent employees totaling almost 19,000. The pineapple companies paid more than $35,500,000 to employees totaling about 11,000. But the biggest employer, governmental agencies, with a payroll of more than $320,000,000 to territorial, county and federal workers. accounted for 45% of all wages. A lively home-building program was being carried on, despite high costs and relative scarcity of residential land.

4. Welfare Services.—Services in Hawaii parallel those of mainland states. The department of public health is second in importance only to that of education. Physicians are employed or subsidized for the benefit of all, however indigent or remote from population centres. The incidence of Hansen's disease (leprosy) has declined greatly so that only about 150 patients are confined. All cases discovered since 1949 have been confined at Hale Mohalu, Pearl City. Oahu, rather than at Kalawao. Tuberculosis hospitals are found on Oahu, Hawaii. Maui and Kauai. Two hospitals on Oahu care for the mentally handicapped. There is one prison system with three units, two of which are minimum security projects. There is also a correctional school for boys and another for girls. The department of health has allocated in one year more than $1,000,000 to the counties for hospital and medical aid to the indigent. All workers in the islands benefit under the social security act and other federal laws concerning child labour, minimum wages and unemployment insurance. In 1945, the local government extended collective bargaining to agricultural labour. As a state, Hawaii automatically benefits by all federal welfare laws.

5. Justice.—Judicial decisions are made by the United States district court of Hawaii and by the state courts. These consist of one supreme court, circuit courts and such inferior courts as the legislature may establish. The supreme court consists of a chief justice and four associate justices. The justices, as well as judges of the circuit courts. are appointed by the governor with the advice and consent of the state senate. from those persons who have practised law before the supreme court of Hawaii for at least ten years. Justices serve seven years and judges of the circuit courts serve six years. Equity and law are kept distinct but with simplified procedures. Appeals may be taken from the federal district court and, when a federal question or a value in excess of $5,000 is involved, from the state supreme court to the federal circuit court of appeals of the ninth circuit, in San Francisco.

6. Education.—Twelve years after the arrival of the first missionaries in 1820 there were 900 schools with 53,000 pupils (40% of the population, mostly adults); 12 years later about 80% were literate. In 1824 the regent and chiefs prescribed schools and compulsory attendance. In 1831 and 1834 there were founded two higher institutions for training teachers and religious assistants, which were also largely manual and industrial training schools, said to be the first of the kind established in what is now the United States. In the 1830s and 1840s pupils came from Spanish California, Kamchatka and other Pacific islands to attend an English-taught school opened in Honolulu in 1833. At first Hawaiian was the language of public instruction. but in 1854 the change was made to English, and American teachers, textbooks and methods became popular.

When Hawaii became a state the educational system included all grades from kindergarten through university, as well as special classes for physically defective or feeble-minded students. There were many evening classes. Much attention was given to agricultural, trade and industrial vocational work, home economics and medical, dental and nutritional needs. School attendance was compulsory for children 6 through 15 years of age. The public school system was under the territorial government; buildings and other physical equipment were under the local governments. There were about 200 public schools, including kindergartens and grades through 12. The total school enrollment was almost 160,000 or about 27.5% of the population of the territory. Of those enrolled, not quite 30,000 were in private schools. Public school teachers numbered about 5,000; they were all under a standard salary schedule regardless of teaching location.

Under the state constitution, a board of education is appointed by the governor, with the advice and consent of the senate, from panels submitted by local school advisory councils. The superintendent of public instruction is appointed by the board. The education system is state wide rather than local, continuing the centralization found under the monarchy and under territorial rule. The constitution provides that "there shall be no segregation in public educational institutions because of race, religion or ancestry."

Prominent among private schools are Punahou, founded in 1841, which specializes in college preparatory courses; the Kamehameha schools (for those of Hawaiian blood). largely industrial: St. Louis college (Catholic, for all races); and Mid-Pacific institute (for all races).

7. University of Hawaii.—The state-supported University of Hawaii lies at the crossroads of the Pacific. There are more than 7,000 students earning credits. The campus in Honolulu lies in Manoa valley, three miles from the business centre and two miles from Waikiki. It was established by the territorial legislature in 1907 and is a federal land-grant institution. Originally called the College of Agriculture and Mechanic Arts (1907–11) and later the College of Hawaii (1911–20), it became the University of Hawaii in 1920. As a state university it receives a major portion of its financial support from the state legislature. Its colleges include arts and sciences, business administration, engineering, education. agriculture and general studies. In addition to the bachelor degree, the university grants the master's degree in 29 departments and the doctor's in 7. Co-operating institutions include the Pineapple Research Institute of Hawaii; the Hawaiian Sugar Planters' association; Fruit Fly laboratory; the U.S. fish and wildlife service. which established the permanent headquarters of its Pacific oceanic fishery investigations on the university campus; the Bernice P. Bishop museum, which built an extensive Polynesian collection; the Pacific and Asian Affairs council; and the Honolulu Academy of Arts. The Gregg M. Sinclair library of the university contains more than 300.000 bound volumes and is a regional depository for C.S. government publications. It holds extensive collections of works in Chinese and Japanese and also books and periodicals concerning Hawaii and the Pacific. The university operates the aquarium at Waikiki and the Hawaii Marine laboratory with a branch at Coconut Island off the north shore of Oahu. It also operates a junior college at Hilo.

Other collegiate institutions in Hawaii are Chaminade college (founded 1957), Honolulu Christian college (1953) and Jackson college (1949), all in Honolulu, and Church College of Hanaii at Laie, Oahu.

8. Armed Forces.—Hawaii is the centre for the unified command of the U.S. armed forces for the entire Pacific area; the admiral in charge is also in command of the Pacific fleet, with headquarters at Pearl Harbor. The army maintains six major posts on the island of Oahu, including Schofield barracks, about 20 mi. from Honolulu. Air defense of the Pacific is a function of the Pacific air force (USAF) with headquarters at Hickam air force base on Oahu. The Hawaii national guard is available for immediate call in time of national emergency and also may be called out by the governor in local emergencies. A national guard fighter squadron is stationed at Hickam air force base.

VI. THE ECONOMY

Hawaii's economy has increasingly expanded in the 20th century because of closer integration into the U.S. national market. and by specializing in four major sources of income. which may then be used to purchase the needs of the population. The four are sugar, pineapples, tourism and government spending. Hanaii grows one-seventh of all the sugar used in the United States, and 75% of all the pineapples marketed in the world. Although Hawaii is predominantly agricultural, the cultivable land is only about 7% of the total area; 40% is suitable only for grazing and another 25% is forest reserves. Three-fourths of the agricultural

acres are used for sugar cane, but the entire sugar crop of more than 1.000,000 tons a year is grown on 221,300 acres — an area about the size of New York city. When Hawaii became a state the sugar crop was worth about $147,000,000 annually, and the pineapple crop about $115,000,000. But the largest source of income was federal expenditures, mostly for defense, including payrolls. purchases and contracts, running to more than $385,000,000 annually. Tourism was a growing industry which may compete with agriculture.

Sandalwood was Hawaii's first important commercial product. The industry (1800–30) originated through the discovery of fur traders that the wood was in demand in China. When the trade was at its height during 1810–2j. the king and chiefs found it so lucrative that they compelled most of the available population to get the wood from the forests. so that it was soon exhausted. But before that time. whaling (1820–80) began. The vessels usually called twice a year for rest. repairs.. supplies, storage or transshipment of oil and whalebone and engagement of Hawaiians as seamen. The annual calls during 1840–60, when the industry was at its height, averaged about 400. Whaling was also carried on locally. The discovery of petroleum (1859) and the destruction of whaling vessels in the Civil War and by the northern ice pack in 1871 lessened its importance. Hawaiians were excellent seamen; in 1846 about a fifth (3,000) of the young men of 15–30 were so engaged.

A. Production

1. Sugar has long been the chief product of the islands. Small quantities were produced from 1802 to 1835. when the industry really began, and yet the output had increased to only 13,036 short tons by 1876, when there was great impetus from the reciprocity treaty with the United States. It increased to 229,414 tons by 1898, the year of annexation. and to 1,035,548 by 1933. after which there was a reduction of about 9% in output under the national quota system. Tonnage was more than 1,000,000 in the 1950s. Laboursaving devices and improved scientific methods have reduced the working force; in the 1950s the same amount of sugar was produced by one-third the number of employees as in the 1930s. In 40 years tons per employee rose from 12.6 to 56.1. Wages paid these unskilled workers increased to an average of $11.10 daily in the second half of the 20th century. Employment is on a year-round basis. The yield per acre is the highest in any sugar area, averaging $7\frac{1}{4}$ tons of sugar per acre, with a maximum of 18 tons. The cane requires 14 to 24 months to mature. and two or three crops at different stages grow at the same time. Nowhere have scientific methods been applied in agriculture more than to the sugar and pineapple industries in Hawaii. About half the area is irrigated — by conduits from mountain streams and pumping from artesian and surface wells. The irrigation system of one plantation cost nearly $6,000,000, and supplies amounts of water that would meet the needs of a medium-sized city. Before a field is harvested it is set on fire to bum off the leaves. Conveyance to the mills is by large trucks. flumes and overhead trolley. The centrifugal drying process for sugar was introduced in Hawaii in 1851. Almost all the sugar is shipped ram, mainly to a co-operative refinery in California. Corporations own the mills and raise most of the cane. In the second half of the 20th century there were 27 sugar plantation companies and some 2.000 independent sugar planters.

2. Pineapple growing, an industry rising in the 20th century, is second only to sugar as a crop. Annual production of all companies increased from 1.893 cases in 1903 to more than 30,000.000 cases of canned fruit and juice in the 1950s. Nine companies dominate the industry, and the working force of about 20.000 persons grows. harvests and processes the fruit. Some of the by-products of processing include citric acid, bran. calcium citrate, alcohol and sugar. Cnlike the sugar industry. the pineapple companies have had to create their market.

3. Other Agriculture. — The livestock, coffee and rice industries have successively occupied third place. There are numerous ranches and dairies. many with thoroughbred stock — cattle. sheep. horses, hogs and poultry. Livestock products brought about $30,000,000 a year in the 1950s. More than 30,000,000 quarts of milk are produced annually. The coffee, valued at about $6,000,000 annually. is of superior quality, known as Kona from the district on western Hawaii where most of it is raised. Rice is a waning industry. Hilo on the island of Hawaii is the centre of the flower trade. The banana supply is steady, though not large. Other industries which are still small or have had their day are silk. cotton. tobacco, rubber. vanilla. sisal. potatoes and wheat. New methods have made a future for the growing of macadamia (Australian) nuts. There is much subsistence farming and a wide variety of diversified crops can be grown in the islands. but for many years the people have found it most economical to grow the two important money crops — sugar and pineapples — by large-scale methods. and to import most of their supplies, chiefly from mainland United States. Purchases by Hawaii from the mainland amount to more than $748,000,000 a year. Little lumber is produced.

4. Fisheries. — Commercial fishermen catch millions of pounds of fish each year, valued at about $3,000,000. Most important commercially are the aku. or ocean bonito, and the *ahi*, or yellow-fin albacore. both of which are canned as tuna. Fishing in island waters, however. does not begin to supply local needs and much frozen fish is imported into Hawaii.

5. Industry. — Although Hawaii is essentially agricultural, the principal industries are such as require much manufacturing directly. as in sugar, pineapple. rice. coffee and fish mills and canneries. and indirectly. as in iron. fertilizer and can works of large size. A petroleum refinery has been erected on Oahu by a large mainland corporation. More than 150 products are made in the islands, from acetylene to zinc sulfate, but all on a small scale. Handicraft items, perfumes. curios. costume jewelry and jams and jellies are exported. Apparel. particularly Hawaiian sportswear, is a growing industry. and annual sales reached more than $10,000,000 in the 1950s.

Practically the only mineral products are building stone, lava aggregates for concrete. lime and salt, but important deposits of bauxite. raw material for aluminum; were identified in the 1950s. There are no local sources of power except a few waterfalls, and most electricity is produced by conversion of imported petroleum.

6. Tourism. — Third largest source of income from industry comes from tourism. In the second half of the 20th century almost 200.000 tourists spent nearly $80,000,000 in the islands annually. The industry has been promoted by the Hawaii Visitors bureau. established in 1903. The tourist income, which unlike sugar and pineapple has no apparent saturation point, may increase greatly and its effects will spread throughout the economy.

B. Trade and Finance

In quantity imports have exceeded exports. approaching a ratio of two to one. but dollar earnings have shown a favourable balance As indicated above (see *Production*) the major exports are sugar and pineapples. and the tourist trade is the third largest source of income. At the time Hawaii became a state about two-fifths of the total dollar income nas based on the export of agricultural products and three-fifths on the sale of services and goods to tourists and to defense agencies and shipping and airlines. Roughly three-fifths of expenditures outside Hawaii were for commodities imported, less than one-fifth for services and other items (like freight and passenger services) and about one-fifth for payments to the federal government.

C. Transport and Communications

The territorial highway system includes more than 3.000 mi. of concrete and macadam roads. There were more than 150.000 passenger cars in Hawaii in the 1950s. The people are served by many bus lines as well. Most of the heavy hauling is done by trucks, since there are virtually no railway lines. Water and air transport is preferred over road transport in these islands. Shipping lines connect with all the ports of the world. Chief shipping terminals in the islands are Honolulu: Hilo, on Hawaii; Kahului, on Maui; and Port Allen, on Kauai. About 50 shipping companies have representatives in Honolulu. There are about 1,200 ship

arrivals annually at. Honolulu harbour with incoming freight of almost 3,000,000 tons and outgoing freight of more than 1,000,000 tons. Eleven commercial airports accommodated travelers. flying more than 400,000 individual passenger trips to and from the territory. and 600,000 individual trips between islands. Eight international airlines use the Honolulu airport. Use of jet planes reduces the flying time from San Francisco to Honolulu to about four hours.

There are about 170,000 telephones in use: the dial system may be used even for calling a party on another island. In 1957 a dual trunk line telephone cable connected Honolulu and San Francisco. capable of carrying 34 conversations simultaneously. Hawaii is also connected with the rest of the world by cable. radio. radio telephone and ship-to-shore radio service. At the time Hawaii was admitted to the union in 1959. there were 16 broadcasting stations in the islands and 6 television stations, of which 3 were in Honolulu.

D. Labour

Unionization in the islands has followed an unusual pattern. Before 1934 there was very little organizing activity by labour unions. Workers mere often of different races and tended to be unfamiliar with U.S. labour movements. Union organization was perhaps delayed by certain paternalistic policies of employers who. in the face of prospective organization. voluntarily improved conditions and supplied various benefits such as housing and medical care. There mas little labour leadership until after the 1934 waterfront strike in San Francisco. During the two years following, some 500 striking seamen were ashore in Honolulu and built up strong sentiment among the stevedores and other workers. 'The International Longshoremen's and Warehousemen's union (I.L.W.U.), formed at that time. became Hawaii's most militant union and organized not only the dock workers but workers in the sugar and pineapple fields and later even had some success in organizing retail clerks in competition with A.F.L.–C.I.O. locals. For a considerable period the rivalry of west-coast organizations such as the Sailors' Union of the Pacific under Harry Lundeberg and the I.L.W.U. under Harry Bridges was reflected in union activities in and pertaining to the islands.

During World War II union activities were necessarily restricted in scope. The pressure of wartime duties, the early curfew and blackout and gasoline rationing all impeded activities of labour as well as other organizations. Moreover. under martial law wage rates were frozen and workers were forbidden to move from one job to another. At the war's end unionization proceeded rapidly. There was a wave of strikes comparable to those on the mainland at that time, reflecting desires to obtain gains in the postwar world and to meet rising living costs. Doubtless here. as elsewhere. resentment over wartime regulation played a role. Late in 1946, the I.L.W.U.–C.I.O. leadership called a strike on 33 plantations involving 28,000 workers. The strike lasted for 7j days, and involved substantial losses to all concerned. An even more important strike occurred in the summer of 1949, the longest major maritime tie-up in U.S. history. when for 178 days shipping between the mainland and Hawaii was suspended. Many persons felt this strike and the territory's means of dealing with it pointed up the need for statehood. That labour controversy had not vanished was evidenced by the sugar strike which began on Feb. 1. 1958, and lasted for 126 days. Its effect on the general economy of the islands was to a substantial extent offset by a continued boom in building construction.

Estimated membership in A.F.L.–C.I.O. locals at mid-century was 10,000. and I.L.W.U. membership at 23.000. There were also four organizations representing federal and territorial employees. Labour union leaders were active politically in the islands and their efforts met with varied success. In the general election of 1946, the political action committee of the C.I.O. endorsed 51 candidates from both parties, of whom 35 were elected. Later attempts in the support of candidates ior the legislature met less clear-cut success. In general, but with exceptions. the unions lent their considerable influence to candidates of the Democratic party. To present a united front in respect to labour controversy the Hawaii Employers council was founded in 1943. In the 1950s it represented more than 200 firms, large and small, employing 46,000 persons.

Grove Day, *Hawaii: a History* (1948); Joseph Theodore Morgan, *Hawaii: a Century of Economic Change, 1778–1876,* with bibliography (1948); J. H. Shoemaker, *The Economy of Hawaii in 1947 (1948);* P. F. Philipp, *Diversified Agriculture of Hawaii* (1953).

Current statistics on production, employment, industry, etc., may be obtained from the pertinent state departments; the principal figures, together with current history, are summarized annually in the *Britannic Book of the Year,* American edition. (A. G. Dy.)

HAWARDEN, a town and civil parish in the East Flint parliamentary division of Flintshire. Wales, 7 mi. W. of Chester by road. Pop. (1951) 13,812. Hawarden castle (1752) stands near the 13th-century castle which suffered in Welsh raids and in the Civil War. The modern house passed to W. E. Gladstone, who lived there for 60 years and added a library and study which he called the 'Temple of Peace. St. Deiniol's library was founded by Gladstone in 1896 and rehoused in 1902. There is also a Gladstone museum. In St. Deiniol's church, an Early English building restored. is a memorial window to Gladstone by Sir E. Burne-Jones. In the town are the William Temple Memorial college for women and a grammar school (1606).

HAWEIS, HUGH REGINALD (1838–1901), English clergyman, lecturer and writer on music, was born at Egham, Surrey: on April 3, 1838. On leaving Trinity college, Cambridge, he traveled in Italy and served under Giuseppe Garibaldi in 1860. On his return to England he was ordained and held various curacies in London, becoming in 1866 incumbent of St. James's Marylebone. His unconventional methods of conducting the service, his dwarfish figure and lively manner, soon attracted crowded congregations.

Haweis was much interested in music, and wrote on violins and church bells. His best-known book was *Music and Morals* (1871). For a time he was editor of *Cassell's Magazine.* He also wrote *Christ and Christianity* (1886–87), a popular work on the origins of Christianity. Other writings include *Travel and Talk* (1896) and similar entertaining books. He died on Jan. 29, 1901.

HAWES, STEPHEN (*fl.* 1502–1521), English poet, was born, if his own statement of his age may be trusted, about 1474. He was educated at Oxford, and traveled in England, Scotland and France. He became groom of the chamber to Henry VII as early as 1502. Hawes could repeat by heart the works of most of the English poets, especially the poems of John Lydgate, whom he called his master. He was still living in 1521. His capital work is *The Passetyme of Pleasure, or the History of Graunde Amour and la Bel Pucel, conteining the knowledge of the Seven Sciences and the Course of Man's Life in this Worlde,* printed by Wynkyn de Worde, 1509, but finished two years earlier. The poem is a long allegory in seven-line stanzas of man's life in this world. It is divided into sections after the manner of the *Morte d'Arthur* and borrows the machinery of romance. Its main motive is the education of the knight, Graunde Amour, based, according to W. J. Courthope *(History of English Poetry,* vol. i, p. 382). on the Mar*riage of Mercury and Philology,* by Martianus Capella, and the details of the description prove Hawes to have been well acquainted with medieval systems of philosophy. At the suggestion of Fame, and accompanied by her two greyhounds, Grace and Governance. Graunde Amour starts out in quest of La Bel Pucel. He first visits the Tower of Doctrine or Science where he acquaints himself with the arts of grammar, logic, rhetoric and arithmetic. After a long disputation with the lady in the Tower of Music he returns to his studies, and after sojourns at the Tower of Geometry, the Tower of Doctrine, the Castle of Chivalry, etc., he arrives at the Castle of La Bel Pucel, where he is met by Peace, Mercy, Justice. Reason and Memory. His happy marriage does not end the story, which goes on to tell of the oncoming of Age, with the concomitant evils of Avarice and Cunning. 'The admonition of Death brings Contrition and Conscience, and it is only when Remembraunce has delivered an epitaph chiefly dealing with the Seven Deadly Sins, and Fame has enrolled Graunde Amour's name with the knights of antiquity, that the story ends. This long poem was widely read and esteemed, and exercised an in-

fluence on the genius of Spenser.

BIBLIOGRAPHY.— *The Passetyme of Pleasure* was edited by T. Wright for the Percy society in 1845 and by W. E. Meade for the Early English Texts society in 1928. *The Convercyon of Swerers* (1509) was edited by David Laing for the Xbbotsford club (186;). Other extant works, all bibliographical rarities, are *The Example of Vertu* (1504?), *Comfort of Lovers* (1512?) and *A Joyfull Medytacyon to all Englande of the Coronacyon of Kynge Henry the Eyght* (1509). See also G. Saintsbury, *The Flourishing of Romance and the Rise of Allegory* (London, 1897), *History of English Prosody*, vol. 1 (London, 1906); J. M. Berdan, *Early Tudor Poetry* (New York, 1920).

HAWES, WILLIAM (1785–1846), English musician, was born in London in 1785 and was for eight years (1793–1801) a chorister of the chapel royal. He subsequently held various musical posts. being in 1817 appointed master of the children of the chapel royal. He also carried on the business of a music publisher, and was for many years musical director of the Lyceum theatre, then devoted to English opera. In the last-named capacity (July 23, 1824), he introduced C. M. von Weber's Der *Freischütz* for the first time in England, at first slightly curtailed, but soon afterward in its entirety. Peter von Winter's Interrupted Sacrifice, W. A. Mozart's Cosi fan *tutte*, Heinrich Marschner's Der *Vampyr* and other important works were also brought out under his auspices.

Hawes died on Feb. 18, 1846.

HAWFINCH, *Coccothraustes coccothraustes*, one of the largest of the finch family (Fringillidae), found over nearly the whole of Europe and north Asia and in Africa north of the Atlas. It breeds in England, Wales and south and east Scotland. It is a grosbeak, the male with black, white and light-brown plumage, rather like a chaffinch (*q.v.*), but its much larger size and enormous beak make it easily recognizable, while the singular bill-hook form of some of its wing feathers will be found remarkable. Though frequenting gardens and orchards as well as woods, it is exceedingly shy. It has an unfortunate predilection for green peas. In winter it may gather in flocks. It is unusual in that courtship begins while the birds are still in flocks, the mated pairs then separating to find individual territories.

HAWICK, a small burgh of Roxburghshire, Scot., 57 mi. S.S.E. of Edinburgh by road. Pop. (1951) 16,717. Area 1.9 sq.mi. One of the chief border towns, it lies at the confluence of the Slitrig with the Teviot, which flows through it. The only church of historical interest is that of St. Mary's, the third of the name, built in 1763. The first church, believed to have been founded by St. Cuthbert (d. 687), was succeeded by one dedicated in 1214, which was the scene of the seizure of Sir Alexander Ramsay of Dalhousie in 1342 by Sir William Douglas. The Buccleuch memorial hall, commemorating the 5th duke of Buccleuch, is used as a technical college and a museum. The Moat or Moot hill at the south end of the town is an earth mound 30 ft. high and 300 ft. in circumference, possibly the place where the court of the manor formerly met. The Baron's tower, founded in 1155 by the Lovels, lords of Branxholm and Hawick, and afterward the residence of the Douglases of Drumlanrig, is said to have been the only building that was not burned down during the raid of Thomas Radcliffe, earl of Sussex, in 1570. It became an inn in 1773 and was visited by W. Wordsworth, his sister Dorothy and Sir Walter Scott. Bridges across the Teviot connect Hawick with the suburb of Wilton where Wilton lodge is now a museum. Leading industries are the manufacture of hosiery, tweeds and knitwear. Markets for livestock are also important.

In 1537 Hawick received from Sir James Douglas of Drumlanrig a charter which was confirmed by the infant Queen Mary in 1545 and remained in force until 1861, when the corporation was reconstituted by act of parliament. Sir Robert Umfraville (d. 1436), governor of Berwick, burned the town about 1417. In 1514, the year after the battle of Flodden, in which Hawick burghers had suffered severely, a number of young men or "callants" routed an English force at Hornshole on the Teviot 2 mi. below the town. This event is celebrated every June in the "Common Riding" ceremony, in which a facsimile of the captured pennon is carried in procession by the "cornet" to the accompaniment of a chorus "Teribus ye Teri Odin" (or, as the other version, "Tyr-ibus ye Tyr Odin") supposed to be an invocation to Thor and Odin—a survival of Northumbrian paganism. An equestrian statue was erected in 1914 to mark the quatercentenary of the victory.

Two miles southwest of Hawick is the massive peel of Goldielands—the "watchtower of Branxholm," a typical border stronghold. One mile beyond it is Branxholm castle, the Branksome hall of The *Lay of* the Last Minstrel, once owned by the Lovels, but since the middle of the 15th century the property of the Scotts of Buccleuch. It was destroyed in 1570 and was rebuilt the next year, the peel forming part of the modern mansion.

HAWK, a name applied generally to any diurnal bird of prey belonging to the families Accipitridae—kites, buzzards and harriers (*qq.v.*), excepting the larger species known as eagles and vultures (*qq.v.*)—and Falconidae—falcons and caracaras (*qq.v.*). The most typical hawks, however, are the goshawks (*q.v.*) and their relatives in the genus *Accipiter*, with about 40 species, and allied genera in the subfamily Accipitrinae. They are small or moderately large, with short wings, comparatively long legs and tail, beak curved directly from the cere and the upper beak edge wavy but not notched. The young are striped below but barred in the adult, and the female is considerably larger than the male. They pursue their prey by raking, or swiftly following its efforts to escape; occasionally destroying poultry and smaller birds, they usually eat small mammals, reptiles, insects and the like. They were used in falconry (*q.v.*). They build nests of sticks well up in trees and lay three to six brown-spotted eggs. The largest is the goshawk, about two feet long, while some of the smaller sparrow hawks, such as *A. minul-*

BY COURTESY OF THE AMERICAN MUSEUM OF NATURAL HISTORY

AMERICAN SPARROW HAWK (FALCO SPARVERIUS), LIKE THE KESTREL

lus of Africa and allied birds in South America, are but slightly larger than a thrush. Cooper's hawk (*A. cooperii*), of southern Canada and the United States, length 15–19 in., like the goshawk is well known to poultry raisers, as is the smaller (11–14 in.) sharp-shinned hawk (*A. striatus velox*), ranging over North America to the Mexican border, with allied races in Cuba, Hispaniola and Puerto Rico. The common sparrow hawk (*A. nisus*) breeds from the limit of trees in Europe and Asia south to the Mediterranean and Himalayas. Other species occur in Central and South America, Africa and Madagascar, Asia, Australia, Malay Islands and nearby Pacific and Indian ocean. (G. F. Ss.)

HAWKE, EDWARD HAWKE, BARON (1705–1781), British admiral, son of a barrister, entered the navy on Feb. 20, 1720, and served the time required to qualify him to hold a lieutenant's commission on the North American and West Indian stations. When war began with Spain in 1739, he served as captain of the "Portland" (50) in the West Indies. His ship was old and rotten. She nearly drowned her captain and crew, and was broken up after she was paid off in 1742. In the following year Hawke was appointed to the "Berwick" (70), and fought his ship in the ill-managed battle of Toulon on Jan. 11, 1744. In July 1747 he attained flag rank, and was named second in command of the Channel fleet. He was sent in command of the 14 ships detached to intercept a French convoy on its way to the West Indies. On Oct. 14, 1747, he fell in with it in the Bay of Biscay, attacked at once and captured six of the eight French ships.

In 1747 Hawke had been elected M.P. for Portsmouth, which he continued to represent for 30 years, though he can seldom have been in his place, and it does not appear that he often spoke. In the interval between the War of the Austrian Succession and the Seven Years' War, Hawke was almost always on active service. From 1748 till 1752 he was in command at home, and he rehoisted his flag in 1755 as admiral in command of the Western Squadron. In June 1756 the news of John Byng's retreat from Minorca reached England. Hawke was at once sent out to relieve him in the Mediterranean command, and to send him home for trial. Minorca had fallen, from want of resources rather than the attacks of the

French, before he could do anything for the assistance of the garrison of Fort St. Philip. He returned to England in January 1757, and next month was promoted full admiral.

When Pitt's great ministry was formed in June 1757, Hawke was not included in the Board of Admiralty, but he was continued in command of important forces in the Channel. In the late summer of 1757 he commanded the abortive expedition against Rochefort. During the end of 1757 and the beginning of 1758 he continued cruising in the Channel in search of the French naval forces In May of that year he was ordered to detach a squadron under the command of Howe to carry out further combined operations He retired in June for a time on the ground of health, but happily he was able to hoist his flag in May 1759, the "wonderful year" of Garrick's song.

France was then collecting an army for the invasion of England in the Morbihan in Brittany; its transport was to be covered by a fleet to be made up by uniting the squadron at Brest with the ships at Toulon. The proposed combination of the French fleet was defeated by the annihilation of the Toulon squadron on the coast of Portugal by Boscawen in May, but the Brest fleet was still untouched and the troops were still at Morbihan. It was the duty of Hawke to prevent attack from this quarter. The way in which he discharged his task marks an epoch in the history of the British navy. Until his time, or very nearly so, it was still believed that there was rashness in keeping great ships out after September. Hawke maintained his blockade of Brest till far into November. By the care he took to obtain fresh food, and the energy he showed in pressing the Admiralty for stores, he kept his men healthy. Early in November severe gales forced him off the French coast, and he anchored in Torbay. His brief absence allowed the French admiral. M. de Conflans, time to put to sea, and to steer for the Morbihan. Hawke, who had left Torbay on Nov. 13, learnt of the departure of the French at sea on the 17th from a look-out ship, and followed the French admiral to the Morbihan. He sighted the French about 40 m. to the west of Belleisle on the morning of Nov. 20. The British fleet was of twenty-one sail. the French of twenty. There was also a small squadron of British ships engaged in watching the Morbihan as an inshore squadron, which was in danger of being cut off. After making a motion to give battle, Conflans changed his mind and gave the signal to his fleet to steer for the anchorage at Quiberon, thinking that the British admiral would not dare to follow him, for the coast is one of the most dangerous in the world, and the wind was rising to a storm. Hawke, however, caught up the rear of the French fleet in the afternoon. It was dark before the action began in Quiberon Bay. Five ships only were taken or destroyed, but others ran ashore, and the French navy as a whole lost all confidence. Two British vessels were lost, but the price was little to pay for such a victory. No more fighting remained to be done. The fleet in Quiberon Bay suffered from want of food, and its distress is recorded in the lines:—

"Ere Hawke did bang
Mounseer Conflang
You sent us beef and beer;
Now Mounseer's beat,
We've nought to eat,
Since you have nought to fear."

Hawke returned to England in Jan. 1760 and had no further service at sea. Sixteen years later (1776) he received a peerage as Baron Hawke of Towton From 1766 to 1771 he was first lord of the Admiralty. His administration was much criticized He was no favourite with Chatham's partizans It is very credible that, having spent all his life at sea, his faculty did not show in the uncongenial life of the shore. As an admiral at sea and on his own element Hawke had no superior. On his death on the 17th of October 1781 his title passed to his son, Martin Bladen (1744–1805), and it is still held by his descendants

MARTIN BLADEN HAWKE 7TH BARON HAWKE (1860–1938), was among the foremost authorities on cricket of his time. He was the son of the 6th Baron Hawke, whom he succeeded in 1887 He was captain of the Yorkshire eleven from 1883 until 1910, and president of the Marylebone Cricket club from 1914 to 1918. Hawke organized and promoted cricket tours to the United States, Canada, South America, Australia, New Zealand, India and South Africa. He died in Edinburgh on Oct. 10, 1938. and was succeeded by his brother. Edward Julian Hawke.

There is a portrait of Edward Hawke in the Painted Hall at Greenwich. His *Life* by Montagu Burrows (1883) superseded all earlier authorities; it is supplemented in a few early particulars by Sir J. K. Laughton's article in the *Dict. Nat. Biog.* (1891).

HAWKER, ROBERT STEPHEN (1803–1875), English antiquary and poet, was born at Plymouth, Devonshire. He became vicar of Morwenstow, a village on the north Cornish coast, in 1834 He had an eccentric and powerful personality and was the original Canon Tremaine of Mortimer Collins' *Sweet and Twenty.* He died in Plymouth on Aug. 1j, 1875. Before his death he was formally received into the Roman Catholic Church, a proceeding which aroused a bitter newspaper controversy. The best of his poems is *The Quest of the Sangraal: Chant the First* (1864). Among his *Cornish Ballads* (1869) the most famous is "The Song of the Western Men," the refrain of which, "And shall Trelawny die," etc., he declared to be an old Cornish saying.

BIBLIOGRAPHY.—C. E. Byles, *Life and Letters of R. S. Hawker* (London, New York, 1905), contains a bibliography of his works; J. G. Godwin edited Hawker's *Poetical Works* (London, 1879) and *Prose Works* (Edinburgh, London, 1893); C. E. Byles (ed.), *Cornish Ballads and Other Poems* (London, New York, 1904), is a complete edition of the poems. *See* also S. Baring-Gould, *Vicar of Morwenstow,* 4th ed. (London, 1899); M. F. Burrows, R. *S. Hawker* (Oxford, 1926).

HAWKERS AND PEDLARS. The designations of itinerant dealers who convey their goods from place to place to sell. The word "hawker" seems to have come into English from the German or Dutch in the early 16th century. In an act of 1533 (25 Henry VIII. c. 9, s. 6) we find "Sundry evill disposed persons which commonly beene called hawkers . . . buying and selling of Brasse and Pewter."

The earlier word for such an itinerant dealer is "huckster," which is found in 1200. "For that they have turned God's house intill hucksteress bothe" (*Ormulum* 1j, 817).

"Pedlar" occurs much earlier than the verbal form "to peddle." which is therefore a derivative from the substantive. The origin is to be found in the still older word "pedder," one who carries about goods for sale in a "ped," a basket or hamper. This is now used only dialectically and in Scotland. The French term for a hawker or pedlar of books. *colporteur,* was adopted by the Bible Society and other English religious bodies as a name for itinerant vendors and distributors of Bibles and other religious literature.

The occupation of hawkers and pedlars has been regulated in Great Britain, and the two classes have also been technically distinguished. The Pedlars act, 1871, defined a pedlar as "any hawker, pedlar, petty chapman, tinker, caster of metals, mender of chairs, or other person who, without any horse or other beast bearing or drawing burden, travels and trades on foot and goes from town to town or to other men's houses, carrying to sell or exposing for sale any goods, wares or merchandise . . . or selling or offering for sale his skill in handicraft." Any person who acts as a pedlar must have a certificate, which is to be obtained from the chief officer of police of the police district in which the person applying for the certificate has resided during one month previous to his application. He must satisfy the officer that he is above 17 years of age, is of good character, and in good faith intends to carry on the trade of a pedlar. The fee for a pedlar's certificate is *js.,* and the certificate remains in force for a year from the date of issue. The act requires a register of certificates to be kept in each district, and imposes a penalty for the assigning, borrowing or forging of any certificate. It does not exempt any one from vagrant law, and requires the pedlar to show his certificate on demand to certain persons. It empowers the police to inspect a pedlar's pack. and provides for the arrest of an uncertificated pedlar or one refusing to show his certificate. A pedlar's certificate is not required by commercial travellers, sellers of vegetables, fish, fruit or victuals, or sellers in fairs. The Hawkers act, 1888, defines a hawker as "anyone who travels with a horse or other beast bearing or drawing burden." An excise licence (expiring on March 31 in each year) must be taken out annually by every

hawker in Great Britain. The duty imposed upon such licence is £2. A hanker's licence is not granted otherwise than by way of licence, except on production of a certificate signed by a clergyman and two householders of the parish or place wherein the applicant resides, or by a justice of the county or place, or a superintendent or inspector of police for the district, attesting that the person is of good character and a proper person to be licensed as a hanker. There are certain exemptions from taking out a licence—commercial travellers. sellers of fish, coal, etc., sellers in fairs and the real worker or maker of any goods. The act also lays down certain provisions to be observed by hawkers and others, and imposes penalties for infringements. In the United States there is no distinction between the words pedlar and hawker. In that country and. in a lesser degree. in Great Britain the improvement in transportation, the increase of the chain or multiple shops and the gron th of the mail-order business caused a great decrease in the number of pedlars. In their place the canvassing salesman became common. the distinction between the two being that the canvassing salesman takes orders from samples, or from pictures of the goods, whereas the pedlar carries his stock with him.

HAWKESWORTH, JOHN (*c.* 171j–1773), English miscellaneous writer. succeeded Samuel Johnson in 1744 as compiler of the parliamentary debates for the *Gentleman's Magazine,* and from 1746 to 1749 contributed poems signed Greville, or H. Greville,, to that journal. In company with Johnson and others he started a periodical called the *Adventurer,* which ran to 140 numbers, of which jo were from the pen of Hawkesworth himself. He died on Nov. 16. 1773, and was buried at Bromley. Kent. where he and his wife had kept a school. Hawkesworth was a close imitator of Johnson both in style and thought, and was at one time on very friendly terms with him. It is said that he presumed on his success, and lost Johnson's friendship as early as 1756. He edited the works of Swift (12 vol., 1754–55, and 27 vol., 1766–79) and Cook's papers relative to his first voyage (3 vol., 1773), and was the author or adapter of several plays.

HAWKHURST, a small town in the Cranbrook rural district of Kent, Eng., 14 mi. E.S.E. of Tunbridge Wells by road, and near the Sussex border. It lies mainly on a ridge above the Kent Ditch, a tributary of the Rother, in hilly and wooded country. The 14th- to 1 jth-century church of St. Lawrence, founded from Battle abbey, was damaged by bombs in World War II. William Penn owned furnaces in this centre of the Weald iron industry.

HAWKINS, or HAWKYNS, **SIR JOHN** (1532–1595), English admiral. was born at Plymouth, the second son of William Hawkins, mayor of Plymouth, who represented the town in parliament and was a successful merchant in the African trade. John's elder brother, William, was also a merchant seaman and became mayor of Plymouth three times; it was owing to this family that Plymouth became the leading port in the west country. Other members of the family distinguished themselves at sea, notably their kinsman Francis Drake and John's son, Richard (*q.v.*).

John followed his father in the African trade, which he extended to the carrying of slaves between Guinea and Brazil or the West Indies. As the first English slave trader he aroused the hostility of the Portuguese, whose example he was following, and the Spanish, whose trade monopoly he infringed without licence. His first independent voyage to Hispaniola in 1562–63 on behalf of a syndicate of London merchants was so successful that a more important group (including the queen herself. who lent him a ship and permitted him to fly her standard) supported his second voyage in 1564–65. The narrative of this expedition introduced to English readers the potato and tobacco, and included Hawkins' famous advice to his men, "Serve God daily, love one another, preserve your victuals, beware of fire, and keep good company." His success led to the grant of a coat of arms with a "demi-Moor proper, bound" as his crest. His third voyage of 1567–68 ended disastrously. The queen again lent him the "Jesus!' and another royal ship, while Drake commanded one of the four other ships. After selling his slaves in the Caribbean, Hawkins was forced by lack of water to take refuge at San Juan de Ulua, the port of Veracruz. After he had gained permission to enter, the Plate fleet arrived unexpectedly, bringing the governor of New Spain. They entered the harbour and made terms with Hawkins, but the Spaniards treacherously attacked the English ships, of which all were captured save two, Hawkins returning home in the "Minion" and Drake in the "Judith." This affair marks the beginning of the long quarrel with Spain which led to open war in 1585.

In 1570, probably at Lord Burghley's instigation, Hawkins offered his services to the king of Spain. Though he was never employed by Spain, he obtained evidence of the complicity of the duke of Norfolk to release Mary, queen of Scots, and overthrow Elizabeth I; he also secured the release of some of the prisoners taken at San Juan de Ulua. In 1571 he became M.P. for Plymouth. After his marriage (in about 1559) to Katherine, daughter of Benjamin Gonson, treasurer of the navy. Hawkins became connected with the administration of the navy board. In 1577 he succeeded his father-in-law as treasurer and in 1589 he also became comptroller, while his brother-in-law was clerk of the ships. He was chiefly responsible for rebuilding the 22 ships inherited by the queen, increasing the fleet to 25 in 1588, rearming it with more guns and encouraging the new and faster type of galleon typified by the "Revenge." He also improved the pay of seamen and was unusually attentive to their health. In 1590 he and Drake founded the Chatham Chest fund, and in 1592 he founded a hospital at Chatham for the relief of sick and aged mariners.

In the Armada campaign he commanded the "Victory" and was knighted by Lord Howard off the Isle of Wight on July 26, 1588. Afterward he was responsible for the only original strategic idea during the remainder of the war, the Azores blockade, by which it was hoped to intercept returning treasure fleets. The idea was in advance of the time and never succeeded in its object, though Hawkins himself sailed with Sir Martin Frobisher on one of the periodic cruises in 1590. In 1591 his first wife died and he married Margaret Vaughan.

His last voyage was in 1595, when he sailed with Drake and 27 ships on a raid on the Spanish West Indies. Their departure was delayed by a Spanish landing at Penzance and by dissensions between the commanders after they had put to sea. Warned of their intentions, the Spanish repulsed their attack on Puerto Rico. On Nov. 12. 1595, the night before the attack, Hawkins died after a short illness.

Hawkins was the leading naval administrator of his age, and though he had his detractors he was as honest as any public servant of that time. In his attacks on the Spanish monopoly he led the way for Drake and others. By his reconstruction of the nation's fleet he was the chief architect of the Elizabethan navy.

Markham (1877), *English Voyages to the Caribbean,* ed. *by* Irene Wright (1929, 1932); M. Oppenheim, *History of the Administration* of *the Royal Navy* (1896). (C. C. L.)

HAWKINS, SIR JOHN (1719–1789), English musical historian, was born in London on March 30, 1719. While apprenticed to an attorney, he spent his scanty leisure studying music, becoming a friend of Handel and in 1749 a member of Johnson's select Thursday Evening club, though Johnson described him as "a most unclubbable man." A wealthy marriage in 1; 53 enabled him to become a collector of rare musical works, many of which he later presented to the British Museum. He became chairman of Middlesex quarter sessions and was knighted in 1772. His *General History of the Science and Practice of Music* was published in five volumes in 1776; contemporaries preferred Burney's history, the first volume of which appeared in the same year, but the 1853 and 1875 editions of Hawkins' work were popular, particularly for their accounts of early 18th-century music. A keen fisherman, Hamkins also published an annotated edition of the *Compleat Angler* (1760; reprinted several times) and in 1789 published a life of Samuel Johnson and a complete edition of his works. He died on May 21, 1789.

HAWKINS, or HAWKYNS, **SIR RICHARD** (*c.* 1560–1622), English seaman, was the only son of Sir John Hawkins (*q.v.*) by his first marriage. In 1582 he sailed with his uncle William to the West Indies, and in 1585 he commanded a ship on Sir Francis Drake's raid on the Spanish Main. In the Armada campaign he

was captain of the royal ship "Swallow" and afterward built a ship of about **300** tons named "Repentance," renamed the "Dainty." Not till 1593 was he able to use her for his own purposes on an intended voyage round the world, following the examples of Drake and Thomas Cavendish.

In June 1593 he sailed from Plymouth in her with two smaller vessels which parted company before reaching the Pacific. In Feb 1594 he sighted what he called Hawkins Maidenland, probably the Falkland Islands, which had been discovered two years previously by John Davis. After burning four ships at Valparaiso, Hawkins continued up the coast until he met six Spanish warships off Callao. He overcame them; but on June **22**, when north of Paita, he mas wounded and forced to surrender after a fight lasting three days with two more Spanish ships. He was imprisoned at Lima and then from 1597 till **1602** in Spain, at which date his ransom of £3,000 was paid. On his return he was knighted and elected mayor and M.P. for Plymouth. In **1608**, after five years as vice-admiral of Devon, he was arrested and fined for condoning piracy. In **1620** he sailed as second in command of Sir Robert Mansell's ineffective expedition against the Algerine corsairs. He died in London on April **18, 1622.**

His *Observations* in *His Voyage Into the South Sea* was printed that year, having been composed about **1603.** This gives the best extant idea of Elizabethan life at sea and was used by Charles Kingsley for *Westward Ho!*

See Richard Hawkins, *Observations* . . , ed. by C R D Bethune, Hakluyt Society (1847), ed. by C. R. Markham, Hakluyt Society (1878), ed. by J A. Williamson (1933); *Monson's Tracts,* ed. *by M.* Oppenheim (1913) (C. C. L.)

HAWKSBILL (*Eretmochelys imbricata),* a marine turtle, so called from the shape of its snout. common in the tropical parts of the Indian, Pacific and Atlantic oceans, and producing the tortoise shell (*q v*) of commerce. Its flesh is valueless, though the eggs are edible. The hawksbill is carnivorous.

See TURTLE.

HAWKSHAW, SIR JOHN (1811–1891), English engineer, was educated at Leeds grammar school. He became chief engineer of the Lancashire and Yorkshire railway, for which he constructed a large number of branch lines.

In **1850** he moved to London and began to practise as a consulting engineer, at first alone, but subsequently in partnership with Harrison Hayter. In London he was responsible for the Charing Cross and Cannon Street railways, together with the two bridges which carried them over the Thames; he was engineer of the East London railway, which passes under the Thames through Sir M. I. Brunel's well-known tunnel; and jointly with Sir J. Wolfe Barry he constructed the section of the underground railway which completed the "inner circle" between the Aldgate and Mansion House stations. Hawkshaw was concerned with many railway works in all parts of the world—Germany, Russia, India, Mauritius, etc,

He advocated, in opposition to Robert Stephenson, steeper gradients than had previously been thought desirable or possible, and he protested against the maintenance of the broad gauge on the Great Western, as he foresaw that it complicated railway extension.

In **1862** he became engineer of the Amsterdam ship canal, and in the next year he may fairly be said to have been the saviour of the Suez canal by presenting a favourable report on the question to the khedive. As a member of the international congress to consider the construction of an interoceanic canal across Central America, he preferred the Nicaraguan route. He regarded the Panamá scheme as impracticable at a reasonable cost, although publicly he expressed no opinion on the matter and left the congress without voting. He mas engineer of the Severn tunnel, one of the most notable engineering undertakings of the 19th century.

Hawkshaw died in London on June **2, 1891.**

HAWKSMOOR, NICHOLAS (1661–1736), English architect, a disciple of Sir Christopher Wren, nas born in Nottinghamshire in **1661** and died in London on March **25, 1736.** Through Wren's influence he became deputy surveyor at Chelsea and Greenwich hospitals and clerk of the works at Whitehall, St. James's and Westminster.

He succeeded Wren as surveyor general of Westminster abbey. Rawksmoor shared in much of the work done by Wren and Sir J. Vanbrugh; the early Gothic designs of the two towers of All Souls, Oxford, north quadrangle, and the library at Queen's college, Oxford. appear, however, to be his own. He also designed several London churches, notably St. Mary Woolnoth (1716–19) and St. George's, Bloomsbury (1 720–30).

See H S. Goodhart-Rendel, *Nicholas Hawksnzoor* (1924).

HAWKWEED, the name given to species of the genus *Hieracium,* of the family Compositae (*q.v.*), containing an enormous number of species inhabiting the northern hemisphere, south Africa and the Andes. The flowering heads, often yellow, are borne, often several at a time, on an elongated axis. Various hawkweeds are serious pests, especially in rundown grasslands.

Hundreds of species occur in the British Isles, and more than **40** are found in North America, including several from the old world. Of the latter, the orange hawkweed or devil's-paintbrush (*H. aurantiacum*) of Europe, the field hawkweed (H. *pratense*), king devil (*H. florentinum*) and mouse-ear hawkweed (*H. pilosella*) are pestiferous in pastures and meadows. Once established, the perennials are almost ineradicable, but the annuals can be eliminated by mowing before flowering. (N. TR.)

HAWKWOOD, SIR JOHN (d. 1394), an English adventurer who attained great wealth and renown as a *condottiere* in the Italian wars of the 14th century. His name is variously spelled as Haccoude, Aucud, Aguto, etc., by contemporaries. He was perhaps the son of a tanner of Hedingham Sibil in Essex, and was apprenticed in London, whence he went, in the English army, to France under Edward III and the Black Prince. He was certainly of knightly rank, which he may have received from Edward III.

On the peace of Bretigny in **1360,** he collected a band of men-at-arms and moved southward to Italy. where the white company, as his men were called. assisted the marquis of Monferrato against Milan in 1362–63 and the Pisans against Florence in **1364.** After several campaigns in central Italy, Hawkwood in **1368** entered the service of Bernabb Visconti. In **1369** he fought for Perugia against the pope, and in 1370 for the Visconti against Pisa, Florence and other enemies.

In 1372 he defeated the marquis of Monferrato, but soon afterward, resenting the interference of a council of war, resigned his command, and the white company passed into the papal service, in which he fought against the Visconti in 1373–75. In 1375 the Florentines agreed to pay him and his companion 130,000 gold florins in three months on condition that he would not fight against them; and in the same year the priors of the arts and the gonfalonier awarded him a pension of **1,200** florins per year.

In 1377, under the orders of the cardinal Robert of Geneva, legate of Bologna, he massacred the inhabitants of Cesena, but in May of the same year, disliking the executioner's work put upon him by the legate, he joined the antipapal league and married. at Milan. Donnina, an illegitimate daughter of Bernabb Visconti. In 1378 and 1379 Hawkwood was constantly in the field; he quarreled with Bernabb in **1378,** and entered the service of Florence receiving, as before, 130,000 gold florins. He served the republic up to **1382,** when for a time he was an English ambassador at the papal court.

He fought in Naples in **1383,** for the marquis of Padua against Verona in **1386,** and in **1388** made an unsuccessful effort against Gian Galeazzo Visconti, who had murdered Bernabb. In 1390 the Florentines took up the war against Gian Galeazzo in earnest, and appointed Hawkwood commander in chief. His campaign against the Milanese army in the Veronese and the Bergamask was a triumph of generalship, and in 1392 Florence forced a satisfactory peace from Gian Galeazzo. Hawkwood's latter years were spent near Florence. On his death in 1394 the republic gave him a public funeral. Paolo Uccello painted his portrait in terre-verte on the inner facade of the cathedral.

Of his children by Donnina Visconti, who was probably his second wife, the eldest daughter married Count Brezaglia of Porciglia, podesta of Ferrara, who succeeded him as Florentine commander in chief, and another a German *condottiere,* Conrad

Prospergh. His son John returned to England and settled at Hedingham Sibil.

The children of the first marriage were two sons and three daughters, of whom the youngest married John Shelley, an ancestor of the poet.

G. Alger in *Register and Magazine of Biography,* vol. i; and article in *Dictionary of National Biography.*

HAWLEY, HENRY (c. 1679–1759), British lieutenant general, entered the army, it is said, in *1694.* Under Cumberland's orders he led the cavalry in the campaign of Culloden, and at that battle his dragoons gained an evil name by their ruthless butchery of the fugitive rebels.

Hawley died at Portsmouth in 1759.

HAWORTH, SIR WALTER NORMAN (1883–1950) British organic chemist, sharer with Paul Karrer of the 1937 Nobel prize in chemistry for his work on carbohydrates and vitamin C, was born on March *18, 1883,* at Chorley. Lancashire. Eng. A graduate of Owens college. Manchester. he received his Ph.D. at Göttingen. From 1911 to *1948* Haworth held positions at the Imperial college. London, at St. Andrews university, at Kings college. Sewcastle (1920–25), and the directorship of the chemistry department at Birmingham university (1925–48). With W H. Perkin, Jr., and Otto Wallach he investigated terpenes. Associated with T. Purdie and J. C. Irvine at St. Xndrews, he turned to carbohydrates. By *1928* he had decided the constitution of maltose, cellobiose, lactose, gentiobiose, melibiose. gentianose. raffinose and the ring structures of glucosides of normal sugars. Examination of polysaccharides settled the basic features of the starch, cellulose, inulin and xylan molecules. In 1932 Haworth developed a method to ascertain the chain lengths in methylated polysaccharides, an important structural problem. In 1934, with E. *L* Hirst Haworth announced the first laboratory synthesis of a vitamin, ascorbic acid. so that less expensive commercial production was made possible. Later work led to further co-ordination of chemistry, physics and biological problems related to bacterial polysaccharides. His book *The Constitution of Sugars* (1929) is a classic. From 1945 he served on the committee for advances in carbohydrate chemistry. He became a fellow of the Royal society in *1928.* Recipient of the Longstaff. Davy and royal medals. he was knighted in 1947 after war service as chairman of a general research board. Retired in *1948,* he died at Birmingham, March *19, 1950* (V. Bw.)

HAWORTH, a former urban district of the West Riding of Yorkshire. Eng., 3 mi. S.S.W. of Keighley. It is picturesquely situated at an altitude of *600* ft. surrounded by wild moorland, on the steep slope of a tributary valley of the Worth, which flows north to join the Aire.

The parsonage was the home of Charlotte, Emily and Anne Bronte (*qq.v.*) and a memorial in St. Michael's church bears their name and that of their father, the Rev. Patrick Bronte; Charlotte and Emily are buried in the church. In 1895 a museum was opened by the Bronte society, and in *1928* the parsonage was presented by Sir James Roberts to the society as a museum and library. The worsted industry of Haworth employs most of the inhabitants. The district was transferred to the borough of Keighley (*q.v.*) in *1938.*

HAWSER, a small cable or thick rope used at sea for the purposes of mooring or warping, in the case of large vessels made of steel. When a cable or towline is made of three or more small ropes it is said to be "hawser laid."

The hawse of a ship is that part of the bows where the hawseholes are made. These are two holes cut in the bows of a vessel for the cables to pass through, having small cast-iron pipes, called hawsepipes, fitted into them to prevent abrasion. In bad weather at sea they are plugged with hawse plugs to prevent water from entering.

HAWTHORN is a shrub or tree of the genus *Crataegus* of the rose family (Rosaceae. *q.v.*), overwhelmingly North American, but known also in Europe. north Africa and Asia Minor. They are unknown south of the equator. In eastern North America there are over 100 species; some estimate the number as nearer 900.

Hawthorns comprise a prolific group of thorny shrubs and trees with alternate, simple leaves. nearly always toothed or lobed. The flowers are white or pink. usually borne in clusters (corymbs), rarely solitary, and followed by often showy, red. blue or black fruits suggesting a miniature apple, containing bony nutlets or stones All have hard wood, hence the name *Crataegus,* from the Greek *kratos,* "strong."

The use of the hawthorn as a boundary for fields certainly dates from Roman times, but its use as a pleached hedge appears to have been since about the end of the 17th century. Annual pruning, to which the hawthorn is particularly amenable, is necessary if the hedge is to maintain its compactness and sturdiness. When the lower part shows a tendency to go bare. the strong stems may be split. bent over and pegged to the ground, so that new growths may start.

BY COURTESY OF GERALD R. MASSIE MISSOURI DIVISION OF RESOURCES AND DEVELOPMENT

HAWTHORN BLOSSOMS AND LEAVES (CRATAEGUS MOLLIS)

The tree is particularly suited to the common practice of ditching and hedging as it thrives on the earth thrown up from the ditch. The combination of sturdy twigs, hard wood and many thorns makes a formidable barrier to cattle and hogs It is seldom used for this purpose in America.

In Great Britain the name hawthorn is confined to two species: *C oxyacantha* and *C. monogyna,* both also called may, hedgerow thorn and ahitethorn They differ in that there is only one stone in the fruit of *C. monogyna,* but two in the fruit of *C. oxvacantha.* The fruit of both are commonly known as haws. Often they are not distinguished as different species because their superficial resemblance is striking.

Both have deeply lobed leaves. many thorns. white or pinkish flowers in May and rather persistent and profuse red fruit. Normally they would be medium sized (15–25 ft.). round-headed trees! but their wide use for hedges and frequent pruning make of them close twigged, practically impenetrable barriers, especially *C. monogyna* which is preferred for hedges.

Hawthorn flowers emit the faint odour of decayed fish as a result of the plant's mixture of coumarin and aminoid compound. Many legends among tustics warn against bringing flowering branches of hawthorn into their houses as it was supposed to portend death in the family. More factual is the avoidance of hawthorn by bees and butterflies. so that the plant is pollinated only by flies.

The cultivation of hawthorns for ornament is extensive in the United States. where the finest collections in the world will be found in the Genesee Valley park at Rochester, N.Y., and at the Arnold arboretum of Harvard university at Jamaica Plain. Mass.

The outstanding species for cultivation, outside the English hawthorn, either for their showy flowers or for their spectacular. often persistent, coloured fruit or both, are the following: the Washington thorn (*C. phaenopyrum*), a tree from the southeastern U.S. with red fruit; the pear haw (*C. calpodendron),* a shrub from eastern North America with orange-red fruit; the cockspur thorn (*C. crus-galli*), a shrubby tree of eastern North America with red fruit; *Crataegus lavallei,* a hybrid hawthorn whose brick-red fruits persist throughout the winter; *Crataegus arnoldiana,* a tree up to 30 ft. high with pear-shaped red fruit, native from Massachusetts to New York; and the red haw (C. *mollis*), a tree from the central U.S with scarlet fruit one inch thick. (N. TR.)

HAWTHORNE, NATHANIEL (1804–1864), one of the greatest fiction writers in .American literature, was born in Salem, Mass.. on July *4, 1804.* His earliest American ancestor, William Hathorne (the *w* was added by Nathaniel himself when he was in college), came from England to Massachusetts Bay Colony with John Winthrop in *1630.* Later, as a magistrate in Salem, he ordered the public whipping of a Quakeress. William's son John

was one of the three judges (the other two being Samuel Sewall and William Stoughton) in the Salem witch trials in 1692. Nathaniel was sensitively aware of the prominence of these 17th-century ancestors, and wondered if the decline of his family's fortunes (his immediate forebears had followed the sea with indifferent success; his father had died in a faraway port when Nathaniel was four years old) might be a retribution for their crimes.

Nathaniel's boyhood was spent in Salem and in Maine, near Lake Sebago, nhere he enjoyed outdoor sports. He attended Bowdoin college, at Brunsnick, Me . and was graduated in the class of 1825. Three fellow collegians became his lifelong friends: Franklin Pierce. 14th president of the United States, belonged to the class just before him; Horatio Bridge, commodore in the United States navy, and Henry Wadsworth Longfellow, the poet, were of his own class.

After college, Hawthorne returned to his mother's home in Salem, and devoted himself closely to mastering the craft of fiction. He read much and wrote much. Being his own severest critic he destroyed much of what he wrote. After publishing a rather undistinguished "college novel," *Fanshawe* (1828), he happily hit upon the short tale as a distinctive métier.

His tales were published first in various periodicals and later collected in book form. *Twice-Told Tales*, his first collection, appeared in 1837; a second, enlarged edition appeared in 1842. Since these volumes brought their author more fame than money (the 1842 *Tales* was highly praised by Poe), he held a job in 1839–40 in the Boston customhouse to eke out his income. and for six months in 1841 he was a resident at Brook Farm (*q.v.*). Meannhile he had met (in 1839) and fallen in love with Sophia Peabody (one of the three famous "Peabody sisters"), and she with him, and after their marriage on July 9. 1842, they went to the "Old Manse" in Concord, Mass , to live. Their life together during the three and one-half years at the Old Manse, as recorded in Hawthorne's *American Notebooks* and his essay "The Old Manse." is a famous marital idyl of American literature.

In Concord, Hawthorne saw a good deal of his neighbours. Ralph Waldo Emerson and Henry David Thoreau; he welcomed their companionship while rejecting their transcendentalism. At the Old Manse, too, he returned to the writing of tales, with the same result as before: literary success, monetary failure *Mosses From an Old Manse,* a new collection, appeared in 1846. Not being able to pay his rent, hotiever. he with his wife and daughter. late in 1845, had moved to his mother's house in Salem. In 1846 he received from the Polk administration (he had always been a loyal member of the Democratic party and he had pulled all the political strings he possibly could to get this appointment) a position in the Salem customhouse. Three years later he was turned out of office when the Whigs came into poner under Zachary Taylor.

Hawthorne uas very angry (especially at the local bigwig Charles Wentworth Upham, whom he was to lampoon recognizably in the character of Judge Pyncheon in *The House of the Seven Cables).* and appealed to influential friends in the effort to force his reinstatement, making the point that literary men nere traditionally entitled to sinecures from government: but the spoils system was already firmly established. Hawthorne later saw his dismissal as a great blessing ("Thank God for my enemies." he said). for in the gloom of his disappointment and chagrin he had sat down to write *The Scarlet Letter*. The book. which appeared in 1850 made him famous. It was eventually to be recognized as probably the greatest of American novels.

The sharp local references in "The Custom House." the introductory essay to *The Scarlet Letter,* made Hawthorne *persona non grata* in Salem, and, looking westward for a change of air. he and his family settled in "the little red house" near Lenox, overlooking the Stockbridge Bowl in the Berkshires. There Han thorne wrote *The House of the Seven Gables,* a sombre study in heredity, which appeared in 1851. And there he enjoyed the stimulating friendship of Herman Melville, who lived in nearby Pittsfield. This relationship was one of the most fortunate in American literature; each encouraged and stimulated the other. Melville wrote an enthusiastic essay, "Hawthorne and His Mosses," in praise of Hawthorne, and was undoubtedly influenced by Hawthorne's work at many points; the similarity between "Ethan Brand" and *Moby Dick* (which appeared in 1851, with a dedication to Hawthorne) is only one instance of Melville's indebtedness. Hawthorne, being 15 years Melville's senior, was less susceptible to influence; but his admiration for Melville and his work was very great.

These two writers at least confirmed each other in the opinion that the romantic, progressive 19th century took much too rose coloured a view of the human condition; that the Emersonian optimism so dominant in the century was premature; that a balanced view of man even in the new world (the essential human condition being indeed the same in the new world as in the old, since the mere expedient of removing to a new continent could hardly be expected to make sinful man sinless) would have to include somenhere along the line something approximating Jonathan Edwards' notion of "original sin." Hawthorne and Melville (patriotic. democratic Americans that they were) would stand together on some such proposition as this in an American world which seemed to believe that Americans could do no wrong.

Late in the autumn of 1851 the Hawthornes—Nathaniel, Sophia, Una (born in 1844), Julian (born in 1846) and Rose (born in 1851) —returned to eastern Massachusetts (Hawthorne had always preferred ocean to mountains), and settled for the minter at West Newton. There Hawthorne wrote *The Blithedale Romance,* a study of a socialist community based upon his residence at Brook Farm. In the spring of 1852 he purchased "The Wayside" in Concord. There. Franklin Pierce having been nominated for the presidency by the Democrats, he loyally wrote a campaign biography, and after Pierce's election he accepted in 1853, the lucrative appointment, generously bestowed by Pierce, to the consulship at Liverpool.

The Hawthornes mere in England from 1853 to 18 j7, Hawthorne resigning his post at the end of Pierce's administration. He performed his consular duties faithfully and efficiently, and at the same time found leisure for much travel and sight-seeing, the rich record of which can be read in his *English Notebooks*. Nearly two years (1858–59) were spent in Italy—in Rome and in Florence —and there again he recorded in a voluminous journal his acute observations *(see* his *Italian Notebooks)*. In the autumn of 1859 the Hawthornes returned to England, where. at Redcar on the German ocean and later at Leamington, Hawthorne wrote *The Marble Faun,* his last completed novel and his most earnest study of the problem of good and evil. The book appeared early in 1860, being published simultaneously in London and in Boston; in London it uas given the title *Transformation,* and it has remained so known and referred to among the English. In June of the same year, the Hawthornes returned to America and settled at The Wayside, after an absence of nearly seven years. The residence abroad had been rewarding. Hawthorne had seen the places he had always longed to see; he had studied sympathetically sculpture, painting and architecture; he had stored up impressions One sorrow, hoaever. darkened both retrospect and prospect Una had nearly died of the fever in Rome, and though improved. did not completely recover upon her return to America.

Mrs. Hawthorne believed that her husband's failing health, noticeable upon their return, was the result of anxiety for Una. and also of some deep-seated Roman infection which he himself had contracted. Whatever the reason, Hawthorne's health after 1860 failed rapidly and mysteriously. He managed to salvage some of the material of the English journals (he had incorporated a good deal of the Italian journals in *The Marble Faun)* in a series of essays published in the *Atlantic Monthly* and later collected under the nostalgic title *Our Old Home*. But his attempts at imaginative literature proved less successful. He filled hundreds of manuscript pages with drafts of stories, but the old skill seemed to have deserted him. *Septimius Felton* and *Dr. Grimshawe's Secret,* published posthumously, were fragmentary and inferior to their author's best work.

In 1862 Hawthorne visited Washington and the battlefields of northern Virginia, and nrote for the *Atlantic* an article entitled "Chiefly About War Matters." which is remarkable for its contemporary portrait of Lincoln. The dedication of *Our Old Home,*

in 1863, to Pierce, who was sympathetic with the Southern side of the war, caused a flurry of protest around Boston. But Hawthorne, while loyal to the North. insisted that the dedication was a fitting and deserved compliment to his friend. "If Pierce is so exceedingly unpopular," he told his publisher, James T. Fields, "there is so much the more need that an old friend should stand by him." He died in his sleep on May 19, 1864, at Plymouth, N.H., where, accompanied by the faithful Pierce, he had stopped overnight. en route to the White mountains. Longfellow's poem "Hawthorne," written soon after the burial in Concord, spoke of his friend's "wand of magic power."

Hawthorne's high rank among American fiction writers, and indeed among the fiction writers of the world, is the result of at least three considerations, which can be particularized with some definiteness.

First, he was a skillful craftsman. He had an architectonic sense, a sense of form. (Henry James was to resemble him in this respect.) The structure of *The Scarlet Letter* is tightly integrated. It has a beginning, middle and end. No chapter, no paragraph, no sentence even, could be omitted without doing violence to the nhole. The four characters — Hester Prynne, Arthur Dimmesdale, Roger Chillingworth and little Pearl — are inextricably bound together in the tangled web of a life situation which seems to have no solution The calculated use of the "scaffold" in three crucial scenes (at the beginning, middle and end) gives unity of place. The tightly woven plot gives unity of action — an action which rises slowly but inexorably to the climactic scene of Arthur's public confession. The same structural virtue is found in Hawthorne's other writings also. especially in the shorter pieces or "tales."

Hawthorne not only had a sense of structure, he had a sense of style. His was the older classic, literary style, but one remarkable nevertheless for its directness, its clarity, its firmness and its sureness of idiom. Fields tells us that when, on occasion, he queried some phrase in a manuscript, Hawthorne could always point to a precedent in the King James Bible. And indeed there is in Hawthorne that infallible rightness of language which is a mark of literary greatness. The great uriter must first of all be master of the word, master of *le mot juste.* This is a truth learned later from Henry James and T S. Eliot, and it is important to give to Hawthorne his rightful place as their predecessor in this tradition.

A second reason for Hawthorne's greatness is his moral insight. He inherited the Puritan tradition of moral earnestness; he was concerned everywhere with what the theologians would call "original sin" But it should be noted that the background of Hawthorne's religious attitudes is not confined to New England Puritanism; it reaches to pre-Reformation times, and can be regarded in certain basic respects as essentially Catholic. As for New England Puritanism. he was critical of its narrowness, intolerance and cruelty. A story like "The Maypole of Merrymount" is just as critical of the bigoted zealots as of the wanton revelers. Hawthorne's general position can more properly be called Christian than Puritan.

Hawthorne was deeply involved in the perennial debate concerning the nature of man In his own century there was a strong "romantic" current of thought which insisted that man is innately good. This view stemmed from Rousseau, and its chief proponent in American literature was Emerson. "Trust thyself." proclaimed Emerson. Hawthorne was not unresponsive to the romantic fascination. His treatment of Hester in *The Scarlet Letter* shows a latent sympathy. Hester is a splendid self-reliant heroine. She is never truly repentant for the act of adultery committed with the minister. She never quite understands the minister's agony of conscience. "What we did," she says to Arthur, "had a consecration of its onn" When she meets the minister at the brookside, she tears the scarlet letter from the bosom of her dress and casts it on the ground. This casting aside of the letter was Hester's "romantic revolt" The action of the story at this point seems to suggest that there is much to be said for Hester's position. It is the kind of action which might have been applauded by great 19th-century romantics like Byron or Browning.

But there is more to be said. the story seems to say, for the claims of law and conscience. Arthur speaks of "the law we broke." Hester redons the letter, at the insistence of the child Pearl. The lovers do not elope, as Hester planned, but instead Arthur, in the profoundly moving climactic scene, mounts the scaffold, speaks his confession to the assembled parishioners and dies with a smile on his lips and Pearl's hand in his own. There is no "romantic escape" here; rather, a firm and resolute facing (heartily approved, incidentally, by 20th-century psychologists) of the psychological and moral facts of the human condition.

All of Hauthorne's fiction shows pride as the great besetting sin, whether it is the intellectual pride of Ethan Brand or the reforming zeal of Hollingsworth in *The Blithedale Romance* or the arrogation to oneself of godlike power, as in the case of Aylmer in "The Birthmark," or a selfish concern for one's reputation, as with Arthur Dimmesdale who played the hypocrite in his Puritan parish for seven years. Man is a fallible, imperfect being in Hawthorne's stories. He is isolated from his fellows by his endless self-involvement; one of his most memorable tales is appropriately entitled "Egotism, or the Bosom Serpent." Man can be "saved" only through humility, only through the surrender of the proud, stubborn individual will to the divine will. Man finds his life only through losing it. Humility (not the vain-boasting "Trust thyself") is the best solvent, the true equalizer in human relations. The tales and novels of Hawthorne embody these truths in enduring dramatic situations.

A third reason for Hawthorne's eminence is his mastery of allegory and symbolism. The allegorical method was depreciated in Hawthorne's own century, but the critics of the 20th century have recognized its merit. All great fables, in a sense, are allegories. Symbols enlarge and deepen the meaning. Hawthorne's symbolism is especially successful in *The Scarlet Letter.* Places. characters and incidents take on larger meanings. The scaffold stands for punishment at the beginning and for expiation at the end. The forest is a place where one goes morally astray. The scarlet letter itself stands for adultery; but more than that, for any sin; and still further, as its scope enlarges more and more, for all faults and limitations which prevent the happy working of human society. The fall of man in Hawthorne, however, is the "fortunate fall." Through sin and suffering, man achieves a depth and wisdom not otherwise attainable. Adam fell, these remarkable fictions seem to say, that we might ultimately rise to a loftier paradise than his.

The craftsmanship, the moral insight, the intensification of symbol — these have recommended Hawthorne's work with special cogency to readers of the mid-20th century and after. The dangers and tensions of the modern atomic. anxious age seem reflected almost clairvoyantly in his symbolic depths.

(R. ST.)

HAWTHORNE, an industrial community of Los Angeles county, Calif., U.S., about 10 mi. S.W. of Los Angeles, was founded in 1906 by B. L. Harding and H. D. Lombard and named by the Harding family in honour of Nathaniel Hawthorne. Its earlier economy centred around a series of small factories producing furniture, clothing and leather goods. Hawthorne grew very slowly for 30 years, being incorporated in 1922 and changing to a city-manager government in 1948.

The chief industry is the Northrop Aircraft corporation, supplemented by more than 100 smaller manufacturing plants within the city limits.

Stimulated by aircraft construction during World War II, the

population tripled in the decade ending 1460. This sudden increase in population. of mixed racial and economic status, brought housing and land-use problems, and considerable delinquency. A unique arrangement with school and county officials resulted in establishment of improved recreational facilities. With over half the city budget devoted to improvement of civic and recreational facilities Haathorne made rapid progress toward developing a balanced industrial and residential city.

For comparative population figures *see* table in CALIFORNIA: *Populatzon.* (R. C. GM)

HAXO, FRANÇOIS NICOLAS BENOÎT, BARON (1774–1838), French general and military engineer, was born at Lunéville on June 24, 1774, and entered the Engineers in 1793. He remained unknown, doing duty as a regimental officer for many years, until, as major, he had his first chance of distinction in the second siege of Saragossa in 1809, after which Napoleon made him a colonel. Haxo took part in the campaign of Wagram, and then returned to the peninsula to direct the siege operations of Suchet's army in Catalonia and Valencia. In 1810 he was made general of brigade, in 1811 a baron, and in the same year he was employed in preparing the occupied fortresses of Germany against a possible Russian invasion. In 1812 he was chief engineer of Davout's 1st corps, and after the retreat from Moscow he was made general of division. In 1813 he constructed the works around Hamburg which made possible the famous defense of that fortress by Davout, and commanded the Guard Engineers until he fell into the enemy's hands at Kulm. After the Restoration, Louis XVIII wished to give Haxo a command in the Royal Guards, but the general remained faithful to Napoleon, and in the Hundred Days laid out the provisional fortifications of Paris and fought at Waterloo. It was, however, after the second restoration that the best work of his career as a military engineer was done. As inspector-general he managed, though not without meeting considerable opposition, to reconstruct in accordance with the requirements of the time, and the designs which he had evolved to meet them, the old Vauban and Cormontaigne fortresses which had failed to check the invasions of 1814 and 1815. For his services he was made a peer of France by Louis Philippe (1832). Soon after this came the French intervention in Belgium and the famous scientific siege of Antwerp citadel. Under Marshal Gérard, Haxo directed the besiegers and completely outmatched the opposing engineers, the fortress being reduced to surrender after a siege of a little more than three weeks (Dec. 23, 1832).

He was after this regarded as the first engineer in Europe, and his latter years were spent in urging upon the government and the French people the fortification of Paris and Lyons, a project which was begun in his time and completed after his death. He died at Paris on June 25, 1838.

He wrote *Mémoire sur le figuré du terrain dans les cartes topographiques* (Paris, n.d.), and a memoir of General Dejean (1824).

HAXTHAUSEN, AUGUST FRANZ LUDWIG MARIA, FREIHERR VON (1792–1866), German economist, was born near Paderborn in Westphalia on Feb. 3, 1792. Having studied at the school of mining at Klausthal and having served in the Hanoverian army, he entered the university of Gottingen in 1815. Finishing his course there in 1818 he was engaged in managing his estates and in studying the land laws. The result of his studies appeared in 1829 when he puhlished *Über die Agrarverfassung in den Fürstentümern Paderborn und Corvey,* a work which attracted much attention and which procured for its author a commission to investigate and report upon the land laws of the Prussian provinces with a view to a new code. After nine years of labour he published in 1839 an exhaustive treatise, *Die ländliche Verfassung in der Provinz Preussen,* and in 1843. at the request of the emperor Nicholas, he undertook a similar work for Russia, the fruits of his investigations in that country being contained in his *Studien über die innern Zustände des Volkslebens, und insbesondere die ländlichen Einrichtungen Russlands* (Hanover, 1847–52). He received various honours, was a member of the combined diet in Berlin in 1847 and 1848, and afterwards of the Prussian upper house. Haxthausen died at Hanover on Dec. 31, 1866.

In addition to the works already mentioned he wrote *Die Eandliche Verfassung Russlands* (Leipzig, 1866) His *Studien* has been translated into French and into English by R Farie as *The Russian Empire* (1856). Other works of his which have appeared in English are: *Transcaucasia; Sketches of thr Nations and Racrs between the Black Sea and the Caspian (1854).* and *The Tribes of the Caucasus* (1855). Haxthausen edited *Das konstitutionelle Prinzip* (Leipzig, 1864), *a* collection of political writings by various authors, which was translated into French (1865).

HAY, SIR GILBERT (SIR GILBERT [OF] THE HAYE) (fl. 1456), Scottish translator of works from the French whose prose translations are the earliest extant examples of literary Scots prose. He probably belonged to the family of the Hays of Errol, and if he was the "Gylbertus Hay" named in the registers of St. Andrews university in 1418 and 1419, must have been born about 1403. That he received degrees as a master of arts and as bachelor in decrees, that he became a knight and that he mas at some time chamberlain to the king of France (Charles VII) are facts known from his own description of himself at the beginning of the manuscript of his prose translations: he is known to have been in France by 1432. By 1456 he had returned to Scotland and had entered the service of the earl of Orkney and Caithness, at whose request he began in that year the translation of three of the most popular works of the middle ages: Honoré Bonet's *L'Arbre des Batailles* (as *The Buke of the Law of Armys* or *Buke of Bataillis*); *Le Livre de l'ordre de chevalerie,* a French version of Rnimon Lull's *Libre de cavaylerza* (as *The Buke of the Order of Knichthood*); and *Le Gouvernement des Princes,* a French version of the pseudo-Aristotelian *Secreta secretorum* (as *The Buke of the Governaunce of Princes).* The second of these precedes William Caxton's translation by at least ten years These remained in manuscript until found in Sir Walter Scott's library at Abbotsford and edited for the Abbotsford club by D. Laing in 1847 An edition for the Scottish Text society (2 vol., 1901–14) by J. H. Stevenson has an introduction containing all that is known of Hay's life.

By 1456 he must have become a priest, for the earl's father-in-law, in a will dated then, left him instructions to say ten psalters for his soul. He was apparently still alive in 1499.

Hay is named as a poet in William Dunbar's *Timor mortis conturbat me* and by Sir David Lyndsay in his *Testament and Complaynt of the Papyngo.* His only extant poetical work, *The Buik of Alexander the Conqueror,* is a translation of the French *Roman d'Alexandre.* It is in heroic couplets and a portion remains in a manuscript copy at Taymouth castle; extracts were printed by A. Herrmann in 1898. This shows interesting differences in treatment from other versions and, like his prose, a thorough knowledge of French, and vigour in the use of his own language.

HAY, JOHN (1838–1905), U.S. statesman and author, was born at Salem. Ind., on Oct. 8, 1838. He graduated at Brown university in 1858, studied law in the office of Abraham Lincoln, was admitted to the bar in Springfield, Ill., in 1861, and soon afterwards was selected by President Lincoln as assistant private secretary. in which capacity he served till the president's death, being associated with John George Nicolay (1832–1901). Hay was secretary of the U.S. legation at Paris in 1865–67, at Vienna in 1867–69, and at Madrid in 1869–70. After his return he was for five years an editorial writer on the *New York Tribune*; in 1879–81 he was first assistant secretary of state to W. M. Evarts. Cpon the inauguration of President McKinley in 1897 Hay was appointed ambassador to Great Britain, from which post he was transferred in 1898 to that of secretary of state, succeeding W. R. Day, who was sent to Paris as a member of the peace conference. He remained in this office until his death at Newburg, N.H., on July 1, 1905. Hay directed the peace negotiations with Spain after the war of 1898. and not only secured American interests in the imbroglio caused by the Boxers in China, but grasped the opportunity to insist on "the administrative entity" of China; influenced the powers to declare publicly for the "open door" in China; challenged Russia as to her intentions in Manchuria, securing a promise to evacuate the country on Oct. 8, 1903. In 1904 he again urged "the administrative entity" of China and took the initiative in inducing Russia and Japan to "localize and limit" the area of hostilities. It was due largely to his management, in concert with Lord Pauncefote, the British ambassador,

that negotiations for abrogating the Clayton-Bulwer treaty and for making a new treaty with Great Britain regarding the Isthmian canal were successfully concluded at the end of 1901; subsequently he negotiated treaties with Colombia and Panamá, looking towards the construction by the United States of a trans-isthmian canal. He arranged the settlement of difficulties with Germany over Samoa in 1899, and the settlement, by joint commission, of the disputed Alaskan boundary in 1903. As secretary of state under Presidents McKinley and Roosevelt his guidance was invaluable during a critical period in foreign affairs, and no man of his time did more to create confidence in the increased interest taken by the United States in international matters. He also represented the best American traditions in literature. He published *Pike County Ballads* (1871)—the most famous being "Little Breeches"—a volume worthy to rank with Bret Harte; *Castilian Days* (1871), recording his observations in Spain; and a volume of *Poems* (1890); with John G. Nicolay he wrote *Abraham Lincoln: A History* (1890), a monumental work indispensable to the student of the Civil War period in America, and published an edition of Lincoln's *Complete Works* (1894). The authorship of the brilliant novel, *The Breadwinners* (1883), is now certainly attributed to him. Hay was an excellent public speaker; some of his best addresses are *In Praise of Omar; On the Unveiling of the Bust of Sir Walter Scott in Westminster Abbey,* May 21, 1897; and a memorial address in honour of President McKinley. The best of his previously unpublished speeches appeared in *Addresses of John Hay* (1906); his correspondence in *Letters of John Hay and Extracts From His Diary* (1908) and in *A Poet in Exile: Early Letters of John Hay,* edited by Caroline Ticknor (1910); and his poems in *Complete Poetical Works of John Hay* (1916).

HAY, OLIVER PERRY (1846–1930), **U.S.** paleontologist and author of many valuable works on fossil vertebrates, was born in Saluda, Ind., May 22, 1846. He was graduated from Eureka college, Ill., in 1870, and joined the college faculty as professor of natural sciences in the same year. He held the same position at Oskaloosa college, Ia., from 1874–76 and at Abingdon college, Ill., from 1877–78. In 1879 he became professor of biology and geology at Butler university, Indianapolis, Ind.. where he remained until 1892. He served as assistant curator of zoology at the Field Museum of Natural History in Chicago from 1895–97 and subsequently went to the American Museum of Natural History in New York where he worked from 1901–07, serving first as assistant and later as associate curator. He was employed by the Carnegie institution, Washington. D.C., where he did research on the history of the vertebrates of the Pleistocene epoch in North America, from 1912 until his retirement in 1926. He was also employed during his lifetime as assistant in the geological surveys of Arkansas (1884–88), Indiana (1891–94 and 1911–12) and Iowa (1911–13). He died in Washington, D.C., Nov. 2, 1930.

Among Hay's works on various phases of vertebrate paleontology the following are outstanding: *The Bibliography and Catalogue of the Fossil Vertebrata of North America* (1902); *The Fossil Turtles of North America* (1908); *Pleistocene Period in Indiana and its Vertebrates* (1912); *Pleistocene Mammals oj Iowa* (1914); and a three volume study of the vertebrates of the Pleistocene epoch in North America (east of the Mississippi river, 1923; the middle region, 1924; the western region, 1927). In 1929–30 Hay published the two volumes of his *Second Bibliography and Catalogue of the Fossil Vertebuata of North America,* and it is for this work and his earlier bibliography and catalogue that he is most noted.

HAY (HAY-ON-WYE), a market town and urban district in the Brecon and Radnor parliamentary division of Breconshire (q *v.*), south Wales, 21 mi. W. of Hereford by road. Pop. (1951) 1,454. Area 0.6 sq.mi. Hay occupies rising ground on the south bank of the Wye, nhich there separates the counties of Brecon and Radnor but immediately below enters Herefordshire, from which the town is separated on the east by the Dulas. Hay guards an important way into Wales between the Radnor forest and the Black mountains. This district was heavily forested in early times and settlement was unimportant until the Norman period. Bernard de Newmarch conquered the district about 1088 and gave the manor of Hay to Sir Philip Walwyn, but it soon reverted to the donor and was subsequently forfeited to the crown as part of the duke of Buckingham's estate in 1521.

The motte and bailey castle, probably built in Newmarch's time and rebuilt by his great-grandson William de Braose, passed on the latter's attainder to the crown, but was again seized by De Braose's second son, Giles, bishop of Hereford, in 1215, and retaken by King John in the following year. In 1231 it was burned by Llewelyn ap Iorwerth, and in the Barons' War it was taken in 1263 by Prince Edward, but in the following year was burned by Simon de Montfort and the last Llewelyn. The castle was largely rebuilt in the 16th century as a private residence.

The Welsh name of the town is Y *Gelli* ("the wood"), or in full (Y) *Gelli ganddryll,* which roughly corresponds to *Sepes Inscissa,* used by Walter Map. Its Norman name, *La Haia* (from the Fr. *haie; cj.* English "hedge"), was probably intended as a translation of *Gelli.*

Hay manor, like that of Talgarth, consisted of an Englishry and a Welshry, the latter, known as Haya Wallensis, comprising Llanigon parish with the hamlet of Glynfach, and in this Welsh tenures and customs prevailed. The manor is mentioned in the act of Henry VIII (1535) as one of those which were then taken to constitute the new county of Brecknock. Even down to John Leland's time Hay was surrounded by a "right strong wall," but the town within the wall had "wonderfully decayed," while to the west of it was a suburb with the church of St. Mary (rebuilt in 1834) overlooking the river. The old chapel of St. John within the walls, not used as a church since the 16th century, has been restored for parochial purposes. There are 18 almshouses for poor women, built and endowed by Frances Harley in 1832–36, and Gwyn's almshouses for six aged persons, founded in 1702 and rebuilt in 1878. Hay is the centre of a rich agricultural country, and cattle and ewe sales are held there as well as a weekly market. There is good fishing in the Wye and other streams.

HAY: *see* GRASSLAND.

HAYA, an East African people of the Interlacustrine Bantu group, also known as the Bahaya, Wahaya, Baziba or Waziba, who inhabit the northwestern corner of Tanganyika between the Kagera river and Lake Victoria. Although forming a single modern administrative district (Bukoba) with a single local government, the Haya peoples, whose language is very similar to that of the Nyoro, were traditionally divided among eight small states (Kiamtuara, Ihangiro, Kianja, Karagwe, Maruku, Bugabo, Kiziba, Missenyi), each under a ruler called the *Mukama.* Together they numbered about 300,000 in 1960. The production of coffee, an indigenous crop, was expanded under German and British administration to form the basis for a thriving modern economy; the staple food, however, is the plantain. (*See* also TANGANYIKA: *Population.*)

As among the Nyoro, there are two main elements in the population: the pastoral Nfula, or Hima (Bahima), and the more agricultural Iru (Bairu). In some of the states, the rulers are apparently Hima, while in others the dynasties are related to the Nilotic Bito (Babito) rulers of the Nyoro. Traditionally, rulers appointed subordinate chiefs and officials from both royal and commoner clans. Age groups of boys were brought to the capital for military and character training. Traditional religion resembled that of the Nyoro.

HAYA DE LA TORRE, VÍCTOR RAÚL (1895–), Peruvian political theorist, founder and *jefe* (leader) of the Aprista party, Peru's largest, was born on Feb. 22, 1895, in Trujillo, Peru. He was educated in Peru and England. As president of the Peruvian federation of students in 1919 he led the students in creating popular universities to educate workers. After leading a mass demonstration May 23, 1923, protesting the dedication of Peru to the Sacred Heart of Jesus he was jailed. When he began a

protest hunger strike he was deported.

Haya founded the Alianza Popular Revolucionaria Americana (American Popular Revolutionary Alliance), popularly known as the Aprista movement, or Apra, May 7, 1924, in Mexico. From 1924 to 1931 he traveled through the Americas and Europe, studying, writing and organizing. After Pres. Augusto Bernardino Leguia y Salcedo (1863–1932) was overthrown, Haya returned to Peru in 1931, as the Aprista candidate for president. The consensus of opinion is that Haya was elected, nevertheless his opponent, Col. Luis M. Sánchez Cerro (1894–1933), was inaugurated president. Sánchez Cerro imposed a sanguinary dictatorship and jailed Haya. Protests in all parts of the world apparently saved Haya from execution. He was released after Sánchez Cerro's assassination in 1933. From 1934 to 1945 Haya lived in hiding in Peru becoming a living legend as his underground life and writings became widely known.

In 1945 the Aprista party was legalized and took the name Partido Popular (Popular party). Desiring a transitional administration, the Apristas helped to elect José Luis Bustamante y Rivero president. His conduct in office and refusal to co-operate with the Apristas led to a new dictatorship under Gen. Manuel Odria in 1948.

Following his party's orders Haya took refuge in the Colombian embassy Jan. 3. 1949. His status became a *cause célèbre* as the governments of Peru and Colombia argued about his right to asylum. The case was taken to the International Court of Justice but the court's decisions were never clear. On April 7, 1954, under pressure from the other American republics. Odria permitted Haya to leave Peru and go to Mexico. His asylum case stimulated the American republics to strengthen their treaty regulating political asylum. Haya returned to Peru July 20, 1957, after constitutional government under Manuel Prado had replaced Odría's tyranny.

Haya de la Torre has written a number of books and scores of articles and manifestos expounding his political theories and experience. He maintains that the people of Latin America live within a historical space-time which molds them and their institutions. To create a better life they must cease imitating Europe and the United States, and establish institutions in harmony with Latin America's character and needs. Specifically, Haya maintains that the Indian population must be brought into the main stream of Peruvian life, democracy must be strengthened and Latin America must be unified and industrialized to spare her from all imperialisms, including Russian Communism. He advocates cooperation between the U.S. and Latin America, which he prefers to call Indo-America. Haya and the Aprista movement have stimulated the founding of indigenous reformist organizations in all parts of Latin America. *See* also PERU: *History*. (H. KR.)

HAYASHI, SENJURO (1876–1943), Japanese army officer and politician. was born on Feb. 23, 1876, in Ishikawa-ken. Educated and trained at the Military academy and Military Staff college, he held many responsible posts. In 1931, as commander of Japanese troops in Korea, he ordered his forces to march into Manchuria without waiting for permission from Tokyo, an action that had much to do with Japan's success in that territory. Promoted to full general in 1932, he was appointed inspector general of military training. one of the three most important positions in the Japanese peacetime army. In 1934 Hayashi succeeded Gen. Sadao Araki as minister of mar. He attempted to purge the army of Araki's supporters. who had strong fascist leanings, and by bold and varied means removed an estimated 5,000 officers from important posts. After his resignation in 1935, he took a position on the supreme war council. However, in Feb. 1936, after the assassination of some of the principal Japanese military leaders, he and the other council members resigned. He became premier in Feb. 1937 but remained in office only a few months; when a general election revealed that he had few supporters, he resigned on May 31. He died in Tokyo on Feb. 4, 1943. (S. L. FK.)

HAYASHI TADASU, COUNT (1850–1913), Japanese diplomat and statesman whose greatest diplomatic triumph was the Anglo-Japanese alliance of 1902. was born in Chiba prefecture on Feb. 22, 1850. Sent to study in England in 1866, he returned home just in time to join Enomoto Buyo (*q.v.*) in his last-ditch defense of the shogunate against the Meiji emperor's armies. Imprisoned until 1871 by the imperial government, he was then assigned as interpreter to the mission headed by Iwakura Tomomi (*q.v.*) to the western powers. Thereafter he joined the diplomatic service and also served in other governmental offices. Appointed vice-minister for foreign affairs in 1891, he played a leading role in the renegotiation of the Anglo-Japanese treaty in 1894. In the following year. after participating actively in the conclusion of the treaty of Shimonoseki, ending the Chinese-Japanese war, Hayashi was dispatched as ambassador to China. In 1897 he became minister to Russia and in 1899 was appointed minister to England. There he nas to achieve his greatest diplomatic triumph. Alarmed by the expansion of Russian power in the far east, which he viewed both as a threat to his country's security and as an obstacle to the extension of Japanese interests, Hayashi was instrumental in concluding the Anglo-Japanese alliance. Renewed several times, the alliance was a pillar of Japanese foreign policy for the next 20 years (*see* JAPAN). After the Russo-Japanese war he completed his diplomatic career by serving as minister for foreign affairs from 1906 to 1908. Hayashi died in Tokyo on July 10, 1913.

HAYDEN, EDWARD EVERETT (1858–1932). U.S. naval officer and meteorologist, was born April 14, 1858, in Boston, Mass. He was educated at the Boston Latin school and at the U.S. Naval academy, from which he was graduated in 1879. He was shortly ordered to duty with the Smithsonian institution and subsequently assigned to the U.S. geological survey. While he was serving with that bureau, an injury necessitated the amputation of a leg. He retired from active service, spent a year (1884) at the observatory at Harvard, and in 1885 was made assistant geologist in the geological survey. He served as marine meteorologist of the U.S. Hydrographic office and editor of the pilot chart issued by that office from 1886–92. During the Spanish-American War he was stationed at Mare Island, Calif., as head of the naval observatory there and in the following year he was transferred to Manila, P.I., as head of the branch hydrographic office. In this capacity he traveled extensively in the Pacific islands making meteorological observations. He was restored to the active list of the navy in 1901 and subsequently served as head of the department of chronometers and time service of the U.S. Naval observatory in Washington, D.C. (1902–10), commandant of the U.S. Naval station at Key West, Fla. (1910–1j) and president of the General Court Martial at the Norfolk, Va., navy yard (1916–21). On June 30, 1921, having reached the rank of rear admiral, he was retired. He died in Baltimore, Md, Nov. 1, 1932.

Hayden was a noted authority on meteorology. particularly in the field of ocean storms. He was the author of numerous monographs and articles on his specialty, including *The Great Storm off the Atlantic Coast of the United States, March 11–14, 1888* (1888). "The Law of Storms" (1889) and many others. He is also notable for the improvements he introduced as head of the department of chronometers and time service at the naval observatory.

HAYDEN, FERDINAND VANDEVEER (1829–1887), U.S. geologist, a pioneer investigator of the western states who clarified many fundamental geological relationships in the Great Plains and Rocky mountains, laying sound groundwork for subsequent researches, was born at Westfield, Mass., on Sept. 7, 1829. He graduated from Oberlin college in 1850 and Albany medical college in 18j3. in which year, with F. B. Meek, he visited the Dakota bad lands. Their discoveries reinforced Hayden's interest in the west and thus began scientific explorations prosecuted for three decades, Hayden's industry and contagious enthusiasm becoming legendary. In 18j4 and 18jj he explored the upper Missouri country aided by American Fur company employees; from 1856 to 1860 he was attached to military expeditions. During the Civil War, he served the Union army as surgeon of volunteers, being breveted lieutenant colonel for meritorious service. He

then became professor of geology at the University of Pennsylvania (1865–1872); he resumed explorations in 1866, and the next year organized the geological and geographical survey of the territories, which continued 12 years and won world-wide acclaim. When federal surveys were consolidated in 1879, he became geologist with the United States geological survey. He played a leading role in the creation of Yellowstone National park, which he had explored; and he popularized western geology throughout the United States. The "Hayden surveys" launched numerous scientists on brilliant careers, and their maps and about 50 published volumes embody scientific information of enduring value. In large measure they laid the foundation for the U.S. geological survey. He died at Philadelphia on Dec. 22, 1887. (F. M. FL.)

HAYDEN, HORACE H. (1769–1844), U.S. dentist, cofounder of the first dental college in the world, was born in Windsor, Conn., Oct. 13, 1769. He was for a time a school teacher and later became an architect, but about 1790 became interested in dentistry. Probably in 1804 he began to practise in Baltimore, where he remained for most of his lifetime. He participated in the War of 1812 as a surgeon, a profession he had studied at the same time he learned dentistry. He was the founder, with Chapin A. Harris, of the Baltimore College of Dental Surgery, the first school of its kind in the world. It opened in 1840, its charter being dated Feb. 1 of that year, with Hayden as its first president and first professor of dental pathology and physiology, a post he retained until his death. The school continued in existence under its original name until 1923, when it became a part of the University of Maryland. In 1840 Hayden also founded the American Society of Dental Surgery, an organization of uhich he was the first president. In addition to his interest in dentistry, he was much interested in geology and wrote a number of essays on geological subjects. Haydenite, a form of the mineral chabazite, was named for him. He died in Baltimore, Jan. 26, 1844.

HAYDN, FRANZ JOSEPH (1732–1809), Austrian composer, was born on March 31, 1732, at Rohrau (Trstnik), a village on the borders of Lower Austria and Hungary. There is sufficient evidence that his family was of Croatian stock: a fact which throws light upon the distinctively Slavonic character of much of his music. He received the first rudiments of education from his father, a wheelwright with 12 children, and at an early age evinced a decided musical talent. This attracted the attention of a distant relative named Johann Mathias Frankh, who was schoolmaster in the neighbouring town of Hainburg, and who, in 1738, took the child and for the next two years trained him as a chorister. In 1740, on the recommendation of the Dean of Hainburg, Haydn obtained a place in the cathedral choir of St. Stephen's, Vienna, where he took the solo part in the services and received, at the choir school, some further instruction on the violin and the harpsichord. In 1749 his voice broke, and the director, Georg von Reutter, took the occasion of a boyish escapade to turn him into the streets.. A few friends lent him money and found him pupils, and in this way he was enabled to enter upon a rigorous course of study (he is said to have worked for 16 hours a day), partly devoted to Fux's treatise on counterpoint, partly to the "Friedrich" and "Wiirttemberg" sonatas of C. P. E. Bach, from which he gained his earliest acquaintance with the principles of musical structure. The first fruits of his work were a comic opera, *Der neue krumme Teufel,* and a *Mass* in F major (both written in 1751), the former of which was produced with success. About the same time he made the acquaintance of Metastasio, who was lodging in the same house, and who introduced him to one or two patrons, among others Señor Martinez, to whose daughter he gave lessons, and Porpora, who, in 1753, took him for the summer to Mannersdorf, and there gave him instruction in singing and in the Italian language.

The turning point in his career came in 1755, when he accepted an invitation to the country house of Freiherr von Fiirnberg, an accomplished amateur who was in the habit of collecting parties of musicians for the performance of chamber works. Here Haydn wrote, in rapid succession, 18 divertimentos which include his first symphony and his first quartet; the two earliest examples of the forms with which his name is most closely associated. Thenceforward his prospects improved. On his return to Vienna in 1756 he became famous as teacher and composer, in 1759 he was appointed conductor to the private band of Count Morzin, for whom he wrote several orchestral works (including a symphony in D major erroneously called his first), and in 1760 he was promoted to the sub-directorship of Prince Paul Esterhazy's Kapelle, at that time the best in Austria.

During the tenure of his appointment with Count Morzin he married Maria Anna Keller, the daughter of a Viennese hairdresser, who had befriended him in the days of his poverty, but the marriage proved to be an unhappy one.

From 1760 to 1790 he remained with the Esterhazys, principally at their countryseats of Esterhàz and Eisenstadt, with occasional visits to Vienna in the winter. In 1762 Prince Paul Esterhazy died and was succeeded by his brother Nicholas, surnamed the Magnificent, who increased Haydn's salary, showed him every mark of favour, and, on the death of Werner in 1766, appointed him Oberkapellmeister. With the encouragement of a discriminating patron, a small but excellent orchestra and a free hand, Haydn made the most of his opportunity and produced a continuous stream of compositions in every known musical form.

To this period belong five *Masses,* a dozen operas, more than 30 clavier-sonatas, more than 40 quartets, more than 100 orchestral symphonies and overtures, a *Stabat Mater,* a set of interludes for the service of the Seven Words, an oratorio, *Tobias,* written for the Tonkiinstler-Societat of Vienna, and a vast number of concertos, divertimentos and smaller pieces, among which were no fewer than 175 for Prince Nicholas' favourite instrument, the baritone.

Meanwhile his reputation was spreading throughout Europe. A Viennese notice of his appointment as Oberkapellmeister spoke of him as "the darling of our nation"; his works were reprinted or performed in every capital from Madrid to St. Petersburg (Leningrad). He received commissions from the cathedral of Cadiz, from the grand duke Paul, from the king of Prussia, from the directors of the Concerts Spirituels at Paris; beside his transactions with Breitkopf and Härtel, and with La Chevardière, he sold to one English firm the copyright of no fewer than 129 compositions. But the most important fact of biography during these 30 years was his friendship with Mozart, whose acquaintance he made at Vienna in the winter of 1781–82. There can have been little personal intercourse between them, for Haydn was rarely in the capital, and Mozart seems never to have visited Eisenstadt; but the cordiality of their relations and the mutual influence which they exercised upon one another are of the highest moment in the history of 18th-century music. "It was from Haydn that I first learned to write a quartet," said Mozart; it was from Mozart that Haydn learned the richer style and the fuller mastery of orchestral effect by which his later symphonies are distinguished.

In 1790 Prince Nicholas Esterhazy died and the Kapelle was disbanded. Haydn, thus released from his official duties, forthwith accepted a commission from Salomon, the London concert-director, to write and conduct six symphonies for the concerts in the Hanover square rooms. He arrived in England at the beginning of 1791 and was welcomed with the greatest enthusiasm, receiving among other honours the degree of D.Mus. from the University of Oxford. In June 1792 he returned home, and, breaking his journey at Bonn, was presented with a cantata by Beethoven, then aged 22, whom he invited to come to Vienna as his pupil. The lessons, which were not very successful, lasted for about a year, and were then interrupted by Haydn's second visit to England (Jan. 1794 to July 1795), where he produced the last six of his Salomon symphonies. From 1795 onward he resided in the Mariahilf suburb of Vienna, and there wrote his last eight *Masses,* the last and finest of his chamber works, the Austrian national anthem (1797), the *Creation* (1799) and the *Seasons* (1801). His last choral composition which can be dated with any certainty was the *Mass in C minor,* written in 1802 for the name-day of Princess Esterhazy. Thenceforward his health declined and his closing years, surrounded by the love of friends

and the esteem of all musicians, were spent almost wholly in retirement. On March 27, 1808, he was able to attend a performance of the Creation, given in his honour, but it was his last effort and on hfay 31, 1809, he died, aged 77. Among the mourners who followed him to the grave were many French officers from Napoleon's army, which was then occupying Vienna.

Haydn's place in musical history is best determined by his instrumental compositions. His operas, for all their daintiness and melody, no longer hold the stage; the Masses in which he "praised God with a cheerful heart" have been condemned by the severer decorum of our own day; of his oratorios the Creation alone survives. In all these his work belongs mainly to the style and idiom of a bygone generation; they are monuments, not landmarks, and their beauty and invention seem rather to close an epoch than to inaugurate its successor. Even the naive pictorial suggestion, of which free use is made in the Creation and in the Seasons, is closer to the manner of Handel than to that of the 19th century; it is less the precursor of romance than the descendant of an earlier realism. But as the first great master of the quartet and the symphony his claim is incontestable. He began, half-consciously, by applying through the fuller medium the lessons of design which he had learned from C. P. E. Bach's sonatas; then the medium itself began to suggest wider horizons and new possibilities of treatment; his position at Eisenstadt enabled him to experiment without reserve; his genius, essentially symphonic in character, found its true outlet in the opportunities of pure musical structure.

The quartets in particular exhibit a wider range and variety of structural invention than those of any other composer except Beethoven. Again it is here that we can most readily trace the important changes which he wrought in melodic idiom. Before his time instrumental music was chiefly written for the *Paradiesen*saal, and its melody often sacrificed vitality of idea to a ceremonial courtliness of phrase. Haydn broke through this convention by frankly introducing his native folk music, and by writing many of his own tunes in the same direct, vigorous and simple style. The innovation was at first received with some disfavour; critics accustomed to polite formalism censured it as extravagant and undignified; but the freshness and beauty of its melody soon silenced all opposition, and did more than anything else throughout the 18th century to establish the principle of nationalism in musical art.

The actual employment of Croatian folk tunes may be illustrated from the string quartets op. 17, No. 1; op. 33, No. 3; op. 50, No 1; op 77, No 1, and the Salomon symphonies in D and E♭, while there is hardly an instrumental composition of Haydn's in which his own melodies do not show traces of the same influence. His natural idiom in short was that of a heightened and ennobled folk song. and one of the most remarkable evidences of his genius was the power with which he adapted all his perfection and symmetry of style to the requirements of popular speech. His music is in this way singularly expressive; its humour and pathos are not only absolutely sincere, but so outspoken that we cannot fail to catch their significance.

In the development of instrumental polyphony Haydn's work was almost as important as that of Mozart. Having at his disposal a band of picked virtuosi he could produce effects as different from the tentative experiments of C. P. E. Bach as these were from the orchestral platitudes of Reutter or Hasse. His symphony Le Midi (written in 1761) already shows a remarkable freedom and independence in the handling of orchestral forces, and further stages of advance were reached in the oratorio of Tobias, in the Paris and Salomon symphonies, and above all in the Creation, which turns to good account some of the debt which he owed to his younger contemporary. The importance of this lies not only in a greater richness of musical colour, but in the effect which it produced on the actual substance and texture of composition. The polyphony of Beethoven was unquestionably influenced by it and, even in his latest sonatas and quartets, may be regarded as its logical outcome.

The compositions of Haydn include 104 symphonies, 16 overtures, 76 quartets, 68 trios, 54 sonatas, 31 concertos and a large number of divertimentos, cassations and other instrumental pieces; 24 operas and dramatic pieces, 16 Masses, a *Stabat Mater,* interludes for the "Seven Words," three oratorios, two Te Deums and many smaller pieces for the church, over 30 songs, over 50 canons and arrangements of Scottish and Welsh national melodies.

His younger brother, JOHANN MICHAEL HAYDN (1737–1806), was also a chorister at St. Stephen's, and shortly after leaving the choir school was appointed Kapellmeister at Grosswardein (1755) and at Salzburg (1762). The latter office he held for 43 years, during which time he wrote over 360 compositions for the church and much instrumental music, which, though unequal, deserves more consideration than it has received. He was the intimate friend of Mozart, who had a high opinion of Haydn's genius, and the teacher of C. M. von Weber.

His most important works were the *Missa hispanica,* which he exchanged for his diploma at Stockholm, a Mass in D minor, a *Lauda Sion,* a set of graduals, 42 of which are reprinted in Diabelli's Ecclesiasticon, three symphonies (1783), and a string quintet in C major which has been erroneously attributed to Joseph Haydn.

Another brother, JOHANN EVANGELIST HAYDN (1743–1805), gained some reputation as a tenor vocalist, and was for many years a member of Prince Esterhazy's Kapelle.

H Hadow, *A Croatian Composer* (1897). (W. H. H.)

HAYDON, BENJAMIN ROBERT (1786–1846), English historical painter and writer, was born at Plymouth on Jan. 25, 1786, and educated at Plymouth, Honiton and Plympton. In 1804 he went to London and attended the Royal Academy schools, of which Henry Fuseli was keeper. There began his lifelong friendship with the Scottish painter, David Wilkie.

In 1807 he first exhibited at the Royal Academy, but because of subsequent quarrels most of his later paintings were shown at the British gallery or at private exhibitions. Among his principal paintings "Leigh Hunt" and "Wordsworth Ascending Helvellyn" are at the National Portrait gallery; "The Raising of Lazarus" and "Punch or May-Day" are at the Tate gallery. Others are at the Royal Albert Memorial museum, the Royal hospital, Chelsea, and Buckingham palace. Two of his paintings are in America: "Napoleon Musing at St. Helena" in the Metropolitan Museum of Art, New York city, and "Christ's Entry Into Jerusalem" at Mount St. Mary's seminary, Norwood, O. The latter contains portrait heads of Wordsworth, Hazlitt and Keats.

Haydon's stormy career, down to 1821, is recorded in his superb Autobiography (1847). This and his unpublished journals mere the basis for Taylor's Life and the Correspondence and Table-Talk edited by Haydon's son. He was a frequent contributor to periodicals and wrote a number of pamphlets on controversial subjects His acquaintance among literary people was extensive.

His friends included Wordsworth, Coleridge, Scott, Lamb, Hazlitt. Keats, the Hunts, Mary Russell Mitford and Elizabeth Barrett, several of whom composed poems to honour him. Intimate glimpses of persons eminent in literature, art, politics and society enliven his writings, for he had a keen eye for character and a striking gift of phrase.

Haydon's fantastic incompetence in financial matters and the disappointment of his hopes resulted in his ruin. Four times he was confined in King's Bench prison for debt, and on June 22,

1846, he committed suicide in his painting room.

His influence upon art was not great. The day of the Raphaelesque "high art" which he upheld had passed; and his attempts to "improve the public taste" were a failure. As a lecturer and writer, however, he advocated social concepts of art which anticipated those of Ruskin and Morris. Haydon is also remembered for his courageous defense of the Elgin marbles, sculptures from the Parthenon, and was largely responsible for their acquisition in 1816 by the nation.

Haydon* (1948); Clarke Olney, *B. R. Haydon* (1952). Haydon's *Lectures on Painting and Design* were published in two vol. (1844–46). Several of his pamphlets are listed in the British Museum catalogue. He wrote the article on painting in the 7th edition of the *Encyclopædia Britannica.*
(C. O.)

HAYES, AUGUSTUS ALLEN (1806–1882), U.S. chemist, noted for his isolation of sanguinarine, an emetic, and for improvements in the smelting of pig iron, was born in Windsor, Vt., on Feb. 28, 1806. He was educated at Captain Partridge's Military academy, Noruich, Vt., from which he was graduated in 1823, and at Dartmouth college, Hanover, N.H., where he began the study of chemistry under James Freeman Dana.

After his graduation in 1826 he was appointed assistant professor of chemistry at the New Hampshire Medical college, remaining there until 1828 when he moved to Boston. Mass., to become consulting chemist for a number of manufacturing industries in that and neighbouring cities. He was for a time director of a large plant for manufacturing colours in Roxbury, Mass., and for the remainder of his life served other concerns in an advisory capacity. For a time he was also state assayer of Massachusetts. He died in Brookline, Mass., on June 21, 1882.

In 1825, while he was still at Dartmouth, he was successful in isolating the alkaloid sanguinarine, present in the plant bloodroot, which is useful as an emetic. In 1838 he devised a notable improvement in the technique of operating steam boilers. He was responsible for improved methods of refining pig iron and copper and for a simple method of discovering the extent of impurities existing in bodies of water used as sources of drinking water. During the U.S. Civil War, noting that the foreign supply of saltpetre, a constituent of gunpowder, might be cut off, he devised a satisfactory substitute, potassium nitrate, manufactured from potassium hydroxide and sodium nitrate.

HAYES, HELEN (HELEN HAYES BROWN) (1900–), U.S. actress of stage, screen. radio and television, was born on Oct. 10, 1900, in Washington, D.C., daughter of Francis and Catherine (Hayes) Brown. She first appeared at the age of five nith the Columbia Players as Prince Charles in *The Royal Family.* Juvenile successes included *Pollyanna, The Prince Chap, Lzttle Lord Fauntleroy* and *The Prince and the Pauper.* She graduated from Sacred Heart academy, Washington, in 1917 and not long after began to play adult roles. Some of her successes were *To the Ladies* (1922), *Caesar and Cleopatra* (192j), *Coquette* (1927), *Mary of Scotland* (1933), *Victoria Regina* (1935), *Happy Birthday* (1946) and *Mrs. McThing* (1952). Miss Hayes was awarded the medal of the Drama League of New York for her performance in *Victoria Regina.* In 1955 she played Mrs. Antrobus in the revival of *The Skin of Our Teeth,* presented in Paris, and the same year the Fulton theatre in New York city was renamed the Helen Hayes in her honour. From 1930 she was heard often in radio drama, and when television developed she performed in that medium. She acted in several motion pictures and received an Oscar in 1932 for her performance in *The Sin of Madelon Claudet.* She married the playwright Charles MacArthur (1895–1956) in 1928. (B. HT.)

HAYES, ISAAC ISRAEL (1832–1881), U.S. arctic explorer who discovered and explored Grinnell Land. was born in Chester county, Pa., on March 5, 1832. He was educated at Westtown academy and received his M.D. degree at the University of Pennsylvania, Philadelphia, in 1853. He immediately volunteered to serve as surgeon with Elisha Rent Kane's expedition in search of the missing explorer. Sir John Franklin. The expedition sailed from New York on May 30, 1853, in the ship "Advance." During the winter of 1853–54, the vessel was beset in Kane basin, northwest Greenland. Hayes took part in several expeditions on Ellesmere Island during this period and discovered Grinnell Land on May 28, 1854. When it became obvious that the ship would have to spend a second winter in the ice, Hayes, with nine men, attempted to reach Upernavik on the west coast of Greenland. This attempt failed and the party was forced to turn back, reaching the "Advance" in Dec. 1854. The following summer the entire crew successfully made the same journey, reaching Upernavik in August and New York in October.

Hayes had determined that there must be an open sea about the north pole and that he would discover it. In July 1860, therefore, he sailed from Boston, Mass.. in command of the schooner "United States." He wintered somewhat south of the point at which the "Advance" had been frozen in. and in the spring of 1861 began to proceed northward by sledge. Although he thought that he reached latitude 81° 35' N. and looked upon the open polar sea that he had set out to find, it is almost certain that he actually reached a point only slightly north of 80° and that the "open polar sea" was only Kennedy channel. In July 1861 he sailed for Boston, arriving in October. He gave his ship to the government to use in the prosecution of the Civil War and became an army surgeon. In July 1869 Hayes again traveled to Greenland with the artist William Bradford. Later in his life he was for a number of years a member of the New York state assembly. He died in New York city on Dec. 17, 1881.

Hayes was a careful scientific observer and his first two expeditions made valuable contributions in natural history, meteorology, glaciology and hydrology. The photographs taken on the second expedition were among the first to be taken in the arctic. Hayes was the author of *An Arctic Boat Journey . . .* (1860). *The Open Polar Sea* (1867), *Cast Away in the Cold* (1869) and *The Land of Desolation* (1871). (H. G. KG.)

HAYES, PATRICK JOSEPH (1867–1938), U.S. Roman Catholic archbishop and cardinal, whose most notable achievement was the unification of Catholic welfare activities under a central agency, Catholic Charities, was born in New York city, Nov. 20, 1867. Upon graduation from Manhattan college in 1888, he entered St. Joseph's Provincial seminary, Troy. N.Y., and was ordained a priest in 1892. After graduate courses at the Catholic University of America, he returned to New York city as curate at St. Gabriel's parish. Subsequently secretary (1895) to Bishop (later Archbishop and Cardinal) John Farley, chancellor of the archdiocese (1903), and first president (1903) of Cathedral college, the archdiocesan preparatory seminary, he became bishop auxiliary to Cardinal Farley in 1914. During World War I he served on the executive committee of the National Catholic War council and as first bishop of the armed forces (1917), in charge of all Catholic chaplains in the army and navy. In Sept. 1919 he succeeded to the archbishopric of New York and five years later was named a cardinal. As archbishop he created Catholic Charities (1920), an organization which became a model for other U.S. dioceses. Cardinal Hayes died in Monticello, N.Y., on Sept. 4, 1938.

See J. B. Kelly, *Cardinal Hayes, One of Ourselves* (1940).
(J. A. RS.)

HAYES, RUTHERFORD BIRCHARD (182 2–1893), 19th president of the United States, 1877–81, was born in Delaware, O., on Oct. 4, 1822. His ancestry was English and Scotch, his people having first settled in America in New England. He attended an academy at Norwalk, O., and later went to a school in Middletown, Conn. In 1842 he graduated from Kenyon college, Gambier, O., and in 1845 from the Harvard Law school. The same year he was admitted to the bar, and began to practise at Lower Sandusky (now Fremont), O. Three years later he moved to Cincinnati. From 1858 to 1861 he was city solicitor there. Hayes was married in 1852 to Lucy Ware Webb (1831–89).

In 1861 Hayes became major of a regiment of volunteers, the 23rd Ohio infantry, and in July of that year was sent to western Virginia for active service. He served throughout the Civil War, and was severely wounded at South mountain. By successive promotions he became a brigadier general of volunteers, and by brevet a major general of volunteers. In 1864 he was

elected a member of congress on the Republican ticket, and again in 1866. In the national legislature he supported his party's program of reconstruction. In 1868 he became governor of Ohio, serving until 1872. In 1875 he was again elected governor after a campaign wherein the Republicans advocated the resumption of specie payment, and the Democrats an increase of fiat paper money.

The "sound money" campaign in Ohio attracted national attention, and in 1876 Hayes received the Republican nomination for the presidency over James G. Blaine. Samuel J. Tilden was the Democratic candidate. Tilden had a reputation as a reformer, having destroyed the "Tweed ring" in New York and been prominently engaged in other public work. The strength of the Democratic candidate, together with the scandals of Pres. Ulysses S. Grant's administrations which had tended to discredit the Republican party, resulted in a close election, which depended upon the contested returns from South Carolina, Florida, Oregon and Louisiana.

Partisans on both sides were much excited. It was agreed, however, to refer the contested returns to an electoral commission created by act of congress. The commission, voting eight to seven, decided all of the contested returns in favour of the Republicans, and Hayes was declared elected on March 2, 1877.

The administration of President Hayes is notable principally for the pacification policy adopted by it with respect to the southern states. The federal troops, which had since the war been stationed in the southern capitals, were withdrawn, thereby bringing about the end of the "carpet-bag governments" conducted often by unprincipled politicians from the north. This action brought Hayes into sharp conflict with many of the political leaders of his party. It, however, made more rapid the slow recovery of the south from the effects of the war, and was highly beneficial to the nation. In his endeavours to bring about reforms in the civil service, and in his advocacy of the establishment of a civil service commission, Hayes also met with the opposition and disapproval of the politicians of his party. The New York faction, under the leadership of Roscoe Conkling, particularly resented his measures in endeavouring to divorce the service from politics.

Another notable accomplishment of the Hayes administration was the provision for the resumption of specie payments on Jan. 1, 1879. Prior to this time Hayes vetoed a bill, known as the Bland-Allison bill, providing that a silver dollar should be coined of the weight of 412½ gr. to become full legal tender for all debts and dues, public and private, except where otherwise expressly stipulated in the contract, but the measure passed over his veto. He was at all times a sincere advocate of sound money.

Hayes has generally been considered an able executive, thoroughly honest and sincerely devoted to the interests of the people and the country generally. He was not, however, popular with the professional politicians of his own party and was exposed to bitter attacks on the part of the Democratic opposition because of the cloud which hung over his election. In the presidential election of 1880 the Republican party carried the day with James A. Garfield after an unusually quiet canvass, largely the result of popular contentment with the existing state of public affairs. On March 4, 1881, Hayes retired to his home at Fremont, O. Various universities and colleges conferred honorary degrees upon him. His remaining years were devoted to active participation in philanthropic enterprises, serving as president of the National Prison association and of the board of trustees chosen to administer the John F. Slater fund for the promotion of industrial education among the Negroes of the south. He was also a member of the board of trustees of the Peabody Education fund for the promotion of education in the south. He died at Fremont, after a short illness, on Jan. 17, 1893.

HAYES AND HARLINGTON, an urban district (1940) and parliamentary division of Middlesex, Eng., 12 mi. W. of London along the Uxbridge road. Pop. (1961) 67,912. Hayes is highly industrialized, the chief products being aircraft and electrical and musical instruments. Its parish church was used by St. Anselm. Archbishop Thomas Cranmer lived for a time at the Manor house. At Harlington, still mainly rural, Overburgh house was the home of William Byrd, the composer, about 1578–93. In Cranford park are stables once used by the Berkeley hunt; the house, a seat of the earls of Berkeley, was razed in 1946. The district's southern boundary overlaps the Bath road and includes a portion of London airport.

HAY FEVER is an inflammation of the membranes of the nose and eyes caused by allergy to the pollens of certain plants. It is manifested by sneezing, congestion of the nose, itching and tearing of the eyes, characteristically recurring at the same season each year, when the causative pollen is in the air. Despite the name. fever is not a usual symptom. Irritation of the membranes by allergy to other dusts in the air may cause similar symptoms, called allergic rhinitis, without the typical seasonal pattern of recurrence. The type of allergy causing hay fever is similar to that causing asthma (*q.v.*) and infantile eczema so that persons affected by one of these diseases are particularly susceptible to others of the group. Unless properly treated, about one-third of patients with hay fever later develop asthma. The tendency to develop allergies of this group is apparently hereditary in certain families. If both parents are affected, more than half the children may be expected to develop allergic diseases.

Hay fever is caused chiefly by plants which depend upon the wind to carry pollen to other plants of the same species for cross-fertilization. In order to ensure perpetuation of the species, such plants produce large amounts of light, buoyant pollen which is blown many miles by the wind. Plants with showy blossoms are in general adapted to cross-pollination by insects, and they produce only small amounts of heavy, sticky pollen which does not blow about. Such flowers rarely cause hay fever except on close contact. For this reason, roses and goldenrod, which have often been blamed for hay fever, are actually relatively minor causes.

The incidence and seasons of hay fever vary greatly in different parts of the world according to the vegetation present. In the temperate zones. most species of trees, certain weeds and essentially all grasses produce wind-borne pollen in large amounts. Among these, the pollens of pine trees and related conifers are relatively inert, but practically all others liberated in adequate amounts are potential causes of allergy in susceptible people. In North America and western Europe, various trees are the principal causes of hay fever occurring in the spring, and the grasses are the cause of hay fever in early summer. In North America, pollens of weeds. particularly ragweed, cause hay fever in the late summer and early autumn. Throughout central and eastern North America ragweed is by far the commonest cause of hay fever; hence late summer and early autumn is the principal season of the disease. Ragweed does not occur in Europe, and the autumn weeds growing there are relatively unimportant as causes of hay fever; hence in that area the late season is less severe than the spring and early summer. In any locality, the season of pollination of each plant is remarkably constant from year to year, so that hay fever due to any one pollen may be expected to recur in the same weeks each year, and one familiar with the plants of the area can usually suspect which pollen is the cause from the dates of onset and cessation.

More conclusive proof of the pollens affecting a particular patient is afforded by skin tests, in which minute amounts of extracts of various pollens are scratched or injected into the upper layers of the skin. Extracts of pollens to which the patient is allergic produce local swelling and redness within a few minutes; others produce no reaction. Patients whose symptoms last through several months are usually allergic to several different pollens.

Absorption of pollen into the membrane of a person allergic to it causes release from the tissues of histamine, a substance intensely irritating to the small blood vessels and the glands which secrete mucus. This produces dilation of the vessels and escape

of fluid through their walls, causing the membrane to become congested and swollen. The occurrence of the reaction does not depend on the nervous system, but its intensity may be influenced by emotional factors which also affect the blood vessels and mucus glands through the nerves. This aggravation occurs only in persons susceptible because of allergy; typical seasonal hay fever cannot be attributed to purely psychic factors.

Temporary relief of symptoms may be afforded by antihistamine drugs, which block the action of the histamine released in the membrane. Even more effective in temporary relief are the drugs related to cortisone, but these are less often used since they may cause undesirable effects elsewhere in the body. All these drugs serve only to suppress symptoms and do not alter the basic allergy. However, in mild cases they may produce adequate relief. (*See* also ANTIHISTAMINES.)

The most effective treatment over a period of time is desensitization or immunization, in which the allergic reaction is lessened by a series of injections of an extract of the causative pollen. The first dose must be very small, subsequent doses being increased gradually as the patient's tolerance is improved. Ordinarily a course of 1j to 20 injections is given, one or two each week, before the full dose is reached. Treatment therefore should be started three or four months before the onset of the season. Such treatment produces relief in 75% to 80% of patients, but must be repeated each season, or may be carried out continuously with injections every two to four weeks throughout the year. The best results are obtained by the continuous or perennial type of treatment, and it is also believed to offer the best chance of permanent relief after several years of treatment. However, the duration of treatment that will be needed ,cannot be predicted with certainty. Attempts are being made to shorten the course of treatment by injecting slowly adsorbed pollen extracts.

Another measure which may be considered is the avoidance of exposure to a particular pollen by traveling during the season to an area in which it does not exist. Relief may also be obtained by air conditioning or air filtration. Attempts to exterminate ragweed have been made in many areas, but have generally failed to prevent hay fever because of the long distances that the pollen may be carried by wind. *See* also ALLERGY AND ANAPHYLAXIS.

(W. B. SN.)

HAYLEY, WILLIAM (1745–1820), English writer, the friend and biographer of William Cowper, was born at Chichester and educated at Eton and Trinity hall, Cambridge. His private means enabled him to live on his patrimonial estate at Eartham, Sussex, and he retired there in 1774. Hayley won contemporary fame by his poetical *Essays and Epistles* addressed to various distinguished men. On Thomas Warton's death in 1790 he was offered the laureateship, which he refused. In 1792, while writing the *Life of Milton* (1794), Hayley made Cowper's acquaintance. A warm friendship sprang up between the two which lasted till Cowper's death in 1800. After Hayley had moved in 1800 to his "marine hermitage" at Felpham, Sussex, William Blake settled near him for three years to engrave the illustrations for the *Life of Cowper*. This, Hayley's best-known work, was published in 1803–04 (Chichester) in three volumes.

In 1805 he published *Ballads Founded on Anecdotes of Animals* (Chichester), with illustrations by Blake, and in 1809 *The Life of Romney*. For the last 12 years of his life Hayley received an allowance for writing his *Memoirs*. He died at Felpham on NOV. 12, 1820.

Hayley's *Poetical Works* were published in 3 vol. (1785); his *Poems and Plays* in 6 vol. (1788). See *Memoirs . . . of William Hayley . . . and Memoirs of his son T. A. Hayley*, ed. by John Johnson, 2 vol. (1823), containing many of Hayley's letters; an article on these memoirs by Robert Southey in the *Quarterly Review*, vol. xxxi (1825); *The Correspondence of William Cowper*, arranged by Thomas Wright, vol. iv (1904), containing many letters to Hayley.

HAYNAU, JULIUS JACOB (1786–1853), Austrian general, was the natural son of the landgrave—afterward elector—of Hesse-Cassel, William IX. He entered the Austrian army as an infantry officer in 1801, saw much service in the Napoleonic wars, and between 1815 and 1847 rose to the rank of field marshal lieutenant. A capable officer, but of violent temper and fanatical hatred of revolutionary movements, he was employed against the Italian revolutionaries in 1848, and became notorious for the severity with which he repressed and punished, not without provocation, a rising in Brescia. Appointed next to command in Hungary, he was successful in the field, but was again accused of brutality.

In London Haynau was attacked and beaten by Barclay and Perkins' draymen when visiting the brewery, and was saved from mob violence in Brussels with difficulty. He died on March 14, 1853.

See R. von Schönhals, *Biographie des K. K. Feldzeugmeisters Julius Freiherrn von Haynau* (Vienna, 1875).

HAYNE, PAUL HAMILTON (1830–1886), U.S. poet, best known as a southern literary leader, was born in Charleston, S.C., Jan. 1, 1830, and attended Coates school there. He was graduated from Charleston (S.C.) college in 1850. After practising law for a short time, he worked on the staff of the *Charleston Evening News* and the Richmond *Southern Literary Messenger*, and was associate editor of the weekly *Southern Literary Gazette*. His first collected verses he published at his own expense in 1855. He was co-editor of the influential *Russell's Magazine*, launched under the leadership of William Gilmore Simms, during its three years of publication (1857–60). For a short time during the Civil War Hayne was an aide to Gov. Francis Pickens, but had to give up active service because of ill-health. He contributed patriotic verse to the *Southern Illustrated News* of Richmond. After the war, his home burned and his fortune destroyed, Hayne and his family moved to a shanty at "Copse Hill" near Augusta, Ga., where he earned his living writing prose and composed some verse. In 1873 he edited a posthumous edition of Henry Timrod's verse. Hayne died on July 6, 1886.

His published works include: *Poems* (1855), *Sonnets and Other Poems* (1857), *Avolio: a Legend of the Island of Cos* (1860), *Legends and Lyrics* (1872), *The Mountain of the Lovers* (1875), *Lives of Robert Young Hayne and Hugh Swinton Legaré* (1878) and *The Broken Battalions* (1885).

See Kate Harbes Becker, *Paul Hamilton Hayne: Life and Letters* (1951).

HAYNE, ROBERT YOUNG (1791–1839), U.S. political leader, born in St. Paul's parish, Colleton district, S.C., on Nov. 10, 1791. He studied law in the office of Langdon Cheves (1776–1857) in Charleston, S.C., and in Nov. 1812 was admitted to the bar there, soon obtaining a large practice. For a short time during the War of 1812 against Great Britain he was captain in a South Carolina regiment. He was a member of the lower house of the state legislature from 1814 to 1818, serving as speaker in the latter year; was attorney general of the state from 1818 to 1822, and in 1823 was elected, as a Democrat, to the U.S. senate. There he was conspicuous as an ardent free-trader and an uncompromising advocate of states' rights, opposed the protectionist tariff bills of 1824 and 1828 and consistently upheld the doctrine that slavery was a domestic institution and should be dealt with only by the individual states. In one of his speeches opposing the sending by the United States of representatives to the Panama congress, he said. "The moment the Federal Government shall make the unhallowed attempt to interfere with the domestic concerns of the States, those States will consider themselves driven from the Union." Hayne is best remembered, however, for his great debate with Daniel Webster (*q.v.*) in Jan. 1830.

The debate arose over the so-called "Foote's resolution," introduced by Sen. Samuel A. Foote (1780–1846) of Connecticut, calling for the restriction of the sale of public lands to those already in the market, but was concerned primarily with the relation to one another and the respective powers of the federal government and the individual states, Hayne contending that the constitution was essentially a compact between the states, and the national government and the states, and that any state might, at will, nullify any federal law which it considered to be in contravention of that compact. He vigorously opposed the tariff of 1832, was a member of the South Carolina Nullification convention of Nov. 1832, and reported the ordinance of nullification

passed by that body. Resigning from the senate, he was governor of the state in 1832–34, and as such took a strong stand against President Jackson, though he was more conservative than many of the nullificationists in the state. He was intendant (mayor) of Charleston, S C , 1835–37, and was president of the Louisville, Cincinnati and Charleston railway 1837–39. He died at Asheville, N.C., on Sept. 24,1839. His nephew, Paul Hamilton Hayne (1830–86). was a poet of some distinction, and in 1878 published a life of his uncle.

See Theodore D Jervey, *Robert* Y. *Hayne and His Times* (1909); and John Bomai Cleveland, *Controversy Between John C. Calhoun and Robert Young Hayne* (1913).

HAY RIVER, 530 mi. long, rises in the foothills of the Rocky mountains in northern Alberta, Can., makes a bend through British Columbia and descends to Great Slave lake, Northwest Territories. Upper Hay river is quite rapid. From Hay Lake (elevation 1,078 ft.) it meanders sluggishly north-northeast through flat muskeg country.

A stretch of rapids culminating in the Alexandra falls (106 ft.), 50 mi from the mouth, is followed by a 46-ft. fall and a 250-ft. deep gorge ahich opens onto the flat country around Great Slave lake (159 ft.).

The hlackenzie highway is parallel to the river, connecting the settlements of Meander River, Alberta and Hay River. on Great Slave lake. (AN. KR.)

HAYTON (HAITHON, HETHUM), king of Little Armenia or Cilicia from 1226 to 1269, was a traveler in western and central Asia; the narrative of his journey, written by a member of his suite. Kirakos Gandaketsi, is one of the earliest and fullest accounts of Mongolian geography and ethnology. Throughout his reign he followed the policy of friendship and alliance uith the overwhelming power of the Mongols. After Mangu's accession in 1251, Hayton was summoned to the court of the new grand khan. Carefully disguised, so as to pass safely through the Turkish states in the interior of eastern Asia Minor (nhere he was hated as an ally of the Mongols against Islam), Hayton made his way to Kars, the central Mongol camp in Great Armenia, and thence by way of Derbent to the residence of Mangu at or near Karakorum, south of Lake Baikal, nhere he arrived on Sept. 14(?), 1254. There the king remained till Nov. 1, when he left with diplomas, seals and letters of enfranchisement ahich promised great things for the Armenian state, church and people. He returned by way of the Urumtsi region. Talas, Samarkand. Merv and Khorasan.

See E Bretschneider, *Mediaeval Researches From Eastern Asiatic Sources,* i, 164–172, "Trubner's Oriental Series" (1888); C R Beazley, *Dawn of Modern Geography,* ii, 381–391 (1901). (WM C. B)

HAYWARD, ABRAHAM (1801–1884), translator of Goethe and author of *The Art of Dining,* was born at Wilton, near Salisbury. Educated at Blundell's school, Tiverton, he entered the Inner Temple in 1824, and was called to the bar in June 1832. Hayward edited the *Law Magazine* from 1829 to 1844, and became a conspicuous figure in London literary society. His translation of Goethe's *Faust* was privately printed in 1833, and a revised edition appeared in 1834 In Feb 1835 he was elected to the Athenaeum club under Rule II., and he remained for nearly 50 years one of its most conspicuous and most influential members. He was also a subscriber to the Carlton, but ceased to frequent it when he became a Peelite. At the Temple, Hayward, whose reputation was rapidly growing as a connoisseur not only of a bill of fare (the famous *Art of Dining* appeared in 1852) but also (as Swift would have said) of a bill of company, gave famous dinners, at which ladies of fdshion appreciated the wit of Sydney Smith and Theodore Hook, the dignity of Lockhart and Lyndhurst and the oratory of Macaulay. At the Athenaeum and in political society he to some extent succeeded to the position of Croker. His sharp pen made him many enemies. He disgusted the friends of Mill by the stories he raked up for an obituary notice of the great economist *(The Times,* May 10, 1873). He broke with Henry Reeve in 1874 by a venomous review of the *Greville Memoirs,* in which Reeve was compared to the beggarly Scot deputed to let off the blunderbuss which Bolingbroke (Greville) had charged. Samuel Warren attacked him (very unjustly, for Hayward was anything but a parasite) as Venom Tuft in *Ten Thousand a Year;* and Disraeli aimed at him partially in Ste. Barbe (in *Endymion),* though the satire here was directed primarily against Thackeray. After his break with Reeve, Hayward devoted himself more exclusively to the *Quarterly.* He died in London on Feb. 2, 1884.

Two volumes of Hayward's *Correspondence* (edited by *H.* E. Carlisle) were published in 1886. In *Vanity Fair* (Nov. 27, 1875) he may be seen as he appeared in later life.

HAYWARD, SIR JOHN *(c.* 1560–1627), English historian, was born at or near Felixstowe, Suffolk, where he was educated, and afterwards proceeded to Pembroke college, Cambridge. In 1599 he published *The First Part of the Life and Raigne of King Henrie IV.* dedicated to Robert Devereux, earl of Essex. This was reprinted in 1642. Queen Elizabeth and her advisers disliked the tone of the book and its dedication, and the queen ordered Francis Bacon to search it for "places in it that might be drawn within case of treason." Bacon reported "for treason surely I find none, but for felony very many," explaining that many of the sentences were stolen from Tacitus; but nevertheless Hayward was put in prison, where he remained until about 1601. On the accession of James I. in 1603 he courted the new king's favour by publishing two pamphlets, one of which, an argument in favour of the divine right of kings, was reprinted in 1683 as "The Right of Succession" by the friends of the duke of York during the struggle over the Exclusion Bill. He died in London on June 27, 1627. Hayward's other works are: *Lives of the Three Norman Kings of England* (1613), *The Life and Raigne of King Edward VI.* (posthumously printed, 1630, included in *Complete History of England,* anon., vol. ii. 1706) and *Certain Yeres of Queen Elizabeth's Raigne* (ed. John Bruce, Camden Society, 1840, with a life of the author).

HAYWARD, a city of Alameda county, Calif., U.S., less than ½ mi. from San Francisco bay and 15 mi. from the centre of Oakland in the rapidly growing bay area. This important commercial centre, situated between Oakland and San Jose, is served by two railways, a municipal airport and a superhighway.

The first inhabitants of the site were Indians who gathered shellfish and salt at San Leandro creek. After 1797 the region was grazed by cattle of the Mission San Jose de Guadalupe. Following the gold rush in 1849, William Haymard purchased land on the Guillerma Castro estate and built the first general store in 1851. The town was incorporated in 1876. Meanwhile the economy of the region shifted from livestock to wheat raising and cherry orchards. After World War II the leading manufactured products were canned fruit, ironwork and electrical equipment.

Pop. (1960) 72,700. For comparative population figures *see* table in CALIFORNIA: *Population.* (R. M. W.)

HAYWOOD, ELIZA (1693?–1756), English writer of sensational romances which made her notorious but prepared the nay for later women novelists, was the daughter of a London tradesman. When very young she married Yalentine Haywood, a middle-aged clergyman; but she appears to have left him to go on the stage, supporting herself by writing. In 1721 she revised *Tlze Fair Captive,* by a Captain Hurst. for Lincoln's Inn Fields theatre. Two original pieces folloned, in one of nhich she acted herself: but she took a dislike to the stage and instead continued to write, in a light, crisp style, the extravagantly passionate fiction for which there was already a great vogue. She produced a total of 70 novels, writing as many as ten in one year (1724).

She became notorious, however, as an imitator of Mrs. Manley *(q.v)* in writing novels based on contemporary scandal. To *Memoirs of a certain Island adjacent Utopia . . .* (1725) she appended a key in which society leaders were denoted by initials: the British museum has a copy giving their full names. *The Secret History of the Present Intrigues of the Court of Caramania* (1725) was similarly explained. This infuriated Pope, who attacked her with coarse brutality in *The Dunciad* (II, 11, 149 *et seq.),* imputing to her a personal immorality that her earlier novels certainly do-not suggest. Although she attempted to retaliate in *The Female Dunciad* (1729) she almost ceased writing for 16 years. Pope's friends attacked her also, Swift calling her a "stupid, infamous,

woman." Later she achieved some success with *The Female Spectator* (1744–46; mod. ed. by Mary Priestley, 1929), the first periodical written by a woman, and with her most realistic novel, *The History of Jemmy and Jenny Jessamy* (1753). She died in London on Feb. 25, 1756.

See C. H. Whicher, Life *and Romances of Mrs. Haywood* (1915).

HAZAEL (fl. 9th century B.C.), king of Damascus. He became king after the death of Benhadad II, under whom he was probably a court official. According to II Kings, Benhadad, who was ill. sent Hazael to the prophet Elisha to inquire concerning his chances of recovery. Elisha prophesied that Benhadad would die and that Hazael would succeed him. Hazael, on his return, smothered Benhadad and became king. He ruled for many years, during which time he fought the kings of Judah and Israel with some success, capturing all Israel's possessions east of the Jordan. He was eventually conquered by Shalmaneser II, king of Assyria, who in 842 and 839 defeated Hazael's forces in battle, the first time taking an enormous toll in lives and equipment and driving Hazael into Damascus and the second time capturing a number of Syrian cities.

HAZARA, a people found in the Hazarajat or Hazaristan in Afghanistan, descended from military colonists settled by Jenghiz Khan in the highlands of the upper Helmund and on the slopes of the Hindu Kush range north of Kabul Probably of almost pure Mongol origin they now speak a Persian dialect. Strict Shiite Moslems by sect, they were only subjugated by the great amir of Afghanistan. Adburrahman Khan, between 1890 and 1893 after a long resistance; but they were then enlisted in his engineer companies, and they were also recruited in pioneer regiments of the Indian army. As Turks and Shiites, intermarriage with them is avoided by the Afghans. and though they may once have intermarried with the Persians, they have preserved the purity of the Mongol type to a marked degree. In the western part of the Hazarajat. extending nearly to Herat and the Harud valley, the Hazaras include four tribes, the Chnhar Aimak, which speak Turki and are Sunni Moslems by sect.

HAZARA, a district in the Peshawar division of West Pakistan. Area 3,030 sq.mi. Pop. (1951) 856,173, predominantly Gujars, who claim to be aboriginal, and Awans. The district includes the acceded princely states of Amb, west of the Indus (area 203 sq.mi.; pop. 1951, 48,656) and Phulra, little more than a small town (pop. 8,jog), 22 mi. N.W. of Abbottabad. The large tribal area (area 2,214 sq.mi.; pop. 427,004) northwest and west of the district proper is administered with it. The district forms a wedge of territory extending far into the Himalayas. The picturesque Kagan valley in the northeast, which is drained by the Kunhar into the Jhelum, became important for communications and economy in the 1950s. About 15 mi. wide and 800 sq.mi. in area, it is shut in by parallel ranges of hills with an average height of 10,000 ft. rising to more than 17,000 ft. in the highest peak. It is connected with Chilas (Gilgit) through Babusar pass (13,690 ft.).

Three main lines of hills with outer ranges divide the district into four main valleys, running from northeast to southwest and drained respectively by the Unar, the Siran, the Dor and the Harroh. all tributaries of the Indus. In the lower valleys of these rivers the country here and there opens into plains of varying extent, the largest of which are Haripur, Rash or Orash. at the southern end of which is Abbottabad. the district capital (pop., 1951, 27,602, including 14,1j6 in cantonment). and Pakhi. in Mansehra tehsil. The plains and the terraced slopes are cultivated for maize, wheat, barley and rice. Many hill slopes are forested, mainly with deodars. Honey is produced. (K. S. AD.)

HAZARD, ROWLAND GIBSON (1801–1888), U.S. manufacturer and author, one of the founders of the Republican party, was born in South Kingstown, R.I., on Oct. 9, 1801. After studying at the academy of the Society of Friends in Westtown, Pa., he entered the Peace Dale woolen mills, founded by his father, and remained with the mills until 1866. Before this time delicate health forced him to spend his winters in the south, but this necessity permitted him to establish personal business contacts with many leading southern planters. In 1841–42 in New Orleans he won the release of free Negroes taken off ship and impressed in the chain gang. He became a bitter opponent of the fugitive slave laws and the extension of slavery into the territories. This led him to the organizational convention of the Republican party at Pittsburgh, Pa., in 1856. He attended three of the first four national conventions of the party and served often on policy-forming committees. Hazard was elected three times to the Rhode Island house of representatives and once to the state senate.

Hazard's literary interests were broad and largely metaphysical. He wrote numerous essays on politics, language, history and philosophy. At the request of William Ellery Channing, to whose views he devoted one of his essays, he prepared a treatise, *Freedom of Mind in Willing* (1864), in answer to Jonathan Edwards' writings on the freedom of the will. He addressed another volume, *Two Letters on Causation and Freedom in Willing* (1869), to his friend John Stuart Mill. This book opened a lengthy debate between Mill and Hazard, for their ideas on causation were in sharp conflict. Hazard was a senior member of the Rhode Island Historical society and a benefactor of Brown university, endowing a chair in physics. He died on June 24, 1888, at Peace Dale, R.I. (N. A. G.)

HAZARD (Span. *azar*, unlucky throw at dice, misfortune, from Arab. *al*, and *zar*, "dice"), a game of dice once popular in England and played for large stakes at the rooms of Crockford and Xlmack, London. In the U.S. the name hazard is applied to a different game. but a game somewhat similar to hazard, called craps, is the principal gambling game; *see* DICE.

HAZARIBAGH, a town and district in the Chota Nagpur division of Bihar state, India. The town is at an elevation of 2,000 ft., 43 mi. N. of Ranchi. Pop. (1951) 33,812.

HAZARIBAGH DISTRICT comprises an area of 7,010 sq.mi. In 1951 the population was 1,937,210. The physical formation of Hazaribagh exhibits three distinct features: (1) a high central plateau occupying the western section, the surface of which is undulating and cultivated; (2) a lower and more extensive plateau stretching along the north and eastern parts; to the north the land is well cultivated, while to the east the country is of a more varied character, the elevation is lower, and the character of a plateau is gradually lost; (3) the central valley of the Damodar river, occupying the southern section. Rice and oilseeds are the principal crops. The most important river is the Damodar, site of an important power and irrigation project. A dam at Tilaiya and the thermal power station at Bokaro were opened in 1953, and a dam at Konar in 1955. The district contains the important Giridih, Bokaro, Rangarn and Karanpura coal fields. A mica-producing belt, which extends into the district of Gaya and Monghyr, produces about half the world's total output of mica. The production of shellac is another local industry of some importance. The subdivisional town of Giridih, on which the export of coal has hitherto centred, had 29,167 inhabitants in 1951. Parasnath hill is annually visited by many Jain worshippers,

HAZE, a slight or moderate diminution of atmospheric visibility. when objects as near as about 1½ mi. are still identifiable, caused either by dry dust or salt particles or by water droplets so small or so widely dispersed as not to be discoverable individually by the unaided eye. There is a "smoky," opalescent or greasy, sometimes dirty-yellow, sometimes whitish, grayish or bluish cast to the air and distant objects. In the U.S. the weather services began in 1938 to distinguish dry haze as one caused chiefly by dust, and damp haze as caused largely by water droplets, but it often happens that dry and water particles are so mixed that the distinction is difficult to make in practice. In Great Britain haze is mainly "damp" and the term is generally used there synonymously with light fog (*q.v.*) or mist. In desert lands the prevalent dry dust haze may be given special names. The shimmering effect of the intensely heated air near the ground on a clear summer day is sometimes called optical haze. (R. G. SE.)

HAZEL, one of three names which in English writings have long been applied to plants and nuts of the genus *Corylus*, the others being filbert and cobnut. The distinction was based wholly upon the relative length of the involucre or husk in comparison with the nut. Filberts were those having husks distinctly longer

than the nuts; cobnuts, those with husks and nuts of about equal length; and hazels, those with husks shorter than the nuts. While, in general, filberts were long nuts. cobnuts of medium length and hazels were short and roundish. it is obvious that these names were not clearly distinctive. especially after the husks were removed. Moreover. the relation of length between nut and husk varied both in different parts of the tree during the same year and in the same tree from year to year.

In an effort to clarify this situation. in 1942, the American Joint Committee on Horticultural Nomenclature officially recognized filbert (*q.v.*) as the one name which henceforth should be applied to this genus.

HAZEN, WILLIAM BABCOCK (1830–1887), U S. soldier, noted for his contributions, as chief signal officer, to the improvement of weather-reporting and forecasting methods. was born in West Hartford, Vt., Sept. 27, 1830. On graduation from the United States Military academy, West Point, N.Y., in 1855, he entered service against the Indians in the west He served with distinction during the Civil War, afterward acting as an infantry colonel on the frontier. In 1880 he was appointed chief signal officer and remained in that capacity until his death, as a brigadier general, on Jan. 16. 1887.

Since 1870, under the first chief signal officer, Brig. Gen. Albert J. Myer, signal corps duties had included provision of the national weather service, using military telegraph lines to transmit weather data gathered at many reporting stations. Hazen continued Myer's practice of employing able meteorologists, notably Cleveland Abbe. Co-operating with other nations in arctic studies (actually the first International Geophysical year), Hazen in 1881 dispatched expeditions to Point Barrow, Alaska, and Ellesmere Island. Can. Members of the latter expedition, under Lieut Adolphus W. Greely (*q.v.*), reached farther north than any white men to that date, but only 7 of the original party of 25 were alive when they were belatedly rescued in 1884. For his public criticism of the secretary of war's ineffective rescue efforts. Hazen was court-martialed and reprimanded. Meanwhile he introduced Abbe's standard-time meridians and improved upon weather-reporting methods and forecasting procedures, such as signaling the approach of storms and cold waves, to the benefit of commerce and agriculture. Hazen published a number of books, including Our Barren Lands (1875) and A *Narrative* of *Military* Service (1885). (G. R. T.)

HAZLETON, a city of Luzerne county in eastern Pennsylvania, U S., stands on Buck Mountain plateau at an altitude of 1,624 ft surrounded by rugged and picturesque terrain 23 mi. S.S.W. of Wilkes-Barre. Laid out in 1836 by the clerk of the newly organized Hazleton Coal company, it was named for Hazel creek, incorporated as a borough in 1856 and as a city in 1891. The city's growth was identified with the expansion of anthracite coal mining. which ended with the depression of 1930 and continued to diminish thereafter in both tons of production and number of workers. Some of the unemployed found jobs in the textile mills, but the population declined as the miners sought work elsewhere. Manufactures include fabrics, clothing, paints and crayons, furniture, electronic tubes, centrifugal pumps, iron wire and steel products, foam rubber; and paper boxes (at West Hazleton, a residential suburb incorporated 1889). The first settlers were from Wales and Ireland, the later ones from central and eastern Europe. The domes of the Greek Orthodox churches, towering above the houses, and the existence of several Protestant and Roman Catholic churches, testify to the transplanting of European culture to Hazleton. For comparative population figures see table in PENNSYLVANIA: Poperlation. (R. G. Co.)

HAZLITT, WILLIAM (1778–1830), English writer. nho worked as journalist lecturer, dramatic critic and painter. but will be remembered for his essays. His interests embraced politics. philosophy, literature and all the arts, but he was basically a student of human life and liberty and it is the humanity of his essays that gives them permanent value. He lived by his pen and his writings are voluminous, much of what he published is no longer of general interest, but many of his essays are classics in their kind and his opinions have permeated the national consciousness more intimately than is commonly appreciated. His intellect nas brilliant, yet his style of writing is "ordinary" in the best sense; it has no conscious artistry or literary pretensions and can be read for sheer enjoyment of the lively intelligence informing it.

Hazlitt was born at Maidstone, Kent, on April 10, 1778. He was the fourth child and younger son of William Hazlitt, Unitarian preacher, and of Grace Loftus. daughter of a Wisbeach ironmonger The elder Hazlitt had settled at Maidstone in 1770, but while William was still an infant the family moved to Ireland and thence to America. the father's sympathies having been with the American rebels. There they remained for three years, but when William was nine they returned to England, settling at Wem in Shropshire. William was described as an exceedingly happy and lively child, but at the age of puberty his character changed and he became somewhat sullen and unapproachable. His father even said of him that he "passed under a cloud, which unfitted him for social intercourse." This tendency persisted through his life, and gave rise to Coleridge's well-known description of his manners as "singularly repulsive — brow-hanging, shoe-contemplative, strange." He was always excessively conscious of himself, jealous and quick to take offense. Yet he could be a generous admirer of genius in others, and his consistent championship of Keats against his critics is always remembered to his credit.

As a youth Hazlitt read intensively and so laid the foundation of the wide knowledge of literature and philosophy that he used so effectively in his writing. Yet he found great difficulty in expressing himself both in conversation and writing, so that he turned first to painting as an outlet for his ambitions. His elder brother John nas already in 1798 established in London as an artist. and his example no doubt had some influence. For several years Hazlitt worked hard at what seemed to be his profession. In 1802 he nent to Paris to nork in the Louvre but war between France and England in 1803 compelled his return. By 1804, when he first met Charles Lamb, he was a more than proficient portrait painter, and his portrait of Lamb (in the National Portrait gallery, London) is sufficient evidence that he could have excelled had he persisted. He was encouraged by Coleridge and Wordsworth, who had been his friends since 1798, but in 1805 he turned from his painting and gave his mind to the metaphysics and philosophy uhich had interested him earlier, publishing his first book On the *Principles* of *Human* Action. Other books followed — Free *Thoughts* on Public Affairs (1806), an abridgment of Abraham Tucker's *Light* of *Nature* Pursued and a Reply to *Malthus's* Essay on *Population* (both 1807). He nas also working on a collection of parliamentary speeches with comments on the speakers; two volumes appeared in 1807. In the same year he formed an attachment to Sarah Stoddart, a friend of the Lambs, and in May 1808 they were married, going to live at Winterslow on Salisbury plain. which was to become Hazlitt's favourite retreat for thought and writing Here he worked on a series of literary projects — a History of Englzsh *Philosophy,* which was abandoned, an English Grammar (1810) and *Memoirs* of *Thomas* Holcroft (1816), the dramatist and novelist and a friend of Hazlitt's for some years up to his death in 1809.

Hazlitt's first child was born at Winterslow in 1809, but did not live. His second child. William, was born in 1811. He had before this again tried to return to painting in London, but he seemed to himself to have failed both as artist and writer, and by the end of 1811 he was penniless. He retrieved his position by a course of lectures on philosophy in London and by reporting for the *Morning Chronicle.* Two years later he was fully established as critic, journalist and essayist, his collected dramatic criticisms being published as *A View* of *the* English Stage (1818). He was also contributing to a number of journals, including Leigh Hunt's *Examiner.* This association led to the publication of The *Round* Table, 2 vol. (1817); 12 of the 52 essays were by Hunt. though Hazlitt's name only appeared on the title page In the same year Hazlitt published his *Characters* of *Shakespeare's* Plays, which met with immediate approval in most quarters. At the same time he was fearlessly expressing himself in forcible terms in the journals and was involved in many quarrels with his friends. In

addition he was savagely attacked by William Gifford in the *Quarterly Review,* the sales of his Shakespeare volume being greatly damaged thereby. In 1815 he had been profoundly upset by what was to him a bitter blow, the defeat of Napoleon at Waterloo. Napoleon had been his idol for some years, and B. R. Haydon, the painter, said that he attempted for a time to drown his mortification with drink. Hazlitt's irritability was accentuated by ill-health. perhaps initiated by his indulgences and certainly made worse by the journalistic battles which came to a head in the action he brought against *Blackwood's Magazine.* This was settled in his favour out of court and in 1819 he had the satisfaction of publishing his *Letter to William Gifford,* paying off old scores with barbed invective to the admiration of his friends, particularly Keats who, with Shelley, had been added to his circle of friends and admirers.

Meanwhile Hazlitt was consolidating his reputation as a lecturer, delivering a course *On the English Poets* (published in 1818) and another *On the English Comic Writers* (published in 1819). Keats was not able to hear the second course, but, having read them, quoted in a letter to his brother, George, "a specimen of his usual abrupt manner and fiery laconicism." In 1819 Hazlitt also published a collection of his political essays written during his years of journalism, adding some "characters" of statesmen first printed in earlier books. He resolved thereafter to withdraw from political controversy and occupied himself during 1819 with preparation of his *Lectures on the Dramatic Literature of the Age of Elizabeth.* These mere the last lectures he delivered, and he subsequently devoted himself chiefly to essays for various journals. especially John Scott's *London Magazine,* of which he temporarily became editor after Scott's death.

Many of these essays were written at Winterslow, where he was often alone, having lived apart from his wife since the end of 1819. When in London he occupied lodgings in Southampton buildings, where he fell in love with Sarah Walker, daughter of his landlord. This girl he intended to marry after completing arrangements in Edinburgh for divorcing his wife. He was a free man by June 1822, but some weeks later it became known that he had been deceived by Sarah Walker, who, while seeming to favour his attentions, had admitted another lover. This rebuff caused him intense suffering, which he sought to "burn out of his mind" by writing an account of his affair. This strange work was published in 1823 under the title *Liber Amoris; or, The New Pygmalion,* and attracted greater notoriety than its merits deserve. Its publication was, however, necessary for its author's peace of mind.

Hazlitt's two most famous books of essays, *Table Talk* (1821) and *The Plain Speaker* (1826), contain all the best essays written in the years 1820–25. Many other essays were collected in posthumously published volumes edited by his *son—Sketches and Essays* (1829), *Literary Remains* (1836) and *Winterslow* (1850); many more remained to be collected as *New Writings,* 1st and 2nd series (1925–27) edited by Hazlitt's biographer, P. P. Howe. Hazlitt also found time to produce a volume of *Characteristics, in the Manner of La Rochefoucauld's Maxims* (1823), to edit a large volume of *Select British Poets* (1824) and to complete sketches of the *Principal Picture Galleries in England* (1824), including his celebrated essay on the Dulwich gallery.

In April 1824 Hazlitt married for the second time, his bride being a widow named Bridgwater whom he had met in a stagecoach; but the presence of the new Mrs. Hazlitt was resented by young William, to whom his father was devoted, and they separated three years later. Hazlitt had spent part of his second period of matrimony in France and Italy, and while in France on this and other occasions worked at his most ambitious and least successful work, the *Life of Napoleon,* 4 vol. (1828–30). His travels in 1824–25 he recorded in his *Notes of a Journey in France and Italy* (1826). He also published in 1825 a series of essays on contemporary figures entitled *The Spirit of the Age,* containing some of his most animated and effective writing. His last book, *Conversations of James Northcote* (1830), was a record of his friendship with that eccentric painter over many years, the "conversations" having been published as a series in the *New Monthly Magazine* (1826–27), and in other journals in 1829.

During these latter years Hazlitt's health had deteriorated and he died of cancer of the stomach at his lodgings in Frith street, Soho, on Sept. 18, 1830. He was buried at St. Anne's, Soho. His last words were reported by his son to have been, "Well, I have had a happy life." Although he had been through unhappy episodes, there is no doubt that his zest for living and his intense interest in human affairs had kept him happy most of his life. It may be said of him in the words which he wrote of Dr. Johnson, "He had faults, but they lie buried with him. He had his prejudices and his intolerant feelings. but his nere not time-serving, heartless, hypocritical prejudices, but deep, inwoven, not to be rooted out but with life and hope. which he found from old habit necessary to his own peace of mind. I do not hate, but love him for them."

Hazlitt's essays are so numerous that it is difficult to select any small number for special mention. But it is generally agreed that he is represented at his brilliant best in essays such as "On Living to One's-self." "The Fight" (an account of his unpremeditated expedition to Hungerford to see Bill Neate fight the Gas-man), "On Disagreeable People," "My First Acquaintance with Poets" (chiefly about Coleridge and Wordsworth), and "Of Persons One would Wish to have Seen."

His *Complete Works* were edited by A. R. Waller and Arnold Glover, with an introduction by W. E. Henley, in 13 vol. (1902–06; reissued, ed. by P. P. Howe, 21 vol., 1930–34). Among selections from the essays are those edited by F. Carr (1889); by A. Ireland, with a memoir (1889); by D. Nicol Smith, on poetry (1901); by C. Whibley (1906); by Jacob Zeitlin (1913); by G. Sampson (1917); by P. P. How-e (1923); by C. H. Gray (1926); and by G. Keynes (1930).

HEAD, the upper portion of the body in man, consisting of the skull with its integuments and contents, including the lower jaw. It is attached to the spinal column by way of the first cervical vertebra, the atlas, and connected with the trunk of the body by the muscles, blood vessels, nerves, etc., that comprise the neck. The term also is used to describe the anterior or fore part of animals other than man.

See also BRAIN; SKULL; articles on the various organs, etc.. that are located in the head. (F. L. A.)

HEAD AND NECK, SURGERY OF, is a term that describes loosely a branch of modern surgery specializing in operations on the face, throat and neck. It does not include surgery of the brain, eye or neurosurgery, nor does it include dental operations. In medical centres in both Europe and America surgeons trained in general surgery, plastic surgery or both perform most of the major head and neck surgery. The largest number of these operations are performed to correct congenital deformities such as cleft lip and palate, to eliminate cancer of the face. oral cavity, larynx, salivary glands and jaws, and to correct the deformities and functional loss suffered as a result of injury to the facial bones and features. Because of the exposed location of the head and neck, deformity subsequent to disease, injury or surgery is extremely important to any patient. As a result, emphasis has been placed on the development of immediate and early reconstructive surgery to make operations less crippling to the patient. Plastic surgery has made great strides in this direction.

The rapid growth of the field of head and neck surgery results from several factors. (1) The use of antibiotics greatly reduced the dangers of infection following surgery; formerly the normal bacteria in the human oral cavity caused devastating infections after operations in which these organisms were allowed to enter the tissues of the neck. (2) The widespread use of blood transfusions has made it possible to carry out long and tedious operations without shock on that part of the body which is notorious for the amount of bleeding produced during surgery. (3) Modern techniques of anesthesia also have greatly reduced the dangers to

the patient, so that even major operations in the head and neck region now carry an operative mortality of less than 1%.

The role of plastic surgery is important, and the experiences of World War II showed surgeons that techniques of rebuilding the human face could be used to great advantage in most head and neck surgery. These techniques include skin grafting to replace missing surface or features, muscle transplants for paralyzed facial muscle, nerve grafts and transplants, bone grafts to rebuild jaws or nose, and blood vessel grafts for arteries.

Maxillo-facial surgery is a term generally used to denote a field related primarily to dental surgery and jaw deformities.

HEADDRESS, a covering for the head, which may be considered as (1) protective, originating as a defense against climate and physical violence; (2) ceremonial, as a badge of rank and office. Frequently combining both functions, its history is bound up with the mask (*q.v.*), the veil, the coiffure and the tonsure (*q.v.*); its aesthetic development belongs to a later period.

The additions and changes made to the hair, the natural protection, whether defensive or ceremonial, appeared first and chiefly among men. Women wore their hair long, while men cut their hair or shaved their heads. The practical band employed to confine the hair and keep it from the eyes, in widespread. use among primitive and savage people, gave rise to a variety of headdresses worn chiefly by women and surviving in historic civilization, while the comb and hairpin, assuming ornamental forms, became essential elements in the woman's headdress in many lands. Two pins, worn right and left, ornamented with artificial flowers and terminating in vestigial spoons are the usual hair ornaments among the women of eastern Asia.

Defensive and protective head coverings fall into two general classes: (1) the hat and helmet type; (2) the cloth or garment tied around or worn over the head, such as the turban. The classic world of Greece and Rome, wearing a garment that when necessary was drawn over the head, eschewed other coverings. The hat or helmet arose as a hide or leather head cover in the north and as a wood or basketry sunshade in the tropics, metal being a later replacement. A round cap, made of cloth or felt, closely fitting the skull or terminating in a peak, and later truncate, appeared early in western Asia. The turban was wound either directly around the head, or usually around such a cap. Its size, shape and colour varied in different countries and in accordance with the rank and occupation of the wearer, and to it, as well as to the felt cap, an aigrette or jewel was sometimes added as a badge of regal and other rank.

Ceremonial headdresses are varied and complex, and their beginnings may be traced to primitive conditions. Like the mask, they were assumed frequently to identify the wearer with a divinity or to perpetuate the tradition of a divine ancestor. Chinese imperial headdresses bear the symbols of the sun and moon. The pointed crown may be regarded as a solar emblem. The custom of shaving the head was common at the initiation of a warrior or priest, but a head ornament or cap was commonly a badge of rank and its prerogatives jealously guarded. In China and Japan a straight, standing knot was left on the top of the head to which the imperial cap was attached by a transverse pin. The North American Indian warrior shaved his head. leaving a medial crest, or wore a similar crest made of the hair of rhe moose in which a tablet bearing the symbol of a bird was embedded. This object, tied to the so-called scalp lock, serves to explain the feathers fastened to his hair as well as his feather headdresses. The peacock feather badge of the Chinese Manchu dynasty had a similar mechanism. The feathers of the Plains Indian war bonnets, assumed to symbolize exploits, may be regarded as a composite and cumulative expression of the bird on the tablet. The horns of these war bonnets were those of the buffalo. A miniature netted shield and two feathered darts, emblems of the Twin War Gods, were of widespread recurrence in the headdress of the Indian warrior. The aboriginal headdresses of the Indian tribes of the North American continent may be regarded as emanations from ancient Mexico, where elaborate headdresses of feathers were worn by the priests and warriors who personated the gods. The military headdress of historic Europe was in the main defensive, but the bear skin shako and lofty plumed hat of the 18th century were intended to increase the apparent height of the wearer and impress the enemy. Ecclesiastic headdresses both east and west had secular origins.

The ceremonial crowns and headdresses of women were borrowed and imitated from those of their consorts, whose rank they shared. The peasant wedding-crowns of central Europe are reminiscent. Flowers, natural and artificial, were their common and widely used hair ornaments, but the rule that women should not appear in church uncovered led to the universal use of the women's head cloth or kerchief in Catholic Europe. The sunbonnet is a combination of this cloth with a band, by which it was tied over the head. The headdress of fashion for both men and women reached its highest development in Europe in the 18th century. Its simplification due to the general adoption of short hair resulted in the employment of the felt hat worn by women in Europe and America. (*See* also COSTUME DESIGN, THEATRICAL; DRESS.)

HEAD-HUNTING. The practice of head-hunting, although no doubt due partly to the acquisitive instinct, arises from a belief in the existence of a more or less material soul matter on which all life depends. In the case of human beings this soul matter, often, apparently, in diminutive human form, is located particularly in the head. In abstracting a head the soul within is captured and thus added to the general stock of soul matter belonging to the community and so contributes to the fertility of the human population, the cattle and the crops; for the soul is conceived of, according to the Karens of Burma at any rate, as a sort of pupa, filled with a vaporous substance which bursts, its contents spreading over and fertilizing the fields, passing again through the eaten grain or herb into the bodies of men or animals and so again into the seminal fluid enabling men and animals to propagate life. While precisely the same formula cannot be postulated of all head-hunters, head-hunting is generally based on a similar belief in a cycle of life dependent on the possession of soul (*see* METEMPSYCHOSIS), and on a belief in life as something concrete and transferable.

Head-hunting is therefore associated (1) with ideas regarding the sanctity of the head as the seat of the soul; (2) with some forms of cannibalism where the body or part of the body is consumed in order to transfer to the eater the soul matter of the viand; and (3) with phallic and often fertility cults intended to imbue the soil with productivity. It may thus develop into human. sacrifice, a practice which has been generally associated with agriculture. Head-hunting, or at any rate some practice closely allied to it, has been found sporadically all over the globe either actually existing or in some degenerate survival.

In Europe the practice actually survived until the early 20th century in the Balkan peninsula, where the taking of the head affected the future life of the soul in some way that is no longer quite clear, but no doubt implied the transfer of the soul matter of the decapitated to the decapitator. The complete head was taken by Montenegrins as late as 1912, it being carried by the lock of hair worn allegedly for that purpose. In the Balkan war of 1912–13 nose-taking was substituted, and it was the practice to cut off the nose and upper lip nith the moustache by which it was carried, just as in Kafiristan and in Assam an ear was sometimes carried off instead of the whole head. In the British Isles the practice continued approximately to the end of the middle ages in Ireland and the Scottish marches; and in Ireland, until the 20th century at any rate, a Martinmas pig was killed that the fields might be sprinkled with blood and so rendered fertile. In some parts of the continent murderers have been known to eat part of their victims to secure themselves against ill will on the part of the ghost. The underlying idea is, no doubt, that the consumption of the flesh leads to spiritual identity.

PORTION OF ASSYRIAN BAS-RELIEF DEPICTING ASSUR-BANI-PAL'S SECOND WAR AGAINST **ELAM**, *c.* 650 B.C.: ON THE LEFT IS SHOWN THE LAST STAND OF TE-UMMAN. **KING** OF **ELAM**, AND TAMRITU. HIS SON. AND IN CENTRE, THE BEHEADING OF TE-UMMAN AND TAMRITU

In Africa the principle involved has shown itself rather in the form of human sacrifice than of true head-hunting. Dahomey and Ashanti being notorious examples; but even here the fact that the human sacrifices in Dahomey made the rain magic more efficacious suggests the working of the same ideas. while an instance is known of a Matabele chief who anointed his body and fertilized his fields with human fat. So, too, the eating of an enemy's heart has been reported from Dahomey and Whydah. and the use of skulls as drinking cups from the Guinea coast. Bona fide head-hunting occurred in Kigeria, where a number of usages strongly suggest Indonesian culture. As in Indonesia, head-hunting among the Kagoro, and perhaps other tribes in Nigeria, mas associated with the fertility of the crops, with marriage, and with the service in the next world by the victim.

In Asia Herodotus mentions head-hunters, and on a bas-relief from Kineveh in the British Museum is represented a battle in the 7th century B.C. between Assur-bani-pal and the king of Elam. in which the Assyrians are depicted as cutting and carrying off the heads of the slain. In Kafiristan on the northwest frontier of India head-hunting was practised until about the end of the 19th century, women showering wheat upon men returning with heads from a successful raid. In the northeast of India. Assam was famous for head-hunting. All the hill tribes living south of the Brahmaputra — Garos, Khasis, Nagas and Kukis — formerly were head-hunters, and some of the Naga tribes continued to practise the decaying cult.

Head-hunting in Assam was normally carried on by parties of raiders who depended on surprise tactics almost entirely. The heads. and sometimes also the hands and feet or even the whole limbs, were cut off and carried home to the village. where the head was usually placed on a stone or pile of stones kept for that purpose. The practice of cutting off the limbs had possibly a ditierent origin, as there were tribes north of the Brahmaputra who did not take heads, but did cut off the feet and hands of slain enemies, presumably to incapacitate the ghost. The skull was subsequently variously treated. After its virtue had passed into the stone on which it was laid: it was either buried face downward (as by the Angami tribe), hung up in trees (as by Semas and Lhotas) or suspended in the chief's house or the bachelors' hall. In the latter case some tribes decorated it with a pair of buffalo horns, probably as a fertility symbol, and with long tassels of a broad-bladed grass which rustled when the skull was swung by a dancer at a feast, much as in Borneo. If several participants in a raid were all in at the death, the head was often divided on a fixed system. certain definite portions going to the first, second and third spears, etc. The insignia and, where tattooing was practised. the tattoo patterns worn by the successful warrior had specific reference to success in head-hunting. Thus the Angami warrior wore one hornbill feather for each success — "touching-meat" as it was called — while the Konyak warrior had his neck tattooed only if he had actually performed the act of decapitation in person, though he might have his chest tattooed for "touching meat" and his face for the act of killing the enemy in person. With the Naga, the genuine head-hunter, a head had to have cut. its teeth to count, and a female head was at least as good as a male; but with the Kuki, whose cult was probably mixed and whose desire for heads was merely to supply a dead relative with servitors in another world, any head, even that of an embryo, was good. The Kagoro and Moroa tribes of West Africa, like the Kuki of Assam and the Kayans of Borneo, desired slaves in the next world rather than soul matter in this. The Naga never took the head of a fellow-villager even though clan feuds within the village were very bitter and lead

to much bloodshed, and even outside the village heads were not as a rule taken between men of the same or nearly related clans, a self-denying ordinance shared with the Kagoro. The younger women were everywhere great instigators of head-hunting, and refused to marry men who had not "touched meat," probably with the idea that until they had taken life they were unlikely to beget offspring.

In Burma several tribes have followed similar customs. The Wa tribe observed a definite head-hunting season when the fertilizing soul matter was required for the growing crop and all wayfarers moved about at their peril. In Borneo, Indonesia generally, the Philippines and Formosa, similar methods of head-hunting obtained, and the hill tribes of Malaya and Indochina probably are or have been head-hunters at some period. The Ibans of Borneo were particularly enthusiastic in this respect. The practice was reported of the Philippines by Martin de Rada in 1577, and was only abandoned by the Igorot and Kalinga of Luzon at the start of the 20th century, while in Formosa it prevailed among the hill tribes. Elsewhere in Indonesia it extended through Ceram where the Alfurs were head-hunters, to New Guinea, where the Motu, like the Lhota Naga of Assam, wore a hornbill's head as the insignia of achievement; here and there, as in the Battak country and in Timorlaut, it seems to have been replaced by cannibalism.

In New Guinea the Tugeris used a bamboo knife for the act of decapitation, perhaps because iron would adversely affect the soul within. Throughout Oceania head-hunting prevailed sporadically till comparatively recently. In the Solomon Islands the actual expedition to obtain a head formed the climax in a series of ceremonial acts extending over a number of years, and the suppression of head-hunting, on which depended an important part of the social life, was a serious factor in the decay of society and the decrease of population which followed under British administration. Throughout Oceania head-hunting was closely associated with cannibalism and the latter institution tended to obscure the former, but in many islands the importance attached to the head was unmistakable. In parts of Micronesia the head of the slain enemy was paraded about with dancing, which served as an excuse for raising a fee for the chief to defray public expenditure, after which the head would be lent to another for the same purpose. In Melanesia the head was often mummified and preserved, and sometimes, as in New Britain, seems to have been worn as a mask in order that the wearer might acquire the soul of the dead man. Even in Australia this underlying principle was active as it was reported that the Australian believed the spirit of a slain enemy entered the slayer. In New Zealand the heads of the foe were dried and preserved so that the tattoo marks and often the actual features were recognizable; this practice led to a development of head-hunting when tattooed heads became desirable curios and the demand in Europe for Maori trophies caused "pickled heads" to become a regular article of ships' manifests.

In North America the general practice was to take the scalp rather than the head, indicating probably that the soul was thought to be located in the hair; an idea present in the Biblical story of Samson; common in Malaya and Indonesia, where Nagas and Borneans used the hair of their dead enemies for ornaments, as did the North American Indians; in Oceania, where the Marquesans used the hair of the victims of their cannibal rites for making arm rings and necklets of magic virtue; and frequent in South America, where the heads were often preserved, as by the Jivaros, by removing the skull and packing the skin with hot sand. thus shrinking it to the size of the head of a small monkey while preserving the features intact as a vivid portrait in caricature. There. again, head-hunting was probably associated with cannibalism in a ceremonial form. and the heads of certain animals were also treated similarly *(see* LYCANTHROPY). Head-hunting, therefore, has been world-wide. It was associated with tribes still living in the stone ages, and may even go back to palaeolithic times; as in the Azilian deposits at Ofnet in Bavaria, heads were found carefully decapitated and buried separately from the bodies, indicating beliefs in the special sanctity or iniportance of the head.

HEALTH AND SAFETY LAWS. One of the earliest and most important objectives of government and law is the provision of public health and safety. In many societies law as a distinct means of social control originates when some official agency is created to protect communal health and safety from some supposed danger threatened by natural or supernatural forces. In primitive cultures, and in western civilization up to the middle ages, this social concern usually was manifested in a negative way by the isolation or destruction of the patient in order to protect the healthy. The public health laws, social legislation and preventive medicine of today largely are the products of the scientific advancements of the 19th and 20th centuries.

This article is divided into the following sections:

I. INTRODUCTION

The interest of the individual and society in health and safety finds expression in the orders of executives, the ordinances and statutes of legislatures and councils and the decisions of courts and administrative bodies. That such an interest is conceded to be among the most important values is also shown by the deference courts have shown for legislative and executive formulations of health and safety policy. In the United States, even during the period when courts wielded their power of judicial review to an unprecedented extent and readily substituted judicial preference for legislative judgment, health and safety laws were subject to milder scrutiny than measures involving, for example, economic experimentation. The common law at times gave priority to health and safety matters over property rights and economic interests.

Ultrahazardous undertakings, the creation or maintenance of dangerous conditions or objects, long have been a basis for special classification. Although most states have rejected the English

doctrine of *Rylands* v. *Fletcher* (1868). which imposes strict liability for the escape of dangerous substances, the concept of nuisance has been construed to cover such cases.

The common law created an implied narranty of fitness for human consumption in the sale of foodstuffs, and the liability of products today may be based on the fact of sale rather than on negligence in processing or failure to inspect. In short, danger to human health and safety is a special circumstance and a paramount value. Summary procedure and something less than the due process usually required may be invoked when health authorities or fire marshals act to cope with emergency, and both the police power of the state and the power of eminent domain may be utilized to protect or promote public health and safety.

II. HISTORY

In addition to isolation of the sick, principles of hygiene and sanitation have been developed by many preliterate peoples. Whenever these matters are deemed to be of sufficient social concern, they receive the coercive sanction of law, as well as the informal sanctions of custom or religion. The preservation of peace and order, the conservation of manpower and a desire to prevent offenses that may provoke the wrath of the gods against the community are among the immediate objectives of law that may be included under the general title of public health and safety laws. They are the forerunners of what is termed the police power of the modern state.

The history of health and safety laws has been determined in large measure by the influences of religion and science and by political and economic forces. A public concern with the health problems of community life, the control of communicable diseases and improvement of environmental and sanitary conditions, such as the provision of food and water, medical care, and sewerage and drainage facilities, may be found in varying degrees in primitive, ancient and modern societies. Moreover, religious and health objectives may be inextricably intermingled, as, for example, in dietary laws, the rules of hygiene and precautions against contagion specified in *Leviticus* and *Numbers,* prohibitions against consanguineous marriages and the merging of functions in priests and shamans. In the western world there was a close relationship, if not identity, between church and state until the Reformation, and for centuries virtually all literate men were clerics. which meant that most scientific knowledge was in their hands and subject to church control.

1. Early Influences. — The emphasis of the early church upon spiritual matters and the belief that disease and death were the wages of sin stood as major obstacles to a positive program for public health and social reform On the other hand, the church and its religious orders did establish and maintain relieving institutions for travelers, the sick and widows, such as that founded by Basil the. Great in AD. 370 at Caesarea; and Pope Leo XIII's encyclical *Rerum novarum* (1891) and Pope Pius XI's *Quadragesimo anno* (1931) were most important for the social reform movement of the 19th and 20th centuries. It is only since the Industrial Revolution, however, that cleanliness has been officially promoted.

The middle ages (about A.D. 500–1500) saw a decline from the standards of hygiene and sanitation of classical Rome. Although we are greatly indebted to the Greeks for principles of personal hygiene and to the Romans for the development of public sanitation, there are records of elaborate programs in even more ancient times. Ruins in the Indus valley and at Harrapa, in the Punjab, reveal that building codes were in effect and that sanitation engineering was far advanced as early as 4000 B.C. Egyptian ruins dating from the middle kingdom (2100–1700 B.C.) include bathroom facilities and sewerage systems as do those of the Incas in the new norld. In addition to the formulation of principles of hygiene, the Greeks were responsible for the first attempt to show a causal relation between environmental factors and disease. The book in the Hippocratic collection known as *Air, Waters and Places* for over 2.000 years served as the basic text on epidemiology and helped to sustain the miasmatic (contaminating atmosphere) theory of disease *(see* HIPPOCRATES AND THE HIPPOCRATIC COLLECTION) until use of the microscope led to the discovery of microbes and the beginning of bacteriology *(q.v.)*. The Romans perceived a relation between swamps and malaria, devised crude respirators to protect workers from dust, in the 2nd century instituted a public medical service built sewerage systems and public baths and engineered 14 great aqueducts. They also built the first hospitals and codified and successfully administered health laws. Officials were appointed to maintain the banks of the Tiber, to guard the aqueducts against pollution, to inspect and maintain sewers, to destroy impure foodstuffs, to check weights and measures and to regulate public baths. brothels and burial grounds. Justinian I, when one of the worst plagues in history came to Byzantium in 532, set up quarantine posts and required certificates of health for admission to that city.

2. Middle Ages. — Upon the disintegration of the Roman empire, there was a general decline of urban culture and with it an abandonment of public health measures. Ryzantium became the cultural and medical centre for Europe, and from there Greco-Roman medical knowledge spread to the Arab world, while in the west, health problems were still dealt with largely in terms of magic and religion. During medieval times some of the larger monasteries had proper water supplies and heating and ventilation facilities. but smaller buildings did not. Most medieval cities had a chronic problem in trying to provide a sufficient supply of nonpolluted nater and in protecting the public from disease. During the middle ages in England the common-law concept of public nuisance provided a means for relief against some flagrant cases of pollution of water supply as did the common-law crime of malicious mischief, and in both England and on the continent, ordinances and statutes were enacted to outlaw some of the most prevalent threats to public health. For example. Douai, France, in 1271, Augsburg, Ger., in 1453 and Rome in 1468 forbade tanners to wash animal skins on the banks of streams. dyers to pour dye residue therein and the public from washing clothes at a river which served as a source of water supply. Early in the 15th century several German cities forbade the construction of hogpens facing the street. In 1185 the streets of Paris were paved to help keep the city clean. London from 1309 had ordinances dealing with sewage disposal, and Milan from the 14th century had statutes regulating cesspools and sewers. Most of these ordinances and laws, however, received only sporadic enforcement and tended to become dead letters.

The health measures that received the most conscientious enforcement during the middle ages were those pertaining to the sale of adulterated or contaminated food and those providing for quarantine in the case of epidemics. Municipal authorities in many places policed the fairs and market place to protect purchasers of food. Inspection mas practised, and detailed regulations were enforced. For example, Augsburg in 1276 ordered meat that was not freshly slaughtered to be sold at a special stand, and the Florentines forbade the sale on Monday of meat that had been offered for sale the previous Saturday.

Although epidemics were regarded by many as a punishment for man's sin, the transmissibility of certain diseases was well known during the middle ages and had been for centuries. Thucydides had portrayed a vivid account of an epidemic during the second year of the Peloponnesian War. Between the plague of Justinian (A.D. 543) and the Black Death (1348) there were a large nurnber of plagues, involving such diseases as leprosy, bubonic plague, smallpox, diphtheria, measles, influenza and sweating sickness, and lesser diseases. The medieval urban dweller lived in constant fear of epidemics, and when leprosy reached serious proportions in the 13th and 14th centuries, quarantine laws were rigidly enforced. At the beginning of the 13th century, in France alone there were about 2,000 leprosaria, and in all of Europe the number probably exceeded 19,000.

The third Lateran council in 1179 promulgated detailed rules to govern the commitment of lepers. The experience with lepers was carried over when the Black Death (bubonic plague) killed thousands of workers in the 14th century *(see* PLAGUE). Suspicious cases were required to report to local authorities who examined them; if the patients were found to have the plague, they were iso-

lated, as were all those who came into contact with them, food and necessities were provided, the dead with their personal effects were buried outside the city, and the place where they had died was fumigated. Venice, the chief port for trade with the orient, usually is credited with originating the pattern of quarantine procedure that was in effect during the middle ages, and other seaports also established observation stations and isolation hospitals.

In England from the 12th to the 15th century more than 720 hospitals were established, 217 of which were for lepers. At the beginning of the 14th century, Paris had about 40 hospitals and at least an equal number of leper houses. During the latter part of the middle ages, cities and guilds took an active part in founding and maintaining hospitals.

3. Later History.—Europe.—By the close of the middle ages, medicine and public health had fallen under local governmental control. Regulations protecting the water supply from pollution were supplemented by other provisions dealing with street cleaning, garbage disposal and the like. all of which collectively might be termed sanitary codes. Physicians and surgeons were required to follow rigid codes and set fee schedules. In addition, writings on nutrition began to appear, and public bathhouses were licensed. When syphilis became widespread early in the 16th century, the first control measures were directed against prostitutes.

The attempt to deal with public health problems on a municipal basis was far from successful. Inland cities were all but defenseless against the spread of disease from the seaports. Moreover, in the larger cities the administration of particular ordinances was delegated to various boards, commissions and officials, so that the net result was a crazy quilt of sanitary committees. London in the 1830s divided such authority between the city corporation and the city companies, 7 boards of commissioners for sewers and nearly 100 paving, lighting and cleansing boards, and there were about 172 vestries of one sort and another and boards of guardians appointed under the poor lams. The parish of St. Pancras alone had 21 paving and lighting boards, on which sat about 900 commissioners.

Colonial America.—Colonial America followed the pattern of utilizing inspection and quarantine for communicable diseases and the enactment of sanitation legislation. The account of George Percy regarding the settlement of Jamestown, Va.. describes the "cruell diseases, Swellings, Fluxes, Burning Fevers" and famine that afflicted that colony. Almost half of the 100 (or 102) Pilgrims that landed at Plymouth, Mass., in Dec. 1620 died within three months after arrival. During the winter before the Pilgrims' arrival, an epidemic reduced the numbers of Indian warriors of New England from 9.000 to a few hundred. Inoculation was brought to the colonies by Zabdiel Boylston and Cotton Mather and later was regulated by colonial legislatures. As early as 1647, ships from the West Indies were quarantined in Boston harbour; and in 1663, during a smallpox epidemic, New York regulated entry into its city by travelers from contaminated regions. Abatement of public nuisances seems to have been in the hands of local authorities throughout most of the 17th century, but a South Carolina statute of 1692 forbade swine running at large in the city of Charleston and directed all persons to cut noisome weeds in and about the lots and streets. During the same year the Massachusetts general assembly empowered selectmen and justices to assign locations for slaughterhouses and places for the testing of tallow and the currying of leather. The charters granted by William Penn to Philadelphia and Chester, Pa., in 1701 conferred power upon mayors and magistrates to abate nuisances. Detailed quarantine regulations were enacted in Massachusetts in 1701. The first American health board was appointed in Baltimore, Md., in 1793, and by 1797 there were similar boards in New York and Massachusetts.

Influence of the Industrial Revolution.—The industrial revolution (q *v.*) occasioned a tremendous increase in urban population, and slum conditions became acute in many manufacturing areas. The first English attempt at slum clearance was in London in the 1760s, when many timbered buildings were pulled down and replaced by brick structures, and streets were paved, drained and lighted. In addition to disease and slum conditions, the urban population faced poverty and frequent unemployment. The Elizabethan poor laws imposed the duty on the individual parish to provide relief for the indigent (see Poor Law).

III. SOCIAL REFORM

By the beginning of the 19th century, in England and on the continent, the interrelationship between poverty, disease, physical environment and crime was apparent, and the view that such conditions were neither inevitable nor irremedial was gaining ground, To the rationalists of the age of reason, a scientific approach to social problems would provide the answers. Industrialists, such as Sir Robert Peel and Robert Owen, and physicians, such as Sir John Simon and Thomas Southwood Smith, joined the social reform movement under the leadership of Jeremy Bentham and Edwin Chadwick. Royal commissions investigated and reported, studies were made, statistics were compiled and, beginning in the 1830s, social legislation was enacted.

An integral part of the social reform movement was the compilation and publication of statistics which afforded a factual basis for legislative and other investigations and reports which were an essential prelude to legislation and which served to create a demand for reform by informing the public of existing conditions. William Farr was perhaps the greatest medical statistician in the 19th century, but the father of political arithmetic was the 17th-century physician, scientist and economist William Petty, who urged the collection of numerical data on population, education, diseases, revenue, etc. Petty's friend John Graunt wrote the first important study of health statistics in 1662. In Germany the philosopher Gottfried Wilhem Leibnitz recommended statistical investigations of health problems and in the 1680's published several essays on the urgent need for vital statistics. Leibnitz's work was carried on and furthered by his contemporary Veit Ludwig von Seckendorff, who is credited with having developed the public health philosophy for Germany that was systematized by Johann Peter Frank and enacted into law by Bismarck. Sweden was the first country, however, to require nationwide reporting of vital statistics, legislation having been passed in 1748, following the recommendations of Pehr Elvius, mathematician and secretary of the Swedish Academy of Science.

In the United States, Massachusetts was the first state to establish a bureau of labour statistics. The first important study of public health was the 1845 report of John Griscom, city inspector for the New York board of health. During the same year the National Institute of Washington undertook a survey of the nation's health. Perhaps the best-knon-n early document dealing with public health problems in America was the Shattuck report, published in Boston in 1850. The report was written by Lemuel Shattuck, a Boston bookseller and publisher, who had helped found the American Statistical society in 1839 and had secured passage in 1842 of a Massachusetts vital statistics law that became a model for other states. Shattuck's work also led to the first effective state health department, namely that created in Massachusetts in 1869. Several other states followed the Massachusetts example within the next few years. In the second half of the 20th century the compilation of vital statistics was regarded as a matter of general public importance and in the United States constituted a proper exercise of police power. Almost all of the health, safety and welfare laws that were passed in the 19th and in the first half of the 20th century were based on factual studies and statistical reports. Louis D. Brandeis, as counsel in a case involving the constitutionality of Oregon's ten-hour day for women workers, secured judicial acceptance of such material when his so-called Brandeis brief was relied upon by the supreme court in its decision.

IV. EARLY LEGISLATION

1. Europe.—There were but few examples of social or health legislation on a national scale before the 19th century. In order to check the high rate of infant mortality and for reasons of public morality, parliament passed a series of gin acts, culminating in an act of 1751 which gave control of licensing to magistrates, and perhaps the first example of social insurance was an act of 1757 "for the relief of coal-heavers working upon the River Thames,"

which required the employer to deduct sums from employees' wages for a fund from which benefits would be paid in case of sickness, invalidity, old age or death. Because of its abuse by employers, however, this early insurance scheme was abolished in 1770 but was revived in 1792, when a similar act mas passed providing for trustees to manage the fund. The Health and Morals of Apprentices act, sponsored by Sir Robert Peel, was enacted in 1802 to improve the conditions of child labour in the cotton mills. Although this legislation was largely ineffective, it did establish the government's interest in industrial conditions and led to agitation for child labour laws in other industries and countries.

The Benthamite reformer Edwin Chadwick, who was convinced people were poor because they were sick, was chairman of both the commission that reported on the poor laws in 1834 and the commission that reported on public health in 1844 and 1845. These reports eventually were embodied in legislation and established national supervision over health, safety and social problems. The Factory act of 1833 was the immediate forerunner of modern industrial legislation, and the Liverpool Sanitary act of 1846 provided for health officers and borough engineers for that city. The Nuisances Removal and Diseases Prevention act and the Baths and Washhouses act, passed the same year, were preludes to the Public Health act of 1848. The first general housing acts were passed under the sponsorship of Lord Shaftesbury in 1851.

In addition to the rise of social legislation in England, similar movements gained momentum in Germany and France. Johann Peter Frank, German pioneer in public health, ambitiously undertook to systematize all existing knowledge on the subject and to devise detailed codes of hygiene for enactment. Frank, because of his broad scholarship, was one of the first to urge international regulation of health problems and creation of a national health authority to co-ordinate matters within the country. Advanced by Wolfgang Thomas Rau and Franz Anton Mai and endorsed by Frank was the creation of "medical police" to make and enforce health and safety regulations. In France, during the Revolution, the constituent assembly, on the motion of Joseph Ignace Guillotin, created a Comité de Salubrité. In 1793 and 1794 a national system of social assistance, including medical care, was passed. Both France and Germany thus became committed to the proposition that government had a positive duty to promote the health, safety and welfare of workers. In 1884, when Bismarck indemnified workers against the risk of industrial accidents and provided for maternity care and benefits or pensions for sickness, disability, old age and death, Germany provided the inspiration and established the model for subsequent social legislation elsewhere in Europe and in America.

2. United States. — In the United States the same patterns that led to English legislation may be found, although English social legislation generally antedated its American counterpart by at least a generation and the American doctrine of judicial review slowed down development. Early in the 19th century there was considerable support for maximum hour laws to protect women and for restrictions upon child labour. A few of the industrial states passed such laws, but there was no effective enforcement because of fear of competitive disadvantage. For example, Massachusetts in 1842 enacted a child labour law, and in 1848 Pennsylvania prohibited the labour of children under the age of 12 in certain mills and limited the hours of work to ten unless there was a special contract. The latter provision was nullified when special contracts became customary, and since in any event the statutory sanction mas merely a $50 fine, the statute had little effect. As early as the 1830s some industrialists suggested national legislation to regulate child labour and hours of work. Until after the American Civil War, state social legislation was regarded as constitutional. The judicial canon of *laissez faire* philosophy that social legislation violated the due process clause or impaired the obligations of contracts did not gain currency until about the 1890s.

Congress enacted only a few pieces of social legislation before the 20th century. In 1798 a federal scheme was established of state insurance for disabled seamen based on a 20 cent per month deduction from wages, and in 1870 the deduction was increased to 40 cents. In 1878 the National Quarantine act was enacted and empowered the surgeon general to enforce port quarantines, and the following year the national board of health was established.

V. RISE OF INDUSTRIAL MEDICINE

In the past most regulation in behalf of the worker was an expression of religious conviction, such as the duties imposed upon the master in Deuteronomy, or a reflection of the ancient concept that a ruler was supposed to be a father to his people. During the middle ages the craft guilds regulated working conditions in detail. Rothari, king of the Lombards, in 643 ordered that bodily harm caused by accidents to builder's labourers should be compensated. The Ordinance of Labourers in 1349 and the Statute of Labourers in 1351, enacted in order to negate the economic bargaining power of the survivors of the Black Plague, impaired the mobility of the workers, as did the settlement laws that were part of the poor laws after 1601. Since workers in England were not free to travel about and to seek other jobs, humanitarian impulses alone furnished an incentive to improve their lot. Of greater direct importance were the decrees issued by Queen Elizabeth in England and Colbert and Vauban in France which regulated working conditions.

Industrial medicine, the enactment of factory laws and safety laws and eventually the expansion of workmen's compensation acts to include occupational diseases in their coverage were a direct application of the new enlightenment. The founder of industrial medicine was Bernardino Ramazzini, professor at Modena and Padua, Italy, uho in 1713 published his book *De morbis artificum diatriba*, which discussed the relation between disease and poverty. Before and after Ramazzini there were reports on industrial health, such as the pamphlet by Ulrich Ellenbog in 1473 "on the poisonous wicked fumes and smoke" that afflicted goldsmiths, the treatise on the diseases of miners by Georgius Agricola in 1556, that by Percivall Pott in 1775 on the diseases of chimney sweeps, and the comprehensive study of industrial disease and poverty by Charles Turner Thackrah in 1831. The latter study was relied upon heavily by social reformers such as Chadwick and Lord Shaftesbury.

1. Liability in Industrial Accidents. — Common-law principles in England and the United States resulted in placing the cost of industrial accidents on injured workers in the vast number of cases. To recover in a suit against his employer, the employee had to prove that the master was either personally at fault or had violated a nondelegable duty. Moreover, the injured worker had to overcome the defenses of contributory negligence, assumption of risk and the fellow servants rule, which meant that if the injured man had himself been careless for his own safety, or knew or should have known of the danger or was hurt because one of his fellow workers was negligent, the employer was not liable for damages. Although the courts recognized that certain nondelegable duties were assumed by the employer, such as an obligation to provide a reasonably safe place to work and reasonably safe machines, tools and appliances, kept in a reasonably good state of repair, and the issuing of safety rules and warnings of dangerous conditions, nonetheless a violation of such duties did not result in employer liability if one of the common-law defenses was applicable. Most significant, the common-law defenses frequently barred employer liability even though the employer had violated a health or safety statute or ordinance, as, for example, when the employee knew of the existing conditions and was said to have assumed the risk.

In England in 1880 parliament enacted the Employers' Liability act, which modified the defense accorded by the fellow servants rule but left untouched the defenses of contributory negligence and assumption of risk and required that there be negligence by the employer or a supervisory employee for the worker to maintain suit against his employer. This act was ineffective because English courts construed it so as to permit employees to contract away their rights under the act. The German compensation insurance laws enacted under the sponsorship of Bismarck in 1884 set the pattern for future legislation, and parliament's Workmen's Compensation act of 1897 was modeled on its provisions, as were the later U.S. statutes *(see* below).

In the Gnited States prior to 1880 five states enacted statutes that made railroads liable to employees upon the same basis as

they were liable to strangers. Georgia enacted such a law in 1855, Montana territory in 1873.

Between 1885 and 1910 most states enacted some kind of employer liability law, either trying to abrogate some of the common-law defenses or to impose safety inspection and regulation upon hazardous industries. In 1906 congress enacted the first federal Employers' Liability act, which covered railroad workers, but that act was held unconstitutional because employees not engaged in interstate commerce were included within its purview. The second Employers' Liability act was passed by congress in 1908 to remedy this defect and subsequently was upheld as constitutional. In effect, these railroad statutes abrogated the common-law defenses but required negligence for recovery. For example, contributory negligence by the employee diminished the amount of recovery had against his negligent employer, and assumption of risk remained a good defense until abolished by amendment in 1939.

2. Workmen's Compensation. — In the U.S., despite temporary setbacks and, for a time, strict judicial construction, workmen's compensation acts came to be enacted by each state. Additional congressional legislation covering occupations related to federal commerce, such as those of stevedores and longshoremen, were passed. All but a few states came to include occupational diseases, as well as accidents, as a basis for recovery when either arises out of and in the course of employment. Also. such acts have been extended beyond so-called hazardous industries to include most industrial and commertial enterprises. See WORKMEN'S COMPENSATION.

VI. PUBLIC WELFARE

Public assistance, unemployment compensation and social insurance of various kinds became the subjects of national legislation in Europe in the 19th century and in the United States in the 20th. Until the poor laws were enacted at the start of the 17th century, care of the indigent usually had been a matter for church charity or mutual aid by people of the same occupation. The Jews made and enforced regulations for the relief of the poor and regarded charity as a duty. Charlemagne ordered his counts to care for the poor at their own expense and made them *advocati* of the distressed. This action was the beginning of secularization and regulation of charity in Europe, and gradually poor relief was abandoned as a general function of the church and was assumed by the parish. From ancient times people in the same social class or occupation banded together in friendly societies that arranged burials, financial help where needed and benefits in case of sickness or widowhood. In time these societies expanded beyond a particular calling, and in England at the beginning of the 19th century they had a membership of 1,000.000 out of a total population of 9,000,000 and were almost as numerous in Holland and Belgium. Neither public nor private assistance, however, was adequate for the problems created by great depressions and chronic unemployments, and a national responsibility for the care of the sick and the poor was repeatedly urged. Sir Thomas More in his *Utopia,* nhich appeared at the beginning of the 16th century, advocated public health measures, social insurance, social security and public housing. "Freeborn John" Lilburne, pamphleteer for the Leveller movement during the Puritan revolution, called for a comprehensive program of government action to cope with social problems. Daniel Defoe in his Essay *Upon* Projects, at the end of the 17th century, proposed many reforms, including social insurance, and Denis Diderot in his Encyclopaedia, in an article on the Hospital, outlined a public assistance scheme, including old-age insurance and medical care.

1. England. — England finally eradicated the last traces of its Elizabethan poor laws in 1948 by the enactment of the National Assistance act, which eliminated the old concepts of parish responsibility, primary family responsibility and the rules as to settlement and removal. Near the end of and immediately following World War II, parliament also passed the Ministry of National Insurance act (1944), the Family Allowances act (1945), the National Health Services act (1945) and the National Insurance act (1946). The report by Sir William Beveridge in 1942, experience with prior legislation, and postwar conditions combined to provide a favourable political climate for a comprehensive welfare system on a national scale. (See SOCIAL SECURITY: Social Insurance in Great Britain and the Commonwealth.)

2. United States. — Federal Legislation. — Although the department of health, education and welfare mas created in 1953, most social legislation continued to be based on federal-state cooperation rather than on an exclusively national basis. For example, such acts as the Sheppard-Towner act of 1921 (Maternity and Infancy act), the National School Lunch act of 1946 and Title V of the Social Security act are based on federal-state cooperation, the federal government extending grants-in-aid and setting standards and the states administering the programs. The United States has not moved as far as England and the Scandinavian countries in creating the welfare state, but there has been a steady trend toward adoption of the insurance principle as a basis for social legislation.

It was not until the depression of the 1930s that public assistance, unemployment compensation, social security benefits and an integrated program of welfare legislation were enacted for the nation as a whole. The Social Security act of 1935 and the Fair Labor Standards act of 1938 were perhaps the most significant pieces of social legislation congress enacted under its constitutional authority to regulate interstate commerce and things which affect such commerce.

Beginning in 1937 the supreme court upheld the validity of such legislation, overruling prior decisions that had held that congress had no authority to abolish child labour or to regulate wages and hours. The separation of powers doctrine was viewed by the court as exacting due deference for the legislative and executive judgment and determination of public policy, and the court declined to substitute its economic and social predilections for those of congress. Most important, the powers reserved to the states or to the people under the 10th amendment were held to be no limitation whatsoever upon federal power granted by the constitution. Consistently with this commitment to judicial humility, the court also permitted state legislatures to experiment with social legislation unless a federal statute or power had pre-empted the field, and state welfare laws mere sustained although analogous statutes formerly had been held unconstitutional. Sociological jurisprudence had replaced the *laissez faire* commitment that had dominated the supreme court from the 1890s to 1937.

Although health, safety and welfare legislation, whether enacted by congress or by the states, was in the second half of the 20th century regarded as a legitimate exercise of the police power of government, there remained many issues as to substance and procedure that might arise under such laws. The principal limitation upon an attempted exercise of federal power was that some basis therefore must be found in the constitution.

States' Powers. — State courts determine the constitutionality of state legislation under state constitutions. Historically, health regulations have presented numerous issues, including problems as to the delegation of authority by the legislature to health officials, the specification of sufficient standards to guide administrators so that an arbitrary discretion is not assigned, the reasonableness of rules and regulations promulgated by officials and the reasonableness of legislative classification. Moreover, local boards are confined to their own territory and must act within it or they are without legal authority. Usually, the courts will not review the judgment of health officials who have legal authority to exercise discretion, and a private person who alleges he was aggrieved by a board's action ordinarily cannot hold officials personally liable for action taken in good faith within the scope of their authority. An arbitrary, capricious or unreasonable exercise of power, or action that lies outside the scope of the power delegated by statute, may raise a due process issue under state or federal law. Courts are reluctant to enjoin health officials except where there is an obvious abuse of authority.

State health officials utilize many methods of regulation, including inspection, destruction of private property to prevent the spread of contagion or to abate a nuisance, closing of public places, disinfection and sterilization, vaccination and quarantine. Compliance with orders may be sought by injunctions or the imposition of fines. Some states do not require health officials to give no-

tice and to provide a hearing before taking summary action where the statute neglects such procedure, a condition which places a heavy burden on the citizen who cares to challenge the validity of the action in a subsequent legal proceeding. The state may act under either its power of eminent domain or its police power. Generally, if it exercises eminent domain, just compensation is due; such is not the case for an expression of police power. A citizen who upon reasonable grounds reports a suspected case of contagious disease to proper health officials usually is not held liable in damages to the person reported when the suspicion turns out to have been in error. One who negligently or deliberately infects another with a contagious disease may be held accountable for damages, at least if there was no consent to such contact.

VII. ENFORCEMENT OF LEGISLATION

1. Food and Drug Laws.—One of the most important areas of health legislation is that pertaining to adulteration. Both Athens and Rome had laws to prevent the adulteration of wine, and England prohibited the adulteration of certain foods from the time of Henry III. Parliament from time to time passed statutes prohibiting the adulteration of such commodities as tea, cocoa and beer, and in 1872 enacted the Adulteration of Food and Drugs act, which had general application to foodstuffs; it provided for inspection and analysis of samples and for levying of a £50 fine for the first violation and six months imprisonment at hard labour for a second offense. After that time additional statutes were passed to plug loopholes and to correct judicial construction.

In the United States an act prohibiting the adulteration of drugs was passed by congress in 1848, and in 1890 a similar statute was passed regarding food. Between 1880 and 1906 there were 103 bills introduced in congress to control interstate traffic in food and drugs, but none were enacted until the Pure Food and Drugs act of 1906 was signed by Pres. Theodore Roosevelt.

Difficulty was encountered in the enforcement of this act because of the definitions given to such terms as adulteration, the narrow construction given by the courts and the "distinctive name" exemption that permitted a manufacturer who adopted a distinctive name for his article to ship what he pleased. Moreover, the sanctions of a maximum fine of $200 for the first offense and $300 or a year's imprisonment, or both, for subsequent offenses, and the seizure provisions, did not prove to be successful deterrents.

Except for minor amendments, the 1906 act and similar state legislation remained in effect until the Federal Food, Drug and Cosmetic act of 1938 was passed following the tragic death in 1937 of at least 73 persons who had taken a drug known as Elixir Sulfanilamide. (Existing legislation did not prohibit the distribution of poisonous or dangerous drugs.) The 1938 act, within the limits of the commerce power, prohibits foods dangerous to health and also prohibits foods, drugs or cosmetics in insanitary or contaminated containers. Loopholes in the 1906 act, such as the distinctive name and compound exemptions, were eliminated. Penalties under the new law include seizure of the offending article and a maximum fine of $1,000 or a year in jail, or both, for each violation charged; in the case of intentional fraud or'a second offense the fine may be $10,000 and imprisonment for three years. In addition, the federal courts were authorized to issue injunctions to restrain further violations. Enforcement of the act was given to a food and drug administration, and inspection stations were set up in several large industrial cities.

In addition to the 1938 Federal Food, Drug and Cosmetic act, state legislation is important in covering food and drugs that are outside the scope of the federal act because of its limitation to interstate commerce. Of jurisprudential significance is the fact that under both the federal law and the statutes of some states it is not essential that there be a specific criminal intent for conviction. It may be enough that the manufacturer or processor intended to ship the articles in question even though he neither knew nor had reason to know that there was a violation.

2. Safety Laws.—The enactment of safety legislation has been contemporaneous with the passage of workmen's compensation acts and public health laws. In this area, however, education and the activities of voluntary groups have almost completely overshadowed legal developments. There has been an intensive safety movement in the 20th century, and safety codes have been devised by engineers for various industries. At the outset humane industrialists promoted accident prevention campaigns by imposing safety rules in plants. In part this may be due to the fact that employers have come to realize that safe working conditions are an asset to the business, particularly if the factory comes under workmen's compensation laws. In the United States, cities and states at an early date required inspections of steam-power boilers, and later on building inspectors, fire marshals and elevator inspectors exercised municipal authority. Mine safety was a subject for legislation in many coal-producing states, and the Safety Appliances act for railroads, originally passed in 1887, and expanded and amended in 1893, 1903, 1910 and 1920, was the first significant federal statute. The Walsh-Healey Public Contracts act of 1936 requires government contractors to comply with the health and safety laws of the state where the contract is being fulfilled. During and since World War II it has been one of the most important statutes because it reinforces state laws that otherwise might be ignored. For the most part, state safety laws have been strictly enforced only in a few industrial states that have provided a sufficient number of inspectors. Substantial progress was mainly due to the efforts of certain large employers and the top priority given by modern management to accident prevention. The American Standards association has promoted a safety code program for American industry, and the International Association of Industrial Accident Boards and Commissions has been a major force in the movement. The United States department of labour and, since 1953, the department of health. education and welfare are both concerned with certain aspects of the general problem of industrial safety. Federal Coal Mine Inspection acts, passed in 1941 and 1952, require inspection and reports, empower the director of the bureau of mines to forbid miners to enter dangerous portions of a mine and specify detailed rules concerning roof support, ventilation, equipment, fire protection and other safety matters.

Before workmen's compensation acts were securely established as constitutional around 1920, most state safety acts relied upon inspection and indirect enforcement through civil litigation in damage suits brought by injured workmen. After 1920, when damage suits all but ceased because most workmen were limited to compensation claims, administrative boards with power to make rules, investigations and reports and to seek injunctions became the mode of enforcement. In a few states, *e.g.*, Washington, educational standards of safety, as well as rules dealing with safe working conditions, were, in the early 1960s, issued by the supervisor of safety. Statutes which provide for apprenticeship systems, limit the hours of work or require rest periods may be classified as safety laws because of their bearing on accident prevention. The constitutionality of safety laws in the second half of the 20th century was usually upheld unless there was a showing of arbitrary action in a particular situation, and such regulations typically were enforced by inspection plus criminal or administrative sanctions. In addition to laws pertaining to industrial safety are statutes concerning regulation of traffic; inspection of theatres, schools and other public places; highways and sidewalks, public carriers, bathing beaches and fire prevention. It should also be noted that collective bargaining agreements frequently contain provisions that have a bearing on industrial safety and that joint committees of management and employees may co-operate in formulating policies and rules.

VIII. INTERNATIONAL EFFORTS

International concern as to health and safety has been expressed in the writings of public health pioneers, such as Johann Peter Frank, in international conventions, such as that held in Paris in 1851, and in health organizations within the framework of the League of Nations and United Nations (UN). The preamble to the constitution of the World Health organization (WHO) provides that "an informed opinion and active co-operation on the part of the public are of the utmost importance in the improve-

ment of the health of the people"; it further declares that every individual has a right to the maximum health his organism permits. The WHO is committed to the principle of mutual aid in dealing with social and health problems, and its work is supplemented by and correlated with the activities of such other UN agencies as the United Nations Children's fund, the Food and Agriculture organization, the International Labour organization and the United Nations Educational, Scientific and Cultural organization.

Private organizations have also laboured in the field of international health and safety problems. The International Association of Industrial Accident Boards and Commissions has promoted safety codes, and the Rockefeller foundation has sponsored major international health work. Numerous international conferences have been held to promote health and safety. In 1833 Mohammed Ali, ruler of Egypt, called a conference to discuss quarantines and international hygiene, the International Association for the Legal Protection of the Poor was organized in Paris in 1900 and the International Labour office was organized at Basel, Switz., in 1901. The Berne conferences of 1905, 1906 and 1913 drew up international conventions prohibiting the use of white phosphorus in the manufacture of matches and employment of women or children under 16 on nightuork and limited their hours of work. President Truman's Point Four program included technical assistance on health matters, and many underdeveloped nations have continued to receive such help from the U.S. and other governments in an effort to eliminate various preventable diseases that were eradicated in Europe and the United States in the 19th century.

The health and safety laws of the future will have to deal with such new matters as radiation from atomic power, fall-out, air pollution and the dangers created by space travel. Such problems may be the subject of international regulation, as well as local law. Air pollution and urban redevelopment have created numerous problems in metropolitan areas. A sound solution of such problems will require the co-operation of local, state and national agencies. The increased urbanization of major industrial countries inevitably will intensify old and proliferate new health and safety problems. However, the prevailing perspective that national and international action is essential and that health and safety programs are no longer solely matters of local concern has made organized and concerted effort possible.

Among many articles having to do with health and safety regulations in general are the following articles: HEALTH INSURANCE; INDUSTRIAL ACCIDENTS; INDUSTRIAL MEDICINE; LABOUR LAW; MEDICAL JURISPRUDENCE; PREVENTIVE MEDICINE; PUBLIC HEALTH; SOCIAL SECURITY; SOCIAL SERVICE; WORKMEN'S COMPENSATION; WORLD HEALTH ORGANIZATION. The reader should look to the index volume for many other articles touching on specific aspects of health and safety laws.

HEALTH INSURANCE, a system for advance financing of health costs that consists of a common fund of contributions or taxes for the payment of health services specified in a policy or law. The key elements are advance payment of premiums or taxes, pooling of funds, the elimination of part or all of the financial barrier to the receipt of medical care, and eligibility for benefits on the basis of contributions or services without an income or means test. Health insurance is sometimes also considered to include cash payments for loss of income due to sickness or disability. A health insurance system may be organized and administered by a private agency, with the provisions specified in a contract; in this case it is a voluntary insurance plan. If the system is financed by taxes and the provisions are specified by statute, it is a governmental health insurance plan, often referred to as compulsory health insurance by its opponents. The contrast between voluntary and compulsory health insurance, however, is not always a clear one. In some countries, governmental subsidies are used to finance part of the cost of health benefits administered by nongovernmental societies. Health insurance is not primarily a method of organizing medical care, although it may be combined with measures to improve the organization and distribution of medical services. It may be coupled with the individual practice of medicine or with group practice. It may involve a limited or a comprehensive scope of medical services. If the plan provides for full payment of the costs to the provider of medical services, it is called a service plan. If the insurance payment is paid in cash to the beneficiary, it is referred to as an indemnity plan.

Health insurance should be distinguished from socialized medicine, which is usually financed as a public service wholly or predominantly from general tax revenues; doctors are employed, directly or indirectly, by a government agency on a full or part-time salaried basis; and health facilities are usually owned or operated by the government.

HEALY, GEORGE PETER ALEXANDER (1813–1894), U.S. painter, known for his portraits of many prominent persons of his day, was born in Boston, Mass., July 15, 1813. In 1834 he went to study in Paris. His vigorous, facile style soon secured for him a large and important clientele, and in his studios in Paris, Chicago and Rome he often painted as many as 50 portraits in a year. Among his subjects were Louis Philippe of France, Pope Pius IX, the princess of Rumania, John C. Calhoun, Henry Clay, Longfellow and a series of U.S. presidents from John Quincy Adams to Grant. He also depicted historical scenes; "Franklin Urging the Claims of the American Colonies Before Louis XVI" and "Daniel Webster's Reply to Hayne" (a monumental portrayal with scores of individuals delineated) are perhaps his best-known compositions. He was the author of *Reminiscences of a Portrait Painter* (1894).

Healy died in Chicago on June 24, 1894.

See Marie de Mare, G. P. *A. Healy, American Artist* (1954).

HEALY, TIMOTHY MICHAEL (1855–1931), Irish politician, was a leader in the fight for Home Rule and became the first governor general of the Irish Free State *(see* IRELAND; IRELAND, REPUBLIC OF). He was born at Bantry, Ire., on May 17, 1855, a son of the clerk of the Bantry union. With three uncles and two brothers who also became members of parliament, he formed the nucleus of the "Bantry band."

Healy began to earn his living at 13, and his early youth mas spent as a shorthand clerk in a railway office at Newcastle upon Tyne. There he became well known in Irish political and literary societies. In 1878 he moved to London. In 1879 Charles Stewart Parnell on his first mission to the U.S. found that he needed a secretary and wired for Healy, who was already known to him. In 1880, after Parnell had been elected chairman of the Irish party, a parliamentary vacancy occurred in Wexford city, and Healy mas elected.

From the first he slapped the house of commons in the face, but he attended very closely to all its business. In 1881 Gladstone's Land bill began the revolution which made the Catholic Irish owners of the land instead of being mere cultivators under landlords.

Gladstone said that, with the exception of three Irish law officers, only Healy understood it, and it is doubtful whether anybody but Healy understood the effect of the famous "Healy clause." Introduced as an amendment, this guaranteed that in the future rent should not be chargeable on tenants' improvements. When the bill became an act, Healy, called to the bar in 1884, defended the tenants' interests in innumerable cases that arose in its application. In 1883, when a Liberal seat became vacant in

County Monaghan, he was selected to make the first nationalist inroad on Ulster. He won.

At the general election of 1885 with the extended franchise Monaghan became a safe seat. Healy attacked South Derry and won the constituency by surprise tactics. In 1886, however, he was defeated, but was returned for North Longford.

His relations with Parnell now became less friendly, and he joined J. G. Biggar in opposing the candidature of Capt. W. H. O'Shea for Galway city. The opposition was overborne only by Parnell's personal intervention. But in 1889, when the divorce petition against Parnell was undefended, Healy drafted the resolution carried by the party in favour of Parnell's remaining at his post. "Parnell," he said, "is not a man, but an institution." Later, however, in face of Gladstone's declaration, he changed his mind, and from the time the split began, no speeches were so envenomed as Healy's.

He was twice publicly beaten, but no form of menace had ever the least effect on him. In 1892 he became member for North Louth, and, as a member of the anti-Parnellite party to which the large majority of Irish nationalists belonged, he was specially supported by the Catholic clergy. His rivals for leadership, William O'Brien and John Dillon, had more following among the laity, but Healy was always a priests' man. At this time he devoted less time to politics, for his practice at the bar was increasing, and in 1899 he became Q.C.

On the reunion of parties in 1900 he joined O'Brien in urging that Redmond, leader of the Parnellite minority, rather than John Dillon, leader of the anti-Parnellites, be chosen as chairman of the united body. But a long indulgence in the savage spirit of faction which followed the Parnell split had rendered Healy difficult to work with, and in 1902, on the motion of O'Brien, he was expelled from the Un ted Irish league, though he retained the support of the Catholic hierarchy and of Murphy's influential newspaper.

In 1906 O'Brien, having split away from Redmond's main body with a few followers, made a working alliance with his former adversary and his brother Maurice, member for Cork city. In 1910, when Healy was beaten in North Louth, O'Brien provided him with a constituency in northeast Cork.

Healy joined the English bar in 1903 and took silk in 1910. He was unceasingly employed on English cases, more especially of a political character, and defended many suffragettes. In parliament no speaker was more able to draw a crowded house, and his wit and eloquence were specially popular with the Tories, because he said more biting things of the Nationalist party than Englishmen could invent. With O'Brien he opposed the budget of 1909 which led to the clash with the house of lords; and on the Home Rule measure of 1912, while giving it general support, he furiously opposed partition.

In 1914 he was a vigorous supporter of Britain in World War I, but the course of events from 1916 onward, culminating in the introduction of conscription, drove him finally to side with Sinn Fein, and in 1918 he resigned his seat to allow an imprisoned Sinn Feiner to be returned.

Little was publicly heard of him during the years of turmoil which followed until, at the close of 1922, the constitution of the Irish Free State having been made law by the Irish parliament, and subsequently by the British, the office of governor general had to be filled. When Healy's name was first mentioned for the post there was general incredulity, but the appointment soon commended itself to Irishmen of all sections. The Free State government, speaking through the mouth of Healy's nephew, Kevin O'Higgins, defended the choice of "an old man of the people," while others realized that Healy. though an extreme nationalist, had in many respects a most conservative mind. Those who feared the worst from a tongue and a temper which he had never before governed were surprised by the result; for during his continuance in office as the representative of King George Healy in no way added to the government's difficulties, while he did more perhaps than any other person to cultivate the good will of the Protestant minority.

He resigned office at the end of his three years' term, in Dec. 1927. In 1928 he published a volume of memoirs, *Letters and Leaders of My Day*.

See Liam O'Flaherty, ***Life*** of ***Tim*** Healy (1927). (S. G.)

HEAPE, WALTER (1855–1929), English zoologist, was a striking example of those amateurs of independent means who have made outstanding contributions to science. He was born in London on April 29, 1855. His formal education was finished early, and until 1879 he was engaged in business. He had an aptitude for scientific pursuits, however, and under the influence of Francis Maitland Balfour (*q.v.*) took up the study of embryology.

Settling in Cambridge in 1879, he assisted Adam Sedgwick in bringing out a new edition of Sir Michael Foster and F. M. Balfour's *Elements of Embryology* (1893). He was demonstrator in animal morphology (1882–8j) and superintendent of the Marine Biological association (1886–88). In 1886 he joined Trinity college and in the same year the honorary degree of M.A. was conferred upon him. In 1890 he was elected to the Balfour studentship. but after three years devoted himself to research, giving intermittent attention to his many business interests, including the Heape and Grylls rapid cinema machine. His earliest original work was on the development of the mole (1886), but it was his elaborate papers on the menstrual cycle in monkeys (*Philosophical Transactions*, 1894–97) that made his name famous. In further papers he dealt with the successful transplantation of fertilized ova, artificial insemination, fertility in sheep and sex determination.

His other works included an important memoir on the "Sexual Season of Mammals" (*Quarterly Journal of Microscopical Science*, 1900) and books on *The Breeding Industry* (1906), *Sex Antagonism* (1913) and *Preparation for Marriage* (1914). Heape was elected a fellow of the Royal society in 1906. He died at Tunbridge Wells on Sept. 10, 1929. (W. J. Bp.)

HEARING is the sense by which an animal is able to perceive sound. All the higher vertebrates, and many more primitive animals, possess a specialized organ, the ear, for the reception of sound waves. In its simpler forms this organ has a particular biological value in mating, as it enables the sexes to find one another, but its most general adaptive function lies in its service in warning of impending danger. In the birds and mammals, hearing is particularly developed for communication, and in man it attains its highest utility in articulate speech and the art of music.

This article is divided into the following sections:

I. PARTS OF THE EAR AND THEIR FUNCTIONS

As treated in detail in the article Ear, Anatomy of, the ear is considered in three parts, the outer, middle and inner ear. The outer ear receives aerial waves; the middle ear conducts them inward; and the inner ear, through its receptor cells, translates their effects into patterns of nerve impulses which are sent through the auditory nerve to the brain centres and finally give

rise to auditory perceptions.

1. The Outer Ear.—The visible portions of the ear include an expanded flap called the auricle or pinna and a short tube, the external auditory meatus. The auricle in man serves no important acoustic purpose. It is too small to deflect sounds into the ear, for to modify the paths of sound a surface must be large with respect to the wave lengths, and this condition is scarcely satisfied even for the highest audible tones. Animals with larger and funnellike pinnas, especially if they are sensitive to sounds still higher than man is, are aided by these members, and have well-developed muscles for moving them.

The meatus is a slightly curved tube about one inch in length, ending at the eardrum. It serves as the path of entrance for aerial waves.

2. The Middle Ear.—Beyond the eardrum is the middle ear cavity, an irregularly shaped, air-filled space in the temporal bone. A chain of three small bones, the auditory ossicles, bridges this space and provides a mechanical link between the drum and the oval window, which forms the entrance to the inner ear.

The drum is broadly conical in form, with its apex directed inward. The outer ossicle, the malleus, is attached at the apex and along one radius. The second ossicle, the incus, links the malleus with the third, the stapes, whose innermost part, the footplate, nearly fills the oval window. The ossicles are interconnected and suspended in the cavity by a number of ligaments. There are two tympanic muscles which act upon the ossicular chain; one, the tensor tympani muscle, is applied to the malleus, and the other, the stapedius muscle, to the stapes.

The function of the middle ear is the efficient transmission of sound energy. The drum presents a large surface on which the air particles impinge, and their total force is applied through the ossicular chain to the smaller surface covered by the footplate; the result is a magnification of pressure. The efficiency of transmission is about 28%, which, though far from perfect, is remarkable in comparison with an estimated one-tenth of one per cent that would obtain if the middle ear mechanism were absent. The difference is apparent in a person who by accident has lost the drum and outer ossicles, for such a person is unable to hear conversation unless people shout or speak directly into his ear.

The tympanic muscles connect the ossicular chain with points of anchorage in the walls of the middle ear cavity, and work together as a protective mechanism. They add to the strength of the ossicular chain and prevent displacements of excessive amplitude. When a loud sound stimulates the ear, a strong reflex contraction is produced which reduces sharply the transmission of the vibrations, and so the inner ear is protected against excessive stimulation. This protection, however, is limited. and a person who must expose himself to intense sounds of either an explosive or a lasting character will need to take extra precautions to guard the ears. He may wear a helmet that covers the ears or use plugs that fit snugly in the meatus to exclude the sounds.

3. The Inner Ear.—The bony labyrinth is a complex space in the temporal bone, two divisions of which, the vestibule and semicircular canals, are concerned with bodily equilibrium; a third division, the cochlea, serves for hearing. The cochlea is shaped like a snail's shell, from which it gets its name; it is a spiral organ, which in man has about two and one-half turns, and if straightened out (fig. 1) would be about one and one-half inches long.

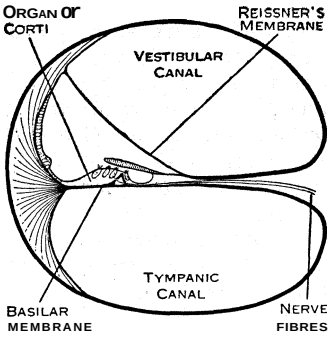

FIG. 2.— CROSS-SECTIONALVIEW OF THE COCHLEA

A partition divides the cochlea into vestibular and tympanic canals, which connect at the tip of the cochlea and contain a fluid, the perilymph. At the basal end each canal has an opening in the bony wall separating it from the middle ear cavity. The opening for the vestibular canal is the oval window, fitted with the footplate of the stapes as already described; that for the tympanic canal is the round window, covered only by a thin membrane.

The partition is made up in part of a fibrous membrane, the basilar membrane, upon which lies a complex structure, the organ of Corti, in which the auditory receptor cells, the hair cells, are imbedded. Around the bases of the hair cells are the ends of the auditory nerve fibres, which run inward toward the axis of the cochlear spiral to form the auditory nerve. This sensory portion of the inner ear is bathed in a separate fluid, the endolymph in the cochlear duct, which is kept from mingling with the perilymph by a thin membrane, Reissner's membrane.

When under the influence of an aerial sound the footplate of the stapes is momentarily pressed inward, the pressure exerted on the fluid of the inner ear is relieved mainly by an outward bulging of the round window membrane. As the footplate moves outward the pressure is reversed, and the membrane is displaced inward. The varying pressures are transmitted from vestibular to tympanic canals and to the cochlear duct by way of the basilar membrane, and in the process the sensory cells are excited. From the hair cells the excitation passes to the auditory nerve fibres, and from there to the higher nerve centres, and a sensation of hearing is produced.

The ear may be stimulated also by bone conduction. If a vibrating body is brought into contact with the bones of the skull the movements are conducted to the inner ear fluids and finally to the hair cells. The sensory effects are the same as in air conduction, but the efficiency is much less since the larger part of the energy is lost in vibrating the massive substance of the head.

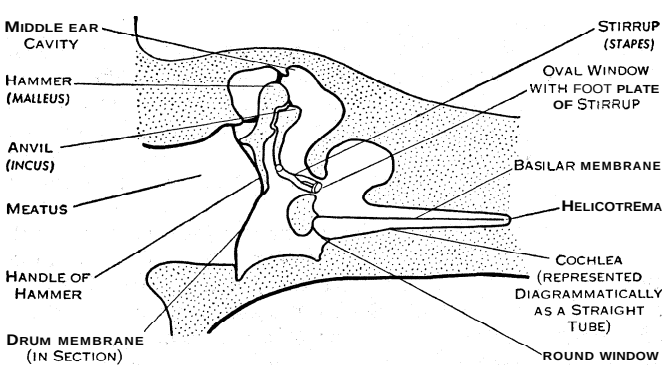

FIG. 1.— DIAGRAM OF SECTION THROUGH MIDDLE AND THE INTERNAL EAR

The drum membrane picks up the sound waves from the air in the meatus, and transmits them through the chain of small bones to the cochlea, where they are analyzed and transformed into stimulations of the nerve of hearing

II. SOUND AND ITS ANALYSIS

Sounds, physically considered, consist of rapid variations in the density of a medium, usually the air. Most often these variations have some uniformity of pattern, in that the same or nearly the same changes occur over and over; such sounds are periodic. Other sounds, which lack any repetitive character, are aperiodic. The periodic sounds are heard as tones, the aperiodic ones as noises. Many sounds have an intermediate quality, and are called noisy tones or pitched noises according to the dominating feature.

The periodic sounds vary in four ways: in frequency, intensity, wave form and phase. Frequency designates the rapidity of recurrence of the pattern; intensity, the energy of the disturbance; and wave form, the nature of the pattern. Phase refers to the particular aspect of the pattern presented at a given instant. Frequency is stated in cycles per second. The simplest wave form is sinusoidal, represented mathematically by a sine (or cosine) function, and special efforts are necessary to produce it; the tuning fork gently struck gives such a wave form. Other waves, like those of the singing voice and most musical instruments, are compound. In simple tones the phase is not perceived. but when two or more tones interact their phase relations become important.

A basic principle of physical acoustics, known as Fourier's law, is that any compound wave may be regarded as the sum of a series of simple waves whose frequencies bear to one another the

ratios 1, 2. 3, 4, 5 and so on. The component of lowest frequency, corresponding to the ratio number 1, is called the fundamental; the others are overtones. For example, the note known as middle C, when produced on the piano, is compound, and consists of a fundamental of 264 cycles; a first overtone of 528 cycles; a second overtone of 792 cycles; and so on. Generally speaking, the earlier members of the series are the most important. and the magnitudes of the higher overtones diminish and finally become negligible.

The resolution of a compound tone into a fundamental and a series of overtones, with indication of the relative magnitudes and perhaps also of the phase relations of the components, may be accomplished by mathematical methods, or by a mechanical device called a harmonic analyzer.

This type of analysis can be achieved also by the ear; this is Ohm's law of hearing. After suitable training a person can recognize that a sound, like the note of a violin, is made up of a fundamental and several overtones, and he can indicate, at least in a general way, how the components vary in strength. This analytic capacity is a remarkable feature of the functioning of the ear, and upon it depends much of the peculiar value of hearing.

1. Distortion. — The ear obeys Ohm's law in a general way, but it does not do so exactly. In some degree it imposes its own characteristics upon sounds as they are heard. The changes in the sound patterns produced within the ear constitute auditory distortion, and take two forms, frequency distortion and nonlinear distortion. Frequency distortion is a reflection of the fact that the ear is limited in range, and fails to respond to sounds below and above certain limits, and the further fact that the sensitivity varies greatly within that range. Therefore, certain components of a complex sound will be favoured, and others will be discriminated against.

Nonlinear distortion represents a failure of the ear's response to correspond in a simple way to the energy of the stimulating sound. It gives rise to a number of peculiar phenomena. One of these is aural overtones. A tone, although physically simple, if it stimulates the ear at anything greater than a very moderate intensity, will produce a compound effect: it is heard as a fundamental with a series of overtones. These overtones are subjective, in that they have their origin within the ear itself. Further phenomena, including the combination tones discussed below, likewise have their origin in the ear through nonlinear distortion. In experiments using human subjects and lower animals, the nature and origin of subjective overtones and combination tones have been carefully studied. It seems clear that the principal seat of nonlinear distortion is the inner ear.

III. PHENOMENA OF HEARING

Auditory experiences vary in three fundamental respects: pitch, loudness and timbre.

1. Pitch. — Tones vary in pitch according to the frequency of the sound vibrations. Slow frequencies give deep or low tones, like the bray of a foghorn. while rapid frequencies give shrill or high tones, like the chirp of a cricket. The normal range of audibility for man covers about 10½ octaves, from a lower limit of about 15 cycles per second to an upper limit of somewhat more than 20.000 cycles. Tones below the lower limit affect the ear, but they give noisy effects and not distinct pitches. Tones above the upper limit are altogether inaudible. Some young persons can hear tones as high as 23,000 cycles, but generally with advancing age the limit becomes lower and lower, so that few persons over 60 years of age are able to hear tones beyond 8,000 cycles.

2. Loudness. — The loudness of a sound depends upon both its energy and its frequency. Generally speaking, two tones of equal energy but different frequency will not seem equally loud; this is true because the ear's sensitivity varies over its range. Sensitivity is greatest for the middle high tones, those of frequencies from about 1,000 to 4,000 cycles, and it falls off progressively for the lower tones and with great rapidity for the higher tones. For the middle frequencies the amount of energy necessary barely to stimulate the ear is almost incredibly small, and it appears that man has developed. for this region, the maximum sensitivity that it is practical to possess, for if the ears were any keener they would respond to the unceasing molecular motions of the air particles themselves. The maximum loudness of sounds is governed by the intrusion of pain and the liability of the ear to damage by excessive stimulation. The amount of energy that becomes dangerous to the ear seems small when measured by ordinary standards, yet it is large compared with that which is just perceptible. Thus the ear operates over a wide energy range, a range of nearly 2,000,000,000,000 times.

Though the physical range of the ear is great, the perceived loudness is less extensive. The ear may be said to compress the intensity dimension, as indeed all our senses do. Within limits, the ear adheres to a general principle of sensation known as Weber's law, which states that an energy change, in order to be perceptible, must be a constant fraction of the original energy level. This means that a smaller energy change is necessary for a faint sound than for a loud one; and more generally that the perceived magnitude of a sound varies as the logarithm of its energy.

3. Timbre. — Two sounds may have the same fundamental frequency. and also may contain the same overtones, but if the distribution of energy among the overtones is different they will seem different to the ear. Such a difference, arising from the relative magnitudes of the components, is called the timbre of a sound.

Timbre is also used more widely to include variations of an aperiodic character, such as the thumps or scrapings incidental to the production of notes on most musical instruments. All instruments, because of their forms of construction and the ways in which they are played, produce sounds of characteristic timbre, through which they may be recognized. Similarly, the voices of singers who are executing the same note may be identified by their individual peculiarities of timbre.

4. Deafness. — Through accident and disease, the ear suffers alterations of its functions which produce deafness in various forms and degrees. Sometimes sensitivity to sounds is lost altogether, but more often the loss is only partial. An impairment may be extensive. in that all tones to be heard must be raised well beyond their usual intensity, or it may be only for certain tones. In general, high tones are more liable to impairment than low tones.

IV. INTERACTION OF TONES

When two tones are presented to the ear at the same time there appear three types of phenomena: beats, combination tones and masking.

1. Beats. — If the two tones differ but little in frequency, and have approximately equal intensities, the result of their simultaneous action is a peculiar periodic variation in the loudness known as beats. The rate of the beats is equal to the frequency difference of the tones; thus two tones of 1,000 and 1,005 cycles will produce five beats a second. The character of the experience changes with the beat frequency. As the frequency of the beats is varied from zero upward, the experience is at first a slow waxing and waning of sound, then changes to an impressive surging or pounding, and finally to an unpleasant roughness, which then fades and finally disappears.

The phenomenon of beats represents a limitation of the ear's powers of analysis; rather, it indicates a kind of synthesis. The two stimulating waves are added, and the beats represent the periodic changes between a maximum when they agree in phase and a minimum when they are opposed in phase. If the ear obeyed Ohm's law perfectly, the two waves would be separated and no beats would be heard.

2. Combination Tones. — When the two tones stimulating the ear are fairly strong, and differ in frequency by 50 cycles or more, other tones may be heard besides the primary pair. These are the combination tones, of which there are two types, difference tones and summation tones. The difference tones are so called because they represent frequency differences between one of the stimulating tones or its multiples and the other tone or its multiples. Similarly, the summation tones represent the sums of these frequencies. These relationships are most simply shown by for-

mulas. If the frequencies of the two stimuli are indicated by h and l, and any simple integers by m and n, the difference tones are derived as $D=mh-nl$, and the summation tones as $S=mh+nl$.

When m and n both are unity the difference and summation tones are of the first order. These are usually the strongest and most easily noticed. The first order difference tone is best heard when its frequency is well below that of either stimulus. For example, tones of 2,000 and 2,500 cycles will give a difference tone of 500 cycles, which is readily recognized. On the other hand, a difference tone is difficult to observe if its frequency lies between the two stimuli; thus 1,000 and 2,500 cycles give a difference tone of 1,500 cycles, which only careful observation will reveal. In general, the combination tones will usually go unnoticed when their frequencies lie close to the stimulating tones, as a result of masking by these tones as explained in the following section.

While only a few combination tones are ordinarily noticeable, special procedures demonstrate a great many. They are a product of nonlinear distortion in the ear, and are accounted for in the same way as the aural overtones, as a transformation of a portion of the stimulus energy into new frequencies. Like the overtones, they originate principally in the inner ear.

3. Masking — Everyone has experienced the difficulty of hearing in the presence of loud noises. Faint sounds, like the sounds of speech, are drowned out or masked, and conversation becomes possible only by vigorous shouting. A study of this phenomenon with simple tones shows that the masking effect is greatest for tones whose frequencies are close to the disturbing tone, and it falls off rapidly for more distant frequencies. Thus a loud tone of 1,000 cycles will have a profound effect upon 900 cycles, but practically none upon 100 cycles.

When either objective or subjective overtones are present (and the subjective overtones at least are inevitable when the tone is loud), there will be masking not only in the area of the fundamental but in the areas of the overtones as well. Since this is true, the masking effect of a given tone is generally greater in the frequency region above it than in that below. The low-pitched noises incidental to most industrial operations are far more disturbing of speech than high-pitched squeakings and hissings of equal loudness.

V. LOCALIZATION OF SOUNDS

We commonly perceive a sound as coming from some particular place in the environment, yet experience has taught that such perceptions are not altogether trustworthy, and we are often confused and misled. Actually our judgments of sound location are determined only in a limited way by the auditory cues, and to a considerable extent they include other signs, especially visual, together with our general knowledge of the surroundings. We look for reasonable sources of the sounds we hear, and infer their locations on the basis of previous experience.

The auditory limitations have both a physical and an anatomical basis. Sounds do not travel in direct lines as light rays do, but bend around obstacles and reflect from broad surfaces, so that their terminal paths are often no proper indication of their true courses. Moreover, the single ear has no way of discerning the paths of the waves that strike it, but can signal only the intensity and character of the effects. Significant cues can be obtained as the head is moved, and, most important, since we have two ears, from differences in the binaural stimulation.

1. The Binaural Cues.—The position of a sound with reference to the right-left dimension is indicated by four types of binaural difference: the relative intensity, time of incidence, phase and complexity. A sound on the right — barring complex reflections —will be stronger in the right ear, both because its path is shorter and because the other ear is somewhat in a shadow cast by the head.

The shadow effect is insignificant for the low tones, because these bend around the head readily, but becomes important around 512 cycles and increasingly so for frequencies above. Because its path is shorter, the sound will reach the right ear sooner; and this temporal cue operates at the onset of the sound, at its cessation, and at any sudden alteration in its character. For simple tones a phase difference is present, as the longer time of travel to the farther ear allows the waves to get out of phase. The phase cue is most important for low tones, but becomes confusing for high tones since these have wave lengths that are of the order of the distance between the two ears, and under such conditions a phase difference may be lacking or even reversed in direction.

Complexity operates as a cue only for compound tones and noises, but for these it is most useful. Because the sound shadow effect is selective, the ear that is screened by the head receives the sound with its high-frequency components greatly attenuated, and a timbre difference results.

The ease and accuracy of localization varies for different kinds of sound because the cues operate differently. For high tones the binaural differences are mainly of intensity; for low tones, chiefly of phase; and for complex tones and noises, they include intensity, time and timbre. Accordingly, the high tones are localized with difficulty, the low tones more readily and noises with comparative ease.

Positions up and down or in front and behind, and the distance away, are not discriminated by the binaural conditions, and are indicated only by secondary cues, such as head movements, or inferred from the general conditions. By turning the head we may change, for example, the relative intensity at the two ears, and by grosser movements, which lead us toward or away from the source, we may change the intensity level. Such exploratory movements give a more certain localization than is possible with the binaural cues alone. At the same time, judgments are formed which include visual cues and our general experience. If the sound is familiar we look for its source in a reasonable place: the cricket's chirp leads us to scan the turf at our feet, and the bird's song to examine the branches overhead. (E. G. W.)

VI. THEORIES OF HEARING

Historically, the so-called theories of hearing that have been proposed have been concerned primarily with anaylsis of sound by the end organ of hearing, the cochlea. They have been theories of cochlear function. A true theory of hearing must take into account not only events within the cochlea but also the patterns of activity set off in the auditory nerve by these events and the changes in the patterns of neural activity during transmission to higher centres of the central nervous system.

1. Place Theory. — According to a place theory of hearing, receptors in a given part of the cochlea are stimulated by a given frequency of sound (or by a narrow band of frequencies), and, in turn, impulses are set off in the particular nerve fibres supplying the receptors. The ability to discriminate between sounds of different frequency depends then upon which receptors and nerve units are excited. When one particular group is activated, a low tone is heard; when another group, a high tone.

In 1857 Hermann von Helmholtz proposed a theory of hearing called the resonance theory. This was a place theory. It stated that the cochlea contained a series of tuned resonators, the transverse fibres of the basilar membrane, and that a given frequency of sound striking the ear caused to vibrate those resonators that were tuned to that frequency. Complex sounds were likewise analyzed, the appropriate resonators being activated by the Fourier components of the sound.

Later research led investigators to conclude that the cochlea does not contain a series of tuned resonators. Experiments done by G. von Békésy showed that the basilar membrane, which stretches from base to apex of the cochlea and upon which the receptor cells lie, is under very weak and approximately equal tension in both its transverse and longitudinal directions and could not be made up of a series of tuned-string resonators. It does differ in elasticity from base to apex in a ratio of about 1:100. This is sufficient to provide for some frequency analysis.

Observation under the microscope of the movements of intracochlear structures when the ear is stimulated by sound, testing of hearing before and after experimental damage to parts of the

intracochlear structures, recording of electrical activity from electrodes implanted at different points within the cochlea, and a number of other experimental techniques were used to accumulate evidence showing quite clearly that, within the cochlea, sounds are analyzed according to frequency. The highest perceptible frequencies at weak intensities set into motion a small part of the basilar membrane near the basal end of the cochlea. The receptor cells on this part of the membrane are stimulated, and they in turn, by some process not clearly understood, cause the firing of impulses in the nerve fibres that supply them. As intensity of the high-frequency sound is increased, there is some spread of activity along the basilar membrane and consequently more receptor cells and their nerve fibres are excited. For these highest frequencies the amount of spread of excitation within the cochlea is not great. Even at very high intensities, it appears that excitation is confined to the basal region of the cochlea. With tones of lower frequency, a wider region of the basilar membrane and the receptor cells it supports are set into motion by near-threshold intensities of the tones, and with increase in intensity the extent of spread of the region of excitation is greater than it is for higher frequencies. There is considerable evidence that tones in the lowest range (500 to 1,000 cycles per second [c.p.s.] and below) at moderate to high intensities may stimulate receptors throughout most of the cochlea.

2. Frequency Theory. — In opposition to place theory, it was early suggested that frequency analysis might not take place in the cochlea but that the latter might act like a telephone transmitter, simply transmitting to the nervous system the same frequencies imposed upon it by sound waves impinging upon the ear. William Rutherford (1886) is usually given credit for this theory, which was appropriately named a telephone theory.

Experiment provided evidence not only in support of a place theory, as noted, but also suggesting that frequency theory may be partly correct. When electrophysiological methods were used to record activity in the auditory nerve, it was found that bursts of impulses in the whole nerve, which is made up of thousands of nerve fibres, were synchronous in frequency with a pure tone applied to the ear; that is, for each cycle per second of the sound wave there was a burst of nerve impulses. This synchronism occurred for frequencies in the lower range only, up to 4,000 to 5,000 c.p.s. For higher frequencies, synchronism between nerve response and stimulus could not be observed.

Since it is known that individual nerve fibres in the auditory nerve of the mammals that were used in these experimental studies do not fire at rates much above 300 per second, a volley principle was advanced to explain the firing of the total nerve in regularly spaced bursts at frequencies of 4,000 or more per second. The volley principle assumes that impulses in some individual nerve fibres are elicited by the first wave of a stimulating tone, others by the second, and so on, the result being that, by the alternate firing of different groups of nerve fibres, the end result of synchronism between total nerve discharge and frequency of the sound stimulus is achieved. There is experimental evidence that the volley principle does hold for response of the auditory nerve. It was suggested by some investigators, therefore, that discrimination of frequencies in the low range of frequencies (1,000 c.p.s. or perhaps 4,000 c.p.s. and below) is based partly on frequency; for example, a tone of 100 c.p.s. is heard when the frequency of nerve impulses in the auditory nervous system is 100 per second, and a tone of 200 c.p.s. is heard as having a higher pitch because the frequency of impulses is 200 per second.

3. Central Neural Mechanisms. — After the early 1940s, increasing attention was given to the events that take place in the central nervous system when the ear is stimulated by sound. It was found that there is topographic projection of the cochlea upon the higher centres in the auditory nervous system. Activity aroused in a small part of the cochlea produces neural excitation in a somewhat restricted part of each auditory pathway and each auditory centre. Since the cochlea does a frequency analysis of the sounds it receives, it follows that the auditory pathways and centres have a tonotopic organization; *i.e.*, a tone of a given frequency produces neural activity in a limited part of a pathway or centre. This evidence of tonotopic organization lent support to a place explanation of frequency discrimination.

Records made of the nerve impulses in higher centres of the auditory nervous system usually indicate that the synchronism between frequency of nerve impulses and frequency of sound stimulating the ear is progressively lost as the nervous system is ascended. Newer methods of recording and analyzing the electrical activity of the auditory system may reveal that the synchronism is maintained, at least in certain parts of the pathways and centres, and is being masked by other neural activity.

4. Conclusions. — It seems clear that both place and frequency principles must be considered in explaining discrimination of differences in frequencies of sound. In addition, auditory theory must account for discriminations that involve other dimensions of sound stimuli. For pure tones — and current theories are restricted almost entirely to dealing with discriminations of pure tones — the other primary dimension of the physical stimulus is intensity.

As noted above, increase in intensity of a pure tone presented to the ear results in spread of activity within the cochlea. More receptor cells along the basilar membrane are excited and nerve impulses are set off in more of the nerve fibres leading from the receptor cells into the central nervous system. In addition, experiments showed that there is an increase in the rate of firing of nerve fibres that are already active. The result is a greater total flow of nerve impulses per unit time as intensity of the stimulus is increased. This relationship between stimulus intensity and rate of flow of nerve impulses appears to be true for higher centres of the auditory nervous system as well as at the periphery.

A theory of hearing needs also to consider the neural events underlying localization of sound in space. Experimentation on this problem has been limited, but both the temporal and intensity differences noted above as being important in sound localization are reflected by temporal and amplitude differences in the nerve responses recorded in higher centres of the auditory system.

(W. D. N.)

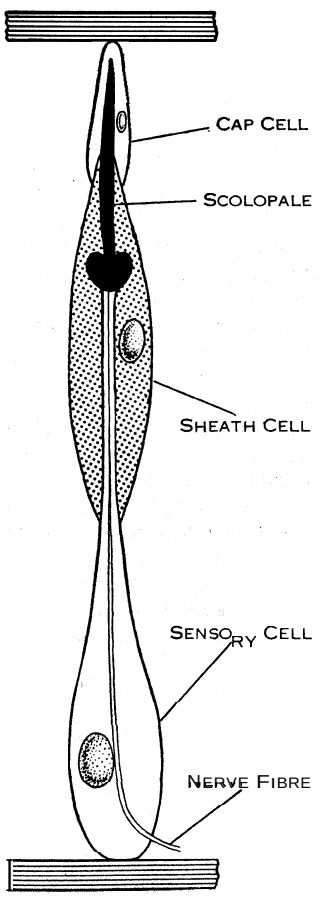

FIG. 3.—A SCOLOPHORE ORGAN (DIAGRAMMATIC)

VII. EVOLUTION OF HEARING

The evidence of comparative biology shows that twice in the course of animal evolution the problem of hearing has been solved, once by the insects and again by the vertebrates. In each case the ear was derived from a more primitive form of mechanical sensibility, but otherwise the two developments were distinct.

1. The Hearing of Invertebrates. — Among the invertebrates hearing is known to exist only in certain species of insects. It is possessed by those few insects that are notable for sound production: the katydids, crickets and grasshoppers among the orthopterans, the cicadas and the water boatmen; and in addition by certain moths which are largely dumb.

The ear of an insect is an elaboration of a simple sensory structure, the scolophore organ, which is widely distributed in insect bodies. In its simplest form (*see* fig. 3), this organ consists of three cells arranged in a column: a sensory cell, a sheath cell and a

cap cell. The sensory cell contains a chitinous rod, the scolopale, which projects out of the cell at one end, where it is snugly enclosed by the sheath cell and surmounted by the cap cell. A nerve fibre, arising from a ganglion cell nearby, enters the sensory cell and ends in or about the scolopale. This columnar structure is usually found stretched across a portion of the body cavity from one point of the integument to another. and bv its form and arrangement seems to be fitted for response to mechanical deformations of the body surface.

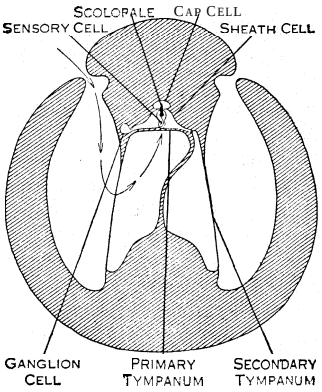

FIG. I.—THE EAR OF THE KATYDID (CROSS SECTION)

Aerial waves take a path indicated by the arrows, passing first through the secondary tympanum before striking the primary tympanum on which the scolophore organ rests

In the particular insect forms mentioned, the scolophore organ has become associated with a thin chitinous diaphragm or tympanic membrane. thereby forming a tympanal organ, which is the insect ear. This organ is situated in different places in the insects: in katydids and crickets on the forelegs; in the water boatman and some moths on the metathorax; and in other moths: grasshoppers. and cicadas on the abdomen—everywhere, indeed, but on the head where it would be expected.

The outer surface of the tympanic membrane is usually, as in grasshoppers. exposed directly to the external sounds, but sometimes. as in katydids. it faces an internal air chamber. in which case there is a secondary drum through which the sound waves first must pass. On the inner surface of the membrane lie the scolophores. with their scolopales pointing away and anchored against some relatively fixed structure.

It is well established that the tympanal organ is an auditory receptor. It is used generally in the process of mating, in which the male produces sounds and the female seeks him out. The most extensive observations have been made on crickets. A normal female let loose in a field was found to make straight for a cage containing a number of chirping males: but when her tympanal organs were destroyed this reaction ceased. Similar seeking behaviour was observed even when the chirp was conveyed over a telephone; here the orientation was to the receiver of the instrument. These experiments prove not only that the insects hear, but that the tympanal organ is the responsible structure.

Detailed results on sensitivity have been obtained only in certain orthopterans by recording the electrical impulses set up in the tympanal nerve during acoustical stimulation. In these the ear was found to be remarkably sensitive to high tones, some and perhaps all forms being superior to man in this respect. In the middle range of frequencies. where the human ear is most sensitive, the insect ear is poor in acuity, and responds only to sounds that to man are uncomfortably intense. From this it follows that the insect's world of sound is vastly different from man's.

2. The Hearing of Vertebrates.— The sensory portion of the vertebrate ear is a side development of the labyrinthine sense, whose primary function is the maintenance of bodily equilibrium (see EQUILIBRIUM. ANIMAL). The whole is a differentiation from the lateral line organ, a sensory apparatus found in adult form only in fishes and some amphibians, and whose function though not fully understood seems to relate to the perception of water currents or slow wave movements.

In fishes, amphibians and the lower reptiles, the endings for hearing are found in the saccule, one of the two main divisions of the labyrinth. In higher forms this auditory part of the saccule is expanded outward to become the cochlea. Evidence for hearing has been obtained in certain species of fishes and in representatives of all the higher vertebrate classes.

While fishes possess the saccular organ, they lack external and middle ears, and can be stimulated only by a process akin to bone conduction in higher animals. Those forms in which hearing is most assured are equipped with a special apparatus, the Weberian ossicles, which takes the place of the middle ear of higher forms.

Many fishes show disturbance from sounds produced in the water in their vicinity, but are largely unaffected by aerial sounds since these fail to penetrate the liquid surface. The clearest evidence of hearing is obtained in experiments in which the fish are trained to obtain food in response to an auditory signal. Sensitivity is shown for fairly rapid vibrations, and there are indications of some ability to discriminate sounds. That the saccule is responsible for the reactions is proved by tests in which this organ or its nerve is interfered with, or impulses are recorded from the nerve.

The amphibians have a middle ear of simple form, but no external ear. Some, like the frog, have an eardrum, which lies flush with the surface beneath the skin of the head. The frog's ear is fairly sensitive to low tones, but poor for high tones.

In the reptiles, the ear has undergone considerable differentiation. Some forms, like the tortoises and turtles, are little better equipped than their amphibian ancestors. Others, like the alligators, have a well-developed middle ear and a true cochlea. The alligators respond to sounds over a wide frequency range, up to 4,000 cycles or more.

The birds, as their songs proclaim, are keen of hearing and have an extensive range. In the pigeon both behavioural and auditory nerve studies indicate a hearing range up to 10,000 cycles.

In mammals the principal advance over lower forms is their further acquisition of range, though possibly there is greater acuity also. Most mammals that have been tested adequately have shown superiority to man in the hearing of high tones. Particularly notable here is the bat, which responds to tones far above man's upper limit, according to some evidence more than two octaves above.

The hearing of the cat has been carefully tested. For frequencies below 2,000 cycles per second its hearing is about like that of man. Above 2,000 cycles per second its sensitivity is much greater than that of man, and it responds to tones at least up to 60,000 cycles per second. The hearing of the dog is similar to that of the cat.

Over most of the hearing range the acuity of the monkey and chimpanzee is similar to man's, but in the high-frequency region they are definitely superior. The upper limit for the chimpanzee extends to about 30,000 cycles.

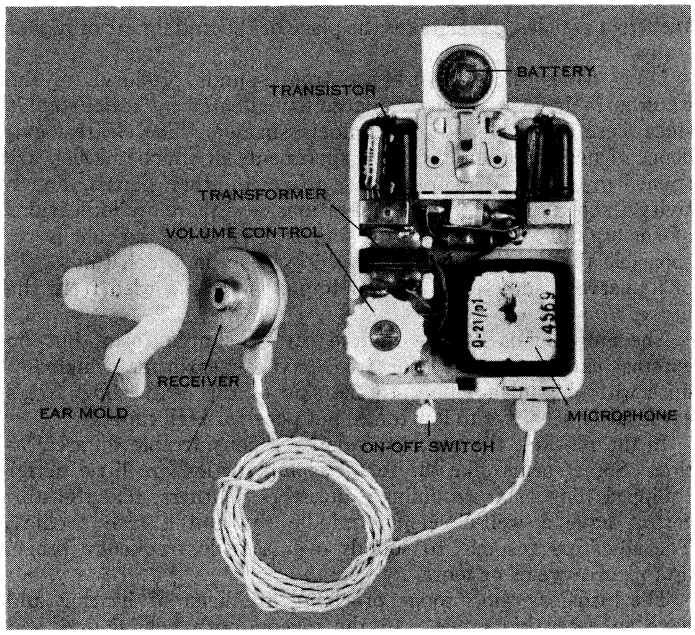
HEARING AID is a sound amplifier: a device that increases the loudness of sounds in the ear of the nearer. The earliest hearing aid was the ear trumpet. Ear trumpets have taken many forms, but they all have a large mouth at one end so as to collect the sound energy from a large area; the sound collected is led through a gradually tapering tube to a narrow orifice which can be inserted in the ear. Ear trumpets, then, amplify sounds simply by collecting the sound energy from a larger area than is possible by means of the unaided ear, and all the sound energy delivered to the ear originates from the sound source. This is fundamentally different from the operation of all later types of hearing aid, in which the energy of an electrical battery is used to boost the original sound.

There are two main classes of electrical hearing aid: the carbon aid and the electronic aid. The carbon aid was used from the beginning of the 20th century up to the early 1930s. It consisted of



BY COURTESY OF MULTITONE ELECTRIC CO LTD

PARTS OF A TRANSISTOR HEARING AID

a carbon microphone, a battery and a magnetic earphone, as in an ordinary telephone. The main difference between the carbon hearing aid and a telephone was that in the aid the electrical arrangement was such that the sound delivered by the earphone was substantially louder than the sound reaching the microphone.

The development of the radio valve made the electronic aid possible. The principal components of the electronic aid are (1) the microphone which converts sound into electric voltage; (2) the amplifier which amplifies this voltage; and (3) the earphone which reconverts the amplified voltage into amplified sound. In some aids a "bone conduction receiver" is used instead of the earphone, and this stimulates the hearing mechanism by vibrating the bones of the skull rather than by generating a sound wave in the external ear.

A typical hearing aid, as used between about 1930 and 1950, had a crystal microphone, a three-valve electronic amplifier and a magnetic earphone. The valve amplifier required two batteries, one supplying anything from 1 j v. to 45 v. and the other 1½ v. or 3 v. In the 1930s the magnetic earphone took the form of a disk of up to two inches in diameter held in place by a headband. In the 1940s this external receiver was gradually replaced by the insert receiver, uhich is only ½ in. to ¾ in, in diameter and is held on the ear by being clipped onto an individually molded plastic insert in the external ear.

In the early 1950s transistors replaced the valves in the amplifier. Transistors are smaller than valves and need only one battery of 1½ v. or 3 v. At the same time smaller, magnetic microphones also became available. All these factors made possible the construction of much smaller aids. While a typical valve aid of the 1940s measured 4½ x 2½ x ¾ in., the modern transistor aid is often as small as 2 x 1 x ½ in., and can even be built into a spectacle frame.

Hearing aids may have widely differing characteristics, and the selecting of the most suitable aid for the needs of a particular user has been extensively investigated. The two characteristics of a hearing aid which influence the understanding of speech most are, first, the amplification of the various components of speech sounds and, second, the intensity at which the sounds are heard by the wearer. As regards the first characteristic, speech sounds contain many components, each of a different frequency, and a hearing aid amplifies each of these components to a varying extent depending on its frequency; the variation of amplification uith frequency is called the frequency response of the aid. Experiments shon that hearing aids with one particular type of frequency response are best for all deaf people. This optimum frequency response (for details see Bibliography) shows that an aid need only amplify sounds within the frequency range 400 cycles per second to 4,000 cycles per second, although the components of speech cover a much wider range. When the aid is used in noise or in very reverberant surroundings, reduced amplification of the low-frequency sounds is preferable. Some hearing aids offer a choice of frequency response, the switch that determines which of the alternatives is selected being called the tone control.

As regards the second characteristic — the intensity at which the sounds are heard — too loud a sound can be as difficult to understand as one that is too quiet; the intensity range over which speech is understood best is wide for some deaf people but narrow for others, and can be narrower than the variations in intensity of normal speech. Hearing aids with automatic volume control (AVC) help in some of these cases by smoothing out the intensity variations. The AVC device varies the amplification of the aid automatically so that the output intensity is kept constant whatever the variations of the input.

Even with an aid with the optimum frequency response and supplying the most suitable output intensity, the user will rarely understand speech as well as people with normal hearing. In some people, deafness produces only a straightforward reduction of auditory sensitivity, and this can be compensated for fairly successfully by the extra amplification provided by the aid. Many deaf people, however, suffer a loss not only of sensitivity but also of auditory discrimination. Such persons. when using an aid, hear sounds more loudly but still find it difficult to distinguish one speech sound from another. Even if the aid does not enable its user to follow a conversation. however, it may still be useful by making him more aware of events around him.

A binaural hearing aid consists of two separate aids, one for each ear. Such an arrangement can, under some circumstances, materially benefit certain classes of deaf users.

In schools for the deaf group hearing aids are common. The group aid consists of a single central amplifier that amplifies the sounds picked up by microphones in different parts of the room. The amplified sounds are heard through earphones by the pupils.

HEARN, LAFCADIO (1850–1904), writer, translator and teacher in Japan, was born June 27, 1850, on Santa Maura, one of the Ionian Islands, west of Greece. He was the son of Surgeon Rlajor Charles Bush Hearn. of Anglo-Irish descent, and Rosa Antonia Cassimati, a Greek native of one of the islands off Greece. Christened Patrick Lefcadio Hearn, he dropped the first name and changed the second to Lafcadio when he came to the United States. In 1856 his father had his marriage annulled in Ireland. Both his parents left the country and each remarried, and Hearn never saw his parents again. Left in charge of a grandaunt, a widow, Sarah Holmes Brenane. before he reached his teens he was enrolled in a Roman Catholic school in Normandy. He then spent four years at St. Cuthbert's college, Ushaw, County Durham. His early schooling led to his developing a hostility to Roman Catholicism. At St. Cuthbert's his left eye was damaged either by the knotted end of a rope flung at him, or as he believed, punched out by a blow from a fist. He lost the sight of this eye. Financial difficulties of his grandaunt forced him to leave college in Oct. 1867. He spent most of 1868 in extreme distress and abject poverty in London. Finally in 1869 he was shipped off to Cincinnati, O., which he reached after a brief period in New York.

He suffered many hardships in Cincinnati. working at odd jobs and often sleeping in the streets. He soon met Henry Watkin, a printer, who exerted a great influence upon him. Watkin taught him the rudiments of his trade, and Hearn became a proofreader. Meanwhile he began to write, and in 1870 and 1871 contributed five articles on freethought under the pseudonym "Fiat Lux" to the Boston Investigator. By 1873 he was on the staff of the Cincinnati *Enquirer,* where both his scholarly and gruesome articles, written in a masterly poetic style, attracted attention. He was dismissed in the summer of 1875 either because of a marriage ceremony with

a Negro woman with whom he had been living or because of political pressure. He was soon taken on the *Cincinnati Commercial* where his articles won even greater acclaim. He wrote about the Negroes and the Jews, continuing to praise and defend the latter for many years. He also began his first translations from the French, of Gautier and Flaubert.

Anxious to visit the south he left for New Orleans, La., in Oct. 1877. He sent back to his paper articles signed "Ozias Midwinter," mostly containing his earliest impressions of New Orleans. In 1878 he became, after penniless months, assistant editor of the *New Orleans Item*. For the next three and a half years he contributed editorials on numerous topics, scientific and literary articles, "fantastics" or prose poems, sketches of life among the Creoles, and a few translations from the French and Spanish. In May 1880 he also began contributing translations to the *New Orleans Democrat*. There appeared the first English translations of De Maupassant and Pierre Loti.

The newly merged *New Orleans Times-Democrat* engaged Hearn in Dec. 1881. For the next five and a half years he contributed translations from French and Spanish writers almost every Sunday. He also published stories and sketches in poetic prose, and adapted from foreign literatures many tales that made up his two earliest works *Stray Leaves From Strange Literature* (1884) and *Some Chinese Ghosts* (1887). He wrote essays and articles on Buddhism, on Hebrew and Arabic subjects, and on French and Russian literature. His editorials ranged over the scientific field from astronomy to archaeology. He also contributed to the *Century Magazine, Harper's Weekly* and *Harper's Bazaar*. In New Orleans he met Elizabeth Bisland, who became his biographer.

His first novel, *Chita,* occupied an issue of *Harper's New Monthly* magazine and appeared in book form in 1889. In 1887 Henry Mills Alden, the editor, encouraged him to go to the French West Indies. Hearn spent the following two years there, and wrote his finest book before he went to Japdn, *Two Years in the French West Indies* (1890). In the tropics he also obtained material for his second novel, *Younza* (1890). He spent the summer of 1889 in Philadelphia, living with George M. Gould. From Oct. 1889 to March 1890, Hearn lived in New York city. There he translated Anatole France's *The Crime of Sylvestre Bonnard* (1890). There he saw much of Henry E. Krehbiel, the musical critic.

Hearn went to Japan on a tentative assignment for *Harper's New Monthly* magazine, arriving at Yokohama, April 4, 1890. He broke with *Harper's* in May. He spent some time living in temples and making pilgrimages. Through the intervention of Capt. Mitchell McDonald to whom he brought a letter of introduction from Elizabeth Bisland and who became his closest friend and literary executor, and two others, one being Basil H. Chamberlain, he obtained a position as a teacher in the ordinary middle school at Matsue in the province of Izumo, beginning his duties Sept. 2, 1890. Through one of the fellow members of the English faculty, he met his future wife, Setsu Koizumi, a Japanese lady of high Samurai rank, whom he married in Jan. 1891.

In Sept. 1891, his articles on Japan began appearing in the *Atlantic Monthly,* while some appeared in Feb. 1892 in the *New Orleans Times-Democrat* and were syndicated in other newspapers. These essays and others were subsequently collected and published in two volumes as *Glimpses of Unfamiliar Japan* (1894). Late in 1891 he had himself transferred to the government college at Kumamoto in Kyushu, where he remained for three years. He was not happy there and began feeling disillusioned about Japanese officialdom. In the late summer or early fall of 1895 he became a Japanese subject in order to protect his wife's citizenship, the legality of their marriage and their rights of property.

Out of the East appeared in 1895 and *Kokoro* in 1896. In the summer of 1896 through the influence of Chamberlain he was invited to teach in the English department of the Imperial university of Tokyo. He moved into Ushigome, a suburb of Tokyo, where he lived for the next six years. These years constituted his most prolific and brilliant period. There he wrote *Gleanings in Buddha-Fields* (1897), *Exotics and Retrospectives* (1898), *In Ghostly Japan* (1899), *Shadowings* (1900) and *A Japanese Miscellany* (1901). He was occupied with themes that had attracted him in the United States — insects, proverbs, names, songs — but they now received a Japanese setting.

About the spring of 1902 Hearn purchased a house at 266, Nishi Okubo where he lived until his death. His next book, *Kottō,* appeared in the fall of 1902. His lectures as taken down by his students were published in the United States (1915–17), edited by John Erskine, as *Interpretations of Literature* (2 vol.), *Appreciations of Poetry* and *Life and Literature*. More complete editions of these lectures have been published in Japan. Also published in Japan, and based on his lectures was *A History of English Literature,* 2 vol. (1927).

In the spring of 1903 Hearn left his position and prepared a series of lectures intending to deliver them at Cornell university, Ithaca, N.Y., but the university withdrew an offer it had previously made. These undelivered lectures became the material for his best-known book on Japan, *Japan: An Attempt at an Interpretation* (1904). Another book, *Kwaidan,* mainly stories, had appeared earlier in the year. In the spring of 1904 he was invited to teach English at Waseda university. Under strain and anxiety he died from a heart attack on Sept. 26, 1904. Though a professed agnostic and not a Buddhist in religion, his funeral was in accordance with Buddhist rites, and his ashes were interred at Zoshigaya cemetery.

Hearn is notable not merely as a writer who revealed an idealized Japan to the western world, but also for his manifold interests. He was a devoted student of fairy tales, folklore and legends that unfolded the mental strata of entire peoples. He sought out kindly and generous emotions, high conceptions of duty and examples of self-sacrifice among the lowly, and delineated them in his unique and at times flowery prose, excelling especially in descriptive writing. He had philosophical preoccupations; he tried to find a linking bond between the doctrine of Karma in Buddhism, *i.e.,* prebirth conduct in one's ancestors, and the role of heredity in the theory of evolution. He dwelt much on race memories as manifested in the individual. He was, however, a rationalist and not a mystic. He was also a profound literary critic. While leaning toward Victorian standards, he leavened these with his proclivities for French romanticism and occasional realism. He was a great admirer of the Russian novelists and Henry James before interest in these writers became common.

HEARNE, SAMUEL (1745–1792), English explorer who played an important part in ascertaining the relations between Hudson bay and the Arctic ocean by his exploration of the Coppermine river. Born in London in 1745, he served in the navy and then joined the Hudson's Bay company in 1766. He was sent northward from Churchill to explore the coast and investigate the possibilities of a whale fishery. Unreliable guides and equipment twice (1769 and 1770) caused his failure to reach a copper mine

whose existence was rumoured by Indians. On his third journey (1770–72), Hearne came to the Coppermine river, which he traced to its mouth (Coronation gulf), saw the copper mine and took a lump of copper, returning to Churchill by way of Great Slave lake and Chipewyan territory. In 1774 he was sent to establish Cumberland house on the Saskatchewan, subsequently returning to command Churchill, which had been rebuilt and named Prince of Wales's fort. There he was captured by J. F. La Pérouse in 1782 and brought to Europe. After release to publish his account of his journey, the company sent him back to command again at the fort. Hearne was recalled to England in 1787 and died there in 1792.

Hearne's *Journey From Prince of Wales's Fort in Hudson's Bay to the Northern Ocean* was published posthumously in 1795.

(E. E. RH.)

HEARNE, THOMAS (1678–1735), English antiquary, was born in July 1678 at Littlefield Green. White Waltham. Berkshire, son of the parish clerk. Educated at St. Edmund Hall, Oxford, he became in 1699 assistant keeper of the Bodleian library, where he worked on the catalogue of books, and in 1712 he was appointed second keeper. As a nonjuror he refused to take the oaths of allegiance to King George I, and early in 1716 he was deprived of his librarianship. He continued to reside in Oxford, and occupied himself in editing the English chroniclers. He died on June 10, 1735.

Hearne's most important work was done as editor of many of the English chroniclers, and until the appearance of the "Rolls Series" his editions were in many cases the only ones extant. Very carefully prepared, they are still of the greatest value to historical students. Perhaps the most important of a long list are Benedict of Peterborough (Benedictus Abbas), *De vita et gesta Henrici II et Ricardi I* (1735); John of Fordun, *Scotichronicon* (1722); the monk of Evesham, *Historia vitae et regni Ricardi* (1729); Robert of Gloucester, *Chronicle* (1724); the *Vita et gesta Henrici V*, wrongly attributed to Thomas Elmham (1727); Titus Livy, *Vita Henrici V* (1716); Walter of Hemingburgh, *Chronicon* (1731); and William of Newburgh, *Historia rerum Anglicarum* (1719). He also edited John Leland, *Itinerary* (1710–12), and *Collectanea* (1715); *W.* Camden, *Annales rerum Anglicarum et Hibernicarum regnante Elizabetha* (1717); Sir John Spelman, *Life of Alfred* (1709); and W. Roper, *Life of Sir Thomas More* (1716). Among his other compilations may be mentioned *Reliquiae Bodleianae* (1703).

Hearne left his manuscripts to William Bedford, who sold them to Richard Rawlinson, who in his turn bequeathed them to the Bodleian. Two volumes of extracts from his voluminous diary were published by Philip Bliss (1857), and afterward an enlarged edition in three volumes appeared (1869). A large part of his diary entitled *Remarks and Collections, 1705–1714,* ed. by C. E. Doble and D. W. Rannie, was published by the Oxford Historical Society (1885–98). *Bibliotheca Hearniana,* excerpts from the catalogue of Hearne's library, was ed. by B. Botfield (1848).

See *Impartial Memorials of the Life and Writings of Thomas Hearne by Several Hands* (1736); *W.* D. Macray, *Annals of the Bodleian Library* (1890). Hearne's autobiography was published in W. Huddesford, *Lives of Leland. Hearne and Wood* (1772). T. Ouvry, *Letters Addressed to Thomas Hearne,* was privately printed (1874).

HEARSAY, a legal term signifying facts given in evidence derived from indirect information, the circumstances under which such evidence is admitted being subject to considerable limitations. *See* EVIDENCE.

HEARSE, a vehicle for the conveyance of the coffin at a funeral. In funeral ceremonies a "herse" or "hearse" seems first to have been a harrow-shaped framework of wood, to hold lighted tapers and decorations placed on a coffin; this developed into a pagoda-shaped erection of woodwork or metal for the funerals of royal or other distinguished persons. It held banners, candles, armorial bearings and other heraldic devices. An elaborate hearse was designed by Inigo Jones for the funeral of James I. The hearse is also found as a permanent erection, of iron or other metal, over tombs.

HEARST, WILLIAM RANDOLPH (1863–1951), U.S. publisher, whose methods profoundly influenced U.S. journalism, was born in San Francisco, Calif., on April 29, 1863. The son of George Hearst, a California pioneer who amassed a large fortune in ranch and mining lands and who served as U.S. senator from 1886 to 1891, he entered Harvard in 1882 and remained two years. Becoming interested in journalism, he visited Boston newspaper offices, studied newspapers from all parts of the country and paid special attention to the success of the *New York World* under Joseph Pulitzer.

On his return to California he first took partial and later, in 1887, complete control of the *San Francisco Examiner,* which the elder Hearst had bought for political reasons. Within two years he made it pay, and with an efficient staff used it for many newspaper experiments.

Hearst invaded New York journalism in Sept. 1895 by buying the unsuccessful *Morning Journal,* which he made a one-cent newspaper of highly popular type. To it he brought many able workers, including Julian Hawthorne, E. W. Townsend, Stephen Crane, Julian Ralph and the cartoonist Homer Davenport, while he immediately raided the *New York World* for the best members of Pulitzer's Sunday staff, including R. F. Outcault, the inventor of the modern coloured comic pictures. By the use of numerous illustrations, coloured magazine sections and glaring headlines, by sensational articles on crime and pseudoscientific topics, and by a jingo policy in foreign affairs, the *Journal* (an evening edition was started in 1896) shortly reached an unprecedented circulation. On the day after the election in 1896 it printed 1,506,000 copies of its several editions.

Under Hearst's control the *Journal* attacked England in the Venezuela affairs, supported William Jennings Bryan in 1896, demanded war with Spain in 1897–98, launched a series of attacks against municipal "franchise grabs" and supported Bryan again in 1900, bitterly assailing William McKinley and Mark Hanna as tools of the trusts. An editorial statement in April 1901 that "if bad institutions and bad men can be got rid of only by killing, then the killing must be done," led Theodore Roosevelt in his first message after McKinley's assassination to denounce "exploiters of sensationalism" in words which he later (1906) declared he meant for Hearst.

The success of the *Journal* led Hearst to establish the *Chicago American* in 1900, the *Chicago Examiner* in 1902 and the *Boston American* in 1904. Other newspapers were purchased in 1912, and in 1917 he launched an energetic policy of expansion, so that by 1925 he owned newspapers in cities of every section of the United States. After 1904, when he supported Alton B. Parker, he paid decreasing attention to editorial leadership. He opposed U.S. entrance into World War I; he waged unremitting warfare against the League of Nations, and demanded payment of the war debts in full. Late in 1916 the British and French governments denied Hearst the use of their mails and cables. But in 1927 he suddenly emerged as the champion of a bond of close friendship and practical co-operation among all English-speaking countries. Meanwhile, he had embarked in other publishing enterprises. He purchased the *Cosmopolitan* monthly in 1905, the *World To-day* in 1911, and *Harper's Bazaar* and other magazines, including *Nash's Magazine* in England, at later dates. He published books, chiefly fiction, and later in his career produced motion pictures on a large scale.

His holdings just after World War I were enormous, but living on a princely estate at San Simeon, Calif., and buying antiques and art on a munificent scale, he strained even his huge income. The long depression beginning in 1930 endangered his empire.

First he had to pool some of his most valuable newspapers in a company which raised $50,000,000 by selling preferred stock; then in 1937 he had to assign control of his chief holding company, American Newspapers, Inc., to a banking-house trustee for ten years. Weak newspapers were ruthlessly sold or consolidated with stronger units. A great part of his collection of furniture, paintings, tapestries and other treasures was sold through department stores in 1941. But during the boom of World War II, 1941–50, his newspaper properties again became profitable; his holdings still included newspapers scattered from Baltimore, New York city and Boston in the east to Los Angeles, San Francisco, and Seattle on the west coast, and several magazines, of which *Cosmopolitan, Good Housekeeping, Motor* and *Town and Country* enjoyed large circulations. He died at Beverly Hills, Calif., on Aug. 14, 1951.

Hearst's role in politics was ambitious but unsuccessful. While serving two inactive terms in the U.S. house of representatives

(1903–07), he ran in 1905 for mayor of New York on an anti-Tammany municipal ownership ticket, and came within 3,000 votes of winning; and the following year, as Democratic nominee for governor of New York he was defeated by Charles E. Hughes. A heavier defeat for mayor of New York followed in 1909, and, though he was later frequently suggested for mayor or governor until his quarrel with Alfred E. Smith in 1924 destroyed his Democratic following, he was never again nominated.

HEART, ANATOMY OF. The human heart, a double muscular pump, lies within the thorax, rests upon the diaphragm, is between and partly covered by the lungs. Each side (pump) has two chambers: the one (atrium) receives, the other (ventricle) expels blood. Together, these four chambers have the shape of a flattened cone, a little larger than the fist, which is covered by a double-walled sac, the pericardium. (See COELOM AND SEROUS MEMBRANES.) The innermost layer is tightly adherent to the cardiac muscle. Between the layers is a small amount of lubricating fluid. The heart of an average-sized adult weighs about 300 g. The ratio of heart weight to body weight is less in adults than in children.

The base of the heart, formed by the atria and great vessels, faces the backbone. Between the fifth and sixth ribs, halfway across the left chest, lies the apex (formed by the left ventricle).

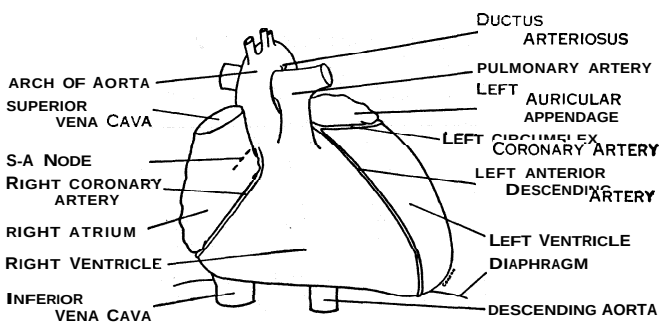

FIG. 1.— FRONT VIEW OF HEART

Seen from the front, the right border of the heart may extend one centimetre to the right of the edge of the breastbone (sternum). The right atrium forms this border but occupies only a finger's breadth of the front (ventral) surface. A similar band of left ventricle forms the left border. These strips of right and left ventricle account for one-third of the ventral surface. The rest is occupied by the right ventricle, which forms almost the entire lower (inferior) edge.

The pulmonary artery is seen at the upper curved edge of this chamber (*see* fig. 1). The inferior (diaphragmatic) surface is composed two-thirds of left, one-third of right ventricle. Separating atria from ventricles is a deep groove containing fat and blood vessels, the atrioventricule (A–V) groove. A shallow groove (interventricular, I–V) containing blood vessels marks the partition between the ventricles (the septum).

Seen from the side, the right atrium lies between the ventricle and the backbone (fig. 2). Entering the upper atrial edge is the superior vena cava, bringing venous blood from the head, arms and upper thorax. The inferior vena cava, draining the lower body, penetrates the diaphragm and immediately enters the lower right atrium. A shallow furrow lying between these veins contains a deep nest of unique cells, the sinoatrial (S–A) node (fig. 1). Within this chamber, the mouth of the superior vena cava is in the upper part and that of the inferior cava is below. The latter is partly surrounded by remnants of the Eustachian valve, which, in the embryo, directed blood from right to left atrium through an opening called the foramen ovale. After birth two membranes, lying in apposition, close the foramen. On the adult septum a depression (fossa ovalis) marks this spot. Near the Eustachian valve is the opening from the coronary sinus, which also has a valve. This sinus is a vein which drains the heart muscle; it runs

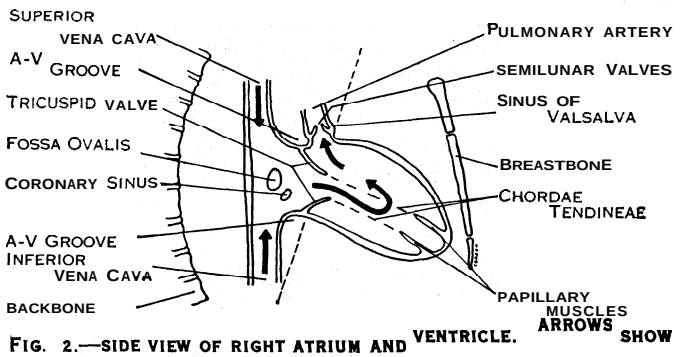

FIG. 2.—SIDE VIEW OF RIGHT ATRIUM AND VENTRICLE. ARROWS SHOW DIRECTION OF BLOOD FLOW

around the inferior A–V groove. Near the coronary sinus opening is another nest of unique cells called the A–V node. Atrial walls are thin enough to be translucent when distended. The inner surface has fine columnar ridges called musculi pectinati. Arrows in fig. 2 show the direction of blood flow from right atrium to ventricle.

The passageway between these chambers is the A–V or tricuspid orifice. A membranous curtain (tricuspid valve) attaches to the cartilagenous ring which surrounds this orifice (fig. 3A). The free edge, serrated to form three cusps, is attached by fibrous bands, chordae tendineae, to the ventricular muscle. When the ventricle is relaxed, the cusps take the position shown in fig. 2. When the filled ventricle begins to contract, the cusps float up to close the opening, thus preventing backflow to the atrium (fig. 3A).

In cross section the right ventricular cavity is crescentic, and partly enfolds the circular base of the left ventricle (fig. 3B). Certain muscular bands, together with the convexity of the septum, give the cavity the shape of a V lying on its side (>). The horizontal arm is the inflow tract from the atrium, the vertical arm the outflow tract to the pulmonary artery (fig. 2). A valve having three semilunar cusps is attached to the inner surface of the artery.

When the ventricle is empty, the cusps fill with blood and drop back to block the artery (fig. 3A). When the ventricle is expelling blood, the emptied cusps are pushed into small dilatations of the arterial wall called sinuses of Valsalva (fig. 2). The wall of the right ventricle has a maximum thickness of four millimetres. Its contraction forces blood through the pulmonary artery to the lungs and thence to the left atrium.

The left atrium lies to the left and back of the right atrium. Between it and the backbone are the left bronchus, the and the descending aorta. The pulmonary veins, two from each lung, return oxygenated blood to it. The endocardia1 (smooth inner) lining is thick, making the colour seem pale. There are no musculi pectinati. The fossa ovalis appears on the septum. Blood flowing horizontally and to the left passes the A–V orifice, which also has a circular membrane, the mitral valve, attached to its periphery. The free border has two flaps which are attached by the chordae tendineae to anterior and posterior projections of the muscular wall (papillary muscles). The cavity of the cone-shaped left ventricle is divided by the large aortic flap of the mitral valve into inflow (atrial) and outflow (aortic) tracts. The aorta has three semilunar valves (see AORTA AND AORTIC VALVES;

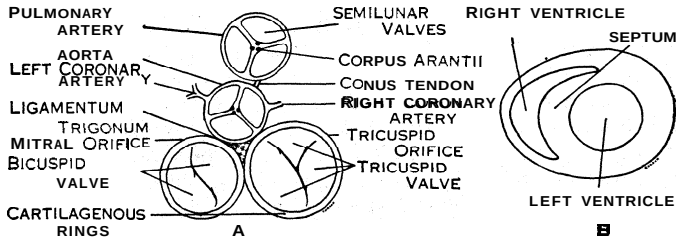

FIG. 9.— (A) CROSS SECTION OF VENTRICULAR BASE: DOTTED LINES SHOWN ON FIG. 2 INDICATE LEVEL. (B) CROSS SECTION (NEARER APEX THAN A) TO SHOW RELATIVE SHAPES AND SIZES OF RIGHT AND LEFT VENTRICLES

ARTERIES). Mouths of the two coronary arteries, which nourish the heart itself, are seen in two of the sinuses of Valsalva. Both septal and lateral walls of this ventricle are thick at the base 10–12 mm.) (fig. 3B). At the apex, between the papillary muscles, the wall is very thin (one millimetre). The I–V muscular septum is absent at the root of the aorta, where a thin tough membrane (membranous septum) separates the ventricles.

Contraction of the left ventricle forces blood through the aorta and to the entire body.

The walls of the atria and of the ventricles are made up of superficial and deep layers. In the ventricles the thin superficial layer attaches to the cartilagenous A–V rings and to the ligaments (fig. 3A). That part attached to the left ring is called bulbospiral (fig. 4A). and that attached to the right sinospiral. Together they cover the entire ventricular surface, spiraling from left to right and from base to apex. At the apex of each ventricle the bands become compact and turn inward so that they come to line the cavities. The leftward spiral is continued as the fibres run to the base and attach to the same rings from which they originated. Some of the innermost (subendocardial) fibres of these superficial muscles are called by special names; *e.g.,* columnae carneae, papillary muscles. Fibrous strands, the chordae tendineae, are replacements of primitive muscle fibres that have degenerated. These serve to attach the papillary muscles to the

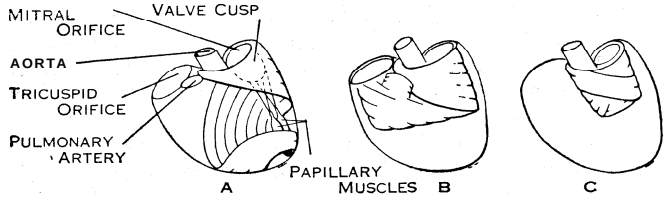

FIG. 4.— (A) SUPERFICIAL BULBOSPIRAL MUSCLE: THIS. TOGETHER WITH ITS COUNTERPART ON THE RIGHT (SUPERFICIAL SINOSPIRAL, SHOWN HERE AS A SPACE). COVERS THE ENTIRE HEART'S SURFACE. (B) DEEP SINOSPIRAL. A CUFFLIKE MUSCLE ENFOLDING BOTH VENTRICLES AND FORMING PART OF THEIR SEPTUM. (C) DEEP BULBOSPIRAL MUSCLE ENCIRCLES THE AORTA AND THE MITRAL ORIFICE

valve cusps. These superficial muscles fix the valve leaflets so they cannot invert back into the atrium when the rest of the ventricle contracts.

A deeper layer of muscle, the deep sinospiral, extends two-thirds the distance from base to apex (fig. 4B). Its fibres are transverse to the long axis of the heart and course through the septum as well as encircle both ventricles. The deficiency, facing the apexes, is entirely filled in by the papillary muscles. Still another heavy muscle band forms a cuff around the mitral orifice and the aorta (fig. 4C). It extends one-third the distance from base to apex. When this muscle, the deep bulbospiral, contracts, it squeezes the last of the ventricular blood into the aorta (see ARTERIES). When it relaxes, the semilunar valves fall into position. Considering these functions, it is obvious that the superficial bands must contract somewhat earlier than the middle layer, and especially before the cuff muscle.

No muscle is continuous from the atria to the ventricles; nevertheless, atrial contraction precedes ventricular in orderly sequence. The stimulus for contraction arises in the S–A node (see above). Later the A–V node is excited. From this node, a band of unique cells, the bundle of His, passes toward the ventricle. This specialized conducting tissue provides for co-ordinated excitation of the muscle areas. Within a few millimetres it enters the membranous septum, where it lies between its two layers, following the lower curved edge. Next it lies on top the muscular I–V septum for 12–15 mm. and then divides into right and left branches. Numerous smaller branches go directly to the septum. The branches divide and subdivide until they penetrate every area of ventricular muscle. (Other expansions of this tissue spread through the atria.) Eventually the cells of this tissue undergo end to end transition into ordinary heart muscle cells. Microscopic sections of heart muscle, stained to show connective tissue, establish that the muscle does not form a syncytial structure (*i.e.,* it consists of isolated units). Lozenge-shaped masses of muscle are wrapped in connective tissue which insulates one area from another. Each such lozenge receives at least one strand from the bundle of His. Electron microscope photographs confirm the absence of syncytial connections even between fibrils.

Nerves supplying the heart are the vagus (parasympathetic, cholinergic) and the cardiac branches of the cervical and upper thoracic ganglia (sympathetic, adrenergic). Superficial and deep plexuses are formed by these nerves. (See also NERVE; NERVOUS SYSTEM.)

Evolution of the Heart.— In the lancelet, a fishlike lower chordate, there is no heart, but only a contractile area where the hepatic veins, the ducts of Cuvier and the ventral aorta meet. The simplest heart is a tube, an enlarged vein with muscular walls. The ends of this tube are fixed; the intermediate part continues to grow, and hence is forced to bend. The curvature is to the right but finally becomes S-shaped. Constrictions divide the tube into four chambers.

The most posterior (footward) is the thin-walled sinus venosus, which receives the systemic veins. The second thin-walled area, the atrium, has lateral bulges. The third chamber, the ventricle, has thick walls and is partly filled with spongy musculature. The most anterior (headward) chamber, the conus arteriosus, is tubular with moderately muscular walls. During the development of the conus four longitudinal ridges form on the inside. Three of these persist and form rows of little pockets, which are the distinguishing characteristic of the conus. Beyond the conus is the aorta. Because of the S-bend, the ventricle is brought near the sinus and the atrium near the conus. Hearts of most fishes are of this type: a continuous tube carrying venous blood, which is oxygenated in the gills.

In vertebrates with four limbs (tetrapods; *e.g.,* newts, salamanders and tailed amphibia) the heart is even more compressed, and the atria bulge around the conus. One edge of the ventricular curve has grown faster than the other, thus causing fusion of the short arms of one S-bend. This gives the ventricle its characteristic shape. Within the atrium a septum has appeared, dividing it into right and left parts. The sinus has twisted anteriorally to lie near the right atrium. Tetrapods have functioning lungs; therefore, two circulations are necessary. Venous blood still comes from the systemic veins to the sinus venosus and the right atrium, and thence to the right ventricle. The pulmonary arteries take the blood to the lungs. Pulmonary veins have developed which bring blood back from the lungs to the left atrium; it passes from there to the left ventricle, thence to the conus and the aorta.

Within the atria, the septum lies between the two streams of blood. Although the two streams are not separated by tissue in the ventricle, they do not mix to any extent. In the conus one of the four ridges (see above) persists and helps to separate the streams. Only one class of fishes, the Dipnoi, have a circulation as advanced as this.

In reptiles the heart is even more crowded together; the sinus venosus is smaller and more anterior; thus the ends of the great veins are brought nearer to the beginning of the large arteries. There are two atria, and a muscular band forms a partial I–V septum. Among reptiles, only crocodiles have a complete I–V septum. The conus is now divided by a spiral structure into three trunks, each having a semilunar valve at the point where it leaves the ventricle. The circulation, though better separated by the new septum and by the valves, is the same as in amphibia.

The similarity of the hearts of birds and mammals is an example of parallel development from a common reptilian ancestor. The sinus venosus has become part of the right atrial wall; the S–A node (see above) is its residuum. Complete septa divide both atria and ventricles, forming four chambers. The great veins empty directly into the right atrium; the pulmonary artery connects to the right, the aorta to the left ventricle. This has come about by the splitting of the conus. Cross section of the rudimentary conus is almost circular and, as stated above, four ridges are within (fig. 5C, D, E). Later an external constriction occurs. The lateral ridges are divided into two portions and the conus into two channels, each having three ridges. Where the two chan-

nels (aorta, pulmonary artery) leave the ventricles, persistent portions of these ridges form the semilunar valves (figs. 3A and 5C, D. E). The arterial and venous blood have become entirely separated and circulate as described for the adult heart.

Embryology. — The heart begins in two areas lying on either side of the coelom well away from the midline (see EMBRYOLOGY). In each of these, two kinds of tissue are found: one eventually hollows out to form an inner lining tube (endocardium); the other develops into muscular and outer covering (epimyocardium). When the originally flat embryo curls under and the edges grow together, these areas are brought into the midline where they fuse to form a single tube having endocardium inside and an epimyocardial mantle outside. This tube is reminiscent of the fish heart (fig. 5A, B), but in the human embryo the constrictions are less evident. This tube does not grow all at once. nor does any one part precede another. Rather there are several areas developing simultaneously, moving toward the midline and fusing.

The developing heart pushes into the small pericardium which

FIG. 5. — SCHEMATICREPRESENTATION OF (A) FISH HEART. (B) TUBULAR HEART OF HUMAN EMBRYO. (C) CROSS SECTION OF CONUS TO SHOW FOUR RIDGES WHICH WILL EVOLVE INTO SEMILUNAR VALVES; (D) BEGINNING OF LATERAL CONSTRICTION; (E) SEPARATION INTO TWO VESSELS. PULMONARY AND AORTA. EACH HAVING THREE VALVES

is to envelop it. The ends of this tube are fixed. Because the central part has to grow within this limited space, it twists and widens laterally. Not all points of the tube grow at the same rate; thus constrictions occur which delimit the various chambers. Where the constriction between the atria and ventricles occurs (atrial canal), anterior and posterior ridges (endocardia1 cushions) touch. fuse, form the septum intermedium and leave right and left A–V openings laterally. From the tip of the ventricle another septum grows up to meet the septum intermedium. This I–V septum is complete at the end of the second month (17–20 mm. embryo). Within the atrial chamber septa also develop. The first (septum primum) grows down from above to meet the fused endocardia1 cushions. The second septum, at the right of the first. is never complete; its curved edge surrounds the foramen ovale. Eventual closure of the foramen occurs when these two septa adhere. Division of the conus into two vessels, each having three semilunar valves, proceeds as described above (fig. 5C, D. E).

Because the developing heart is forced to rotate, the aorta and pulmonary artery are somewhat entwined in the adult. With further development the spongy muscular mass of the ventricle becomes somewhat hollowed out (one theory supposes this to be the result of pressure erosions or aneurysms). Some of this early muscle becomes transformed into fibrous tissue and persists as the A–V valves and the chordae tendineae. See also CIRCULATION OF BLOOD; HEART, COMPARATIVE PHYSIOLOGY OF; HEART, DISEASES OF THE; HEART AND LUNG, SURGERY OF; MUSCLE AND MUSCULAR SYSTEM.

HEART, COMPARATNE PHYSIOLOGY OF. The bodies of all except the simplest animals contain fluids that circulate through the body in a constant direction. Such circulation requires a repeating pump to propel the fluid, and any such pumping device is called a heart. To keep the fluid moving in a constant direction the heart must either compress the fluid in a continuous progressing wave, or it must have valves to prevent backflow. Both systems are found in animal hearts, sometimes one or the other and sometimes both together. Propulsion by contractile waves is characteristic of worms, whereas rhythmic contractions with valves to prevent backflow characterizes arthropods, mollusks and vertebrates (including man).

The most characteristic feature of heart muscle tissue is its capacity for rhythmic contractions, a property that is also inherent in many nerve cells and in visceral muscles. Embryonic heart tissue is capable of spontaneous rhythmic contractions; in the early embryos of vertebrates the heart beats without anything regulating the contractions, and pieces of embryonic heart tissue cultured outside the body may develop rhythmic contractions. Such spontaneous contractions probably are a response of the muscle protoplasm to conditions of the cellular environment; perhaps the energy produced by intracellular oxidation builds up to a critical level. discharges, rebuilds to the critical level, etc., in an automatic cycle.

Adult heart muscle of all animals, however, seems to contract only as a result of stimulation. Heart muscle is extremely susceptible to stimulation. a great variety of artificial stimuli causing it to respond by contracting. As with other muscle tissue —skeletal muscle and smooth muscle—a stimulus must have a certain minimal intensity and a certain minimal duration in order to bring about a contraction. These values vary widely in different animals, and even from time to time in the same tissue as local conditions change. Like many other tissues, heart muscle also exhibits a refractory period, a brief period immediately followuing stimulation during which it is wholly unexcitable. The refractory period is not so clearly marked in invertebrates as in vertebrates. Each contraction of the vertebrate heart is maximal; *i.e*, the heart contracts in "all or none" fashion. and a stronger stimulation will not induce more powerful contraction. In invertebrates. on the contrary, a normal contraction of the heart is never maximal. (See ALL-OR-NONE LAW.)

The demands made upon the heart by the body are constantly changing; demands may be temporarily increased several hundred per cent in an athlete following a 100-yd. dash, for example. Simple animals with low metabolic rates and open circulatory systems require less regulation of the heart than do active animals with closed systems under high pressure; the heart of a clam, for example, need not be as efficient as the heart of a bird or mammal. Nevertheless. the behaviour of even the simplest hearts is regulated to conform to the changing requirements of the body. Such controls are largely chemical, although the heart also responds to variations in such physical factors as temperature and pressure.

Pacemakers. — In all adult animals a special tissue, called a "pacemaker," initiates each heart beat. The pacemaker is always located within the heart itself, and two very different kinds of pacemaker tissue occur in animals. In vertebrates and mollusks the beat originates in the heart muscle tissue itself, and these are called myogenic hearts. In vertebrates the pacemaker is localized in the muscle tissue of the sinus venosus (fishes and frogs) or the atrioventricular node (birds and mammals), which differ from the muscle of other regions of the heart in recovering excitability very rapidly after a contraction. In mollusks the pacemaker is less localized; the beat can originate in muscle at any point over the heart.

Mammals and birds have in addition a special conduction system that greatly increases the efficiency of the heart and appears to be an adaptation to high body temperatures. In these animals the wave of excitation originating in the atrioventricular node is first spread over the atria and then is spread over the ventricles through special rapidly conducting tissue (called Purkinje tissue)

that carries the wave to all parts of the ventricles at almost the same instant. In worms, arthropods and ascidians the beat originates in nerve cells located in or on the heart, and these are called neurogenic hearts. The two kinds of pacemaker tissue react very differently to certain drugs, notably acetylcholine, which inhibits myogenic hearts and accelerates neurogenic hearts. The striking differences in the two types of pacemaker mechanism indicate that they arose quite independently during the course of evolution. The myogenic pacemaker is more primitive than the neurogenic. *(See* CIRCULATION OF BLOOD: *Physiological Properties of the Heart.)*

Nervous Regulation of Hearts.— The heart rate of most animals is regulated by reflex nervous controls; and most hearts also respond to variations in blood pressure within the heart itself, the rate increasing when blood pressure falls and slowing when blood pressure rises.

In vertebrates, nerve fibres from the tenth cranial nerve (the vagus) pass from the brain to the heart, and stimulation of these fibres slows the heart and reduces the amplitude of its contraction. Fibres from the sympathetic nervous system reach the heart in all vertebrates except fishes; stimulation of these fibres accelerates the heart. Nerves seem to affect the heart rate by means of chemical mediators. Acetylcholine is associated with activity in the vagus; and sympathin, an adrenalinelike substance, is associated with activity in the sympathetic fibres. Acetylcholine inhibits vertebrate hearts, and adrenaline accelerates the hearts of both vertebrates and invertebrates.

In invertebrates various inhibitory and accelerator nerves pass from the central nervous system to the heart. These heart-regulating nerves form no consistent pattern among the various invertebrate groups, and the manner in which they affect heart rate is not well understood. *(See* also CIRCULATION OF BLOOD: *The Nervous Regulation of the Heart Beat.)*

Heart Rates.—Among warm-blooded vertebrates each species has a "normal" heart rate, the average rate at which the heart beats in a healthy individual at rest. In cold-blooded animals body temperature varies with environmental temperature, and the heart rate also varies with the temperature of the animal's environment. In all animals the rate of the heart beat varies widely with changes in bodily activity, with stress and with body temperature—in other words, the heart rate is directly related to the metabolic rate of the body. Therefore, statements of heart rate are almost meaningless unless the conditions under which the rates were counted are clearly stated. For example, the human heart normally beats about 72 times per minute, but disease, nervous tension, emotion and many other factors may increase the rate to 100 or more, and the rate may temporarily exceed 200 following violent physical exertion.

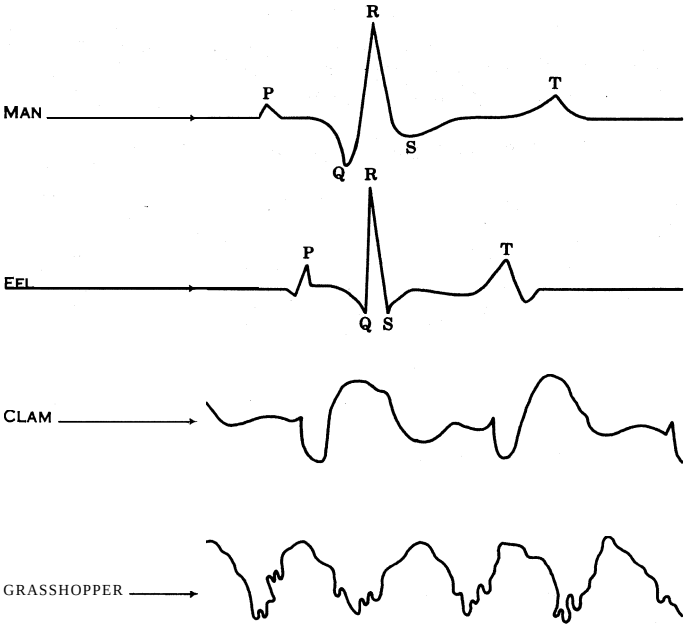
The requirements of the tissues of an animal's body vary from time to time, often from moment to moment. For any cardiovascular system to function efficiently, therefore, there must be a mechanism to increase or decrease heart rate. Since the heart muscle itself uses oxygen, however, an equilibrium point is soon reached beyond which the heart itself uses up the additional oxygen resulting from any further increase in heart rate.

In general, heart rate is faster in active animals than in sluggish animals. The heart rate is 40–80 per minute in squids, which are active mollusks, whereas in the much more sluggish clams and mussels it is only 2–20 per minute. This is not always true, however. In the hare the heart beats about 64 times per minute, whereas in the more sluggish rabbit the rate is about 200 per minute.

Heart rate is partly related to body size, large animals tending to have slower rates than small animals. In large mammals such as elephants and horses the heart beats 25–40 times per minute, whereas in rats and mice the rate is 300–500 per minute. In birds the heart rate is very high, and this is related at least in part to their high body temperatures. In the domestic fowl the rate is 150–180, and in small birds it is 200 or more per minute.

Electrocardiograms.— Activity of heart muscle. like that of many other tissues, is accompanied by changes in electrical potential, and such changes can be measured by suitable instruments. A heart beat consists of a succession of events, each involving a different part of the heart, and each with its own characteristic change in electrical potential. A recording of the sequence of these changes is called an electrocardiogram, which is therefore a graphic record of the varying electrical potential of the heart during one or more complete beats.

The electrocardiogram pattern is similar for all vertebrates, consisting of a series of slow waves representing positive and negative deflections. In the electrocardiograms shown in the figure, the patterns for man and the eel, both of which are vertebrates, are seen to be almost identical. There can be no doubt that the points of positive and negative deflection in these patterns



ELECTROCARDIOGRAMS ILLUSTRATING THE COMPARATIVE PHYSIOLOGY OF THE HEART

(to which the symbols P, Q, R, S, T are conventionally applied in man) relate to the same events in all vertebrates. Electrocardiograms from other myogenic hearts likewise consist of slow electrical waves, but the patterns are not the same as for vertebrates. The difference is evident in the electrocardiogram of a clam, an invertebrate with a myogenic heart, in the figure. Neurogenic hearts, such as those of arthropods, produce very different electrocardiograms, as is illustrated by the electrocardiogram of a grasshopper. Electrocardiograms from neurogenic hearts are "oscillatory"; *i.e.*, each wave is accompanied by numerous small deflections instead of being smooth as in myogenic hearts. It is believed that the oscillations in electrocardiograms from neurogenic hearts correspond to discharges from the pacemaker ganglion cells.

HEART, DISEASES OF THE. Evidence for the existence of some forms of diseases of the heart was found in the oldest Egyptian mummies. Disordered heart action was recognized by the Greek physicians, although of course its significance was not understood. It was not until William Harvey discovered the true nature of the circulation of the blood in **1628** that the background for more understanding was established. Several important anatomical studies of diseases of the heart were made in the latter part of the 17th century. From then on, there were sporadic contributions to the pathology and pathological physiology of heart diseases, but antemortem diagnosis made little

progress until René Laënnec invented the stethoscope in 1819. Stephen Hales nas the first to measure arterial blood pressure. in 1733. Rudolf Virchow contributed most to knowledge of the pathology of the circulatory system. The discoveries of X-ray by Wilhelm Rontgen in 1895, and of electrocardiography by Willem Einthoven in 1903 also contributed greatly to increased precision in diagnosis of diseases of the heart.

Clinicians who added much to knowledge concerning the nature and treatment of heart disease were William Withering, William Stokes. Dominic Corrigan, John Cheyne, Robert Adams, James Mackenzie and Thomas Lewis. all of the English or Irish school. Austin Flint. Jacob DaCosta, William Osler and James B. Herrick were the principal contributors in the United States.

At mid-20th century, diseases of the heart and blood vessels accounted for approximately one-third of all the deaths in the western world. They had increased in frequency with the lengthening of life expectancy among adults in the older age groups. The following represent the more important forms of diseases of the heart.

Congenital Heart Disease.—Congenital heart disease is that form of heart trouble which is present at birth. There are several anatomical varieties, some incompatible with extrauterine life, some causing no trouble whatever and all gradations in between. The outlook for some of these patients was greatly improved by the perfection of surgical procedures, the first of which was successful in 1938.

Rheumatic Fever.—This affects all parts of the heart but is most likely to involve the valves of the left side. Its cause, and therefore means of preventing it. have not been discovered, although streptococcus infection of the nose and throat have been implicated. At mid-20th century it was the most important cause of death of children between the ages of 5 and 19. Sometimes the scars on the valves cause them to be incompetent and sometimes to be narrowed, and often both. The severity of the valvular damage largely determines the course of the disease. The patient may develop congestive heart failure early, or he may live to old age without further trouble from this source.

Subacute Bacterial Endocarditis.—This is an infection, usually with streptococcus, always superimposed on a pre-existing rheumatic valvular lesion or on a congenital heart defect. It was uniformly fatal until the introduction of treatment with large doses of penicillin in 1944.

Hyperthyroidism and Hypothyroidism.—These cause heart troubles of different kinds. Each can usually be successfully treated medically, and the former can be treated surgically if need be.

Cardiovascular Syphilis.—Cardiovascular syphilis affects chiefly the big artery which distributes blood from the left side of the heart (the aorta). It causes trouble in one of three ways or a combination thereof. The vessel may dilate to form an aneurysm. This may rupture. causing instant death. Syphilis may involve the aortic valve, making it insufficient. The mechanics of this lesion are quite similar to those of rheumatic aortic involvement. Syphilis may narrow the mouths of the coronary arteries, the blood vessels which supply the heart muscle itself with blood. In this case, there is usually severe chest pain. The incidence of cardiovascular syphilis in the white population has steadily diminished because of the improvement in its prevention and treatment. The introduction of penicillin in the treatment of syphilis in 1942 further curtailed this disease.

Anaemia.—Anaemia, from whatever cause, if of sufficient severity and duration may cause heart failure. This is because the heart has to overwork constantly and does not get sufficient oxygen and other nutriments. When properly treated it results in no permanent heart damage.

Obesity.---Obesity may, by itself, cause heart trouble but is far more often a complicating feature in other forms of heart disease. It causes difficulty because the heart has to supply blood to the extra tissue 24 hours a day, and the patient and his heart have to work harder whenever he attempts any form of exertion. Furthermore, there may be a deposit of fat between the heart muscle fibres in a way that interferes with their mechanical efficiency.

Hypertension (High Blood Pressure).—Hypertension is one of the commonest causes of disability and death. Its cause is unknown in most instances. although in a few, certain kinds of kidney disease may be held responsible. The course of the disease varies greatly from person to person. In some it is compatible with many years of active life without any symptoms whatever. In others it leads to death within a year of its discovery. The mechanism of death from high blood pressure is usually one of three: heart failure; a vascular accident in the brain; or kidney failure. Various forms of medical treatment had been tried by mid-20th century, as well as operations on the sympathetic nervous system. None of these were wholly successful, but in a given case one or more of them seemed to alleviate symptoms and to prolong life.

Arteriosclerosis.—This chiefly affects the heart through hardening of the coronary arteries. These may be either narrowed or actually occluded. In the latter instance, the vessel may be shut off by the hardening itself or, more often, by the development of a blood clot at the site. The chief symptoms are those of angina pectoris or coronary thrombosis. These consist in pains in the chest. frequently radiating to one or both arms or to the neck and teeth. In the former, the pain is usually of short duration, lasting no longer than 15 minutes, and usually caused by exertion or excitement. In the latter, the pain usually lasts more than an hour and may last for several days. The occlusion usually causes a withering of the portion of the heart muscle supplied by the occluded branch of the coronary tree. This muscle is replaced by scar tissue if the patient lives. Both of these are compatible with a reasonably active existence in many patients for many years. The freer use of oxygen, the discovery of heparin and dicumarol to retard the clotting of the blood and other measures improved the outlook considerably.

Psychoneurosis Affecting the Circulatory System.—This is usually one of two kinds. Neurocirculatory asthenia (effort syndrome) is primarily a psychiatric disorder. The heart does not respond well to exercise in patients with this difficulty, but that is because they will not exercise enough to keep it toned up. Of much more importance is the anxiety neurosis directed toward the heart in patients with or without organic heart disease. This may be produced in some patients by physicians who are alarmists. It causes needless incapacity and worry.

Arrhythmias.—They may accompany any form of heart disease or occur in an otherwise strictly normal heart. They vary in severity from those of no clinical importance. such as simple sinus arrhythmia, which nearly all children have, through ventricular fibrillation, which produces sudden death. Sinus arrhythmia merely means that the heart rate varies with the phases of respiration. Premature systoles (extra systoles) are usually of no importance. A heartbeat is touched off from either the top or the bottom part of the heart prematurely and usually replaces the next normal beat. Even when they occur frequently in an otherwise normal heart, they are in no way incapacitating. Paroxysmal tachycardia is usually harmless unless it occurs as a complicating feature of some other form of heart disease or in the elderly, or if it lasts a long time. It is characterized by attacks of very rapid regular heart action. beginning and ending suddenly, ranging in rate from 160 to 200 beats per minute and lasting from a few seconds to a few weeks.

Auricular flutter and auricular fibrillation are close cousins in which the top part of the heart (the auricles) is the primary seat of the disturbance. In flutter, the auricles beat very rapidly, usually around 300 times a minute, and the bottom part of the heart may be regular or have a regular irregularity with coupled beats. The ventricle rarely beats more than 150 times a minute in the presence of flutter. In auricular fibrillation, auricular activity is chaotic and the ventricles beat with a completely irregular rhythm. When uncontrolled by digitalis, the ventricular rate is usually well over 100. Both of these disturbances can occur in attacks, but more often auricular fibrillation becomes the established rhythm. Both can, but rarely do, occur in otherwise normal hearts. The paroxysmal variety may be prevented by the use of quinidine. Auricular fibrillation is compatible with years of active life in many instances but is to be regarded as a more serious arrhythmia than

the ones previously described.

Heart blocks of various degrees represent interference in some portion of the pathway over which the impulse to contract travels through the heart. They range from partial auriculoventricular block through intraventricular conduction defects, bundle branch blocks, to complete heart block. The first represents a delayed conduction from auricle to ventricle; the second, a slowing down of the impulse within the ventricular walls; the third, a block in the pathway on one or the other side of the heart; and the last, a complete dissociation of auricular contractions from ventricular ones, with each chamber establishing its own rate. Most forms of heart block are the result of a diffuse process going on in the heart muscle which happens to catch that portion of the conducting mechanism appropriate to the label of the block. Most forms of heart block represent signs of an alteration of the outlook for the worse.

Congestive Heart Failure. — Congestive heart failure may occur as a result of any of the types of organic heart disease. It represents a failure of the one function of the heart, namely, to pump blood adequately. This results in an increase in venous pressure and usually in a failure to deliver adequate amounts of oxygen to the tissues. The increase in venous pressure, plus some other factors, may result in swelling of the liver and ankles and congestion in the kidneys and intestinal tract. When the left side of the heart is chiefly at fault, the lungs may be the site of most of the congestion, with an outpouring of watery fluid into the air sacs. Congestive failure may be acute or chronic. The acute variety may cause death in a few minutes, and the chronic variety may last for many years. The proper use'of digitalis, the introduction of theophylline derivatives and mercurial diuretics, better knowledge of proper dietary regimens and especially of the importance of a low intake of sodium ion greatly improved the outlook in nearly all of these cases. (E. B. By.)

HEART AND LUNG, SURGERY OF. Surgery of the heart and great vessels developed particularly during the first half of the 20th century, with rapid and dramatic advances especially after 1939, and continued into the second half. Operations within the chest remained unsafe until the early 1930s. After that time rapid advances were made and the risk of removal of a portion of a lung was reduced to a minimum. Thus it was inevitable that removal of lung tissue eventually was applied in treatment of numerous pulmonary lesions.

SURGERY OF THE HEART AND GREAT VESSELS

Heart Wounds. — Traumatic injuries of the heart, either by a foreign body or by a sharp object, are usually fatal if both entrance and exit wounds are produced. Fatality more often results from filling of the pericardial cavity with blood (cardiac tamponade), thus interfering with heart function, than from loss of blood. If death does not immediately ensue, heart function may be maintained by aspiration (removal) of blood from the pericardial cavity, while preparations are being made for closing the defect by suture.

Although J. Roberts suggested closure of heart wounds by surgery in 1881, report of a successful operation by L. Rehn did not appear until 1896. More reports of successful cases soon followed and until 1940 it was thought that all wounds required closure by suture. In 1943 A. Blalock and M. M. Ravitch reported that many of these injuries could be satisfactorily managed by improving the return flow of blood to the heart through repeated aspiration of blood from the pericardial cavity. If bleeding continued, however, suture of the wound was required.

Traumatic injury to large vessels within the pericardial cavity is usually attended by immediate death, since this wound does not tend to seal as do wounds of the heart muscle, and cardiac tamponade becomes severe.

Foreign bodies may lodge in the heart muscle and remain for an indefinite period of time. If the blood supply to the heart through the coronary circulation is not materially affected, and the object is not large, it may cause no dysfunction. Larger foreign objects are apt to cause complications and should be removed. This removal usually can be accomplished without undue risk.

Congenital Cardiovascular *Defects.* — *Patent ductus arteriosus* is a persistence of the opening between the aorta and pulmonary artery, which is necessary before birth. The ill effects caused by this lesion result from increased work put on the heart by abnormal recirculation of blood through the lungs. In some cases an infection develops in the ductus, and a blood stream infection ensues. Occasionally an aneurysm may form in this communication, with eventual death from its rupture.

Although surgical obliteration of a patent ductus was first suggested by J. C. Munro in 1907, this operation was not successfully performed until 1939 by R. E. Gross. Many successful operations for this lesion have since been performed. By closing this shunt from the systemic to the pulmonic circulation, either through division and suture or ligation (tying) of the ductus, normal circulatory arrangements are re-established. Life expectancy is returned to normal unless irreparable damage to the heart has already occurred.

Tetralogy of Fallot is a congenital abnormality, the so-called blue baby disease. It consists of (1) stenosis (constriction) of the pulmonary artery; (2) a persistent defect in the wall between the ventricles; (3) an aorta so positioned (overriding) at the wall defect that it receives blood from both the right and left ventricles; and (4) thickening (hypertrophy) of the right ventricular walls. The epochal work of A. Blalock and H. Taussig, in 1945, on the operative treatment of this condition was one of the major advancements in this field of surgery. Ill effects of these lesions result chiefly from a deficient flow of blood through the lungs. The Blalock procedure produces a shunt from a systemic artery (subclavian) to a pulmonary artery, thus bypassing obstruction of the inlet of the main pulmonary artery. An operation similar in principle was reported by W. J. Potts, S. Smith and S. Gibson in 1946. This entailed uniting the aorta directly to a pulmonary artery by the use of a specially devised clamp.

The results of surgery in cases of tetralogy of Fallot are both dramatic and satisfactory; cyanosis (blueness of the skin) is relieved, exercise tolerance is greatly raised, and significant elevations of blood oxygen saturation levels are attained. The risk of the operation has been reduced to approximately 5% to 10%. Closure of the ventricular wall defect under direct vision under extracorporeal circulation gives more satisfactory permanent results but carries a greater risk. The results of surgery have been very gratifying in that many children suffering from this heart abnormality have been returned to a relatively normal way of life.

Pulmonic and infundibular stenosis are a narrowing of the pulmonic valve or of the entrance to the pulmonic valve, named the infundibulum. They may occur without other abnormalities within the heart. In many such patients there is an associated defect in the wall between the atria. The ill effects of this lesion are similar to those in tetralogy of Fallot, since insufficient blood passes through the lungs for oxygenation of the tissues. R. C. Brock of London, Eng., in 1948 devised a direct approach to this problem by cutting and dilating the constricted valve with a specially constructed knife. His operation was also used in some cases of tetralogy of Fallot in which the pulmonary artery was enlarged beyond a constricted valve. In the case of pulmonic stenosis, dramatic results are achieved by opening this constricted valve, thus allowing a normal flow of blood from the right heart through the lungs. Correction of these lesions under direct vision, after reducing the body temperature to a very low level, has given better results at little or no greater risk. If cyanosis has been present previously because of a defect in the wall between the atria, this condition immediately disappears and strain on the right heart is relieved.

Coarctation of the aorta consists of almost complete constriction of the thoracic aorta at the point where the ductus arteriosus unites the aorta with the pulmonary artery before birth. Constriction of the vessel causes the blood pressure in the upper extremities and head region to become much elevated, while that below the site of constriction is below normal. This condition occurs in spite of the development of considerable collateral circulation around the point of stricture. Excessive heart strain with failure, the production of aneurysms and cerebral hemorrhages are

common results of this lesion.

Until 1945, when C. Crafoord of Stockholm, Swed., corrected this condition by cutting out the constricted portion and uniting the cut ends by suture, the life span of patients with this lesion was much shortened. Crafoord's accomplishment was duplicated soon thereafter by R. E. Gross. The risk of operation is less than 5%.

Septal defects consist of a communication between the right and left sides of the heart, either between the atria or between the ventricles. The deformity results from a failure of completion of the septum, or wall, between the two sides. A septal defect between the ventricles is likely to produce more harmful effects and be more difficult to repair than one between the atria. The ill effects of these lesions are usually caused by added strain on the heart with ultimate heart failure.

Operative repair of these defects was still in the developmental stage in the late 19jos, although an increasing number of successful surgical results were being reported. A closed method of repair was devised and reported by C. P. Bailey and others in 1952 and by T. Sondergard, V. O. Bjork and Crafoord in 1953. Open or semiopen methods (under direct vision) were used by R. Gross and C. A. Hufnagel and by J. Gibbon. The results following surgical closure may be excellent. However, if insufficient tissue is available for closing the defect. the results are less satisfactory.

Factors that have been of help during these operations include (1) hypothermia or lowering of the body temperature to as low as 30° C.; and (2) extracorporeal circulation, in which the venous blood is removed from the body by a system of tubes and pumped into the arterial system after being reoxygenated (heart-lung bypass). Closure of ventricular septal defects under direct vision, using heart-lung bypass, became the method of choice in 1956.

Acquired Defects.—Aortic and Mitral *Insufficiency* or *Stenosis.*—Following an attack of rheumatic fever, infection of the aortic and mitral valves may ultimately lead to constriction of the valve opening or otherwise prevent it from functioning properly. The chief ill effect of this defect is increased work on the heart with ultimate failure.

Although clinical investigation of mitral stenosis, and an attempt to relieve this condition by surgery, was reported as early as 1922, sustained satisfactory results were not obtained until C. P. Bailey devised an operation known as commissurotomy in 1948. Dilatation of the valve, by either finger or instrument, in many instances leads to return of valvular function to such a degree that the patient achieves normal status. The risk of operation is largely dependent upon the status of the valve and the heart at the time of surgery. For early cases mortality is less than 5%; however. for persons who have developed the severe stage of the disease, the risk may be 25% or more.

Surgical treatment of mitral insufficiency and aortic stenosis and insufficiency was still in the developmental stage in the late 1950s. Operative correction under direct vision using heart-lung bypass (see above) or hypothermia gave encouraging results. A plastic valve devised by C. Hufnagel benefited many patients with aortic insufficiency. Valves made of plastic, steel and other materials have been used in laboratory animals with varying degrees of success. In the late 1950s surgery of these valvular lesions by direct vision appeared more promising than did the use of artificial valves.

Constrictive *Pericarditis.*—In constrictive pericarditis, as the term indicates, the heart is tightly constricted by an envelope of scar tissue, which develops in the pericardial cavity as a result of chronic infection in that area. Rheumatic fever and tuberculosis are thought to be the commonest causes of this malady. The ill effects result from prevention of return flow of blood into the heart from the venous circulation. Removal of the constricting envelope of thickened pericardium and scar tissue was first proposed by E. D. Délorme of France in 1898. It was first successfully performed by L. Rehn of Germany in 1920 and resulted in complete relief of symptoms. In the United States E. D. Churchill in 1929 reported the first successful case. When the operation is properly performed, most patients who do not have irreparable heart damage are completely relieved and live out a normal life span. (See also HEART, DISEASES OF THE.)

SURGERY OF THE LUNGS

Cancer of the Lung.—This tumour constitutes approximately 10% of all malignant tumours. After 1925 it increased by at least 400%. Although the cause has not been proved, the irritating effects of certain chemicals on the lining of the air passages undoubtedly contributes to its etiology.

Cancer of the lung was a hopeless condition until 1933, when E. A. Graham and J. J. Singer reported the first successful removal of an entire lung (pneumonectomy) for this lesion. The patient, a physician, was living and free of evidence of tumour more than 2j years after the operation. Concentrated studies of both cancer of the lung and of surgical means of alleviation have been made. In some early cases, especially in older persons, removal of less than the entire lung has given highly satisfactory results with less risk. Early detection of tumour by mass X-ray mobile unit screening should greatly aid (1) in increasing the percentage of removable tumours; (2) in increasing the percentage of cures following surgery; and (3) in avoiding strain on the heart since less lung removal is necessary. In younger persons (under 50) the risk of pneumonectomy is less than 5%. The risk in older patients is approximately 15%. All available means for making an early diagnosis should be utilized. These include the use of bronchoscopy and of improved techniques of X-ray study and examination of the sputum for cancer cells.

Congenital Malformation of the Lung.—Cystic disease of the lung may be congenital. Abnormal development of the lung may lead to the formation of cysts, which may be single or multiple, large or small. This abnormality interferes with pulmonary function in one of two ways, either by infection of the cyst and the production of a condition somewhat like lung abscess or bronchiectasis, or by overdistention of the cystic space, thus collapsing the normal lung tissue. This congenital type of cystic condition should not be confused with the acquired type, which consists of emphysematous blebs and bullae which are not lined by respiratory epithelium. This latter type usually occurs in persons over the age of 40 or 50, whereas the congenital type is seen at any age. After resection of lung tissue became safe in 1931, this therapy was applied to cystic disease of the lung. Removal of involved portions while sparing all possible functioning lung tissue is the object of surgical treatment. Since in most patients the disease is limited to less than one-fourth the entire lung, removal of the involved part returns the person to practically normal status.

Congenital malformation of the lung may involve chiefly the vascular elements. A common form of this is a fistula (communication) between the arterial and venous sides of the circulation within the lung. Since this condition returns unoxygenated blood directly to the left heart, the ill effects of the lesion are produced by lowering arterial blood oxygen saturation. These fistulas tend to increase progressively in size and may rupture, causing a fatal hemorrhage. Treatment consists of the surgical removal of the involved part. In an otherwise normal person, the risk of operation is less than 5%.

Pulmonary Tuberculosis.--One of the greatest contributions of chest surgery has been in the field of pulmonary tuberculosis. Before 1940, because of its safety and effectiveness, collapse of the chest wall by the removal of several ribs was the surgical procedure of choice. This operation (known as thoracoplasty) was first attempted in Europe by de Cerenville in 188j. L. Brauer (1909), L. P. Friedrich (1911) and F. Sauerbruch contributed to the development of the operation. Collapse therapy by a modified type of thoracoplasty in one stage with removal of only a small portion of one rib and using a paraffin prosthesis has been most useful in selected cases.

Resection (or excision of part) of the lung for tuberculosis made little progress until antituberculosis drugs became available. The risk of resection in 1942 was approximately 45% for pneumonectomy and 26% for lobectomy. With the development of the antimicrobial agents streptomycin in 1944, para-aminosalicylic acid in 1946 and isonicotinic acid hydrazide in 1952, surgical resection became much safer and could be applied to many more

severely involved patients. Also, with the use of these drugs, better control of the disease was obtained, and therefore lesions of a much lesser magnitude were presented for therapy. In addition to pneumonectomy (which was seldom performed after 1955) and lobectomy, segmental resection was added and is applicable in a high percentage of patients requiring surgical therapy. Of even greater importance is the marked improvement that may be anticipated from surgical therapy. In 1942 the results following pneumonectomy were satisfactory in only 41% and following lobectomy in 69%. whereas by 1955 excellent results could be anticipated in 95% of cases of segmental resection or lobectomy and in 85% to 90% of pneumonectomy.

Bronchiectasis.—Bronchiectasis, meaning dilatation of the bronchus, is the infection and destruction of the wall of the air passage with resultant dilatation and infection of the surrounding lung. After 1930 when resection of the lung had become a safe procedure, treatment was almost entirely surgical, and after 1945 the risk of operation was less than 2%. Removal of only the involved portion of the lung along segmental lines is usual. Since the disease is not infrequently bilateral, portions of either lung may be removed in stages with very satisfying results.

Lung Abscess.—With the development and use of antibiotics and the sulfonamides, the incidence of lung abscess decreased markedly. Furthermore, with various surgical advances, the occurrence of lung abscess following operations about the mouth, nose and throat became infrequent. A high percentage of these lesions respond to medical management. Those which resist this form of treatment may be managed either by simple drainage or by resection of that portion of the lung. The risk of operation is slight (5% or less), and highly satisfactory results may be expected.

HEARTH, the part of a room where a fire is made. usually of stone, bricks. tiles, etc., having a chimney above, the fire being lighted either on the hearth itself or in a receptacle placed there for the purpose.

The word is also applied to the fire and cooking apparatus on board ship; the floor of a smith's forge; the floor of a reverberatory furnace on which the ore is exposed to the flame; and the lower part of a blast furnace through which the metal goes down into the crucible. An open-hearth furnace is a regenerative furnace of the reverberatory type used in making steel; hence open-hearth steel process (*q.v.; see* also IRON AND STEEL).

The term is also used as equivalent to the home or household. (For the tax in England based on hearths, *see* HEARTH TAX.)

HEARTH TAX. This impost was a tax imposed in England at a rate of 2*s.* for each hearth: it was levied upon all houses unless the occupier (1) was exempt from paying church or poor rates, or (2) was certified as living in a tenement under the value of 20*s.* per annum, and not having land to that value, nor possessing goods to the value of £10. It was first levied in 1662, but because of its unpopularity it was repealed in 1689, although it was producing £170,000 a year. The principle of the tax was not new in the history of taxation. for in Anglo-Saxon times the king derived a part of his revenue from a *fumage*, or tax of smoke, levied on all hearths except those of the poor. It appears also in the hearth-penny or tax of a penny on every hearth.

HEARTS, a game of cards which appeared in the United States about 1880, possibly a descendant of reversis as played in the 18th century. In all variants. the chief object is to avoid winning any hearts in tricks. The full pack of 52 cards is used. and all the cards are dealt out. With more or less than four players (the usual number), some small cards are discarded from the pack to equalize the hands. Eldest hand makes the opening lead, and the rules of play are as in whist, but there is no trump suit. Other hands must follow suit to a lead if able; the highest card of the suit led wins the trick; the winner of a trick leads to the next.

In the simplest form of the game, each heart counts one point against the player winning it in a trick. A running total score is kept for each individual, and final settlement of stakes is made on the difference of totals—the lowest score of course being best. It is usually preferred to make settlement after every deal, on the Howell plan. Equal numbers of chips are distributed to the participants at the outset. After play of a deal, each player pays into a pool as many chips for each heart he has taken as there are players in the game other than himself. He then takes out of the pool one chip for every heart out of 13 that he did not win. The pool is thus exhausted with every deal. Another alternative is "sweepstake" settlement. The pool is built up in the same way, but can be won only by a player who was "clear" (won no hearts) or split by two who were clear. In all other cases the pool is a "jack" and remains to be won with the ensuing pool.

In *Spot Hearts* the penalty value of each heart depends on its rank; the ace costs 14, king 13, queen 12, knave 11, others their pip value. In *Joker Hearts*, the joker is added to the pack and the deuce of hearts is discarded. The joker ranks as a heart, between the knave and the ten. It may not be played by discard, unless a higher heart has previously been discarded upon the same trick. Where each other heart costs the winner one chip, the joker costs five.

The basic game has largely been supplanted by variants that have borrowed features from other games (polignac, reversis, French whist). Most played is *Black Lady Hearts*. Besides the hearts, each counting one, the penalty cards include the queen of spades, counting 13. Prior to the opening lead, each player passes any three cards of his original hand to his right (or left) neighbour. *Omnibus Hearts* adds two more rules: the ten (or knave) of diamonds counts 10 *plus* for the player winning it in a trick, and if a player captures all the hearts, the queen of spades, and the ten of diamonds, he scores plus 26 instead of minus 16.

In *Domino Hearts* each hand is dealt only six cards. The balance of the pack is placed face down in the centre. In the early play, discarding is not permitted. A player unable to follow suit must draw cards from the top of the pack until he can. Discarding is allowed after the pack is exhausted. Each hand drops out of play on getting rid of his last card, and the last survivor must add his remaining cards to his tricks. Usually only the hearts are counted as "minus" cards.

Other variants are adaptations of the game to more or less than four players. In a two-hand version, each is dealt 13 cards. The rules of play are as usual, but after each trick the winner and then his opponent draws one card from the top of the pack. When the pack is exhausted, the 13 cards remaining in each hand are played out. The queen of spades is usually counted against the winner, as well as all hearts.

In *Cancellation Hearts*, for six to ten players, two packs are shuffled together and dealt out into equal hands. Odd cards remaining are put in a widow, which goes to the winner of the first trick. When two identical cards fall on the same trick, they cancel each other—neither can win the trick. When an entire trick is thus cancelled out, it remains on the table and goes to the next winner of a trick. Usually the hearts and the queen of spades are the only cards counted in scoring.

HEAT is a general term. applied to that branch of physical science which deals with the effects produced by heat on material bodies, the laws of transference of heat and the transformations of heat into other kinds of energy.

In this broad field of science, little progress was made until the early 19th century. In line with the division of the elements by the ancient Greek philosophers into earth, air, fire and water, heat was generally believed to be a separate, although weightless. substance. A body was supposed to be hot or cold in proportion to the quantity of this substance with which its pores were permeated. When an object became hot under hammering, it was explained that

the impact had forced the imponderable substance, which was named "caloric," to the surface. (See *The Nature* of *Heat*, below.) The phenomenon of combustion was similarly explained; an object burned rapidly or with difficulty in accordance with the amount of another mythical substance, named "phlogiston," that it contained.

Even after the "phlogiston" theory had been upset and the real nature of combustion had been established by Antoine Laurent Lavoisier in 1775, belief in "caloric" persisted. Lavoisier himself listed it among the simple substances, or elements, in his *Traité élémentaire de chimie,* published in *1789. (See* CHEMISTRY: *History* of *Chemistry.)*

The object here is to indicate the relation of the different branches of the science of heat and their historical development, which are discussed in greater detail in separate articles. Advances in the theories of the influence of heat on the properties of matter are discussed under QUANTUM MECHANICS.

For developments in the measurement of the effects of heat and applications in various fields of science and engineering *see* under THERMODYNAMICS, THERMOMETRY and HEATING AND VENTILATION.

This article is divided into the following sections:

I. DEFINITIONS

The term heat is employed in ordinary language in a number of different senses. This makes it a convenient term to employ for the general title of the science, but the different meanings must be carefully distinguished in scientific reasoning. For the present purpose, omitting metaphorical significations, we may distinguish four principal uses of the term: (1) sensation of heat; (2) temperature, or degree of hotness; (3) quantity of thermal energy; (4) radiant heat, or energy of radiation.

(1) From the sense of heat, aided in the case of very hot bodies by the sense of sight, we obtain our first rough notions of heat as a physical entity, which alters the state of a body and its condition in respect of warmth, and is capable of passing from one body to another. By touching a body we can tell whether it is warmer or colder than the hand, and, by touching two similar bodies in succession, we can form a rough estimate, by the acuteness of the sensation experienced, of their difference in hotness or coldness over a limited range. If a hot iron is placed on a cold iron plate, we may observe that the plate is heated and the iron cooled until both attain appreciably the same degree of warmth; and we infer from similar cases that something which we call "heat" tends to pass from hot to cold bodies, and to attain finally a state of equable diffusion when all the bodies concerned are equally warm or cold. Ideas such as these derived entirely from the sense of heat, are, so to speak, embedded in the language of every nation from the earliest times.

(2) From the sense of heat, again, we naturally derive the idea of a continuous scale or order. expressed by such terms as summer heat, blood heat, fever heat, red heat, white heat, in which all bodies may be placed with regard to their degrees of hotness, and we speak of the temperature of a body as denoting its place in the scale, in contradistinction to the quantity of heat it may contain.

(3) The quantity of heat contained in a body obviously depends on the size of the body considered. Thus a large kettleful of boiling water will evidently contain more heat than a teacupful, though both may be at the same temperature. The temperature does not depend on the size of the body, but on the degree of concentration of the heat in it; *i.e.,* on the quantity of heat per unit mass, other things being equal.

It may be taken as axiomatic that a given body in a given state under given conditions must always contain the same quantity of heat, and that different quantities of the same substance in the same state under the same conditions must contain quantities of heat proportional to their several masses, except for the effect of shape on vibrational heat, normally not detectable. But it is for experiment to determine how the heat content varies for any given substance in different states, or for different substances in similar states and how it is affected by variations of temperature and pressure in each case.

(4) It is a matter of common observation that rays of the sun or of a fire falling on a body warm it and it was in the first instance natural to suppose that heat itself somehow traveled across the intervening space from the sun or fire to the body warmed, in much the same way as heat may be carried by a current of hot air or water. But we now know that energy of radiation is not the same thing as heat, though it is converted into heat when the rays strike an absorbing substance. The term radiant heat, however, is generally retained, because radiation is commonly measured in terms of the heat it produces and because the transference of energy by radiation and absorption is the most important agency in the diffusion of heat.

II. TEMPERATURE

1. Evolution of the Thermometer.— The first step in the development of the science of heat was necessarily the invention of a thermometer, an instrument for indicating temperature and measuring its changes. The first requisite in the case of such an instrument is that it should always give, at least approximately the same indication at the same temperature.

The air thermoscope of Galileo, illustrated in fig. 1, which consisted of a glass bulb containing air, connected to a glass tube of small bore dipping into a coloured liquid, though very sensitive to variations of temperature, was not satisfactory as a measuring instrument, because it was also affected by variations of atmospheric pressure.

The French doctor Jean Rey describes in a letter dated 1631 a

thermometer in which the expansion of water itself was used to indicate temperature, but it is not clear from his description whether the thermometer tube was left open or closed.

The type of thermometer familiar at the present time, containing a liquid hermetically sealed in a glass bulb with a fine tube attached. was first brought into general use by the grand duke Ferdinand II of Tuscany and he is said to have possessed such instruments as early as 1654. They were much employed by the members of the Accademia del Cimento founded under his protection at Florence, and were long known as Florentine thermometers.

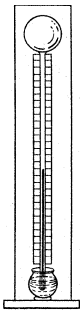

FIG. 1.—GALILEO'S AIR THERMOSCOPE

Alcohol was the liquid first employed and the degrees, intended to represent thousandths of the volume of the bulb, were marked with small beads of enamel fused on the stem, as shown in fig. 2, which represents two thermometers as depicted in the Saggi *di naturali esperienze* published by the Accademia del Cimento in 1667.

In order to render the readings of such instruments comparable with each other, it was necessary to select a fixed point or standard temperature as the zero or starting point of the graduations. Instead of making each degree a given fraction of the volume of the bulb, which would be difficult in practice, and would give different values for the degree with different liquids, it was soon found to be preferable to take two fixed points, and to divide the interval between them into the same number of degrees. It was natural in the first instance to take the temperature of the human body as one of the fixed points. In 1701 Sir Isaac Newton proposed a scale in which the freezing point of water was taken as zero, and the temperature of the human body as 12°. About the same date (1714) Gabriel Daniel Fahrenheit (for biographies of scientists mentioned in this article, see individual articles under their names) proposed to take as zero the lowest temperature obtainable with a freezing mixture of ice and salt. and to divide the interval between this temperature and that of the human body into 12°. To obtain finer graduations the number was subsequently increased to 96°.

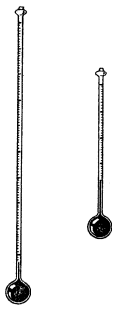

FIG. 2.—EARLY FLORENTINE THERMOMETERS, 1667

Alcohol in glass, graduated with enamel beads on stem

The freezing point of water was at that time supposed to be somewhat variable, because as a matter of fact it is possible to cool water several degrees below its freezing point in the absence of ice. Fahrenheit showed, however, that as soon as ice began to form the temperature always rose to the same point, and that a mixture of ice or snow with pure water always gave the same temperature. At a later period he also showed that the temperature of boiling water varied with the barometric pressure, but that it was always the same at the same pressure, and might therefore be used as the second fixed point (as Edmund Halley and others had suggested) provided that a definite pressure, such as the average atmospheric pressure, were specified. The freezing and boiling points on one of his thermometers, graduated as already explained, with the temperature of the body as 96°, came out in the neighbourhood of 32° and 212° respectively, giving an interval of 180° between these points. Shortly after Fahrenheit's death (1736) the freezing and boiling points of water were generally recognized as the most convenient fixed points to adopt, but different systems of subdivision were employed. Fahrenheit's scale, with its small degrees and its zero below the freezing point, possesses undoubted advantages for meteorological work, and is still retained in most English-speaking countries. For general scientific purposes, however, the centigrade system. in whirh the freezing point is marked 0° and the boiling point 100°, is now almost universally employed, on account of its greater simplicity from an arithmetical point of view. For work of precision the fixed points have been more exactly defined (see THERMOMETRY), but no change has been made in the fundamental principle of graduation.

2. Comparison of Scales Based on Expansion. — Thermometers constructed in the manner already described will give strictly comparable readings, provided that the tubes be of uniform bore, and that the same liquid and glass be employed in their construction; but they possess one obvious defect from a theoretical point of view, namely, that the subdivision of the temperature scale depends on the expansion of the particular liquid selected as the standard. A liquid such as water, which, when continuously heated at a uniform rate from its freezing point, first contracts and then expands, at a rapidly increasing rate, would obviously be unsuitable; but there is no a priori reason why other liquids should not behave to some extent in a similar way. As a matter of fact, it was soon observed that thermometers carefully constructed with different liquids, such as alcohol, oil and mercury, did not agree precisely in their indications at points of the scale intermediate between the fixed points, and diverged even more widely outside these limits. Another possible method. proposed in 1694 by Carlo Renaldini (1615–1698), professor of mathematics and philosophy at Pisa. would be to determine the intermediate points of the scale by observing the temperatures of mixtures of ice-cold and boiling water in varying proportions. By this method, the temperature of 50° C. would be defined as that obtained by mixing equal weights of water at 0° C. and 100° C.; 20° C., that obtained by mixing 80 parts of water at 0° C. with 20 parts of water at 100° C. and so on. Each degree rise of temperature in a mass of water would then represent the addition of the same quantity of heat. The scale thus obtained would, as a matter of fact, agree very closely with that of a mercury thermometer, but the method would be very difficult to put into practice, and would still have the disadvantage of depending on the properties of a particular liquid. namely, water, which is kno n to behave in an anomalous manner in other respects.

At a later date, the researches of Joseph Gay-Lussac (1802) and Henri Regnault (1847) showed that the laws of the expansion of gases are much simpler than those of liquids. Whereas the expansion of alcohol between 0° C. and 100° C. is nearly seven times as great as that of mercury, all gases (excluding easily condensable vapours) expand equally, or so nearly equally that the differences between them cannot be detected without the most refined observations. This equality of expansion affords a strong a priori argument for selecting the scale given by the expansion of a gas as the standard scale of temperature, but there are still stronger theoretical grounds for this choice, which will be indicated in discussing the absolute scale (see in *Mechanical* Theory of Heat, below). Among liquids mercury is found to agree most nearly with the gas scale, and is generally employed in thermometers for scientific purposes on account of its high boiling point and for other reasons.

The differences of the mercurial scale from the gas scale having been carefully determined, the mercury thermometer can be used as a secondary standard to replace the gas thermometer within certain limits, as the gas thermometer would be very troublesome to employ directly in ordinary investigations.

For certain purposes, and especially at temperatures beyond the range of mercury thermometers, electrical thermometers, also standardized by reference to the gas thermometer, have been generally employed in recent years; while for still higher temperatures beyond the range of the gas thermometer. thermometers based on the recently established lams of radiation are the only instruments available. For a further discussion of the theory and practice of the measurement of temperature, see the article THERMOMETRY.

III. CHANGE OF STATE

Among the most important effects of heat is that of changing the state of a substance from solid to liquid. or from liquid to vapour. All substances, with the exception of some unstable compounds, are known to be capable of existing in each of the three states under suitable conditions of temperature and pressure.

The transition of any substance, from the state of liquid to that of solid or vapour under the ordinary atmospheric pressure, takes place at fixed temperatures, the freezing and boiling points, which are very sharply defined for pure crystalline substances, and serve in fact as fixed points of the thermometric scale. A change of state cannot, however, be effected in general without the addition or subtraction of a certain definite quantity of heat. If a piece of ice below the freezing point is gradually heated at a uniform rate, its temperature may be observed to rise regularly until the freezing point is reached. At this point it begins to melt, and its temperature ceases to rise. The melting takes a considerable time, during the whole of which heat is being continuously supplied without producing any rise of temperature, although if the same quantity of heat were supplied to an equal mass of water the temperature of the water would be raised to the extent of nearly 80° C.

Heat thus absorbed in producing a change of state without rise of temperature is called latent heat, a term introduced by Joseph Black, who was one of the first to study the subject of change of state from the point of view of heat absorbed.

When a substance may be found in two or more characteristically different states which will continue to maintain their separate existence while in contact with each other, these states are called the phases of the system; thus a vessel containing ice and liquid water, with an atmosphere of water vapour above the surface provides a system of three phases, and is said to have one component since it is made up of only one basic substance. It is possible to have systems of two or more components which also exhibit several different phases; thus a solution of salt and water can provide three phases in coexistence. When heat is added or withdrawn so that some of the substance is converted from one phase to another phase, the process is known as a phase change of the first order.

In 1933 P. Ehrenfest pointed out that phase changes also are found in which the latent heat is theoretically of zero magnitude and the significant change lies in the values of the heat capacity above and below the transition point; he suggested the term second order phase change for such processes. There are also certain exceptional classes of phase changes which take place over a temperature interval rather than at a point. The mathematical and statistical theory of the different kinds of phase changes was critically reviewed by H. N. V. Temperly in 1956.

1. General Phenomena of Fusion. — There are two chief varieties of the process of fusion, crystalline and amorphous, which are in many ways distinct, although it is possible to find intermediate cases which partake of the characteristics of both. The melting of ice may be taken as a typical case of crystalline fusion. The passage from rigid solid to mobile liquid occurs at a definite surface without any intermediate stage or plastic condition. The change takes place at a definite temperature, the fusing or freezing point, and requires the addition of a definite quantity of heat to the solid, which is called the latent heat of fusion. There is also in general a considerable change of volume during fusion, which amounts in the case of ice to a contraction of 9%.

Some typical cases of amorphous solidification are those of silica, glass, plastic sulfur, pitch, alcohol and many organic liquids. In this type the liquid gradually becomes more and more viscous as the temperature falls, and ultimately attains the rigidity characteristic of a solid, without any definite freezing point or latent heat. The condition of the substance remains uniform throughout. if its temperature is uniform; there is no separation into the two distinct phases of solid and liquid, and there is no sudden change of volume at any temperature.

The melting or freezing of a pure crystalline solid is characterized most clearly by the perfect constancy of temperature during the process. In fact, the law of constant temperature, which is generally stated as the first of the so-called laws of fusion, does not strictly apply except to this case. The constancy of the freezing point of a pure substance is so characteristic that change of the freezing point is often one of the most convenient tests of the presence of foreign material.

In the case of substances like ice, which melt at a low temperature and are easily obtained in large quantities in a state of purity, the point of fusion may be very accurately determined by observing the temperature of an intimate mixture of the solid and liquid while slowly melting as it absorbs heat from surrounding bodies. In the majority of cases, however, it is more convenient to observe the freezing point as the liquid is cooled. By this method it is possible to ensure perfect uniformity of temperature throughout the mass by stirring the liquid continuously during the process of freezing, whereas it is difficult to ensure uniformity of temperature in melting a solid, however gradually the heat is supplied, unless the solid can be mixed with the liquid. It is also possible to observe the freezing point in other ways, as by noting the temperature at the moment of the breaking of a wire, of the stoppage of a stirrer or of the maximum rate of change of volume, but these methods are generally less certain in their indications than the point of greatest constancy of temperature in the case of homogeneous crystalline solids.

The table contains some of the most recent values of fusing points of metals determined (except the last three) with platinum thermometers. These points are often utilized as fixed points on the thermometric scale, especially for the calibration of thermocouples.

2. Superfusion, Supersaturation. — It is generally possible to cool a liquid several degrees below its normal freezing point without a separation of crystals, especially if it is protected from agitation. which would assist the molecules to rearrange themselves. A liquid in this state is said to be "undercooled" or "superfused." The phenomenon is even more familiar in the case of solutions (*e.g.*, sodium sulfate or acetate) which may remain in the "metastable" condition for an indefinite time if protected from dust. The introduction into the liquid under this condition of the smallest fragment of the crystal, with respect to which the solution is supersaturated, will produce immediate crystallization, which will continue until the temperature is raised to the saturation point by the liberation of the latent heat of fusion. The constancy of temperature at the normal freezing point is due to the equilibrium of exchange existing between the liquid and solid. Unless both solid and liquid are present, there is no condition of equilibrium, and the temperature is indeterminate.

Fusion Points of Common Metals

Sodium	97.5	Silver	960.8
Tin	231.9	Gold	1063.0
Bismuth	271.0	Copper	1083.0
Cadmium	320.9	Nickel	1455.0
Lead	327.4	Palladium	1558.0
Zinc	419.5	Platinum	1769.3

It is important to see clearly that the undercooling of a pure (one component) liquid and the supersaturation of a liquid solution (two or more components) are phenomena sharing essentially the same mechanism. In either case, a component is retained in a liquid condition at a temperature at which it normally would change into the crystalline phase if perfect equilibrium were established. This also emphasizes the close relationship between melting and dissolving into solution.

3. Freezing of Solutions and Alloys. — The phenomena of freezing of crystalline mixtures may be illustrated by the case of aqueous solutions and of metallic solutions or alloys, which have been most widely studied. The usual effect of an impurity, such as salt or sugar in solution in water, is to lower the freezing point, so that no crystallization occurs until the temperature has fallen below the normal freezing point of the pure solvent, the depression of freezing point being nearly proportional to the concentration of the solution. When freezing begins, the solvent generally separates out from the solution in the pure state. This separation of the solvent involves an increase in the strength of the remaining solution, so that the temperature does not remain constant during the freezing, but continues to fall as more of the solvent is separated. There is a perfectly definite relation between temperature and concentration at each stage of the process, which may be repre-

sented in the form of a curve as AC in fig. 3, called the freezing point curve.

The equilibrium temperature, at the surface of contact between the solid and liquid. depends only on the composition of the liquid phase and not at all on the quantity of solid present. The abscissa of the freezing point curve represents the composition of that portion of the original solution which remains liquid at any temperature. If instead of starting with a dilute solution we start with a strong solution represented by a point N, and cool it as shown by the vertical line ND, a point D is generally reached at which the solution becomes "saturated." The dissolved substance or "solute" then separates out as the solution is further cooled, and the concentration diminishes with fall of temperature in a definite relation, as indicated by the curve CB, which is called the solubility curve. Though often called by different names, the two curves AC and CB are essentially of a similar nature.

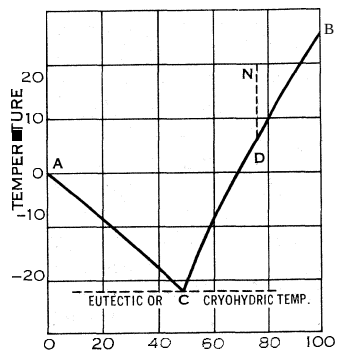

FIG. 3.— FREEZING POINT. OR SOLUBILITY CURVE: SIMPLE CASE

To take the case of an aqueous solution of salt as an example. along CB the solution is saturated with respect to salt, along AC the solution is saturated with respect to ice. When the point C is reached along either curve. the solution is saturated with respect to both salt and ice. The concentration cannot vary further. and the temperature remains constant while the salt and ice crystallize out together. maintaining the exact proportions in which they exist in the solution. The resulting solid was termed a cryohydrate by F. Guthrie, but it is really an intimate mixture of two kinds of crystals. and not a chemical compound or hydrate containing the constituents in chemically equivalent proportions. The lowest temperature attainable by means of a freezing mixture is the temperature of the freezing point of the corresponding cryohydrate. In a mixture of salt and ice with the least trace of water a saturated brine is quickly formed, which dissolves the ice and falls rapidly in temperature, because of the absorption of the latent heat of fusion. So long as both ice and salt are present, if the mixture is well stirred, the solution must necessarily become saturated with respect to both ice and salt, and this can only occur at the cryohydric temperature, at which the two curves of solubility intersect.

The curves in fig. 3 also illustrate the simplest type of freezing point curve in the case of alloys of two metals A and B which do not form mixed crystals or chemical compounds. The alloy corresponding to the cryohydrate, possessing the lowest melting point. is called the eutectic alloy, as it is most easily cast and worked. It generally possesses a very fine-grained structure, and is not a chemical compound. (See ALLOYS.)

4. Calorimetry by Latent Heat.—In principle, the simplest and most direct method of measuring quantities of heat consists in observing the effects produced in melting a solid or vaporizing a liquid. It was, in fact, by the fusion of ice that quantities of heat were first measured. If a hot body is placed in a cavity in a block of ice at 0° C., and is covered by a closely fitting slab of ice, the quantity of ice melted will be directly proportional to the quantity of heat lost by the body in cooling to 0° C. None of the heat can possibly escape through the ice, and conversely no heat can possibly get in from outside. The body must cool exactly to 0° C., and every fraction of the heat it loses must melt an equivalent quantity of ice.

Apart from heat lost in transferring the heated body to the ice block, the method is theoretically perfect. The only difficulty consists in the practical measurement of the quantity of ice melted. Black estimated this quantity by mopping out the cavity with a sponge which was weighed beiore and after the operation. But there is a variable film of water adhering to the walls of the cavity, which gives trouble in accurate work.

In 1780 Pierre Simon Laplace and Lavoisier used a double-walled metallic vessel containing broken ice, which was in many respects more convenient than the block, but aggravated the difficulty of the film of water adhering to the ice. In spite of this practical difficulty, the quantity of heat required to melt unit weight of ice was for a long time taken as the unit of heat. This unit possesses the great advantage that it is independent of the scale of temperature adopted.

At a much later date R. Bunsen in 1870, adopting a suggestion of Sir John Herschel's, devised an ice calorimeter suitable for measuring small quantities of heat, in which the difficulty of the water film was overcome by measuring the change in volume due to the melting of the ice. The volume of unit mass of ice is approximately 1.0920 times that of unit mass of water, so that the diminution of volume is 0.092 of a cubic centimetre for each gram of ice melted.

Since the ice calorimeter of necessity operates at 0° C., a temperature considerably below room temperature, there is always the necessity of taking precautions to prevent the unwanted leakage of heat from the room into the calorimetric vessel; this introduces both difficulties and inaccuracies into the procedure. In order to avoid this source of trouble, calorimeters have been built using diphenyl oxide instead of water as the calorimetric liquid. Since diphenyl oxide has a melting point of 27° C., and can be obtained easily in a high state of purity, this type of calorimeter is especially useful.

For measuring large quantities of heat, such as those produced by the combustion of fuel in a boiler, the most convenient method is the evaporation of water, which is commonly employed by engineers for the purpose. The natural unit in this case is the quantity of heat required to evaporate unit mass of water at the boiling point under atmospheric pressure.

5. Thermometric Calorimetry.— For many years the most accurate method for calorimetry was the observation of the rise in temperature of a known mass of water when the heat was introduced into it under suitable conditions which prevented unwanted heat leaks. This method was employed from a very early date by Count Rumford and was brought to a relatively high pitch of perfection by Regnault in his extensive calorimetric researches. It is still nidely used, especially in combustion calorimetry. After the first decade of the 20th century. however. this method was superseded by procedures based on the electrically heated vacuum calorimeter of Walter Nernst whenever the highest accuracy was desired, particularly in the measurement of heat capacity and of latent heats associated with phase changes.

A weighed sample of the substance to be studied is placed in a sealed sample container, usually a small thin-walled can of copper, plated with gold or some other metal which will resist corrosion. Attached in close thermal contact to this can are a heating coil of known electrical resistance and an electrical resistance thermometer. This unit is placed in a vacuum chamber and usually surrounded by a thermal shield, maintained at a temperature as close to that of the sample container as possible. If an electrical current of known strength is passed through the heater for a measured interval of time, one can calculate the heat introduced which is easily measurable with a precision of 0.01% or better. One can also measure the temperature increment with comparable accuracy. By means of the vacuum and the thermal shield, any unwanted leakage of heat into or out of the sample container can also be reduced to an amount so small in ratio to the electrical heat produced, that the heat capacity of the sample can be calculated with an accuracy of 0.1% to 0.01% depending on the extent of the precautions taken.

As carried out especially by W. F. Giauque and K. S. Pitzer and their collaborators at the University of California, Berkeley, by G. S. Parks and others at Stanford university. Calif., by H. M. Huifman and Guy Waddington at the U.S. bureau of mines Bartlesville (Okla.) station, by F. G. Brickwedde and his associates at the U.S. national bureau of standards and by other investigators especially in the U.S., this method produced a vast amount of thermodynamic data which is the cornerstone on which the understanding of the role of heat in chemistry is based.

6. Watt's Indicator Diagram; Work of Expansion. — The rapid development of the steam engine (see STEAM: *Steam Engine*) in England during the latter part of the 18th century had a marked effect on the progress of the science of heat. In the first steam engines the working cylinder served both as boiler and condenser, a very wasteful method, as most of the heat was transferred directly from the fire to the condensing nater without useful effect. The first improvement (about 1705) was to use a separate boiler, but the greater part of the steam supplied was still wasted in reheating the cylinder. which had been cooled by the injection of cold water to condense the steam after the previous stroke.

In a patent of 1769 James Watt showed how to avoid this waste by using a separate condenser and keeping the cylinder as hot as possible. In his earlier engines the steam at full boiler pressure was allowed to raise the piston through nearly the whole of its stroke. Connection with the boiler was then cut off, and the steam at full pressure was discharged into the condenser. Here again there was unnecessary waste, as the steam was still capable of doing useful work. He subsequently introduced "expansive working," which effected still further economy. The connection with the boiler was cut off when a fraction only. say $\frac{1}{4}$, of the stroke had been completed. the remainder of the stroke being effected by the expansion of the steam already in the cylinder with continually diminishing pressure. By the end of the stroke, when connection was made to the condenser, the pressure was so reduced that there was comparatively little waste from this cause. Watt also devised an instrument called an indicator, in which a pencil. moved up and down vertically by the steam pressure. recorded the pressure in the cylinder at every point of the stroke on a sheet of paper moving horizontally in time with the stroke of the piston. The diagram thus obtained made it possible to study what was happening inside the cylinder, and to deduce the work done by the steam in each stroke. The method of the indicator diagram has since proved of great utility in physics in studying the properties of gases and vapours.

Fig. 4 represents an imaginary indicator diagram for a steam engine. taken from one of Watt's patents. Steam is admitted to the cylinder when the piston is at the beginning of its stroke at S. ST represents the length of the stroke or the limit of horizontal movement of the paper on which the diagram is drawn. The indicating pencil rises to the point A, representing the absolute pressure of 60 lb. per square inch. As the piston moves outward the pencil traces the horizontal line AB, the pressure remaining constant until the point B is reached, at which connection to the boiler is cut off. After cutoff at B the steam expands under diminishing pressure, and the pencil falls gradually from B to C, following the steam pressure until the exhaust valve opens at the end of the stroke. The pressure then falls rapidly to that of the condenser, which for an ideal case may be taken as zero, following Watt. The work done during expansion is found by dividing the area under segment BC as shown. into a number of small rectangles.

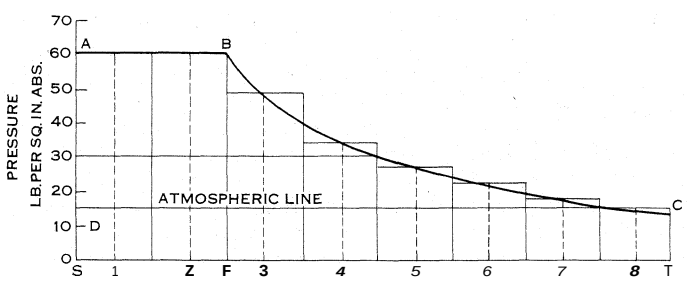

FIG. 4.— WATT'S INDICATOR DIAGRAM

The whole work done in the forward stroke is represented by the area ABCTSA, or by the average value of the pressure p over the whole stroke multiplied by the stroke l. This area must be multiplied by the area of the piston a in square inches to get the work done per stroke in foot-pounds.

7. Thermal Efficiency. — The thermal efficiency of an engine is the ratio of the work done by the engine to the heat supplied to it. According to Watt's observations, confirmed later by Clément and Desormes, the total heat required to produce 1 lb. of saturated steam at any temperature from water at 0° C. was approximately 6jo times the quantity of heat required to raise 1 lb. of water 1" C. Since one pound of steam represented on this assumption a certain quantity of heat, the efficiency could be measured naturally in foot-pounds (ft.lb.) of work obtainable per pound of steam, or conversely in the pounds of steam which are consumed per horsepower-hour.

In his patent of 1782 Watt gives the following example of the improvement in thermal efficiency obtained by expansive working. Taking the diagram already given, if the quantity of steam represented by AB, or 300 cu.in. at 60 lb. pressure, were employed without expansion, the work realized, represented by the area ABSF. would be $6{,}000/4 = 1{,}500$ ft.lb. With expansion to 4 times its original volume, as shown in the diagram by the whole area ABCTSA. the mean pressure (as calculated by Watt. assuming Boyle's law) would be 0.58 of the original pressure, and the nork done would be $6{,}000 \times 0.58 = 3{,}480$ ft.lb. for the same quantity of steam, or the thermal efficiency would be 2.32 times greater.

The advantage actually obtained would not be so great as this, on account of losses by condensation, back pressure, etc., which are neglected in Watt's calculation, but the margin would still be very considerable. Three hundred cubic inches of steam at 60 lb. pressure would represent about .0245 of 1 lb. of steam, or 28.7 B.T.U.. so that. neglecting all losses, the possible thermal efficiency attainable with steam at this pressure and four expansions ($ cutoff) would be 3480/28.7, or 121 ft.lb. per B.T.U.

About 1820. it was usual to include the efficiency of the boiler with that of the engine. and to reckon the efficiency or "duty" in foot-pounds per bushel or hundredweight of coal. The best Cornish pumping-engines of that date achieved about 70,000,000 ft.lb. per hundredweight, or consumed about 3.2 lb. per horsepower-hour. which is roughly equivalent to 43 ft.lb. per B.T.U. The efficiency gradually increased as higher pressures were used, with more complete expansion, but the conditions upon which the efficiency depended were not fully worked out until a much later date. Much additional knowledge with regard to the nature of heat. and the properties of gases and vapours, was required before the problem could be attacked theoretically.

IV. THE NATURE OF HEAT

In the early days of the science it was natural to ascribe the manifestations of heat to the action of a subtle imponderable fluid called caloric, with the power of penetrating. expanding and dissolving bodies, or dissipating them in vapour. The fluid was imponderable, because the most careful experiments failed to show that heat produced any increase in weight. The opposite property of levitation was often ascribed to heat, but it was shown by more cautious investigators that the apparent loss of weight because of heating was to be attributed to evaporation or to upward air currents. The fundamental idea of an imaginary fluid to represent heat was useful in helping the mind to a conception of something remaining invariable in quantity through many transformations, but in some respects the analogy was misleading, and tended greatly to retard the progress of science. The caloric theory was very simple in its application to the majority of calorimetric experiments. and gave a fair account of the elementary phenomena of change of state, but it encountered serious difficulties in explaining the production of heat by friction. or the changes of temperature accompanying the compression or expacsion of a gas.

The explanation which the calorists offered of the production of heat by friction or compression was that some of the latent caloric was squeezed or ground out of the bodies concerned and became "sensible." In the case of heat developed by friction, they supposed that the abraded portions of the material were capable of holding a smaller quantity of heat, or had less "capacity for heat," than the original material. From a logical point of view, this was a perfectly tenable hypothesis, and one difficult to refute. It was easy to account in this way for the heat produced in boring

cannon and similar operations, where the amount of abraded material was large.

To refute this explanation, Count Rumford in 1798 presented before the Royal society the results of his celebrated experiments with a blunt borer in one of which he succeeded in boiling by friction 26.5 lb. of cold water in 2 3 hr., with the production of only 4,145 g. of metallic powder. He then showed by experiment that the metallic powder required the same amount of heat to raise its temperature 1°, as an equal weight of the original metal, or that its "capacity for heat" (in this sense) was unaltered by reducing it to powder; and he argued that "in any case so small a quantity of powder could not possibly account for all the heat generated, that the supply of heat appeared to be inexhaustible, and that heat could not be a material substance, but must be something of the nature of motion."

Unfortunately Rumford's argument was not quite conclusive. The supporters of the caloric theory appear, whether consciously or unconsciously, to have used the phrase "capacity for heat" in two entirely distinct senses without any clear definition of the difference. The phrase "capacity for heat" might very naturally denote the total quantity of heat contained in a body. which they had no means of measuring, but it was generally used to signify the quantity of heat required to raise the temperature of a body one degree, which is quite a different thing, and has no necessary relation to the total heat.

In proving that the powder and the solid metal required the same quantity of heat to raise the temperature of equal masses of either one degree, Rumford did not prove that they contained equal quantities of heat, which was the real point at issue in this instance. The metal tin actually changes into powder below a certain temperature, and in so doing evolves a measurable quantity of heat. A mixture of the gases oxygen and hydrogen, in the proportions in which they combine to form water, evolves. when burned, sufficient heat to raise more than 30 times its weight of water from the freezing to the boiling point; and the mixture of gases may. in this sense, be said to contain so much more heat than the water. although its capacity for heat in the ordinary sense is only about half that of the water produced. To complete the refutation of the calorists' explanation of the heat produced by friction, it mould have been necessary for Rumford to show that the powder when reconverted into the same state as the solid metal did not absorb a quantity of heat equivalent to that evolved in the grinding; in other words that the heat produced by friction was not simply that attributed to the change of state of the metal from solid to powder.

Shortly afterward, in 1799, Humphry (later Sir Humphry) Davy described an experiment in which he melted ice by rubbing two blocks together. This experiment afforded a very direct refutation of the calorists' view, because it was a well-known fact that ice required to have a quantity of heat added to it to convert it into water, so that the water produced by the friction contained more heat than the ice. In stating as the conclusion to be drawn from this experiment that "friction consequently does not diminish the capacity of bodies for heat," Davy apparently uses the phrase capacity for heat in the sense of total heat contained in a body, because in a later section of the same essay he definitely gives the phrase this meaning, and uses the term "capability of temperature" to denote what we now term capacity for heat.

The delay in the overthrow of the caloric theory, and in the acceptance of the view that heat is a mode of motion. was no doubt partly due to some fundamental confusion of ideas in the use of the term "capacity for heat" and similar phrases. A still greater obstacle lay in the comparative vagueness of the motion or vibration theory. Davy speaks of heat as being "repulsive motion," and distinguishes it from light. which is "projective motion"; though heat is certainly not a substance—according to Davy in the essay under discussion—and may not even be treated as an imponderable fluid, light as certainly is a material substance, and is capable of forming chemical compounds with ordinary matter. such as oxygen gas. which is not a simple substance, but a compound, termed phosoxygen, of light and oxygen.

Accepting the conclusions of Davy and Rumford that heat is not a material substance but a mode of motion, there still remains the question, what definite conception is to be attached to a quantity of heat? What do we mean by a quantity of vibratory motion, how is the quantity of motion to be estimated and why should it remain invariable in many transformations? The idea that heat was a "mode of motion" was applicable as a qualitative explanation of many of the effects of heat, but it lacked the quantitative precision of a scientific statement, and could not be applied to the calculation and prediction of definite results. The state of science at the time of Rumford's and Davy's experiments did not admit of a more exact generalization. The way was paved in the first instance by a more complete study of the laws of gases, to which Laplace, John Dalton, Gay-Lussac, Pierre Louis Dulong and many others contributed both on the experimental and theoretical side. Although the development proceeded simultaneously along many parallel lines, it is interesting and instructive to take the investigation of the properties of gases, and to endeavour to trace the steps by which the true theory was finally attained.

V. THERMAL PROPERTIES OF GASES

The most characteristic property of a gaseous or elastic fluid, namely, the elasticity, or resistance to compression, was first investigated scientifically by Robert Boyle (1662), who showed that the pressure p of a given mass of gas varied inversely as the volume v, provided that the temperature remained constant. This is generally expressed by the formula $pv = C$, where C is a constant for any given temperature, and v is taken to represent the specific volume, or the volume of unit mass, of the gas at the given pressure and temperature. Boyle was well aware of the cffcct of heat in expanding a gas, but he was unable to investigate this properly as no thermometric scale had been defined at that date.

According to Boyle's law, when a mass of gas is compressed by a small amount at constant temperature, the percentage increase of pressure is equal to the percentage diminution of volume (if the compression is $v/100$, the increase of pressure is very nearly $p/100$). Adopting this law, Newton showed, by a most ingenious piece of reasoning, that the velocity of sound in air should be equal to the velocity acquired by a body falling under gravity through a distance equal to half the height of the atmosphere, considered as being of uniform density equal to that at the surface of the earth. This gave the result 918 ft. per second (280 m. per second) for the velocity at the freezing point. Newton was aware that the actual velocity of sound was somewhat greater than this, but supposed that the difference might be due in some way to the size of the air particles, of which no account could be taken in the calculation. The first accurate measurement of the velocity of sound by the French Académie des Sciences in 1738 gave the value 332 m. per second as the velocity at 0° C. The true explanation of the discrepancy was not discovered until nearly 100 years later.

The law of expansion of gases with change of temperature was investigated by Dalton and later by Gay-Lussac (1802), who found that the volume of a gas under constant pressure increased by $\frac{1}{267}$ of its volume at 0° C. for each 1° C. rise in temperature. This value was generally assumed in all calculations for nearly 50 years. More exact researches show that the precise value of the coefficient should be $\frac{1}{273.15}$. Thus in round numbers the value of the coefficient should be $\frac{1}{273}$. According to this law the volume of a gas at any temperature t° C. should be proportional to $273 + t$; *i.e.*, to the temperature reckoned from a zero 273° below that of the centigrade scale, which was called the absolute zero of the gas thermometer. If $T = 273 + t$, denotes the temperature measured from this zero, the law of expansion of a gas may be combined with Boyle's law in the simple formula

$$pv = RT \qquad (1)$$

which is generally taken as the expression of the gaseous laws. If equal volumes of different gases are taken at the same temperature and pressure, it follows that the constant R is the same for all gases. If equal masses are taken, the value of the constant R

for different gases varies inversely as the molecular weight or as the density relative to hydrogen.

Dalton also investigated the laws of vapours, and of mixtures of gases and vapours. He found that condensable vapours approximately followed Boyle's law when compressed, until the condensation pressure was reached, at which the vapour liquefied without further increase of pressure. He found that when a liquid was introduced into a closed space, and allowed to evaporate until the space was saturated with the vapour and evaporation ceased, the increase of pressure in the space was equal to the condensation pressure of the vapour, and did not depend on the volume of the space or the presence of any other gas or vapour provided that there was no solution or chemical action. He showed that the condensation or saturation pressure of a vapour depended only on the temperature, and increased by nearly the same fraction of itself per degree rise of temperature, and that the pressures of different vapours were nearly the same at equal distances from their boiling points. The increase of pressure per degree centigrade at the boiling point was about $\frac{1}{28}$ of 760 mm. or 27.2 mm., but increased in geometrical progression with rise of temperature. These results of Dalton's were confirmed, and in part corrected, as regards increase of vapour pressure, by Gay-Lussac, Dulong, Regnault and other investigators, but were found to be as close an approximation to the truth as could be obtained with such simple expressions.

More accurate empirical expressions for the increase of vapour-pressure of a liquid with temperature were soon obtained by Thomas Young. J. P. L. A. Roche and others, but the explanation of the relation was not arrived at until a much later date.

1. Specific Heats **of** Gases.—In order to estimate the quantities of heat concerned in experiments with gases, it was necessary in the first instance to measure their specific heats, which presented formidable difficulties. The earlier attempts by Lavoisier and others, employing the ordinary methods of calorimetry, gave very uncertain and discordant results, which mere not regarded with any confidence even by the experimentalists themselves. Gay-Lussac devised an ingenious experiment. which, though misinterpreted at the time, is very interesting and instructive. With the object of comparing the specific heats of different gases, he took two equal globes A and B connected by a tube with a stop-cock. The globe B was exhausted, the other A being filled with gas. On opening the tap between the vessels, the gas flowed from A to B and the pressure was rapidly equalized. He observed that the fall of temperature in A was nearly equal to the rise of temperature in B. and that for the same initial pressure the change of temperature was very nearly the same for all the gases he tried, except hydrogen, which showed greater changes of temperature than other gases. He concluded from this experiment that equal volumes of gases had the same capacity for heat, except hydrogen, which he supposed to have a larger capacity, because it showed a greater effect. The method does not in reality afford any direct information with regard to the specific heats, and the conclusion with regard to hydrogen is evidently wrong.

At a later date Gay-Lussac adopted A. Crawford's method of mixture, allowing two equal streams of different gases, one heated and the other cooled about 20° C., to mix in a tube containing a thermometer. The resulting temperature was in all cases nearly the mean of the two, from nhich he concluded that equal volumes of all the gases tried, namely. hydrogen, carbon dioxide, air, oxygen and nitrogen, had the same thermal capacity. This was correct, except as regards carbon dioxide, but did not give any information as to the actual specific heats referred to water or any known substance.

About the same time, F. Delaroche and J. E. Bérard made direct determinations of the specific heats of air, oxygen, hydrogen, carbon monoxide, carbon dioxide, nitrous oxide and ethylene, by passing a stream of gas heated to nearly 100° C. through a spiral tube in a calorimeter containing water. Their work was a great advance on previous attempts, and gave the first trustworthy results. With the exception of hydrogen, which presents peculiar difficulties, they found that equal volumes of the permanent gases, air, oxygen and carbon monoxide, had nearly the same thermal capacity, but that the compound condensable gases, carbon dioxide, nitrous oxide and ethylene, had larger thermal capacities in the order given. They were unable to state whether the specific heats of the gases increased or diminished with temperature, but from experiments on air at pressures of 740 mm. and 1,000 mm., they found the specific heats to be .269 and .245 respectively, and concluded that the specific heat diminished with increase of pressure. The difference they observed was really due to errors of experiment, but they regarded it as proving beyond doubt the truth of the calorists' contention that the heat disengaged on the compression of a gas was due to the diminution of its thermal capacity.

Dalton and others had endeavoured to measure directly the rise of temperature produced by the compression of a gas. Dalton had observed a rise of 50° F. in a gas when suddenly compressed to half its volume, but no thermometers at that time were sufficiently sensitive to indicate more than a fraction of the change of temperature.

Laplace was the first to see in this phenomenon the probable explanation of the discrepancy between Newton's calculation of the velocity of sound and the observed value. The increase of pressure because of a sudden compression, in which no heat was allowed to escape, or as we now call it an adiabatic compression, would necessarily be greater than the increase of pressure in a slow isothermal compression, on account of the rise of temperature. As the rapid compressions and rarefactions occurring in the propagation of a sound wave were perfectly adiabatic, it was necessary to take account of the rise of temperature because of compression in calculating the velocity. To reconcile the observed and calculated values of the velocity, the increase of pressure in adiabatic compression must be 1.410 times greater than in isothermal compression. This is the ratio of the adiabatic elasticity of air to the isothermal elasticity. It mas a long time, however, before Laplace saw his way to any direct experimental verification of the value of this ratio. At a later date he stated that he had succeeded in proving that the ratio in question must be the same as the ratio of the specific heat of air at constant pressure to the specific heat at constant volume.

2. Experimental Verification **of** the Ratio **of** Specific Heats.—This was a most interesting and important theoretical relation to discover, but unfortunately it did not help much in the determination of the ratio required, because it was not practically possible at that time to measure the specific heat of air at constant volume in a closed vessel. Attempts had been made to do this, but they had signally failed, on account of the small heat capacity of the gas as compared with the containing vessel. Laplace endeavoured to extract some confirmation of his views from the values given by Delaroche and Bérard for the specific heat of air at 1.000 and 740 mm. pressure. On the assumption that the quantities of heat contained in a given mass of air increased in direct proportion to its volume when heated at constant pressure, he deduced, by some rather obscure reasoning, that the ratio of the specific heats S and s should be about 1.5 to 1, which he regarded as a fairly satisfactory agreement with the value $\gamma = 1.41$ deduced from the velocity of sound.

The ratio of the specific heats could not be directly measured, but a few years later, N. Clément-Desormes succeeded in making a direct measurement of the ratio of the elasticities in a very simple manner. He took a large globe containing air at atmospheric pressure and temperature, and removed a small quantity of air. He then observed the defect of pressure p_0 when the air had regained its original temperature. By suddenly opening the globe. and immediately closing it, the pressure was restored almost instantaneously to the atmospheric, the rise of pressure p, corresponding to the sudden compression produced. The air, having been heated by the compression, was allowed to regain its original temperature, the tap remaining closed, and the final defect of pressure p_1 was noted. The change of pressure for the same compression performed isotherm'ally is then $p_0 - p_1$. The ratio $p_0/(p_0 - p_1)$ is the ratio of the adiabatic and isothermal elasticities, provided that p_0 is small compared with the whole atmospheric pressure. In this way he found the ratio 1.354, which is not

much smaller than the value 1.410 required to reconcile the observed and calculated values of the velocity of sound.

Gay-Lussac and J. J. Welter repeated the experiment with slight improvements, using expansion instead of compression, and found the ratio *1.375.* The experiment has often been repeated since that time, and there is no doubt that the value of the ratio deduced from the velocity of sound is correct, the defect of the value obtained by direct experiment being due to the fact that the compression or expansion is not perfectly adiabatic. Gay-Lussac and Welter found the ratio practically constant for a range of pressure 144 to *1.460* mm., and for a range of temperature from $-20°$ to $+40°$ C. The velocity of sound at Quito, Ecuador, at a pressure of *544* mm. was found to be the same as at Paris at *760* mm. at the same temperature. Assuming on this evidence the constancy of the ratio of the specific heats of air, Laplace showed that. if the specific heat at constant pressure was independent of the temperature, the specific heat per unit volume at a pressure p must vary as $p^{1/\gamma}$ according to the caloric theory. The specific heat per unit mass must then vary as $p^{1/\gamma-1}$ which he found agreed precisely with the experiment of Delaroche and Bérard already cited. This was undoubtedly a strong confirmation of the caloric theory. S. D. Poisson by the same assumptions obtained the same results, and also showed that the relation between the pressure and the volume of a gas in adiabatic compression or expansion must be of the form $pv^\gamma =$ constant.

P. L. Dulong, adopting a method attributed to E. F. F. Chladni, compared the velocities of sound in different gases by observing the pitch of the note given by the same tube when filled with the gases in question. He thus obtained the values of the ratios of the elasticities or of the specific heats for the gases employed. For oxygen, hydrogen and carbon monoxide, these ratios were the same as for air. But for carbon dioxide, nitrous oxide and ethylene gas, the values were much smaller. showing that these gases experienced a smaller change of temperature in compression. On comparing his results with the values of the specific heats for the same gases found by Delaroche and Bérard, Dulong observed that the changes of temperature for the same compression were in the inverse ratio of the specific heats at constant volume, and deduced the important conclusion that "Equal volumes of all gases under the same conditions evolve on compression the same quantity of heat." This is equivalent to the statement that the difference of the specific heats, or the latent heat of expansion R' per 1°, is the same for all gases if equal volumes are taken.

Assuming the ratio $\gamma = 1.410$, and taking Delaroche and Bérard's value for the specific heat of air at constant pressure $S = .267$, we have $s = S/1.41 = .189$, and the difference of the specific heats per unit mass of air $S - s = R' = .078$. Adopting Regnault's value of the specific heat of air, namely, $S = .238$, we should have $S - s = .069$. This quantity represents the heat absorbed by unit mass of air in expanding at constant temperature T by a fraction $1/T$ of its volume v, or by $\frac{1}{273}$ of its volume at 0° C.

If, instead of taking unit mass, we take a volume $v_0 = 22.301$. at 0° C. and *760* mm. being the volume of the molecular weight of the gas in grams, the quantity of heat evolved by a compression equal to v/T will be approximately 2 cal., and is the same for all gases. The work done in this compression is $pv/T = R$, and is also the same for all gases, namely, *8.3* joules. Dulong's experimental result. therefore, shows that the heat evolved in the compression of a gas is proportional to the work done. This result had previously been deduced theoretically by Nicolas Sadi Carnot *(1824).* At a later date it was assumed by Julius Mayer, Rudolf Clausius and others, on the evidence of these experiments, that the heat evolved was not merely proportional to the work done, but was equivalent to it. The further experimental evidence required to justify this assumption was first supplied by James Joule.

VI. CARNOT: ON THE MOTIVE POWER OF HEAT

A practical and theoretical question of greatest importance was first answered by Nicolas Carnot about this time in his *Réflexions sur* la *puissance motrice du feu (1824).* How much motive power (defined by Carnot as weight lifted through a certain height) can be obtained from heat alone by means of an engine repeating a regular succession or "cycle" of operations continuously? Is the efficiency limited, and, if so, how is it limited? Are other agents preferable to steam for developing motive power from heat?

In discussing this problem, we cannot do better than follow Carnot's reasoning which, in its main features. could hardly be improved. Carnot points out that in order to obtain an answer to this question, it is necessary to consider the essential conditions of the process, apart from the mechanism of the engine and the working substance or agent employed. Work cannot be said to be produced from heat alone unless nothing but heat is supplied, and the working substance and all parts of the engine are at the end of the process in precisely the same state as at the beginning.

For instance a mass of compressed air, if allowed to expand in a cylinder at constant temperature, will do work, and will at the same time absorb a quantity of heat which, as we now know, is the thermal equivalent of the work done. But this work cannot be said to have been produced solely from the heat absorbed in the process, because the air at the end of the process is in a changed condition, and could not be restored to its original state at the same temperature without having work done upon it precisely equal to that obtained by its expansion. The process could not be repeated indefinitely without a continual supply of compressed air. The source of the work in this case is work previously done in compressing the air, and no part of the work is really generated at the expense of heat alone, unless the compression is effected at a lower temperature than the expansion.

1. Carnot's Axiom. — Carnot here, and throughout his reasoning, makes a fundamental assumption, which he states as follows: "When a body has undergone any changes and after a certain number of transformations is brought back identically to its original state. considered relatively to density, temperature and mode of aggregation, it must contain the same quantity of heat as it contained originally." Clausius and others have misinterpreted this assumption, and have taken it to mean that the quantity of heat required to produce any given change of state is independent of the manner in which the change is effected, which Carnot does not here assume.

Heat, according to Carnot. in the type of engine we are considering, can evidently be a cause of motive power only by virtue of changes of volume or form produced by alternate heating and cooling. This involves the existence of hot and cold bodies to act as boiler and condenser, or source and sink of heat, respectively. Wherever there exists a difference of temperature, it is possible to have the production of motive power from heat; and conversely, production of motive power, from heat alone, is impossible without difference of temperature. In other words the production of motive power from heat is not merely a question of the consumption of heat, but always requires transference of heat from hot to cold. What then are the conditions which enable the difference of temperature to be most advantageously employed in the production of motive power, and how much motive power can be obtained with a given difference of temperature from a given quantity of heat?

2. Carnot's Rule for Maximum Effect. — In order to realize the maximum effect, it is necessary that, in the process employed, there should not be any direct interchange of heat between bodies at different temperatures. Direct transference of heat by conduction or radiation between bodies at different temperatures is equivalent to wasting a difference of temperature which might have been utilized to produce motive power. The working substance must throughout every stage of the process be in equilibrium with itself (*i.e.,* at uniform temperature and pressure) and also with external bodies, such as the boiler and condenser, at such times as it is put in communication with them. In the actual engine there is always some interchange of heat between the steam and the cylinder, and some loss of heat to external bodies. There may also be some difference of temperature between the boiler steam and the cylinder on admission, or between the waste

steam and the condenser at release. These differences represent losses of efficiency which may be reduced indefinitely, at least in imagination, by suitable means, and designers had even at that date been very successful in reducing them. All such losses are supposed to be absent in deducing the ideal limit of efficiency, beyond which it would be impossible to go.

3. Carnot's Description of His Ideal Cycle.—Carnot first gives a rough illustration of an incomplete cycle, using steam much in the same way as it is employed in an ordinary steam engine. After expansion down to condenser pressure the steam is completely condensed to water, and is then returned as cold water to the hot boiler. He points out that the last step does not conform exactly to the condition he laid down, because although the water is restored to its initial state, there is direct passage of heat from a hot body to a cold body in the last process. He points out that this difficulty might be overcome by supposing the difference of temperature small, and by employing a series of engines, each working through a small range, to cover a finite interval of temperature. Having established the general notions of a perfect cycle, he proceeds to give a more exact illustration, employing a gas as the working substance. He takes as the basis of his demonstration the well-established experimental fact that a gas is heated by rapid compression and cooled by rapid expansion, and that if compressed or expanded slowly in contact with conducting bodies, the gas will give out heat in compression or absorb heat in expansion while its temperature remains constant. He then goes on to say:

This preliminary notion being settled, let us imagine an elastic fluid, atmospheric air for example, enclosed in a cylinder *abcd* (fig. 5) fitted with a movable diaphragm or piston *cd*. Let there also be two bodies A, B, each maintained at a constant temperature, that of A being more elevated than that of B. Let us now suppose the following series oi operations to be periormed:

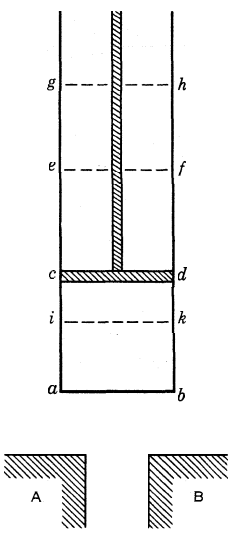

FIG. 8.—CARNOT'S CYLINDER (see TEXT)

1. Contact of the body A with the air contained in the space *abcd*, or with the bottom of the cylinder, which we will suppose to transmit heat easily The air is now at the temperature of the body A, and *cd* is the actual position oi the piston.

2. The piston is gradually raised, and takes the position ef. The air remains in contact with the body A, and is thereby maintained at a constant temperature during the expansion. The body A furnishes the heat necessary to maintain the constancy of temperature.

3. The body A is removed and the air no longer being in contact with any body capable of giving it heat, the piston continues nevertheless to rise, and passes irom the position *ef* to gh. The air expands without receiving heat and its temperature falls Let us imagine that it falls until it is just equal to that of the body B At this moment the piston is stopped and occupies the position *gh*.

4. The air is placed in contact with the body B; it is compressed by the return of the piston, which is brought from the position *gh* to the position *cd*. The air remains meanwhile at a constant temperature, because of its contact with the body B to ahich it gives up its heat.

5. The body B is removed, and the compression of the air is continued. The air being now isolated. rises in temperature. The compression is continued until the air has acquired the temperature of the body A. The piston passes meanwhile irom the position *cd* to the position ik.

6. The air is replaced in contact with the body A, and the piston returns from the position ik to the position *ef*, the temperature remaining invariable.

7. The period described under (3) is repeated, then successively the periods (4), (5), (6); (3), (4), (5), (6); (3), (4), (5), (6); and so on.

Durinr these operations the air enclosed in the cylinder exerts an effort more or less great on the piston. The pressure-of the air varies both on account of changes of volume and on account of changes of temperature; but it should be observed that ior equal volumes, that is to say, for like positions of the piston, the temperature is higher during the dilatation than during the compression. Since the pressure is greater during the expansion, the quantity of motive power produced by the dilatation is greater than that consumed by the compression. We shall thus obtain a balance of motive power, which may be employed for any purpose. The air has served as working substance in a heat-engine; it has also been employed in the most advantageous manner possible, since no useless re-establishment of the equilibrium of heat has been allowed to occur

All the operations above described may be executed in the reverse order and direction. Let us imagine that after the sixth period, that is to say, when the piston has reached the position *ef*, we make it return to the position ik, and that at the same time we keep the air in contact with the hot body A; the heat furnished by this body during the sixth period will return to its source, that is, to the body A, and everything will be as it was at the end oi the fifth period. If now we remove the body A, and if we make the piston move from ik to *cd*, the temperature of the air will decrease by just as many degrees as it increased during the fifth period, and will become that of the body B. We can evidently continue in this way a series of operations the exact reverse oi those which were previously described; it suffices to place oneself in the same circumstances and to execute for each period a movement of expansion in place of a movement oi compression, and vice versa.

The result of the first series oi operations was the production of a certain quantity of motive power, and the transport of heat from the body A to the body B; the result of the reverse operations is the consumption of the motive power produced in the first case, and the return of heat from the body B to the body A, in such sort that these two series of operations annul and neutralize each other.

The impossibility of producing by the agency of heat alone a quantity of motive power greater than that which we have obtained in our first series of operations is now easy to prove. It is demonstrated by reasoning exactly similar to that which we have already given. The reasoning will have in this case a greater degree of exactitude; the air of which we made use to develop the motive power is brounht back at the end of each cycle of operations precisely to its initial state, whereas this was not quite exactly the case for the vapour of water, as we have already remarked.

4. Proof of Carnot's Principle.—Carnot considered the proof too obvious to be worth repeating, but, unfortunately, his previous demonstration. referring to an incomplete cycle, is not so exactly worded that exception cannot be taken to it. We will therefore repeat his proof in a slightly more exact form.

Suppose that a reversible engine R, working in the cycle above described, takes a quantity of heat Q from the source in each cycle, and performs a quantity of useful work W_r. If it were possible for any other engine S, working with the same two bodies A and B as source and refrigerator, to perform a greater amount of useful work W, per cycle for the same quantity of heat Q taken from the source, it would suffice to take a portion W_s of this motive power (since W_s is by hypothesis greater than W_r) to drive the engine R backward, and return a quantity of heat Q to the source in each cycle. The process might be repeated indefinitely. and we should obtain at each repetition a balance of useful work $W_s - W_r$, without taking any heat from the source, which is contrary to experience. Whether the quantity of heat taken from the condenser by R is equal to that given to the condenser by S is immaterial. The hot body A might be a comparatively small boiler, since no heat is taken from it. The cold body B might be the ocean, or the whole earth. We might thus obtain without any consumption of fuel a practically unlimited supply of motive power, which is absurd.

5. **Carnot's** Statement of His Principle.— If the foregoing reasoning be admitted, we must conclude with Carnot that the motive power obtainable from heat is independent of the agents employed to realize it. The efficiency is fixed solely by the temperatures of the bodies between which, in the last resort, the transfer of heat is effected. "We must understand hare that each of the methods of developing motive power attains the perfection of which it is susceptible. This condition is fulfilled if, according to our rule. there is produced in the body no change of temperature that is not due to change of volume, or in other words, if there is no direct interchange of heat between bodies of sensibly different temperatures."

It is characteristic of a state of frictionless mechanical equilibrium that an indefinitely small difference of pressure suffices to upset the equilibrium and reverse the motion. Similarly in thermal equilibrium between bodies at the same temperature, an indefinitely small difference of temperature suffices to reverse the transfer of heat.

Carnot's rule is therefore the criterion of the reversibility of a cycle of operations as regards transfer of heat. It is assumed

that the ideal engine is mechanically reversible, that there is not, for instance, any communication between reservoirs of gas or vapour at sensibly different pressures, and that there is no waste of power in friction. If there is equilibrium both mechanical and thermal at every stage of the cycle, the ideal engine will be perfectly reversible. That is to say, all its operations will be exactly reversed as regards transfer of heat and work, when the operations are performed in the reverse order and direction. On this understanding Carnot's principle may be put in a different way, which is often adopted, but is really only the same thing put in different words: The efficiency of a perfectly reversible engine is the maximum possible, and is a function solely of the limits of temperature between which it works. This result depends essentially on the existence of a state of thermal equilibrium defined by equality of temperature, and independent, in the majority of cases, of the state of a body in other respects. In order to apply the principle to the calculation and prediction of results, it is sufficient to determine the manner in which the efficiency depends on the temperature for one particular case, since the efficiency must be the same for all reversible engines.

Carnot endeavoured to test his results by calculating the amount of work obtainable from an engine on his cycle, using steam as a working substance, and comparing the result with an engine performing a similar cycle, using air as the working substance. He found, using the experimental data available at that time, that the work to be obtained from 1,000 g.cal. of heat was roughly independent of the working substance, being about 1.13 kilogram-metre per kilocalorie per 1° fall at 100° C.; *i.e.*, when the limits of temperature of the cycle are 101° C. and 100° C. He was able to show that the efficiency per degree fall probably diminished with rise of temperature, but the experimental data at that time were too inconsistent to suggest the true relation. He took as the analytical expression of his principle that the efficiency W/Q of a perfect engine taking'in heat Q at a temperature $t°$ C., and rejecting heat at the temperature 0° C., must be some function Ft of the temperature t, which would be the same for all substances. The efficiency per degree fall at a temperature t he represented by F't, the derived function of Ft. The function F't would be the same for all substances at the same temperature, but would have different values at different temperatures. In terms of this function, which is generally known as Carnot's function, the results obtained in the previous section might be expressed as follows:

The increase of volume of a mixture of liquid and vapour per unit-mass vaporized at any temperature, multiplied by the increase of vapour-pressure per degree, is equal to the product of the function $F't$ by the latent heat of vaporization.

The difference of the specific heats, or the latent heat of expansion for any substance, multiplied by the function F't, is equal to the product of the expansion per degree at constant pressure by the increase of pressure per degree at constant volume.

Since the last two coefficients are the same for all gases if equal volumes are taken, Carnot concluded that: "The difference of the specific heats at constant pressure and volume is the same for equal volumes of all gases at the same temperature and pressure."

Taking the expression $W = R T \log, r$ for the whole work done by a gas obeying the gaseous laws $pv = R T$ in expanding at a temperature T from a volume 1 (unity) to a volume r, or for a ratio of expansion r, and putting $W = R \log, r$ for the work done in a cycle of range 1°, Carnot obtained the expression for the heat absorbed by a gas in isothermal expansion.

$$Q = R \log, r/F'(t) \qquad (2)$$

He gives several important deductions which follow from this formula, which is the analytical expression of the experimental result already quoted as having been discovered subsequently by Dulong. Employing the above expression for the latent heat of expansion, Carnot deduced a general expression for the specific heat of a gas at constant volume on the basis of the caloric theory. He showed that if the specific heat mas independent of the temperature (the hypothesis already adopted by Laplace and Poisson) the function $F'(t)$ must be of the form

$$F'(t) = R/C\ (t + t_0) \qquad (3)$$

where C and t_0 are unknown constants. A similar result follows from his expression for the difference of the specific heats. If this is assumed to be constant and equal to C, the expression for $F'(t)$ becomes R/CT, which is the same as the above if $t_0 = 273$. Assuming the specific heat to be also independent of the volume, he shows that the function $F'(t)$ should be constant. But this assumption is inconsistent with the caloric theory of latent heat of expansion, which requires the specific heat to be a function of the volume. It appears in fact impossible to reconcile Carnot's principle with the caloric theory on any simple assumptions. As Carnot remarks: "The main principles on which the theory of heat rests require most careful examination. Many experimental facts appear almost inexplicable in the present state of this theory."

Carnot's work was subsequently put in a more complete analytical form by B. P. E. Clapeyron, who also made use of Watt's indicator diagram for the first time in discussing physical problems. Clapeyron gave the general expressions for the latent heat of a vapour, and for the latent heat of isothermal expansion of any substance, in terms of Carnot's function, employing the notation of the calculus. The expressions he gave are the same in form as those in use at the present time. He also gave the general expression for Carnot's function, and endeavoured to find its variation with temperature; but having no better data, he succeeded no better than Carnot.

Unfortunately, in describing Carnot's cycle, he assumed the caloric theory of heat, and made some unnecessary mistakes, which Carnot (who, we now know, was a believer in the mechanical theory) had been very careful to avoid. Clapeyron directs one to compress the gas at the lower temperature in contact with the body B until the heat disengaged is equal to that which has been absorbed at the higher temperature. He assumes that the gas at this point contains the same quantity of heat as it contained in its original state at the higher temperature, and that, when the body B is removed, the gas will be restored to its original temperature, when compressed to its initial volume. This mistake is still attributed to Carnot, and regarded as a fatal objection to his reasoning by many writers.

W. Thomson (Lord Kelvin) stated in 1852 that "Carnot's original demonstration utterly fails," and he introduced the "corrections" attributed to James Thomson and Clerk Maxwell respectively. In reality Carnot's original demonstration requires no correction.

VII. MECHANICAL THEORY OF HEAT

According to the caloric theory, the heat absorbed in the expansion of a gas became latent, like the latent heat of vaporization of a liquid, but remained in the gas and was again evolved on compressing the gas. This theory gave no explanation of the source of the motive power produced by expansion. The mechanical theory had explained the production of heat by friction as being the result of transformation of visible motion into a brisk agitation of the ultimate molecules, but it had not so far given any definite explanation of the converse production of motive power at the expense of heat. The theory could not be regarded as complete until it had been shown that in the production of work from heat, a certain quantity of heat disappeared, and ceased to exist as heat; and that this quantity was the same as that which could be generated by the expenditure of the work produced. The earliest complete statement of the mechanical theory from this point of view is contained in some notes written by Carnot, about 1830, but published by his brother in 1878. Taking the difference of the specific heats to be .078, he estimated the mechanical equivalent at 370 kilogram-metres. But he fully recognized that there were no experimental data at that time available for a quantitative test of the theory, although it appeared to afford a good qualitative explanation of the phenomena. Carnot therefore planned a number of crucial experiments such as the porous plug experiment, to test the equivalence of heat and motive power.

His early death in 1832 put a stop to these experiments, but many later were made independently by other observers.

The most obvious case of the production of work from heat is in the expansion of a gas or vapour, which served in the first instance as a means of calculating the ratio of equivalence, on the assumption that all the heat which disappeared had been transformed into work and had not merely become latent. Marc Séguin, in his *De l'influence des chemins de fer* (1839), made a rough estimate in this manner of the mechanical equivalent of heat, assuming that the loss of heat represented by the fall of temperature of steam on expanding was equivalent to the mechanical effect produced by the expansion. He also remarks that it was absurd to suppose that "a finite quantity of heat could produce an indefinite quantity of mechanical action, and that it was more natural to assume that a certain quantity of heat disappeared in the very act of producing motive power." J. R. Mayer in 1842 stated the equivalence of heat and work more definitely, deducing it from the old principle, *causa aequat effectum* ("cause equals effect").

Assuming that the sinking of a mercury column by which a gas was compressed was equivalent to the heat set free by the compression, he deduced that the warming of 1 kg. of water 1° C. would correspond to the fall of a weight of 1 kg. from a height of about 365 m. But Mayer did not adduce any fresh experimental evidence. and made no attempt to apply his theory to the fundamental equations of thermodynamics. It has since been urged that the experiment of Gay-Lussac (1807), on the expansion of gas from one globe to another (see *Thermal Properties of Gases: Specific Heat of Gases*, above), was sufficient justification for the assumption tacitly involved in Mayer's calculation. But Joule was the first to supply the correct interpretation of this experiment, and to repeat it on an adequate scale with suitable precautions. Joule was also the first to measure directly the amount of heat liberated by the compression of a gas, and to prove that heat was not merely rendered latent, but disappeared altogether as heat, when a gas did work in expansion.

1. Joule's Determinations of the Mechanical Equivalent. — The honour of placing the mechanical theory of heat on a sound experimental basis belongs almost exclusively to Joule, who showed by direct experiment that in all the most important cases in which heat was generated by the expenditure of mechanical work, or mechanical work was produced at the expense of heat, there was a constant ratio of equivalence between the heat generated and the work expended and vice versa. His first experiments were on the relation of the chemical and electric energy expended to the heat produced in metallic conductors and voltaic and electrolytic cells; these experiments were described in a series of papers published in the *London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science*, 1840–43. He first proved the relation. known as Joule's law, that the heat produced in a conductor of resistance R by a current C is proportional to C^2R per second. He went on to show that the total heat produced in any voltaic circuit was proportional to the electromotive force E of the battery and to the number of equivalents electrolyzed in it. Michael Faraday had shown that electromotive force depends on chemical affinity. Joule measured the corresponding heats of combustion, and showed that the electromotive force corresponding to a chemical reaction is proportional to the heat of combustion of the electrochemical equivalent. He also measured the electromotive force required to decompose water, and showed that when part of the electric energy EC is thus expended in a voltameter, the heat generated is less than the heat of combustion corresponding to EC by a quantity representing the heat of combustion of the decomposed gases.

Joule's papers so far had been concerned with the relations between electrical energy, chemical energy and heat which he showed to be mutually equivalent. The first paper in which he discussed the relation of heat to mechanical power was entitled "On the Calorific Effects of Magneto-Electricity. and on the Mechanical Value of Heat." In this paper in 1843 he showed that the heat produced by currents generated by magnetoelectric induction followed the same law as voltaic currents. By a simple and ingenious arrangement he succeeded in measuring the mechanical power expended in producing the currents, and deduced the mechanical equivalent of heat and of electrical energy. The amount of mechanical work required to raise 1 lb. of water 1° F. (1 B.T.U.), as found by this method, was 838 ft.lb. In a note added to the paper he states that he found the value 770 ft.lb. by the more direct method of forcing water through fine tubes.

In a paper in 1845 "On the Changes of Temperature produced by the Rarefaction and Condensation of Air," he made the first direct measurements of the quantity of heat disengaged by compressing air, and also of the heat absorbed when the air was allowed to expand against atmospheric pressure; as the result he deduced the value 798 ft.lb. for the mechanical equivalent of 1 B.T.U. He also showed that there was no appreciable absorption of heat when air was allowed to expand in such a manner as not to develop mechanical power, and he pointed out that the mechanical equivalent of heat could not be satisfactorily deduced from the relations of the specific heats, because the knowledge of the specific heats of gases at that time was so uncertain.

He attributed most weight to his later determinations of the mechanical equivalent made by the direct method of friction of liquids. He showed that the results obtained with different liquids, water, mercury and sperm oil, were the same, namely, 782 ft.lb.; and finally repeating the method with water, using all the precautions and improvements which his experience had suggested, he obtained the value 772 ft.lb., which was accepted universally for many years, and has only recently required alteration on account of the more exact definition of the heat unit, and the standard scale of temperature *(see* CALORIMETRY). The great value of Joule's work for the general establishment of the principle of the conservation of energy lay in the variety and completeness of the experimental evidence he adduced. It was not sufficient to find the relation between heat and mechanical work or other forms of energy in one particular case. It was necessary to show that the same relation held in all cases which could be examined experimentally, and that the ratio of equivalence of the different forms of energy, measured in different ways, was independent of the manner in which the conversion was effected and of the material or working substance employed.

As the result of Joule's experiments, we are justified in concluding that heat is a form of energy, and that all its transformations are subject to the general principle of the conservation of energy. As applied to heat, the principle is called the hrst law of thermodynamics, and may be stated as follows: When heat is transformed into any other kind of energy, or vice versa, the total quantity of energy remains invariable; that is to say, the quantity of heat which disappears is equivalent to the quantity of the other kind of energy produced and vice versa.

The number of units of mechanical work equivalent to one unit of heat is generally called the mechanical equivalent of heat, or Joule's equivalent, and is denoted by the letter J. Its numerical value depends on the units employed for heat and mechanical energy respectively.

The values of the equivalent in terms of the units most commonly employed are as follows:

778.	foot-pounds	= 1 B.T.U. (lb. deg. Fahr.)
1,401	foot-pounds	= 1 lb. deg. C. (lb.-calorie)
426.85	kilogram-metres	= 1 kilogram-deg. C. or kilocalorie
426.85	gram-metres	= 1 gram-deg. C.
4.1840	abs. joules or watt-seconds	= 1 or def. gram calorie
1.1628	watt-hours	= 1 def. kg. calorie
1.162	kilowatt-hours	= 1 ton calorie

The defined calorie above is based on the electrical equivalent of heat which is the most reproducibly measurable quantity of energy; it is closely equivalent to the amount of heat necessary to raise one gram of water from 14.5° to 15.5° C., one of the more common older definitions. The degree of temperature is based on the International Temperature scale adopted in 1948 by the International Committee of Weights and Measures. The acceleration of gravity used is 980.7 centimetre-gram-second (c.g.s.) units. For further details see CALORIMETRY.

The second law of thermodynamics is a title often used to denote Carnot's principle or some equivalent mathematical expression. In some cases this title is not conferred on Carnot's principle itself, but on some axiom from which the principle may be indirectly deduced. These axioms, however, cannot as a rule be directly applied, so that it would appear preferable to take Carnot's principle itself as the second law.

It may be observed that, as a matter of history. Carnot's principle was established and generally admitted before the principle of the conservation of energy as applied to heat, and that from this point of view the titles, first and second laws, are not particularly appropriate.

2. Combination of **Carnot's** Principle With the Mechanical Theory. — R. J. E. Clausius and W. J. M. Rankine were the first to develop at mid-19th century the correct equations of thermodynamics on the mechanical theory. When heat was supplied to a body to change its temperature or state, part remained in the body as intrinsic heat energy E, but part was converted into external work of expansion W and ceased to exist as heat. The part remaining in the body was always the same for the same change of state, however performed, as required by Carnot's fundamental axiom, but the part corresponding to the external work was necessarily different for different values of the work done. Thus in any cycle in which the body was exactly restored to its initial state, the heat remaining in the body would always be the same, or as Carnot puts it, the quantities of heat absorbed and given out in its diverse transformations are exactly "compensated," so far as the body is concerned. But the quantities of heat absorbed and given out are not necessarily equal. On the contrary. they differ by the equivalent of the external work done in the cycle. Applying this principle to the case of steam, Clausius deduced a fact previously unknown, that the specific heat of steam maintained in a state of saturation is negative, which was also deduced by Rankine about the same time.

In applying the principle to gases Clausius assumes (with Mayer and C. H. A. Holtzmann) that the heat absorbed by a gas in isothermal expansion is equivalent to the work done, but he does not appear to be acquainted with Joule's experiment, and the reasons he adduces in support of this assumption are not conclusive. This being admitted, he deduces from the energy principle alone the propositions already given by Carnot with reference to gases, and shows in addition that the specific heat of a perfect gas must be independent of the density.

W. Thomson (Lord Kelvin) in a paper "On the Dynamical Theory of Heat" published in *1852,* gave a very clear statement of the position of the theory at that time. He showed that the value $F't = J/T$, assumed for Carnot's function by Clausius without any experimental justification, rested solely on the evidence of Joule's experiment, and might possibly not be true at all temperatures. Assuming the value J/T with this reservation, he gave as the expression for the efficiency over a finite range t_1° to t_0° C., or $T_1°$ to $T_0°$ *K.*, the result,

$$W/Q = (t_1 - t_0)/(t_1 + 273) = (T_1 - T_0)/T_1 \qquad (4)$$

which, he observed, agrees in form with that found by Rankine.

3. The Absolute Scale of Temperature. — Since Carnot's function is the same for all substances at the same temperature, and is a function of the temperature only, it supplies a means of measuring temperature independently of the properties of any particular substance. This proposal was first made by Lord Kelvin in *1848,* who suggested that the degree of temperature should be chosen so that the efficiency of a perfect engine at any point of the scale should be the same, or that Carnot's function *F't* should be constant. This would give the simplest expression for the efficiency of the caloric theory, but the scale so obtained, when the values of Carnot's function were calculated from Regnault's observations on steam, was found to differ considerably from the scale of the mercury or air thermometer. At a later date, when it became clear that the value of Carnot's function was very nearly proportional to the reciprocal of the temperature *T* measured from the absolute zero of the gas thermometer, he proposed a simpler method in *1854,* namely, to define absolute temperature *T* as proportional to the reciprocal of Carnot's function. On this definition of absolute temperature, the expression $(T - T_0)/T$ for the efficiency of a Carnot cycle with limits *T* and T_0 would be exact. and it became a most important problem to determine how far the temperature by gas thermometer differed from the absolute temperature. With this object he devised a very delicate method, known as the porous plug experiment (see THERMOMETRY), of testing the deviation of the gas thermometer from the absolute scale. The experiments were carried out in conjunction with Joule, and finally resulted in showing in *1862* that the deviations of the air thermometer from the absolute scale as above defined are almost negligible, and that in the case of the gas hydrogen the deviations are so small that a thermometer containing this gas may be taken for all practical purposes as agreeing exactly with the absolute scale at all ordinary temperatures. For this reason the hydrogen thermometer has since been generally adopted as the standard.

VIII. AVAILABILITY OF HEAT OF COMBUSTION

Taking the value of 1.13 kilogram-metres per kilocalorie for *1°* C. fall of temperature at 100° C., Carnot attempted to estimate the possible performance of a steam engine receiving heat at 160° C. and rejecting it at 40° C. Assuming the performance to be simply proportional to the temperature fall, the work done for 120° fall would be 134 kilogram-metres per kilocalorie. To make an accurate calculation required a knowledge of the variation of the function *F't* with temperature. Taking equation (4) above the work obtainable is *118* kilogram-metres per kilocalorie, which is *28%* of *426.* the mechanical equivalent of the kilocalorie in kilogram-metres. Carnot pointed out that the fall of 120° C. utilized in the steam engine was only a small fraction of the whole temperature fall obtainable by combustion, and made an estimate of the total power available if the whole fall could be utilized, allowing for the probable diminution of the function *F't* with rise of temperature. His estimate was 3,900,000 kilogram-metres per kilogram of coal. This was certainly an overestimate. but was surprisingly close, considering the scanty data at his disposal.

In reality the fraction of the heat of combustion available, even in an ideal engine and apart from practical limitations, is much less than might be inferred from the efficiency formula of the Carnot cycle, by taking the temperature obtainable by the combustion of the fuel as the upper limit of temperature in the formula. For carbon burned in air at constant pressure without any loss of heat, the products of combustion might be raised 2,300° C. in temperature, assuming that the specific heats of the products were constant and that there was no dissociation. If all the heat could be supplied to the working fluid at this temperature, that of the condenser being 40° C., the possible efficiency by equation (4) above would be 89%. But it is obvious that this could not be done even under the most ideal conditions. The heat given up by the products of combustion in cooling to atmospheric temperature could not be received by the boiler at 2,300° but at intermediate temperatures from 2,300° to 40°, which would reduce the mean effective temperature of heat reception from 2,300° to 1,640°, and the ideal efficiency from *89%* to *62%.* This, however, assumes a perfect regenerative boiler in which the working fluid leaves the boiler at a temperature of 2,300°, although the mean temperature of heat reception cannot exceed 1,640°. Carnot foresaw that there would be further limitations in the case of the steam engine owing to the properties of the working fluid.

The greater part of the heat required for generating steam in a boiler is the latent heat of vaporization, which is necessarily received by the steam at the saturation temperature corresponding to the pressure at which the boiler is designed to work. Thus at a pressure of *680* lb. per square inch, the latent heat of vaporization, amounting to about *400* cal.. would be received at a temperature of only 260° C. (500° F.) permitting an ideal efficiency of 41% for the conversion of this part of the heat. But if the feed water from the condenser at 40° is pumped directly into the boiler. to heat it to 260°. the heat required, amounting to about *230* cal., would be received by the feed water at intermediate temperatures, and could not be so efficiently utilized. Rankine

in 1854 was the first to show how the work obtainable from this part of the heat could be calculated. His formula gives an ideal efficiency of conversion of 25% for heat supplied in equal instalments between 40" and 260°. This would reduce the efficiency of an engine using the Rankine cycle with saturated steam at 680 lb. pressure to 35% as compared with 41% for the Carnot cycle, in terms of the heat actually received by the steam. If the temperature of the boiler were further raised to 360° C.. corresponding to a pressure of 2,700 lb. (nearly four times as great as at 260°), the ideal efficiency of the Carnot cycle would be just over 50%, or half the latent heat could be utilized by a perfect engine. But the latent heat at 360° is only 177 cal., and is less than half the heat required for feed heating, which amounts to 400 cal.. so that the corresponding efficiency of the Rankine cycle is only 38%, nhich is very near the limit theoretically attainable in this cycle with saturated steam.

1. Advantages of Internal Combustion. — As Carnot pointed out, the chief advantage of using atmospheric air as a working fluid in a heat engine lies in the possibility of imparting heat to it directly by internal combustion. Even with internal combustion. however. the full range of temperature is not available. because the heat cannot in practice be communicated to the working fluid at constant temperature, owing to the large range of expansion at constant temperature required for the absorption of a sufficient quantity of heat. Air engines of this type, such as the Rev. R. Stirling's or John Ericsson's, taking in heat at constant temperature, though theoretically the most perfect, are bulky and mechanically inefficient.

In practical engines the heat is generated by the combustion of an explosive mixture at constant volume or at constant pressure. The heat is not all communicated at the highest temperature. but over a range of temperature from that of the mixture at the beginning of combustion to the maximum temperature. The earliest instance of this type of engine is the lycopodium engine of M. M. Niepce. discussed by Carnot, in which a combustible mixture of air and lycopodium powder at atmospheric pressure was ignited in a cylinder. and did work on a piston. The early gas engines of E. Lenoir (1860) and N. Otto and E. Langen (1867) operated in a similar manner nith illuminating gas in place of lycopodium. Combustion in this case is effected practically at constant volume. and the maximum efficiency theoretically obtainable is $1 - \log_e r/(r - 1)$. where r is the ratio of the maximum temperature T to the initial temperature T,. In order to obtain this efficiency it would be necessary to follow Carnot's rule. and expand the gas after ignition without loss or gain of heat from T down to T_0, and then to compress it at T_0 to its initial volume. If the rise of temperature in combustion were 2 300° C., and the initial temperature were 0° C. or 273° K.. the theoretical efficiency would be 73.3%, which is much greater than that obtainable with a boiler. But in order to reach this value. it would be necessary to expand the mixture to about 270 times its initial volume, which is obviously impracticable.

Because of incomplete expansion and rapid cooling of the heated gases by the large surface exposed. the actual efficiency of the Lenoir engine was less than 5%, and of the Otto and Langen, nith more rapid expansion, about 10%.

Carnot foresaw that in order to render an engine of this type practically efficient, it would be necessary to compress the mixture before ignition. Compression is beneficial in three nays: (1) it permits a greater range of expansion after ignition; (2) it raises the mean effective pressure, and thus improves the mechanical efficiency and the power in proportion to size and neight; (3) it reduces the loss of heat during ignition by reducing the surface exposed to the hot gases. In the modern gas or gasoline motor compression is employed as in Carnot's cycle, but the efficiency attainable is limited not so much by considerations of temperature as by limitations of volume. It is impracticable before combustion at constant volume to compress a rich mixture to much less than one-fifth of its initial volume, and. for mechanical simplicity, the range of expansion is made equal to that of compression.

The cycle employed was devised in 1862 by Alphonse Beau de Rochas, but was first successfully carried out by Otto (1876). It differs from the Carnot cycle in employing reception and rejection of heat at constant volume instead of at constant temperature. This cycle is not so efficient as the Carnot cycle for given limits of temperature, but, for the given limits of volume imposed, it gives a much higher efficiency than the Carnot cycle. The efficiency depends only on the range of temperature in expansion and compression, and is given by the formula $(T_1 - T_2)/T_1$, where T_1 is the maximum temperature, and T_2 the temperature at the end of expansion. The formula is the same as that for the Carnot cycle with the same range of temperature in expansion. The ratio T_1/T_2 is $r^{\gamma-1}$ where r is the given ratio of expansion or compression. and γ is the ratio of the specific heats of the working fluid. Assuming the working fluid to be a perfect gas mith the same properties as air, we should have $\gamma = 1.41$. Taking $r = 5$ the formula gives 48% for the maximum possible efficiency. The actual products of combustion vary with the nature of the fuel employed, and have different properties from air, but the efficiency is found to vary with compression in the same manner as for air. For this reason a committee of the Institution of Civil Engineers in 1905 recommended the adoption of the air standard for estimating the effects of varying the compression ratio, and defined the relative efficiency of an internal combustion engine as the ratio of its observed efficiency to that of a perfect air engine with the same compression.

2. Effect of Dissociation and Increase of Specific Heat, —One of the most important effects of heat is the decomposition or dissociation of compound molecules. Just as the molecules of a vapour combine with evolution of heat to form the more complicated molecules of the liquid, and as the liquid molecules require the addition of heat to effect their separation into molecules of vapour, so in the case of molecules of different kinds which combine with evolution of heat, the reversal of the process can be effected either by the agency of heat, or indirectly by supplying the requisite amount of energy by electrical or other methods. Just as the latent heat of vaporization diminishes with rise of temperature, and the pressure of the dissociated vapour molecules increases. so in the case of compound molecules in general the heat of combination diminishes with rise of temperature, and the pressure of the products of dissociation increases. There is evidence that the compound carbon dioxide, CO_2, is partly dissociated into carbon monoxide and oxygen at high temperatures. and that the proportion dissociated increases with rise of temperature.

There is a very close analogy between these phenomena and the vaporization of a liquid. The laws which govern dissociation are the same fundamental laws of thermodynamics. but the relations involved are necessarily more complex on account of the presence of different kinds of molecules, and present special difficulties for accurate investigation in the case where dissociation does not begin to be appreciable until a high temperature is reached.

It is easy, however, to see that the general effect of dissociation must be to diminish the available temperature of combustion, and all experiments go to show that in ordinary combustible mixtures the rise of temperature actually attained is much less than that calculated above by Carnot on the assumption that the whole heat of combustion is developed and communicated to products of constant specific heat. The defect of temperature observed can be represented by supposing that the specific heat of the products of combustion increases with rise of temperature. This is the case for CO_2 even at ordinary temperatures, according to Regnault, and probably also for air and steam at higher temperatures. Increase of specific heat is a necessary accompaniment of dissociation, and from some points of view may be regarded as merely another may of stating the facts. It is the most convenient method to adopt in the case of products of combustion consisting of a mixture of CO, and steam with a large excess of inert gases, because the relations of equilibrium of dissociated molecules of so many different kinds would be too complex to permit of any other method of expression.

Although Carnot's principle makes it possible to calculate in

every case what the limiting possible efficiency would be for any kind of cycle if all heat losses were abolished. it is very necessary, in applying the principle to practical cases, to take account of the possibility of avoiding the heat losses which are supposed to be absent, and of other practical limitations in the working of the actual engine. An immense amount of time and ingenuity has been wasted in striving to realize impossible margins of ideal efficiency, which a close study of the practical conditions would have shown to be illusory. As Carnot remarks at the conclusion of his essay: "Economy of fuel is only one of the conditions a heat-engine must satisfy; in many cases it is only secondary. and must often give way to considerations of safety, strength and wearing qualities of the machine, of smallness of space occupied, or of expense in erecting. To kno how to appreciate justly in each case the considerations of convenience and economy, to be able to distinguish the essential from the accessory, to balance all fairly, and finally to arrive at the best result by the simplest means, such must be the principal talent of the man called on to direct and co-ordinate the work of his fellows for the attainment of a useful object of any kind."

IX. TRANSFERENCE OF HEAT

There are three principal modes of transference of heat, namely (1) convection, (2) conduction and (3) radiation:

(1) In convection, heat is carried or conveyed by the motion of heated masses of matter. The most familiar illustrations of this method of transference are the heating of buildings by the circulation of steam or hot water, or the equalization of temperature of a mass of unequally heated liquid or gas by convection currents, produced by natural changes of density or by artificial stirring.

(2) In conduction, heat is transferred by contact between contiguous particles of matter and is passed on from one particle to the next without visible relative motion of the parts of the body. A familiar illustration of conduction is the passage of heat through the metal plates of a boiler from the fire to the water inside, or the transference of heat from a soldering bolt to the solder and the metal with which it is placed in contact.

(3) In radiation, the heated body, through the thermal vibratory motion of its atoms, radiates out into space vibratory waves of an electrodynamic nature. these waves being visible light (in part) if the body is at a sufficiently high temperature (e g, red-hot); if the body is at a lower temperature, the waves are so called infrared radiation (invisible) which is similar in nature to light but contains just enough less energy per unit (photon) so that it cannot excite the optic nerve and be perceived by the human eye. But these waves can be absorbed by matter on nhich they impinge and can be reconverted into heat; *i.e.*, into thermal vibrations of the atoms.

The different modes of transference are subject to different laws, and the difficulty of disentangling their effects and subjecting them to calculation is often one of the most serious obstacles in the experimental investigation of heat. In space void of matter, we should have pure radiation, but it is difficult to obtain so perfect a vacuum that the effects of the residual gas in transferring heat by conduction or convection are inappreciable. In the interior of an opaque solid we should have pure conduction, but if the solid is sensibly transparent in thin layers there must also be an internal radiation, while in a liquid or a gas it is very difficult to eliminate the effects of convection. These difficulties are well illustrated in the historical development of the subject by the experimental investigations which have been made to determine the lans of heat transference, such as the laws of cooling, of radiation and of conduction.

1. Newton's Law of Cooling.—There is one essential condition common to all three modes of heat transference, namely, that they depend on difference of temperature, that the direction of the transfer of heat is always from hot to cold and that the rate of transference is, for small differences, directly proportional to the difference of temperature. Without difference of temperature there is no transfer of heat. When two bodies have been brought to the same temperature by conduction, they are also in equilibrium as regards radiation, and vice versa. If this were not the case. there could be no equilibrium of heat defined by equality of temperature.

A hot body placed in an enclosure of lower temperature. *e.g.*, a calorimeter in its containing vessel, generally loses heat by all three modes simultaneously in different degrees. The loss by each mode will depend in different ways on the form, extent and nature of its surface and on that of the enclosure, on the manner in nhich it is supported. on its relative position and distance from the enclosure and on the nature of the intervening medium. But provided that the difference of temperature is small, the rate of loss of heat by all modes will be approximately proportional to the difference of temperature, the other conditions remaining constant. The rate of cooling or the rate of fall of temperature will also be nearly proportional to the rate of loss of heat, if the specific heat of the cooling body is constant, or the rate of cooling at any moment will be proportional to the difference of temperature.

This simple relation is commonly known as Newton's law of cooling, but is limited in its application to comparatively simple cases such as the foregoing. Newton himself applied it to estimate the temperature of a red-hot iron ball, by observing the time which it took to cool from a red heat to a known temperature, and comparing this with the time taken to cool through a known range at ordinary temperatures. According to this law if the excess of temperature of the body above its surroundings is observed at equal intervals of time, the observed values will form a geometrical progression with a common ratio. Supposing. for instance, that the surrounding temperature were 0° C., that the red-hot ball took 25 min. to cool from its original temperature to 20° C., and 5 min. to cool from 20° C. to 10° C.. the original temperature is easily calculated on the assumption that the excess of temperature above 0° C. falls to half its value in each interval of 5 min. Doubling the value 20° at 25 min. five times, we arrive at 640° C. as the original temperature. No other method of estimation of such temperatures mas available in the time of Newton, but, as we now know, the simple law of proportionality to the temperature difference is inapplicable over such large ranges of temperature. The rate of loss of heat by radiation, and also by convection and conduction to the surrounding air, increases much more rapidly than in simple proportion to the temperature difference, and the rate of increase of each follows a different law.

At a later date Sir John Herschel measured the intensity of solar radiation at the surface of the earth, and endeavoured to form an estimate of the temperature of the sun by comparison with terrestrial sources on the assumption that the intensity of radiation was simply proportional to the temperature difference. He thus arrived at an estimate of several million degrees. which we now know would be about a thousand times too great. The application of Newton's lam necessarily leads to absurd results when the difference of temperature is very large, but the error will not in general exceed 2% to 3% if the temperature difference does not exceed 10° C., and the percentage error is proportionately much smaller for smaller differences.

2. Surface **Emissivity.**—Similar considerations apply to many attempts which have been made to determine the general value of the constant termed by Jean Fourier and early writers the "exterior conductibility," but now called the surface emissivity. This coefficient represents the rate of loss of heat from a body per unit area of surface per degree excess of temperature, and includes the effects of radiation, convection and conduction. As already pointed out, the combined effect will be nearly proportional to the excess of temperature in any given case provided that the excess is small, but it is not necessarily proportional to the extent of surface exposed except in the case of'pure radiation. The rate of loss of heat by convection and conduction varies with the form of the surface, and. unless the enclosure is very large compared with the cooling body. the effect depends also on the size and form of the enclosure. The effects of conduction and radiation may be approximately estimated if the conductivity of the gas and the nature and forms of the surfaces of the body and enclosure

are known, but the effect of convection in any case can be determined only by experiment. It has been found that the rate of cooling by a current of air is approximately proportional to the velocity of the current, other things being equal. It is obvious that this should be the case, but the result cannot generally be applied to convection currents. Values which are commonly given for the surface emissivity must therefore be accepted with great reserve. They can be regarded only as approximate, and as applicable only to cases precisely similar to those for which they were experimentally obtained. There cannot be said to be any general law of convection. The loss of heat is not necessarily proportional to the area of the surface, and no general value of the coefficient can be given to suit all cases. The laws of conduction and radiation admit of being more precisely formulated, and their effects predicted, except in so far as they are complicated by convection.

X. CONDUCTION OF HEAT IN SOLIDS

The transference of heat in the interior of a solid body formed one of the earliest subjects of mathematical and experimental treatment in the theory of heat. The law assumed by Fourier was of the simplest possible type, but the mathematical application, except in the simplest cases, was so difficult as to require the development of a new mathematical method. Fourier succeeded in showing how, by his method of analysis, the solution of any given problem with regard to the flow of heat by conduction in any material could be obtained in terms of a physical constant, the thermal conductivity of the material, and that the results obtained by experiment agreed in a qualitative manner with those predicted by his theory. But the experimental determination of the actual values of these constants presented formidable difficulties which were not surmounted until a later date.

The law of conduction, which forms the basis of the mathematical theory, although seldom explicitly stated as an experimental law, should really be regarded in this light, and may be briefly worded as follows: "The rate of transmission of heat by conduction is proportional to the temperature gradient." The rate of transmission of heat is here understood to mean the quantity of heat transferred in unit time through unit area of cross section of the substance, the unit area being taken perpendicular to the lines of flow. It is clear that the quantity transferred in any case must be jointly proportional to the area and the time. The "gradient of temperature" is the fall of temperature in degrees per unit length along the lines of flow.

The thermal conductivity of the substance is the constant ratio of the rate of transmission to the temperature gradient. To take the simple case of the "wall" or flat plate considered by Fourier for the definition of thermal conductivity, suppose that a quantity of heat Q passes per second through an area A of a plate of conductivity k and thickness x, the sides of which are constantly maintained at temperatures t_1 and t_2. The rate of transmission of heat is Q/A, and the temperature gradient, supposed uniform, is $(t_1 - t_2)/x$, so that the law of conduction leads at once to the equation

$$Q/A = k(t_1 - t_2)/x$$

This relation applies accurately to the case of the steady flow of heat in parallel straight lines through a homogeneous and isotropic solid, the isothermal surfaces, or surfaces of equal temperature, being planes perpendicular to the lines of flow. If the flow is steady, and the temperature of each point of the body invariable, the rate of transmission must be everywhere the same. One of the simplest illustrations of the rectilinear flow of heat is the steady outflow through the upper strata of the earth's crust, which may be considered practically plane in this connection. This outflow of heat necessitates a rise of temperature with increase of depth. The corresponding gradient is of the order of 1° C. in 100 ft., but varies inversely with the conductivity of the strata at different depths.

A different type of problem is presented in those cases in which the temperature at each point varies with the time, as is the case near the surface of the soil with variations in the external conditions between day and night or summer and winter. The flow of heat may still be linear if the horizontal layers of the soil are of uniform composition, but the quantity flowing through each layer is no longer the same. Part of the heat is used up in changing the temperature of the successive layers. In this case it is generally more convenient to consider as unit of heat the thermal capacity c of unit volume, or that quantity which would produce a rise of 1° of temperature in unit volume of the soil or substance considered. If Q is expressed in terms of this unit in equation (5), it is necessary to divide by c, or to replace k on the right-hand side by the ratio k/c. This ratio determines the rate of diffusion of temperature, and is called the thermometric conductivity or, more shortly, the diffusivity. The velocity of propagation of temperature waves will be the same under similar conditions in two substances which possess the same diffusivity, although they may differ in conductivity.

1. Variable-flow Methods.—In these methods the flow of heat is deduced from observations of the rate of change of temperature with time in a body exposed to known external or boundary conditions. No calorimetric observations are required, but the results are obtained in terms of the thermal capacity of unit volume c, and the measurements give the diffusivity k/c, instead of the calorimetric conductivity k. Since both k and c are generally variable with the temperature, and the mode of variation of either is often unknown, the results of these methods are generally less certain with regard to the actual flow of heat. As in the case of steady flow methods, by far the simplest example to consider is that of the linear flow of heat in an infinite solid, which

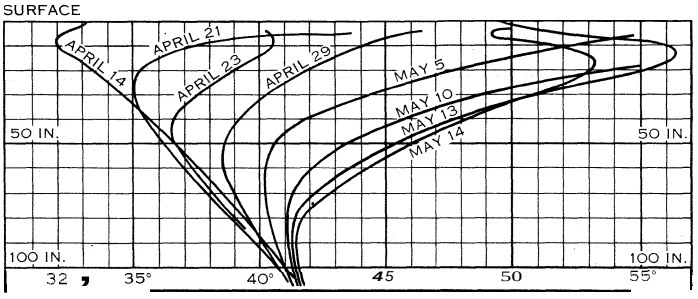

FIG. 6.—CURVES SHOWING THE VARIATION OF TEMPERATURE WITH DEPTH, AT VARIOUS DATES

is most nearly realized in nature in the propagation of temperature waves in the surface of the soil. One of the best methods of studying the flow of heat in this case is to draw a series of curves showing the variations of temperature with depth in the soil for a series of consecutive days. The curves given in fig. 6 were obtained from the readings of a number of platinum thermometers buried in undisturbed soil in horizontal positions at McGill university, Montreal.

The method of deducing the diffusivity from these curves is as follows: The total quantity of heat absorbed by the soil per unit area of surface between any two dates, and any two depths, x' and x'', is equal to c times the area included between the corresponding curves. This can be measured graphically without any knowledge of the law of variation of the surface temperature, or of the laws of propagation of heat waves. The quantity of heat absorbed by the stratum $(x'x'')$ in the interval considered can also be expressed in terms of calorimetric conductivity k. The heat transmitted through the plane x is equal per unit area of surface to the product of k by the mean temperature gradient (dt/dx) and the interval of time in seconds. The mean temperature gradient is found by plotting the curves for each day from the daily observations. The heat absorbed is the difference of the quantities transmitted through the bounding planes of the stratum. We thus obtain the simple equation.

$$k'(dt'/dx') - k''(dt''/dx'') = \text{c (area between curves)/time in sec.} \quad (6)$$

by means of which the average value of the diffusivity k/c can be found for any convenient interval of time, at different seasons of the year, in different states of the soil.

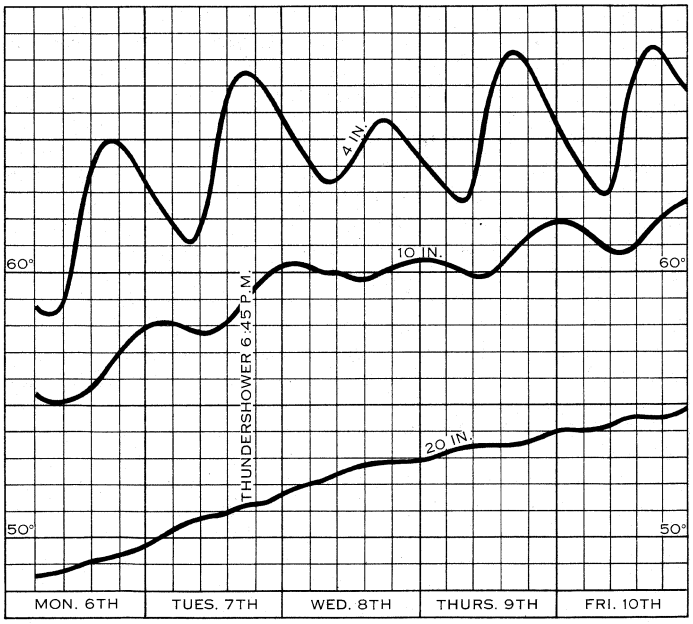

FIG. 7.— EXAMPLES OF DIURNAL SUBSURFACE TEMPERATURE VARIATIONS FOR DEPTHS OF 4, 10 AND 20 IN. (MONTH OF MAY)

For the particular soil in question it was found that the diffusivity varied enormously with the degree of moisture, falling as low as .0010 c.g.s. in the winter for the surface layers, which became extremely dry under the protection of the frozen ice and snow from December to March, but rising to an average of .0060 to .0070 in the spring and autumn. The greater part of the diffusion of heat was certainly due to the percolation of water. On some occasions, because of the sudden melting of a surface layer of ice and snow, a large quantity of cold water, percolating rapidly, gave for a short time values of the diffusivity as high as 0300. Excluding these exceptional cases, however, the variations of the diffusivity appeared to follow the variations of the seasons with considerable regularity in successive years. The presence of water in the soil always increased the value of k/c, and as it necessarily increased c, the increase of k must have been greater than that of k/c.

2. Periodic **Flow of** Heat.—The foregoing method is perfectly general, and can be applied in any case in which the requisite observations can be taken. A case of special interest and importance is that in which the flow is periodic. The general characteristics of such a flow are illustrated in fig. 7, showing the propagation of temperature waves caused by diurnal variations in the temperature of the surface.

The daily range of temperature of the air and of the surface of the soil was about 20° F. On a sunny day, the temperature reached a maximum about 2 P.M. and a minimum about j A.M. As the waves were propagated downward through the soil the amplitude rapidly diminished, so that at a depth of only 4 in. it was already reduced to about 6° F., and to less than 2° at 10 in. At the same time, the epoch of maximum or minimum was retarded, about 4 hours at 4 in., and nearly 12 hours at 10 in., where the maximum temperature was reached between 1 and 2 A.M. The form of the wave was also changed. At 4 in. the rise was steeper than the fall, at 10 in. the reverse was the case. This is due to the fact that the components of shorter period are more rapidly propagated. For instance, the velocity of propagation of a wave having a period of a day is nearly 20 times as great as that of a wave with a period of 1 year; but on the other hand the penetration of the diurnal wave is nearly 20 times less, and the shorter waves die out more rapidly.

3. Laboratory Methods.—Measurements of thermal conductivity present peculiar difficulties on account of the variety of quantities to be observed, the slowness of the process of conduction, the impossibility of isolating a quantity of heat and the difficulty of exactly realizing the theoretical conditions of the problem. The following are some of the special cases which have been utilized experimentally:

The "Wall" or Plate Method.—This method endeavours to realize the conditions of equation (5), namely, uniform rectilinear flow. Theoretically this requires an infinite plate, or a perfect heat insulator, so that the lateral flow can be prevented or rendered negligible. This condition can generally be satisfied with sufficient approximation with plates of reasonable dimensions. To find the conductivity, it is necessary to measure all the quantities which occur in equation (5) to a similar order of accuracy. The measurement of the temperature gradient in the plate generally presents the greatest difficulty. If the plate is thin. it is necessary to measure the thickness with great care, and it is necessary to assume that the temperatures of the surfaces are the same as those of the mediums with which they are in contact, since there is no room to insert thermometers in the plate itself. This assumption does not present serious errors in the case of bad conductors, such as glass or wood. but has given rise to large mistakes in the case of metals.

Tube Method.—If the inside of a glass tube is exposed to steam, and the outside to a rapid current of water, or vice versa, the temperatures of the surfaces of the glass may be taken to be approximately equal to those of the water and steam, which may easily be observed. If the thickness of the glass is small compared with the diameter of the tube, say one-tenth, equation (j) may be applied with sufficient approximation.

Forbes's Bar Method.—Observation of the steady distribution of temperature along a bar heated at one end was very early employed by Fourier, César Mansuète Despretz and others for the comparison of conductivities. Originated by James David Forbes, it is the most convenient method. in the case of good conductors, on account of the great facilities which it permits for the measurement of the temperature gradient at different points; but it has the disadvantage that the results depend almost entirely on a knowledge of the external heat loss or emissivity, or, in comparative experiments, on the assumption that it is the same in different cases.

Calorimetric Bar Method.—To avoid the uncertainties of surface loss of heat, it is necessary to reduce it to the rank of a small correction by employing a large bar and protecting it from loss of heat. The heat transmitted should be measured calorimetrically. and not in terms of the uncertain emissivity. The apparatus shown in fig. 8 was constructed by H. L. Callendar and J. T. Nicolson with this object. The bar was a special sample of cast iron, the conductivity of which was required for some experiments on the condensation of steam. It had a diameter of 4 in, and a length of 4 ft. between the heater and the calorimeter. The emissivity was reduced to one-quarter by lagging the bar like a steampipe to a thickness of 1 in. The heating vessel could be maintained at a steady temperature by high-pressure steam. The other end was maintained at a temperature near that of the air by a steady stream of water flowing through a well-lagged vessel surrounding the bar. The heat transmitted was measured by observing the difference of temperature between the inflow and the outflow, and

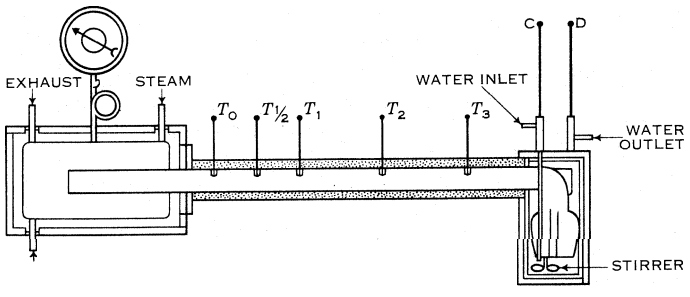

FIG 8 — CALORIMETRIC BAR METHOD IN WHICH HEAT FLOW IS MEASURED BY RISE OF TEMPERATURE OF COOLING WATER. GRADIENT IS MEASURED BY MERCURY THERMOMETERS

the weight of water which passed in a given time. The gradient near the entrance to the calorimeter was deduced from observations with five thermometers at suitable intervals along the bar. The results obtained by this method at a temperature of 40° C.

varied from .116 to .118 c.g.s. from observations on different days, and were probably more accurate than those obtained by the cylinder method. The same apparatus was employed in another series of experiments by the periodic flow method, but this involves a knowledge of c, and is very laborious.

4. Electrical Methods.—There are two electrical methods which have been usefully applied to the measurement of the conductivity of metals, (1) the resistance method, devised by Callendar, and applied by him, and also by R. O. King and J. D. Duncan, (2) the thermoelectric method, devised by Friedrich Kohlrausch, and applied by W. Jaeger and H. Dieselhorst. Both methods depend on the observation of the steady distribution of temperature in a bar or wire heated by an electric current. The advantage is that the quantities of heat are measured directly in absolute measure, in terms of the current, and that the results are independent of a knowledge of the specific heat. Incidentally it is possible to regulate the heat supply more perfectly than in non-electric methods.

(1) In the practice of the resistance method, both ends of a short bar are kept at a steady temperature by means of solid copper blocks provided with a water circulation, and the whole is surrounded by a jacket at the same temperature, which is taken as the zero of reference. The bar is heated by a steady electric current, which may be adjusted so that the external loss of heat from the surface of the bar is compensated by the increase of resistance of the bar with rise of temperature. In this case the curve representing the distribution of temperature is a parabola, and the conductivity k is deduced from the mean rise of temperature $(R - R_0)/aR_0$ by observing the increase of resistance $R - R_0$ of the bar, and the current C. It is also necessary to measure the cross section q, the length I and the temperature-coefficient a for the range of the experiment.

In the general case the distribution of temperature is observed by means of a number of potential leads. The differential equation for the distribution of temperature in this case includes the majority of the methods already considered, and may be stated as follows. The heat generated by the current C at a point x, where θ = excess temperature, is equal per unit length and time (t) to that lost by conduction $-d(qkd\theta/dx)/dx$, and by radiation $hp\theta$ (emissivity h, perimeter p), together with that employed in raising the temperature $qcd\theta/dt$, and absorbed by the Thomson effect $Cd\theta/dx$. We thus obtain the equation

$$C^2R_0(1 + a\theta)/l = -d(qkd\theta/dx)/dx + hp\theta + qcd\theta/dt + sCd\theta/dx \quad (7)$$

If C = o. this is the equation of Angstrom's method. If h also is zero, it becomes the equation of variable flow in the soil. If $d\theta/dt$ = o, the equation represents the corresponding cases of steady flow.

In the electrical method, observations of the variable flow are useful for finding the value of c for the specimen, but are not otherwise required. The last term, representing the Thomson effect, is eliminated in the case of a bar cooled at *both* ends, since it is opposite in the two halves, but may be determined by observing the resistance of each half separately. If the current C is chosen so that $C^2R_0a = hpl$, the external heat loss is compensated by the variation of resistance with temperature. In this case the solution of the equation reduces to the form

$$\theta = x(l - x)C^2R_0/2lqk \quad (8)$$

By a property of the parabola, the mean temperature is two-thirds of the maximum temperature; we have therefore

$$(R - R_0)/aR_0 = lC^2R_0/12qk \quad (9)$$

which gives the conductivity directly in terms of the quantities actually observed. If the dimensions of the bar are suitably chosen, the distribution of temperature is always very nearly parabolic, so that it is not necessary to determine the value of the critical current $C^2 = hpl/aR_0$ very accurately, as the correction for external loss is a small percentage in any case. The chief difficulty is that of measuring the small change of resistance accurately, and of avoiding errors from accidental thermoelectric effects. In addition to the simple measurements of the conductivity made at McGill university in the 1890s, some very elaborate experiments were made by King on the temperature distribution in the case of long bars with a view to measuring the Thomson effect. Duncan of McGill, using the simple method under King's supervision, found the conductivity of very pure copper to be 1.007 for a temperature of 33° C.

(2) The method of Kohlrausch. as carried out by Jaeger and Dieselhorst, consists in observing the difference of temperature between the centre and the ends of the bar by means of insulated thermocouples. Neglecting the external heat loss, and the variation of the thermal and electric conductivities k and k', we obtain, as before, for the difference of temperature between the centre and ends, the equation

$$\theta_{max} - \theta_0 = C^2Rl/8qk = ECl/8qk = E^2k'/8k \quad (10)$$

where E is the difference of electric potential between the ends. Lorenz, assuming that the ratio $k/k' = a\theta$, had previously given

$$\theta^2_{max} - \theta_0^2 = E^2/4a \quad (11)$$

which is practically identical with the preceding for small differences of temperature. The last expression in terms of k/k' is very simple, but the first is more useful in practice, as the quantities actually measured are E, C, I, q, and the difference of temperature. The current C was measured in the usual way by the difference of potential on a standard resistance.

The external heat loss was estimated by varying the temperature of the jacket surrounding the bar, and applying a suitable correction to the observed difference of temperature. But the method (1) previously described appears to be preferable in this respect, since it is better to keep the jacket at the same temperature as the end blocks. The variation of thermal conductivity with temperature is small and uncertain. whereas the variation of electrical conductivity is large and can be accurately determined, and may therefore be legitimately utilized for eliminating the external heat loss.

One of the chief objects of these experiments was to test the combined hypotheses of G. Wiedemann (1853) and L. Lorenz (1872), that the ratio of the thermal to the electrical conductivity was the same for all metals. and varied directly as the absolute temperature. This relation was strongly supported as a result of the development of the electron theory of conduction in metals by P. K. Drude (1900) and H. A. Lorentz (1905), and was approximately verified for some of the pure metals by Jaeger and Dieselhorst between o° and 100° C. But the ratio appears to be affected in a marked degree by the presence of impurities which reduce the electric conductivity, and the majority of alloys give much higher values than the pure metals. It has since been shown by the experiments of C. H. Lees (1908), H. Kamerlingh Onnes (1914) and W. F. Meissner (1920), that the remarkable increase of electric conductivity of some pure metals at very low temperatures does not extend to the thermal conductivity. Sir J. J. Thomson in his *Corpuscular* Theory of *Matter* (1907) had already pointed out that there were serious difficulties in the electron theory of Drude and Lorentz, and proposed an alternative theory which did not require the presence of a large number of free electrons in the metal. With the development of quantum mechanics in the decade following 1926 a much more penetrating understanding was achieved of the nature of both thermal and electrical conductivity. New statistical laws were proposed by Paul A. M. Dirac and independently by Enrico Fermi which accounted qualitatively, at least, for the values observed.

XI. CONDUCTION IN GASES AND LIQUIDS

The theory of conduction of heat by diffusion in gases has a particular interest, since it is possible to predict the value of the conductivity on certain assumptions, if the viscosity (*q.v.*) is known. On the kinetic theory the molecules of a gas are relatively far apart and there is nothing exactly analogous to friction between two adjacent layers A and B in relative motion. There is, however, a continual interchange of molecules between A and B, which produces the same effect as viscosity in a liquid. Faster-moving particles diffusing from A to B carry their momentum with

them, and tend to accelerate B; an equal number of slower particles diffusing from B to 4 act as a drag on A.

This action and reaction between layers in relative motion is equivalent to a frictional stress tending to equalize the velocities of adjacent layers. The magnitude of the stress per unit area parallel to the direction of flow is evidently proportional to the velocity gradient, or the rate of change of velocity per centimetre in passing from one layer to the next. It must also depend on the rate of interchange of molecules, that is to say, (1) on the number passing through each square centimetre per second in either direction, (2) on the average distance to which each can travel before collision (*i.e.*, on the "mean free path"), and (3) on the average velocity of translation of the molecules, which varies as the square root of the temperature. Similarly if A is hotter than B, or if there is a gradient of temperature between adjacent layers, the diffusion of molecules from A to B tends to equalize the temperatures, or to conduct heat through the gas at a rate proportional to the temperature gradient, and depending also on the rate of interchange of molecules in the same may as the viscosity effect.

Conductivity and viscosity in a gas should vary in a similar manner since each depends on diffusion in a similar way. The mechanism is the same, but in one case we have diffusion of momentum, in the other case diffusion of heat. Viscosity in a gas was first studied theoretically from this point of view by J. Clerk Maxwell, who predicted that the effect should be independent of the density within wide limits. This, at first sight, paradoxical result is explained by the fact that the mean free path of each molecule increases in the same proportion as the density is diminished, so that as the number of molecules crossing each square centimetre decreases. the distance to which each carries its momentum increases, and the total transfer of momentum, is unaffected by variation of density. Maxwell himself verified this prediction experimentally for viscosity over a wide range of pressure. By similar reasoning the thermal conductivity of a gas should be independent of the density. Maxwell predicted a value 0.00005j c.g.s. for the conductivity of air, and a value seven times greater for hydrogen on account of the greater velocity and range of its molecules. 4. Kundt and E. Warburg found that the rate of cooling of a thermometer in air between 150 mm. and 1 mm. pressure remained constant as the pressure was varied. At higher pressures the effectof conduction was masked by convection currents.

The question of the variation of conductivity with temperature is more difficult. If the effects depended merely on the velocity of translation of the molecules, both conductivity and viscosity should increase directly as the square root of the absolute temperature; but the mean free path also varies in a manner which cannot be predicted by theory and which appears to be different for different gases. Experiments by the capillary tube method have shown that the viscosity varies more nearly as $\theta^{\frac{3}{4}}$, but indicate that the rate of increase diminishes at high temperatures. The conductivity probably changes with temperature in the same way. being proportional to the product of the viscosity and the specific heat; but the experimental investigation presents difficulties on account of the necessity of eliminating the effects of radiation and convection, and the results of different observers often differ considerably from theory and from each other. The values found for the conductivity of air at 0° C. range from .000048 to .000057, and the temperature coefficient from .0015 to .0028.

Experimental determinations of the thermal conductivities of gases are still somewhat scarce and discordant because of the great practical difficulties, but are of special interest for the elucidation of the law of action between molecules. The hot-wire method of T. Andrews (1840) offers special facilities for relative measurements, such as the comparison of conductivities of different gases, or of the same gas at different temperatures, and has frequently been applied with this object in recent years. It has also been improved by introducing the usual compensation for end effects, and employing more accurate methods of electrical measurement, but it remains liable to the difficulties depending on the small dimensions of the wire and the elimination of the corrections for radiation. The determination of the thermal conductivities of gases gives a means of testing the value of the numerical coefficient f in the relation, $k = fgs$, between the conductivity k, the viscosity η, and the specific heat s at constant volume. According to the theoretical investigations of S. Chapman (1911) the value of the coefficient f should be 2.5 for a gas constituted of spherically symmetrical molecules. which agrees with Maxwell's theory based on the inverse fifth-power law of force, and also with experiment for monatomic molecules. Unfortunately the variation of viscosity with temperature does not satisfy the fifth-power law. which requires that the viscosity should be directly proportional to T. The conclusion is that monatomic gases may have spherically symmetrical molecules, but that the law of force is different. Theory gives no clear indication with regard to the appropriate value of f for other types of molecules. Experiment gives approximately a linear relation, $f = 2.816\gamma - 2.2$, between f and the ratio γ of the specific heats. This gives $f = 7/4$ for diatomic gases, which show fair agreement with each other. The experimental values for polyatomic gases are much less certain.

The thermal conductivity of liquids shows in one respect a remarkable contrast to that of gases, in that it has little or no relation to the viscosity. Excluding liquid metals, different liquids, such as water and glycerine. may vary widely in viscosity and yet differ little in conductivity. Most liquids show a very rapid diminution of viscosity nith rise of temperature, without any corresponding change of similar magnitude in conductivity. But the experimental evidence is very discordant, as in the case of gases. The conductivity of liquids has been investigated by similar methods. generally variations of the thin plate or guard-ring method.

The whole subject of heat conduction, both from the theoretical and experimental aspect, was reviewed critically in 1954 by L. R. Ingersoll, O. J. Zobel and A. C. Ingersoll. The subject has acquired a particularly intriguing facet through the discovery of heat conduction anomalies in the case of the so-called superfluids. Kamerlingh Onnes found in 1911 that certain metals lose all resistance to the flow of electricity when cooled to within a few degrees of the absolute zero of temperature (−273.15° C.). This appears to be caused by the shift of a certain number of electrons from the normal to the so-called superconducting state. These electrons can pass through the body of the metal without receiving or giving heat to their surroundings. Other apparently related anomalies have been found in the study of liquid helium. When cooled below −271° C., that is to within less than 2.2" of the absolute zero of temperature. some of the helium atoms can move freely through the body of the liquid without receiving or giving heat to their neighbours. See also LOW-TEMPERATURE PHYSICS (CRYOGENICS); SUPERCONDUCTIVITY.

XII. RADIATION

It was at one time supposed that there were three distinct kinds of radiation — thermal, luminous and actinic, combined in the radiation from a luminous source such as the sun or a flame. The first gave rise to heat, the second to light and the third to chemical action. The three kinds were partially separated by a prism, the actinic rays being generally more refracted, and the thermal rays less refracted than the luminous. This conception arose very naturally from the observation that the feebly luminous blue and violet rays produced the greatest photographic effects. which also showed the existence of dark rays beyond the violet, nhereas the brilliant yellow and red mere practically without action on the photographic plate. A thermometer placed in the blue or violet showed no appreciable rise of temperature, and even in the yellow the effect was hardly diicernible. The effect increased rapidly as the light faded toward the extreme red, and reached a maximum beyond the extreme limits of the spectrum (Sir Frederick William Herschel), showing that the greater part of the thermal radiation was altogether nonluminous.

It is now a commonplace that chemical action, colour sensation and heat are merely different effects of one and the same kind of radiation, the particular effect produced in each case depending on

the frequency and intensity of the vibration and on the nature of the substance on which it falls. When radiation is completely absorbed by a black substance, it is converted into heat, the quantity of heat produced being equivalent to the total energy of the radiation absorbed, irrespective of the colour or frequency of the different rays. The actinic or chemical effects, on the other hand, depend essentially on some relation between the period of the vibration and the properties of the substance acted on. The rays producing such effects are generally those which are most strongly absorbed. The spectrum of chlorophyll, the green colourinp matter of plants, shows two very strong absorption bands in the red. The red rays of corresponding period are found to be the most active in promoting the growth of the plant. The chemically active rays are not necessarily the shortest. Even photographic plates may be made to respond to the red rays by staining them with pinachrome or some other suitable dye. The action of light rays on the retina is closely analogous to the action on a photographic plate. The retina, like the plate, is sensitive only to rays within certain restricted limits of frequency. The limits of sensitiveness of each colour sensation are not exactly defined, but vary slightly from one individual to another, especially in cases of partial colour blindness. and are modified by conditions of fatigue. We are not here concerned with these important physiological and chemical effects of radiation, but rather with the question of the conversion of energy of radiation into heat. and with the laws of emission and absorption of radiation in relation to temperature. We may here also assume the identity of visible and invisible radiations from a heated body in all their physical properties.

It has been abundantly proved that the invisible rays, like the visible, (1) are propagated in straight lines in homogeneous mediums; (2) are reflected and diffused from the surface of bodies according to the same law; (3) travel with the same velocity in free space, but with slightly different velocities in denser mediums, being subject to the same law of refraction; (4) exhibit all the phenomena of diffraction and interference which are characteristic of wave motion in general; (5) are capable of polarization and double refraction; (6) exhibit similar effects of selective absorption.

These properties are more easily demonstrated in the case of visible rays because of the great sensitiveness of the eye. But with the aid of the thermopile or other sensitive radiometer, they may be shown to belong equally to all the radiations from a heated body, even such as are 30 to 50 times slower in frequency than the longest visible rays. The same physical properties have also been shown to belong to electromagnetic waves excited by an electric discharge. whatever the frequency, thus including all kinds of ethereal radiation in the same category as light.

1. Theory **of** Exchanges. — Pierre Prevost enunciated the theory of exchanges in 1791. Prevost's leading idea was that all bodies, whether cold or hot. are constantly radiating heat. Heat equilibrium. he says, consists in an equality of exchange. When equilibrium is interfered with, it is re-established by inequalities of exchange. If a refracting or reflecting body is introduced into a locality at uniform temperature. it has no effect in the way of changing the temperature at any point of that locality. A reflecting body, heated or cooled in the interior of such an enclosure, will acquire the surrounding temperature more slowly than would a nonreflector; it will less affect another body placed at a little distance: but will not affect the final equality of temperature. Apparent radiation of cold, as from a block of ice to a thermometer placed near it. is due to the fact that the thermometer being at a higher temperature sends more heat to the ice than it receives back from it. Although Prevost does not make the statement in so many words, it is clear that he regards the radiation from a body as depending only on its own nature and temperature, and as independent of the nature and presence of any adjacent body.

Heat equilibrium in an enclosure of constant temperature such as that postulated by Prevost. has often been regarded as a consequence of Carnot's principle. Since difference of temperature is required for transforming heat into work, no work could be obtained from heat in such a system, and no spontaneous changes of temperature can take place, as any such changes might be utilized for the production of work. This line of reasoning does not appear quite satisfactory, because it is tacitly assumed, in the reasoning by which Carnot's principle was established, as a result of universal experience, that a number of bodies within the same impervious enclosure, which contains no source of heat, will ultimately acquire the same temperature, and that difference of temperature is required to produce flow of heat. Thus although we may regard the equilibrium in such an enclosure as being because of equal exchanges of heat in all directions, the equal and opposite streams of radiation annul and neutralize each other in such a way that no actual transfer of energy in any direction takes place. The state of the medium is everywhere the same in such an enclosure, but its energy of agitation per unit volume is a function of the temperature, and is such that it would not be in equilibrium with any body at a different temperature.

2. "Full" and Selective Radiation. Correspondence **of** Emission and Absorption. — The most obvious difficulties in the way of this theory arise from the fact that nearly all radiation is more or less selective in character. as regards the quality and frequency of the rays emitted and absorbed. It was shown by J. Leslie, M. Melloni and other experimentalists that many substances such as glass and water. which are transparent to visible rays, are extremely opaque to much of the invisible radiation of lower frequency; and that polished metals, which are perfect reflectors, are very feeble radiators as compared with dull or black bodies at the same temperature. If two bodies emit rays of different periods in different proportions, it is not at first sight easy to see how their radiations can balance each other at the same temperature.

The key to all such difficulties lies in the fundamental conception, so strongly insisted on by Balfour Stewart, of the absolute uniformity (qualitative as well as quantitative) of the full or complete radiation stream inside an impervious enclosure of uniform temperature. It follows from this conception that the proportion of the full radiation stream absorbed by any body in such an enclosure must be exactly compensated in quality as well as quantity by the proportion emitted, or that the emissive and absorptive powers of any body at a given temperature must be precisely equal.

A good reflector, such as polished metal, must also be a feeble radiator and absorber. Of the incident radiation it absorbs a small fraction and reflects the remainder, which together with the radiation emitted (being precisely equal to that absorbed) makes up the full radiation stream. A transparent material, such as glass, absorbs part of the full radiation and transmits part. But it emits rays precisely equal in quality and intensity to those which it absorbs, which together with the transmitted portion make up the full stream.

A thin platinum tube heated by an electric current appears feebly luminous as compared with a blackened tube at the same temperature. But if a small hole is made in the side of the polished tube, the light proceeding through the hole appears brighter than the blackened tube, as though the inside of the tube mere much hotter than the outside, which is not the case to any appreciable extent if the tube is thin. The radiation proceeding through the hole is nearly that of a perfectly black body if the hole is small. If there were no hole the internal stream of radiation would be exactly that of a black body at the same temperature however perfect the reflecting power, or however low the emissive power of the walls, because the defect in emissive power mould be exactly compensated by the internal reflection.

Balfour Stewart gave a number of striking illustrations of the qualitative identity of emission and absorption of a substance. Pieces of coloured glass placed in a fire appear to lose their colour when at the same temperature as the coals behind them. because they compensate exactly for their selective absorption by radiating chiefly those colours which they absorb. Rock salt is remarkably transparent to thermal radiation of nearly all kinds. but it is extremely opaque to radiation from a heated plate of rock salt, because it emits when heated precisely those rays which it absorbs. A plate of tourmaline cut parallel to the axis absorbs almost

completely light polarized in a plane parallel to the axis, but transmits freely light polarized in a perpendicular plane. When heated its radiation is polarized in the same plane as the radiation which it absorbs. In the case of incandescent vapours, the exact correspondence of emission and absorption as regards wave length or frequency of the light emitted and absorbed forms the foundation of the science of spectrum analysis. Joseph von Fraunhofer had noticed the coincidence of a pair of bright yellow lines seen in the spectrum of a candle flame with the dark D lines in the solar spectrum, a coincidence which was afterward more exactly verified by W. A. Miller. Jean B. L. Foucault found that the flame of the electric arc showed the same lines bright in its spectrum, and proved that they appeared as dark lines in the otherwise continuous spectrum when the light from the carbon poles was transmitted through the arc. Sir George Stokes gave a dynamical explanation of the phenomenon and illustrated it by the analogous case of resonance in sound. G. R. Kirchhoff completed the explanation of the dark lines in the solar spectrum by showing in *1860* that the reversal of the spectral lines depended on the fact that the body of the sun giving the continuous spectrum was at a higher temperature than the absorbing layer of gases surrounding it.

Whatever be the nature of the selective radiation from a body, the radiation of light of any particular wave length cannot be greater than a certain fraction E of the radiation R of the same wave length from a black body at the same temperature. The fraction E measures the emissive power of the body for that particular wave length, and cannot be greater than unity. The same fraction, by the principle of equality of emissive and absorptive powers, will measure the proportion absorbed of incident radiation R'.

If the black body emitting the radiation R' is at the same temperature as the absorbing layer, $R = R'$, the emission balances the absorption, and the line will appear neither bright nor dark. If the source and the absorbing layer are at different temperatures, the radiation absorbed will be ER', and that transmitted will be $R' - ER'$. To this must be added the radiation emitted by the absorbing layer, namely ER, giving $R' - E(R' - R)$. The lines will appear darker than the background R' if R' is greater than R, but bright if the reverse is the case. The D lines are dark in the sun because the photosphere is much hotter than the reversing layer. They appear bright in the candle flame because the outside mantel of the flame, in which the sodium burns and combustion is complete. is hotter than the inner reducing flame containing the incandescent particles of carbon which give rise to the continuous spectrum. This qualitative identity of emission and absorption as regards wave length can be most exactly and easily verified for luminous rays, and we are justified in assuming that the relation holds with the same exactitude for nonluminous rays, although in many cases the experimental proof is less complete and exact.

3. Relation Between Radiation and Temperature.—Assuming, in accordance with the reasoning of Balfour Stewart and Kirchhoff, that the radiation stream inside an impervious enclosure at a uniform temperature is independent of the nature of the walls of the enclosure, and is the same for all substances at the same temperature, it follows that the full stream of radiation in such an enclosure, or the radiation emitted by an ideal black body or full radiator. is a function of the temperature only. The form of this function may be determined experimentally by observing the radiation between two black bodies at different temperatures. which will be proportional to the difference of the full radiation streams corresponding to their several temperatures. The law now generally accepted was first proposed by Joseph Stefan as an empirical relation.

John Tyndall had found that the radiation from a white-hot platinum wire at 1,200° C. was 11.7 times its radiation when dull red at 525° C. Stefan *(1879)* noticed that the ratio 11.7 is nearly that of the fourth powers of the absolute temperatures as estimated by Tyndall. On making the somewhat different assumption that the radiation between two bodies varied as the difference of the fourth powers of their absolute temperatures, he found that it satisfied approximately the experiments of Dulong and A. T. Petit and other observers. According to this law the radiation between a black body at a temperature T and a black enclosure or a black radiometer at a temperature T_0 should be proportional to $(T^4 - T_0^4)$. The law was very simple and convenient in form. but it rested so far on very insecure foundations. The temperatures given by Tyndall were merely estimated from the colour of the light emitted, and might have been some hundred degrees in error. We now know that the radiation from polished platinum is of a highly selective character, and varies more nearly as the fifth power of the absolute temperature.

The agreement of the fourth-power law with Tyndall's experiment appears therefore to be attributed to a purely accidental error in estimating the temperatures of the wire. Stefan also found a very fair agreement with J. W. Draper's observations of the intensity of radiation from a platinum wire, in which the temperature of the mire was deduced from the expansion. Here again the apparent agreement was largely the result of errors in estimating the temperature, arising from the fact that the coefficient of expansion of platinum increases considerably with rise of temperature.

So far as the experimental results available at that time were concerned, Stefan's law could be regarded only as an empirical expression of doubtful significance. But it received a much greater importance from theoretical investigations which were even then in progress. James Clerk Maxwell *(Electricity* and *Magnetism, 1873)* had shown that a directed beam of electromagnetic radiation or light incident normally on an absorbing surface should produce a mechanical pressure equal to the energy of the radiation per unit volume. A. G. Bartoli (1875) took up this idea and made it the basis of a thermodynamic treatment of radiation. P. N. Lebedev in *1899,* and E. *F.* Nichols and G. F. Hull in 1901, proved the existence of this pressure by direct experiments. L. Boltzmann *(1884)* employing radiation as the working substance in a Carnot cycle, showed that the energy of full radiation at any temperature per unit volume should be proportional to the fourth power of the absolute temperature.

The proof given by Boltzmann may be somewhat simplified if we observe that full radiation in an enclosure at constant temperature behaves exactly like a saturated vapour, and must therefore obey Carnot's or Clapeyron's equation *(see* THERMODYNAMICS). The radiation pressure at any temperature is a function of the temperature only, like the pressure of a saturated vapour. If the volume of the enclosure is increased by any finite amount, the temperature remaining the same, radiation is given off from the walls so as to fill the space to the same pressure as before. The heat absorbed when the volume is increased corresponds with the latent heat of vaporization. In the case of radiation, as in the case of a vapour, the latent heat consists partly of internal energy of formation and partly of external work of expansion at constant pressure.

Since in the case of full or undirected radiation the pressure is one-third of the energy per unit volume, the external work for any expansion is one-third of the internal energy added. The latent heat absorbed is, therefore, four times the external work of expansion. Since the external work is the product of the pressure P and the increase of volume V, the latent heat per unit increase of volume is four times the pressure. But by Carnot's equation the latent heat of a saturated vapour per unit increase of volume is equal to the rate of increase of saturation pressure per degree divided by Carnot's function or multiplied by the absolute temperature. Expressed in symbols we have,

$$T(dP/dT) = L/V = 4P \qquad (12)$$

where (dP/dT) represents the rate of increase of pressure. This equation shows that the percentage rate of increase of pressure is four times the percentage rate of increase of temperature, or that if the temperature is increased by 1%, the pressure is increased by 4%. This is equivalent to the statement that the pressure varies as the fourth power of the temperature, a result which is mathematically deduced by integrating the equation.

4. Experimental Verification of the Fourth-Power Law.—The verification of this law requires (1) a black body or bodies capable of emitting full radiation at a series of different tempera-

tures over an extended range, (2) a thermometer or thermometers capable of measuring these temperatures on the absolute scale, (3) a bolometer or thermopile (see below) capable of giving accurate relative values of the intensity of the radiation emitted in each case.

These conditions were approximately satisfied by the experiments of Schneebeli (1884), who employed an air thermometer heated to various temperatures in a furnace, and observed the radiation from the bulb through a small aperture in the walls of the furnace. With this arrangement the radiation observed would be nearly that of a black body, but the verification was rather rough in some respects. Measurements by J. T. Bottomley, A. Schleiermacher, L. C. H. F. Paschen and others, of the radiation from electrically heated platinum, failed to give results in agreement with the fourth-power law on account of variations in the quality of the radiation, but greatly extended and improved methods of measuring radiation in other respects.

The most complete series of experiments, covering the range of the gas thermometer at the time available. were those of O. R. Lummer and E. Pringsheim (1897). They used a black body heated by steam at 100° C., for standardizing their bolometer, and, as their radiator, a black body consisting of a copper sphere heated in a salt bath for the range zoo° to 600° C., and an iron cylinder heated in a gas muffle for the range 600° to 1,250° C. The temperatures were taken with a high-range mercury thermometer, and with thermocouples. corrected to the gas-scale by direct comparison with a gas thermometer up to 1,150° C. One of the chief experimental difficulties of this investigation is the wide range of variation of the intensity of the radiation to be measured, which is nearly 450 times as great at 1,250° C. as at 100° C. They employed a very sensitive form of bolometer. and a galvanometer capable of giving a deflection of 336 mm. under standard conditions. with a beam of radiation 16 mm. square at a distance of 633 mm. from the black body at 100° C. For the higher intensities it was necessary to reduce the sensitivity in a known ratio by varying the distance of the bolometer from the source, and the current in the bolometer circuit. The results for the relative intensities agreed on the average to about 1% with the fourth-power law over the nhole range of the observations. The law has since been verified up to 1,500° C. by extending the range of the gas thermometer and thermocouples, and down to −250° C. with bolometers.

5. Sensitive Radiometers. — The term radiometer may be applied to any instrument adapted for measuring radiation, but we are here concerned chiefly with those types which are equally sensitive to radiant energy of all the wave lengths present in the radiation from a hot body. We may therefore omit the selenium cell which is very sensitive to luminous radiation. and the photoelectric cell for actinic rays, since these are comparatively insensitive to the infrared rays. and do not satisfy the condition of measuring total energy irrespective of wave length. The instruments chiefly employed at the present time for measurements of heat radiation, are the thermopile and the bolometer. the action of which depends on the same principles as those involved in the construction and operation of the corresponding types of electrical thernzometers, namely the thermocouple and the electrical resistance thermometer, the theory of which is more fully discussed in the article THERMOMETRY.

The thermopile and bolometer are in fact essentially electrical thermometers, with sensitive receiving surfaces for the absorption of radiation, and especially designed for measuring the small differences of temperature thereby produced. The sensitivity and accuracy of these instruments depend to a great extent on the galvanometer and electrical measuring apparatus with which they are employed.

One of the oldest and most sensitive radiometers is the Melloni thermopile, the invention of which led to so many advances in the theory and measurement of radiation. Sensitivity is secured by using antimony and bismuth alloys (A and B), a single couple of which may give as much as 120 μv for a difference of temperature of 1° C. between the hot and cold junctions. With 100 couples connected in a continuous series **A–B–A–B–A** and so on, packed as usual in the form of a cube with alternate junctions on opposite faces, an electromotive force of 12 mv would be obtainable per 1° C. difference of temperature between the receiving surfaces of the pile. The chief defect of this type of instrument in practice is that it has a large thermal capacity because of its massive construction, and takes a long time to reach its maximum temperature. For many purposes quickness of action is quite as important as sensitivity in millivolts per degree, and the accuracy obtainable depends to a great extent on constancy of zero. In such cases the Melloni pile will be a most unsuitable instrument to employ, though it is still often used for demonstration purposes.

The conditions affecting quickness and constancy were first clearly elucidated by C. V. Boys (1888) in the construction of his radiomicrometer, in which the thermopile and galvanometer were combined in a single instrument. This was effected by attaching a very light A–B couple to a loop of copper wire suspended between the poles of a powerful magnet by means of a fine quartz fibre, which made it possible to combine the advantage of maximum deflection for weak sources of radiation with quickness of action and constancy of zero.

A similar arrangement was adopted some years later by W. Duddell in his thermogalvanometer, for measuring small alternating currents. The current to be measured is passed through a small heater fixed close below the suspended thermocouple, the deflections of which are approximately proportional to the square of the current. The radiomicrometer is essentially the same instrument except that the suspended thermocouple is heated by radiation incident on a blackened disk of copper or silver foil, and that its constant is determined by exposure to a known source of radiation, such as a standard candle at a considerable distance. The instrument must be set up like a sensitive galvanometer and carefully leveled on a good foundation in a permanent position, and the radiation to be measured must be brought to the receiver in a horizontal direction. In this respect the combination of the thermopile and sensitive galvanometer in a single instrument is less convenient in practice than the use of a separate thermopile in conjunction with a fixed galvanometer. since in the latter case the thermopile can be adjusted in any desired position independently of the galvanometer, and the sensitivity may easily be altered in a known ratio according to requirements by varying the resistance in the circuit without changing the position of either source or receiver.

The bolometer invented by S. P. Langley in 1878 depends for its action on change of electrical resistance. and consists essentially of a pair of grids of thin blackened foil of nearly equal resistance balanced one against the other in a Wheatstone bridge. Both are equally affected by changes in the temperature of the instrument, but if one grid is exposed to radiation while the other is screened, the resulting difference of temperature between them produces a current through the galvanometer approximately proportional to the intensity of the radiation. The whole exposed area of the grid constitutes the receiving surface, and extreme quickness of action can be secured by using very thin foil. The bolometer permits a wide range of variation of sensitivity since (in addition to other methods available with the thermopile) the current through the grids may be increased with a proportional increase in the deflection of the galvanometer. For this reason the sensitivity of a bolometer may considerably exceed that of a thermopile under othernise similar conditions. There is, however, a practical limit to the increase of sensitivity thus obtainable, because of the heating effect of the current which produces a rise of temperature in the grids proportional to the square of the current. When this becomes excessive. the zero is liable to wander and no further improvement in accuracy of measurement can be gained. One can obtain the greatest change of specific electrical resistance for a small increment of temperature and, as a consequence, the greatest bolometric sensitivity by the use of a strip of metal or alloy maintained at a temperature so low that the material is just within the superconducting state; under these conditions the thermal fluctuations (Brownian movement) are also reduced to a minimum.

A linear thermopile, in which all the sensitive junctions are arranged in a vertical line, is entirely free from this source of trouble and is generally superior to the bolometer in point of stability of zero. Fig. g illustrates the construction of the Moll linear thermopile which is probably the most perfect instrument of this type in respect to constancy of zero as well as quickness of action. There are 20 thermocouples arranged with their hot junctions in a vertical line behind the centre of the slit. The metals employed are the alloys constantan and manganin, both of which possess the property that their resistance does not vary appreciably with temperature. These alloys have the required mechanical properties and can be rolled into very thin strips, which afford excellent receiving surfaces and respond with extreme quickness. One half of each strip consists of constantan and the other half of manganin. The strips are connected in a continuous series, C–M–C–M–C and so on, the cold junctions on either side being soldered to copper studs fixed in insulating blocks at right angles to the plane of the strips. The function of these studs is to keep the cold junctions at a uniform temperature as nearly as possible the same as that of the enclosing case. Great constancy of zero and steadiness of deflection is thus obtained. Thus although the thermoelectric power of a single constantan-manganin couple is only about 40 μv per degree, or less than a third of that obtainable with the antimony-bismuth alloys (which are brittle and difficult to work) the superior quickness and constancy and facility of construction of the constantan-manganin pile make the latter a more accurate and convenient instrument in practice

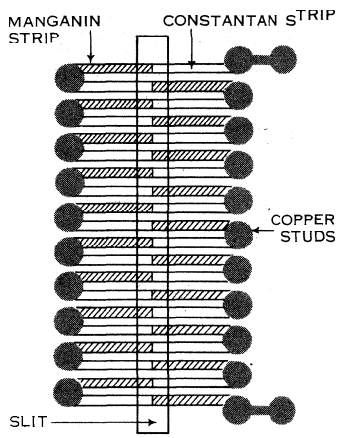

FIG. 9.—MOLL LINEAR THERMOPILE

Thermocouples of manganin and constantan strips with alternate junctions in a vertical line

In measuring the intensity of radiation at a distance from the source, where there is no restriction on the area of the beam received, the bolometer has the advantage that it can easily be made of any desired area, and that increase of area permits an increase of sensitivity. This condition cannot be satisfied easily in practice with a thermopile since the multiplication of couples involves a corresponding increase of resistance; but in dealing with images, such as spectral lines, of limited area, the thermocouple has the advantage that its sensitive receiving surface can be made to coincide with that of the image to be measured, as in the coronal pile for observing the sun's corona. Thus in the extreme case of a point image, such as that of a star, the single couple has a great advantage over the bolometer, which could not easily be made of the required size.

By using very small single couples enclosed in a vacuum to reduce external loss of heat. W. W. Coblentz (Lick observatory, 1915) succeeded in obtaining remarkably accurate measurements of the relative thermal intensities of star images in a large reflecting telescope. The vacuum thermopile devised by Moll, with a differential pair of junctions enclosed in a vacuum, would probably be well suited for this kind of work, as the effect of sky radiation would be compensated very accurately.

The Crookes' radiometer, with a delicately suspended vane in a vacuum of about 0.02 mm., as improved by Nichols, can be made nearly equal in sensitivity to the radiomicrometer of Boys, but has the disadvantage of requiring the radiation to be introduced through a window, which may in many cases give rise to uncertainty because of selective absorption, in addition to the difficulty of maintaining a constant vacuum.

During World War II there arose a military need for fast and sensitive devices for detecting infrared radiation, a need which stimulated the development of several new types of radiometric methods marking an advance in this field. It was found possible to produce thin ribbons of semiconductors which had a remarkably high change of electrical resistance for a small increment in temperature caused by impinging heat radiation; the term thermister has been used to designate these units. Marcel Golay and his associates developed a thermopneumatic cell in which the heat radiation caused a small amount of gas to expand, thereby moving a thin diaphragm with a mirror surface and deflecting a visible light beam across a photoelectric cell; this came to be generally spoken of as the "Golay detector" and has had wide use, especially in infrared spectrographs where extremely sensitive and fast detection is required.

D. H. Andrews and his associates built an infrared detector, using as the receiver a ribbon of niobium nitride. maintained in the intermediate zone between the normal and the superconducting state. The very low temperature (−258° C.), necessary to get this special kind of electrical conduction, is produced by a mixture of liquid and crystalline hydrogen kept under a partial vacuum in a small vacuum-jacketed copper vessel called a cryostat. The ribbon of niobium nitride (5 mm. long, 0.3 mm. wide and 0 006 mm. thick) is cemented to the top of a small copper post with a plastic adhesive and located in the vacuum chamber behind a rock-salt window which permits the heat radiation from the object under observation to pass from the atmosphere into the vacuum chamber and onto the receiver. Since very low heat capacity and very low thermal noise are associated with the temperature region near absolute zero in which the device is operated, both speed and sensitivity of detection are extremely high. The rate of change of electrical resistance with temperature is about 10 ohms per degree centigrade; and a change of temperature of as little as one ten-millionth of a degree in the receiver can be detected. This means that an amount of heat as little as one ten-million-millionth of a calorie can be observed in a single pulse of heat radiation falling on the bolometer. The instrument responds in less than one thousandth of a second. Because of this it is possible to use the device as a receiver in infrared television, a special kind of television by which the images of distant moving objects can be detected in complete darkness by means of the invisible heat radiation which they emit; the objects are scanned by an oscillating mirror and the images are presented to the observer on a fluorescent screen, similar to that used in standard television. This type of heat receiver is commonly referred to as a superconducting bolometer.

These devices developed during World War II are described in the *Journal of the Optical Society of America* (1946) together with a critical evaluation of their respective speed and sensitivity by Bell, Buhl, Nielsen and Nielsen. The superconducting bolometer appears to have the highest figure-of-merit of any detector of heat radiation developed by the late 1950s; *i.e.*, the best combination of sensitivity and speed. It was subsequently used by R. D. Fowler, M. C. Williams and D. H. Andrews to detect the heat pulse produced by the impact of a single helium atom (alpha particle) ejected by a radioactive polonium atom (1949).

6. Absolute Measurement of Radiation. — The absolute measurement of the constant of radiation a in the fourth-power law

$$R = \sigma(T^4 - To^4) \qquad (13)$$

is required for estimating the quantity of radiation R emitted per second per unit area by a black surface at the absolute temperature T. The law having been verified qualitatively, as previously described, by observing relative values at different temperatures, it suffices for the determination of the constant σ to select one particular temperature of the source, and to observe the intensity of the radiation received at a known distance with a receiver capable of giving the result in absolute measure, such as watts per second.

It is first necessary that the temperature of the emitter should be uniform and accurately known. For this reason a black body enclosure at 100° C. or T = 373.1 is commonly selected. The objection to this is that the intensity of the radiation is comparatively feeble and the quantity of heat to be measured inconveniently small as compared with accidental errors. A high temperature such as T = 1273° gets over this difficulty, but such

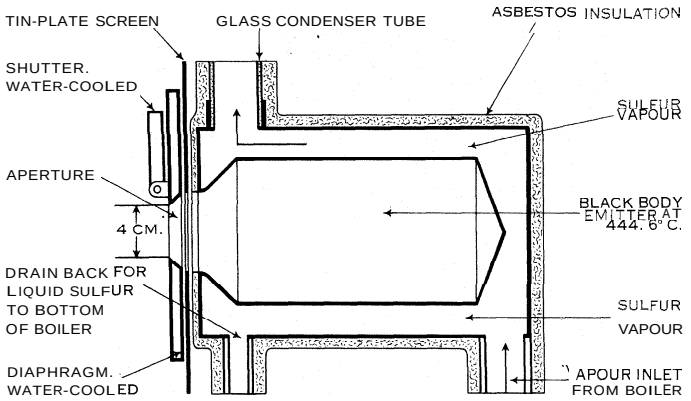

FIG. 10.— BLACK BODY EMITTER HEATED BY SULFUR VAPOUR. FOR MEASURING INTENSITY OF FULL RADIATION FROM A SOURCE AT A TEMPERATURE OF 444.6° C., THE BOILING POINT OF SULFUR

temperatures are not known with sufficient accuracy, and are not easily regulated with the necessary uniformity and constancy. It appears best to select an intermediate temperature, such as the boiling point of sulfur (S.B.P.) at 444.6° C. or $T = 717.6°$, which has been determined with great care, and is easily maintained constant.

Fig. 10 shows the essential points of a black body emitter employed for this purpose. The black body consists of a double-walled enclosure constructed of sheet iron with brazed or welded joints, which must be absolutely tight to prevent any escape of the vapour. The sulfur is boiled in an iron boiler located in a fume cupboard at a lower level, and the vapour is brought up to the apparatus through a long iron tube to avoid any possibility of superheating. When the sulfur boils, the heavy brown vapour soon makes its appearance in the glass condenser tube at the top of the apparatus. This tube is open at the top, and is exposed without lagging for a height of two or three feet. The boiler flame is regulated to keep the level of the vapour constant about halfway up the tube. The condensed liquid flows back through a small tube to the bottom of the boiler, and the apparatus will work for days with hardly any attention. The actual temperature inside the enclosure is observed occasionally with a long platinum thermometer, and is always a few tenths of a degree lower than that of the vapour because of loss by radiation. The inside of the enclosure is usually blackened in the first instance with platinum black, but soon becomes coated in any case with a protecting film of black oxide of iron, which is generally black enough for the purpose. The emitted beam is defined by an accurately turned aperture in a blackened diaphragm, cooled by a copious circulation of water at or near the atmospheric temperature.

The method of taking an observation consists in exposing the receiver, at a distance d from the diaphragm along the axis of the aperture, to the full normal beam of radiation, and taking a reading of the heat received. The aperture is then closed by the water-cooled shutter shown in the figure, and a zero reading is taken. The effect of closing the shutter is to substitute for the beam of full radiation at the temperature T of the enclosure, a beam from an exactly equal area of the shutter at the temperature T_0, which is the same as that of the diaphragm. The observed diiference between the two readings gives the value of $u(T^4 - T_0^4)$ as required in the equation, and eliminates any accidental stray radiation, which may affect the zero of the receiver, but is not altered by closing the shutter. If $T = 717.6°$ and $T_0 = 290°$, the correction for T_0^4 is less than 1.6%, so that a defect of 5% in the effective blackness of the diaphragm or shutter would give an error of less than ▮ in 1000 in the result for the constant σ, and it is not necessary to know the value of T_0 with great accuracy. The case is quite different, however, in using a black body at 100° C. or 373.1° K. in the same manner. The correction for T_0 mould then amount to nearly 37%, or 23 times larger, and a defect of 5% in the blackness of the shutter might produce an error of nearly 2% in the result.

This fact, in addition to the other difficulties above mentioned, has often led to appreciable errors in the use of a black body at 100° C. for purposes of reference, and is one of the chief reasons why it is desirable to use a black body at a reasonably high temperature for the determination of the constant σ. Accidental errors of this kind, resulting from invisible reflections and stray radiation, are most perfectly avoided by completely enclosing the receiver in a water-cooled aluminum casting (aluminum for lightness and high conductivity) at the same temperature as the diaphragm and shutter. The casting has a removable lid permitting easy access for preliminary measurements and adjustments of distance, etc., but this method is so elaborate that it has seldom been attempted. It is also essential to exclude products of combustion such as CO, CO_2 and SO_2 which are highly absorbent for infrared radiation.

7. Absolute Radiometers. — The measurement of the radiation in absolute units is a more difficult part of the problem than that of securing a good approximation to full radiation at a known temperature. Instruments designed for absolute measurement were first developed for measuring the intensity of solar radiation. and were called pyrheliometers. The usual method, as first employed in C. S. M. Pouillet's pyrheliometer, was to receive the solar radiation on a blackened disk of known area and thermal capacity and to observe the rise of temperature produced in. a given time. The original apparatus was rather sluggish in action, and the correction for heat loss somewhat uncertain. The method was improved by Sir G. G. Stokes, J. Violle and A. Crova, by using disks of small thermal capacity and high conductivity, protected from stray radiation by an enclosure at constant temperature. It is still largely employed for solar radiation, but is much less suitable for weak sources, such as are generally used in laboratory experiments, for which some electrical method of compensation is more convenient and accurate.

Angstrom *Pyrheliometer*.—One of the oldest and best of these compensation methods was first devised by K. Angstrom (1893) for measuring solar radiation. His pyrheliometer is illustrated in figs. 11 and 12, and depends on balancing the radiation by electric heating.

The front view, fig. 11, shows the pair of blackened strips of very thin manganin, 2 cm. long and 2 mm. wide, one of which is exposed to the radiation to be measured while the other is heated to the same temperature by an electric current. In this case the heat received from the radiation by one strip would evidently be equal to that generated by the current in the other, provided that the two were alike in all respects. Thus if R^1 is the radiant heat absorbed per square centimetre, b the breadth of the strip, C the current in amperes and r the resistance in ohms per centimetre, the value of R^1 in watts per square centimetre is given by the simple relation, $R^1 = C^2 r/b$. The ebonite block carrying the strips and their connecting terminals is fitted in a brass tube the front of which is closed by a cap with two slits corresponding in position with the strips. A swiveling shutter behind the cap permits the screening of either strip. The current is turned on the screened strip by the switch at the back and is adjusted by the rheostat until the galvanometer connected to the thermocouple indicates equality of temperature by absence of deflection. The thermocouple consists of a loop of fine constantan wire, the ends of which are connected to strips of copper foil attached to the backs of manganin strips as indicated in the diagram of connections (fig. 12). Each copper strip is attached as closely as possible to its manganin strip. but is insulated from it by thin silk paper and shellac. The copper strips provide a reliable attachment for the two junctions of the couple and help to equalize the temperature of the strip.

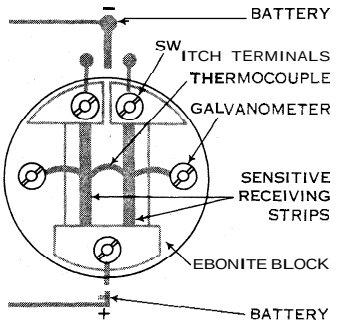

FIG. 11.—ÅNGSTRÖM PYRHELIOMETER, SHOWING FRONT VIEW OF STRIPS

Radiation received by one strip is measured by heating the other with an electric current to same temperature, as indicated by a thermocouple

The object of balancing one strip against the other is to make the reading as sensitive as possible and to eliminate any disburbances depending on changes of temperature of the case, which would affect both strips equally. To eliminate small differences between the strips, the reading is repeated with the second strip screened and heated by the current while the first is exposed to radiation. The mean of the results is free from errors resulting from want of symmetry, provided that such errors are small. In this balance method of observation the result is practically independent of the accuracy of the galvanometer, but an error of 1% in the current C as measured by the ammeter would give an error of 2% in the result: since it depends on C^2. The result also depends on the breadth of the strip b and on its resistance r per centimetre, both of which are difficult to measure accurately, more especially when the strip is blackened with smoke, which makes the edge somewhat ill-defined. In any case the value of R, representing the heat actually absorbed, will depend on the coefficient of absorption of the smoke film, which is generally taken as 98% but may vary somewhat for different wave lengths and different smoke films.

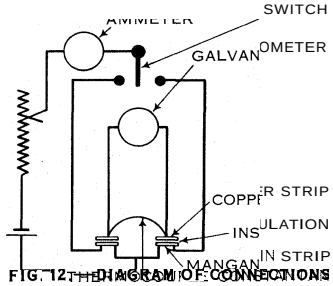

FIG. 12.—DIAGRAM OF CONNECTIONS OF THE ÅNGSTRÖM PYRHELIOMETER
Shown are ammeter circuit and insulated copper strips for attachment of thermojunctions

Kurlbaum's bolometric method can be applied to any sensitive bolometer of suitable construction, and avoids some of the difficulties of measurement inherent in Angstrom's method, but introduces others which make it less convenient for solar radiation. The method consists in observing the deflection D of the galvanometer when the bolometer is exposed to the radiation to be measured and is traversed by the small current c usually employed. The grid is then screened from radiation, and the current is increased to a larger value C such that the galvanometer gives the same deflection D because of the additional heat generated by the current in the grid. The intensity of the radiation R^1 in watts per square centimetre is given in terms of the resistance r per square centimetre of the grid by the formula, $R^1 = r(C^2 - c^2)C/c$. The difficulty of measuring the width of the strips may be avoided by using a pair of similar grids, adjusted in such a way that the strips of the second are behind the spaces between the strips of the first. The whole area of the grid may thus be utilized, and r is the whole resistance in ohms divided by the area in square centimetres. The factor C/c is required in the formula to allow for the fact that the deflection D of the galvanometer for a given increase of resistance of the grid is directly proportional to the current. The accuracy of measurement of the currents C and c is rather more important than in Angstrom's method, but the bolometric method avoids the measurement of b and makes that of r very easy. On the other hand it is necessary to balance the bolometer against manganin resistances which are not appreciably affected by the current C. This makes it impossible to compensate for changes in the temperature of the surroundings in the usual way (by balancing the receiving grid against a precisely similar grid) since both would be equally heated by the current C. F. Kurlbaum employed a black body at 100° C. as source, and the actual rise of temperature of the grid due to the incident radiation with the small current c was only about a tenth of 1° C. The rise of temperature caused by increasing the current from c to C would be less than this in the ratio c/C. The successive observations of radiation and current heating would be unequally affected by any change in the surrounding conditions, and the difficulties of the method make it unsuitable for employment except in the laboratory with weak sources under very steady conditions.

Employing this method Kurlbaum (1898) found the value $\sigma = 5.32 \times 10^{-5}$ ergs per square centimetre per second, or 5.32×10^{-12} w. per square centimetre, but this rested on a somewhat doubtful estimate of the absorption coefficient of the bolometer employed, and was raised at a later date (1912) from 5.32 to 5.45. L. C. Paschen and W. Gerlach (1912) employed a modification of Angstrom's method, but with a single strip (in place of a pair of strips) of measured area and resistance, which was alternately exposed to the radiation to be measured and heated by a measured electric current. The rise of temperature of the strip was indicated, and adjusted approximately to the same value in either case, by observing the deflection of a galvanometer connected to a linear pile fixed in position close behind the strip but not in contact with it.

The method is inferior in some respects to Angstrom's, especially in the absence of a balancing strip, and in its dependence on the accurate observation of successive deflections. On the other hand the single strip employed by Paschen and Gerlach is easier to make than the compound strip employed by Angstrom, and the measurement of its breadth b and resistance r per centimetre should be more accurate. They used a linear thermopile equal in length to the strip, and deduced the value of r per centimetre from measurements of the whole length and resistance, whereas Angstrom measured r by observing the potential difference between a pair of needlepoint potential terminals fixed at a distance of 1 cm. apart, and brought into contact with the central portion of the strip while a measured current was passing through it. This was a delicate operation, but was necessitated by the fact that he used a single couple at the centre of the strip, and that there might be some uncertainty about the resistance of the contacts at the end of the strip, since the compound strip could not be soldered satisfactorily to the terminal plates.

Gerlach's later measurements (1916), in which corrections were applied for the imperfect blackness of platinum black and for atmospheric absorption, gave a final value $\sigma = 5.80 \times 10^{-12}$ w. per square centimetre which, though appreciably lower than his original uncorrected value, 5.85, was still nearly 7% higher than Kurlbaum's final value 5.45 by the bolometric method. It was suggested that these discrepancies might be because of inequalities of temperature resulting from loss of heat by conduction from the ends of the strip. Coblentz and Emerson (1916) endeavoured to avoid this difficulty by attaching potential terminals to the strip at a short distance from the ends. These terminals tend to cool the strip locally, but they estimate the cooling effect as only about 0.35%. Comparing a number of different receivers of this type they found variations amounting in some cases to 2%, with a probable order of 1% for the accuracy of the mean. They gave a final value 5.73 for the constant after applying corrections for imperfect blackness and atmospheric absorption.

The radio balance, employed by H. L. Callendar (1910), was the first serious attempt to eliminate uncertain coefficients of absorption (which depend on the wave length of the radiation as well as on the blackness and conductivity of the film) by employing a black body receiver, designed to give complete absorption with an error of less than 0.1%. The construction of this receiver which can be used in any position, is illustrated in fig. 13, on an enlarged scale. The radiation to be measured is admitted through an optically worked aperture of 2 mm. diameter (which is com-

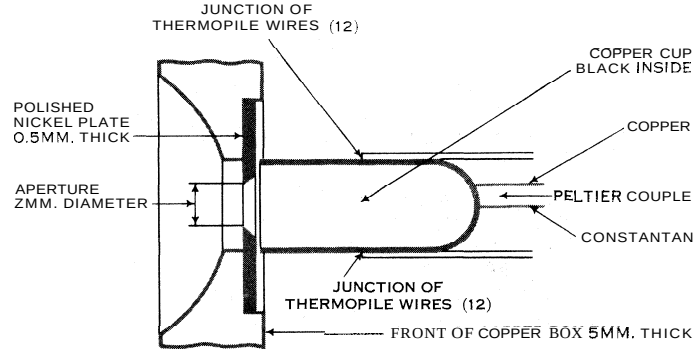

FIG. 13.— BLACK BODY RECEIVER OF RADIO BALANCE
The radiation to be measured is received in a blackened copper cup giving practically complete absorption, and is balanced by heat absorbed in a Peltier thermojunction

paratively easy to measure with the requisite degree of accuracy) and falls on the bottom of a small copper cup, where it is directly compensated by the absorption of heat arising from the Peltier effect in a thermojunction formed between the cup and a constantan wire through which a suitable current is passed. Any change of temperature of the cup is indicated by a sensitive galvanometer, connected to a thermopile in which the cup is mounted as shown in fig. 14. The junctions of the pile are insulated from the cup by thin silk paper and paraffin wax, which is nonhygroscopic, and are bound firmly round the cup aith a lapping of fine silk. The pile wires are iron and constantan, each 0.2 mm. in diameter and are sufficiently stiff to hold the cup securely in place. The cold junctions of the pile are similarly fixed to a copper cylinder screwed to the base of the copper box 5 mm. thick, enclosing the sensitive parts of the apparatusat a uniform temperature, which is indicated by a delicate mercury thermometer with its bulb inserted between the two piles. Since it is always desirable to take observations by a balance method (most especially in measuring strong sources of radiation, such as 1 cal. per square centimetre per minute, or 0.07 w. per square centimetre, which would give unbalanced deflections of the galvanometer of the order of 7,000 mm.) the cup exposed to radiation is balanced against a similarly mounted cup, as indicated in the diagram of connections in fig. 15, the piles in which the cups are mounted being connected in opposition in the galvanometer circuit. This method gives perfect elimination of external disturbances because of the small size and high conductivity of the copper box in which the two piles are enclosed.

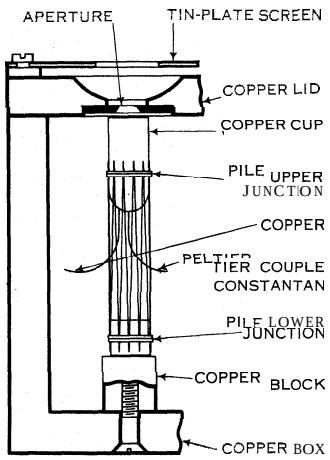

FIG. 14.—CUP AND PILE OF RADIO BALANCE, SHOWING MOUNTING OF CUP IN SENSITIVE THERMOPILE WITH 12 JUNCTIONS INSIDE COPPER BOX

The advantage of using the Peltier effect for the absolute measurement of radiation, in place of the more familiar Joule effect employed in other instruments such as the Ångström pyrheliometer, is that heat reception can be directly compensated by heat absorption, and that the heat absorbed is proportional to the current C (instead of to C^2) and changes sign when the current is reversed. The value of the Peltier coefficient P for a single copper-constantan junction as here employed is approximately 12 my, which when multiplied by the current C in amperes gives the heat absorption PC in milliwatts. Thus with an aperture of .2 mm. in diameter the current required to compensate radiation of intensity 0.07 w. per square centimetre, which is near the mean for sunshine, is about 200 milliamperes with a single couple. In actual practice the same current C is passed through the Peltier junctions of both cups so that the exposed cup is cooled while the screened cup is heated. This doubles the effect and requires a current of 100 milliamperes only, in the case above given, and makes it possible to measure strong sources up to 0.4 w, per square centimetre, without changing the 2 mm. aperture.

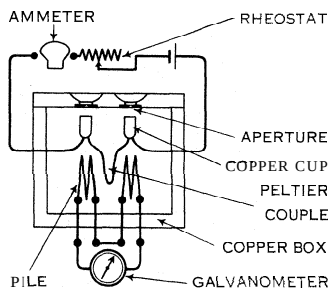

FIG. 15.— DIAGRAM OF CONNECTIONS FOR RADIO BALANCE
Both cups, with circuit of Peltier junction separate from that of piles and galvanometer, are shown

In taking readings by this method, one cup is exposed to radiation while the other is screened, and the current is adjusted to reduce the deflection of the galvanometer to zero. After reading the current, the radiation is switched over to the other cup (by moving a shutter close in front of the aperture and behind the tin-plate screen in fig. 14) and the current is simultaneously reversed without altering its value. This procedure has the effect of exactly eliminating any small heating effect in the wires conveying the current to the cups, and gives the simple formula $R' = 2PC/a$, for the intensity R' of the radiation received in terms of the aperture a in square centimetres. If the radiation is variable, as is usually the case with sunshine even on the clearest day, it is preferable to keep the current constant and to observe the small residual deflections of the galvanometer, which are readily translated into milliamperes by observing the deflection produced by reversing a small current when both cups are screened. If the piles are not accurately balanced, or if the areas of the apertures are not exactly equal, the appropriate value of the balancing current will be different for the two cuPs. Any small differences of this kind may be treated in the same way by observing galvanometer deflections, but should not exceed a small fraction of 1%.

The value of the coefficient P is most easily determined by observing the thermoelectric power p of a junction made of the same wires, and multiplying by the absolute temperature T. Both factors in the product Tp increase with temperature, so that it is necessary to know the temperature to 0.2° C. in order to secure an order of accuracy of 0.1% in R', since the temperature coefficient of P is usually in the neighbourhood of 0.5% per 1° C. A more direct method is to balance the Peltier effect in each cup against the heating effect in a resistance coil fitting the cup. This method affords the most simple and accurate verification of the thermodynamic theory, and measures the effect under working conditions for the actual couples employed. To find the value of σ by observing the radiation emitted from a black body such as that illustrated in fig. 10, with a water-cooled aperture of radius b, it is necessary to adjust the aperture a of the receiver to be coaxial with that of the emitter and to measure the distance d between their planes. The normal intensity R' as measured by the receiver is given in terms of the black body intensity R in formula (13) by the simple relation $R' = Rb^2/(d^2 + b^2)$, which may be found in most textbooks of geometrical optics.

Observations taken with a radio balance in conjunction with the black body illustrated in fig. 10, by N. L. Jones gave a mean result $a = 5.690 \times 10^{-12}$ w. per square centimetre. The observations were taken at night under favourable conditions, but no correction was applied for atmospheric absorption, as the distance (20 to 33 cm.) was not varied sufficiently. Later observations made by Callendar using a black body at 100° C. with the same instrument, in which the distance d was varied from 6 to j6 cm. under similar conditions, gave a result 5.752 when corrected for atmospheric absorption. The Peltier couple in this instrument was tested by the thermoelectric method using samples of the same wires, iron and constantan respectively. Another balance, with a copper-constantan couple, tested by both methods with consistent results, and corrected for atmospheric absorption in the same way, gave a slightly higher result, 5.766. The differences between observations taken on different days averaged about 0.2% and appeared to depend mainly on variations of atmospheric absorption, the correction for which doubled the time and labour of taking observations. The percentage absorbed varies to some extent with the quality of the radiation as determined by the temperature of the emitter as well as the state of the atmosphere, and is not simply proportional to the distance traversed as commonly assumed. The observations with the black body at 444.6' C., when corrected by reference to hygrometric records, using the coefficient found at 100° C., were raised from a mean value 5.690 to 5.804, which suggests that the absorption correction should be smaller for radiation at 444.6' C. than at 100° C. The mere presence of an observer radiating heat and exhaling variable quantities of CO_2 is a source of uncertainty in absolute measurements. Apart from atmospheric absorption, the instrument appeared to be capable of an order of accuracy of at least 0.1%. It was accordingly decided to enclose the receiver in a water-cooled metal casting from which absorbing gases could be excluded. Unfortunately at this stage the work was interrupted by World War I; no favourable opportunity subsequently occurred for making the final corrections for absorption. It appears,

however, that the result would probably be intermediate between those of Gerlach and Coblentz by the Angstrom method. The range was further extended in 1942 to the region just beyond 100μ with the aid of a superconducting bolometer and a source of radiation which was maintained at temperatures between 24° and 54° Kelvin. Some experienced observers have found values as high as 6.5, but there are many most insidious sources of error in these difficult experiments.

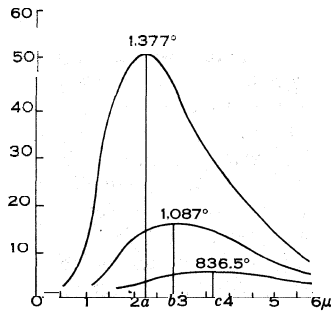

FIG. 16.— DISTRIBUTIONOF ENERGY IN THE SPECTRUM OF A BLACK BODY

8. Wien's Displacement Law.---Assuming that the fourth-power law gives the quantity of full radiation at any temperature, it remains to determine how the quality of the radiation varies with the temperature, since as we have seen both quantity and quality are determinate. This question may be regarded as consisting of two parts. (1) How is the wave length or frequency of full or "black" radiation changed when its temperature is altered? (2) What is the form of the curve expressing the distribution of energy between the various wave lengths in the spectrum of full radiation, or what is the distribution of heat in the spectrum? The researches of Tyndall, Draper, Langley and other investigators had shown that while the energy of radiation of each frequency increased with rise of temperature, the maximum of intensity was shifted or displaced along the spectrum in the direction of shorter wave lengths or higher frequencies. W. Wien (1898), applying Doppler's principle to the adiabatic compression of radiation in a perfectly reflecting enclosure, deduced that the wave length of each constituent of the radiation should be shortened in proportion to the rise of temperature produced by the compression, in such a manner that the product AT of the wave length and the absolute temperature should remain constant. According to this relation, which is known as Wien's displacement law, the frequency corresponding to the maximum ordinate of the energy curve of the normal spectrum of full radiation should vary directly (or the wave length inversely) as the absolute temperature, a result previously obtained by H. F. Weber (1888). Paschen, Lummer and Pringsheim verified this relation by observing with a bolometer the intensity at different points in the spectrum produced by a fluorite prism. The intensities were corrected and reduced to a wave length scale with the aid of Paschen's results on the dispersion formula of fluorite (1894). The curves in fig. 16 illustrate curves obtained by Lummer and Pringsheim (1899) at three different temperatures, namely, 1,377°, 1,087° and 836.5' K., plotted on a wave length base with a scale of microns or millionths of a metre. The wave lengths *Oa*, Ob, *Oc*, corresponding to the maximum ordinates of each curve, vary inversely as the absolute temperatures given. The constant value of the product AT at the maximum point was found to be 2,920. Thus for a temperature of 1,000° K. the maximum is at wave length 2.92,~at 2,000° the maximum is at 1.46,~.

9. Distribution of Energy in the Spectrum.— Assuming Wien's displacement law, it follows that the form of the curve representing the distribution of energy in the spectrum of full radiation should be the same for different temperatures with the maximum displaced in proportion to the absolute temperature, and with the total area increased in proportion to the fourth power of the absolute temperature.

Observations taken with *a* bolometer along the length of a normal or wave length spectrum would give the form of the curve plotted on a wave length base. The height of the ordinate at each point would represent the energy included between given limits of wave length, depending on the width of the bolometer strip and the slit. Supposing that the bolometer strip had a width corresponding to .01μ and were placed at 1.0μ in the spectrum of radiation at 2,000° K., it mould receive the energy corresponding to wave lengths between 1.00 and 1.01μ. At a temperature of 1,000° K. the corresponding part of the energy, by Wien's displacement law, would lie between the limits 2.00 and 2.02μ, and the total energy between these limits would be 16 times smaller. But the bolometer strip placed at 2.0μ would now receive only half of the energy, or the energy in a band .01μ wide, and the deflection would be 32 times less. Corresponding ordinates of the curves at different temperatures will therefore vary as the fifth power of the temperature, when the curves are plotted on a wave length base. The maximum ordinates in the curves already given are found to vary as the fifth powers of the corresponding temperatures.

The equation representing the distribution of energy on a wave length base must be of the form

$$E = C\lambda^{-5} F(\lambda T) = CT^{5}(\lambda T)^{-5}F(\lambda T) \qquad (14)$$

where $F(\lambda T)$ represents some function of the product of the wave length and temperature, which remains constant for corresponding wave lengths when T is changed. If the curves were plotted on a frequency base, because of the change of scale, the maximum ordinates would vary as the cube of the temperature instead of the fifth power, but the form of the function F would remain unaltered. Reasoning on the analogy of the distribution of velocities among the particles of a gas on the kinetic theory, which is a very similar problem, Wien was led to assume that the function F should be of the form $e^{-c/\lambda T}$, where e is the base of Napierian logarithms, and c is a constant having the value 14,600 if the wave length is measured in microns. This expression was found by Paschen to give a very good approximation to the form of the curve obtained experimentally for those portions of the visible and infrared spectrum where observations could be most accurately made. The formula was tested in two ways: (1) by plotting the curves of distribution of energy in the spectrum for constant temperatures as illustrated in fig. 17; (2) by plotting the energy corresponding to a given wave length as a function of the temperature. Both methods gave very good agreement with Wien's formula for values of the product AT not much exceeding 3,000.

A method of isolating rays of great wave length by successive reflection was devised by H. Rubens and E. F. Nichols (1897). They found that quartz and fluorite possessed the property of selective reflection for rays of wave length 8.8μ and 24μ to 32μ respectively, so that after four to six reflections these rays could be isolated from a source at any temperature in a state of considerable purity. The residual impurity at any stage could be estimated by interposing a thin plate of quartz or fluorite which completely reflected or absorbed the residual rays, but allowed the impurity to pass. H. Beckmann, under the direction of Rubens, investigated the variation with temperature of the residual rays reflected from fluorite employing sources from −80° to 600° C., and found the results could not be represented by Wien's formula unless the constant c were taken as 26,000 in place of 14,600. In their first series of observations extending to 6μ, O. R. Lummer and E. Pringsheim (1899) found systematic deviations indicating an increase in the value of the constant c for long waves and high temperatures. In a theoretical discussion of the subject, Lord Rayleigh (1900) pointed out that Wien's law would lead to a limiting value $C\lambda^{-5}$, of the radiation corresponding to any particular wave length when the temperature increased to infinity, whereas according to his view the radiation of great wave length should ultimately increase in direct proportion to the temperature. Lummer and Pringsheim (1900) extended the range of their observations to 18μ by employing a prism of sylvine in place of fluorite. They found deviations from Wien's formula increasing to nearly 50% at 18μ, where, however, the observations were very difficult on account of the smallness of the energy to be measured. Rubens

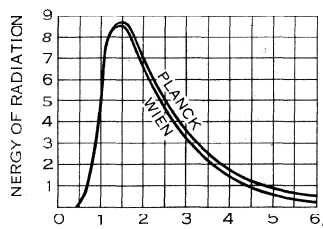

FIG. 17.— DISTRIBUTION OF ENERGY IN THE SPECTRUM OF FULL RADIATION AT 2,000° K., ACCORDING TO FORMULAS OF PLANCK AND WIEN

and F. Kurlbaum (1901) extended the residual reflection method to a temperature range from −190° to 1,500° C.. and employed the rays reflected from quartz 8.8μ, and rock salt 51μ, in addition to those from fluorite.

It appeared from these researches that the rays of great wave length from a source at a high temperature tended to vary in the limit directly as the absolute temperature of the source, as suggested by Lord Rayleigh, and could not be represented by Wien's formula with any value of the constant c. The formula now generally accepted is that proposed by Max Planck (1901) namely,

$$E = C\lambda^{-5}(e^{c/\lambda T} - 1)^{-1} \qquad (15)$$

which agrees with Wien's formula when T is small, where Wien's formula is known to be satisfactory, but approaches the limiting form $E = C\lambda^{-4}T/c$, when T is large, thus satisfying the condition proposed by Lord Rayleigh. The accepted value of the constant c in Planck's formula was 1.4385 cm.-deg. In order to compare Planck's formula graphically with Wien's, the distribution curves corresponding to both formulas are plotted in fig. 17 for a temperature of 2,000° K., with a scale of wave length in microns. The curves in fig. 18 illustrate the difference between the two formulas for the variation of the intensity of radiation with temperature for a fixed wave length 30μ which is five times as long as the limit 6μ of the curves in fig. 17. But at 2,000° K. the energy to be measured at 30μ is about ten thousand times less than at the maximum of the curve in fig. 18.

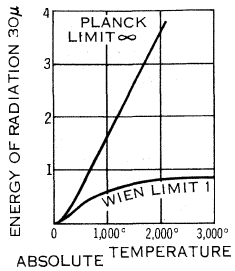

FIG. 18.—VARIATION OF ENERGY OF RADIATION CORRESPONDING TO WAVE LENGTH 30μ WITH TEMPERATURE OF SOURCE

Assuming Wien's displacement law, the curves may be applied to find the energy for any other wave length or temperature, by simply altering the wave length scale in inverse ratio to the temperature, or vice versa. Thus to find the distribution curve for 1.000° K.. it is only necessary to multiply all the numbers in the wave length scale of fig. 17 by 2; or to find the variation curve for wave length 60μ the numbers on the temperature scale of fig. 18 should be divided by 2. The ordinate scales must be increased in proportion to the fifth power of the temperature, or inversely as the fifth power of the wave length respectively in figs. 17 and 18 if comparative results are required for different temperatures or wave lengths.

XIII. THE NATURE OF HEAT IN MATTER

1. Classical Theory of Heat.—Following the proof that heat was essentially motion or energy and not a mysterious caloric fluid, the next major step in the understanding of its nature came out of the study of the relation of heat to the principles of probability. Many lines of evidence showed that the thermal motion of the atoms in a gas like helium could be thought of as something like the motions of a large number of small round shot violently agitated in a closed jar. Thus the shot (atoms) fly through the air in straight lines except when colliding with each other or the walls of the jar. Conceivably under these circumstances the atoms might all move with the same speed, but actually it has been proved that they move with a great variety of speeds, some very fast! some very slow and many at the various speeds in between, grouped about an average or mean velocity. Again, if one were to watch a single particular atom it would be seen continually changing its speed at each collision with other atoms or the walls. Occasionally after a collision it would be found moving very fast, occasionally very slowly, thus covering over a length of time the whole gamut of speeds, which one had seen at a single instant distributed among the entire assembly of atoms when observing the gas as a whole at a single glance. Similarly if one observed at a single instant the positions of the atoms in the vessel, they would be found to be almost evenly distributed throughout the entire space inside the jar; or if one were to observe, over a period of time, the wanderings of a single particular atom it would be found to pass through roughly every part of the jar, spending about equal lengths of time in each part in the course of its travels.

One can see the relation of space distribution to probability by means of an example, such as two helium atoms, which we will label respectively A and B, existing in the gaseous state confined within a small box. We postulate that we can see the positions of the two atoms as they bounce back and forth in the box colliding with the walls and with each other, executing the motions which constitute the heat they possess; in particular, we can distinguish uhen each atom is in the left half or in the right half of the box. There are four possibilities of distribution between the two halves of the box. (1) A and B may both be in the left half of the box; (2) A may be in the left half and B in the right half; (3) B may be in the left half and A in the right half; and (4) A and B may both be in the right half. We note that this parallels the possible distribution of "heads" and "tails" if one were to toss two coins, A and B: (1) both may come up "heads"; (2) A may be "heads" and B "tails"; (3) B may be "heads" and A "tails"; or (4) A and B both may come up "tails." Thus, one may expect that there is twice the chance of throwing one "heads" and one "tails," case (2) or (3), as there is of throwing both "heads," case (1); and in the same way one might conclude that there is twice the chance of finding the atoms distributed evenly through the box, case (2) or (3), as there is of finding both atoms in the left side, case (1).

Now, the law of probability states that if the coins are identical in every respect, the chance of throwing "heads" is exactly the same as the chance of throwing "tails," the 50–50 chance, each 50% or one-half of the total probability taken as 100% or one. And the statistical theory of heat asserts that under uniform conditions there is an equal chance of finding atom A in the left half of the box or in the right half; of course, the same holds for atom B. Thus we conclude that, just as the case of "one heads and one tails" is twice as probable as "both heads," the case of uniform distribution of the atoms, one "right" and one "left" is twice as probable as "both left." This seemingly simple principle has been extended in application throughout the complex domain of the motions which constitute heat, not only in the gaseous state of matter but in liquids and solids as well, and has resulted in an exact and profound understanding of the vast and complicated phenomena of physical and chemical equilibriums and changes of state. Since the addition or subtraction of heat is certainly one of the most universal means of bringing about changes and of producing varieties of matter and interactions between matter, this principle and its applications constitute a cornerstone of the foundations of all science. And the story of the evolution of these ideas is a fascinating chapter in the history of thought.

It was largely the result of the work of J. Clerk Maxwell and Luduig Boltzmann that the relation between heat and probability was first made plain They showed the plausibility of the concept that each distribution of atoms with respect to space and matter properly specified was equally probable; in our example, each of the four distributions of the two atoms A and B between the two halves of the box was equally probable. In order to extend the mathematical analysis to much more complicated situations, use was made of the concept of multidimensional space; i *e* , space of more, in this case vastly more, than the three dimensions, length. breadth and height, of the ordinary space in which we instinctively feel we live and move and have our being.

At first thought, the idea of even conceiving of such a space as an imaginary entity seems to have been deeply repellent to the human mind. It was so profoundly different from natural space and so boundless in its potential for generating further strange and novel forms. possibly of a monstrous nature, that to admit even the logic of the idea was to open a door which led out of the comfortable security of a familiar garden into a limitless *terra* ***incognita*** that seemed to be almost a domain for the mad.

The credit for taking this first almost inconceivably bold step in thought certainly should go to H. G. Grassman (1809–1877) although the possibility was suggested previously in the work of W. R. Hamilton; the application to heat was first made clear in detail by W. Gibbs who immediately followed Grassman's pioneering adventure. In Gibbs's phase space we conceive of the motion

of a single point in a space of $6n$ dimensions, where n is the number of elementary particles with which we are concerned. In our example of two helium atoms, $n = 2$ and this imaginary space would have 6×2 or 12 dimensions. The first three represent the position of atom A in the box with respect to the Cartesian co-ordinate system X, Y, Z or the length, width and height of the box.. The second set of three provides similarly a way of representing the position of atom B. The third set of three provides a way of representing the momentum of atom A (in effect its speed, since momentum is the product of speed or velocity times mass). The faster the atom is moving lengthwise in the box (direction x) the further to the right of the centre or zero point of the co-ordinate system will be the phase point or dot which tells by its position in the 12 dimensional space where our atoms are and how they are moving. Similarly, the position of the point with respect to the fourth set of three dimensions tells the velocity of atom B.

The fact that these two atoms are confined in the box means that the phase point must lie within a volume of space on the first three dimensions corresponding to the volume of the box and within a similar volume on the second three dimensions. If our system possesses a fixed amount of energy, and we will assume it does, then the point will have to lie within a certain volume in the third set of dimensions and similarly in the fourth, defined by a so-called hypersphere in the six dimensions of momentum space.

The fundamental assumption is made that there are a certain number of positions possible for the point within this hypervolume in 12 dimensions, and that each one of these positions is equally probable. This assumption is the extension of the logic that each kind of throw of the two coins is equally probable and that each of the four space distributions of the atoms A and B between the two halves of the box is equally probable.

The effect of heat on matter is thus based on the laws of probability or statistics. From this chain of logic there evolved the Maxwell-Boltzmann law for the distribution of energy among the atoms of a gas and the generalizations of statistical thermodynamics which stem from the Gibbsian concept of multidimensional phase space. During the latter part of the 19th century when these theories were being worked out, it seemed logical to believe that there were an indefinite number of values of energy possible for each atom. There was no evidence for any atomization of energy; it seemed reasonable that the amount of energy could be varied by infinitesimally small amounts. and that the points in phase space representing the possible states of the system lay infinitesimally close together. This was the classical basis for the theory of heat.

One of the most important conclusions drawn from this classical theory was the principle of the equipartition of energy. For example, a gaseous atom like helium could move in three dimensions in physical space. It was said to have three degrees of freedom of motion. Moving in free space there was certainly no difference between motion along the X axis, lengthwise in the box, or motion along the Y axis, crosswise; likewise motion along the Z axis, or up and down should be no different from the other two; accordingly all were regarded as equally probable. According to the principle of equipartition, energy was then shared equally on the average among all three degrees of freedom of the so-called translational motion. Calculation showed that the amount in each should be $\frac{1}{2}RT$, where R is the gas constant with a value of roughly two calories per degree per gram molecule and T is the absolute temperature in degrees Kelvin. Since the heat capacity is the rate of increase of energy with temperature, it is clear that one should find the value $\frac{1}{2}R$ per degree of freedom, or $\frac{3}{2}R$ for the heat capacity of one gram molecule of a monatomic gas like helium when measured at constant volume. This value was precisely confirmed experimentally for a number of monatomic gases.

In the case of a diatomic gas such as nitrogen we have the two atoms joined together to make a kind of dumbbell-shaped molecule. In this case the dumbbell can rotate in space. This adds tno more degrees of freedom of rotation which summed with the three degrees of freedom of translation makes five in all; lve therefore expect and actually find experimentally a heat capacity of $\frac{5}{2}R$. In other words, although the two kinds of motion are superficially quite different — translation or straight-line motion across the box contrasted with rotation or spinning — the principle of equipartition of energy states that energy is still shared equally among all the degrees of freedom.

Suppose now that the atoms are cooled down and condense first into a liquid and finally freeze into crystalline form, how will the situation alter? In the crystal we expect that instead of moving freely through space as in a gas. the atom will vibrate back and forth about a mean position under the influence of forces of attraction and repulsion between it and its neighbouring atoms. It will now possess both kinetic energy of motion and potential energy because of the action of the forces. Classical mechanics tells us that under these conditions, with these two kinds of energy present, the total average energy per degree of freedom will be twice as much. and the heat capacity accordingly will be $3R$ per gram atom in the crystalline state as contrasted with $\frac{3}{2}R$ in the gaseous state for a monatomic substance like helium. Since most metals exist in the crystalline state as individual atoms, not joined to form molecular groups, one would expect the heat capacity of metals to be $3R$ per gram atom. This fact had been observed experimentally and was known as the rule of Dulong and Petit.

On the whole, by the end of the 19th century there were a large number of experimental observations to confirm the classical theory of heat, but a certain number of notable exceptions remained unexplained. For example, some of the light elements exhibited values of the heat capacity which fell farther and farther below $6R$ as temperature was lowered, for example, carbon, boron and silicon. With the increasing use of liquified gases such as oxygen, nitrogen and hydrogen to produce temperatures of 200° or more below 0° C., these anomalies became more and more striking. Sir James Deuar carried out a series of heat-capacity measurements at low temperatures, made possible by the invention of the "dewar" flask which provided the necessary thermal insulation to preserve liquid hydrogen for hours at a time, which provided quantitative proof of this deviation.

2. Einstein's Theory. — It was just at this time that Planck had challenged the classical idea of the continuous range of values of energy nith his quantum hypothesis, Albert Einstein was the first to see the connection between the quantum theory and the anomnlies in heat-capacity values at low temperatures. He pointed out that the atoms of carbon, for example, might be expected to vibrate in the crystalline state with a single frequency, each atom behaving pretty much like an independent oscillator. Planck's theory would lead one to believe that the energy in such an oscillator would not take on a range of continuous values but that only a number of discrete values would be possible. In phase space this meant that. in effect, only a discrete and relatively small number of regions. usually referred to as cells, could be occupied by the phase point. Retaining the idea of equal probability for distribution of the energy as a whole. but over this finite number of cells, one calculated an entirely different formula for the heat capacity. One found first of all a parametric temperature (usually given the symbol Θ. called the characteristic temperature and expressed on the absolute scale of temperature) which provided an index to the behaviour of the substance. For example, Θ for lead is approximately 100° while Θ for diamond (crystalline carbon) is approximately 2,000°. When heat capacity is measured at the characteristic temperature it will be $0.9 \times 3R$; at twice the characteristic temperature it will be almost exactly $3R$; but at a temperature of one-half the characteristic temperature it will fall to less than one-half the Dulong and Petit value of $3R$. The heavier the atom which vibrates, the lower will be the characteristic temperature. Thus lead will have a heat capacity close to $3R$ at room temperature (300° K.), which is three times its characteristic temperature, while diamond will have a heat capacity far below $3R$, since room temperature is only about one-sixth of the characteristic temperature of diamond.

Einstein's formula for the heat capacity s at constant volume per gram atom is given by the expression:

$$s = 3Rz^2e^z/(e^z - 1)^2;\ z = \frac{h\nu}{kT} \qquad (16)$$

where h is Planck's constant, k is Boltzmann's constant, v is the

characteristic frequency at which the atom vibrates and T is the temperature in degrees absolute. Einstein showed (1907) that the experimental results of H. F. Weber on the variation of the heat capacity of diamond from T = 222° to 1,258° K. were in good agreement with his formula. Taking the substances, calcium fluoride, sodium chloride, calcium carbonate and silicon dioxide for which the optical frequencies of absorption (ν_0) in the infrared were known. he pointed out that the values of ν required by his formula were in reasonable agreement with the values of ν_0 optically observed. This was a major triumph for the newly created quantum theory of Planck.

3. Debye's Theory. — The interest aroused by Einstein's theory of the heat capacity of solids led to an important series of measurements of heat capacity by W. Nernst, F. A. Lindemann (Lord Cherwell) and their collaborators. They studied a number of metals and salts for which the optical frequencies were known, extending the experiments to the lowest temperatures available with liquid hydrogen and making use of the precise calorimetric methods developed at their laboratory. The results showed that while the Einstein theory was satisfactory in explaining the results at the higher temperatures, it failed to account for the heat capacity at the lower end of the temperature scale; values were many times higher than the theory predicted.

The explanation of this anomaly was put forward by P. Debye (1912) who pointed out that one would not expect the atoms in the crystal lattice to vibrate independently as Einstein had postulated, but rather in joint modes of motion. In a cube-shaped crystal the longest mode would have a wave length twice the distance from one face of the cube to the opposite face. The shortest mode would have a wave length twice the distance between two neighbouring atoms. If the crystal were 1 cm. across, there would be a set of waves with the wave length varying about 100,000,000 times from the longest to the shortest value. While these waves contain in their motion the heat of the crystal, they also may be regarded as acoustic waves or sound; if sound waves in the air impinge on the crystal, elastic waves similar in type to the heat waves will be set up, carrying the sound through the crystal.

According to a theorem attributed to Lord Rayleigh (1877) the number of possible degrees of freedom of a system of N discontinuous mass points will be $3N$. According to another theorem by the same author (1900), the number of possible frequencies in a given volume of a continuous medium between the limits v and v + dv may be represented by $C\nu^2 d\nu$ where C is a constant dependent on the volume and on the velocity of propagation. The total number of possible frequencies from o up to a limit ν_m is $C'\nu_m^3/3$. If we equate this to $3N$, we find $C = \frac{9N}{\nu_m^3}$. Adopting Planck's expression for the energy of a harmonic oscillator with one degree of freedom as applying to each mode, we obtain the energy $(RT/N)Z/(e^z - 1)$ for each frequency. Multiplying by the number of frequencies and integrating from o to ν_m we can obtain the energy of a gram atom at T, and thence obtain the heat capacity by differentiation with respect to T. This yields a rather complicated expression which is similar to Einstein's in general form, being a function of Θ/T, but which has much higher values of the heat capacity precisely in the low-temperature region where Einstein's function is so unsatisfactory. This is because Debye's function takes into account the existence of the vibrational modes with long wave length which retain their heat at very low temperatures (the range where the short-wave vibrations, on which Einstein's theory was based, have effectively no heat at all). Debye's theory thus predicts that at very low temperatures the heat capacity will vary as the cube of the absolute temperature, a relationship which has been found experimentally to hold in dozens of cases. The major features of Debye's theory are thus experimentally substantiated and there is no doubt but that it marks an important step forward in our understanding of the nature of heat in solids.

One of the weakest points in the Debye theory lies in the use of the formula for the distribution of frequencies in a continuous medium while equating the total number of frequencies to $3N$ as expected in discontinuous lattice. Obviously, real crystals are made up of discontinuous sets of mass points; and the theory of such lattices has offered a challenge to investigators ever since the importance of crystal dynamics became apparent. M. Born and T. von Karman pioneered in working out mathematical methods for lattice problems (1912). Since 1935 M. Blackman has carried on a series of studies, improving the earlier methods and applying them to many substances. Starting in 1944, E. W. Montroll and his associates have made important contributions to clarify our understanding of the theory.

An especially interesting application of the mathematics of topology (*q.v.*) to the problem was suggested by L. van Hove (1953). All these developments were critically summarized by Blackman in 1955.

Thus, the investigations over this period have shown that, by and large, the Debye theory accounts with astonishing precision for the variation of heat with temperature in many varieties of crystalline substances, in spite of the doubtful assumption of the continuous distribution of frequencies which Debye himself clearly pointed out to be an approximation. On the other hand. if a new theory can be based strictly on the dynamics of discontinuous lattices, it is clear from the results already obtained that much more important information on the distribution of heat in crystals may be expected.

A still more complex problem is posed by molecular lattices made up of molecules, where groups of atoms are bound together in groups by the relatively strong forces of chemical bonds, while these groups are in turn bound to neighbouring groups in the rows of the crystal lattice by relatively weak forces. The lattice of crystalline benzene (C_6H_6) is of this sort, typical of organic compounds and of some inorganic ions such as SO_4^-. With considerable accuracy, the Debye theory even accounts for the heat contained in the vibration of these complex molecules against each other, as shown by R. C. Lord, J. E. Ahlberg and D. H. Andrews (1937). In this case there appear to be coupled torsional waves as well as the translational waves found in monatomic crystals.

The heat contained in the vibrations of the atoms within the molecule, however, must be calculated by an Einstein function, since the coupling between molecules is so weak that the individual molecules vibrate within themselves independently of each other. Consequently, the frequencies do not lie in a nearly continuous band as in the Debye case, but are a discrete set of 3n–6 values where n is the number of atoms in the molecule. Occasionally because of molecular symmetry, or similar factors, the values for different types of motion will be equivalent numerically and this reduces the number of distinct values below the number $3n–6$. The Einstein formula has been widely applied in calculating the heat capacity caused by these internal molecular vibrations, both for solids and for gases. Thus, although this formula has been completely supplanted by the Debye formula in the case of heat distribution in lattices, the case for which Einstein originally developed it, the applications for calculating the internal heat in molecules have made its uses ultimately far more numerous than those of the Debye formula. These applications are discussed in the final section of this article dealing with the heat capacity of gases.

4. Heat, Entropy and Information. — During World War II new and profound advances were made in understanding the basic nature of "information," so novel in fact as to constitute the beginning of a new field of science. This came about simultaneously in several related fields such as the improvement of radio and telephone communication, the making and breaking of secret codes and the development of various servomechanisms such as automatically controlled antiaircraft weapons. As the theory of information developed there appeared an astonishing parallelism to the theory of heat, because probability enters into the communication of information in much the same way that it enters into the equilibration of heat. The initial developments along these lines were attributed primarily to the work of C. E. Shannon; and the advances in the decade after the war were summarized by L. Brillouin in 1956.

The measure of information I is now generally defined by the

formula $I = K \ln P$ where I is the information of one outcome in a situation which had P possible outcomes all equally probable, K is an arbitrary constant, and ln means logarithm to the base *e*. The customary measure of the probability of a given heat distribution is, of course, the entropy S customarily defined by the Boltzmann expression: $S = k \ln W$, where k is the Boltzmann gas constant, and *W* is the number of microscopic ways in which the macroscopic state corresponding to *S* can be realized. The identity in form of these two expressions reveals a very profound relationship between the two fields.

The similarity of the theory of heat to the theory of information also is striking in many other ways. The second law of thermodynamics states that the entropy always increases in any spontaneous change; in the limit, entropy remains constant if the change takes place reversibly; and it never decreases spontaneously. Similarly, information always decreases as the result of being communicated; in the limit it remains constant as the communication becomes perfect; *i.e.,* when no randomness such as electrical noise is introduced in the act of communication; but information never increases as the result of communication. Thus entropy and information are strictly isomorphic quantities, though differing in "sign," the first increasing and the second decreasing when randomness occurs.

Now there is every reason to believe that our increasing knowledge about the nature of information will aid our understanding of the nature of thought itself. And since thermal energy or heat plays such a vital part in governing the course of chemical reactions, including biochemical processes, we may expect that advances in the theory of heat will help in our understanding of basic neurological action. Thus, at the common frontier where these two closely related fields meet in the physiological and epistemological aspects of the brain, one may expect important developments.

In this connection it should be pointed out that the representation of the phenomena associated with heat distribution by means of multidimensional space, as initiated by Gibbs, was the beginning of a trend of thought which has spread far since that time, a change in epistemological attitude which has shifted emphasis from the analytic to the synthetic. Thus Debye took into account the action of heat in the whole crystal, instead of treating it as atomized into independent oscillators as Einstein did. The mathematical structure of the new quantum mechanics (*q.v.*) has emphasized still further the "aspect of the whole" as representable in generalized space, a point frequently made by H. Weyl in his studies of the philosophy of mathematics and the physical sciences. In quantum mechanics we find probability in wave-clothing dominating the behaviour of elementary particles with a formalism isomorphic with the generalized Debye treatment of heat in crystals.

In the new information theory we find probability and generalized space again, once more closely isomorphic with fundamental aspects of the theory of heat. In all this we are surely glimpsing a profound change in our knowledge of the physical world and in knowledge itself.

The philosophical implications of this aspect of the whole were discussed by N. Bohr (1958) who stressed the importance of this point of view in interpreting the relationships between processes at the atomic level and at the biological level. The essential, characteristic feature of the living organism is dynamic stability. While the individual building blocks of the organism, the atoms, come and go by the trillion or more through respiration and metabolism, the structure of the organism retains its characteristic form relatively unchanged for a period of time billions or more times longer than the interval required for an individual atomic replacement.

We therefore must regard this characteristic form as a dynamic energy pattern which subtly combines change with invariance. Its dynamism is heat, the warmth of life, but because this heat embodies form, there emerges a stable entity of the whole, which in its survival through time possesses a reality that dominates and transcends its ephemeral and ever-changing material parts.

5. Heat Capacities of Gases.—Early attempts at understanding the nature of heat inside molecules like benzene were hampered by a lack of knowledge of the proper set of frequencies to use in the Einstein equation. The discovery of the new type of spectrum bearing his name, by Sir C. V. Raman in 1928, marked a major advance in providing adequate data for the thermal analysis of molecules.

Shortly after Raman's first work, E. B. Wilson and his collaborators began a long series of studies, combining quantum mechanics and the mathematical theory of groups to provide methods for the exact analysis of the thermal motions of molecules. The improvement of instrumental techniques in the study of infrared spectra also contributed greatly in making it possible to calculate accurately the internal heat capacity of molecules. Advances in this field were summarized by Wilson, J. C. Decius and P. C. Cross in 1955. At that time something like 50 molecules of considerable complexity had been subjected to precise vibrational analysis. This not only made possible the accurate calculation of heat capacities in the gaseous state, but, coupled with experimental measurements of thermal properties in the solid and liquid state, it provided thermodynamic data for quantities like entropy and free energy in a form which permitted calculations with regard to chemical behaviour under conditions such as high temperature, high pressure and complex composition where the direct experimental approach becomes difficult or impossible. This part of the theory of heat has yielded invaluable information to industry especially in the fields of petroleum chemistry and synthetic organic chemistry.

HEAT EXCHANGER. In many engineering applications it is desirable to increase the temperature of one fluid while cooling another. This double action may be economically accomplished with the aid of an apparatus called a heat exchanger, Some important applications are the cooling of one petroleum fraction while warming another, the cooling of air or other gases with water between stages of compression, and the preheating of combustion air supplied to a boiler furnace using hot flue gas as the heating medium. Others are the transfer of heat from liquid metals to high-pressure water in atomic power plants and the reclaiming of heat energy from the exhaust of a gas turbine by transferring heat to the compressed air on its way to the combustion chambers. There are also many other applications.

The primary function of a heat exchanger is to provide two paths of flow, one for the warm fluid and one for the cold, by means of which heat can be transferred through walls or partitions separating the fluids.

The quantity of heat transferred is governed by three factors, namely: (1) the amount and nature of the heat transfer surface area exposed to the two fluids; (2) the over-all coefficient of heat transfer from one fluid through the intervening wall to the other fluid; and (3) the mean temperature difference across the intervening wall from one fluid to the other.

Numerous flow arrangements and geometrical designs are possible. Perhaps the simplest is the concentric tube or double pipe heat exchanger in which one pipe is placed inside another. The fluids flow in the inner pipe and in the space between the two pipes. The flow may be either parallel (fig. 1) or counterflow (fig. 2) with temperature relations between fluids as illustrated. Concentric tube heat exchangers are built in several ways such as, for example, in the form of a coil or in straight sections placed

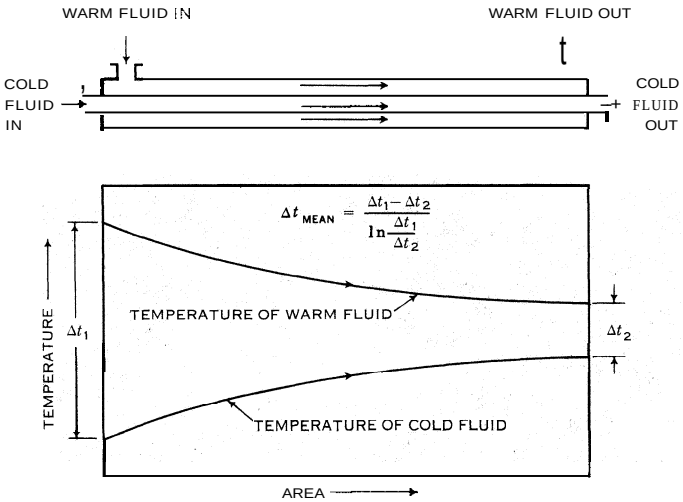

FIG. I.— PARALLELFLOW IN A CONCENTRIC TUBE HEAT EXCHANGER

side by side and connected in series.

The commonest type of heat exchanger is the shell and tube type illustrated in fig. 3. Here one fluid flows through tubes while the other flows back and forth across the tubes between baffles. Over-all direction of flow may be either parallel or counter, but is usually the latter.

Another commonly employed type heat exchanger is the regenerative type in which hot and cold gas streams flow in opposite directions through opposite halves of a rotating drum

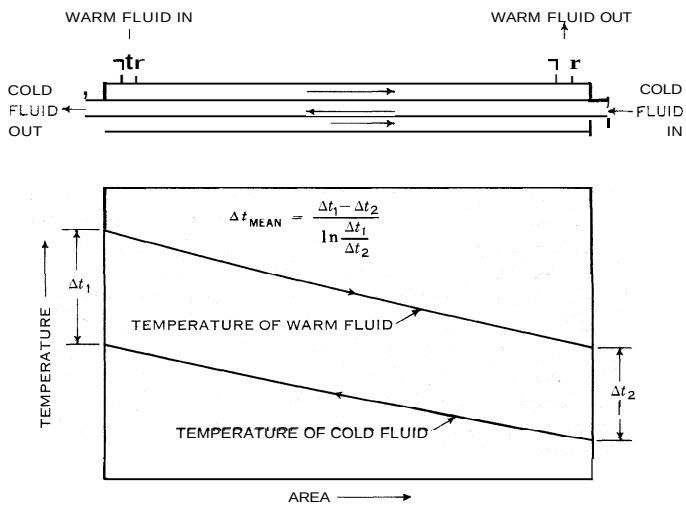

FIG. 2.— COUNTERFLOWIN A CONCENTRIC TUBE HEAT EXCHANGER

composed of honeycombed metal sections through which the gases can pass. As the drum slowly rotates the honeycombed metal alternately absorbs heat from the hot gas stream and surrenders it to the cold gas stream thus effecting the desired heat interchange between the two gases. This type exchanger is widely used in power plants for preheating combustion air while simultaneously reclaiming waste heat from the boiler flue gases.

HEATH, NICHOLAS (*c.* 1501–1j78) archbishop of York and lord chancellor, was born in London He was educated at Oxford and at Christ's college. Cambridge. and after minor preferments he was appointed archdeacon of Stafford in 1534. He

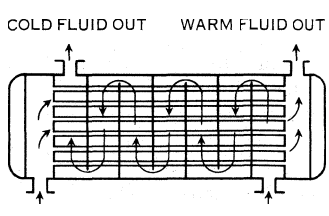

FIG 3.—SHELL AND TUBE HEAT EXCHANGER

then accompanied Edward Fox (*q.v.*), bishop of Hereford, on his mission to the Lutheran princes of Germany. In 1539 he was made bishop of Rochester and in 1543 succeeded Hugh Latimer at Worcester. He accepted the earlier reforms of Edward VI and the first Book of Common Prayer after it had been modified by the house of lords in a Catholic direction.

His definite breach with the Reformation occurred on the question of the Ordinal drawn up in 1550. Heath was one of the bishops appointed to prepare a form for ordination, but he refused to accept the version suggested by Archbishop Cranmer. He was imprisoned and in 1551 was deprived of his bishopric. On Mary's accession he was restored, made president of the council of the Marches and Wales, and in 1555 was promoted to the archbishopric of York. After the death of Stephen Gardiner he was appointed lord chancellor.

On Mary's death Heath as lord chancellor at once proclaimed Elizabeth I. Like Sir Thomas More, Heath held that it was entirely within the competence of the national state, represented by the parliament. to determine questions of the succession to the throne Although Elizabeth did not renew his commission as lord chancellor, he continued to sit in the privy council until the government had determined to complete the breach with the Roman Catholic Church. and as late as April 1559 he assisted the government by helping to arrange the Westminster conference and reproving his more truculent coreligionists.

Heath refused to crown Elizabeth because she would not have the coronation service accompanied with the elevation of the Host and ecclesiastical ceremonies and doctrine could not, in Heath's view, be altered or abrogated by any mere national authority. Hence he steadily resisted Elizabeth's acts of supremacy and uniformity, although he had acquiesced in the acts of 1534 and 1549. Like others of Henry's bishops, he had been convinced by the events of Edward VI's reign that Sir Thomas More was right and Henry VIII was wrong in his attitude toward the claims of the Roman Catholic Church.

Heath was therefore necessarily deprived of his archbishopric in 1j59, but he remained loyal to Elizabeth. After a temporary confinement, he passed the remaining 19 years of his life in peace and quiet. never attending public worship and sometimes hearing mass in private

HEATH, WILLIAM (1737–1814), American soldier, was born in Roxbury. Mass., on March 2, 1737 (old style). In 1765 he entered the Ancient and Honourable Artillery company of Boston, of which he became commander in 1770. In the same year he wrote to the *Boston Gazette* letters signed "A Military Countryman," urging the necessity of military training. He directed the pursuit of the British from Concord (April 19, 1775), was promoted to be provincial major-general on June 20, 1775, and two days later mas commissioned fourth brigadier-general in the Continenta! army.

He became major-general in 1776. In Jan. 1777 he attempted to take Ft Independence, near Spuyten Duyvil, but at the first sally of the Hessian garrison his troops became panic-stricken and a few days later he withdrew. Washington reprimanded him. In May 1779 he nas appointed a commissioner of the board of War. He nas placed in command of the troops on the east side of the Hudson in June 1779, and of other troops and posts on the Hudson in November of the same year. In July 1780, he met the French allies under Rochambeau on their arrival in Rhode Island; in October of the same year he succeeded Benedict Arnold in command of West Point and its degendencies: and in Aug. 1781, when Washington nent south to mket Cornwallis, Heath was 'left in command of the army of the Hudson to watch Clinton. After the war he nas a member of the Massachusetts convention which ratified the federal constitution in 1788.

Heath died at Roxbury Jan. 24, 1814.

HEATH, the English form of a name given in most Teutonic dialects to the common ling or heather (*Calluna vulgaris*), but now applied to all species of Erzca, an extensive genus of monopetalous plants. belonging to the family Ericaceae. The heaths are evergreen shrubs, with small narrow leaves, in whorls usually set rather thickly on the shoots; the persistent flowers have four

sepals, and a four-cleft campanulate or tubular corolla, in many species more or less ventricose or inflated; the dry capsule is four celled and opens, in the true heaths, in four segments, to the middle of which the partitions adhere, though in the ling the valves separate at the dissepiments. The plants are mostly of low growth, but several African kinds reach the size of large bushes, and a common south European species, *E. arborea,* occasionally attains almost the aspect and dimensions of a tree.

One of the best known and most interesting of the family is the common heath, heather or ling, *Calluna vulgaris,* placed by most botanists in a separate genus on account of the peculiar dehiscence of the fruit, and from the coloured calyx, which extends beyond the corolla, having a whorl of sepallike bracts beneath. This shrub derives some economic importance from its forming the chief vegetation on many extensive wastes in the more sterile lands of northern and western Europe, which are hence known as heaths. When growing erect to the height of three feet or more. as it often does in sheltered places, its purple stems, close-leaved green shoots and feathery spikes of bell-shaped flowers render it one of the handsomest of the heaths; but on more arid slopes it frequently rises only a few inches above the ground. In all moorland countries the ling is applied to many rural purposes; the larger stems are made into brooms, the shorter tied up into bundles that serve as brushes, while the long trailing shoots are woven into baskets. Pared up with the peat about its roots it forms a good fuel, often the only one obtainable on the drier moors.

The shielings (huts) of Scottish Highlanders were formerly constructed of heath stems, cemented together with peat mud worked into a kind of mortar with dry grass or straw; hovels and sheds for temporary purposes are still sometimes built in a similar way and roofed in with ling. Laid on the ground, with the flowers above, it forms a soft springy bed, the luxurious couch of the ancient Gael. The young juicy shoots and the seeds, which remain long in the capsules, furnish the red grouse of Scotland with the larger portion of its sustenance; the ripe seeds are eaten by many birds. The purple or Scotch heath, *E. cinerea,* one of the most beautiful of the genus, abounds on the lower moors and commons of Great Britain and western Europe, in such situations being sometimes more prevalent than the ling. The flowers of both these species yield much honey.

The genus contains about 500 known species, by far the greater part being indigenous to the western districts of south Africa, but it is also a characteristic genus of the Mediterranean region, while several species extend into northern Europe. No species is native in America, but ling occurs as an introduced plant on the Atlantic side from Newfoundland to New Jersey, and E. *tetralix* occurs on Nantucket. Five species occur in Britain: *E. cinerea, E. tetralix* (cross-leaved heath), both abundant on heaths and commons, E. *vagans* (Cornish heath): found also in western Europe, *E. ciliaris* in the west of England and Ireland and *E. mediiterranea* in Ireland. *E. arborea,* the white heath, found in southern France and elsewhere in the Mediterranean region, is known as *bruyère,* and its stout underground roots yield the "briarwood" used for pipes.

FLOWERING BRANCH OF THE LING OR HEATHER (CALLUNA VULGARIS) In flower, the small corolla is concealed by rose-coloured sepals' at base of which are four small green bracts

Among cultivated heaths the south African species excel, but only in the cool greenhouse or outdoors in California. Among the finest are *E. melanthera,* E. *verticillata* and *E. ventricosa.*

BY COURTESY OF NATIONAL PARK SERVICE

RED HEATHER FROM CRATER LAKE. ORE.

HEATHCOAT, JOHN (1783–1861), English inventor of lacemaking machinery, was born at Duffield near Derby on Aug. 7, 1783. After being apprenticed to a framesmith, he constructed in 1808 a machine to produce an exact imitation of pillow lace, which was the most expensive and complex textile apparatus then existing. A mill at Loughborough for the exploitation of the new process, owned by Heathcoat and his partner Charles Lacy, a Nottingham manufacturer, was attacked by the Luddites in 1816, and the 55 lace frames were destroyed. Heathcoat then constructed new and greatly improved machines at Tiverton, Devon. He followed his great invention by others, including contrivances for ornamenting net while in course of manufacture and for making ribbons and plaited and twisted net upon his machines, improved yarn spinning frames and methods for winding raw silk from cocoons. He also patented a steam plow and an improved process for extracting and purifying salt.

In 1832 Heathcoat was elected a member of parliament for Tiverton, where he died on Jan. 18, 1861.

See William Felkin, *A History of the Machine-Wrought Hosiery and Lace Manufactures* (1867). (K. R. G.)

HEATHER, a plant name properly applied only to *Calluna vulgaris,* also termed ling, but often used loosely to include the heaths *(Erica)* in addition.

See ERICACEAE; HEATH.

HEATH HEN *(Tympanuchus cupido cupido),* an extinct North American grouse, an eastern race of the prairie chicken (*q.v.*), which inhabited wooded districts. Once numerous, this choice game bird subsequently disappeared, as a result of overhunting and the opening of farm lands, from all parts of its range except the island of Martha's Vineyard, Mass., where, despite attempts to protect the race, only one bird was found in the spring of 1930.

HEATH RIVER rises on the lower slopes of the Cordillera Oriental, Bolivia, and flows northeast through heavily forested and sparsely inhabited country to its confluence with the Madre de Dios near Puerto Heath.

Along its 100 mi. length are numerous rapids making navigation possible only by small craft. The Heath is named for the American, Edwin Heath, whose explorations in 1879 revealed the wealth of the region, chiefly rubber. Col. P. H. Fawcett, employed on a 1910 boundary survey project by the Bolivian government, explored the Heath to its source. The river forms part of the

boundary between Bolivia and Peru. (J. L. TR.)

HEATING AND VENTILATION. These two branches of engineering are so closely interrelated that they usually are treated as a dual subject. Both are concerned with providing a required atmospheric environment within a space, the former with respect to heat supply to produce a desired temperature for maintaining comfort, health or efficiency of the occupants, the latter with regard to supply and removal of air, frequently with emphasis on contamination of the air. A third subject, air conditioning (*q.v.*), is closely related to both heating and ventilation.

HEATING

While the necessity for heat in cold climates seems self-evident, actually the matter is not so simple when the physiology of the human being is taken into account. The food and oxygen intake of the body is converted into energy, and the body dissipates this energy in the form of heat and work. Even on a cold day a person vigorously exercising is conscious of perspiring, so that he is losing heat by evaporation. Why, then, must the body require heat if it is losing heat?

The body of a healthy person is generally at a temperature of 98.6" F. and normally produces heat at a rate of from 300 to 2,000 B.T.U. per hour (a British thermal unit, or B.T.U., is the quantity of heat required to raise the temperature of one pound of water 1° F.). This heat must be dissipated at the same rate it is produced if the body temperature is not to rise or fall. If heat is lost too rapidly, the body temperature falls; when this happens, life is endangered.

The purpose of heating, then, is to prevent the too-rapid loss of heat from the body. By heating the ambient air or walls, ceiling or floor, the rate of heat loss from the body is controlled. When the rate of heat loss is properly controlled, the individual feels comfortable.

The output of heat, and consequently the degree to which heat must be supplied, depends on the degree of physical activity (see Table I). For example, when a man is engaged in heavy work he must dissipate from 1,400 to 1,600 B.T.U. per hour; for his body to do this, the atmospheric environment must be cool to allow the interchange of heat from his body to the surroundings. When he is relaxed in a chair, dissipating only 400 B.T.U. per hour, his environment must be warmer to provide for the lower rate of heat exchange.

How the Body Loses Heat. — Some concepts of heating were gradually changed as engineers obtained more precise knowledge about how the body loses heat. Insufficient attention formerly was paid to loss by radiation, which is the transmission of energy in the form of waves from a body to surrounding bodies at a lower temperature, independent of the air temperature between. The human being also loses heat by conduction (through his clothes) and convection, the latter by air currents past his skin or outside clothing surface, and also by evaporation of moisture from his skin (perspiration) and by respiration.

TABLE I.—Heat Output of Human Beings

Activity	Heat output, B.T.U. per hour	Activity	Heat output, B.T.U. per hour
Seated, relaxed	325–400	Light factory work	725–825
Office worker	425–500	Moderately heavy work	900–1,100
Walking	450–575	Heaw work	1,400–2,000

Note: Lower values for women, higher for men.

The loss by radiation depends on the temperature of the walls, floor and ceiling of the enclosure which the human being is occupying. The lower these temperatures are, the greater the loss by radiation. The mean radiant temperature (M.R.T.) is the weighted average of the various floor, wall and ceiling temperatures. When the M.R.T. is below 80° F., the average surface temperature of a normally clothed adult, the body loses heat by radiation to the surroundings; when the M.R.T. is higher than 80° F., the body is gaining heat by radiation. The effect of low M.R.T. on the comfort of room occupants was noticed as early as 1857, when the commissioners of the London board of health laid down a rule that for comfort the walls of an apartment should be warmer than the air.

Loss of heat by convection is dependent on air temperature and rate of air motion. The cooler the air in the room, the more the body heat loss by convection, and the greater the air motion, the greater the loss by convection.

Evaporation of moisture from the skin (and expired air) depends on the relative humidity, air movement and air temperature. Evaporation increases as the relative humidity of the air decreases and as air movement increases. Loss by evaporation decreases with increase of air temperature.

Heat can be lost from the body or gained by radiation or convection; evaporation always results in a heat loss. Consequently, it is not possible to indicate the proportions of these losses unless the specific conditions are stated. For the specific case of a nude person in a 76° F. air-and-wall-temperature environment, low relative humidity and no air motion, the heat loss is one-fifth by evaporation, less than two-fifths by radiation and more than two-fifths by convection.

Measures of Heating Effectiveness. — Within certain limits, it is possible to vary the heat loss by different means, increasing one and decreasing another, and still maintain a constant net loss and consequently, the same feeling of comfort. For example if, because of cold walls, the loss by radiation is high, the loss by convection and evaporation can be reduced by maintaining a higher air temperature. The result is that, since there are so many variables, there are many combinations of air temperature, mean radiant temperature, relative humidity and air movement that will result in a comfortable environment. Many attempts have been made to combine these variables into one scale of numbers or indexes which will define the environmental condition in terms of body heat loss as it relates to comfort.

Principal among these are the following:

Effective *Temperature.*—This scale is determined by subjective tests of the feeling of comfort under various combinations of air temperature, humidity and air motion, but without taking M.R.T. into account. This scale, devised by the American Society of Heating and Air Conditioning Engineers, Inc., applies only to the United States and only to still air (air movement not more than 25 ft. per minute). The effective temperature scale as applied to winter heating conditions is illustrated in fig. 1. Combinations of air temperature and humidity resulting in a 65° or 70" effective temperature (E.T.) were satisfactory to 85% of the subjects tested, while 95% were comfortable at 66° and 69" E.T. and 97% were comfortable at an E.T. of 67°. Most comfortable of all was an E.T. of 68°, at which 99% of the subjects were comfortable. The 68° E.T. curve is a plot of the combinations of temperature and humidity which were most, and equally, popular.

The chart in fig. 1 applies to convection (not radiant panel) heating systems of the central type only.

Equivalent Temperature. — This scale, developed in Great Britain, measures the combination of effects of radiation, air temperature and air motion but not humidity. It appears to be the best available index of warmth within the limit of 75° F., beyond which it does not apply.

Equivalent Warmth. — Also a British scale, this takes into account humidity, mean radiant temperature, air temperature and air motion. It is reported that it gives results very close to that of the resultant temperature, a scale developed in France. Neither of these scales is used in the U.S.

Operative Temperature. — A scale developed in the John B. Pierce Laboratory of Hygiene in New Haven, Conn., takes into account mean radiant temperature and air temperature. Since it applies only to moderate air movement, it can be said to take air motion into account within limits. Humidity is not included. For practical purposes, the mean between the air temperature and the mean radiant temperature can be taken as the operative temperature. Thus if the air temperature is 70" F. and the mean radiant temperature is 60° F., the operative temperature is 65°.

Environmental Standards. — All of the foregoing has considerable practical significance. For example, drafts (another term for air motion) increase the convection and evaporative heat loss

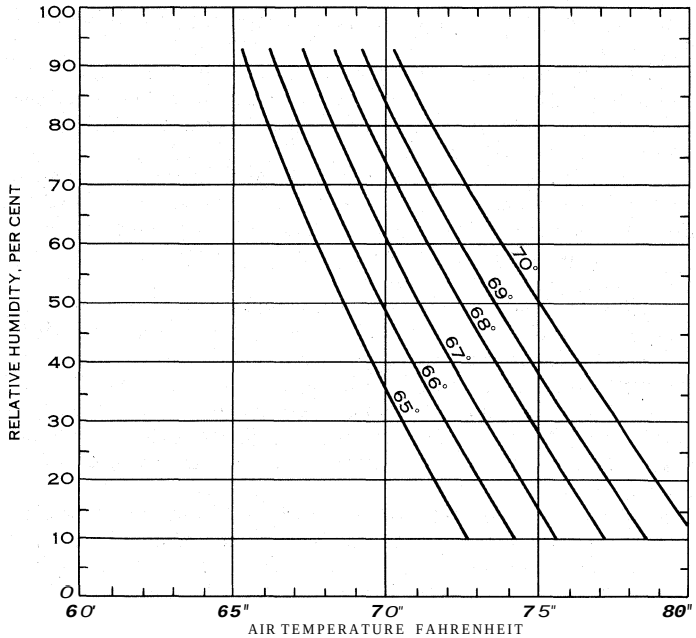

FIG. 1.— EFFECTIVE TEMPERATURE CURVES SHOWING COMBINATIONS OF TEMPERATURE AND RELATIVE HUMIDITY DEFINED BY THE AMERICAN SOCIETY OF HEATING AND AIR CONDITIONING ENGINEERS, INC., AS REPRESENTING RELATIVE SUBJECTIVE FEELINGS OF COMFORT. THE 68° F. EFFECTIVE TEMPERATURE LINE REPRESENTS THE MOST NEARLY IDEAL COMBINATIONS FOR MOST PERSONS

and may produce a feeling of chill. Less appreciated is the fact that when the walls are cold, the occupant can lose so much heat by radiation that he is cold, complains of drafts (which may not be present) and is uncomfortable even with a relatively high air temperature. This loss of heat by radiation is especially noticeable if a person is sitting next to a window when the glass is cold. At the same time another occupant who is not losing heat by radiation may feel quite comfortable. Such situations cause great irritation among occupants of homes and offices.

Since there is no universally accepted standard in regard to mean radiant temperature, relative humidity and air motion, air temperature is, in actual practice, the primary basis for design.

Other variables enter into the picture — quantity of clothes worn, age and sex of the individual, environment to which the individual is accustomed and state of health — but the heating system must be designed for the average case. The number of these variables involved is an indication of the difficulty in setting a precise standard.

In the United States an inside design temperature of 70° F. is commonly used for most buildings where the occupants are sedentary or even exercising lightly, with lower temperatures, from 55° to 65° F., employed for various industrial buildings. Actually, however, the temperature maintained is usually above 70° in residential, commercial and institutional buildings, depending on the amount of outside wall space. For rooms with one outside wall, 71° is nearly ideal, while 73° is common for rooms with two cold walls.

The effect of these cold walls is to increase the heat loss by radiation from the body; the higher air temperature reduces the loss by convection and evaporation and maintains the thermal balance.

In Great Britain, inside temperatures are usually much lower. British people feel very uncomfortable at the higher air temperatures maintained in American buildings, but are comfortable at temperatures from 60° to 65° F. The human body can in time adjust itself to the standards of either region.

Industrial buildings, gymnasiums and other buildings where the degree of activity is high, as compared with homes, maintain lower air temperatures, because the heat loss from the body is greater, and the lower air temperatures thus permit greater evaporation and convection losses to maintain the heat balance.

HEAT LOSS AND INSULATION

The determination of the capacity or size of the various components of the heating system is based on the fundamental concept that heat supplied to a space equals heat lost from the space.

The requisite capacity of the boiler or furnace and, in fact, of the whole heating system depends on the amount of heat to be supplied, and the equation shows that this equals the heat lost. Heat lost from the space is made up of two principal items of which the first is the heat lost through walls, roof, windows, doors and floors.

Heat Loss From Buildings. — To explain how heat is lost through walls, roofs and floors, it is necessary to have some understanding of how heat transfer takes place. Heat flows from a region of higher temperature to one of lower temperature, just as water flows downhill, and it does this in three ways: (1) by conduction, the flow of heat through matter unaccompanied by visible motion of the material, as in an iron rod. one end of which is held in a flame. (2) by convection, the transfer of heat by moving matter (in the case of buildings, air); when air is heated it becomes less dense and rises while the colder, denser air falls and displaces it, and in turn becomes heated. (3) finally, heat is transferred by radiation, the process by which energy is transferred through space, the energy being in the form of waves similar to light or radio waves, but longer. The energy is emitted from a hot or warm surface, is transmitted through the air or space, and when the waves fall on a cooler surface the energy is converted to heat. All three of these processes are involved in heat loss from buildings.

For example, in the simple wall of a house shown in fig. 2, heat flows in winter by conduction from the inside of the building through the plaster and the plasterboard. The warm surface transfers some of its heat by convection to the air in the air space, and this air, in turn, gives up some of its heat to the cooler surface. In addition, the warm surface emits radiant energy which flows in waves across the air space, and this is absorbed by the cooler surface and becomes heat. The heat then continues its flow by conduction through the sheathing and stucco, and finally this heat is transferred by convection to the cold outside air and by radiation to surrounding cold objects.

There is, therefore, a great deal more to be considered in the design of a wall or roof than making it aesthetically pleasing and rainproof. Its heat transfer properties are of the greatest importance and should be such that the heat transmitted will be at a minimum so that the quantity of fuel used also will be low. To accomplish this, wherever winters are other than mild, insulation is necessary.

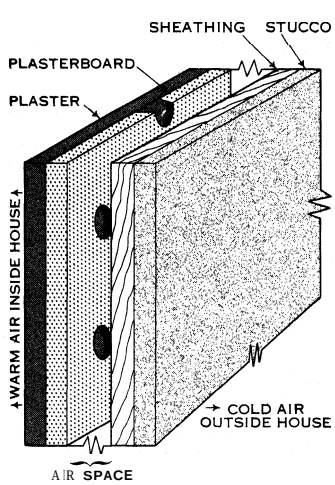

FIG. 2.— SECTION OF A SIMPLE HOUSE WALL

Characteristics of Insulating Materials. — Insulation does not completely stop heat flow, but rather reduces the flow. Broadly speaking, denser materials are better conductors of heat, so that stone walls, for example, lose heat rapidly. This can be overcome by making the walls or roof very thick, but except in the case of monumental buildings such as cathedrals this generally is impractical.

Conversely, less dense materials are better insulators in retarding heat flow by conduction. Usually, too, a material transmits more heat when it is damp than when it is dry.

The quantity of heat which flows through one square foot of a material one inch thick in one hour when the temperature is 1° F. higher on one side than the other is called the conductivity of that material. According to an arbitrary classification, when this conductivity is less than 0.5 the material is considered an insulator. The conductivities of some common building materials are given in Table II.

Since the figures given in Table II are per inch thickness they are not directly usable; for example, there is no such thing as a one-inch-thick brick wall. Furthermore, walls and roofs are always made up of a combination of materials. However, the figures in Table II do show the relative rate of heat transfer, and obviously the last five materials conduct far less heat than the first five.

TABLE 11.—*Conductivity of Common Building Materials*

(Figures are in B.T.U. per square foot per inch thickness per hour per 1° temperature difference)

Material	Conductivity	Material	Conductivity
Brick	4.6 to 9.9	Cork	0.27 to 0.35
Concrete	2.3 to 12.0	Glass fibre	0.22 to 0.33
Plaster	2.5 to 4.0	Mineral wool	0.25 to 0.33
Granite	19.0 to 20.5	Insulating board	0.33 to 0.40
Wood	0.6 to 1.1	Vermiculite	0.32 to 0.48

Types of Insulating Materials.—Some insulating materials are supplied in the form of boards or rigid sheets; these are termed insulating boards. Others, such as loose rock wool or vermiculite, can be poured into the air spaces between joists or studs. A third type is the bat, which is a more or less loose insulation held together in heavy paper which can be tacked onto wood joists or studs. Finally, and in a class by themselves, are the reflective insulators which do not insulate against conducted heat but against radiated heat.

The dense materials which are good conductors of heat*differ from the insulators in that in the latter there are tiny air spaces, and in ultrasmall spaces air is a very good insulator. However, when the air spaces are large, the heat transfer is aided by convection currents and the air space is not then a particularly good insulator. The conductivity of an air space (per inch) is 1.09. Above $\frac{3}{4}$ in., the addition of thickness of the air space is of little value in reducing conduction.

From fig. 2 and Table II, it becomes obvious that the use of an insulating board of low conductivity in place of the wood sheathing would reduce the heat transfer through the wall. Similarly, use of a mineral wool in the air space would sharply decrease the convection air currents and would eliminate the radiation across the space, since radiation takes place only across a space, so that the wool-filled wall would also be a good insulator. If both the insulating board and mineral wool were used, the wall would be improved even further.

Heat transfer by radiation across the air space can be retarded in still another way—by use of a reflective metal foil. This material, usually aluminum, reflects the radiant rays back to their source; only a very small amount of the energy is absorbed as heat by the foil and conducted to the outside. This type of insulation is useful on either the warm or cold side of an air space, or in an air space, inasmuch as it is not only a good reflector but also a poor radiator of heat energy.

Since the transfer of heat across an air space is aided by convection currents, the use of reflective foil insulation is of more value in winter for floors than for ceilings. This is because the warm surface is at the top of the air space and the foil below the air space in the case of the floor, so that there is virtually no convection. In the ceiling, the reverse is true, and convection is at a maximum. On the other hand, reflective insulations are especially good insulators in roofs in the summer to prevent heat entering the house.

Use of Insulating Materials.—Among the different types of insulation, each has its advantages and uses. The loose or bat type can be used to advantage in filling up air spaces to reduce both conduction and convection. On the other hand, such materials do not add to the strength and rigidity of the building as do the insulating boards, which can be used both as sheathing and as the plaster base or in place of plaster. Finally, the reflective type is advantageous in air spaces to retard heat flow; it may be used in conjunction with other insulating materials or by itself, especially in floors.

It is understandable that each additional increment of insulation yields less return in fuel savings than the first increment, so that there have been attempts to determine how much insulation is justified. Unfortunately, during periods of monetary inflation the cost of fuel may rise far above that contemplated originally, so that a few years later an originally accurate computation becomes highly unbalanced, and far more insulation would have been justified.

Similarly, a more expensive fuel may be employed at a later date, which would justify more insulation than was the case when a low-cost fuel was burned.

In general, then, for a new house it is well to consider the maximum possible use of insulation. For example, bats or loose fill between attic floor joists and reflective insulation on the attic roof; reflective insulation below floors exposed to unheated spaces, and edge insulation along slab floors laid on the ground; insulating board for sheathing and either loose fill or reflective insulation in the air spaces; sealed double windowpanes for all large windows and at least storm windows on others; storm doors on all doors; and windows weatherstripped.

Calculation of Heat Losses.—The heat lost from a building through the walls, windows, roofs, doors and floors is calculated from the equation

$$\text{Heat lost} = \text{coefficient of transmission} \times \text{temperature difference} \times \text{area.}$$

In this equation, heat lost is in terms of B.T.U. per hour; the coefficient is in B.T.U. per square foot of area per hour per degree difference in temperature between the inside and outside; temperature difference is that between the inside temperature and the outside design temperature in degrees (Table III); and area is the area in square feet of floor, roof, wall and window in the space involved. The coefficients can be found in engineering tables.

Thus the heat to be supplied increases (1) as the areas of walls, roofs, glass and doors increase; (2) as the temperature difference increases (in other words, the lower the outside design temperature. the greater the temperature difference and therefore the more heat necessary); and (3) as the heat transmission coefficient increases.

TABLE 111.—*Outside Design Temperatures for Various Cities*

Havana, Cuba	50	Vienna, Aus.	5
Honolulu, Hawaii	60	Winnipeg, Man.	−35

In addition to the heat lost by conduction through the building enclosing surfaces there is a second loss, that by infiltration. Cold air leaks into a building through cracks around doors and windows and through doors and windows when opened. All such air must be heated, adding to the heat lost, because for every cubic foot of air that enters, a cubic foot of warm air leaks out. The importance of infiltration is indicated by the fact that in a typical five-room house infiltration can account for as much as 37% of the total heat loss. The infiltration loss is calculated from the equation

$$\text{Heat lost by infiltration} = \text{air volume entering per foot of crack} \times .018 \times \text{temperature difference} \times \text{feet of crack.}$$

In this equation, heat lost is in B.T.U. per hour, air volume in cubic feet per hour is from engineering tables based on tests, temperature difference is as previously defined, the length of crack is as measured and .018 is the B.T.U. necessary to raise the temperature of one cubic foot of air one degree.

Similarly, for ventilation air, B.T.U. per hour is determined by

Heat lost by ventilation = volume of ventilation air × .018 × temperature difference.

Generally, for homes and apartments, the infiltration air is enough to supply ventilation. In public buildings the necessary quantity of ventilation air is considerable and the resulting heat load is more important than the infiltration loss.

Heat flows from a region of higher temperature to one of lower temperature in proportion to the difference in temperature. In a wall, for example, with room air on the inside at 70° and cold air on the outside at 0°, there will he 70 times as much heat flow through each square foot as when the inside is at 70° and the outside at 69°. In the former there is a 70° temperature difference, in the latter a 1° difference.

Outside design temperatures are based on the lowest temperature experienced in the locality. This outside design temperature is not the lowest temperature of record but ordinarily is the lowest temperature which occurs at least once every three to five years. Table III shows common values of outside design temperatures in a number of important cities.

In calculating the heat loss, each room is figured separately, then the totals added. Since there is no heat flow between rooms at the same temperature, usually only the outside walls have to be considered.

A special case in insulation is that of concrete slab floors laid directly on the ground. Since an important part of the heat lost through the slab is that around the edges, insulation should be applied around these outside edges.

Insulation and Secondary Effects.—The influence of insulation in reducing fuel consumption is so great that this aspect usually overshadows other important advantages of insulation. The temperature of the surface of the inside wall (or roof or floor) is greatly affected by the construction of the wall; and this temperature is higher with insulated than with uninsulated construction. It has been shown that the human body loses heat by radiation to cold surroundings. If the inside surfaces of the walls and windows are relatively cold, this radiation loss greatly affects the feeling of comfort of the occupants. To overcome this, the air temperature is maintained higher than would be the case if the walls were warmer. Since the occupants feel more comfortable when not losing too much heat by radiation, an advantage of the insulated room is that lower air temperatures can be maintained with equal feeling of comfort.

A second advantage concerns the staining of surfaces, especially ceilings. It is commonly believed that the alternating strips of light and dark on, for example, a wood lath and plaster ceiling are caused by the dust left when air passes through the plaster between the laths. This is not the case. Actually, this stain occurs because convection currents of air are created when there is a difference in temperature between the surface and the adjacent air. The surface friction of these currents generates a charge of static electricity of random polarity, the intensity of which depends upon the air velocity, which in turn is governed by the temperature difference between the surface and air. The dust particles suspended in the air have the same polarity as the air, usually negative. The surface, which usually has a charge of positive polarity, attracts the negative dust particles and discoloration results.

If the polarity of the surface and the air happens to be the same, the dust particles are repelled and a noticeably clean streak appears on the surface. Since the temperature difference between the surface and air is less with insulation (*i.e.*, in the areas backed by laths), the velocity of the convection currents is lower, the static charge is less, the attraction of the dust particles is weaker and less discoloration occurs.

With floors, perhaps more than with other surfaces, the effect of warmth or coolness is of great importance. A warm floor can be obtained directly by radiant heating in the floor. In this case it is important that the floor temperature be about 77° F., with 85° as a maximum (an exception is the bathroom floor, where a higher temperature may be pleasant). The floor frequently can be kept at a desirable temperature by use of insulation.

Insulation and Condensation.—The combination of rather high relative humidity in a house, especially when a humidifier is used, low outside temperature and insulation creates the problem of condensation within the wall or roof structure.

With a wall made up of different elements and with a high temperature on the inside and a low one on the outside, the temperatures of the inner surfaces will be somewhere between those of the outer surfaces. Air inside the building, when it has a high relative humidity, also has a high dew point temperature—the temperature at which the moisture in the air will begin to condense. Building materials are permeable to the vapour in the air, and when the temperature inside the wall is at or below the dew point, the moisture from inside the house will condense inside the wall and may cause damage.

To overcome this, the usual practice is to apply a vapour barrier on the warm side of the wall. In some cases this is a sheet of paper containing asphalt; in others the vapour-resistant material is applied to an insulating board. In either case, the resistant material should be continuous, with no openings through or around it. Also, it is important that the material he in the warm or inside portion of the wall. If placed on the outside it can make the problem worse.

Vapour barriers are more necessary with a high degree of insulation than with little or no insulation, more necessary the colder the climate and more necessary the greater the amount of moisture release inside the house from humidifier, cooking and washing. It is especially important that vapour barriers be well overlapped and tightly sealed so that the vapour cannot flow through leaks in the barrier.

Heating Load

The subject of heat loss thus far has been treated entirely on the design basis; that is, the maximum hourly heat loss that is anticipated for extremely cold days. Obviously this does not represent the average load, nor does it give much indication of the total load or fuel consumption for a whole winter.

In the early 1920s it was discovered that the gas consumption of a number of heating plants was proportional to the difference between 65° and the daily mean temperature when the latter was below 65°. This difference multiplied by 1 (day) gave the number of degree-days for that day. For example, on a day when the mean temperature is 42° there are 65 − 42 = 23 degree-days. The total number of degree-days from fall to spring in a given city is the degree-day total for that city for that heating season. A long-time average of such seasonal totals gives the normal number of degree-days for that city (see Table IV).

The degree-day has several uses. One is based on the fact that a building will consume fuel in any period at a rate in proportion to the number of degree-days in that period. For example, if in a winter having 5,000 degree-days a house used 2,000 gal. of oil, and if the next winter there were only 4,000 degree-days, the oil used in the second winter will be —— or 80% as much as in the first, or 1,600 gal. In short, use of the degree-day makes it possible to measure with precision the effect of a cold winter or a mild winter on fuel consumption.

Table IV.—Normal Number of Degree-Days per Heating Season in Typical U.S. and Canadian Cities

City	No. of degree-days	City	No. of degree-days
Atlanta, Ga.	2,811	Louisville, Ky.	4,279
Birmingham, Ala.	2,780	Minneapolis, Minn.	7,853

An ingenious use of the degree-day is to anticipate fuel usage. For example, at the end of three months the fuel oil supplier finds that a house used 600 gal. of oil and during that period there were 1,200 degree-days; the house is thus using 0.5 gal. of oil per degree-day. From past experience, he knows that the subsequent two months will have a probable 2,300 degree-days; therefore he

knows that the house will need 1,150 gal. of oil in that period. By this method he can predict when the oil tank will be nearly empty and deliver oil before the fuel supply runs out.

From the normal number of degree-days kept on a monthly basis for each city, it is possible also to predict reasonably well the average percentage of the total winter's fuel consumption which will be used each month (see Table V).

The degree-day on a 65° base is used in the U.S. and Canada. The degree-day is used also in the British Isles, but there, because

of lower inside temperatures, the base is 60°. The figure 4,200 is a good average seasonal total of such degree-days for England.

FUELS

Fuels commonly used for heating buildings include coal, oil, manufactured and natural gases and wood. There are two other not uncommon sources of energy for building heating: electricity, and steam or high-pressure, high-temperature water piped to groups of buildings from a remotely located generating plant. The latter is a special case, usually called district or institutional heating in the U.S.

Wood.—In early times this was the only important fuel and was burned in fireplaces and later in stoves designed for heating. It was gradually displaced by coal and by the 20th century had become a relatively unimportant fuel in North America and much of Europe.

Coal.—Bituminous (soft) coal, which contains not only carbon but hydrocarbons as well, is an important fuel for heating buildings, but rather more so for larger buildings than for homes. It can be fired by hand or by mechanical stokers, and it is the lowest-cost fuel in many areas. However, it is relatively dirty, ash removal is a task and even a mechanical stoker is not completely attention-free, so that its use has declined.

Anthracite (hard) coal is almost pure carbon and once ignited burns with less attention than soft coals. While cleaner than bituminous coals, its disadvantages are much the same, and in addition it is more expensive.

Oil.—Fuel oil was used first for building heating on the Pacific coast of the U.S. and became of some consequence in the early 1920s. By the end of that decade it had made important inroads on coal in the heating of houses and larger buildings, especially the former. Its primary advantage is that, being a liquid, it can be controlled more precisely and burned automatically under control of a room thermostat. In addition, and of great interest to home occupants, it is stored in a tank with no attendant dust, and it leaves no dirty ash which requires periodic removal. As a result of these advantages, and in spite of the higher price of oil during the early days, oil began seriously to displace coal as a heating fuel in the mid-1920s, and this trend continued unbroken except for wartime periods of shortage.

Gas.—Natural gas has long been used for building heating, but its use at first was confined to areas in close proximity to gas deposits, from which it was piped to buildings. Manufactured gas, made by a variety of processes from coal and oil and first widely used for illumination and later for cooking, was considered too expensive for heating, relatively, until about 1920, when it began to be burned in house-heating plants of persons with high incomes.

Gas has all the advantages of oil, plus a few of its own, including the fact that it is even easier than oil to burn and to control, the homeowner needs no storage tank and pays for the fuel after he has used it, the burner can be operated, if necessary, when electric service is interrupted because of storms, and fuel delivery is unaffected by snowstorms or forgetfulness. The apparatus needed is simpler than that required for oil and has few moving parts. The cost, however, is relatively high except in locations near gas deposits. After 1940 the commercial production and marketing of liquefied propane has greatly increased as a result of the popularity of gas fuel in districts isolated from natural-gas pipelines. (See also GAS INDUSTRY.)

Electricity.—This form of energy ranks highest in ease of control for heating and in simplicity of apparatus, but the cost in most cases is far too high for widespread use. Exceptions to this are areas near hydroelectric generating plants. Electricity also has a wide range of possible applications as a secondary or supplementary form of heat, as for bathrooms, buildings used only occasionally (such as churches), rooms with poor heating facilities where the cost of correcting the trouble would be high, and similar special cases.

Solar Heating.—Another source of heat with promise of greater importance at mid-20th century is energy from the sun. By careful orientation of the house with respect to the sun it is possible, with proper shading, to allow sunlight to enter the windows in winter when the sun is far to the south and to prevent it from entering in the summer when the sun is overhead. (See also SOLAR ENERGY, UTILIZATION OF.)

FUEL-BURNING EQUIPMENT

Among the more important types of self-contained heat sources are (1) the fireplace; (2) space heaters, room cabinets or stoves fired by coal, oil or gas; (3) radiant heaters, burning gas or containing electric resistance coils, and of either the portable or fixed type; and (4) convection unit heaters burning gas or containing electric resistance coils and equipped with a fan to blow air over the hot surfaces. All these are of the more or less self-contained type for individual room use.

For central heating, where the fuel is burned in one place—the basement or utility room—and from which steam, hot water or warm air is distributed to adjacent and remote spaces to be heated, there are (1) hand-fired coal furnaces and boilers; (2) stokers for automatically burning coal; (3) oil burners, oil furnaces and oil boilers; and (4) gas burners, gas furnaces and gas boilers.

History and Development of Heating **Equipment.**—At the beginning of the Christian era, the Romans had developed a central heating system which utilized conduction, convection and radiation. A furnace was constructed beneath the floor of a building or adjacent to it. The products of combustion were conveyed under the floor, up through flue panels in the walls, and finally discharged to the atmosphere. Several of these systems were uncovered in London after World War II, relics of the ancient Roman occupation. Similar systems are used in certain provinces in China and Japan.

While feudalism was reaching its crest during the 11th and 12th centuries, fortified castles were built. The castles were multiple-storied structures and the disposition of smoke from the fireplaces presented a problem. A solution was achieved by moving the fireplaces to niches in outside walls and providing sloping passages through the wall through which the smoke could escape. The chimney was not introduced until the 14th century.

The great halls or assembly rooms of the castles were provided with one or more large fireplaces, while the occupants of the smaller rooms depended for warmth on individual metal baskets or braziers, filled with coals. It is interesting to note that the interior walls opposite the great fireplaces were constructed of solid masonry of much greater thickness than was structurally necessary. These walls of tremendous thermal capacity absorbed radiation from the fireplaces and reradiated heat to the room long after the fires had burned low. This idea was retained and reappeared in the U.S. early in the 19th century. Many brick houses had two fireplaces on one side of the room while the opposite wall was constructed of solid brick masonry 27 in. or more in thickness.

The fireplace remained in wide use at mid-20th century. In England, although it was gradually giving way to central heating, the

fireplace was still an important source of heat in residences.

The earliest reported improvement in the fireplace was that of Louis Savot, who in 1624 developed for the Louvre a fireplace in which room air was drawn through passages under the hearth and behind the fire grate and then discharged into the room through a grille in the mantelpiece, so that occupants were warmed by convected as well as radiant heat. A century later there was introduced a fireplace which warmed air drawn from either the inside or outside of the building.

Fireplaces produce warmth principally by radiation from the fire and from hot bricks at the back and hearth. Air passes through the fire and up the chimney, carrying most of the heat outside, and cold outside air must be drawn into the room to replace the air thus exhausted. Consequently, the fireplace is only about one-third as efficient as a good stove.

Stoves.— The first stove of record was produced in 1490 at Alsace, France. It was constructed of brick and tile. The products of combustion escaped from the stove through a heavy brick and tile flue. Later developments resulted in the Scandinavian stove, which had a tall hollow iron flue containing iron baffles arranged to lengthen the gas travel, and the Russian stove, which had as many as six thick-walled masonry flues. This type of stove is in common use in the regions bordering the North sea. The stove is often built at the intersection of inside partition walls in such a manner that a portion of the stove and its flue is in each of four rooms. A fire is maintained until the stove and flues are thoroughly warmed; then the fire is extinguished and the flues are closed. The stored heat is delivered to the rooms by radiation and convection.

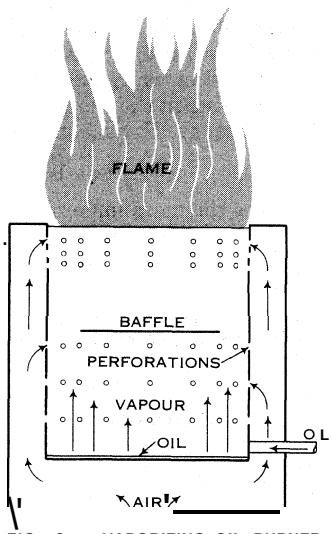

FIG. 3.— VAPORIZING OIL BURNER THE OIL BURNS AFTER BEING EVAPORATED TO GAS

The first manufactured cast-iron stove was produced at Lynn, Mass., in 1642. The stove had no grates and was simply a cast-iron box.

In 1744 Benjamin Franklin improved the stove which bears his name and which was used in conjunction with the fireplace. He also established basic principles of stove design. At about the same time (1792), William Strutt, in England, made a further advance by passing air from a stove through channels so that more remote rooms could be heated.

The first round cast-iron stoves with grates were manufactured at Philadelphia, Pa., in 1800 by Isaac Orr. The base-burner stove for burning anthracite coal was invented in 1833 by Jordan A. Mott.

Although petroleum was known and animal and vegetable oils were used in crude lamps during ancient times for warmth, it was not until the 19th century that oil-burning equipment was specifically designed for producing warmth.

Coal Burning Equipment.— The basic requirements for burning any form of coal efficientlyare (1) a grate on which the fuel is burned and through which air can pass to the fuel bed, and which can be shaken to drop ashes to a pit below; (2) means for carrying the products of combustion to the outside, usually a chimney; (3) means for providing a draft so that air will flow into the ashpit through the grate and provide the primary air necessary to allow sufficient oxygen to mix with the carbon in the coal during the combustion process; (4) means for admitting a secondary supply of air over the fire to supply oxygen for burning the volatile gases and hydrocarbons in the coal, this being of more importance in burning bituminous coal than anthracite; (5) a metal surface, over which the hot products of combustion pass, sufficiently large that heat is transferred to that surface, which in turn will heat water or air; and (6) a chamber of sufficient volume surrounding the grate to allow the air to mix with the fuel.

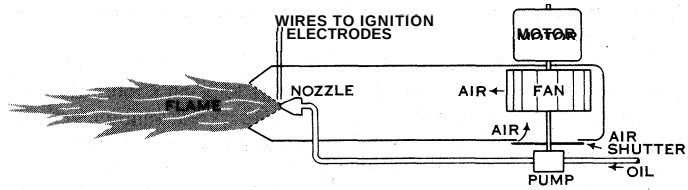

FIG. 4.— ATOMIZING OIL BURNER. BURNING OCCURS AFTER THE OIL HAS BEEN CHANGED TO A GAS BY BEING FORCED UNDER PRESSURE THROUGH A SMALL NOZZLE INTO AN AIR STREAM

All these requirements are fulfilled in hand-fired coal-burning furnaces and boilers, as well as in mechanical stokers, which, in addition to the above, provide means for feeding coal gradually and automatically to the grate and make the process of firing including the disposal of the ashes to a pit, a continuous one. Such stokers have wide application in industrial and commercial installations, but for residences the stoker, which had wide popularity during the 1930s and early 1940s, gradually lost ground because of the advantages of oil and gas.

Oil Burners.— Oil burners used in residences are of two principal types— vaporizing and atomizing. In burning oil, the liquid must be gasified to burn, and the vaporizing burner accomplishes this by evaporation, the oil being heated for this purpose.

In fig. 3 the principle of one type of vaporizing burner is illustrated. Oil is fed to the bottom of a bucket-shaped perforated vessel; vapour rises from the oil and is mixed with the primary air and finally, at the top, begins to burn, with a secondary supply of air fed to the flame through the perforation at the top. The heat of the flame itself causes more oil to vaporize, so that the process is continuous.

In the atomizing- or pressure-type burner, illustrated in fig. 4, the oil is atomized or broken up into small drops by pressure. The air pressure is supplied by a motor-driven fan, the air supply being regulated by a shutter. Oil is fed to a nozzle under pressure by a pump and is ejected from the nozzle in a cone-shaped spray into the air stream. This burner is also called a gun-type burner.

Another type of atomizing burner is the rotary burner. The rotary type employs a motor-driven cup or disk from which the oil is thrown off in a cone-shaped spray.

In large installations there is an increasing tendency to use burners so designed that they can burn either gas or oil, or pulverized coal, arranged for convenient change from one to the other. The advantage is that when one fuel becomes more expensive than another, or when one is in short supply, another may be used.

Gas Burners.— Gas burners are generally of simple design. Gas is supplied to the burner at a pressure sufficient to induce a supply of primary air to mix with it, the mixture then passing through orifices or ribbonlike openings over which secondary air is admitted. In the usual case this is all accomplished without a forced draft, so that the mechanism is simple and trouble-free.

Requirements for burning gas also include a combustion chamber and means of heat transfer and, finally, venting to the atmosphere for safety. The fuel used is completely independent of the method for transferring the heat to the rooms to be heated; that

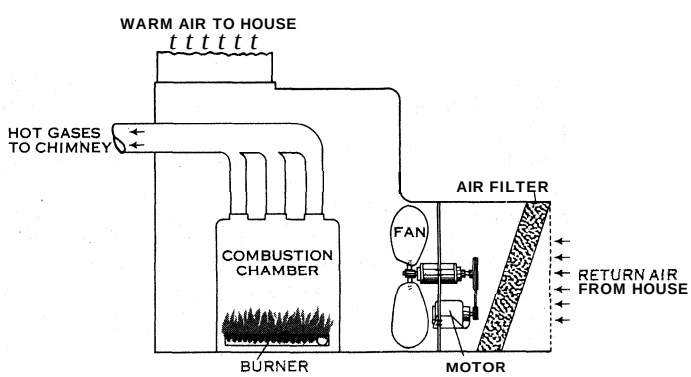

FIG. 5.— FORCED WARM-AIR FURNACE

is, whether the heating system utilizes warm air, steam or hot water, the fuel can be coal, oil or gas.

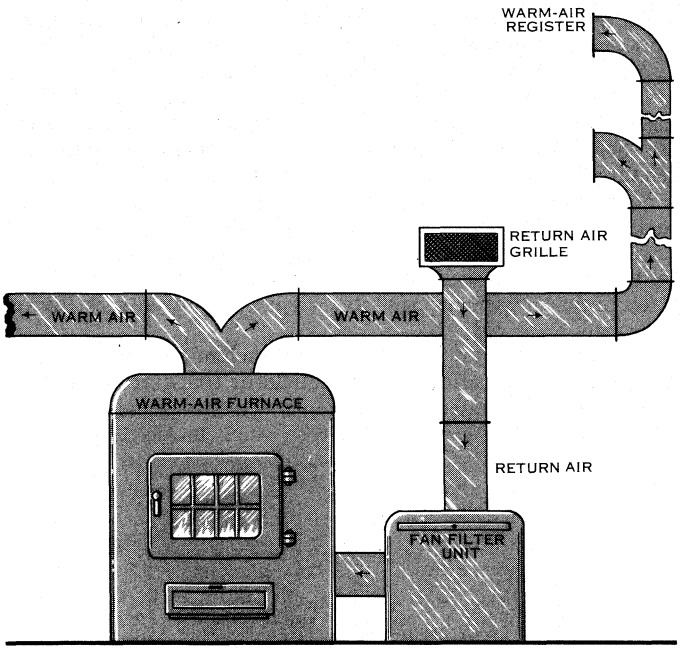

FIG. 6.— FORCED WARM-AIR SYSTEM. HEATED AIR IS BLOWN TO ROOMS BY A FAN. AND THE AIR RETURNS TO THE FURNACE FOR REHEATING

Electricity. — Although not a fuel, electricity is a form of energy used for heating, and the commonest method of converting the energy to heat is by coils or other. means of introducing resistance into the circuit, so that the heating elements become hot and directly heat air or water or, in other cases, emit radiant energy.

Heating Systems

Heat is generated by fuel burning either in a furnace, an arrangement by which air is warmed by contact with metal surfaces heated in turn by the hot gases of combustion, or in a boiler, a vessel containing water heated by contact with hot surfaces. The boiler can be either a steam or hot-water boiler and may be used with a steam or hot-water system.

Warm Air. — The principle of the warm-air furnace is illustrated in fig. 5. The furnace is conventionally made of steel, and the essential requirements are that (1) the combustion chamber and its connections to the flue must be gastight to prevent fumes from getting into the stream of air supplied to the house; (2) there must be sufficient metal surface to provide for the transfer of most of the heat of combustion to the air; (3) there must be a tight casing around the whole apparatus; and (4) the furnace should be compactly arranged. The drawing is simplified to show the principle; a centrifugal fan rather than a propeller fan usually is employed.

The warm air from a furnace, being lighter than the cooler air around it, can be carried by gravity in pipes or ducts to the room to be heated, and until about 1930 this was the usual method. A gravity system, however, required sheet metal ducts of 8 to 14 in. in diameter to reduce air friction, and this resulted in the basement's being filled with ductwork. The pressure, or head, resulting from the difference in density of the air is quite small, and for this reason rooms distant from the furnace, especially those to windward, frequently were underheated. Use of a motor-driven fan to move the air made possible the use of small, compact, rectangular ducts giving a neat installation and forcing heated air to the most remote rooms.

The heated air is introduced into the room through registers, grilles or diffusers in a variety of types, including arrangements resembling baseboards along outside malls. The heated air, after giving up its heat to the room, is returned to the furnace, usually through one or two return ducts, as shown in fig. 6. An advantage of this method of forced warm-air heating is that the air can be passed through filters and cleaned as it circulates through the system.

Hot-Water Heating. — Hot-water heating seems to have originated in France early in the 18th century and was used first in a greenhouse. An incubator for hatching chickens for the Paris market was heated by a hot-water circuit even before the French Revolution. Hot-water pipes were employed by Sir John Stone in 1792 to heat the Bank of England, but it was not until about 1840 that Robert Briggs began the installation of hot-water heating in the U.S.

A hot-water system consists of the boiler and a system of pipes connected to radiators suitably located in rooms to be heated, the principle being shown in fig. 7. The pipes, usually of steel or copper, feed hot water to radiators or convectors: which give up their heat to the room. The water, now cooled, is returned to the boiler for reheating. Two important requirements of a hot-water system are (1) provision to allow for the expansion of the water in the system, which fills the boiler, radiators and piping; and (2) means for allowing air to escape from each radiator by a manually or automatically operated valve.

Early hot-water systems, like warm-air systems, operated by gravity, the cool water, being more dense, dropping back to the boiler, forcing the heated lighter water to rise to the radiators. Neither the gravity warm-air nor gravity hot-water system could be used to heat rooms below the furnace or boiler. Consequently, motor-driven pumps or circulators introduced to supply positive means of circulating water made it possible to locate the boiler anywhere with regard to its elevation compared to the radiators—even in the attic if desired. As with warm air, smaller pipes can be used when the fluid is pumped than with gravity operation.

Steam Heating. — Steam heating on a practical scale was investigated by James Watt in 1784, and in 1791 a Halifax inventor patented a steam-heating method. Thomas Tredgold in 1824 employed cast-iron pipes to heat by steam a silk mill in Watford. Eng. Early Americans who contributed to the development of steam heating included John H. Mills, who in 1877 designed an overhead downfeed one-pipe steam system. Frederick Tudor in 1883 developed the modulating valve and in 1902 made improvements in a return line system vented to the atmosphere. In 1899 James A. Trane developed a vapour system. and in 1903 C. A. Dunham marketed a fluid-filled thermostatic trap for steam systems.

Steam systems are those in which steam is generated, usually at less than 5 p.s.i. in the boiler (fig. 8) and the steam is led to the

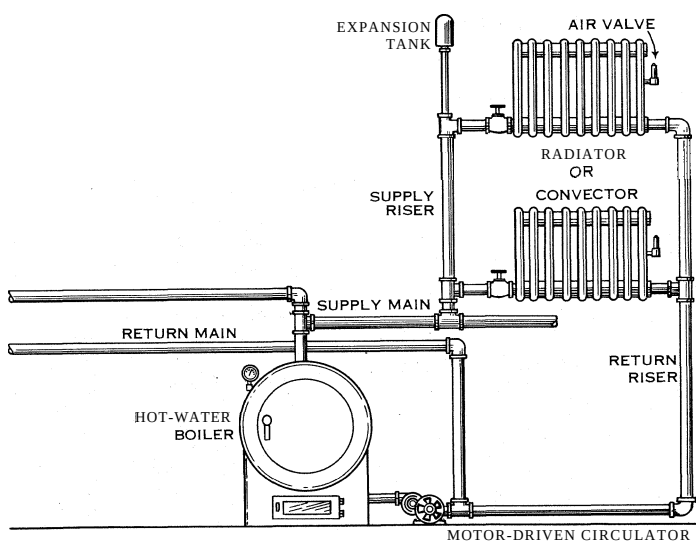

FIG. 7.— FORCED HOT-WATER SYSTEM. WATER IS DRIVEN THROUGH THE SYSTEM BY A CIRCULATOR

radiators through steel or copper pipes. The steam gives up its heat to the radiator and the radiator to the room, and the cooling of the steam condenses it to water. The condensate is returned to

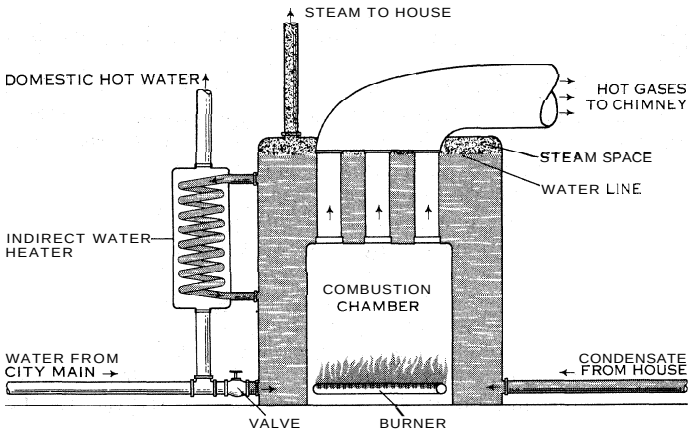

FIG. 8.— STEAM HEATING BOILER

the boiler either by gravity or by a pump. Arrangement of a simple one-pipe system is shown in fig. 9. The air valve on each radiator is necessary to allow air to escape. Otherwise it would prevent steam from entering the radiator.

The vapour system (fig. 10) differs from the one-pipe system in that (1) the condensed steam returns from the radiator through a return pipe to the boiler (instead of through the supply pipe); (2) a trap. a device which allows uater and air but not steam to leave the radiator, guards the return outlet; and (3) air is eliminated through a device at the boiler instead of through air valves on each radiator.

A system widely used in larger buildings is the vacuum system (fig. 11). A vacuum pump maintains a pressure below that of the atmosphere in the return lines, draws all the air and water to it, expels the air and pumps the water back into the boiler. A feature of this system is its ability to raise the condensate from a radiator below the boiler.

Much ingenuity has been applied to steam heating, including methods for controlling the steam temperature. By maintaining a vacuum in the radiator as well as in the return lines, the pressure inside the radiator can be reduced to such a point that water will boil at temperatures well below the 212° F. at atmospheric pressure. Consequently, on the coldest days no vacuum is applied, and the steam in the radiator is at 212°. The warmer the day, the more vacuum is applied. until at 65° outside a vacuum sufficient to cause boiling at below 100° will result in a lower radiator temperature, and so on through the whole range of outside temperatures expected. In this way, the radiator is constantly emitting heat in proportion to the demand and is not alternately heating and then cooling off.

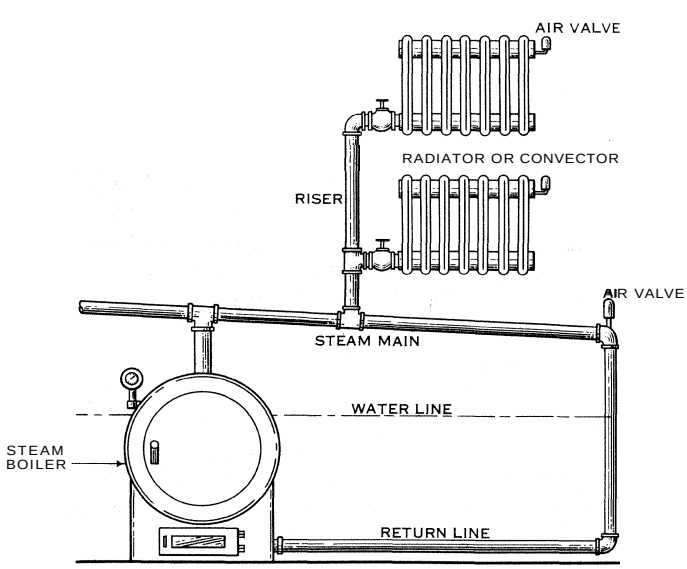

FIG. 9.— SIMPLE ONE-PIPE SYSTEM IN WHICH STEAM FLOWS UPWARD THROUGH A RISER TO THE RADIATORS, WHILE CONDENSATE FROM THE RADIATORS IS RETURNING DOWNWARD THROUGH THE SAME PIPE TO THE BOILER

The hot-water system differs from both warm-air and steam systems in an important respect—both warm air and steam, being gases, have a low mass as compared with hot water. As a result, with an intermittently fired fuel, such as oil or gas, in which the fuel is burning at one period and off the next, the hot-water system can "hold" heat for a longer period and not undergo the sharp temperature fluctuations of steam and warm-air systems.

To perform most efficiently. steam systems require more apparatus than hot-water or warm-air systems. As a result, warm air and hot water have largely replaced steam in house heating. On the other hand, in larger structures, such as office buildings, hotels and apartment houses, steam has such advantages that it is strongly preferred.

Heat Distribution Devices.—With each of the three systems there are many variations in the method of transferring the heat to the space to be heated. For example, with steam and hot water, an alternative to the common radiator (which: incidentally, is mis-

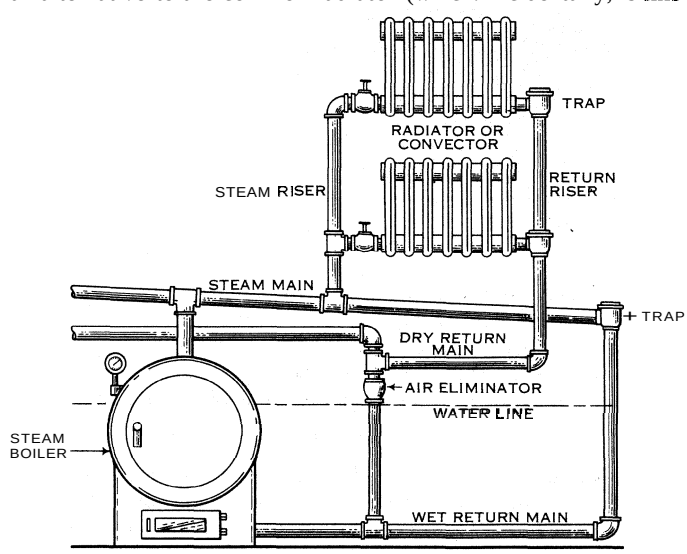

FIG. 10.—VAPOUR SYSTEM, IN WHICH THE AIR IS REMOVED FROM THE SYSTEM AT A CENTRAL ELIMINATOR RATHER THAN THROUGH VALVES ON EACH RADIATOR

named, because it emits much of its heat by convection) is the convector. an arrangement of finned pipes through which the heating fluid circulates at the base of an enclosure open at top and bottom; air flows upward over the heating surface and is discharged at the top of the enclosure; cooled air drops to the floor and re-enters the convector.

Still another arrangement is the baseboard radiator or convector, usually placed along the bottom of an outside wall to counteract the loss of heat through the walls.

Many industrial buildings are heated with a special form of heater called the unit heater, which consists of an arrangement of finned tubes through which hot water or steam circulates, and a motor directly connected to a fan which forces air over the tubes. Unit heaters are made both in suspended types, mounted above the floor (fig. 12), and in floor-mounted units. The forced convection results in a rapid rate of heat transfer.

There are many combination systems using steam and hot water aith warm air. called split systems. Many public buildings are heated by hot-blast systems in which steam is generated in a boiler and flows to large banks of heat-transfer surfaces over which air is blown by large fans; the warmed air is supplied to rooms through ducts. This type of system is often used for air conditioning, the heat-transfer surface being fed cold water in summer, steam in winter.

For residences there is an arrangement of hot water piped to small heat-transfer devices below the floor or in the walls; over them air is blown by fans and enters the room through grilles. In the summer, chilled water circulates to the heat-transfer units,

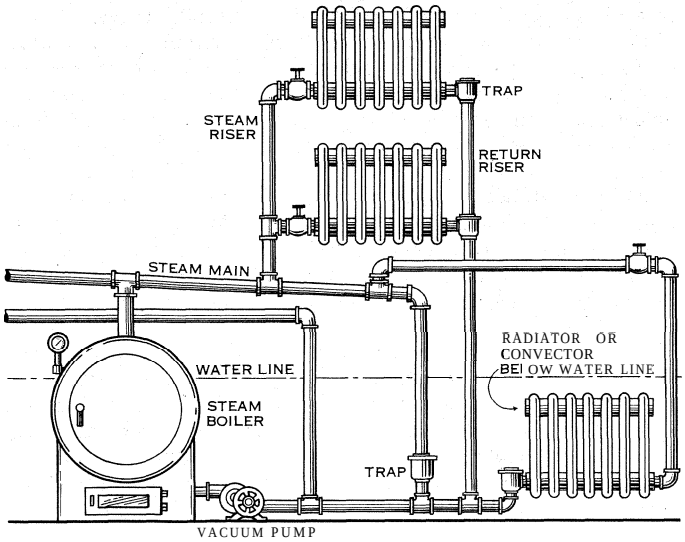

FIG. 11.— VACUUM SYSTEM IN WHICH CONDENSED STEAM IS PUMPED BACK INTO THE BOILER. THE SYSTEM OPERATES AT LESS THAN ATMOSPHERIC PRESSURE

which are located throughout the house so that no long runs of space-consuming ductwork are needed. All these methods are primarily convection types of heating, although there is some transfer by radiation.

Radiant Heating.— The Roman hypocaust system, in which a hollow wall or floor was heated by gases from a fire below and in turn radiated heat into a room, was the first application of what is now known as radiant or panel heating. This principle was ignored for centuries until 1908, when A. H. Barker of England observed the comfortable effect obtained from walls warmed by chimneys. He later patented several arrangements for heating floors, walls and ceilings, and many such systems were installed in England. The idea was first widely adopted in the U.S. not long before World War II.

Although there are many variations, radiant heating systems usually employ either (1) hot-water pipes embedded in the floor or ceiling (occasionally in the walls); (2) warm-air ducts embedded in the floor; or (3) some form of electrical resistance panels applied to ceiling or walls or, in some cases, the floor. The energy in the heated surface is transmitted through the air in the form of infrared rays, with practically no temperature effect on the air, and converted to heat when the rays impinge on solids, whether room surfaces, furniture or human beings. With many of these systems there is no visible heating equipment in the room, and this is an advantage in decorating. A disadvantage is the extent to which a ceiling or floor might be ruined in the case of trouble with corroded or faulty hot-water piping where this method is employed.

Heating Controls.— Oil and gas fuels never would have attained their great popularity had it not been for automatic operation of the heating plant. Automation was made possible principally by the thermostat, a device which, when the temperature in a space drops to a predetermined point, will actuate the heating plant until the demand for heat is satisfied.

Other important controls include (1) the limit control, which, when the air, water or steam temperature from the furnace or boiler reaches a point considered dangerous, will shut off the heating plant even if the thermostat still calls for heat; (2) boiler water level control, which either shuts off the burner or opens a valve to admit water to the boiler if the water level in the boiler has fallen to a dangerously low level; and (3) the flame control! which shuts off the fuel supply if the ignition system for lighting the oil or gas flame fails. Modern heating plants are so protected by such devices that nearly every conceivable circumstance which could be dangerous is anticipated and controlled.

Chimneys and Draft.— The products of combustion from oil, gas or coal must be vented to the air, and the chimney provided to carry them away must be of sufficient height to produce a certain minimum draft. The one-story house in particular presents a problem, because if the chimney is to be adequate its height may be out of proportion to the scale of the house.

Service Hot Water.— The heating of water for bathing, washing and other purposes is part of the over-all heating problem. In houses, formerly, a very small hand-fired coal boiler commonly was used for this purpose alone. This was largely superseded by (1) the separate gas, electric or oil water heater in which the heating burner or element is included in the same unit as the hot-water storage; when hot water is drawn off, cold water enters, affecting a thermostat which turns on the heat until the tank temperature again reaches the predetermined level; or (2) a heat exchanger of small size connected to the house-heating boiler and extracting heat from the boiler water to heat the service water (see fig. 8).

With the separately fired unit, the heating system and hot-water system are entirely independent of each other, an advantage in case of trouble and during seasons when the heating system is not needed. With the combination system, the heat used to heat the water is by no means all waste heat, and a larger boiler must be provided if an indirect heater is to be installed. On the other hand, some tests have indicated greater economy with the indirect heater. With a warm-air furnace the homeowner has little choice but to use a separate, direct-fired heater.

The total hot-water use ranges from 7 to 12 gal. per day per person on the average, although the range may be as much as 4 to 25 gal. per day per person, and some authorities even use a figure as high as 40 gal. per day per person. The figure varies widely with different families.

The trend is toward higher temperature hot water because of (1) the importance of killing bacteria in dishwashing, tests of which have demonstrated the need for temperatures of at least 180°; and (2) the desirability of very hot water for washing clothes Since it is impracticable to carry 180° water in the whole system and in fact actually dangerous because of possible scalding, dish-mashing machines are often equipped with electric heaters to raise the temperature of the water.

District Heating.— First put into practice in Lockport, N.Y., in 1877, the arrangement of piping steam (or hot water) from a steam plant to a number of buildings became fairly widespread. In many large cities, especially in the U S., the business became a sideline of electric utility companies, and the steam lines served the business districts of the city—the larger buildings; supplying private homes aith this service was not deemed profitable. On the other hand, there were hundreds of small towns served by municipally owned utilities whose principal function was residential heating.

Centrally located private plants serving a number of buildings are still commonplace in the U.S in two other cases: first, in large institutions, such as colleges and hospitals, and, second, in large housing projects. The former application has existed for decades. In the latter case, however, the practice began in the 1930s when the federal government sponsored or built many such plants

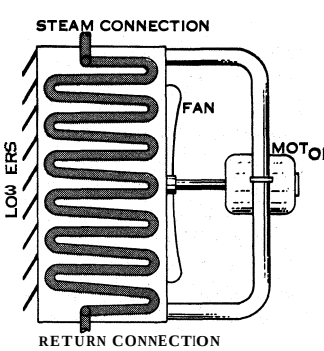

FIG 12 —UNIT HEATER THROUGH WHICH AIR IS BLOWN BY A FAN ADJUSTABLE LOUVERS DEFLECT HEAT IN DESIRED DIRECTION

VENTILATION

As early as 1553 a rotary fan was used by Georgius Agricola to ventilate a mine; and during the 18th century, French, English and Swedish inventors were concerned with improving the fan for mine and ship ventilation. The reason behind the need for ventilation, however, was a mystery: some investigators said it was excessive heat; others disputed this and said the reason mas inequality of temperature in the room or space In 1777 the French chemist Antoine Lavoisier suggested that the increase of carbon dioxide in an occupied space was the objectionable factor, but Max Joseph von Pettenkofer in 1363 showed that this was quantitatively too small (0.03% to 0.05%)

to explain the results observed. Similarly, the reduction of oxygen content was said to be small, from a normal 21% to about 20%.

In the late 19th century the French physiologist Charles Edward Brown-Séquard advanced the theory that the harmful effects of air in an occupied space were attributable to certain poisonous substances in the air called anthropotoxins or morbific matter.

All these theories were finally abandoned, as a result of the work of Karl Flugge in 1905, F. G. Benedict in 1907 and J. S. Haldane in 1907. Flugge showed that (1) chemical changes in the air in occupied spaces are not harmful; (2) headaches, nausea and dizziness in ill-ventilated space are solely due to deficient heat loss (from the body); and (3) the temperature, humidity and movement are far more important than chemical changes in the air.

Essentially this covers the theory subsequently adopted, although there are special cases including (1) factories where dangerous fumes are given off, or even homes where unvented gas appliances can result in dangerous conditions; and (2) situations in which the effect of odours is important. The modern theory can be summed up in the statement that for places of general assembly the purpose of ventilation is to carry away excess heat and odours, and that normally ten cubic feet per minute of outside air per person is sufficient to accomplish this objective. In buildings such as homes, the leakage of air through cracks around doors and windows is usually sufficient to meet this requirement.

Industrial Building Ventilation.— Industrial buildings often present special problems in ventilation. Certain processes are accompanied by the production of air-borne dust, fumes, toxic vapours and gases which are hazardous to the health of workers. Research has determined the limits of concentration permissible for human tolerance to prolonged exposure. The problem of industrial ventilation is also complicated by the hazards of fire and explosion of combustible dust and gases.

Successful methods have been developed for the control of the concentration of toxic gases and harmful dusts within safe limits for the health of the occupants of spaces, but the control of inflammable and explosive concentrations of gases and dusts is much more difficult and uncertain.

Three types of ventilating systems are in use for the control of dangerous gases and dusts: exhaust systems, dilution systems and combinations of the two. Exhaust systems require the least amount of air and are most effective when the contaminants originate at localized spots. The contaminated air is exhausted at high velocity from hoods which have sufficient entrance velocity to pick up the contaminants. Exhaust systems are least effective in the ventilation of bins, coal bunkers, etc.

The dilution method is used when the sources of contamination are not localized but are dispersed over a wide area. It is very effective but is seldom used to dilute heavy concentrations because of the large quantities of air required. The cost of heating the air is often prohibitive.

The third method of control by ventilation is a combination of exhaust and dilution, and is used when contaminants can be confined to and exhausted from booths. The development of air-cleaning devices and air-purification processes makes it possible in many cases to recirculate the air and greatly reduce the quantity of fresh air required, thus reducing the expense of operation.

Motor-driven fan systems are not always necessary, and natural forces — gravity and wind — may be used to facilitate air movement. In a building where the air temperature inside is higher than that outside, the difference in density can be employed as it is in a chimney. Any opening in the roof can be employed, and the warm, light air flows out, its place being taken by cooler air flowing in below. This method is crude, because rain can enter through the opening and because the air flow is very low when the difference between inside and outside temperatures is small.

Ventilating Apparatus.— To overcome these disadvantages, many types of roof ventilators have been designed. A typical gravity roof ventilator is designed so that wind rotates it into such a position that the flow of air past the ventilator draws room air through the ventilator and also so that rain or snow cannot enter. Motor-driven roof ventilators also are made to give air movement regardless of available wind and temperature differences.

In winter the exhausting of air from a building at any point necessarily results in cold outside air entering elsewhere, and this cold air can produce disagreeable drafts. Consequently make-up air-heating units are frequently employed to heat the outside air introduced so as to balance the warm air being exhausted. (See also FAN [MECHANICAL].)

Attic Ventilation.— A fan located in the attic may be so arranged in a house with open stairways that during the summer the fan operates at night when temperatures drop and, with open windows in the house, drams warm air from the house through the fan and discharges it to the outside, cool night air being drawn in through the open windows.

Fans which exhaust directly to the outside from the attic space should be located so that they discharge with and not against the prevailing wind. Those which exhaust into the attic from the space below should be located over a central hall. The discharge from the fan should be as far as possible from adjacent walls and chimneys. A minimum distance of six to eight feet should be maintained, if possible.

Air Sanitation.—Although ventilation was formerly concerned with the supply of fresh air (a misnomer for outside air) to and the removal of hot and contaminated air from the space, it gradually came to embrace — or at least to be associated with — what can be termed air sanitation, the cleaning of air, whether the contaminating substance be dust, toxic fumes, odours or bacteria.

Air pollution in large cities is caused by the dumping into the atmosphere of exhaust gases from gasoline and diesel engines and coal, oil and gas-fired boilers, and dusts and fumes from a wide variety of industrial operations. Of these the most attention formerly was paid to coal boiler operations, and the problem was generally believed to be a smoke problem. Perhaps the turning point in this viewpoint was the Donora, Pa., disaster in 1948, when smog, a combination of factors — fumes from an industrial plant, a natural fog, and a valley location isolated from breezes at the time — caused 20 deaths. This disaster coincided with a rapid decrease in the number of coal-fired steam locomotives, which were replaced by diesel engines, but which formerly were among the important smoke producers. As a result, there was an increasing tendency to look on air pollution as a problem comprising more factors than control of smoke-producing apparatus alone would eliminate. (See also SMOKE AND SMOKE PREVENTION.)

Dust can be removed from the air by four basic methods: (1) filters, mechanical devices of porous mediums through which dust-laden air is passed and in which the dust trapped by impinging upon or enmeshing in the filter medium, a common type being coated with a viscous substance to which the dust clings; (2) electrical precipitation, by which the dust particles are attracted and held by oppositely charged wires; (3) the wet method, or washing of the air by water sprays; and (4) dynamic precipitation, by which the dust is thrown off by centrifugal force in a mechanical device such as the so-called cyclone.

In general, air filters are used where the dust concentration is relatively low and does not exceed 4 gr. per 1,000 cubic feet of air. The dusts these filters remove can be termed temporary atmospheric impurities, including house dust and pollens. which are specific nuisances to persons allergic to them. The filtering medium varies, and glass fibre, wire screen, steel wool, animal hair and hemp fibres have all been employed.

Electric precipitators are of two types — one of the ionizing type in which dust particles are given a charge in passing through an ionizing zone, and the second variety having charged collectors by means of which the energized, collecting medium induces a charge on the particles. These machines are highly efficient in removing dusts so fine that they have no gravitational settling tendency. Precipitators are especially useful for removing smoke from the air.

There are a number of different types of wet collectors wherein the contaminant is brought into contact with water in order to remove the dust from the air stream. This type of dust collector is particularly adapted to high-temperature, moisture-laden gases. Generally, however, its use is in the industrial field rather than in

the field of comfort ventilation.

Dynamic precipitators are also of several types, of which the cyclone is widely employed for the removal of coarse dust from an air stream or as a separator to remove dust from industrial operations.

Indications are that in the future ultrasonic agglomerators may have wide application. High-intensity sound can be used to coagulate very fine aerosols such as smoke, fumes or fine dusts into particles large enough to be collected by one of the types of dust-collection equipment previously described. *(See* ULTRASONICS.)

About the only practical method for removing odours from air is adsorption of the odour by activated carbon. which is effective against cooking, body and tobacco odours. Some of the bacteria in contaminated air are removed by filters and electric precipitators; however, a better method is by ultraviolet irradiation. Propylene glycol mists also have been found effective against certain types of bacteria. However, the killing of bacteria and the removal of chemical fumes are both matters needing far more research. The impetus for this is expected to come from the demand by urban centres for lessening atmospheric contamination.

HEATON, SIR JOHN HENNIKER, 1ST BART. (1848–1914), English postal reformer. was born at Rochester, Kent. on May 18, 1848, the only son of Lieut. Col. John Heaton. of Heaton, Lancashire. After studying at Kent House school and King's college, London, Heaton went to Australia in 1864 and spent several years in the bush. He then moved to Paramatta, New South Wales, where he joined the staff of the *Paramatta Mercury* and served a three-month appointment as town clerk. In the following years he worked on the *Goulburn Penny Post* and the *Australian and County Journal* (Sydney). In 1879 he published a reference work, *The Australian Dictionary of Dates and Men* of *the Time,* and in 1883 represented New South Wales at the Amsterdam exhibition. His first attempt at postal reform came in 1885 at the Berlin International Telegraphic conference nhen he succeeded in obtaining a rate reduction for cable messages to Australia.

Returning to England in 1884, Heaton was elected to parliament as a member for Canterbury the following year. In this post, which he held for the next 26 years. Heaton worked persistently for postal reform and particularly for the reduction of postal and telegraphic rates. Through his exertions, the telegraphic rates from England to various parts of the world were greatly reduced and in 1898 it became possible to send mail to any part of the British empire, except Australia, for a penny. In 1908, the penny post was extended to those letters destined for America, and between the years 1905 and 1911, Australia was gradually admitted to low-cost mail rates. After the election of 1892, Heaton was offered a baronetcy if he would give up his parliamentary seat to another member who had been defeated. Heaton refused. Three other times he rejected offers to make him a knight commander of St. Michael and St. George.

As the dissolution of parliament in 1910, Heaton retired because of ill-health. The following year, while he was visiting Australia, a baronetcy was conferred upon him and, upon his return to London, a public welcome was held under the auspices of the British Empire league. In Sept. 1914, while returning from Carlsbad, Bohemia, where he had gone for his health. Heaton was taken ill and died at Geneva. Switz., on Sept. 8. 1914.

HEATSTROKE: *see* SUNSTROKE AND HEATSTROKE.

HEAT-TREATMENT. The heat-treatment of metals and alloys is carried out to alter their mechanical properties. For industrial applications *see* ANNEALING. The following discussion of heat treatment is divided into three categories: (1) recovery and recrystallization, which are accomplished by heating a metal that has been plastically deformed at room temperature; (2) precipitation. or age hardening, which is characteristic of the alloys that have a decreasing solubility of one constituent in another with decreasing temperature; and (3) alloys which undergo a phase change in the solid state on heating or cooling through certain temperature ranges.

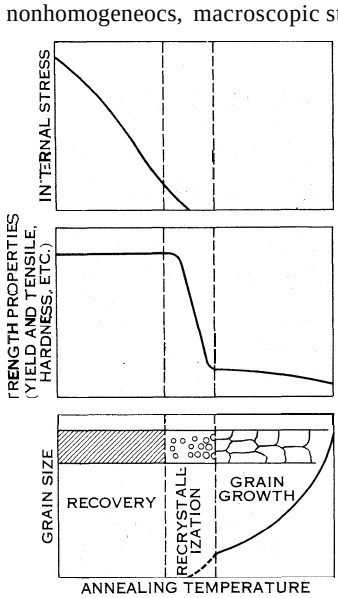
RECOVERY AND RECRYSTALLIZATION

The atoms of a metal crystal that is not strained or deformed are arranged in an orderly pattern. Two of the commoner atomic arrangements are those of the body-centred cube and the face-centred cube *(see* ALLOYS: *Structure of Alloys).* A crystal composed of the body-centred cubic arrangement would simply be a repetition of this arrangement to form the lattice structure of the crystals.

Metals and alloys used for engineering applications are not single crystals but are made up of many crystals. These crystals are called grains in the metal. When a metal is plastically deformed or cold-worked at a low enough temperature; *i.e.,* room temperature for most metals, the metal is strain-hardened. The strain hardening results from the fact that slip is occurring on the crystallographic planes of the grains and the orderly arrangement of atoms is replaced by a distorted lattice *(see* CRYSTALS, DISLOCATION OF).

The normal equiaxed grains of the unstrained material are replaced by elongated grains resulting from the plastic deformation. The plastic deformation is accompanied by an increase in the tensile strength, yield strength and hardness, and a decrease in ductility as measured by elongation and reduction of area in the tensile test. Obviously the cold working could be carried out to the point where fracture would occur.

Since the cold work as performed in commercial processes is nonhomogeneocs, macroscopic stresses are set up in the metal. A cold-drawn wire will have residual compressive stresses at the [illegible] and tensile stresses at the surface of the wire. In addition, there are microscopic stresses set up because of the slip that occurs on the atom planes during the cold working of the metal or material. These residual stresses may or may not influence the quality of the part.



FROM SACHS AND VAN HORN, "PRACTICAL METALLURGY"; REPRODUCED BY PERMISSION OF AMERICAN SOCIETY FOR METALS

FIG. 1.— DIAGRAMMATIC REPRESENTATION OF THE DIFFERENT TYPES OF CHANGES IN PROPERTIES PRODUCED BY ANNEALING A COLD WORKED METAL

If the residual stresses are in tension at the surface of the part, they are detrimental as far as fatigue and stress corrosion are concerned. If the residual stresses are in compression at the surface, they are beneficial as far as fatigue is concerned.

The heat treatment of a cold-worked part simply involves heating of the metal to some elevated temperature to allow diffusion; *i.e.,* atom movement. to take place. This tends to allow the atoms to again assume an orderly pattern. Two distinct processes occur on heating a cold-worked metal. The first! which is termed recovery, occurs at low temperatures and results primarily in relieving the residual stress without any appreciable change in hardness or microstructure. The elongated grains of the cold-worked metal are unaffected during the recovery period. Process equip-

ment, such as welded pressure vessels, is frequently subjected to a low-temperature anneal after welding in order to remove the residual stresses produced during the welding operation.

The second process is termed recrystallization and grain growth. When the temperature is increased to a sufficient degree, very small unstrained grains begin to replace the strained grains of the cold-worked metal; in other words, the metal is undergoing recrystallization. Grain growth is merely an enlargement of the recrystallized grains.

Recovery and recrystallization and growth are time dependent Increasing the temperature increases the rate at which both occur. and if the temperature is high enough both processes will proceed simultaneously. The temperature of recrystallization varies a great deal from metal to metal, and is also dependent on the amount of cold work applied to the metal, the grain size of the metal, composition of the alloy and purity of the metal.

Recrystallization and grain growth are accompanied by a lowering of the strength of the cold-worked metal. This is shown schematically in fig. 1. It can be seen from this diagram that the residual stress is relieved to a great extent before any change in strength or microstructure occurs. Recrystallization occurs over a narrow temperature range for a constant time of annealing, and grain growth occurs on heating to higher temperatures.

Many commercial products are fabricated by cold-stamping or -drawing operations. In many instances it is necessary to subject the partially formed parts to annealing treatments so that recrystallization occurs which restores the ductility to the material and conditions it so that further cold-working operations may be carried out.

The manufacture of cartridge cases illustrates an operation of this type. Most of the cartridge cases are made of an alloy composed of 70% copper and 30% zinc. This alloy is a solid solution where the zinc atoms substitute for the copper atoms in the face-centred cubic lattice of the copper crystal. The manufacture of a cartridge case begins with a flat plate which is blanked into a circular disk and cold formed into a cup. The effect of the cold work resulting from cupping must be removed by annealing before any further cold forming can be carried out. In the production of the cartridge case it may be necessary to perform as many as seven annealing treatments depending upon the size of the cartridge case.

PRECIPITATION OR AGE HARDENING

Many of the useful alloys are heat-treated by precipitation or age hardening. The alloys which respond to this heat-treating process are in the alloy systems which have a decreasing solubility of one constituent in another constituent with decreasing temperature. This is illustrated schematically in fig. 2, which shows a phase diagram of alloys of metals A and B. The solubility of B in A is represented by the line xy. An alloy composition represented by the dotted line is composed entirely of a solid solution when heated to and maintained at temperature T_3. The solid solution δ consists of atoms of B dissolved in metal A. (At the opposite side of the diagram, solid solution β consists of atoms of A dissolved in metal B. the θ phase is discussed below.) Two types of solid solutions are possible, namely, substitutional and interstitial. The substitutional solid solution is formed by atoms of B substituting for atoms of A in the crystal lattice of the metal A. An interstitial solid solution is formed when atoms of B fit in between the atoms in the lattice of metal A. Practically all of the solid solutions useful for the age-hardening process are of the substitutional type.

FIG. 3.— EFFECTOF AGING TEMPERATURE UPON THE PRECIPITATION HARDENING OF AN ALLOY CONTAINING 95% ALUMINUM. 5% COPPER. WHICH WAS SOLUTION HEAT-TREATED AT 1,000° F. AND WATER QUENCHED

When the solid solution formed by heating to temperature T_3 is slowly cooled to room temperature T_1, a precipitate will form at the grain boundaries because the solubility of B in A is less at T_1 than at T_3. The line xy represents the saturation limit for the solubility of B in A at any given temperature. and on slow cooling precipitation begins as soon as the dotted line intersects the line xy. and continues as the temperature decreases to T_1. The precipitate formed is not the metal B, but is the next phase on the diagram, which is θ. This diagram shows θ as an intermetallic compound and these compounds are frequently assigned chemical composition formulas; *e.g.*, $CuAl_2$, Fe_3C, etc. In many instances the slowly cooled condition described above produces inferior mechanical and corrosion resisting properties.

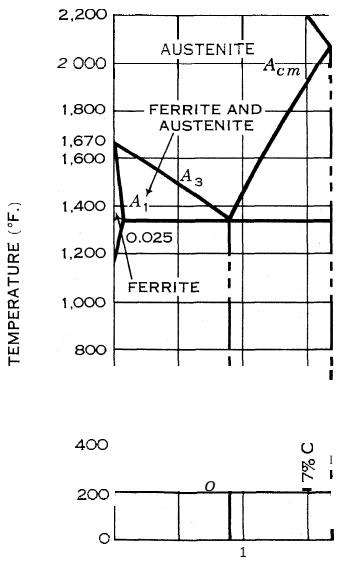
When the solid solution produced by heating to temperature T_3 is quickly cooled by quenching into water, the precipitation of the θ phase is prevented and the condition existing at temperature T_1 is a highly supersaturated solution of B in A. Reheating the quenched alloy to the temperature T_2 and holding for a period of time allows θ to precipitate from the supersaturated solid solution. However, the θ phase does not precipitate out at the grain boundaries as was the case in the slowly cooled condition, but precipitates out as minute particles in the crystal lattice on planes of cleavage of the solid solution. These particles are too small to be seen under the optical microscope, but their presence is detected by the changes in the mechanical and physical properties of the alloy which accompany the aging process. Not all of the useful industrial alloys require that the quenched alloy be reheated to a temperature of T_2 for the submicroscopic particles to form, since age hardening does occur on holding at room temperature in some of the alloys.

Subcooling—as by packing in dry ice—those alloys which age-harden at room temperature will prevent the age-hardening process from taking place. The precipitation of the submicroscopic particles in the lattice of the solid solution increases the hardness, tensile strength and yield strength and decreases the ductility of the alloy.

Many of the industrially important alloys are hardened by this heat-treating process. Among the more important of these age-

hardenable alloys are the aluminum and copper base alloys. The aluminum base copper alloy is selected to illustrate the general age-hardening process.

Copper is soluble in aluminum to the extent of 5.5% at 1,018° F. and to less than 1% at room temperature. An alloy of 5.0% copper when heated to 1,000° F. and auenched into water is a supersaturated solution of copper in aluminum. It will not age-harden to any great extent on holding at room temperature. However, on heating to various temperatures above room temperature, the age-hardening process will take place. Since this age-hardening process depends upon atom movements: *i.e.*, diffusion. and since the rate of diffusion is increased with increasing temperature, the increase in strength will be accomplished in shorter periods of time at higher temperatures than at lower temperatures. However, the precipitation and growth of the precipitated phases are not uniform and since an optimum particle size of the precipitated phase is necessary to produce the maximum increase in the hardness and strength of the alloy, the lower temperatures of aging are the ones that produce these conditions, although the time of aging is necessarily longer.



BY COURTESY OF C. A. SIEBERT

FIG. 4.—A PORTION OF THE IRON-CARBON EQUILIBRIUM DIAGRAM

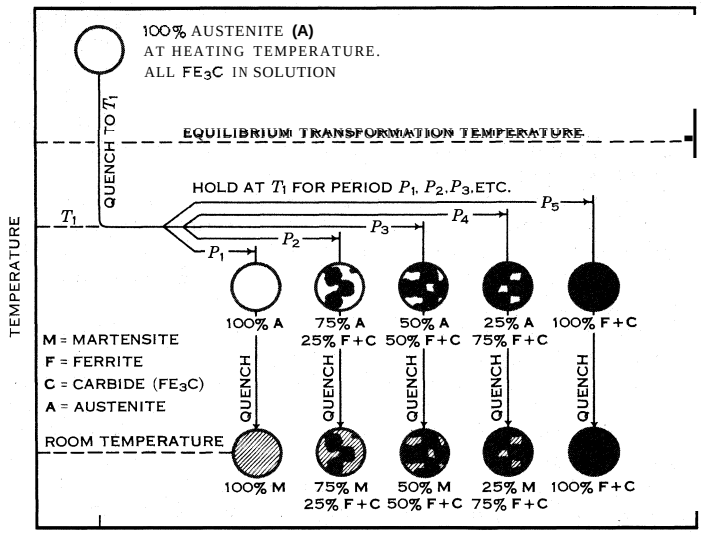
The lower temperatures of aging produce a greater number of nuclei, *i.e.*, centres for precipitated particles to form on and a greater number of small particles are formed than is the case at the higher temperatures. The increase in strength results from interference that these particles offer to plastic deformation. Therefore, the greater the number of these particles of an optimum size the greater the strength of the material. However, since diffusion continues at these higher temperatures with time, the particles of the precipitated phase continue to grow and therefore there are fewer particles of a larger size to offer resistance to plastic deformation.

The material decreases in strength and is considered overaged. This is illustrated for a 5% copper, 95% aluminum alloy in fig. 3. The increase in hardness above the as-quenched condition, which is an indication of the increase in strength, at room temperature after 30 days is approximately 8 Rockwell F. The increase in hardness after aging at 300° F. for approximately two days is 32 Rockwell F. On holding at 300° F. longer periods than two days, the alloy became softer, or overaged. The aging temperatures of 400°, 500°, and 600° F. show lower maximum hardness peaks and shorter times of overaging setting in with increasing temperatures. The actual time-temperature sequence which is used for a given alloy in an industrial application naturally depends upon economics. The strength level needed and the length of aging time required to produce it, and therefore the cost, become primary considerations.

HARDENING PHASE CHANGES

A number of alloys undergo hardening and therefore an increase in strength because of a phase change from one type of lattice structure to another occurs in the alloy with a change in temperature. When the equilibrium condition is disturbed by rapid cooling a whole new series of microstructures is produced, resulting in a whole new series of mechanical properties in these alloys. The most important alloys of this classification are the steels and their alloy modifications, and the heat-treatment of steel will be discussed to illustrate this process.

The metal iron has the atoms arranged in a body-centred cubic lattice from room temperature to 1,670° F., and in a face-centred

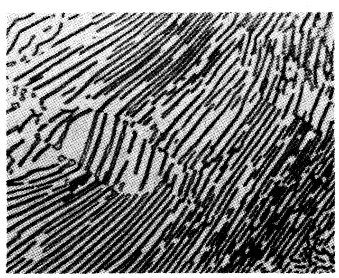


FROM W. CRAFTS AND J. LAMONT, "HARDENABILITY AND STEEL SELECTION"; REPRODUCED BY PERMISSION OF PITMAN PUBLISHING CORPORATION

FIG. 5.— HEAT-TREATING CYCLES EMPLOYED IN STUDIES OF ISOTHERMAL TRANSFORMATION

cubic lattice from 1,670° F. to 2,535° F. Carbon dissolves rather readily in the face-centred cubic lattice but only to a very slight extent in the body-centred cubic lattice. It is this difference in solubility of carbon in the two phases of iron which accounts for the fact that steel can be heat treated.

It is necessary to consider the equilibrium conditions of the iron-carbon system in order to appreciate the nonequilibrium conditions which exist in hardened steel. Fig. 4 shows a portion of the iron-carbon equilibrium diagram. There is a eutectoid (pearlite) at 0.83% carbon which forms from the solid solution of carbon in face-centred cubic iron (austenite) at a temperature of 1,333° F. Pearlite is a mechanical mixture of ferrite (solid solution of carbon in body-centred iron) and cementite (Fe_3C).



FROM W. CRAFTS AND J. LAMONT, "HARDENABILITY AND STEEL SELECTION", REPRODUCED BY PERMISSION OF PITMAN PUBLISHING CORPORATION

FIG. 6.— COARSE PEARLITE FORMED AT 1,300° F. (MAGNIFIED 2,000 ×.)

An 0.5% carbon steel, heated to 1,600° F. has a microstructure of 100% austenite at that temperature. On very slow cooling the austenite would begin to reject ferrite when the temperature reached the A_3 line on the diagram (fig. 4) and would continue to do so until the temperature reached the A_1 line on the diagram. While the temperature was changing from the A_3 to the A_1 level and ferrite was being rejected, the carbon content of the austenite was increasing from 0.5% to 0.83%, the latter being the eutectoid composition. The A_3 line in fig. 4 represents the saturation limit of carbon in austenite. Therefore in steels having a carbon content greater than 0.83%, cementite would precipitate on cooling, and the carbon content of the austenite mould again approach 0.83% as the temperature approached 1,333° F.

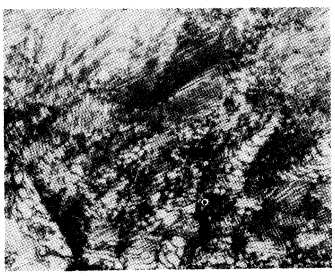
The above illustrates the decomposition of austenite on slow cooling approaching equilibrium conditions. The nonequilibrium condition associated with the hardening of steel can best be illustrated by considering the isothermal decomposition of austenite at temperatures below 1,333° F.

Suppose a number of thin wafers of 0.83% carbon steel were heated to a high temperature where the microstructure was 100% austenite, and then quenched into a molten lead bath maintained at some temperature T_1 which is below 1,333° F. Individual specimens could then be removed from the lead bath after varying time intervals, and quenched into water. The process is illustrated in fig. 5. The time period P_1 was not long enough for the austenite

to begin to decompose into pearlite, so on subsequent quenching to room temperature it showed a structure of 100% martensite (the nature of martensite is discussed below). Time period P_2 was long enough for some austenite to transform to pearlite, and time periods P_3 and P_4 show an increasing amount of pearlite, while time period P_5 is long enough for all of the austenite to transform to pearlite.

It can be seen that the above process depends upon nucleation and diffusion, with the nuclei of pearlite (ferrite and cementite) forming at the austenite grain boundaries. As the temperature T_1 is lowered the pearlite becomes increasingly finer in texture, as shown in figs. 6 and 7.

Repeating the above experiment at various temperature levels would result in the accumulation of data for the beginning and ending of austenite decomposition at the various temperature levels. The data could then be plotted as a conventional time-temperature-transformation (T-T-T) diagram. The T-T-T diagram shown in fig. 8 is a schematic diagram for carbon steels and includes the proeutectoid line for ferrite and carbide, which applies to steels of less than or greater than 0.83% carbon respectively.



FROM W. CRAFTS AND J. LAMONT, "HARDENABILITY AND STEEL SELECTION"; REPRODUCED BY PERMISSION OF PITMAN PUBLISHING CORPORATION

FIG. 7.—FINE PEARLITE FORMED AT 1,185° F. (MAGNIFIED 2,000 ×.)

It should be noted that the proeutectoid line joins the beginning of pearlite transformation line at approximately 1,000° F. This means that only pearlite would be present when fully transformed at this temperature, regardless of the carbon content of the steel, and the carbon content of the pearlite in any steel other than 0.83% carbon can only have that value when transformed at 1,333° F.

The transformation of austenite by isothermal decomposition below the knee of the diagram (1,000° F.) results in the formation of a microstructure distinctly different from pearlite formed above 1,000° F., and this structure, called bainite, is shown in fig. 9. The degree of fineness of the bainite structure increases as the temperature of formation is lowered from 1,000° F. It is generally thought that pearlite is nucleated by cementite and bainite by ferrite.

As the temperature of the quenching bath is lowered, a temperature level is reached where austenite will undergo some transformation instantaneously on reaching that temperature. A period of inactivity when held at that temperature is followed by further decomposition to bainite for longer holding times. The microstructure formed immediately on reaching this temperature is martensite. Martensite will continue to form instantaneously as the temperature is lowered but will not form isothermally. The temperature at which the first martensite is formed is termed the M, temperature and the temperature for 100% martensite formation is called the M_f temperature. The M_s temperature depends upon the composition of the steel and can be estimated from the following formula:

$$M_s(^\circ \text{F.}) = 1{,}000 - (650 \times \%\ \text{C}) - (70 \times \%\ Mn) - (35 \times \%\ \text{Ni}) - (70 \times \%\ \text{Cr}) - (50 \times \%\ Mo)$$

The M_f temperature cannot be calculated from the composition of the steel.

The transformation of austenite to martensite does not depend upon nucleation and diffusion, as is the case for pearlite and bainite formation, but solely on reaching a temperature level where the face-centred cubic lattice tends to transform to a more stable type of lattice. The lattice formed is a tetragonal body-centred type with the carbon atoms trapped as an atomic dispersion in the interstices of this lattice.

The primary purpose of quenching a steel is to produce martensite. Therefore it is necessary to employ cooling rates fast enough to prevent the steel from dwelling in the higher temperature ranges where ferrite, pearlite and bainite will form. Alloying elements shift the T-T-T diagrams to the right; *i.e.,* to longer times for the beginning of transformation, which permits slower rates of cooling for the formation of 100% martensite.

FIG. 9.—BAINITE FORMED AT ABOUT 700° F. (MAGNIFIED *2.000* ×.)

HEAVEN, the firmament or vaulting arch of spatial expanse surrounding the earth in which the sun, moon, planets and stars seem to be placed. In most of the religions of mankind heaven is considered to be the abode of deity, for as deity is "higher" than humanity, so the home of deity is high "above" the earth which is the home of man. Likewise, as the presence of deity exposes all evil and deceit, so heaven, being the eternal abode of deity, is the place of eternal light in contrast to the partial and total darkness of other regions in the cosmos. Consequently, heaven is thought to be forbidden territory for human beings except as they meet the terms set down by deity or are granted special admission by deity. Such humans are then said to have been "born from above" or to have been called "out of darkness into marvelous light."

Old Testament and Judaism. — In the Old Testament understanding of the structure of the universe, the heavens, *shamayim,* referred chiefly to the upper half of the universe in contradistinction to the other half, the earth. The phrase in Gen. i, 1, "the

heavens and the earth," literally comprehended the whole of creation. The earliest traditions of the Israelites associated Yahweh with the sky, but while Yahweh's abode was the heavenly regions, not even the heavens' heavens could contain him. It was he aho created the firmament and placed the heavenly bodies in it; from the heavens he looks down upon the inhabitants of earth and directs the destinies of men and nations, and therefore men pray toward the heavens.

It was not. until late Old Testament times that the Israelites began to regard heaven as being also the final abode of the righteous. Throughout most of the Old Testament period (c. 1750 B.C. to c. 587 B.c.) the Israelites thought of Sheol as the great democracy of all the dead. Sheol was located somewhere "under" the earth. When "the breath of life" had gone out of a man and returned to Yahweh from whom it originally came. and when his buried body had decomposed, the residue of his individuality slept in Sheol. The state of the dead was one of neither pain nor pleasure. Neither reward for the righteous nor punishment for the wicked was associated with Sheol. The good and the bad alike, tyrants and saints. kings and orphans, Israelites and gentiles—all slept together without awareness of one another in the lifeless existence of Sheol. The devout Israelite dreaded death and Sheol because these marked the end of his fellowship with Yahweh and not because they would confront him with a final judgment upon the quality of his life.

It was not until the 3rd or 2nd centuries before Christ that Jews in any number came to think of heaven as the destination of the righteous after death. As the hope increased and was formulated for the resurrection of the righteous and unrighteous to another bodily life of reward or punishment befitting the mortal life already lived. Jewish thought fixed on life with God in the heavens as the destiny of the righteous and external torture or second death as the destiny of the unrighteous. Jewish rabbinical and apocryphal literature occasionally refer to seven or ten heavens, with paradise being the third of seven or the seventh of ten. This paradise was thought to house all the treasures intended for the righteous, and some rabbis taught that the righteous dead themselves lodged there until the Last Judgment when God would resurrect them and translate them into his presence in the highest heaven. With reference to the unrighteous, consideration of natural death, during this period, was lost sight of in the greater consideration given to the final judgment of the human spirits subsequent to physical death. The horrors of this spiritual death are suggested in Jesus' figures of "outer darkness" and "weeping and gnashing of teeth" used to describe the lot of the unrighteous.

New Testament and **Christianity.**—In the New Testament heaven derives its significance and engages the attention of the writers from the fact that it is believed to be the place from which Christ came and to which he returned (Mark xvi, 19; Acts i, 11). Heaven is therefore the scene of his present life and activity. There, in the presence of God, he works in behalf of his followers (Heb. ix, 24) and there his glory is already apparent (John xvi, 24), whereas on earth his followers only dimly apprehend that glory (I John iii, 2 j. Heaven, however. is the destination of all his followers (John xiv, 2). In heaven the Holy Spirit, in company of the angels, searches out "the depths of God" and is sent to earth to reveal these mysteries to men (I Cor. ii, 10; I Pet. i, 12). In the New Testament there is also a current of thought that speaks of a renewal of the heavens as well as of the earth in the consummation God will bring about for his creation (II Pet. iii, 12–13; Rev. xxi, 1).

The New Testament uses the word paradise (Luke xxiii, 43; II Cor. xii, 3; Rev. ii, 7). This was originally a Persian word for a nobleman's park or garden. but coming as it does to the New Testament through Jewish and especially rabbinic usage, its use there reflects the influence of the Old Testament story of man's pristine innocence and community with God in the Garden of Eden.

(E. PE.)

The Christian idea of heaven never achieved great explicitness. As the early church resolved the meaning of its existence as a historical body with the realization that Christ's return to consummate the messianic promise would be delayed, sacramental acts, particularly the eucharistic mysteries, came to symbolize the union of the church with Christ in heaven. In the Eucharist and the other sacraments Christians already felt themselves to be partaking in the life above.

Nevertheless, in the Christian community in the post-apostolic period there may be found cosmological speculation, seeking to penetrate the unknown upper world. at the same time resisting the temptation to go as far as the Gnostics with their imaginative but unbiblical cosmologies. In the east Origen (for example in *Contra Celsum,* vi. *21* and *De Principiis,* ii, iii. 6). St. Basil (*Homiliae* I, 5; *Patrologia Graeca* XXIX. 13.) and other writers made comments about the number of "heavens"; on the belief that Christians, following the pattern of Christ, ascend to heaven; and about the relation of heaven to the observable upper world—stars, planets. etc. St. Augustine in the west attempted to avoid the pitfalls of the cosmological approach in conceiving of the heavenly city. the New Jerusalem. In the Old Testament this was prefigured in the vision of Ezek. xl ff. In the high middle ages the old science and the rediscovered tools of ancient'logic were united to devise. together with Christian revelation, St. Thomas Xquinas' monolithic edifice of ideas about the hierarchy of being. The poetic realization of Dante's ***Divine*** *Comedy* is a similar medieval expression. Piled layer upon layer, the reality of the material world. for them, blended into the splendours of the celestial realm and into the terrors of the inferno.

'Since the scientific revolution. cosmological theories about heaven have tended to be discredited as science has pushed the limits of space to an incomprehensible distance. In their place personalistic understandings of heaven. such as prevail in literature or common parlance? have often obscured the meaning of heaven in a religious sense. In the modern idiom heaven has come to signify various types of personal fulfillment. However, for Christians. emphasis upon the Bible and church tradition continues to help maintain the symbolic meaning of heaven as the counterpart of the liturgical and historical experience of the revelation of Christ. In essence the Christian view of heaven means the state of life with Christ. Since this ideal is believed to be reflected in the .church, it has been difficult to conceive of its transcendent meaning in other terms. (C. S. J. W.)

Other Religions — Anotion similar to that of the New Testament paradise is found in the Greek mythological Elysium or Elysian field. This latter, the home both of the pods and of those mortals upon whom the gods chose to confer a life of bliss. was thought to be located in the western ocean or in the lower world.

In Chinese religion. specifically the Confucian tradition, heaven. *T'ien,* is synonymous with the Divine Will. Heaven is the head of the cosmic family. of which nature and human society are the other two members. The popular Buddhism of China (Pure Land Buddhism) offered the Chinese a heavenly abode after death as alternative to the notion of the disembodied spirits of the ancestors remaining near the haunts of their mortal days. The literature of Pure Land Buddhism describes in vivid language the "western paradise" which is available to all those who receive the saving grace of Amitabha. the man who became a Buddha through his vow of salvation for every living creature.

Orthodox Buddhism does not regard paradises and heavens as ultimate. precisely because these notions preserve the conditions of distinctive existence. By definition; orthodox Buddhists maintain, any existence is conditioned and not ultimate and is therefore not capable of expressing unconditioned bliss; hence the monks in this tradition must strive for something beyond the life of the heavens. Nevertheless. these Buddhists believe that there are heavens and that men may be born into them. But emancipation from existence. nirvana, is something other than birth into either the sensual heaven where sexual pleasures exist, or the material heavens inhabited by gods liberated from sensual desires, or even the indescribable life of the nonmaterial heavens.

In Hinduism the conceptions of heaven are numerous and varied. Generally speaking, the heavens are conceived as distinct regions in a complex configuration of worlds, sometimes said to be 3 in number, and again 14. The three worlds are the earth, which is the land of mortals; the sky, which is the playground of the lumi-

naries; and the heavens, the residence of divinities and other immortals. The 14 worlds are believed to rise to seven tiers above the earth and descend to seven distinct depths below the earth. Whether 3 or 14. the intent is to represent the innumerable degrees of proximity to and distance from the perfection which is the destiny of every creature.

In the worship of Vishnu, the god of the masses of Hindus, heaven is understood in terms very similar to those of biblical religion. It is a locale or condition in which suffering, fear and death are completely absent and in which the glory of Vishnu is the eternal light.

The extremely explicit descriptions of heaven in Islam run the entire gamut of human aspiration. Suffice it to say that heaven is conceived as the Garden or Mansion of Eternity in which humans enjoy abundant fulfillment of all the physical, mental, moral and spiritual desires of mortal men. *See* also EDEN; MILLENNIUM. HEAVISIDE, OLIVER (1850–1925), English physicist who, independently but shortly after A. E. Kennelly of Harvard, suggested the presence of a conducting layer in the upper atmosphere which prevents electromagnetic waves from spreading out into space. This layer, for many years called the Kennelly-Heaviside layer, became more commonly known as the ionosphere (*q.v.*). Heaviside was born in London on May 13, 1850. He was employed by the Great Northern Telegraph company, Newcastle. Increasing deafness forced him to retire in 1874, when he went to live in Devonshire and devoted himself to theoretical investigations on electricity.

Heaviside had some difficulty in getting his papers accepted for publication, probably because he made use of unusual methods of his own in solving his problems. Consequently, in 1892 he published his collected papers in two volumes under the title of *Electrical Papers.* In these papers he dealt with the theoretical aspect of a number of practical problems, such as quadruplex and multiplex telegraphy, electrostatic and electromagnetic induction between parallel wires, and the high-frequency resistance and inductance of a concentric main.

His work on the theory of the telephone made long-distance telephony practicable. His *Electromagnetic Theory* also dealt with a number of important problems. He worked out the theory of an electric charge moving with uniform velocity and predicted the change in the mass of such a charge when the velocity is large.

He died at Torquay on Feb. 3, 1925.

HEAVY WATER: *see* **DEUTERIUM** AND TRITIUM.

HEBBEL, (CHRISTIAN) FRIEDRICH (1813–1863), German poet and one of the greatest of German dramatists, was born, a Danish subject. March 18, 1813, in Wesselburen, Dithmarschen (Schleswig-Holstein). The son of a builder, he and his brother were brought up in great poverty, which in later life deeply influenced Hebbel's outlook. After his father's death in 1827 he spent seven years as clerk and messenger to a tyrannical parish bailiff. He founded a literary circle, and a local paper published the first of his poems. Others were printed by a Hamburg fashion magazine whose editor, Xmalie Schoppe (1791–1858), a popular journalist and writer of nursery tales, invited him to Hamburg in 1835 to enable him to prepare for the university. In March 1835 he started a diary which was to become a most revealing and valuable literary document. At this time Elise Lensing, a seamstress nine years his senior, provided Hebbel with both spiritual and material support. She sacrificed herself entirely for him in the difficult years that followed.

In 1830. with a small income provided by his patrons. he went to Heidelberg and studied law, but soon finding this uncongenial rnoved on to Munich, where he devoted himself to philosophy, history and literature. No one would publish his poems or stories and in 1839, without money or means of livelihood, he was forced to return to Hamburg on foot. Ill and exhausted, he was nursed by Elise. Although he lived with her and she bore him two children (b. 1840 and 1844), neither of whom lived long, he could not make up his mind to marry her.

His personal conflicts, however, did not affect his creative power. In 1840 the prose play, *Judith* (Eng. trans. 1914), was performed in Berlin and Hamburg. Its theme—a woman struggling for her rights—was to obsess him from this time. In 1841 he finished the broadly conceived poetic drama *Genoveva.* In 1844 *Maria Magdalena* was published, with a critical and philosophical preface. This realistic tragedy of lower middle class prejudice was first performed in 1846. Meanwhile need had driven Hebbel to Copenhagen, where he procured a traveling grant from the king which allowed him to spend one year in Paris and one in Italy.

On his return at the end of 1845 he met in Vienna the well-known actress Christine Enghaus. His marriage to her in 1846 was the turning point in his life which now ran a more tranquil course, though as a result of his privations he was permanently weakened by rheumatic fever. Through Christine's intervention he became reconciled with Elise. His marriage brought him a daughter and the theatrical tours on which he accompanied his wife gave him new stimulus.

After his marriage, besides some slighter plays of social criticism (*Ein Trauerspiel in Sizilien* and *Julia,* 1847) and the fairy tale comedy *Der Rubin* (1849), which was as unconvincing as the earlier *Der Diamant* (1841), Hebbel wrote the verse play *Herodes und Mariamne* (1848; performed 1849). This depicts the conflict between the oriental despot and his wife, who believes in the dignity of man. The prose tragedy *Agnes Bernauer* which he wrote in 1851 (performed 1852; Eng, trans. 1909) contains the central problem of Hebbel's philosophy—the clash between the necessities of the state and the rights of the individual. The poetic drama *Gyges und sein Ring* (1854), which praises the purity of woman and the dauntlessness of man, is probably the poet's most mature work. From 1855 to 1860 he worked on the dramatization of the Nibelung epic. The trilogy (performed in Weimar in 1861) consists of *Der gehornte Siegfried, Siegfrieds Tod* and *Kriemhilds Rache.* In 1855 he published a volume of Novellen and stories and in 1857, following the 1842 and 1848 collections of poems, his collected lyrics appeared. In many of these a fine balance is reached between feeling and reflection; the night poems and some of the more sombre ballads are among the best German lyrics. In 1859 came the narrative poem *Mutter und Kind,* a social and deeply human document.

Newspaper articles, notably those written in 1848 (he was a liberal conservative and a supporter of constitutional monarchy), many essays of literary criticism and an unfinished play on Demetrius complete the picture of Hebbel's achievement. On his 50th birthday he received many honours, including the Schiller prize. He died at Vienna on Dec. 13, 1863.

Hebbel's speculative ideas—the expression of the tensions of his own personality—circle round the relationship between the Ego and the universe. He depicts the tragic lot of the individual who, in the necessary process of world evolution! sets himself against the existing state of affairs in order to make possible further progress toward a humane system of morality.

HEBBURN, an urban district in the Jarrow parliamentary division of County Durham. Eng., 44 mi. below Newcastle upon Tyne. Pop. (1961) 25,042. There are extensive shipbuilding and engineering works.

HEBDEN RQYD, an urhan district in the Sowerby parliamentary division of the West Riding of Yorkshire. Eng.. 8 mi. W.N.W. of Halifax. Pop. (1961) 0.109. The town. surrounded by moorland. is in a well-wooded steep-sided valley. at the confluence of Hebden water and the Calder river. The chief industry is the making of clothing; other manufactures include cotton, blankets and machine tools. There are large poultry farms.

The district, formed in 1937, combines the former urban districts of Hebden Bridge, and Mytholmroyd.

HEBE (Gr. "young maturity," "bloom of youth"), daughter of Zeus and Hera (*Odyssey,* xi, 603). In Homer. this divine princess, in accordance with the simple northern manners of the Achaean nobles, does housework, much as the human princess, Nausicaa. does the family washing. Therefore, she harnesses her mother's horses (*Iliad,* v, 722). bathes her brother Ares (ibid., 905) and pours the wine at table (iv, 2).

It is in her capacity as cupbearer to the gods that she is oftenest mentioned, and is sometimes said to have been superseded by Ganymede (*q.v.*). As goddess of youth. she is generally worshipped along with her mother, of whom indeed she may be regarded as a sort of emanation or specialized form. She is also combined. both in cult and in mythology. with Hercules (*q.v.*), whose bride she became when he was received into heaven (Odyssey, 1, c)

The most important seats of her worship were Phlius and Secyon nhere she was called Ganymeda and Dia (Pausanias, ii, 13. 3: Strabo, viii, 6, 24). (*See* Preller-Robert, i, 489. and the classical dictionaries.)

A Latin deity with whom she is sometimes identified is Iuventas, whom, however. Dionysius Halicarnassensis (iv, 15, 5) calls Neotes, not Hebe. The hellenized cult of Iuventas-Hebe dates from 218 B.C. (Livy, xxi. 62,9).

See Wissowa, *Religion und Kultur der Römer,* **p.** 135, and the classical dictionaries.

HEBER, REGINALD (1783–1826), English bishop, ,who made a distinctive contribution to the development of Anglican hymnody. Born at Malpas, Cheshire. April 21. 1783, he entered Braicnose college. Oxford, in 1800 and won prizes for a Latin poem (1800), an English poem. *Palestine* (1803; publ. 1807, set to music by W. Crotch. 1812) and an essay, *The Sense of Honour* (1805). Elected a fellow of All Souls (1805), he took orders in 1807 and was presented to a family living at Hodnet, Shropshire. A moderate high churchman of scholarly interests, he showed the direction of his sympathies by his concern at his own equivocal position as parish priest and lord of the manor. his provision of more and better services, and his attention to education, as well as by his Bampton lectures on *The Personality and Office* of the *Christian Comforter* (publ. 1816) and his edition of Jeremy Taylor (1822). At Hodnet he planned his collection, *Hymns Adapted to the Weekly Church* Services of *the Christian Year* (1827), writing 57 of them himself. This anticipated the work of John Keble (*q.v.*) in providing hymns suited for use in liturgical worship adapted to the plan of the Christian year.

His own hymns,—*e.g.,* "From Greenland's Icy Mountains," "Brightest and Best of the Sons of the Morning," "God that Madest Earth and Heaven" and "The Son of God goes Forth to War"—show vivid pictorial imagination, free treatment of rhythm and a loftiness of conception which indicate a real, if minor, poetic gift. and ensure their continued populsrity.

In 1823 Heber became bishop of Calcutta. His conscientious care of a vast diocese hastened his sudden death (at Trichinopoly. April 3, 1826), but he had made a deep impression by his gentleness and courtesy.

His introduction of prayers for the rajahs into church services, his insistence that the clergy learn Hindustani and his attempts to improve relations between missionaries and ministers to European congregations set the trend for future developments and his death from overwork led to much-needed administrative reforms.

HEBER, RICHARD (1773–1833). English book collector, the half-brother of Reginald Heber. was born in London on Jan. 5, 1773.

As an undergraduate at Brasenose college, Oxford, he began to collect a purely classical library, but. his taste broadening. he became interested in early English drama and literature and began his outstanding collection of rare books in those departments.

He attended continental hook sales. purchasing sometimes single volumes, sometimes whole libraries. Sir Walter Scott. whose intimate friend he was and who dedicated to him the sixth canto of *Marmion,* classed Heber's library as "superior to all others in the world"; he was described by Lord Campbell as "the fiercest and strongest of all the bibliomaniacs."

He did not confine himself to the purchase of a single copy of a work. "No gentleman," he remarked, "can be without three copies of a hook, one for show, one for use, and one for borrowers."

His library grew to such a size that it overran eight houses, some in England and some on the continent. It was estimated to have cost more than £100.000, and after his death the sale of that part of his collection stored in England realized more than £56,000. He was known to have owned 150.000 volumes and probably many more.

Heber was member of parliament for Oxford university. 1821–26. and was one of the founders of the Athenaeum club, London. He died in London, Oct. 4, 1833.

HÉBERT, JACQUES RENÉ (1757–1794), French political journalist who under the pen name of "le Père Duchesne" made himself the spokesman of the sans-culottes and of popular extremism during the French Revolution, was born in Alençon in Normandy of a good bourgeois family. His youth was rowdy. and he fell into trouhle in 1776. Going to Paris in 1780, he was for many years destitute or existed from hand to mouth (from 1786 to 1788 he was employed in the box office at the Théâtre des Variétés) and so became familiar with the conditions in which the common people lived.

Early in 1790 Hébert, enthusiastic for the Revolution. began his career as a journalist by collaborating on a pamphlet. La Lnnterne *magique, ou Fléau* des *aristocrates.* This was followed by Le Petit *Carême* de *l'abbé Maury,* and, in June. by Vie *privée* de *l'abbé Maury,* lively and ribald satires on the future cardinal (*see* MAURY, JEAN SIFFREIN). Having found his vocation. Hébert next took for himself a name which was already common property among publicists, that of "le Père Duchesne." a comic figure of the popular imagination, sententious. outspoken and coarse in his expressions but at the same time candid and jocular. His paper. Le *Père Duchesne,* first appeared in Nov. 1790. and by June 1792, when he broke with the original printer. Denis Tremblay, to work with J. C. Marquet. it had become an established success; Hébert was able to live in comfort with Françoise Goupil, the unfrocked nun whom he married on Feb. 7. 1792.

After Louis XVI's flight to Varennes (June 1791), Hirbert. who had previously concentrated his vituperation on the aristocracy, began to aim farther, and in the spring of 1792 he launched a virulent campaign against the court and the monarchy. Already an influential member of the club of the Cordeliers (*q.v.*), he represented the Bonne Nouvelle section of Paris in the insurrectionary commune of Aug. 10, 1792, which led to the fall of the monarchy; and he was elected acting procurator general of the Paris commune on Dec. 22.

A member also of the Jacobin club, he made his paper the mouthpiece of the sans-culottes. demanding the death sentence for Louis XVI, the elimination of the Girondins and the establishment of the Revolutionary government. In the last-named cause he did so much that the events of Sept. 4–5, 1793, which brought the Reign of Terror into full vigour and inaugurated the state-controlled economy. have been described as an "Hébertist" movement. The anti-Christian campaign of autumn 1793 was also largely inspired by Hébert. Once the Revolutionary government was in power, however, it found Hébert dangerous. Le *Père Duchesne* represented the opposition of the Cordeliers and had, moreover, too strong an appeal to the people.

In the winter of 1793–94 the popular movement for which Hébert had fought was brought to a halt. The committee of public safety strengthened its hand; and the "Indulgents," led by Danton and Camille Desmoulins, attacked the extremism of the Hébertists. now described as "Exagérés." When a food shortage was stimulating popular discontent, Hébert on 14 Ventôse (March 4, 1794) denounced the *modérantisme* of the Dantonists at the Cordeliers club, which declared itself for insurrection; but the sans-culottes did not respond, and on 24 Ventôse the Hébertists were arrested. Brought to trial on 1 Germinal (March 21). Hébert and his friends were convicted of conspiracy and executed three days later.

See F Rraesch, *Le Père Duchesne d'Hébert* (1938); *L*. Jacob, *Hébert, le Père Duchesne, chef des sans-culottes* (1960). (A So.)

HEBRA, FERDINAND VON (1816–1880), Moravian physician who founded the so-called New Vienna school of dermatology and whose concepts and teachings became the basis for modern dermatology. He was born in Brünn, Moravia, Czech., on Sept. 7, 1816, and received his medical degree from the University of Vienna in 1841. He was a disciple of Karl Rokitansky (1804–1878), the outstanding Austrian pathologist of the 19th century. Hebra applied his training in pathology to the classification of all skin diseases. This classification, published in 1845, gave a clarity to the understanding of the processes of diseases of the skin that compelled universal recognition. Basically this classification is still in use.

Von Hebra was a voluminous contributor to medical literature and his textbook of dermatology, *Lehrbuch der Hautkrankheiten*, published in 1860, is even now one of the most stimulating books in dermatology.

He died in Vienna on Aug. 5, 1880.

HEBREO, LEÓN (LEONE EBREO; JUDAH ABRAVENEL) (*c.* 1460–*c.* 1521), Spanish philosopher, physician, and writer of the *Dialoghi di amore*, the fullest Renaissance exposition of a doctrine of love, which had great influence on Spanish literature and has been rediscovered in the 20th century as an important source for Spinoza's philosophy. The eldest son of Isaac Abrabenel (*q.v.*), he was born in Lisbon, *c.* 1460, and in 1483 fled to Seville with his father, who had been implicated in the duke of Braganza's conspiracy.

In 1492, when the Jews were expelled from Spain. the family went to Naples. where León Hebreo, who had become a doctor, nas appointed personal physician to the viceroy (1505). He became acquainted with the humanist and philosopher Giovanni Pontano. and, later, in Florence, with members of the Platonic academy. He is last heard of in 1521 and probably died soon after then, in Naples.

The *Dialoghi* (publ. Rome, 1535), reveal the synthesizing tendencies of the time in the effort to harmonize Mosaic, Aristotelian and Platonic viewpoints. Being cast in dialogue form, not embedded in a learned commentary. and more profound and far-reaching than other *trattati di amore*, the work appealed as both literature and philosophy. It was translated into Latin, French, Spanish and Hebrew, and every succeeding writer of a *trattato di amore* showed its influence, which was most fecund in the mystical and religious writers of Spain.

HEBREW LANGUAGE. In the Old Testament, Hebrew is called *sĕphath Kĕna'an* "the lip of Canaan," or *Yĕhûdhîth*, "Jewish"; the later Jews designated it *lĕshôn haqqôdhesh*, "the sacred tongue"; the term *'ibhrith*, "Hebrew," was coined by the Rabbis of Palestine. The English name comes from the Greek ἑβραῖος, "Hebrew," whose adverb ἑβραϊστί, "in Hebrew," is applied to Biblical Hebrew in the Prologue to Ecclesiasticus (c. 130 B.C); this adjective is derived from the Aramaic *'ibhray*, "Hebrew."

Hebrew is a Semitic language *(see* SEMITIC LANGUAGES), and monuments in it range from the 9th or 10th centuries B.C. to the present day. It was a mixed speech, to whose composition elements from several Semitic languages contributed; further, a few primitive words may have come from a non-Semitic people who, archaeology shows, once inhabited Palestine. Egyptian and Babylonian documents prove that a West-Semitic (Canaanite) language resembling Hebrew was current in Canaan before the coming of the Hebrews. Egyptian documents from the 16th century B.C. onwards reveal over 1,200 Semitic words, some common to various Semitic languages, others peculiar to the Syro-Canaanite branch; *e.g.*, Eg.-Can. *'nb* (Hebr. *'ĕnābh*), "grape," occurred in Aramaic and Arabic, but Eg.-Can. *brt* (=Hebr. *bĕrîth*), "covenant," was confined to Hebrew. The feminine nouns preserved the primitive ending *-t*, which had already become *-h* in the Old Testament; *e.g.*, Eg.-Can. *spt* (=Hebr. *'ashpāh*), "quiver." In the earlier words the plural and dual took *-n*, as in Aramaic, but later *-m*, as in classical Hebrew; thus the Eg.-Can. *krmyn* (c. 1200 *B.C.)* gave place to *krmym*, which was closer to the Hebrew *kĕrāmîm*, "vineyards" (*c.* 1100 B.C.). The form in *-n* survived in the North-Palestinian dialect of Hebrew, as *ṣîdōnîn* for *ṣîdōnîm*, "Sidonians"; similarly the Eg.-Can. *sh-* corresponded with the dialectical Hebr. *she-* (for the correct *'ăsher*), "who," "which." These texts exhibit many names of places afterwards famous, as well as those of deities like *'shtrt* (=Hebr. *'ashtōreth*), "Astarte," and of persons like *'brm* (=Hebr. *'abrām*), "Abram," especially in composition. Many terms describing common objects, either in composition or independently, appear early in the texts; *e.g.*, Eg.-Can. *rsh* (=Hebr. *rō'sh*), "head," and Eg.-Can. *kmh* (=Hebr. *qemah*), "flour." Others, having changed their meanings or not having survived in Hebrew literature, emphasize the fact that much has disappeared from the Hebrew vocabulary. The cuneiform correspondence found in Egypt, chiefly between the Egyptian kings and their vassals in Syria and Palestine (c. 1400 B C.), also exhibits a language similar to, but older than, biblical Hebrew. These letters were written in a Babylonian exhibiting Western peculiarities closely approximate to Hebrew idiom: the Babylonian permansive tense, expressing properly a state, served also to describe a past action, like the Hebrew perfect with whose form it was identical; the Babylonian preterite, like the Hebrew imperfect with which its form agreed, served to express incomplete action in present time; the first person singular of the permansive (perfect) was closer to Hebrew than to Babylonian; *e.g.*, Bab.-Can. *naṣrâti* (=Hebr. *nāṣartî*, not Bab. *naṣrâku*) "I have kept"; a passive is formed by the internal modification of the vowels; *e.g.*, Bab.-Can. *yudan* (=Hebr. *yuttan)*, "is given." This passive type, though unknown in Babylonian, is found sporadically in Hebrew and regularly in Arabic. But the principal evidence lies in the Canaanite glosses which, more than 100 in number, were added to explain Babylonian terms; for they closely resemble pure Hebrew. Thus the Bab. *ina qātishu* is explained by the Can. *badiu* (=Hebr. *bĕyādhô*), "in his hand," Bab. *elippu*, by Can. *anaya* (=Hebr. *'ŏnîyāh*), "ship," and so on. Again, the language of these glosses is earlier than Hebrew; *e g.*, Bab.-Can. *yakwun*, "is," in which the half-vowel *w* is retained, is older than a form like the Hebr. *yāqûm*, "he arises," in which it has been assimilated to the *u* (cf. Pun. *ichon*, "he is"); it preserved also the old feminine *-t*, as in *abadat* (cf. Hebr. *'ābhĕdhāh*), "is ruined," which rarely appeared in Biblical Hebrew. These texts prove the pronominal suffix *-mô*, which is a Iate poetical variety of the usual *-m*, "their," to be a genuine archaism; for example, Bab.-Can. *panimu* corresponds with the archaistic Hebr. *pānêmô*, not the classical Hebr. *pĕnêhem*, "their face." Most place-names, many of them afterwards found in the Old Testament, and some personal names exhibit purely Canaanite forms; and divine names like the Bab.-Can. *ba'alu* or *dagan*, contained in various proper names, are identical with the Hebr. *ba'al*, "Baal," and *daghdn*, "Dagon." Clearly, Canaanite, as reflected in these ancient Egyptian and Babylonian texts, though not merely a form of Hebrew, certainly

contributed much to it.

The central group (Aramaic) made some contribution to Hebrew. This is illustrated by certain differences in the vowels: where old Aramaic prefers a, Canaanite and Phoenician prefer *u* (o), while the alternations in Hebrew betray its composite origin; for example, *rō'sh,* "head," goes back to the Can. and Phoen. rush, but *rā'shîm,* "heads," to the Aram. *rā'sh.* Again, in certain weak verbs Hebrew prefers the Aramaic a in the active but the Canaanite *u* (*o*) in the reflexive (passive) voice; for example, the active *naḥtî* agrees with the Aram. *nāḥt* against the Can. *nuḥti,* "I rested," while a form like the passive *nākhôn,* ('was established," reflects the Canaanite vocalization. The vocabulary, however, exhibits few words which are undoubtedly old Aramaic.

Another element comes from the Eastern (Accadian or Assyro-Babylonian) branch of the Semitic family. Through this it obtained a few Sumerian loan-words, like *hêkhāl,* "temple," through Acc. *ēkallu,* "palace," from Sum. *E.GAL,* "great house." Those weak verbs, whose last two consonants are identical, show this Accadian (and Aramaic) element; for example, the alternatives *qaṣaṣ* and *qaṣ* represent the Acc. *qasiṣ* and the Aram. *qaṣ* "cut," respectively. Similarly the alternatives *mîshôr* and *mêshār,* "justice," represent the Phoen. *misor* and the Acc. *mîshāru,* "justice," respectively.

A number of alternative words confirms this view. The Hebr. *'ānōkhî* and *'ănî* reflect, the first, the Bab.-Can. *anuki* (cf. Acc. *anâku*) and the second, the Aram. *'ănâ* (cf. vulgar Arab. *'anî*), "I"; the Hebr. *'ēl* and *'ĕlō'ăh* reflect the Bab.-Can. ilu and Phoen. el (cf. Acc. *ilu*) and the Aram. *ĕlāhâ* (cf. Arab. *'ilâh*), "God," respectively.

There are even occasionally three synonyms each from a different source in current use.

Hebrew, therefore, has drawn upon Assyro-Babylonian, old Aramaean (Amorite) and Canaanite. Now the correspondence 'from Tallu-'l-'Amarnâ tells of people called *Ḫabiru* pressing into Syria and Palestine from the north-east and the east. The name can hardly be dissociated from that of the Hebrews (cf. Bab.-Can. *ḫaparu*=Hebr. *'āphār,* "dust," in illustration of the philological equation); but the people are not the biblical Hebrews, if only because of their time and manner of entering Palestine. Cuneiform sources, however, relate that they came from Mesopotamia, through Hittite territory, into Syria and Palestine; so tradition asserts that Abraham came from Babylonia by Haran, through Hittite and Amorite territory, into Palestine. The analysis, too, of the Hebrew language shows that those who spoke it borrowed elements from and therefore in all probability passed through lands whose inhabitants spoke the Babylonian, Amorite (or Aramaean) and Canaanite languages. Thus history and philology confirm the traditional origin of the Hebrew people.

Hebrew retained but few traces of dialect; the reason lies probably in the Masoretic editing of the sacred text, which obliterated all local peculiarities. The Amorites substituted *s* for *sh;* and a trace of this is seen when the Ephraimites said *sibbōleth* for *shibbōleth.* Another mark of dialect was the Gileadite use 'of *shōmēă'* (cf. Ass, *shāmeānu* and Eth, *samā'i*), "hearer," for *'ēdh,* "witness." Again, the North-Palestinian narratives preferred *'attî* to *'att,* "thou" (fem.), *zōh* to *zō'th,* "this" (fem.), and exhibited a few other Aramaizing peculiarities, notably in certain pronominal suffixes. This explanation probably accounts for certain infinitives, like *hălōkh* for lekheth, "to go," used by the Elohist. The use of *mĕlôkhāh* for molkhdh, "rule," *'ālaz* for *'ālaṣ,* '(exulted," and *'al,* "upon," for 'el, "unto," may also be dialectical. But certainty on this point, in view of the lack of sufficient evidence, is unattainable.

Hebrew was written in the common Semitic alphabet, used alike by Moabites, Hebrews, Phoenicians (who transmitted it to the Greeks), and Aramaeans. The earliest Hebrew examples occur on the Calendar from Gezer (c. 8th century B.C.) and on the inscription in the Pool of Siloam (c. 700 B.C.); there are, however, earlier instances in other languages. This character remained longest unaltered in Hebrew and Phoenician. The transition to the "square script" was effected first in Aramaic and later in Hebrew, undoubtedly in consequence of the growing influence of Aramaic immediately before the Christian era. It was called the "Assyrian script" on the assumption that it was the hand of the Eastern Aramaeans, which the Jews adopted about the 5th century B.C. Tradition ascribed this change to Ezra; but inscriptions, ostraka and papyri, prove that it was a gradual process which was not completed in Hebrew by 400 B.C. Another form of this hand is found in Egyptian Aramaic in the 5th and 4th centuries B.C. From these were developed the "square" characters used in biblical manuscripts, important texts and most printed books; the "Rabbinic" script, used in every kind of treatise, and the "cursive" writing of letters and informal documents, which was not generally printed. Hebrew palaeography is not sufficiently advanced to determine accurately the date of a manuscript, but the country of its origin can be recognized. The clearest distinctions are between Spanish, French, Italian, Maghrebi, Greek, Syrian and Egyptian, Yemenite, Persian and Karaite hands. This alphabet numbered 22 letters, whose order the evidence of certain acrostic poems proves not always to have been precisely that which afterwards prevailed; and there are signs that it was not definitely fixed even when the Greek version of the Old Testament was made. In default of figures the consonants served also as numerals, of which usage the earliest traces are found on Maccabaean coins. On these, too, abbreviations, which are unknown in the Old Testament but are extremely common afterwards, make their first appearance.

This alphabet was purely consonantal, except that w and y could denote *u* and *i,* while ' (*'āleph*) sometimes marked a and more rarely o, and h supported various final vowels; the first two also indicated the diphthongs au (6) and *ai* (*ê*). In inscriptions these helping consonants were rarely written and were inserted in the Scriptures only by later scholars, often wrongly. That this alphabet was imperfect, apart from the absence of vowels, is evident; for, firstly, the versions prove that h and ' (*'ayin*) each represented a harder and a softer sound, which Arabic distinguishes by diacritical points; secondly, the Masoretes inserted a point in b, g, d, k, *p* and *t,* to distinguish their unaspirated from their aspirated sounds. Yet it was over-rich in the possession of five sibilants: *z,* a strongly articulated s, two forms of *s* which were so alike that one of them almost fell into desuetude, and sh.

The writing was from right to left. On the earliest inscriptions the words were divided by a point; but this was not so on gems and coins, and separation of the words was probably irregular in early manuscripts of the Scriptures; for the versions not infrequently imply a different division. It seems, however, to have been completed, like the introduction of special final forms of k, *m, n, ṗ* and *ṣ,* before the time of the Masoretes, As Hebrew became ever more the language solely of the learned, the need of preserving the original pronunciation in the reading of the Scriptures was increasingly felt; for this the vowel-less text was a very imperfect instrument. The insertion of *w* and *y'* (*'āleph*) and h to mark long vowels and diphthongs was the first step; that of ' (*'āleph*) and h was very early; but, since the Greek version often implies a reading without such a w or y, they had probably not been generally introduced even after the 2nd century B.C. The system of vowels found in modern Bibles was a much later invention, having been gradually developed by Jewish grammarians in the 6th and 7th centuries A.D., imitating the Syriac vocalization. Two main systems were invented: the Babylonian with mostly supra-linear signs, and the Palestinian, in which they were chiefly put under the line. The Palestinian, as elaborated by the scholars of Tiberias, is that found in modern Bibles. It was so exact as to show all the vowel-changes occasioned by lengthening, by tone, by gutturals, and so on, which other languages seldom indicate in writing. This vocalization, which was little used except in Bibles, represented the traditional pronunciation observed in reading the Scriptures in synagogues and schools; but doubts have, on good grounds, been raised whether it represents the true pronunciation of ancient Hebrew. This can be shown by the Assyrian writing of Hebrew names and by the Greek and Latin transcription of Hebrew names and words. Thus "Dibon" (Hebr. *Dibhôn*) should probably be pronounced "Daibon" (Hebr. *Daibhôn*) if the Greek Δαιβων is to be trusted. (See GREEK

LANGUAGE.) It is also noteworthy that the punctuation often exhibits a later i or e where the Septuagint preserves an a which comparative philology proves to be original. Yet caution is necessary; for the alphabet into which a word is being transcribed may not possess any means of representing the necessary sound; for example, the Assyrian transcription *Ausi'* and *Usi'* for "Hoshea" (Hebr. *Hôshēă'*) does not imply any different pronunciation, since Assyrian had no signs for *h,* o and e; the Greek Ωσηε, as far as it can, here confirms tradition. In fact, although the Masoretic vocalization might sometimes be wrong, internal reasons as well as the analogy of the cognate languages testify to the general faithfulness of the tradition. At the same recension, or soon afterwards, other signs, such as a complicated system of accents, different in the prose-works and the poetical books were added. There are now two pronunciations of Hebrew current, viz., the Polish and German, which partly resembles that of Syriac, and the Spanish and Portuguese, which approaches that of Arabic; Christians, after Reuchlin, generally prefer the latter to the former.

In development Hebrew was later in many respects even than classical Arabic, which hardly began till several centuries after Hebrew had ceased to be spoken. Classical Arabic, like early Babylonian, had case-endings (sing. nom. *-u,* acc. -a, gen. *-i*). Of these there are traces of a nom. -9 (or *-ô*), found only with a following genitive case, in the Calendar found at Gezer in which *yarhû* stands besides *yeraḥ,* "month," and sporadically in the Old Testament in names like "Methushael" (Hebr. *Mĕthûshā'ēl,* cf. Bab. *mutu shâ ili,* "man of God") and in certain phrases like *ḥayĕthô* (for *ḥayyath*) *'ereṣ,* "beasts of the earth." The acc. *-āh* survived as an adverbial ending, chiefly denoting place and time; otherwise it had no force, as in *laylāh* (for layil), "night" (cf. ἡ νύκτα for ἡ νύξ in Romaic). No genitive ending is found in Hebrew; for the termination -i, sometimes attached to nouns governing the genitive case, was probably a binding vowel, like the *-i* of early Babylonian. The plur. *-îm* and du. -aim were properly acc. endings, as Babylonian (plur., nom. *-û* and acc.-gen. *-î;* du. nom. *-ân* and acc.-gen. *-ên*) and Arabic (plur., nom. *-ûna* and acc.-gen. *-îna;* du. nom. *-âna* and acc.-gen. *-aina*) show. The Canaanite glosses *shamuma* and *shamema* (cf. Hebr. *shāmaim*), "heaven," show two plural cases; of these the alternative forms of the name "Penuel" (Hebr. *Pĕnû'ēl*) and "Peniel" (Hebr. *Pĕnî'ēl*), "face of God," of which the plur. *pānîm* (cf. Bab. Ass. *pânû*), "face," is an element, were the sole surviving trace in Hebrew. The earliest Hebrew, then, was on a level with modern Arabic or Greek; for the accusative had become the only case.

Classical Hebrew construction was almost exclusively paratactic, subordinate conjunctions being extremely rare. In pre-exilic writings many verses and even whole chapters can be found, exhibiting no conjunction other than 9- or *wĕ-,* "and." Yet there is no monotony; for extraordinary skill is displayed in varying the tenses and the order of the words, often with good effect; *e.g.,* Hebrew says graphically "this do and live" for the ordinary English "if you do this, you will live." Further relief was provided by "*wāw*-consecutive," a construction almost confined to biblical Hebrew; elsewhere it is found only in one Moabite and one Aramaic inscription, and died out before Mishnaic Hebrew arose. This construction was the normal method of connecting each fresh verb in the narration of a series of events with the preceding clause. Hebrew tenses involved no relations to actions as past or future but only as complete or incomplete: by it, therefore, in past time only the first verb stood in the perfect and the narration was continued in the imperfect; in present or future time, the first verb stood in the imperfect and the subsequent verbs in the perfect. This progress in the sequence of time was indicated by a variety of the ordinary conjunction we- or *û-* "and," which either had a heavier vocalization or altered the accent of the verb; for example, *hāla'khtā wat-tiqṭōl* meant "thou hast gone and killed"; similarly, *tēlēkh wĕ-qāṭaltā'* meant "thou wilt go and kill." In the first the imperfect represented the action as emergent; accordingly, when combined with a conjunction connecting the event introduced by it with a point already reached by the narrative, it represented it as the development of the part which preceded it; thus, *wat-tiqṭōl* meant "and thou wentest on to kill," while *wĕ-tiqṭōl* is simply "and thou wilt kill." In the second the perfect *wĕ-qāṭaltā'* meant "so thou hast killed," the possible occurrence of the event being confined to a particular area previously implied or defined, whereas the simple perfect *wĕ-qāṭa'ltā* would mean unconditionally "and thou hast killed." The various uses of this construction afford a relief to the monotony of a long string of clauses co-ordinated rather than subordinated to one another. But this idiom began, under Aramaic influence after the exile, to die out, and the simpler constructions, like *hālakhtā wĕ-qāta'ltā,* "thou hast gone and killed," and *tēlēkh wĕ-tiqṭōl,* "thou shalt go and kill," become a mark of later Hebrew. The participle also in all periods was freely used to eke out the inadequacy of these two tenses. Another device was the "circumstantial clause," whereby a clause introduced by "and" served as a secondary predicate; *e.g.,* the Hebrew said "he found him (and) he ploughing" instead of "he found him ploughing," using the participle and not a finite verb in a parallel, in place of a subordinate, clause.

The material for forming a judgment on Hebrew is itself scanty and inadequate. Even so, the smallness of the vocabulary and the paucity of adverbs, adjectives and abstract nouns are noticeable. The first difficulty was obviated by prepositional phrases, auxiliary verbs and similar devices, the second by apposition or a descriptive genitive case. The lack of abstract nouns, which only became frequent after the exile, was circumvented by the feminine singular or plural adjective; thus *rā'āh* (fem. sing.) stands for "wickedness" and *qāshôth* (fem. plur.), "harsh things," for "harshness." Another feature was the expression of the abstract under a concrete form; thus *kābhēdh,* "was heavy," meant also "was honourable," and from it both *kābhēdh,* "liver" (as the "heavy" organ), and *kābhôdh,* "abundance" and "honour," were both derived. It is, on the contrary, a sign of lateness when an abstract noun like *môdha'* "acquaintance," designated a concrete person.

Hebrew was less suited for the definite expression of studied thought and the treatment of abstract subjects than for poetry. There was a great lack of particles to express the more subtle connection of ideas; there were few words or inflexions to indicate slight modifications of meaning, although possibly Hebrew, like other Semitic languages, formerly distinguished verbal moods in a way now obscured by the Masoretes. The use of the tenses was largely determined, especially in poetry, by the imagination, which regarded things unaccomplished as accomplished, the past as present and the future as fulfilled. It must, however, be remembered that living Hebrew never had to express abstract ideas; Ecclesiastes, which alone grappled with an abstract subject in plain prose, was composed when Hebrew was already dying out.

In prose, especially of the pre-exilic period, considerable differences of form and style can be detected, due partly to the time and place of composition, partly to the individuality and talent of the authors. Through them especially the various documents woven into the text can be disentangled. Yet the structure and, except in isolated cases, the vocabulary and phraseology, were much the same. The post-exilic literature shows a constantly closer approximation of the language to the cognate Western Aramaic idiom. The process was very gradual; for literary Hebrew was still understood, if not spoken, by the people at least in the 2nd century B.C.; and its extensive use in popular religious literature, partly preserved in the liturgy and elsewhere, proves that it was not entirely forgotten even in the 3rd century A.D. The poetical language employed peculiar words and meanings, forms especially of prepositions and pronominal suffixes, inflexions and constructions; but these distinctions were not so marked as in Greek. Many of them, being found in ordinary use in the cognate languages, notably in Aramaic, were often probably archaisms from the common Semitic vocabulary, surviving in Hebrew only in poetry; for example, the late and poetical kethem, "gold," has now been found in Canaanite. In other cases, possibly, Hebrew poets deliberately embellished their language with Aramaisms; for there is evidence that Aramaic was known to educated Hebrews in the latter part of the 8th century B.C. Apart from Arama-

isms, there was a definite poetical vocabulary; for example, *'ōraḥ* for derekh, "way." There was, particularly, a tendency to substitute adjectives for nouns; for example, *lĕbhānāh,* "the white one," for *yārēăḥ,* "moon." The article and *'ēth,* the sign of the accusative, were frequently omitted; the relative particle was freely dropped; the shortened imperfect was more widely employed; the governing power of prepositions was extended; the greater scope allowed to the imagination in the use of the tenses frequently obscures the sequence of events to a Western reader; and a forceful brevity of expression was affected. Poetry was accentual and was distinguished from prose by rhythm and parallelism. The poetical instinct was seemingly satisfied by lines of approximately the same length, combined normally into groups of two, three or four lines and constituting verses which marked more distinct pauses in the thought than the separate lines. The line normally consisted of seven or eight syllables, but there was apparently no rule on the subject; when it was longer than seven or eight syllables, a caesura commonly divided it into halves, each of so many beats. The fundamental form of the verse was the two-lined couplet, of which the second either repeated or re-enforced or completed the thought of the first. These couplets exemplified the main principle of Hebrew poetry, the parallelism of two roughly equal clauses, of which the second answered or completed the first. This might be synonymous, in which the second repeated the thought of the first line; antithetic, in which the thought of the one was contrasted with that of the other line; constructive, in which the second supplemented the thought of the first line; or climactic, in which the second line took up words from and completed the first line, which was incomplete. The poets sometimes grouped their verses into stanzas, marking the close by a refrain; but the number of verses in a stanza was never, according to the Masoretic text, more than approximately uniform in any poem. The *qînāh,* "elegiac rhythm," in which the line consisted of two members, the first containing one beat more than the second, exhibited the clearest scheme. Rhyme was as accidental as in classical Greek or Latin poetry; but both rhyme and quantitative metre were introduced, after the Arabic model, by mediaeval poets, who combined them with the vocabulary and idiom, as far as possible, of the earlier language.

At first foreign words were rare. There are occasional Egyptian words like *'āḥû* (Eg. *'hw*), "reeds," and qeseth (Eg. gsty), "inkhorn," and Assyrian words like *sĕ'ôn* (Ass. *shênu*), "boot," learnt probably from invading soldiers. The Babylonian *pûru,* "lot," was introduced in the plural *pûrîm,* "lots," to designate a post-exilic feast. Persian words also, like *dāth* (Pers. ddta), "law," came in. But late Aramaic, as closely resembling Hebrew, exerted, especially after the exile, an ever-increasing influence. Aramaic words and forms appeared: the Hebr. -6h began to be displaced by the Aram. *-â* in feminine nouns, and the Hebr. *dābhār* to yield to the Aram. *millĕthā'* in the Hebraized form *millāh,* "word," which even has two plur. forms (Hebr. *millîm* and Aram. *millîn*) in the same book. Hebrew words were sometimes Aramaized in form, as when the Hebr. *nāṣar* became *nāṭar* like the Aram. *nĕṭar,* "kept," or in meaning, as when the Hebr. *ṭa'am,* "taste," came to mean "decree" like the Aram. *ṭe'êm* (cf. Ass. *ṭêmu*), "command." Abstract nouns in *-ûth,* like *malkhûth,* "kingdom," became common and are even formed from infinitives, like hashma'zith, "proclaiming," on the Aramaic model. The pronominal suffixes were weakened, so that such an Aramaism as *karmî shellî,* "my vineyard which is to me," tended to oust the simple Hebrew *karmî,* "my vineyard." The classical *'ăsher,* "who, which," lingered chiefly in combinations based on the old literary language, while the dialectical she- on the analogy of the Aramaic *dĕ-* displaced it in those derived from the popular Aramaic.

This post-exilic Hebrew showed also great simplicity and uniformity of style, again largely due to Aramaic influence. For some centuries the Jews must have been bilingual, still understanding Hebrew but speaking Aramaic, the official language of the western provinces of the Persian empire; by the time of Christ, however, Aramaic versions of the Scriptures, called *targûmîm,* were becoming necessary. Meanwhile Hebrew, without dying out, became gradually a *lĕshôn ḥăkhāmîm,* "language of scholars," as indeed it had begun to be in the later Scriptures. Roughly from 100 B.C. to A.D. 100 little is known of it; but, after that it was greatly developed in the *Mishnāh* (c. A.D. 200). It was still a living language, though mainly confined to the schools and clearly distinct from Biblical Hebrew. In the Scriptures the range of subjects was limited; in the *Mishnāh* it was much extended. Matters of daily life were minutely discussed and words and phrases were adopted from the earlier and presumably popular speech; further, since the language was no longer in the same sense familiar, greater definiteness of expression was required in the written style.

The first alteration noticeable was the confusion of consonants, especially of the gutturals, which classical Hebrew had kept distinct. This change shows that the writers were accustomed to the daily use of Aramaic. Greek and Latin words, relating to the affairs of ordinary life, for whose writing the rules of classical orthography were violated, crept in. For example, biblical Hebrew almost universally required that initial *w* should become y, as in *yeledh* for the very rare *wālādh* (cf. Arab. waladu), "boy"; but barbarisms like *wĕthas* (Gr. εὐθύς), "at once," and *wîlôn* (Lat. velum), "curtain," were admitted, and henceforward the objection to forms like wa'ad (B. Hebr. *mô'ēḏ*), "meeting," was less strongly felt.

Biblical Hebrew, having lost the case-endings, used *'ēth* to mark the definite accusative case; but Mishnaic Hebrew employed *'ēth* not only to introduce the direct object, but also to serve alone as a definite article or, with a pronominal suffix, as a pronoun meaning "that" or "the same." Fresh pronouns, too, were coined by combining those already existing into compound forms or by adopting or adapting many from Aramaic. New adverbs, prepositions and conjunctions, especially subordinating conjunctions, were freely invented or imported from Aramaic.

The vocabulary was greatly enriched. Many biblical words remained, although some nouns changed their meaning; thus B. Hebr. *gōlem,* "embryo," became the M. Hebr. *gôlem,* "lump," "mass." New nouns were coined from biblical roots; so beside the B. Hebr. hemedh, "desire," there arose the M. Hebr. himmzidh, "desire," from *ḥāmadh,* "desired." Especially noticeable are the numerous quadriliteral and quinqueliteral formations, which were rare in biblical Hebrew. Lastly, good Hebrew words appear which, though unknown in the Scriptures, must have belonged to the old spoken language. Beside the numerous Greek and Latin words, a few Persian (or Arabic) words crept in. These generally retained their original appearance, while one Greek word passed over in the genitive case (M. Hebr. *'andrî'antôs* = Gr. *ἀνδριάντος,* from *ἀνδριάς,* "statue"); only rarely were they furnished with Hebrew terminations. The inflection of nouns remained unchanged; but many masculine nouns acquired feminine endings, and the Aramaic masculine plural ending -in was much commoner than the Hebrew *-îm,* although the Hebrew feminine ending -6th was regularly retained. Finally, the "construct state," whereby a noun governing a genitive case undergoes phonetic modification, survived sporadically; but a periphrasis with shel- ("which is to"), "of," the preposition ל, "to," or the Aram. *dĕ-,* "of," tended to displace it. This relative particle she-, which belonged to dialect in biblical Hebrew, completely ousted the classical *'ăsher,* "who," "which," from Mishnaic Hebrew.

The supply of verbs also was much enlarged. Foreign verbs, being ill suited to the Hebrew conjugations, were rarely adopted, but a few were formed from nouns; *e.g., sāphagh,* "absorbed," from *sĕphôgh* (Gr. σπόγγος), "sponge." The imperatives *kîrî* (written חיי = Gr. χαῖρε) "hail!" and *wîwî* (written חיי = Lat. vive), "live," are exceptions. But Aramaic verbs, which closely resembled Hebrew verbs, were readily assimilated, while some classical verbs received new meanings; *e.g., zākhāh,* "was innocent," acquired the sense of "succeeded." Others, used originally in the simple theme, afterwards affected a derived theme. Many roots known only from derived nouns or quite unknown in biblical Hebrew, became general. Additional verbs were coined from derivative nouns; *e.g., tāram,* "exacted the heave-offering" (B. Hebr. *tĕrûmāh*) and *mishkēn,* "took a pledge" (M. Hebr. *mishkôn*), "pledge." Quadriliteral and quinqueliteral verbs, rare in biblical

Hebrew, became common. The conjugations remained substantially unchanged; but the third person feminine singular took *-eth (-ath)* in place of *-āh* in the reflexive theme. Certain weak verbs also deviated slightly from the classical norm.

The themes underwent some slight changes. Canaanite had marked the active and passive voices by modifying the vowel *(cf. laqaḥu,* "they took," but *laqiḥu,* "they were taken"), and biblical Hebrew sporadically preserved this difference between transitive and intransitive verbs *(cf.* between *zākhar,* "remembered," and *shākhēn,* "dwelt"). Of an internally formed passive the only certain survival is the participle; *e.g., zākhûr,* "remembered." Other traces are probably concealed under certain forms which the Masoretes obscured. In its place, biblical Hebrew used the passives of the derived themes. These (according to the paradigm of *pa'al,* "did") were the reflexive *niph'al,* the intensive and causative *pi'ēl,* the causative *hiph'îl* and the reflexive *hithpa'ēl.* The *niph'al* easily acquired a passive force; the *pu'al,* less often the *hoph'al* (the passives of the *pi'ēl* and *hiph'îl* respectively), were often also so used. But in later Hebrew the *niph'al* and even more the *hoph'āl* tended, because of ambiguity in their meanings, to become less frequent, whereas the *hithpa'dl* became extremely common, both with a reflexive and less often with a passive force. Simultaneously a new form, the *nithpa'ēl,* of which biblical Hebrew offers but three examples, became extremely common with a purely passive sense. Of the active themes the *pi'el* served extensively in forming new verbs from nouns and replacing the simple theme customary with many classical verbs and the *hiph'îl* extended its usage. An Aramaic causative theme, formed by prefixing *sha-* or *sa-,* instead of *hi-,* was not unknown.

The old tense system was inadequate, and the loss of "*wāw*-consecutive" made it even more inadequate. The perfect expressed only completed action in past time; and more than the old imperfect was required for incomplete action in the past, present and future. Various periphrases were therefore devised. Past incomplete action was denoted by the verb *hāyāh,* "was," with the participle; *e.g., hāyāh 'ômēr,* "he was saying," was distinguished from *'āmar,* "he said," while the imperfect *yômēr* was left with a jussive force, meaning "he should say." The present participle alone connoted present time; but a pronominal subject, being no longer implicit or explicit in inflection, had to be expressed; *e.g., 'ănî 'ômēr* or *'ômēr 'ănî,* "I say." This gave rise to a completely new Aramaizing tense, formed by combining the participle with the following pronouns; for example, *'ômĕranî,* "I say." The future was expressed by the adjective *'athidh,* "ready," or the noun *sôph,* "end," with a pronominal suffix referring to the subject, followed by the infinitive introduced by *lĕ-,* "to"; *e.g., 'ănî 'āthîdh lômar,* "I am ready to say," or *sôphî lômar,* "my end (is) to say"; viz., "I will say"; or by *lĕ-* and the infinitive alone, as sometimes in biblical Hebrew, denoting rather what ought than what will happen; *e.g., 'anî lômar,* "I am to say." To express obligation, for which biblical Hebrew had no regular phrases, mishnaic Hebrew used the adjective *ṣārîkh,* "needed," with the infinitive; *e.g., 'ănî ṣārîkh lômar," I* must say." Thus Hebrew, with its archaic stiffness, lost also the austere beauty and stately dignity of its prime. In exchange it acquired simplicity and flexibility and adapted itself better to the needs of every day, though the disappearance of much that is characteristically Hebrew before the invasion of Aramaic cannot but be regretted. Hebrew still lives as the language of Jewish scholars, though coloured in varying degrees with the writer's own speech, whether Persian, Arabic, French, German or whatever it may be. The structure is Hebrew; the vocabulary is often very foreign. This must be increasingly so, for ancient Hebrew is ill adapted to modern needs. As mediaeval grammar and philosophy demanded Arabic terms, so modern science requires European terms, often borrowed through Arabic. *(See.* YIDDISH LANGUAGE *AND* LITERATURE.) (G. R. D.)

HEBREW **LITERATURE.** Works in Hebrew were written by Rabbanite and Karaite Jews, by Samaritans, and some also, in the 16th and 17th centuries, by Christians. Rabbanite Jewish literature, with which this article deals, includes for practical purposes Jewish writings in Aramaic and certain Arabic works current in Hebrew translations. Other Jewish literatures exist in Yiddish, in Judaeo-Spanish and in other languages.

Biblical Literature.—All works preserved from the biblical period *(c.* 1200–586 B.C.) are included in the Bible *(q.v.),* but the titles of several other books are mentioned, especially in the Books of Chronicles. The oldest literary remains are some fragments of epic poems (Gen. iv, 23; Num. xxi, 17–18 and xxiii-xxiv; Judg. v). According to M. Cassuto large parts of the Pentateuch and of the books of Joshua and Judges still betray their original epic form. Biblical poetry closely resembles in form and phraseology the Canaanite epics from Ugarit (Ras Shamra) of the 14th century B.C. or earlier. It differs from prose in vocabulary and in syntax and is distinguished by parallelism: each verse consists of two parts of roughly equal length expressing identical or complementary ideas. Other metrical features were still under debate at mid-20th century. *See* G. B. Gray, *The Forms of Hebrew Poetry* (London, 1915); W. H. Cobb, *A Criticism of Systems of Hebrew Metre* (Oxford, 1905). The style of the historical books of the Bible was based on that of the royal chancelleries, whose official chronicles they used *(cf.* the style of the Lachish letters, ed. by N. H. Torczyner, Oxford, 1938). Deuteronomy is in a rhetorical prose style of its own. Dialogue often exhibits marked colloquial features—evidence of observation and stylistic maturity.

The Period of the Second Temple, 539 **B.C.–A.D.** 70.—The literary output of the period of the Second Temple was large *(cf.* Eccles. xii, 12): some of it was included in the biblical canon, while other works, excluded because they were written or used by sectarians (*i.e.,* non-Pharisees), remained in translations in Christian hands *(see* APOCALYPTIC LITERATURE; APOCRYPHAL LITERATURE); of some only the titles are known; and new works come to light with the discoveries in the caves near the Dead sea (1947 *et seq.).* The language of this literature—as far as it is possessed in Hebrew—is a somewhat degenerated Biblical Hebrew. The formal conventions of biblical prose and poetry are adhered to. The only new genre is *midrash,* the interpretation of biblical texts so as to bring out their relevance for the commentator's time or their practical legal application.

The use of Biblical Hebrew was artificial. The spoken language in Judaea until the 1st century A.D. mas Mishnaic Hebrew *(see* M. H. Segal, "Mišnaic Hebrew and its Relation to Biblical Hebrew and to Aramaic," *Jewish Quarterly Review,* xx, pp. 647–737 (London, 1908); H. Birkeland, *Språk og Religion hos Jøder og Arabere* (Oslo, 1949). The Pharisees used the Mishnaic colloquial for their oral teaching, as handed down in tannaitic works. For prayer, they used the same dialect but enriched it with extensive borrowings from Biblical Hebrew, especially from its poetry. They did away with parallelism: instead, they used short lines, mostly of four words, often in sets of three. Simple rhymes occur; this may be the earliest use of this device in poetry *(see* K. G. Kuhn, *Das Achtzehngebet, der Vaterunser und der Reim,* Tiibingen, 1950). These old prayers now make up only a small part of the Jewish liturgy and differ in wording according to the rites. See *The Authorized Daily Prayer Book,* annotated ed. by I. Abrahams (London, 1914); N. Glatzer (ed.), *Language of Faith* (New York, 1947), an anthology; G. Elbogen, *Der jüdische Gottesdienst in seiner geschichtlichen Entwicklung* (Berlin, 1913); W. O. E. Oesterley and G. H. Box, *A Short Survey of the Literature of Rabbinical and Medieval Judaism* (New York and London, 1920).

In the synagogues weekly portions of the Bible were read and then interpreted in the vernacular with a limited use of *midrash* technique. Hence all ancient versions, whether Greek, Aramaic *(see* TARGUM), the Syriac Peshitta or Jerome's Vulgate, include midrashic elements.

The last work of this type is the Arabic version by Seadiah (d. 941/942). Some of the late Targums (*e.g.,* those on Canticles, Ecclesiastes and Esther) incorporate so much *midrash* as to be independent writings rather than translations. *See* P. Kahle, *The Cairo Geniza* (Toronto and Oxford, 1947); B. J. Roberts, *The Old Testament Text and Versions* (Cardiff, 1951); I. L. Seeligmann, *The Septuagint Version of Isaiah* (Leyden, 1948); L. Prijs, *Jüdische Tradition in der Septuaginta* (Leyden, 1948).

The Tannaitic and Amoraic Periods, 70–200 **and** 200–500. —The oral teaching of the Pharisees and, after A.D. 70, of the rab-

bis concerned either legal and ritual matters (halakhah, "walking," viz., in the way of God) or theological and ethical questions (aggadah or haggadah, *q.v.*, "telling"). Even when such teachings were purely traditional (the Oral Law) or avowedly of recent innovation, it was sought, especially since Rabbi 'Akiba (d. between 130 and 140), to attach them to Scripture. This was done by means of hermeneutic rules (middoth), which were most probably derived from Hellenistic rhetoric (cf. D. Daube, "Rabbinic Methods of Interpretation and Hellenistic Rhetoric," Hebrew Union College Annual, xxii, Cincinnati, 1949; S. Lieberman, Hellenism in Jewish Palestine, New York, 1950).

In Halakhah these rules were few and strict, while in Aggadah, where nothing was binding and reciprocally exclusive views could coexist, much more liberal methods were used. The influence of rhetoric is also discernible in the style of the aggadah, the nearest thing in this period to literature in our sense. Aggadah freely reshapes biblical history; a composite view of the resulting picture is given by L. Ginzberg, Legends of the Jews, 7 vol. (Philadelphia, 1909–38). For an analysis of its thought see M. Kadushin, The Rabbinic Mind (New York, 1952); also I. Heinemann, *Darkhe ha-Aggadah* (Jerusalem, 1940).

For the books of the period, see TALMUD and MIDRASH. In Mishnah and Tosefta the tannaitic teachings are arranged by subjects (often disturbed by older, mnemonic, arrangements); in the tannaitic midrashim they are arranged in the order of the biblical laws to which they refer. All these works include aggadah. The Babylonian and Palestinian Talmuds summarize in Aramaic the discussions of the Amoraim on the Mishnah, point by point, but in doing so often stray far from the subject and for whole pages give only aggadah. Much tannaitic material is preserved only in these discussions (Baraita).

While as books these works are shapeless and unsystematic, the individual paragraphs are often constructed with consummate art. In Rabbi 'Akiba ben Joseph, by E. Ben-Yehudah (Jerusalem, 1945), an attempt is made to evaluate the style of an individual tanna.

The halakhic method of the Babylonian Talmud is highly developed, while its aggadah is crude and affected by Mesopotamian demonology. In the Palestinian Talmud the halakhic discussions are simple and there is much less careful editing; the aggadah is of a national and messianic character and more artistic in style. The aggadah of the Babylonian Talmud is extracted in 'En Ya'akov by Jacob ibn Habib (1460–1515) (tr. by S. H. Glick, New York, 1922), that of the Palestinian Talmud in Yefeh Mar'eh by Samuel Yaffe (16th century).

The Literary Revival and the Gaonic Period, 500–1000.—In Justinian's Novella CXLVI "De rebus iudaicis," of A.D. 553, note is taken of the attempt of some Jewish groups to enforce the exclusive use of Hebrew in the ritual of the synagogue. This tendency was part of a Hebrew revival that began in Palestine and spread westward but reached Babylonia (*i.e.*, southern Iraq) only in the 10th century.

Midrash.—The aggadic thought of the Amoraic age was now built into skilfully constructed sermons. Sayings originally Aramaic are mostly translated into a Hebrew strongly influenced by the style of the liturgy. The earlier works, foremost among them Genesis Rabba (translated in The *Midrash* Rabba by M. Simon and H. Freedman, 10 vol., London, 1948), are largely concerned with theological controversy against gnostics. In the later collections, represented mainly by the Tanhuma cycle, the sermons are given in greater detail and are purely ethical. For the first time real books with a sustained theme appear. Besides a large number of minor midrashim, two deserve special note: *Tanna* de-be Eliyahu, a lofty ethical work, and Pirke Rabbi Eliezer (tr. by G. Friedlander, London, 1916), mystical in tone. A whole literature, the Hekhaloth writings, describes the mystic's ascent to heaven and vision of God. Their symbolism influenced the numerous additions which were during this period made to the liturgy, as well as the piyyut (cf. G. Scholem, Major Trends in Jewish Mysticism, pp. 57–63, rev. ed., Ne York, 1946). Mystical cosmology is the theme of Sefer Yezirah or "Book of Formation" (tr. by K. Stenning, 1923). See further L. Zunz, Die *gottesdienstlichen* Vortriige der Juden (Berlin, 1832).

Piyyut.—Synagogues began in this period to appoint official precentors (hazzanim), part of whose duty it was to compose poetical additions to various parts of the liturgy on special Sabbaths and festivals. The authors of such compositions were called *poytan* = ποιητής (the more usual form, *paytan*, is Babylonian usage), their poems piyyutim. There are numerous similarities between these and the Byzantine and Syriac hymns of the time.

The keynote is messianic fervour and religious exuberance. Besides employing the entire Biblical, Mishnaic and Aramaic vocabularies, the *paytanim* coined thousands of new words, sometimes for new ideas, but more often simply recherche' and full-sounding synonyms. The poems presuppose a highly educated audience. They abound in recondite allusions to halakhic and aggadic literature and contain exhaustive lists of rites and laws, so much so that it was at one time believed that their purpose was to teach the law during periods when the rabbinic schools were suppressed. Persons are rarely mentioned by name but nearly always introduced by ingenious allusions. There are often elaborate strophic arrangements, with rhymes or refrains. Already the Bible knows acrophonic poems (*e.g.*, Ps. ix, x, xxv, xxxiv); in *piyyut* there are all kinds of ingenious arrangements involving the beginnings of lines, words in the middle, or even all words. Frequently the initial letters of lines spell out the name of the author. These "signatures" help to establish the history of this literature, which is still largely unknown. It is known that the most outstanding poets—Phineas the Priest, Yose ben Yose, Yannai (poems ed. by M. Zulay, Berlin, 1938) and Eleazar ha-Kalir or ben Kalir—lived in that order, but of none of them is it known when or where in Palestine he lived.

Many piyyutim are still used in the synagogue. The Service of the Synagogue, ed. by I. Davies and H. Adler (London, 1906 et seq.), contains many famous ones with translations and has lists of poets at the end of each volume. All known *piyyutim* are listed by I. Davidson, Ozar ha-shirah ha-'ivrith (New York, 1924–33). For history see L. Zunz, Die synagogale Poesie (Berlin, 1855) and Literaturgeschichte der *synagogalen* Poesie (1865); also I. Elbogen, *op. cit.*

Halakhah.—Babylonian Jewry took no part in the literary renaissance. During the 6th and 7th centuries the Saboraim edited the Babylonian Talmud. After this the Geonim—the heads of the academies (Yeshiboth) of Sura and Pumbeditha—worked to spread the influence of the Talmud by encouraging communities everywhere to submit legal problems to them. They answered these in responsa (she'eloth u-teshuvoth). Such responsa remained a characteristic form of Hebrew literature. B. Cohen, Kuntres *ha*-teshuvoth (Budapest, 1930), lists 1,795 collections of them, some containing thousands of items; works of this kind were still being published at mid-20th century. They are an invaluable source for social history. See Z. Frankel, Entwurf zu einer Geschichte der Literatur der nachtalmudischen *Responsen* (Breslau, 1865); S. B. Freehof, The Responsa Literature (Philadelphia, 1954).

The responsa often deal with controversial points left unsolved in the Talmud; their authors thus act as decisors (*posekim*). Such problems were discussed in formal set lectures (she'iltoth) at the semiannual Kalla conferences. There is a collection of such speeches by Rabbi Ahai (d. 762). Yehudai Gaon (680–761) was the first one to arrange compendiums of practical rulings, which were important as a weapon in the struggle against Palestinian halakhah. This activity culminated in complete epitomes of the halakhic material in the Talmud. The earliest is by Simon Kayyara (9th century), the latest and most authoritative by Isaac al-Fasi of Lucena in Spain (1013–1103).

The Classicist Revival.—The rise of the Karaites (or Qaraites, *q.v.*) with their insistence on return to the Bible may have been a contributory factor in bringing about the intensification of Bible study among the Rabbanites in the 9th century. It is no longer held that these studies originated with the Karaites. Fragments from the Cairo Genizah, however, prove that some atheistic sceptics actually used Biblical Hebrew in writing against the Bible. One fragment was edited by S. Schechter (Jewish Quarterly Re*vim*, xiii, 1901); the work of Hiwi of Balkh is known through

Seadiah's retort (ed. by I. Davidson, New York, 1915). Seadiah Gaon (*q.v.*; d. 941/942), who wrote several works in biblical style, points out the names of other works in this genre in his autobiography. The reason for the choice of Biblical Hebrew appears to be the desire to emulate the Arabs' zeal for keeping their language pure, by cultivating the Hebrew equivalent to pre-Islamic Arabic. This was all the easier as Mishnaic Hebrew never had been a living idiom among Babylonian Jews, and they were at this time exchanging their Aramaic speech for Arabic. Seadiah had to translate the Bible into Arabic and to add Arabic translations to his compositions in biblical style. At the same time Seadiah introduced piyyut to Babylonia. His *piyyutim* are much more difficult and artificial than those of the Palestinians.

Metrical Poetry.—Soon after Seadiah, probably by his pupil Dunash ben Labrat (c. 920–80; poems ed. by N. Allony, Jerusalem, 1947), the Arabic system of quantitative metre was adapted for Hebrew by equating the Hebrew reduced vowels (shewa and *hathefs*) with the Arabic short vowels (since the former long and short vowels of Hebrew were no longer distinguished), as in the following example of the metre *basit*,

Arabic: *wal-bai-tu lā / yub-ta-ni / il-lā la-hū / 'u-mu-dun*
wa-lā 'i-mā- / da i-dhi / lam tur-sa au- / tā-dū
Hebrew: *zi-yon hi-lo / tish-'ă-li / lish-lom i-si- / ra-yikh*
dor-she shĕ-lo- / mekh wĕ-hem / ye-ther 'ă-da- / ra-yikh

At first the piyyut form was retained for religious poems, and the new metres were used only for secular poetry, which closely imitated Arabic models and was, like the latter, chiefly employed for laudatory addresses to prominent people. For poems see J. Mann, The Jews in Egypt and *in* Palestine under the *Fatimid* Caliphs, vol. 2 (New York and London, 1922).

Spheres of *Influence*.—During the Roman empire, Jewish communities settled throughout western Europe and North Africa. They spoke Greek and, in the west later on, Latin and possessed writings in those languages (cf. D. S. Blondheim, *Les* Parlers *judéo-romains* et la *Vetus* Latzna, Paris, 1925). They came first under the influence of the Palestinian renaissance; soon after they were affected by the missionary activities of the Babylonian schools. The results differ in each country. On the whole, Italy, southern France and the Carolingian empire remained within the Palestinian orbit but accepted the Babylonian Talmud and some of Seadiah's work, particularly the Beliefs and Opinions in a Hebrew translation couched in piyyut phraseology. Spain and North Africa continued for a while to cultivate piyyut but otherwise completely adopted the outlook of the Babylonian centre, including the revived biblical style and the Arabic metres. In the 10th and 11th centuries northern France and Germany (but not Italy or Provence and Languedoc) adopted the Palestinian ("Ashkenazi") pronunciation.

The Jews of South Arabia adopted the Babylonian Talmud and the Babylonian method of vowel-notation (though their pronunciation is Palestinian), but retained the Palestinian devotion to midrash (an important collection, *Midrash* Hagadol, exists only among them) and produced piyyut until modern times.

With the political and economic decline of the Abbasid empire after 932, oriental Jewry rapidly lost its prosperity and cultural hegemony. The last Geonim were among the greatest. Sherira (fl. 968–998) outlined in a *responsum* for the first time the history of halakhic studies (French tr. by L. Landau, Antwerp, 1904). His son Hai (939–1038) was a philosopher, a commentator of Bible and Talmud along scientific lines, and a poet (Moral Instruction, tr. by H. Gollancz, London, 1922). With him the Babylonian gaonate ceased; a much reduced activity continued for a while in Palestine and Syria, but the focus of Hebrew literature shifted to the west. The opposition between Babylonian and Palestinian thought and writing was from then on replaced by that of their spiritual heirs: Spain on the one hand and northwestern Europe on the other.

The Palestinian Tradition in Europe, 800–1300.—From Palestine, the Hebrew renaissance soon spread into the Byzantine empire. A remnant of literary work in the Balkans is the *Midrash* Lekah Tov by Tobias ben Eliezer of Castoria (Bulgaria, c. 1100). Learned Jews from Byzantium or from Byzantine refugee communities on the Black Sea coast converted in the 9th and 10th centuries the Khazar princes on the lower Volga. Russian heroic ballads contain references to Hebrew singing (cf. J. Yasser in Jewish Social Studies, xi, 21–48, New York, 1949).

In Sicily and southern Italy (which belonged to Byzantium) a number of important *paytanim* were at work. Their poems are often extremely artificial. Midrash was extensively cultivated. Midrashic commentaries to biblical books outside the Pentateuch and the Five Scrolls were produced there by extracting from the older midrashim (including some now lost) and the Talmuds incidental comments on verses from those books (*e.g.*, Samuel, Proverbs, Psalms and Job). Compilations of this kind for the whole Old Testament are called yalkut, "haversack": Yalkut *Shim'oni* (Germany, 13th century); Yalkut Mekhiri (southern France, 14th century); Yalkut Talmud Torah (Sicily, 1331).

Before 1000 there began in Italy a secular literature: the phantastic travelogue of Eldad the Danite; the historical romance Sefer ha-Yashur, which deals with the Pentateuchal period; and *Josippon,* which is Josephus' Antiquities translated from Hegesippus' abridgment and filled up with legendary incident (English abridgment by Peter Morvyn, 1558). This last-named book was popular until modern times and translated, inter alia, into Arabic and Ethiopic. Mainly for entertainment too, was the family chronicle of the *paytan* Ahima'az, in rhymed prose and piyyut style (The Chronicle *of* Ahimaaz, ed. and tr. by M. Salzman, New York, 1924). Jews took part in the work of the medical academy at Salerno. The philosopher and mystic Sabbethai Donnolo (913–983) wrote a book of *materia medica* in Hebrew (ed. by Z. Muntner, Jerusalem, 1949); this makes it probable that it was possible for a doctor to train himself through Hebrew works. Some contact with the philological scholarship of the Latins is also probable in the case of Nathan ben Jehiel, who in 1101 completed at Rome a dictionary of Talmudic Aramaic and Hebrew, the 'Arukh, "one of the greatest monuments of medieval scholarship" (G. Sarton). It is still used, especially in the modernized form (Aruch *Completum*) given to it by the New York rabbi A. Kohut (Vienna, 1878–92).

Of the literary activity of Provence and Languedoc, which laid the foundations for the high scientific culture which evolved there after 1100, little has been preserved. Raimundus Martin, in his Pugio Fidei, quotes extensively from a *Midrash* Bereshith Rabbathi by Moses ha-Darshan of Narbonne (11th century), presumably because it would be acknowledged as the best authority by Jews; yet only extracts have been preserved (ed. by H. Albeck, Jerusalem, 1940). The Bible commentaries of this scholar and of Menahem ben Helbo are known only through quotations in Rashi.

Members of the North Italian family Kalonymos brought Talmudic studies and piyyut to Mainz in the middle of the 10th century. The academy there became a centre of studies under the direction of Gershom ben Judah, "the Luminary of the Diaspora" (960–1028 or 1040). As a poet, he established the distinctive style of European *piyyut*—simple language, uncomplicated strophic arrangements and personalized emotion—in poems that read very much like early European popular poetry (Selihoth *u-Pizmonim,* ed. by A. M. Habermann, Jerusalem, 1944). The greatest alumnus of the Mainz academy was, of course, Rashi (*q.v.*), himself a poet of note. The characteristic contribution of the later Franco-German school to halakhic thought was the Tosafoth, brief but extremely profound glosses on the Babylonian Talmud. Also, following a practice begun by the last Geonim, they produced works of comprehensive practical guidance on specific legal matters.

The slaughter during the crusades drove large masses of Jews to seek refuge in a new home in eastern Europe, whither they carried their German speech (see YIDDISH LANGUAGE AND LITERATURE), but hardly any literary culture, so that their descendants had to start from a new basis. In Germany accounts of the disaster were written in a new prose style, permeated with poetry (see A. Neubauer and M. Stern, Hebraische Berichte, Berlin, 1892); liturgical poetry became henceforth mainly a chronicle of persecutions. These sufferings inspired an important mystical movement, which was influenced by Seadiah (in the old translation) and by contemporary Christian asceticism. Its teachings were largely transmitted through stories; the chief collections are the *Ma'aseh*

Book (tr. by M. Gaster, Philadelphia, 1934) and the Sefer *Hasidim* of Judah the Pious of Regensburg (d. 1217), who also wrote the Songs *of* Unity, mystical prayer-poems of great force (tr. in The Service *of* the Synagogue). Another mystic, Eleazar of Worms (1176–1238), composed the legal compendium Sefer *Mizwoth Gadol* (*"Semag"*) with a preface on asceticism.

The Jews of Angevin England belong entirely to French Jewry. They produced some works on halakhah and a grammatical treatise which betrays acquaintance with work done in Spain. Berakhyah ha-Nakdan, a French Jew who made a summary of Seadiah's philosophy (tr. by H. Gollancz, *Ethical* Treatises, London, 1902) and wrote a collection of "Fox Fables," may have lived for a time in England: he translated Adelard of Bath's *Quaestiones naturales* (ed. by H. Gollancz, London, 1920). See C. Roth, Intellectual Activities *of* Medieval English Jewry (British Academy Supplemental papers, viii).

Pethahiah of Regensburg, of the circle of Judah the Pious, described his travels to Russia and to the orient (German trans. by J. Griinhut, Frankfurt, 1905). Benjamin of Tudela (in Christian Spain) travelled in the years 1160–73 as far as India; his account gained lasting popularity (tr. by M. N. Adler, London, 1907). Though living in Toledo, Abraham ibn Da'ud (1110–80) adhered to northwestern European tradition in his histories of Rome, of the Second Temple (tr. by Peter Morvyn, 1561) and of the Oral Law.

"The Golden Age" in Spain, 900–1200.—Spanish Jewry began to flourish under the caliphate of Cordova (912–1002); the vizier Hasdai ibn Shaprut (c. 915–970/90) was the first Maecenas of Hebrew letters. His secretary Menahem ben Saruk wrote a biblical lexicon, which was trenchantly criticized by Dunash ben Labrat when the latter arrived from Baghdad and introduced in Spain the arabicized poetry that he had invented. The dispute was continued by their pupils. Already Samuel ha-Nagid, vizier of Granada (990–1jj), himself a poet (ed. by M. Habermann and M. Abramson, Jerusalem, 1947) and philologist, gathered around him a group of poets, most outstanding among whom was Ibn Gabirol (*q.v.*). Moses ibn Ezra of Granada (1060–1139) was the centre of the most brilliant circle of poets. He wrote in Arabic a history of Hebrew poetry and ars *poetica* (available only in a Hebrew tr. by B. Halper, Shirath *Yisra'el*, Leipzig, 1924). He wrote in his youth poems full of the joy of life (Selected Poems, trans. by S. Solis-Cohen, Philadelphia, 1934), later mainly penitential prayers. Like all earlier poets, he employed the Arabic metres and biblical idiom only for his secular poems, while his religious poetry followed patterns of *piyyut,* though its language, too, had by now become almost purely biblical. Moses' kinsman, Abraham, the poet, philosopher, grammarian and Bible-commentator, attacked the language and style of the early *paytanim* (comm. on Eccles. v, 1): he and Judah ben Samuel Halevi (*q.v.*) were the first to use the metres in religious poems.

This poetry was entirely dominated by Arab standards of taste. It dealt with the themes of Arabic poetry—friendship, love, drinking and self-praise—and often reproduced Arabic phrases. It was court-art, written to be appreciated by a small circle of connoisseurs. Except for the Odes to Zion of Halevi, they are mainly elegant expression of conventional sentiments. With the collapse of Jewish prosperity in Moslem Spain, this art lost its *raison d'être.* The last major poet in Spain was Judah al-Harizi (1165–123j), an important translator of philosophical works. He achieved the feat of translating al-Hariri's Maqamat into Hebrew (Mahberoth *Ithi'el,* ed. by T. Chenery, London, 1872; *cf.* J. Schirmann, Die hebraische *Uebersetzung* der *Maqamen,* Frankfurt, 1930). He then composed an original set of equally scintillating jeux *d'esprit, Tahkemoni* (partial German tr. by S. Kaempf, Prague, 1858). See F. Delitzsch, Zur Geschichte der judischen Poesie (Leipzig, 1836); J. M. Millás Vallicrosa, La Poesia *sagrada hebraicoespañola,* 2nd ed. (Madrid, Barcelona, 1940); H. Brody and M. Wiener, *Anthologia* hebraica (Leipzig, 1922), with a partial translation by C. de Mouilleron, *Poèmes hébreux* anczens (Limoges, 1947).

The use of Biblical Hebrew was made possible by the work of the philologists. The science of grammar began with the Massoretes (see BIBLE) whose system was followed by Seadiah and Rashi. Of great importance was the creation of comparative linguistics by Judah ibn Kuraish (ed. by D. B. Goldberg and J. J. L. Barges, Paris, 1857) and Isaac ibn Barun. Following the advances made by Arab grammarians, Judah Hayyuj, a disciple of Menahem ben Saruk, recast the system. In the form given to it by David Kimhi of Narbonne (1160–1235), the new system was taken over by the Christian humanists and through them by modern scholarship. The first complete Hebrew grammar, Kitab al-luma', was written by Ibn Janah of Cordova (990–1050). Like most of the Spanish grammarians, he wrote Arabic. All of them concentrated exclusively on Biblical Hebrew. The philological method was the principal feature of the Spanish Bible-commentaries, among which those of Abraham ibn Ezra and David Kimhi are the most important. See W. Bacher, Die hebraische *Sprachwissenschaft* (Trier, 1892); H. Hirschfeld, Literary History *of* Hebrew Crammarians and Lexicographers (London, 1926); L. Prijs, Die grammatikalische Terminologie des Abraham *ibn* Ezra (Basle, 1950).

While hardly any Jews wrote poetry in Arabic, the philosophers (often the same men as the poets) wrote only in Arabic. On the whole the Jewish writers were not so much concerned with creating general systems of philosophy—the only exception is Ibn Gabirol in his Fons Vitae—as with demonstrating the harmony between the Jewish faith and the system of philosophy accepted by their readers. Neoplatonists, like Ibn Gabirol, were Judah Halevi (*q.v.*) and Bahya ibn Paquda (fl. 1080), whose Duties of the Heart (French tr. by A. Chouraqui, Paris, 1950) is the Jewish counterpart to the Imitatio Christi and was equally influential. With the historian Abraham ibn Da'ud (see above), Aristotelianism came upon the scene (*Emunnah Ramah,* German tr. by S. Weil, Frankfurt-am-Main, 1852). The Guide (1190) of Maimonides (*q.v.*) already constitutes a new philosophy in some ways independent of Aristotle. It should be noted that all Arab and Jewish Aristotelians introduce some Neoplatonist elements into the master's system. See I. Husik, A History of Mediaeval Jewish Philosophy (New York, 1916); J. Guttmann, Die Philosophie des Judentums (Munich, 1933); J. Klatzkin, Anthologiah *shel* ha-philosophiah ha-'Ivrith (Berlin, 1926); Thesaurus philosophicus linguae hebraicae (Berlin, 1928–33).

Though, apart from Isaac Israeli (North Africa, *c.* 845–*c.* 940) and Maimonides, few Jews made original contributions to science, the Spanish Jews shared the best scientific education. Thus, when in the 11th century European scholars flocked to Toledo in order to translate Arabic scientific literature, they found learned Jews able to serve as interpreters. Among these, Abraham bar Hiyya Savasorda (*i.e.,* "chief of police"; d. *c.* 1136) of Barcelona was an original mathematician (he solved $x^2 + b = ax$) who wrote in Hebrew works on mathematics, astronomy and philosophy. including a scientific encyclopaedia (ed. by J. M. Millás Vallicrosa, Madrid, 1952) and the Liber Embadorum, a geometry textbook which in the Latin translation by Plato of Tivoli (1145) became "one of the fountainheads of European mathematics" (G. Sarton). There is little doubt that he wrote for the Jewish public of Provence and Languedoc; hence he also employed the late Mishnaic Hebrew current among them, not the biblical style of the Spanish writers of belles-lettres. The same style was also used by Abenezra.

When the Almohades expelled the Jews from Moslem Spain in 1148, many learned refugees came to Languedoc and Provence and were there invited by local groups to translate scientific and philosophical works. The most ,important translators were Judah ibn Tibbon (1120–90) and his son Samuel (1150–1230) at Lunel. By 1400 more than 100 translators had made available works by more than 150 authors, some in several renderings. This was much more than was at the disposal of Christian students. Often the Hebrew version was preserved when the Arabic original had disappeared. The translators coined hundreds of new technical terms, but also, at any rate to present taste, followed Arabic syntax and idiom too slavishly. See M. Steinschneider, Die hebraischen *Uebersetzungen* des Mittelalters (Berlin, 1893).

The Period of Retrenchment, 1200–1750.—This is the era of the ghetto, during which the area of western European Hebrew culture shrank to a remnant in Italy, while a new and entirely different culture arose in eastern Europe.

The Decline of Philosophy.—The appearance of the Hebrew ver-

sion of Maimonides' Guide (1204) provoked orthodox circles into opposition to all secular studies (cf. J. Sarachek, Faith and Reason; the *Conflict* over the Rationalism of Maimonides, i, Williamsport, Pa., 1932). Philosophy was defended by Shemtob Palquiera (d. c. 1290), author of an interesting propaganda pamphlet, The Searcher, and by the mathematician Levi ben Gerson (Gersonides, *q.v.*; 1288–1344), who wrote philosophical commentaries on the Bible. Hasdai Crescas (1340–1410) attacked philosophy by its own methods, using talmudic devices of argumentation (see H. A. Wolfson, Crescas' Critique of Aristotle, Cambridge, Mass., 1929). Dogmatic theology was popularized by the 'Zkkarim of Joseph Albo (1380–1444; tr. by I. Husik, Philadelphia, 1929–30).

Already Savasorda had delivered philosophical sermons in his Meditation of the Soul. Jacob Anatoli (fl. 1231) was the first to write such sermons to the whole Pentateuch (see I. Bettan, "The Sermons of Jacob Anatoli," Hebrew Union College Annual, xi, pp. 391–424, 1936). The most popular work of this genre is 'Akedath Yizhak by Isaac Arama (1440–1505).

Philosophy, midrash and mysticism are mixed in the ethical collectanea, generally ascetic in outlook, which soon became the "learning" of the semieducated. The oldest is Israel an-Nakawah's *Menorath* ha-Ma'or (ed. by H. G. Enelow, New York, 1929–35), elaborately classified according to virtues. It was, however, overshadowed by an imitation of the same title by one Isaac Aboab (German tr. by S. Bamberger, Hamburg, 1923). Equally popular remained Prince and *Hermit,* an adaptation by Abraham ibn Hasdai (d. 1240) of the Buddha story *Barlaam* and Josaphat (*q.v.*). The vanity of all earthly things was preached in elegant Biblical Hebrew by Jedaiah of Béziers (Yedaiah Bedaresi, 1270–1340) in his *Examination of the World* (tr. by T. Goodman, London, 1806).

The real reaction to Maimonidism, however, was the return of Neoplatonist mysticism, with an admixture of gnostic elements, in the form known as kabbalah. Beginning with the Pentateuch commentary of Moses Nahmanides (1194–1270), it culminated in the theosophy of the Zohar (c. 1290), which during the remainder of this period exercised an influence comparable only with that of the Bible and Talmud. See CABALA; also A. Neubauer and E. Renan, Les *Écrivains juifs français* du *14e siècle* (Paris, 1893).

The Final Codification of *Halakhah.*—Maimonides' code still remains the most systematic digest of Jewish law and ritual ever written. Though some Talmud students condemned the very idea of a code, another compendium, closer to Franco-German practice, was compiled by Jacob ben Asher (1269–1343), called *Arba' Turim* or simply Tur. Joseph Karo (or Qaro; 1488–1575), rabbi in Adrianople and later at Safed, digested in a commentary on the *Tur* all previous halakhic writings and decided all controversial matters; he then (1555) summed up his results in the *Shulhan* 'Arukh ("Well-laid Table"), which is always printed with glosses by Moses Isserles of Cracow (c. 1525–72) and is still, in this form, the authoritative guide to orthodox Jewish practice, though for present-day usage in everyday matters the *Kizzur* ("Abridgment") made in 1864 by S. Ganzfried (tr. by A. Goldin, 1928) should be consulted. Karo also left a diary recording mystical revelations granted to him by the personified Mishnah (cf. H. L. Gordon, The Maggid of Caro, New York, 1949).

Artistic Writing.—In Provence and Languedoc much poetry and rhymed prose was written, mostly nugatory displays of linguistic skill. The tradition remained alive until modern times among the Spanish exiles in North Africa and Turkey. Kabbalistic sexual symbolism brought back emotional poetry, a fine example of which is the Sabbath hymn Lekhah Dodi by Solomon Alkabez (Safed, 16th century; tr., Authorized Daily Prayer Book, p. 111). Israel Najara (1542–1619) used sensuous erotic images to describe Israel's relation to God in rhythms borrowed from popular airs (cf. M. Wiener, Die Lyrik der Kabbalah, Leipzig, 1920).

Though reduced to miniature scale in keeping with the size of the ghettos, western Hebrew culture was kept alive in Italy after the expulsion of the Jews from England (1290), from France (1326) and from Spain (1492) and remained in contact with contemporary Christian thought. Immanuel of Rome (c. 1270–c. 1330) exhibits in his picaresque *Mahbaroth* (ed. by M. Habermann, Tel Aviv, 1946) the influence of Dante (cf. Tophet and Eden, tr. by H. Gollancz, London, 1921). Isaac Abrabanel (*q.v.*) was fully conversant with European thought. Others, for example, Jacob Mantinus (d. 1549), acquainted the Latin reader with Jewish philosophy and Kabbalah. Azariah de' Rossi (1513–78) applied historical criticism to Jewish sources. Leon of Modena (1571–1648) rejected Kabbalah and perhaps more (cf. Simon Stern, Der Kampf des Rabbiners gegen den Talmud, Breslau, 1902). Poetry followed the developments of Italian taste. Judah Sommo (1527–92), author of an Italian handbook of drama, wrote the first Hebrew play (ed. by H. Schirmann, Jerusalem, 1946). The most gifted representative of this tradition was M. H. Luzzatto (*q.v.*), whose play La-Yesharim Tehillah was taken as a model by so many Haskalah authors. See C. Roth, History of the *Jews* of Italy (Philadelphia, 1946); J. Schirmann, Mivhar ha-shirah *ha-'ivrith be-Italiah* (Berlin, 1934).

The Marranos who after 1600 returned to Judaism and settled in Amsterdam were often highly educated and, though narrowly orthodox in religious matters, remained in close contact with happenings in general literature. Their own culture is typified by Menasseh ben Israel (*q.v.*). Their artistic writing followed Italian models: for example the allegorical drama Prisoners *of* Hope by Joseph Penço (1650–92). D. F. Mendes (1713–92) combined Racine's *Athalie* and Metastasio's *Gióas* into one Hebrew play. See J. Melkman, David *Franco* Mendes (Amsterdam, 1951), for a general survey of Dutch-Jewish culture at this time.

Eastern Europe and the Religious *Crisis.*—In the kingdom of Poland (which then extended from Lithuania to the Black sea) refugees from German persecution mingled with earlier Byzantine emigrés to create, by the 15th century, a prosperous Jewry with extensive autonomy.. Their culture was not a continuation of western European Hebrew civilization, but a new creation. The Bible (except for the Pentateuch) was neglected, while the Babylonian Talmud—hitherto studied only by specialists—became the basis of all intellectual life, particularly since the *pilpul* method of Jacob Pollak (1460–1541) had turned its study into an exciting form of mental gymnastics. The typical literature consisted of novellae (*hiddushim*), ingenious discussions of talmudic minutiae written in an ungrammatical mixture of Hebrew and Aramaic. Imaginative literature existed only in Yiddish, for women and the uneducated.

The expulsion from Spain in 1492 produced a wave of messianic emotion. Kabbalah flourished in the new Palestinian centre, the meeting place of Spanish, European and oriental Jews. There, in 1570–72, Isaac Luria (*q.v.*) created a cosmic messianism. Though its formulation, in the writings of Hayyim Vital (1543–1620), was abstruse and esoteric, its phraseology penetrated the widest masses, as a result of the introduction of Kabbalistic prayers, and coloured all later Hebrew writing. Luria's teachings were developed by the false messiah Sabbatai Sebi (see SABBATAI ZEBI) in the next century, for and against whom a vast literature was written.

The sufferings of Polish Jewry in the Cossack massacres of 1648—described in a long poem by the talmudist Yomtob Lippmann Heller (1579–1654)—opened their country to Lurianic mysticism. Out of popular Kabbalistic elements, Israel Ba'al Shem Tov in Podolia (1700–60) produced Chasidism (Hasidism). His teaching, like that of his successors, was oral and, of course, in Yiddish; but it was noted by disciples in a simple, colloquially flavoured Hebrew. Since they taught mainly through parables, there is here a beginning of the Hebrew short story. Indeed these narratives exercised, and still exercise, a profound influence on Modern Hebrew writers. See L. I. Newman and Samuel Spitz, The Hasidic Anthology (New York, London, 1934); and M. Buber, *Hundert* Chassidische Geschichten (Berlin, 1935), Geschichten des Rabbi Nachman (Frankfurt, 1906) and other works.

The **Haskalah Period,** 1750–1880.—Chasidism rapidly spread over all eastern Europe except Lithuania. There the Gaon Elijah of Wilna (1720–97), a writer of unusually wide scope, advocated a better-graded course of talmudic training and a modicum of secular studies; he himself wrote a handbook of mathematics. Shne'ur Zalman of Ladi (1747–1812) created the highly systematized and elaborate *Habad* Chasidism which was widely accepted in Lithuania. The Mussar movement of Israel Salant (1810–83) encouraged the study of the mediaeval ethical writers.

In the Berlin of Frederick the Great, young intellectuals from Poland and elsewhere, brought in as teachers by the families of wealthy "privileged" Jews, met the representatives of European enlightenment. They came under the influence of Moses Mendelssohn (*q.v.*), but they also met some representatives of Italian-Dutch Hebrew culture. One was the Dane N. H. Wessely (1725–1805), a friend of D. F. Mendes, who wrote several works on the Hebrew language and an epos on the life of Moses. The other. the Italian S. A. Romanelli (1757–1814), a much more modern personality then Wessely, wrote and translated plays; he is notable for an amusing account of his stay in Morocco. Out of these contacts grew Haskalah (perhaps best translated as "cultivation of the mind"), a moderate tendency toward westernization that retained a somewhat rationalist Jewish orthodoxy and contained as an essential element the veneration of Hebrew and of mediaeval western Jewish literature. Its ideals were expressed by the periodical *Ha*-Me'assef (1784–1811, with long interruptions). Wessely's program for the paper banned love poems, mention of classical deities and criticism of the Jewish religion. In fact, it contained principally translations of German poems and book reviews. Among German Jews, then already in a rapid process of germanization, this Hebrew movement had no place. Only in Breslau — which until recently had been part of eastern Europe — it continued for another generation. There a young Hungarian student, M. Kunizer, wrote in 1796 a historical character play (Beth Rabbi, published in Vienna, 1805), and David Samosz (1789–1864) published in 1821 and 1829 two short plays about contemporary Jewish life.

To Galicia, a centre of Chasidism, the Enlightenment was somewhat brusquely introduced by the Toleranzedikt (1782) of the emperor Joseph II. By supporting some of its aims, the Hebrew writers incurred hatred and persecution. Their chief weapon was satire. The imitation by J. Perl (1773–1839) of the Epistolae obscurorum *virorum* and the essays of I. Erter (1791–1851) are classics of the genre. There was only one poet, M. Letteris (1800–71), and one dramatist, N. I. Fischman (1800–75), who wrote two interesting biblical plays. Galicia's chief contribution was to the Judische Wissenschaft, a school of historical research with romanticist leanings. Its centre was in Germany (see ZUNZ, LEOPOLD), but the Galicians N. Krochmal (*q.v.*) and the biographer S. J. Rappoport (1790–1867) employed Hebrew, thereby gaining a much wider popular audience for their writings. Several excellent semi-learned periodicals appeared in Vienna. See M. Weissberg, Die neuhebraische Aufklarungsliteratur in *Galizien* (Leipzig, Vienna, 1898); B. Wachstein et al., Die hebruische Publizistik in Wien, 3 pt. (Vienna, 1930).

The impact of Haskalah ideas upon the humanistic Italo-Hebrew tradition produced a short literary renaissance. Its main connections were with the Jiidische Wissenschaft, to which I. S. Reggio (1784–185j) materially contributed. S. D. Luzzatto (1800–65), a prolific essayist, philologist, poet and letter writer, became prominent by his philosophy of Judaism, which he opposed as a superior form of human life to an amoral and rationalist "Atticism"; this led him to reject also all rationalist forms of Judaism. The poetess Rachel Morpurgo (1790–1871) strikes some remarkably modern chords. See Luzzatto's Discorsi storico-religiosi (Padua, 1870) and *Autobiografia* (Padua, 1882).

For the Jews of the Russian empire the Enlightenment may be said to have begun with I. B. Levinsohn (1788–1860) in the Ukraine and with M. A. Ginzberg (1795–1846) in Lithuania, who spread general knowledge and discussed religious questions in Hebrew. In the 1820s an orthodox reaction against such activities set in; it coincided with the rise of a romanticist Hebrew school of writers. A. D. Lebensohn (Adam ha-Cohen, 1794–1878) wrote fervent love songs to the Hebrew language. His son Micah Joseph (Mikhal, 1828–52), the most gifted pdet of the Haskalah period, wrote biblical romances and pantheistic nature lyrics. The first Hebrew novel, The Love of Zion by A. Mapu (1808–67), was a romantic idyll, which however had a powerful effect just because of the difference between the conditions that it depicted and the squalor of Jewish life (tr. by F. Jaffe, 1887). Mapu's second novel, The Guilt of Samaria, is in the grandiose manner. Like all Haskalah writers, he employed the melizah style; *i.e.,* phrases culled from the Bible and more or less ingeniously adapted to the thought that the writer wished to express.

The Realist *Movement.*—Mapu's third novel, The Hypocrite (1857–69) marks a new departure: it deals with contemporary life and attacks its social evils; and it portrays a new type, the *maskil* (possessor of Haskalah) in his fight against orthodox obscurantism. His last novel, The Visionary, which intended to expose Chasidism, was banned. The new, aggressive Haskalah soon came under the influence of Russian left-wing writers such as N. G. Chernyshevsky and Dmitry Pisarev. Literary criticism began. In 1867 A. D. Lebensohn published his 20-year-old allegorical drama Truth and Faith, but times had changed, and A. J. Paperno (1840–1919) rejected it as out-of-date, not least on account of its *melizah* style. Like Mapu. J. L. Gordon (1830–92) had started as a romantic writer on biblical subjects. From 1871 onward he produced a series of ballads exposing the injustices of traditional Jewish life. M. L. Lilienblum (1843–1910) began as a moderate religious reformer — his struggle with orthodoxy is the theme of the novel Religion and Life by R. A. Braudes (1851–1902) — but later became absorbed by social problems: in the Mishnah of *Elisha* ben Abuyah (1878) be used the figure of the heretic friend of Rabbi 'Akiba to preach a Jewish socialism. Later Lilienblum became a Zionist. P. Smolenskin (1840–85) created in six novels a kaleidoscope of Jewish life in which he rejects the westernized Jew as much as the orthodox reactionaries.

Modern Hebrew Literature. — If thus the realists had become impatient with Haskalah ideals, the Russian pogroms seemed to demonstrate the futility of its aims. That part of eastern European Jewry which read Hebrew books (*i.e.,* the middle classes) turned to Jewish nationalism. Zionist activity, coupled with the movement for speaking Hebrew which was started *c.* 1880 by Eliezer Ben-Jehudah (E. Perelman, 1857–1922), widened the circle of Hebrew readers. Hebrew daily papers began to appear in 1886. Writers abandoned *melizah* for a blend of Biblical and Mishnaic Hebrew with extensive borrowings from the mediaeval translators, as well as from European languages. The new character of Hebrew was symbolized by Ben-Jehudah's lexicon Thesaurus *totius* hebraitatis, which includes words from all periods.

S. J. Abramovich (1835/6–1917), who wrote under the pseudonym Mendele Mokher Sefarim ("Mendele the Itinerant Bookseller"), holds a key position in the transition to modern writing. His first novel (1868) was inspired by Ivan Turgenev. He soon became convinced that the Biblical Hebrew of the Haskalah was unsuitable for modern subjects and turned to writing in Yiddish. From 1886 onward he went back to Hebrew, into which he also translated his Yiddish stories. By extensive use of Hebrew and Aramaic phrases from the Talmud (without abandoning the Biblical vocabulary) he matched the homeliness of Yiddish and conveyed the atmosphere of Jewish life to perfection. In his stories life was, for the first time, depicted as it really was, with a warm humour that made the basically critical attitude of the author acceptable. Since the study of the Talmud was the chief education in traditional circles, Mendele's talmudic style and more positive attitude to traditional values attracted a much wider circle of readers than Haskalah literature had ever possessed. The fact that the life that Mendele described was rapidly disappearing added a nostalgic appeal. Stories of ghetto life remained the most characteristic and fertile genre of Hebrew literature until the middle of the 20th century. His *Fishke* the Lame is translated by A. S. Rappoport (London, 1928).

The *National* Revival. — "Grandfather Mendele" became the spiritual mentor of a galaxy of exceptionally gifted writers at Odessa. This group holds a position similar to that of J. W. von Goethe and J. C. F. von Schiller in German literature. Asher Ginzberg (1856–1927) wrote from 1889 onward, under the pen name of Ahad Haam ("One of the People"), a series of articles in which he brought modern sociological thought to bear upon Jewish affairs and evolved a philosophy of secular Jewish nationalism and of a "cultural centre in Palestine. His style, based largely upon the mediaeval translators, was European in spirit. In his monthly *Hashiloah* (founded 1896) he applied editorial standards hitherto unknown in Hebrew. During his stay in London (1907–21) he

inspired a minor Hebrew renaissance in England. In Tel Aviv from 1921, he devoted his last years to the edition of his correspondence, a valuable documentary of a vital period (1,700 letters, 6 vol., Jerusalem, 1923–25). See his complete works, Am Scheidewege, tr. by I. Friedlander and H. Torczyner (Berlin, 1923 et seq.); for Eng. tr., by L. Simon, see Selected Essays (Philadelphia, 1912), Ten Essays (London, 1922) and Essays, Letters, Memoirs (New York and London, 1947); see also N. Bentwich, *Ahad* Ha-am and his Philosophy (London, 1927).

Much influenced by Ahad Haam (he was for a time literary editor of Hashiloah) was H. N. Bialik (*q.v.*). Bialik was an important essayist, editor and anthologist of mediaeval literature and, during his stay in Palestine (1924–34), an arbiter on linguistic matters. His main role, however, was that of the "national poet," whose poems gave expression to the inner struggles of a generation much concerned about its attitude to Jewish tradition and who, in some of his utterances, reached an almost prophetic intensity. See his Complete Poetic Works, tr. and ed. by I. Efros (New York, 1948); also the autobiographical Aftergrowth, and Other Stories, tr. by I. M. Lask (Philadelphia, 1940).

In sharp contrast with Bialik, Saul Chernikhovsky (1875–1943) was unconcerned with the burden of tradition. Born in the Crimea, he studied in Germany and, from 1931, lived in Palestine. His poems, in strongly Biblical language, deal with the nature of these three countries, with love and with beauty. He was attracted by Greek culture and inspired by the gods of ancient Canaan. Where he touches upon Judaism, his approach is secular and militant, yet he lovingly depicted Russian-Jewish village life in a series of idylls. He translated the Iliad, the Odyssey, Hiawatha and many other works of world literature into Hebrew and did important work to establish the medical and scientific vocabulary of Hebrew. See his complete works, 10 vol. (Berlin, 1930); his poems (Jerusalem, 1948); and L. V. Snowman, Tchernichovski and His Poetry, With Renderings From the Hebrew (London, 1929).

The short stories of J. L. Peretz (1851–1915), who wrote both in Hebrew and Yiddish, introduced the Chasidic milieu into literature. The emotionalism and simple joy-of-life of that milieu henceforth exercised a powerful influence upon Hebrew artistic writing, and the language absorbed many Chasidic terms. His works include: *Jüdische* Geschichten, German tr. by A. Eliasberg (Leipzig, n.d.); Bontshe the Silent, tr. by A. S. Rappoport (London, 1927); The Three *Gifts,* tr. by M. Fine (London, 1946); and Stories and Pictures, tr. by H. Frank (Philadelphia, 1906).

The "New Trend." — Already Bialik sensed the conflict between the demands of Judaism and the natural instincts and needs of the Jew. This psychological interest dominates the work of a group of short-story writers, outstanding among whom is the literary critic D. Frischman (1860–1922) who did more than anyone to impose European standards on Hebrew literature. In In the Desert he projects the conflict back into Moses' time. M. J. Berdichevsky (1865–1921), in a neoromantic vein, idealized in his stories the uneducated manual worker, the pariah of traditional society. It was the literary historian R. Brainin (1862–1939) who discerned the presence of a "new trend" (ha-mahalakh he-hadash) and postulated *l'art* pour *l'art* and concentration on generally human problems.

The Emigre' Writers. — With this, Hebrew literature became fully co-ordinated with European tendencies. However, the next generation of writers were uprooted by the two Russian revolutions, emigrated to western Europe and gradually drifted to Palestine. The U.S.S.R. at first favoured Hebrew culture but then banned it (*cf.* W. Blattberg, The Story of the Hebrew and Yiddish *Writers* in the Soviet Union, New York, 1953); in other eastern European countries the culture decayed with the deterioration of the Jewish position; and many writers were killed by the Germans after the rise of Adolf Hitler. The writing of the emigre' generation is profoundly pessimistic. A hopeless rootlessness is the keynote of the stories of U. N. Gnessin (1880–1913) and J. H. Brenner (1881–1921); the delicate thumbnail sketches of G. Schofmann (1880–) are pervaded by perplexity; Z. Shne'ur (1887–1959) sings of revolt and desperate passion.

Palestinian Literature. — Almost all writers active in Palestine before 1939 were born in the Diaspora. An exception was J. Burla (1888–), an oriental whose novels deal with oriental Jewry. The Palestinian milieu with its colourful types attracted the attention of other writers. too: notably D. Shim'oni (1886–1956), whose idylls describe the agricultural chalutz immigrants; and A. Smilansky (1874–1953), whose stories are inspired of Arab life. The majority of Palestinian writers, however, were more concerned with nostalgic descriptions of life in eastern Europe or with the past — as for instance was A. A. Kabak (1881–1945), author of an especially interesting novel on the life of Jesus, In the Narrow Path.

The transition from the ghetto to Palestine was achieved only by few, among them being A. Barash (1889–1952), who after many stories and novels on life in Galicia wrote descriptions of the early struggles of Palestinian Jewry. This preoccupation with the early stages of the new life is also marked in the later work of S. J. Agnon (1888–), the outstanding Hebrew prose writer of his generation. Agnon developed an original Hebrew narrative style by going back to the midrash and the popular stories and ethical writings of earlier centuries. While his earlier stories were set in Galicia, he began in the 1940s to write about Palestine. At a still later stage the Kafkaësque atmosphere, found already in some of his early stories, became predominant in short sketches set in contemporary Israel. See his Buch von den *polnischen Juden* (Berlin, 1916); In der Gemeinschaft der Frommen, tr. by N. N. Glatzer and G. Scholem (Berlin, 1933); and the English translations by I. M. Lask, The Bridal Canopy (New York, 1937), Land of Israel Earth (Jerusalem, 1942), In the Heart of the Seas (New York, 1948).

Although the writers were hesitant to grapple with contemporary life, the Hebrew-speaking surroundings exercised an influence upon their style, which became more natural and expressive. The translation of world literature became a pressing need, occupying many first-class writers, and did much to increase the suppleness of the language. Poetry, especially, was profoundly changed by the transition from the Ashkenazi pronunciation with its penultimate stress to the Palestinian pronunciation with its alternation of stress positions.

In contrast with prose, poetry immediately concerned itself with Palestinian life. Among a large number of good writers, mention should be made of Rachel (R. Blovstein, 1890–1931) whose intensely personal poems, many of which have been set to music, are universally beloved; U. Z. Greenberg (1894–), a political poet whose *vers libre* reaches almost prophetic grandeur; and the symbolist school led by A. Shlonsky (1900–). See D. Vardy, The New Hebrew Poetry (Tel Aviv, 1947).

World War II and the Arab-Israeli war of 1948–49 brought to the fore numerous "Sabra" (Palestinian-born) writers who deal, in a racy and ever more difficult Hebrew, almost exclusively with the problems of their own milieu. Among the published diaries of youngsters who fell in the war are some of considerable literary merit. See J. Melkman, En een geslacht Komt (Amsterdam, 1952); Judd L. Teller, "Modern Hebrew Literature of Israel," Middle East Journal, vii (Washington. D.C., 1953).

Hebrew Literature in the United States. — After World War I, U.S. Jewry began to develop a school of Hebrew writers of its own, including novelists, poets and essayists. At first a scion of the emigre' school, it drew closer to Israeli style, while at the same time undergoing U.S. influence. There is also a number of important scholarly works in Hebrew. Various literary periodicals and even a Hebrew medical journal exist. See M. Ribalow, Anthology of Hebrew Poetry in America (New York, 1938); A. Epstein, *Soferim* 'ivrim be-Amerikah (Jerusalem, 1953).

BIBLIOGRAPHY. — G. Karpeles, *Geschichte* der jiidischen Literatur, 2nd ed. (Berlin, 1909); M. Waxman, A History of Jewish Literature from the Close *of* the Bible to Our Own Days, 2nd ed., 4 vol. (New York, 1938–47); E. L. Dietrich, in Handbuch der Orientalistik, iii, 1 (Leyden, 1953). The histories of the Jews by H. Graetz (*q.v.*) and S. Dubnow (German trans., 10 vol., Berlin, 1925–29) deal with many literary figures. For information on authors, etc., see The Jewish Encyclopaedia (New York, 1901–06) and the German Encyclopaedia *Judaica* (A-L, 11 vol., Berlin, 1928 et seq.). See also A Marx, Essays in Jewish Biography (Philadelphia, 1948); S. Schechter, Studies in Judaism (London, 1938). A valuable reference work is S. Shunami, Bibliography of Jewish Bibliographies (Jerusalem, 1936; London,

1937). Anthologies: J. Winter and A. Wiinsche, *Die jüdische Literatur*, 3 vol. (Trier, 1891–96); B. Halper, *Post-Biblical Hebrew Literature* (Philadelphia, 1921); L. I. Feuer and A. Eisenberg, *Jewish Literature since the Bible* (Cincinnati, 1937–41).

Haskalah and Modern Literature.—The standard work is J. Klausner, *Historiah shel ha-Sifruth ha-'Ivrith ha-Hadashah*, 6 vol. (Jerusalem, 1930–50). Other major Hebrew works are P. Lachover, *Toledoth ha-Sifruth ha-'Ivrith ha-Hadashah*, 3 vol. (Tel Aviv, 1929–48), and A. Orinowski, *Toledoth ha-Sifruth ha-'Ivrith ha-Hadashah* (Tel Aviv, 1946–). Volumes iii and iv of Waxman's *History* deal with this period. For introduction: J. Klausner, *A History of Modern Hebrew Literature* (London, 1932); S. Spiegel, *Hebrew Reborn* (New York and London, 1930); S. Halkin, *Modern Hebrew Literature, Trends and Values* (New York, 1950); J. S. Raisin, *The Haskalah Movement in Russia* (Philadelphia, 1913). Anthologies: A. Barash, *Mivhar ha-shirah* (Jerusalem, 1938); P. M. Raskin, *Anthology of Modern Jewish Poetry* (New York, 1927). The semiannual *Israel Argosy* (Jerusalem) contains translations of contemporary prose. (C. RN.)

HEBREW RELIGION. The Hebrews were western Semites, and from the Semites sprang Judaism, Christianity and Islam (or Mohammedanism) (*qq.v.*).

By Judaism is meant the religion of the Jews (*i.e.*, properly "Judaeans") based upon the Old Testament. There are, however, striking differences within the Old Testament; *e.g.*, between the piety of the Psalms, the pessimism of Ecclesiastes and the eroticism of Canticles, or between the popular stories in Genesis and the priestly ritual in Leviticus. Moreover, it is instructive to compare and contrast the treatment of the history of the monarchy in Samuel–Kings with the parallel portions in Chronicles.

Further, the prophets condemn the polytheistic and degrading cults of the Israelite religion of their day, although the Israelites felt that they stood apart from their neighbours, whether Canaanites within the land or other peoples without: Edom, Ammon, etc. In fact, "Israel" is a much more restricted term than "Hebrew" (see JEWS). Israel, which strictly includes both Judah and the northern tribes (Joseph, Ephraim, etc.), was closely related to Edom (its "brother"), Moab and Ammon, the Aramaeans of north Syria and the Arabs of the desert. Hence, while the Old Testament (with the religion of Israel) led to both Judaism and Christianity, one must not ignore the religious beliefs and practices over the larger world of which Israel formed part. The ideas which made the monotheistic religion of Israel unique are best appreciated when it is seen how they developed, now in touch with and now in reaction against, the contemporary religions.

By Hebrew religion, therefore, we mean the religion of the Hebraic background upon which Israel grew up and developed its monotheism, and which extends outside the chronological limits of the Old Testament. (See BIBLE: *Old* Testament; JUDAISM.)

HEBREWS, EPISTLE TO THE, a book of the New Testament.

In the oldest manuscripts it bears no other title than "To Hebrews." This brief heading embraces all that on which Christian tradition from the end of the and century was unanimous; and it says no more than that the readers addressed were Christians of Jewish extraction. This would be no sufficient address for an epistolary writing (xiii, 22) directed to a definite circle of readers, to whose history repeated reference is made and with whom the author had personal relations (xiii, 19, 23). Probably, therefore, the original and limited address, or rather salutation, was never copied when this treatise in letter form, like the epistle to the Romans, passed into the wider circulation which its contents merited.

Authorship.— In the earlier manuscripts it is anonymous; and the Roman church, where the first traces of the epistle occur, about A.D. 96 (1 Clement), and which was in constant connection with provincial churches, was at a later date sure only that it was not by Paul (Euseb., *Eccl.* Hzst., iii, 3). The Alexandrine tradition, on the other hand, dwells on its affinities to Paul's thought. Origen implies that "the men of old" regarded it as Paul's. But he feels that the language is un-Pauline, though the "admirable" thoughts are not second even to Paul's. Thus he is led to the view that the ideas were orally set forth by Paul, but that the written form was attributable to some one's giving free interpretation of his mind. According to some this was Clement of Rome; others named Luke; but the truth, says Origen, is known to God alone. (Euseb., vi, 25; cf. iii, 38).

From the time of Origen the theory of Paul's own authorship became prevalent in the east. The earliest North African tradition, preserved by Tertullian (*De pudicitia*, c, 20) but hardly invented by him, ascribed the epistle to Barnabas. Yet it was probably only an inference, as if this "word of exhortation" (xiii, 22) must needs be by the Son of Exhortation (Acts iv, 36; *see* BARNABAS). On the whole, then, the earliest traditions in east and west alike agree that it was not by Paul but by one of his associates.

This is also the result reached by modern scholarship. Following the lead of Erasmus, Luther (who suggests Apollos) and Calvin added the decisive argument that Paul, who lays such stress on the fact that his gospel was not taught him by man (Gal. i), could not have written Heb. ii, 3. And since the revival of the historical sense, more than a century ago, opinion has set irrevocably against Pauline authorship. Its type of thought is really different. The Jewish law is viewed not as a code of "works of righteousness," as by Paul, but as a system of religious rites (vii, 11) shadowing forth the way of access to God in worship, of which the Gospel reveals the archetypal realities (ix, 1, 11, 15, 23 *et seq.*; x, 1 *et seq.*, 19 *et seq.*). The old and the new Covenants are related to one another as imperfect (earthly) and perfect (heavenly) forms and methods of salvation—differing in point of spiritual reality—each with its own type of sacrifice and priesthood. Thus the conception of Christ as high priest emerges, for the first time, as a central point in Christianity. The Old Testament is cited after the Alexandrian version more exclusively than by Paul, even when the Hebrew differs. Nor is this accidental. The author was, in fact, a Hellenist who lacked knowledge of the Hebrew text and derived his metaphysic and his allegorical method from the Alexandrian rather than the Palestinian schools.

Yet the epistle has Pauline affinities and can hardly have originated beyond the Pauline circle, to which it is related not only by the author's friendship with Timothy (xiii, 23) but by many echoes of the Pauline theology and even, it seems, of passages in Paul's epistles (*see* Holtzmann, *Einleitung in das N.T.*, p. 298 [1892]). Everything turns, then, on internal criticism of the epistle, together with such personal allusions as it affords.

Readers.—As to its first readers, with whom the author stood in close relations (xiii, 19, 23; *cf.* vi, 10; x, 32–34), it used to be agreed that they were "Hebrews" or Christians of Jewish birth. But this cannot be inferred simply from the fact that the epistle approaches Christian truth through Old Testament forms. That was the common method since the Jewish scriptures were the word of God to all Christians alike.

Still the exclusive use of the argument from Mosaism, as itself implying the Gospel of Jesus the Christ as final cause (τέλος), does favour the view that the readers were of Jewish origin. Further, there is no allusion to the incorporation of "strangers and foreigners" (Eph. ii, 19) with the people of God. Yet the readers are not to be sought in Jerusalem (see, *e.g.*, ii, 3), nor anywhere in Judaea. The whole Hellenistic culture of the epistle (let alone its language) and the personal references, notably that to Timothy in xiii, 23, are against any such view. Caesarea, as a city of mixed population and lying just outside Judaea proper, would satisfy many conditions of the problem. Yet these might exist among other members of the Dispersion, like "the Jews of Asia" whose zeal for the Temple and the Mosaic ritual customs led to Paul's arrest in Jerusalem (Acts xix, 27 et seq.; cf. 20 et seq.). The dispersed Christian Jews, who kept in touch with the Temple by annual contribution to its services, would tend to continue their reliance on those services for the forgiveness of their recurring "sins of ignorance" even after the great initial messianic forgiveness coming with faith in Jesus. Accordingly many of them, while placing their hope for the future upon Messiah and His return in power, might seek continuous cleansing of conscience in the old mediatorial system.

In particular the annual Day of Atonement might be relied on, and that in proportion as the expected Parousia tarried and the first enthusiasm of a faith that was largely eschatological died away, while ever-present temptations pressed the harder as disappointment and perplexity increased.

Its Argument.— Such was the general situation of the readers, men who rested partly on the Gospel and partly on Judaism. For lack of a true theory as to the relation between the two, they were now drifting away (ii, 1) from effective faith in the Gospel, as being mainly future in its application, while Judaism was a very present, concrete and impressive system of religious aids—to which also their sacred scriptures gave constant witness. The points at which it chiefly touched them may be inferred from the author's counterargument, with its emphasis on the spiritual ineffectiveness of the whole Temple system, its high priesthood and its supreme sacrifice on the Day of Atonement. With passionate earnestness he sets over against these his constructive theory as to the efficacy, the heavenly yet unseen reality, of the definitive "purification of sins" (i, 3) and perfected access to God's inmost presence, secured for Christians as such by Jesus the Son of God (x, 9–22); and traces their moral feebleness and slackened zeal to want of progressive insight into the essential nature of the Gospel as a "new Covenant," moving on a totally different plane of religious reality from the now antiquated Covenant given by Moses (viii, 13).

The following plan of the epistle may help to make apparent the writer's theory of Christianity as distinct from Judaism, which is related to it as "shadow" to reality:

Thesis: The finality of the form of religion mediated in God's Son, i, 1–4.

i. The supreme excellence of the Son's Person (i, 5–iii, 6), as compared with (a) angels, (b) Moses.
Practical exhortation, iii, 7–iv, 13, leading up to:

ii. The corresponding efficacy of the Son's high priesthood (iv, 14–ix).
1. The Son has the qualifications of all priesthood, especially sympathy.
Exhortation, raising the reader's thought to the height of the topic reached (v, 11–vi, 20).
2. The Son as absolute high priest, in an order transcending the Aaronic (vii) and relative to a Tabernacle of ministry and a Covenant higher than the Mosaic in point of reality and finality (viii, ix).
3. His sacrifice, then, is definitive in its effects (τετελείωκε) and supersedes all others (x, 1–18).

iii. Appropriation of the benefits of the Son's high priesthood, by steadfast faith, the paramount duty (x, 19–xii). More personal epilogue (xiii).

As lack of insight lay at the root of their troubles, it was not enough simply to enjoin the moral fidelity to conviction which is three parts of Faith to the writer, who has but little sense of the mystical side of faith so marked in Paul. There was need of a positive theory based on real insight, to inspire faith for more strenuous conflict with the influences tending to the apostasy from Christ, and so from "the living God," which already threatened some of them (iii, 12). Such "apostasy" was not a formal abjuring of Jesus as Messiah, but the subtler lapse involved in ceasing to rely on relation to Him for daily moral and religious needs, summed up in purity of conscience and peace before God (x, 19–23; xiii, 20 et seq.).

This "falling aside" (vi, 5; cf. xii, 12 et seq.), rather than conscious "turning back," is what is implied in the repeated exhortations which show the intensely practical spirit of the whole argument, These exhortations are directed chiefly against the dullness of spirit which hinders progressive moral insight into the genius of the new Covenant (v, 11–vi, 8). The antidote to such "profane" negligence (ii, 1, 3; xii, 12 et seq., 15–17) is an earnestness animated by a fully assured hope and sustained by a "faith" marked by patient waiting (μακροθυμία) for the inheritance guaranteed by Divine promise (x, 11 et seq.). The outward expression of such a spirit is "bold confession" and mutual encouragement therein (iii, 6, 12 et seq.); while the sign of its decay is neglect to assemble together for mutual stimulus, as if it were not worth the odium and opposition from fellow Jews called forth by a marked Christian confession (x, 23–25; xii, 3)—a very different estimate of the new bond from that shown by readiness in days gone by to suffer for it (x, 32 et seq.).

Their special danger, then, the sin which deceived (iii, 13) the more easily that it represented the line of least resistance (perhaps the best paraphrase of "the besetting sin" in xii, 1), was the exact opposite of "faith" as the author uses it, especially in the chapter of Old Testament illustrations, and of which Jesus Himself was at once the example and the inspiration (xii, 2 *et* seq.). To quicken this by awakening deeper insight into the real objects of "faith," as these bore on their actual life, he develops his high argument on the lines already indicated.

The Special Situation.— Their situation was so dangerous just because it combined inward debility and outward pressure, both tending to the same result; viz., practical disuse of the distinctively Christian means of grace, as compared with those recognized by Judaism, and such conformity to the latter as would make the reproach of the Cross to cease (xiii, 13; *cf.* xi, 26). But the practical surrender of what was distinctive in their new faith meant a theoretic surrender of the value once placed on that element, when it was a living religious experience far in advance of what Judaism had given them (vi, 4 et *seq.;* x, 26–29). This twofold infidelity, in thought and deed, God, the "living" God of progress from the "shadow" to the substance, would yet visit (x, 30 et seq.; xii. 22–29). For it meant turning away from an appeal that had been known as "heavenly," for something inferior and earthly (xii, 25); from a call sanctioned by the incomparable authority of a greater than Moses and all media of the old Covenant, even the Son of God.

Thus the key of the whole exhortation is struck in the opening words, which contrast the piecemeal revelation. "to the fathers," in the past, with the complete and final revelation to themselves in the last stage of the existing order, in a Son of transcendent dignity (i, 1 et seq.; cf. ii, 1 et seq.; x, 28 et seq.; xii, 18 et *seq.*). This goes to the root of their difficulty, ambiguity as to the relations of the old and the new elements in Judaeo-Christian piety, so that there was danger of the old overshadowing the new, since national Judaism remained hostile. At a stroke the author separates the two. There is no use, religiously, in falling back upon the old forms, in order to avoid the social penalties of a sectarian position within Judaism, when the secret of religious "perfection" or maturity (vi, 1; cf. the frequent use of the kindred verb) lies elsewhere.

Hence the moral of his whole argument as to the two Covenants, though it is formulated only incidentally amid final detailed counsels (xiii, 13 et seq.) is to leave Judaism and adopt a purely Christian standing on the same footing with their non-Jewish brethren in the local church. For this the time was now ripe; and in it lay the true path of safety—eternal safety as before God, whatever man might say or do (xiii, 5 et seq.). The obscure section xiii, g et *seq.,* is to be taken as "only a symptom of the general retrogression of religious energy" (Jiilicher) and not as bearing directly on the main danger of these "Hebrews." The "foods" in question probably refer neither to temple sacrifices nor to the Levitical laws of clean and unclean foods, nor yet to ascetic principles, but rather to some form of the idea, found also among the Essenes, that food might be so partaken of as to have the value of a sacrifice and thus ensure divine favour.

Over against this view, which might well grow up among the Jews of the Dispersion as a sort of substitute for the possibility of offering sacrifices in the Temple—but which would be a lame addition to the Christianity of their own former leaders—the author first points his readers to its refutation from experience and then to the fact that the Christian's "altar" or sacrifice (*i.e.,* the supreme sin-offering) is of the kind which the law itself forbids to be associated with "eating." If Christians wish to offer any special sacrifice to God, let it be that of grateful praise or deeds of beneficence.

External Occasion.— In trying further to define the readers addressed one must note the stress laid on suffering as part of the divinely appointed discipline of sonship (ii, 10; v, 8; xii, 7 et seq.), and the way in which the analogy in this respect between Jesus, as messianic Son, and those united to Him by faith, is set in relief. He is both the inspiring example for heroic faith in the face of unbelievers (xii, 3 et seq.) and the mediator qualified

by experience of suffering to sympathize with His tried followers, and so to afford them moral aid (ii. 17 seq., v. 8 seq., cf. iv. 15). This means that suffering for Christianity, at least in respect of possessions (xii. 5 seq, cf. x. 34), was imminent for those addressed; and it seems as if they were mostly men of wealth and position (xiii. 1–6, vi. 10 seq., x. 34). Such would also possess a mental culture (cf. v. 11 seq.) capable of appreciating the form of an epistle "far too learned for the average Christian" (Jiilicher), yet for which its author apologizes as inadequate (xiii. 22). It was now long since they themselves had suffered seriously for their own faith (x. 32 seq.) and the writer's impatience to hurry to their side implies that the crisis was both sudden and urgent.

Place and Author.— Many attempts have been made to identify the home of the Hellenistic Christians addressed in this epistle. For Alexandria little can be urged. "Alexandrine" idealism and allegorism was a mode of thought diffused throughout the Eastern Mediterranean, and the divergencies from Philo's spirit are as notable as the affinities (cj. Milligan, ut *infra* 203 sqq.). For Rome there is more to be said, in view of the reference to "them of Italy" (xiii. 23 seq.); and the theory has found many supporters. It usually contemplates a special Jewish-Christian house-church, like that meeting in the house of Prisca and Aquila (Rom. xvi. 5)—a chapter which some hold to have been part of a recension sent to Ephesus (see ROMANS, EPISTLE TO). Little, however, really points to Rome and a good deal points away from it. The words in xii. 4 "Not yet unto blood have ye resisted," would ill suit Rome after the Neronian "bath of blood" in A.D. 64 (as is usually held), save at a date too late to suit the reference to Timothy. Nor does early currency in Rome count for much, any more than do the words "they of Italy salute you." Read in the light of the reference to Timothy they rather suggest that he had been in prison in Rome and was about to return, possibly in the writer's company, to the region which was apparently the headquarters of both. Now this in Timothy's case, as far as we can judge, was Ephesus; and it is natural to ask whether it will not suit all the conditions of the problem. It suits those of the readers, as analysed above, a house-church which the gospel had reached as it had also the writer himself through certain hearers of the Lord (ii. 3), not necessarily apostles (cf. the Ephesian group of Acts xix. 1 sqq.). And it has the merit of suggesting to us as author the very person of all those described in the New Testament who seems most capable of the task, Apollos, the learned Alexandrian (Acts xviii. 24 sqq), connected with Ephesus and with Paul and his circle (cf. 1 Cor. xvi. 12), yet having his own distinctive manner of presenting the Gospel (1 Cor. iv. 6). That Apollos visited Italy during Paul's imprisonment in Rome is a reasonable inference from Titus iii. 13 (see PAUL); and if so, it is quite natural that he should be there again about the time of Paul's martyrdom. With that event it is again natural to connect Timothy's imprisonment, his release from which our author records in closing; while the news of Jewish success in Paul's case would enhance any tendency among Asian Jewish Christians to shirk "boldness" of confession in fear of further aggression from their compatriots. On the chronology adopted in the article PAUL, this would yield as date for the epistle A.D. 61–62. The place of writing would be some spot in Italy ("they of Italy salute you") outside Rome, probably a port of embarkation for Asia, such as Brundisium.

Historical Significance.— Be this as it may, the epistle is of great importance, as reflecting a crisis inevitable in the development of the Jewish-Christian consciousness, when a definite choice between the old and the new form of Israel's religion had to be made, both for internal and external reasons. It seems to follow directly on the situation implied by the appeal of James to Israel in dispersion, in view of Messiah's winnowing-fan in their midst (James i. 1–4, ii. 1–7, v. 1–6 and especially v. 7–11). It may well be the immediate antecedent of that revealed in 1 Peter, an epistle which perhaps shows traces of its influence (*e.g.*, in i. 2, "sprinkling of the blood of Jesus Christ"). It is also of high interest theologically, as exhibiting, along with affinities to several types of New Testament teaching (see STEPHEN), a type all its own, and one which has had much influence on later Christian thought (*cf.* Milligan. ch. ix). Indeed, it shares with Romans the right to be styled "the first treatise of Christian theology."

BIBLIOGRAPHY.—The older literature may be seen in F. Rleek, *Der Briej an die Hebraer* (1828–40); the more recent in G. Milligan, *The Theology of the Epistle of the Hebrews* (1899), a useful summary of all bearing on the epistle, and in the large New Testament Introductions (*e.g.*, Jiilicher or Moffatt). *See* also Hastings, *Dict. of the Bible*, the *Encycl. Biblica*, *A. S.* Peake in *The Century Bible* and J. Moffatt in the *Internat. Crit. Comm.* (J. V. B.)

HEBRIDES, THE, a group of islands off the west coast of Scotland, between 55° 35′ and 58° 30′ N. and 5° 26′ and 8° 40′ W., also known as the Western Isles. They have been broadly classified into Outer and Inner Hebrides, the hlinch and Little Minch dividing them. The chief islands of the crescentic chain of the Outer Hebrides are Lewis-with-Harris (or Long Island), North Uist, Benbecula, South Uist. Barra. the Shiants. St. Kilda and the Flannan Isles, or Seven Hunters, about 20 mi. N.W. of Gallan head in Lewis. Of these the Lewis portion of Long Island, the Shiants and the Flannan belong to the county of Ross and Cromarty. and the remainder to Inverness-shire. The total length of this group, from Barra head to the Butt of Lewis, is 130 mi.. the breadth varying from less than 1 mi. to 30 mi. The Inner Hebrides include Skye, Small Isles (Canna, Sanday. Rum. Eigg and Muck), Coll, Tiree, Lismore. Mull. Clva, Staffa, Iona. Kerrera, the Slate Islands (Seil. Easdale, Luing, Shuna, Torsay), Colonsay, Oronsay, Scarba, Jura, Islay and Gigha. Of these Skye and Small Isles belong to Inverness-shire, and the rest to Argyllshire. The Hebridean islands exceed 500 in number, of which less than one-fifth are inhabited. The population of the Hebrides is unevenly distributed and depopulation has been variable in onset and progress. The 1951 census gave the following figures: Lewis-with-Harris 26,465; Skye 8,267; Mull 2,420; Small Isles 215; Coll 210; Tiree 1.216.; Colonsay and Oronsay 233; Jura 258; Islay 4,267. The population of Lewis-with-Harris in 1951 was 79% of its maximum reached in 1911; of Mull, 25% of maximum (1821); Islay, 28% of maximum (1831); Skye, 37% of maximum (1841). Several small islands have been evacuated.

The Hebrides are extremely interesting geologically. The stupendous cliff scenery of St. Kilda, 40 mi. W. of the main chain of the Outer Hebrides, is formed of igneous gabbro. which also forms the Cuillin hills of Skye (3.309 ft.), the most spectacular and awe-inspiring massif in Britain. The Outer Hebridean chain is of Lewisian gneiss. the oldest rock in the world; Skye, Mull, Canna and Eigg are largely of volcanic basalt. a formation which gives the columnar scenery of Staffa and the Shiant Isles. Jura is almost wholly metamorphic quartzite.

The islands are hilly or mountainous and only the basalt islands are intrinsically and potentially fertile; the middle area of Lewis is covered by deep peat and a tundralike herbage of limited pastoral value; but the Atlantic side of the southern Outer Hebrides. North Uist, Benbecula. South Uist and Barra is a low platform of gneiss overlaid by shell sand from the Atlantic ocean. The whole of Tiree and the western sides of Coll and Colonsay are similarly affected. These sand-covered grassy plains (the *machair*) with their high soil content of calcium carbonate are fertile cattle-raising areas and support a predominantly agricultural population. The rocky, peaty. much-indented eastern side of the Hebrides is infertile and the inhabitants of this more sheltered coast are mainly fishermen and weavers.

The shell-sand *machair* greatly increases the cultivable area of the Outer Hebrides and Tiree and differentiates them from the Inner Isles. Nevertheless. it must not be plowed for many years in succession or the organic matter is lost and the sand blows disastrously. The *machair* is particularly interesting in Highland economy because of the adaptation of husbandry to the special conditions. The primitive four-rowed barley or bere was the bread corn until recently, a cereal fitted to such highly calcareous soil. The common oat does not grow in such soil, and its place is taken by the bristle-pointed oat. *Avena strigosa*, which would be considered a weed anywhere else. This crop is used entirely for cattle feed, garnered as hay. Potatoes are an important arable crop on both *machair* and peaty land. Cultivation of turnips has almost completely declined because of the high incidence of finger-

and-toe disease. Great quantities of seaweed or tangle (*Laminaria*) are used on the *machair* land. while on the east side of the Outer Isles, wrack (*Fucus*) is cut from the rocky shores and carried to the lazy beds or terracelike. peaty cultivated ground.

The manufacture of the so-called Harris tweed of the Outer Hebrides provides part-time occupation for the crofters, *i.e.*, the small landholders. The tweed is of ancient origin. the wool being vegetable-dyed. hand-spun and hand-woven in the crofters' own homes. The earl and countess of Dunmore, who had a sporting estate in Harris, developed the crofters' marketing of the tweed during the 1860s to 1880s. Thus the name "Harris" tweed. The old type of tweed is now mostly produced in the Uists. but a much greater quantity of aniline-dyed, machine-spun, hand-woven tweed is produced in Lewis.

Stornoway in Lewis is still a herring-fishing centre, but most of the local fleets of herring boats have sadly declined. Many men from the Outer Hebrides join the merchant marine.

Steamer services leave Glasgow daily for Islay and thrice weekly for Jura; Oban daily for Lismore and Mull and thrice weekly for Coll, Tiree. Barra and South Uist; Kyle of Lochalsh daily for Skye and thrice weekly for Harris and the Uists. There are also services, augmented in summer, from Kyle of Lochalsh and Mallaig to the smaller isles. Air services from Glasgow and Inverness serve the Outer Hebrides and Tiree.

The wildlife of the Hebrides is particularly rich. There are red deer in Lewis, Harris. North Uist. Skye. Mull. Jura and Islay; the Atlantic gray seal is numerous. with considerable nurseries on North Rona, the Treshnish Isles. Haskeir (North Uist). Sound of Harris and Oronsay. There are several pairs of golden eagles. and many spectacular sea-bird cliffs. On the island of Soay there is a race of primitive sheep of moufflon type.

The fine Megalithic stone circle at Callanish (Lewis) is the Hebrides' largest prehistoric monument and is well preserved. There is a long barrow as far afield as Hirta (St. Kilda) and chambered cairns, duns and standing stones are of frequent occurrence. Early Christian cells are found on many small and remote islands, and Iona. Oronsay, Rodil (Harris). Inchkenneth (Mull) and Islay are rich in early mediaeval Christian carved stones and architectural remains.

History. — The Goidelic inhabitants of the 1st millennium A.D., Christianized from Iona after Columba's voyage there in j63 A.D., suffered increasingly from Norse raids from the 8th century. Harald Fairhair eventually placed the-Hebrides under Norse sovereignty and it was not until the treaty of 1266 that the Norwegians renounced their claim. The present Gaelic language is surprisingly little affected by Norse, though place names are often pure Norse and may predominate over Gaelic place names in some districts. *e.g.*, Skye. The fusion of Norsemen and Goidel produced a period of relatively high culture and material well-being in the 11th and 12th centuries, and the dynasty of the lordship of the isles was founded hy Somerled. The clan system was strong throughout the region until the Jacobite risings of 1715 and 1745. The hereditary jurisdictions of the chiefs were abolished in 1748 and forfeited estates were not restored until 1784. The clan system with its notion of *jus sanguinis* was at bottom egalitarian but disruption brought about the feudal notion that the land belonged to the chief. With the merging of the chiefs into the life of the Cnited Kingdom, the culture moved much more onto a money basis. At the same time, through cultivation of the potato, vaccination and cessation of internecine warfare, the population increased rapidly and came against the ceiling of subsistence.

There began in the later 18th century a period of social unrest. The central government did or could do little. The chiefs were put into awkward positions in which some of them acted highhandedly, while others were impoverished trying to order a bursting economy. Emigration to Canada and later to Australia became common. The infiltration of southern upland sheep farmers paying high rents for large acreages of ground caused many evictions of small tenants and resettlement in townships on the coasts where, with small plots of land, the people were expected to supplement their living from fishing. The potato famines of 1846 and 1847 were responsible for much destitution.

Gradually, the central government took more part, ponderously, in that urban administrative ideas were unsuitably applied. A royal commission (1883) under Lord Napier reported in 1884. The result was the Crofters' Holdings (Scotland) act of 1886, which gave the crofter security of tenure and heritability of tenure, fair rents being established by a crofters' commission. From this point. the government of the United Kingdom took an increasing part in administration and became the largest landowner of crofting estates in the islands. Economically, the Hebrides continued in parlous state. and in 1944 the Development commission made possible the establishment of the West Highland survey. a research body which investigated the problem sociobiologically in considerable detail.

HEBRON, a city of Jordan about 20 mi. S.W. of Jerusalem and about 3.000 ft. above sea level (pop. 1952, 35,983), almost all Moslems. The town, no longer walled, with its stone houses, boasting curious vaulted cupolas, and narrow. winding streets, stands on the eastern slope of a shallow valley. It has many wells and two large reservoirs, one of which is generally identified with the Pool of Hebron (2 Sam. iv. 12).

History. — Reputed one of the oldest cities (Num. xiii. 22), it was closely connected with Abraham in Bible tradition and was destroyed by Joshua (x. 26). From Hebron Joseph set out to seek his brethren at Shechem. David made it his home for a period. Absalom was born there and Abner was treacherously murdered at its gates by Joab. Absalom made the town the headquarters of his revolt. It was fortified by Rehoboam, captured from the Edoniites by Judas Maccabaeus and destroyed by the Romans. It revived under the Moslems and was a substantial town when captured by the crusaders.

Haram.—Hebron's chief interest is its haram, an enclosure (198 ft. by 112 ft.) built over the traditional side of the cave of Machpelah. The ancient wall which encloses it rises to a height of 40 ft. (above that rise modern walls) and in construction and masonry closely resembles that of the haram in Jerusalem. Within the enclosure is a mosque formerly a crusaders' church (12th century). which in its turn was built on the site of a basilica of Justinian's time. Within the mosque are the cenotaphs of Abraham, Isaac. Jacob. Sarah. Rebecca and Leah, erected above the places where their tombs are presumed to he in the cavern beneath. The mosque is approached by two flights of steps, but Jews are not permitted to go beyond the seventh step. At the fifth is an aperture believed to lead to the tomb of the patriarchs.

HECATAEUS OF ABDERA (or OF TEOS) (*fl.* 4th century B.C.). Greek historian and Sceptic philosopher, accompanied Ptolemy I Soter to Syria and sailed up the Nile to Thebes with him. His travels were described in Αἰγυπτιακά and Περὶ Ὑπερβορέων, which mere used by Diodorus Siculus.

Fragments in C. W. Müller, *Frag. Hist. Graec.;* Diels, *Fragmente dev Vorsokratiker,* vol. 2, 4th ed. (1922).

HECATAEUS OF MILETUS (6th–5th century B.C.), Greek historian and traveller, son of Hegesander. flourished during the time of the Persian invasion. He tried to dissuade the Ionians from revolt against Persia, and (Herodotus, v. 36, 125) in 494, when they were obliged to sue for terms, he was one of the ambassadors to the Persian satrap. whom he persuaded to restore the constitution of the Ionic cities (Diod. Sic.. x, 25). He is by some credited with a geographical work entitled Τῆς περίοδος ("Travels Round the Earth"). in two books, one on Europe, the other on Asia, the account of Egypt being especially comprehensive; the book was accompanied by a map. based upon that of Anaximander. The authenticity of the work is, however, strongly

attacked by J. Wells in the *Journal* of *Hellenic Studies* (1909), xxix, pt. i. The only certainly genuine work of Hecataeus was the Γενεηλογίαι or Ἱστορίαι, a systematic account of the traditions and mythology of the Greeks. He was probably the first to write a serious prose history and employ critical method to distinguish myth from fact, though he accepts Homer and the other poets as trustworthy authority. Herodotus, though he once at least (vi, 137) controverts his statements, is indebted to Hecataeus not only for facts, but also in regard to method and general scheme, but the extent of the debt depends on the genuineness of the Γῆς περίοδος.

Stud.,* as above, and in reply, Max Carey in *J.H.S.* xxx.

HECATE (Gr. Ἑκάτη, "she who works from afar"), a goddess in Greek mythology. According to the generally accepted view, she was of Hellenic origin, but Farnell regards her as a foreign importation from Thrace, the home of Bendis, with whom Hecate had many points in common. She is not mentioned in the *Iliad* or the *Odyssey,* but in Hesiod *(Theogony,* 409) she is the daughter of the Titan Perses and Asterie. She is there represented as a mighty goddess, having power over heaven, earth and sea; hence she is the bestower of wealth and all the blessings of daily life. Hecate is frequently identified with Artemis, and both occasionally with the moon.

Later, Hecate is the chief goddess who presides over magic arts and spells; hence occasionally she is referred to as the mother of Circe, and her name is very common in charms. She is said to have been worshipped at Samothrace, and is closely connected with Demeter. Alone of the gods besides Helios, she witnessed the abduction of Persephone, and, torch in hand, assisted Demeter in her search for her daughter. On moonlight nights she was seen at the crossroads (hence her name τριοδῖτις, Lat. *Trivia),* accompanied by ghosts and hell-hounds. There, on the last day of the month, eggs and fish were offered to her. Black puppies and she-lambs (black victims being offered to chthonian deities) were also sacrificed (Schol. on Theocritus, ii, 12), the former unusual but not quite unparalleled victims in Greece. Pillars like the Hermae, called Hecataea, stood, especially in Athens, at crossroads and doorways, perhaps to keep away the spirits of evil. It is to be noted that Hecate plays little or no part in mythological legend.

In older times Hecate is represented as single-formed, clad in a long robe, holding burning torches; later she becomes *triformis,* "triple-formed," with three bodies standing back to back—probably in order to look all ways at once from the crossroad. In her six hands are various emblems.

See L. R. Farnell, *Cults of the Greek States,* ii, ch. xvi, xix; Preller-Robert i, p. 321 et seq.; O. Gruppe, *Griechische Mythologie,* ii, p. 1,288 (1906); and the classical dictionaries.

HECATOMB, originally, perhaps, the sacrifice of a hundred victims, then of any large number. Hence in modern languages, the destruction of a multitude of living, or even of inanimate, things. (Gr. ἑκατόμβη from ἑκατόν, "a hundred.")

HECK, BARBARA RUCKLE (1734–1805), the "mother of Methodism" in the United States and Canada, was born in the county of Limerick, Ireland, in 1734. Her grandparents had been among the Palatines who fled from Germany before the invasion of Louis XIV. But she was reared in the Wesleyan faith and early welcomed among her associates as a religious counselor. In 1760 she married Paul Heck whose background was similar to that of her own. With him and a company of neighbours. including her cousin Philip Embury, a local Methodist preacher, she sailed for New York, arriving on August 10.

Philip Embury is often called the founder of American Methodism but Barbara Heck takes precedence in that role by several years Embury grew disheartened in the new world and for nearly five years lost his zeal in the cause for the promotion of which he had come to America.

Barbara Heck maintained her evangelizing fervour but was unable to stimulate him to pursue his mission during this period. In 1765 a second band of former neighbours, some of them Methodists, joined this earlier company. Barbara Heck, when visiting one of the newly arrived families, found some of its members engaged in a card game of chance. Her wrath aroused, she seized the cards, threw them into a fire, and rebuked the players Seeking out Philip Embury, she then persuaded him that his ohlipation to preach was imperative. She collected his first small congregation, organized and attended the first Methodist society in America, and started the movement that resulted in the erection of the first Methodist church in any of the colonies.

At the outbreak of the revolution, being British sympathizers, Barbara and Paul Heck, accompanied by their three sons, and several other devout members of their faith, crossed the border into lower Canada, near Montreal, and from there went to Augusta, in upper Canada in 1775. They formed the earliest Methodist society in Canada about 1778.

Barbara Heck died in 1805, sı viving her husband 12 years. They were buried in Augusta, Canada.

HECKER, FRIEDRICH KARL FRANZ (1811–1881), German revolutionary, was born at Eichtersheim in the Palatinate on Sept. 28, 1811, the son of a revenue official. On entering the second chamber of Baden in 1842, he at once began to oppose the government. A speech, denouncing the projected incorporation of Schleswig and Holstein with Denmark, delivered in the chamber of Baden on Feb. 6, 1845, spread his fame beyond the limits of his own state, and his popularity was increased by his expulsion from Prussia on the occasion of a journey to Stettin. In 1847 he became president of the *Volksverein,* where, with Struve, he drew up the Radical program carried at the Liberal meeting held at Offenburg on Sept. 12, 1847 (entitled "thirteen claims put forward by the people of Baden"). In addition to the Offenburg program, the *Sturmpetition* of March 1, 1848 demanded further far-reaching concessions. New demands were made at Offenburg on March 19, and Hecker moved a resolution in the preliminary parliament of Frankfort that Germany should be declared a republic.

On April 12, Hecker and Struve sent a proclamation to the inhabitants of the *Seekreis* and of the Black Forest "to summon the people who can bear arms to Donaueschingen at mid-day on the 14th, with arms, ammunition and provisions for six days." They expected 70,000 men, but only a few thousand appeared. The troops of Baden and Hesse marched against them, under the command of General Friedrich von Gagern, and Hecker was defeated at Kandern (April 20). Hecker escaped to Switzerland, and in Sept. 1848 retired to the United States, where he had a fnrrn at Summerfield, Ill. During the second rising in Baden in the spring of 1849 he returned, and had got as far as Strasbourg when he had to retreat before the victories of the Prussian troops over the Baden insurgents.

After his return to the United States he fought in the Civil War as colonel of a regiment which he had himself got together on the Union side in 1861 and 1864. In a famous festival speech at St. Louis in 1871 he expressed the enthusiasm of the German Americans for their newly-united fatherland. He received a less favourable impression during a journey he made in Germany in 1873. He died at Summerfield on March 24, 1881.

Hecker was very much beloved of all the German democrats. The song and the hat named after him (the latter a broad slouch hat with a feather) became famous as the symbols of the middle-classes in revolt. In America, too, he won great esteem, not only on political grounds but also for his personal qualities.

Hecker's works are: *Die Erhebung des Volkes in Baden für die deutsche Republik* (Baden, 1848); and *Reden und Vorlesungen* (Neerstadt, a. d. H.. 1872). *See* F. v. Weech, *Badische Biographien,* iv

(1891); L. Mathy, ***Aus dem Nachlasse von K. Matty, Briefe aus den Jahren** 1846–1848* (1898).

HECKER, ISAAC THOMAS (1819–1888), U.S. Roman Catholic priest, founder of the Paulist Fathers, was born of Protestant German immigrant parents in New York city, Dec. 18, 1819. His early education came chiefly from private reading and activity in local politics. Later, at Brook Farm, he made contact with Brownson, Emerson, Dana. Alcott, Ripley and Thoreau. Baptized a Catholic in 1844, he became a Redemptorist priest in 1849 and with four other convert priests gave the first organized missions in English by the Redemptorists, who were chiefly Germans. The enthusiastic response of the people in New York and in many other places along the eastern coast suggested the need of an English-speaking house, and Hecker was delegated to urge this upon the rector major in Rome. He was expelled from the order for having come to Rome without permission; but on appeal, Pope Pius IX dispensed him and his four associates from their vows, encouraging them to work under local bishops. Four of them, with Hecker as superior, founded the Paulist Fathers, a diocesan organization for missionary work in New York.

Hecker wrote three books—*Questions of the Soul* (1855), *Aspirations of Nature* (1857) and The Church and the Age (1887)—and established the Catholic Publication society and two magazines, the Catholic World and the Young Catholic. He addressed the bishops at the Second Plenary Council of Baltimore, and accompanied Archbishop Spalding to the Vatican council as theologian. After his death on Dec. 22, 1888. Cardinal Newman declared, "We had begun a work of the same kind, he in America and I in England." The French translation of Hecker's biography occasioned a controversy on "Americanism" which Leo XIII settled in 1899 by the encyclical *Testem* Benevolentiae.

The Paulist Fathers became a papal institute in 1940, and by that time they had houses in the United States, Canada, Rome and South Africa.

HECTOGRAPH: see OFFICE MACHINES AND APPLIANCES.

HECTOR, son of Priam and Hecuba and husband'of Andromache. In Homer he is the chief Trojan warrior. He is an especial favourite of Apollo. and later poets even describe him as son of that god. After Achilles (*q.v.*) had killed him. Aphrodite and Apollo preserved his body from corruption and mutilation. Priam. guarded by Hermes. went to Achilles and prevailed on him to give back the body. which was buried with great honour. Hector was afterward worshipped in the Troad and also at Tanagra.

HECUBA, in Greek Hekabe, principal wife of Priam, daughter of the Phrygian king. Dymas (or of Cisseus, or of the river-god Sangarius). When Troy was captured and Priam slain, she was made prisoner by the Greeks. Her fate is told in various ways, most of which connect her with the promontory Cynossema ("dog's monument") on the Hellespont. According to Euripides (in the *Hecuba*), her youngest son Polydorus had been placed during the siege of Troy under the care of Polymestor. king of Thrace. When the Greeks reached the Thracian Chersonese on their way home she discovered that her son had been murdered, and in revenge put out the eyes of Polymestor and murdered his two sons. Later. she was turned into a dog, a legend variously rationalized by later writers, and her grave became a mark for ships (Ovid, *Metam.*, xiii, 399–573: Juvenal. x. 271, and Mayor's note).

HEDA, WILLEM CLAESZ (1594–1680/82), one of the earlier Dutch 17th-century still-life painters. was born probably in Haarlem. where he worked and died. Early in his career he produced some figure subjects. but nearly all of his known works are still lifes, of which the earliest dated example is a "Vanitas" of 1621. His most characteristic compositions are of glass and metal vessels delicately arranged on a table with oysters, a half-peeled lemon or other motifs that display his precise draftsmanship and his skill in imitating the varied qualities of different light-reflecting surfaces. His colour range is a subdued one of silvery grays and browns, the naturalistic effects being achieved by accurate tone values. Heda's pictures are not uncommon in public and private collections. (R. E. W. J.)

HEDGE BINDWEED (*Convolvulus sepium*), a perennial vine of the morning glory family, Convolvulaceae (*q.v.*), called also great bindweed, bracted bindweed and Rutland beauty. It is cosmopolitan in temperate regions, found in North America from Newfoundland to British Columbia and southward to Mexico, and occurring in hedges and thickets in the British Isles. It is an extensively trailing or high-climbing vine, 3 ft. to 10 ft. high, with slender-stalked, spear-shaped leaves and handsome solitary flowers, pink with white stripes or entirely white, about 2 in. long. The species varies greatly and several races have been described, some of which are cultivated for ornament. See BINDWEED.

HEDGEBOT or HAYBOTE, an ancient legal term signifying the right of a tenant or copyholder to take or cut wood for specific purposes such as the repairs of fences and hedges for the upkeep of the premises as distinguished from the cutting of timber for building purposes, which constituted an infringement of the law.

HEDGEHOG, a mammal of the order Insectivora (*q.v.*), remarkable for its armature of spines and short tail. The common hedgehog (Erinaceus *europaeus*), the type of the family Erinaceidae, extends over nearly the whole of Europe but is found nowhere in the new world.

JOHN MARKHAM
COMMON HEDGEHOG (ERINACEUS EUROPAEUS), NATIVE TO EUROPE

The upper jaw is longer than the lower, the eyes small, the snout long and flexible and the claws long but weak. The animal is about 10 in. long, the lower surface covered with coarse hair. The brain is remarkable for its low development.

When startled during its nightly foragings the hedgehog rolls itself up into a ball, from which the spines stand out in every direction; these are sharp, hard and elastic and form an efficient defense. The moment it is touched, or even hears the report of a gun, it rolls itself up by the action of four muscles beneath the skin, while the same contraction effects the erection of the spines. Though insectivorous, the hedgehog will devour mice, frogs, snakes, birds' eggs and young, and toads, as well as plants and fruits.

The hedgehog does not emerge from its retreat, a hollow stump or rocky crevice. during the daylight unless urged by hunger or by the necessities of its young. During the winter it passes into a state of hibernation (*q.v.*), rolled up in a nest of dry leaves.

In July or August the female brings forth four to eight young; at birth the spines—which ip adult are brownish-black with yellowish tips—are white and soft, but soon harden, attaining their full size in the succeeding spring. The spines of the hedgehog are not barbed like those of the porcupine (*q.v.*), but they are still sharp enough to dissuade attackers. The fox, however, often rolls the prickly ball into water, where it immediately opens up to swim thus exposing its vulnerable parts to the predator.

The family is represented by about a score of species among which are the moonrats and gymnures ranging over Europe, Asia except the Malay countries, and Africa.

HEDGE NETTLE (*Stachys palustris*), a plant of the mint family (Labiatae). called also marsh woundwort, marsh betony and clownheal. widely distributed in Europe, Asia and North America.

The plant is an erect, slender, sometimes slightly branched, rather stiffly hairy perennial, 1 ft to 4 ft. high. with lance-shaped, more or less sharply toothed leaves and purplish flowers. about ¾ in. long borne usually in elongated clusters at the end of the stem but sometimes also in the upper axils of the leaves. This plant is typically representative of the botanical genus Stachys, embracing about 200 species, found (except in Australia) throughout the world; about 20 are native to the United States and Canada and 4 others, including the woundwort (*S. officinalis*), occur in Great Britain.

HEDGE SPARROW, small old-world birds belonging to the

family Prunellidae, related to the thrushes, old-world warblers and finches, also called accentors from their sweet accented songs. The most common is the European hedge sparrow *(Prunella modularis)*, also called dunnock or shufflewing, common about hedges. It has a reddish-brown back, iron-gray head and under parts, and the wing coverts are tipped white. The sexes are similar in appearance.

In England it is one of the earliest breeders in spring. The warmly built nest, in which the hedge sparrow lays its greenish-blue eggs, is often chosen by the European cuckoo as a place to leave its egg for the hedge sparrow to incubate, as noted by Shakespeare in *King Lear*.

Other species occur in Europe and northern Asia to China and Japan. A few of these are similar to the European hedge sparrow in habitat, but most species occupy rocky regions and higher mountain ranges. A Siberian species (P. *montanella*) is known as the mountain accentor. The Alpine accentor (P. *collaris)* is plumper and more brightly coloured than the dunnock. (G. F. Ss.; X.)

HEDGING: *see* FUTURES.

HEDIN, SVEN ANDERS (1865–1952), Swedish explorer, was born in Stockholm, Feb. 19, 186j He was educated at Uppsala university and later studied in Berlin and Halle. In 1885–86 he travelled through Persia and Mesopotamia, and in 1890 was attached to King Oscar's embassy to the shah of Persia. In the same year he visited Khurasan and Turkestan and reached Kashgar in 1891. His travels in Tibet placed him in the first rank of modern Asiatic explorers. Between 1893 and 1897 he travelled across the Asiatic continent from Orenburg by the Urals over the Pamirs and the plateau of Tibet to Peking During two other expeditions he made valuable additions to the scientific knowledge of these tracts and explored especially the sources of the Sutlej, the Indus and the Brahmaputra. In 1902 he became a Swedish noble. and in 1909 the Indian government invested him with the K.C I E. In 1927 he directed the Sino-Swedish expedition to China and spent many of the last years of his life preparing the results of this expedition for publication.

Sven Hedin's writings include: *Journey Through Persia and Mesopotamia and the Caucasus* (1887); *Journey Through Khorasan and Turkestan* (1892–93); *Through Asia* (1898); *Central Asta and Tibet* (1903); *Adventures in Tibet* (1904), *Scientific Results of a Journey in Central Asia 1899–1902*, 8 vol (1904–07); *Transhimalaya*, 3 vol (1909–12); *Overland to India*, 2 vol (1910); *To Jerusalem* (1917); *Southern Tibet*, 12 vol (1917–22); *My Life as an Explorer* (1926); *The Gobi Desert* (1928; Eng ed 1931); *Scientific Results of the Sino-Swedish Expedition 1927–35*, 30 vol (1937–42).

HEDJAZ: see HEJAZ.

HEDON, a municipal borough in the Bridlington parliamentary division of the East Riding of Yorkshire, Eng, 6 mi. E of Hull and 2 mi from the Humber river. Pop (1951) 1,994. Area 0.7 sq mi. Standing on Hedon haven, it was formerly a considerable port, but it lost its importance with the growth of Hull at the end of the 13th century; it is now largely agricultural The manor formed part of the lordship of Holderness which William the Conqueror granted to Eudes, count of Aumale. An undated charter of Henry II contains the first certain evidence of settlement By it. the king granted to William. count of Aumale, free borough rights in Hedon. In 1200 King John granted a confirmation of these liberties, and for this second charter the burgesses themselves paid 70 marks. In 1272 Henry III granted to Edmund, earl of Lancaster, and Avelina his wife, then lord and lady of the manor, the right of holding an eight-day fair at Hedon. After the countess' death the manor came to Edward I. In 1280 it was found by an inquisition that the men of Hedon "were few and poor" and that if the town were demised at a fee-farm rent, the town might improve. Apparently the grant was not made until 1346. Hedon was incorporated by Charles II in 1661, and James II gave the burgesses the charter. granting, among other privileges, that of holding two extra fairs. The church of St. Augustine is of Early English. Decorated and Perpendicular styles. with a 15th-century central tower 130 ft. high. The west front is particularly fine, and there is a lofty clerestory. The corporation possesses a remarkable mace of 15th-century workmanship The borough sent two members to parliament from 1295 to 1832. Hedon is said to mean "the rise covered with heather."

HEDONISM, in ethics, a general term for all theories of conduct in which the criterion is pleasure of one kind or another (Greek *hedone,* "pleasure," from *hedys,* "sweet," "pleasant"). Hedonistic theories of conduct have been held from the earliest times. They have been regularly misrepresented by their critics because of a simple misconception, namely, the assumption that the pleasure upheld by the hedonist is necessarily purely physical in its origins. This assumption is in most cases a complete perversion of the truth. Practically all hedonists recognize the existence of pleasures derived from fame and reputation, from friendship and sympathy, from knowledge and art. Most of them have urged that physical (or "lower") pleasures are not only ephemeral in themselves but also involve, either as prior conditions or as consequences, such pains as to discount any greater intensity that they may have while they last. *(See* ETHICS; ETHICS, HISTORY OF.)

The earliest and most extreme form of hedonism is that of the Cyrenaics (*q.v.*) as stated by hristippus, who argued that the only good for man is the sentient pleasure of the moment. Since, as Protagoras maintained, knowledge is solely of momentary sensations, it is useless to try to calculate future pleasures and to balance pains against them. The true art of life is to crowd as much enjoyment as possible into each moment.

No school has been more subject to the misconception noted above than the Epicurean. Epicureanism is completely different from Cyrenaicism. For Epicurus (*q.v.*) pleasure is indeed the supreme good, but his interpretation of this maxim is profoundly influenced by the Socratic doctrine of prudence and Aristotle's conception of the best life. The true hedonist will aim at a life of enduring pleasure, but this is obtainable only under the guidance of reason. Self-control in the choice and limitation of pleasures with a view to reducing pain to a minimum is indispensable. "Of all this, the beginning, and the greatest good, is prudence." This negative side of Epicureanism developed to such an extent that some members of the school found the ideal life rather in indifference to pain than in positive enjoyment.

In modern times Jeremy Bentham (*q.v.*) revived hedonism both as a psychological and as a moral theory. Each man has no other end than his own greatest pleasure. Each man ought to pursue the greatest pleasure. It would seem to follow that each man inevitably always does what he ought. Bentham sought the solution of this paradox on different occasions in two incompatible directions. Sometimes he says that the act which I do is the act which I *think* will give me most pleasure, whereas the act which I ought to do is the act which *really will* give me most pleasure: calculation is salvation, sin is shortsightedness. Alternatively he suggests that the act which I do is that which will give me most pleasure, whereas the act I ought to do is that which will give all *those affected by it* most pleasure. *(See* UTILITARIANISM for further developments of this second solution.)

The psychological doctrine that a man's only aim is pleasure was effectivelyattacked by Bishop Joseph Butler. He pointed out that each desire has its own specific object and that pleasure comes as a welcome addition or bonus when the desire achieves its object; hence the paradox that the best way to get pleasure is to forget it and to pursue wholeheartedly other objects. Butler went too far in maintaining that pleasure cannot be pursued as an end. Normally, indeed, when I am hungry or curious or lonely, I desire to eat, to know or to have company; and these are not desires for pleasure. But I can also eat sweets when I am not hungry, for the sake of the pleasure that they give.

Moral hedonism has been attacked by most moralists since Socrates. though they too have tended to go to the extreme of holding that I never have a duty to bring about pleasure. It does seem odd to say that I have a duty to give myself pleasure, but the pleasures of others certainly seem to count among the factors relevant in making a moral decision. One particular criticism which may be added to those usually urged against hedonists is that whereas they claim to simplify ethical problems by introducing a single standard, namely pleasure, in fact they have a double standard: "Nature has placed mankind under the governance of

two sovereign masters, pain and pleasure" (Bentham). Hedonists make the mistake of thinking of pleasure and pain as if they were, like heat and cold, degrees on a single scale, when they are really different in kind.

See further *G. E.* Moore, *Principia Ethica* (1903). (J. D. M.)

HEDRICK, ULYSSES PRENTISS (1870–1951), U.S. horticulturist, was born at Independence, Ia., on Jan. 15, 1870. He graduated in 1893 from Michigan Agricultural college, in which he was assistant horticulturist, 1893–95. He was professor of horticulture in Oregon Agricultural college in 1895–97, in Utah Agricultural college in 1897–99 and in Michigan Agricultural college in 1899–1905. In 1905 he became horticulturist at the New York agricultural experiment station, Geneva, conducting extensive researches in fruit growing, especially in pomology. He was director of the station from 1928 until his retirement in 1937. He died on Nov. 14. 1951, in Clifton Springs, N.Y.

His works include *Grapes of New York* (1908); *Plums of New York* (1910); *Cherries of New York* (1915); *Peaches of New York* (1917); *Sturtevant's Notes on Edible Plants* (1919); *Cyclopedia of Hardy Fruits* (1921); *The Pears of New York* (1922); *Systematic Pomology* (1923); *A History of Agriculture in the State of New York* (1933); *Grapes and Wines From Home Vineyards* (1945).

HEDWIG, JOHANN (1730–1799), German botanist, was the first scientist to interpret correctly the microscopically small sex structures of mosses and to exploit the spore-distributing mechanism of the capsule to classify those plants. Born at Kronstadt. Rumania (Transylvania), on Dec. 8, 1730, he studied in Leipzig and practiced medicine there and in Chemnitz. At the University of Leipzig he became professor of pharmacology in 1786 and professor of botany in 1789. Six volumes, published in Latin between 1782 and 1798, are highly regarded because of their hand-coloured plates of mosses and other plants. Hedwig followed the binomial system of naming plants instituted by his contemporary Linnaeus, and recognized more mosses than any man of his day owing to his skill with the microscope.

Hedwig died on Feb. 18, 1799, while working on his greatest contribution to the knowledge of mosses—Species Muscorum Frondosorum . . . Published in 1801, and later followed by four supplements, this posthumous treatise has been designated by international botanical congresses as the beginning point in the naming of mosses. (P. D. V.)

HEEL, in anatomy, is that part of the foot in man which is situated below and behind the ankle; by analogy, the calcaneal part of the tarsus in other vertebrates. The heel proper in digitigrades and ungulates is raised off the ground and is commonly known as the "knee" or "hock," while the term "heel" is applied to the hind hoofs.

HEEM, JAN DAVIDSZ DE (1606–1683/84), Dutch painter, was born at Utrecht. He was, if not the first, perhaps the greatest painter of still life in Holland. Sometimes De Heem painted alone or in company with men of his school, Madonnas or portraits surrounded by festoons of fruit or flowers, but his most numerous and characteristic works are still-life subjects. These are sometimes arrangements of fruits, metal dishes, wine-glasses, etc., in the manner of the Haarlem school, but they include also compositions of books and of musical instruments and some examples of the popular "Vanitas" theme, with a skull, hourglass and other suitably symbolic articles.

At one time Jan de Heem signed with initials, at others with Johannes, at others again with the name of his father (DAVID I DE HEEM, *c.* 1570–*c.* 1632) joined to his own. He entered the Antwerp guild in 1635–36 and became a burgher of that city in 1637, maintaining his residence there until 1667, when he moved to Utrecht. His death is recorded in the guild books of Antwerp.

CORNELIS DE HEEM (1631–95), the son of Jan Davidsz, was in practice as a flower painter at Utrecht in 1658, and was still active in 1671 at The Hague. His pictures are not equal to those of his father, but they are all well authenticated, and most of them are in the galleries of The Hague, Dresden, Cassel, Vienna and Berlin. In the Staedel at Frankfurt is a fruit piece, with potherbs and a porcelain jug, dated 1658; another, dated 1671, is in the museum of Brussels.

DAVID II DAVIDSZ DE HEEM, David I's second son, entered the guild of Utrecht in 1668 and that of Antwerp in 1693. The best piece assigned to him is a table with a lobster, fruit and glasses in the Rijksmuseum, Amsterdam; others bearing his signature are in the museums of Florence, Leningrad and Brunswick. (R. E. W. J.)

HEEMSKERCK, MAARTEN VAN (MAARTEN VAN VEEN) (1498–1574), Dutch Mannerist painter, was born at Heemskerck in Holland. He spent a period (c. 1528) in the Haarlem studio of Jan van Scorel, then lately returned from Italy. Heemskerck's earliest works—a portrait of his father (New York), "Ecce Homo" (Ghent), "Judah and Thamar" (formerly Potsdam) and "St. Luke Painting the Portrait of the Virgin" (Haarlem), all dated 1532—while adhering closely to the Romanist style of Scorel, seek to outdo it by dramatic lighting and illusionistic effects of plasticity which do, indeed, achieve an effect of surprise, but fail to conceal a certain spiritual vacuity which was to remain characteristic of Heemskerck's painting.

From 1532 to 1535 he was in Rome recording in innumerable sketches, some of which are preserved in Berlin, the architecture and sculpture of classical antiquity and the painting of the High Renaissance. Of the latter he directed his attention particularly to the frescoes of Michelangelo in the Sistine chapel and those of Raphael in the Villa Farnesina.

Throughout the rest of his long career, which was spent almost exclusively in Haarlem (where he died), he drew liberally on this garnered store of Roman motifs. Among the more notable of the religious paintings of his maturity are a great "Crucifixion" altar (1538–43, Linkoping cathedral. Sweden), a "Crucifixion" (1543, Ghent), an "Annunciation" and "Adorations of the Kings and Shepherds" (1546, Haarlem), two triptychs with Passion subjects (1559–60, Haarlem and Brussels), the "Story of Momus" (1561, Berlin) and the "Baptism of Christ" (1566, Brunswick). He also painted portraits, among them a self-portrait with the Colosseum (1553, Fitzwilliam museum, Cambridge), and from 1548 onward he produced many designs for engravings.

Heemskerck was one of the leading Dutch artists of his day and a painter of undoubted ability, yet it is hard to avoid the conclusion that his native force was stifled by his Mannerist practice of imitating and reproducing the most admired models. Relying on these, and neglecting nature, he evolved a style which, though not without originality, remains inexpressive and second-hand. The tendency to reduce the forms, textures and colours of nature to arid, abstract formulas extends even to his portraits, though these are perhaps his most attractive work. (D. KG.)

HEEMSKERK, JOHAN VAN (1597–1656), Dutch poet, born at The Hague on Feb. 27, 1597. He was educated at Bayonne, and at the University of Leyden in 1617. In 1621 he went abroad. He settled in 1640 in Amsterdam where he died on Feb. 27, 1656. For the last 12 years of his life he sat in the upper house of the states-general.

Heemskerk published volumes of poems—Minnekunst (1622), *Minnepligt* (1625) and Minnekunde (1628); but he is famous as the author of Batavische Arcadia (1647), which introduced the Italian pastoral romance into Holland.

HEEMSKERK, THEODORE (1852–1932), Dutch statesman, son of Jan Heemskerk, entered the second chamber in 1888. He made a great reputation as a jurisconsult, and as prime minister (1908–13) reserved for himself the portfolio of the interior. He was minister of justice (1918–25) and minister of state (1926). He was the leader in the second chamber of the Anti-Revolutionary party.

HEER, JAKOB CHRISTOPH (1859–1925), a prolific Swiss novelist, was born at Toss (Canton Zürich) on July 17, 1859, and died on Aug. 20, 1925. After some experience as a teacher and editor, he devoted himself to writing romantic novels, chiefly dealing with Swiss life and marked by a certain old-fashioned air that enhances rather than detracts from their charm.

Heer's best work is An Heiligen *Wassern* (1898), but the most popular is Der Konig der Bernina (1900), describing an interesting phase in the history of the Grisons. His Tobias Heider (1923) is autobiographical in character.

See G. H. Heer, ***Jakob Christoph Heer*** (1927).

HEER, OSWALD (1809–1883), Swiss geologist and naturalist, was born at Nieder-Utzwyl in Canton St. Gallen on Aug. 31, 1809. He was a pioneer in paleobotany, distinguished for his researches on the Miocene flora. In 1851 he became professor of botany in the University of Zurich, and he directed his attention to the Tertiary plants and insects of Switzerland. For some time he was director of the botanic garden at Zurich. He died at Lausanne on Sept. 27, 1883.

He published *Flora Tertiaria Helvetiae,* 3 vol. (1855–59); *Die Urwelt der Schweiz* (1865), and *Flora fossilis Arctica* (1868–83).

HEEREN, ARNOLD HERMANN LUDWIG (1760–1842). German historian, was born on Oct. 25, 1760 at Arbergen, near Bremen. He studied history at Gottingen, and was appointed (1787) one of the professors of philosophy, and then of history in his university. He died at Gottingen on March 6, 1842. Heeren regarded the states of antiquity from an altogether fresh point of view; he examined their economic relations! their constitutions, their financial systems, and thus threw a new light on the development of the ancient world. He was a pioneer in the movement for the economic interpretation of history.

Heeren's chief works are: *Ideen über Politik, den Verkehr, und den Handel der vornehmsten Völker der alten Welt* (2 vol., Göttingen, 1793–96; 4th ed., 6 vol., 1824–26; Eng. trans. 1833); *Geschichte des Studiums der klassischen Litteratur seit dem Wiederaufleben der Wissenschaften* (2 vol., Gottingen, 1797–1802; new ed., 1822); *Geschichte der Staaten des Altertums* (Gottingen, 1799; Eng. trans., Oxford, 1840); *Geschichte des europäischen Staatensystems* (Gottingen, 1800; 5th ed., 1830; Eng. trans., 1834); *Versuch einer Entwickelung der Polgen der Kreuzzüge* (Gottingen, 1808; French trans. 1808), a prize essay of the Institute of France. With Friedrich August Ukert (1780–1851) he founded the famous historical collection, *Geschichte der europäischen Staaten* (Gotha, 1819 *seq.),* and contributed many papers to learned periodicals.

HEERENVEEN, a town of the Netherlands on the railway Leeuwarden-Zwolle; pop. (1947) 7,621. The nearby castle Oranjewoud was established in the 17th century by the Frisian stadtholders.

HEERLEN, a town of the Netherlands in the south of the province of Limburg, on the railway about 3 mi, from the German frontier at Alsdorf. Pop. (1947) 35,001. The town is one of the centres of the coal field. The most important mines are the Orange-Nassau I, II and IV and the state mine, Emma.

HEFELE, KARL JOSEF VON (1809–1893), German Catholic theologian, was born at Unterkochen, Württemberg, on March 15, 1809. and was educated at Tubingen, where, after minor appointments elsewhere, in 1840 he became professor of church history and patristics. From 1842 to 1845 he sat in the national assembly of Wurttemberg, and in 1869 was enthroned bishop of Rottenburg. Previous to this appointment. Hefele had won a reputation for scholarship by his early publications: *Patrum Apostolicorum Opera* (1839, 4th ed. 1855), *Der Kardinal Ximenes* (1844, 2nd ed. 1851), *Chrysostomuspostille* (1845, 3rd ed. 1857) and particularly the *Conciliengeschichte* (1855–74, 2nd ed. 1873–90, Eng. trans. 1871). He opposed the decrees of papal infallibility at the Vatican council of 1870, and did not submit until 1871.

Hefele died at Rottenburg on June 6, 1893.

HEGEL, GEORG WILHELM FRIEDRICH (1770–1831), German philosopher, was born at Stuttgart on Aug. 27, 1770. His father was a revenue officer. He learned the elements of Latin from his mother before he went to the Stuttgart grammar school, where he remained until he was 18. As a schoolboy he made a collection of extracts, alphabetically arranged, comprising annotations on classical authors, passages from newspapers, treatises on morals and mathematics from the standard works of the period.

In 1788 he went to Tiibingen as a student with a view to taking orders, as his parents wished. He studied philosophy and classics for two years and took his Ph.D. in 1790. Thereafter he took the theological course; but he was impatient with the orthodoxy of his teachers, and the certificate given to him when he left in 1793 states that while he had devoted himself vigorously to philosophy, his industry in theology was intermittent. He was also said to be a poor orator, and this deficiency in oral exposition was to dog him throughout his life. His fellow students called him "the old man" but he liked cheerful company and a "sacrifice to Bacchus" and he enjoyed kisses too. His chief friends were J. C. F. Holderlin, the poet, his contemporary, and F. W. J. Schelling, the philosopher, five years his junior. Together they read the Greek tragedians and celebrated the glories of the French Revolution.

On leaving college, he did not enter the ministry. He wished to have leisure for the study of philosophy and Greek literature and became a private tutor. For the next three years he lived in Berne, with time on his hands and the run of a good library where he read Edward Gibbon and Montesquieu, as well as the Greek and Roman classics. He also studied Rant and was stimulated by his essay on religion to write certain papers which remained unpublished until 1907 *(see* below). Kant had maintained that, while orthodoxy requires a faith in historical facts and in doctrines which reason alone cannot justify and while it imposes on the faithful a moral system containing many arbitrary commands alleged to be revealed, Jesus had originally taught a rational morality, reconcilable with the teaching of Kant's ethical works, and a religion which, unlike Judaism. was adapted to the reason of all men. Hegel accepted this teaching but, being more of a historian than Kant was, brought it to the test of history by writing two essays: first, a life of Jesus in which he attempted to reinterpret the Gospel on Kantian lines; and secondly an answer to the question of how Christianity had ever become the authoritarian religion that it was if in fact the teaching of Jesus was not authoritarian at all but essentially rationalistic.

Hegel was lonely in Berne and was glad to move, at the end of 1796, to Frankfurt-on-Main, where Holderlin had been able to get another tutorship for him. His hopes of more companionship were unfulfilled: Holderlin was engrossed in a love affair with his employer's wife and shortly afterward lost his reason. Hegel began to suffer from melancholia and. to cure himself. worked harder than ever, especially at Greek philosophy and modern history and politics. He read and made cuttings from English newspapers, wrote about the internal affairs of his native Württemberg and studied economics. This immersion in studies which had had little effect on Kant enabled Hegel to free himself from the domination of his master's influence and to look with a fresh eye on the problem of Christian origins.

It is impossible to exaggerate the importance which this problem had for Hegel. His early theological writings contain plenty of hard sayings about Christianity and the churches, but the object of his attack is orthodoxy, not theology itself. All that he wrote at this period throbs with a religious conviction which is totally absent from Kant and his other 18th-century teachers. Above all. he is inspired by a doctrine of the Holy Spirit. The spirit of man, his reason. is the candle of the Lord and therefore cannot be subject to the limitations which Kant had imposed on it in the *Critique of Pure Reason.* This faith in reason, with its religious basis, animates the whole of Hegel's work henceforward.

His outlook has also become that of a historian, and this again distinguishes him from Kant. who was much more influenced by the conceptions of physical science. Every one of Hegel's major works is a history, and indeed it was among historians and classical scholars rather than among philosophers that his work mainly fructified in the 19th century.

When in 1798 he turned back to look over the essays he had written two or three years earlier in Berne, he saw with his historian's eye that under Kant's influence he had misrepresented the life and teachings of Jesus and the history of the Christian church. His new-won insight found expression then in his essay on *The Spirit of Christianity,* likewise unpublished until 1907. This is one of Hegel's most remarkable works. Its style is often difficult and the connection of thought not always plain, but it is written with passion, insight and conviction.

He begins by sketching the essence of Judaism, which he paints in the darkest colours. The Jews were slaves to the

Mosaic law, leading a life unlovely in comparison with that of the ancient Greeks and content with the material satisfaction of a land flowing with milk and honey. Jesus taught something entirely different. Men are not to be the slaves of objective commands: the law is made for man. They are even to rise above the tension in moral experience between inclination and reason's law of duty, for the law is to be "fulfilled" in the love of God wherein all tension ceases and the believer does God's will wholeheartedly and single-mindedly. A community of such believers is the Kingdom of God.

This was the kingdom which Jesus came to teach. It is founded on a belief in the unity of the divine and the human. It is one life which flows in them both, and it is only because man is spirit that he can grasp and comprehend the Spirit of God. Hegel works out this conception in an exegesis of passages in St. John. The kingdom, however, can never be realized in this world: man is not spirit alone but flesh also. "Church and state, worship and life, piety and virtue, spiritual and worldly action can never dissolve into one."

In this essay the leading ideas of Hegel's system of philosophy are rooted. Kant had argued that we could have knowledge only of a finite world of appearances; if reason attempted to go beyond this sphere and grapple with the infinite or with ultimate reality, it became entangled in insoluble contradictions. Hegel, however, found in love as a union of opposites a prefigurement of spirit as the unity in which contradictions, such as infinite and finite, were embraced and synthesized. His choice of the word *Geist* to express this his leading conception was deliberate: the word means "mind" as well as "spirit" and is commonly so translated; but the English word "mind" has no religious overtones and therefore does not convey Hegel's meaning adequately. Contradictions in thinking at the scientific level of Kant's "understanding" are indeed inevitable, but thinking as an activity of spirit or "reason" can rise above them to a synthesis in which the contradictions are resolved. All this, expressed in religious phraseology, is contained in the manuscripts written toward the end of Hegel's stay in Frankfurt. "In religion," he says in the paper which his editor unfortunately called *Fragment of a System,* "finite life rises to infinite life." Kant's philosophy has to stop short of religion because it rests on an opposition between thought and its object and must place the true infinite beyond its confines. But there is room for another philosophy, based on the conception of spirit, which will distill into conceptual form the insights of religion. This was the philosophy now within Hegel's grasp, and he felt himself ready to expound it.

Fortunately his circumstances had changed for him at this moment, and he was at last able to embark on the academic career that had long been his ambition. His father's death in 1799 had put him in possession of an inheritance, slender indeed, but sufficient to enable him to surrender a regular income and to take the risk of becoming a *Privatdocent.* By the end of 1800 he was ready to burn his boats, and in Jan. 1801 he arrived in Jena, where Schelling had been a professor since 1798. The golden age of Jena was over. J. L. Tieck, Novalis and the Schlegels, who had made it the headquarters of their fantastic mysticism, and Fichte, who had developed certain aspects of Kant's ethics rather one-sidedly in the direction of revolutionary idealism, had all left the place. The precocious Schelling, who was but 26 on Hegel's arrival, had several books behind him already, for he was apt to "philosophize in public" and was fighting a lone battle in the university against rather dull followers of Kant. It was suggested that Hegel had been summoned as a new champion to aid his friend, and this impression received some confirmation from the Latin dissertation by which Hegel qualified as a university teacher and which betrays the influence of Schelling's philosophy of nature, as well as from Hegel's first publication, an essay on the difference between Fichte and Schelling (*Differenz des Fichte'schen und Schelling'schen Systems der Philosophie,* Jena, 1801), in which preference is given to the latter. Nevertheless, even in this essay, and still more in its successors, Hegel's difference from Schelling is clearly marked; they had a common interest in the Greeks, they both wished to carry forward Kant's work, they were both iconoclasts, but Schelling had too many romantic enthusiasms for Hegel's liking, and all that Hegel took from him, and then only for a very short period, was a terminology.

Hegel's lectures, in the winter of 1801–02, on logic and metaphysics, were attended by about 11 students. Later, in 1804, we find him with a class of about 30, lecturing on his whole system; but his average attendance was rather less. Besides philosophy, he once at least lectured on mathematics. As he taught, he was gradually able to work out his system, and notice after notice of his lectures promised a textbook of philosophy — which, however, failed to appear.

After the departure of Schelling from Jena (1803), Hegel was left to work out his own views untrammeled. Besides philosophical and political studies, he made extracts from books, attended lectures on physiology and dabbled in other sciences. As a result of representations made by himself at Weimar, he was in Feb. 1805 appointed extraordinary professor at Jena; and in July 1806, on Goethe's intervention, he drew his first stipend—100 thalers. Though some of his hearers became attached to him, Hegel was not yet a popular lecturer.

Hegel, like Goethe, felt no patriotic shudder when Napoleon won his victory at Jena (Oct. 14, 1806): in Prussia he saw only a corrupt and conceited bureaucracy. Writing to his friend F. I. Niethammer (1766–1848) on the day before the battle, he speaks with admiration of the "world-soul," the emperor, and with satisfaction of the probable overthrow of the Prussians. Hegel's fortunes were now at the lowest ebb. Yet at this time he finished and published his first great work, the *Phenomenology of Mind (Phanomenologie des Geistes,* Bamberg and Würzburg, 1807). He was, therefore, glad to become editor of the *Bamberger Zeitung* (1807–08). This, however, was not a suitable vocation, and he gladly accepted the rectorship of the Aegidiengymnasium in Nuremberg, a post which he held from Dec. 1808 to Aug. 1816. There Hegel inspired confidence in his pupils and maintained discipline without pedantic interference in their associations and sports.

In 1811 Hegel married Marie von Tucher (22 years his junior), of Nuremberg. The marriage was entirely happy. His income at Nuremberg amounted to 1,500 gulden and a house (in Heidelberg, as professor, he was to receive about the same sum; in Berlin, about 3,000 thalers, more than twice as much). His wife bore him two sons: Karl (1813–1901), who became eminent as a historian; and Immanuel (1814–91), whose interests were theological. The family circle was joined by Ludwig, a natural son of Hegel's from Jena.

At Nuremberg in 1812 appeared *Die objektive Logik,* being the first part, in two sections, of his *Science of Logic (Wissenschaft der Logik),* which in 1816 was completed by the second part, *Die subjektive Logik.* This work. in which his system was first presented in what, with minor alterations, was its ultimate shape, earned him the offer of professorships at Erlangen, at Berlin and at Heidelberg. He accepted the chair at Heidelberg, in succession to J. H. Fries (1816). For use at his lectures there he published his *Encyclopaedia of the Philosophical Sciences* (*Encyklopädie der philosophischen Wissenschaften im Grundrisse,* Heidelberg, 1817), an exposition of his system as a whole.

In 1818 Hegel accepted the renewed offer of the chair of philosophy at Berlin, which had been vacant since Fichte's death. There his influence over his pupils was immense, though his expectation of other government employment was not fulfilled. After the publication of his *Philosophy of Right (Naturrecht und Staatswissenschaft im Grundrisse,* alternatively entitled *Grundlinien der Philosophie des Rechts,* Berlin, 1821), he seems to have devoted himself almost entirely to his lectures. Between 1823 and 1827 his activity reached its maximum. His notes were subjected to perpetual revisions and additions. We can form an idea of them from the shape in which they appear in his published writings. Those on *Aesthetics,* on the *Philosophy of Religion,* on the *Philosophy of History* and on the *History of Philosophy* have been published by his editors, mainly from the notes of his students, under their separate heads; while those on logic, psychology

and the philosophy of nature are appended in the form of illustrative and explanatory notes to the sections of his *Encyclopaedia*. During these years hundreds of hearers from all parts of Germany and beyond came under his influence. His fame was carried abroad by eager or intelligent disciples.

Three courses of lectures are especially the product of his Berlin period: those on aesthetics, on the philosophy of religion and on the philosophy of history. In the years preceding the revolution of 1830, public interest, excluded from political life, turned to theatres, concert rooms and picture galleries. At these Hegel became a frequent and appreciative visitor and made extracts from the art notes in the newspapers. In his holiday excursions, his interest in the fine arts more than once took him out of his way to see some old painting. This familiarity with the facts of art, though neither deep nor historical, gave a freshness to his lectures on aesthetics, which, as put together from the notes of 1820, 1823, 1826, are among his most successful efforts.

The lectures on the philosophy of religion are another application of his method. Shortly before his death he had prepared for the press a course of lectures on the proofs for the existence of God. In his lectures on religion he dealt with Christianity, as in his philosophy of morals he had regarded the state. On the one hand he turned his weapons against the rationalistic school, who reduced religion to the modicum compatible with an ordinary worldly mind. On the other hand he criticized the school of Schleiermacher, who elevated feeling to a place in religion above systematic theology. His middle way attempts to show that the dogmatic creed is the rational development of what was implicit in religious feeling. To do so, of course, philosophy becomes the interpreter and the superior.

The lectures on the history of philosophy are especially remarkable for their treatment of Greek philosophy. Hegel worked mainly with the Renaissance editions of Plato and Aristotle and without the indexes and annotated editions which are at the disposal of modern scholars. In these circumstances his grasp and understanding' of these authors is astounding, and it is only just to recognize that it was from Hegel that the scholarship lavished on Greek philosophy in the century after his death received its original impetus.

A Hegelian school began to gather. The flock included intelligent pupils, empty-headed imitators and romantics who turned philosophy into lyric measures. Opposition and criticism only served to define more precisely the adherents of the new doctrine. Though he had soon resigned all direct official connection with the schools of Brandenburg, Hegel's real influence in Prussia was considerable—even if largely exaggerated in popular estimate. In the narrower circle of his friends his birthdays were the signal for congratulatory verses. In 1831 he received a decoration from Frederick William III. In 1830 he was rector of the university.

One of the last literary undertakings in which he took part was the establishment of the Berlin *Jahrbiicher fur wissenschaftliche Kritik*.

The revolution of 1830 was a great blow to him, and the prospect of mob rule almost made him ill. His last literary work, the first part of which appeared in the *Preussische Staatszeitung* while the rest was censored, was an essay on the English Reform bill of 1831, considering its probable effects on the character of the new members of parliament and the measures which they might introduce. In the latter connection he enlarged on several points in which England had done less than many continental states for the abolition of monopolies and abuses.

In 1831 cholera entered Germany. Hegel and his family retired for the summer to the suburbs, and there he finished the revision of the first part of his *Science of Logic*. At the beginning of the winter session he returned to his house in the Kupfergraben. On Nov. 14, after one day's illness, he died of cholera and was buried, as he had wished, between Fichte and Karl Solger.

Hegel in his classroom was more impressive than fascinating. You saw a plain, old-fashioned face, without life or lustre—a figure which had never looked young and was now prematurely aged; the furrowed face bore witness to concentrated thought. Sitting with his snuffbox before him and his head bent down, he looked ill at ease and kept turning the folios of his notes. His utterance was interrupted by frequent coughing; every sentence came out with a struggle. The style was no less irregular: sometimes in plain narrative the lecturer would be specially amkward, while in abstruse passages he seemed specially at home, rose into a natural eloquence and carried away the hearer by the grandeur of his diction.

PHILOSOPHY

Hegel took seriously Plato's saying that the philosopher is "the spectator of all time and all existence." His philosophy is a systematic whole, an attempt to comprehend the entire universe; he tried to do for the modern world what Aristotle had done for the ancient.

The system is grounded in faith. In the Christian religion God has been revealed as truth and as spirit. Since spirit alone can comprehend spirit, it is only because man is spirit that he can receive this revelation. In receiving it, he knows God; *i.e.*, he knows absolute truth. In religiop this truth is veiled in imagery; but in philosophy the veil is torn aside.

The task of philosophy is thus to know the infinite and to see all things in God. Hegel's system is a spiritual monism, but it is a monism in which differentiation is essential; *i.e.*, it accords with the Christian faith in God as triune, not with Islam.

Hegel accepts from Aristotle the conception of God as pure thought thinking itself and from his predecessors in modern philosophy the central importance of mind's knowledge of itself as mind. In these instances thought and the object of thought are identical, and in that identity alone does thinking attain the through-and-through intelligibility which is the goal of all its endeavour as thinking. The identity is reached, however, only through an experience of difference. Truth is the absence of error, but it is known to be true only because error has been experienced and truth has triumphed. God, in Hegel's view, is infinite only because he has assumed the limitations of finitude and triumphed over them. Adam and Eve were innocent in the Garden of Eden, but their fall was necessary if man was to attain moral goodness. Only if the universal particularizes itself can it come to know itself as universal. Spirit knows itself as spirit only by contrast with nature. Spirit must always give itself forms through which it can work; it must objectify itself in a creed or in an institution if it is not to wither away. The letter killeth, yet the letter is spirit's indispensable expression and self-manifestation.

The infinite spirit's eternal enjoyment of himself as spirit thus necessitates the existence of the finite in the form of nature, finite spirits and all the imperfection and evil of the world. But Hegel's system finds room for all these and yet remains monistic because it seeks to show that the truth, the essential substance, of the finite is the infinite whose manifestation, in varying degrees, the finite is: there is a heart of goodness in evil, and this heart is all the reality that it has; the rest perishes and passes away into nothingness.

The system is monistic too in having a single theme. What makes the universe intelligible is to see it as the eternal cyclical process whereby absolute spirit comes to knowledge of itself as spirit (1) through its own thinking; (2) through nature; (3) through finite spirits and their self-expression in history and their self-discovery, in art, in religion and in philosophy, as one with absolute spirit itself.

Hegel's terminology presents difficulties to those who approach his works for the first time, even if German be their native language. He prided himself in having taught philosophy to speak German instead of Greek or Latin, but on some of the German words that he uses he imposes his own technical meaning. But he uses them consistently and it is not difficult to learn them, especially if their ancestry in Proclus and in Martin Luther is borne in mind. Hegel was a master of language, whichever of his differing styles he chose.

The early theological writings and the *Phenomenology* of *Mind* are packed with brilliant metaphors. In his later works, which were produced as textbooks for his lectures, the *Encyclopaedia*

of the Philosophical Sciences and the Philosophy *of* Right, he compresses his material into relatively short, numbered paragraphs. It is only necessary to translate them to appreciate their conciseness and precision. The common idea that Hegel's is a philosophy of exceptional difficulty is quite mistaken. Once his terminology is understood and his main principles grasped, he presents far less difficulty than Kant, for example. One reason for this is a certain air of dogmatism. Kant's statements are often hedged around with qualifications; Hegel had, as it were, seen a vision of absolute truth and he expounds it with confidence.

The **Phenomenology** of Mind. — This, perhaps the most brilliant and the most difficult of Hegel's books, describes how the human mind has risen from mere consciousness, through self-consciousness, reason, spirit and religion, to absolute knowledge. The native attitude of consciousness toward existence is reliance on the evidence of the senses; but a little reflection is sufficient to show that the reality attributed to the external world is as much due to intellectual conceptions as to the senses and that these conceptions elude us when we try to fix them. If consciousness cannot detect a permanent object outside itself, so self-consciousness cannot find a permanent subject in itself. It may, as in Stoicism, assert freedom by holding aloof from the entanglements of real life; or it may sceptically regard the world as a delusion; or finally, as the "unhappy consciousness" (*unglückliches Bewusstsein*), it may be a recurrent falling short of a perfection which it has placed above itself in the heavens. But in this isolation from the world, self-consciousness has closed its gates against the stream of life. The perception of this is reason. Reason, convinced that the world and the soul are alike rational, observes the external world, mental phenomena and specially the nervous organism as the meeting ground of body and mind. But reason, finding much in the world that recognizes no affinity with her, turns to practical activity and seeks in the world the realization of her own aims. Reason abandons her efforts to mold the world and is content to let the aims of individuals work out their results independently, intervening only to lay down precepts by the rules of formal logic.

So far we have seen consciousness on one hand and the real world on the other. The stage of Geist reveals the consciousness no longer as critical and antagonistic but as the indwelling spirit of a community, as no longer isolated from its surroundings but the union of the single and real consciousness with the vital feeling that animates the community. This is the lowest stage of concrete consciousness — life, and not knowledge; the spirit inspires, but does not reflect. It is the age of unconscious morality, when the individual's life is lost in the society of which he is an organic member. But increasing culture presents new ideals, and the mind, absorbing the ethical spirit of its environment, gradually emancipates itself from conventions and superstitions. This emancipation prepares the way for the rule of conscience, for the moral view of the world as subject of a moral law. From the moral world the next step is religion: the moral law gives place to God. But the idea of Godhead, too, as it first appears, is imperfect, and has to pass through the forms of nature worship and of art before it reaches a full utterance in Christianity. Religion in this shape is the nearest step to the stage of absolute knowledge; and this absolute knowledge — "the spirit knowing itself as spirit" — is not something which leaves these other forms behind but the full comprehension of them as the organic constituents of its empire; "they are the memory and the sepulchre of its history and at the same time the actuality, truth and certainty of its throne." Here, according to Hegel, is the field of philosophy.

The Hegelian System and Dialectic. — The compendium of Hegel's system, the Encyclopaedia of the Philosophical Sciences, is in three parts: "Logic," "Nature" and "Mind" (or "Spirit"). The relation between these is dialectical and the method of exposition within each of them is dialectical again. The notion of dialectic Hegel took both from the Greek philosophers and from Kant; it means, originally, "discussion." In a discussion between two people who are both seeking the truth of the topic which is being discussed, diametrically opposed points of view may be advanced in the first instance. Each party, however, may gradually come to understand the other's position, and ultimately both of them may come to agree to reject their own partial views and to accept a new and broader view which does justice to the substance of what each of them had begun by maintaining; the original opposition has been reconciled in a higher synthesis.

Hegel believed that thinking always proceeded according to this pattern: it begins by laying down a positive thesis which is at once negatived by its antithesis; then further thought produces the synthesis. But this in turn generates an antithesis and the same process continues once more, but not indefinitely, for it is circular. Ultimately thinking reaches a synthesis which is identical with its starting point, except that all that was implicit there has now been made explicit.

What is it that drives thinking on in this way? Hegel answers: the power of the negative. Any process of development has two inseparable aspects: (1) the positive aspect of growth, the emergence of something new; and (2) the negative aspect of rejection, the discarding of the old. We become men by putting away childish things, but not by that alone; there must be growth as well. Hegel's point is that thinking itself, as a process, has negativity as one of its constituent moments. In a discussion, the positive thesis advanced by one party is negatived by the other party, so that negation comes from the outside. But thinking, as the discourse of the soul with itself, is dialectical because it carries the negation within itself. Or, to give Hegel's doctrine its theological background, the infinite and the finite are not set over against one another, for if the finite were outside the infinite, the infinite itself would not be all-embracing and would only be another finite; on the contrary, the finite is part and parcel of the infinite itself — its implicit negative moment, to which explicit reality must be given, as God's self-manifestation, in order that spirit's knowledge of itself as a unity of opposites may be complete.

The presence of this element of negativity within thinking itself is, in Hegel's view, the clue to development of all kinds. Suppose a man to be capable of intellectual advance; there is then a clash between his achievement and his potentialities; but the potentialities are actually his and there thus arises for him. as self-conscious mind, a tension between them and his achievement; if they are to be realized the achievement must be rejected, and yet the achievement and a series of achievements are necessary to the realization of the potentialities. The power of mind is infinite, but mind in thinking must think something definite and so something finite; but the finite thing thought is in contradiction to the infinity of thinking and must therefore be rejected in favour of some thought less inadequate to that infinity. This is the sort of dialectical process of which Hegel's system provides an account in three phases.

"Logic". — The system begins with an account of God's thinking "before the creation of nature and finite spirit"; *i.e.,* with the categories or pure forms of thought, which are the structure of all physical and intellectual life. The Phenomenology of Mind has already described the process by which the philosopher has come to occupy the vantage ground from which such an account can be given. Throughout we are dealing with pure essentialities, with spirit thinking its own essence; and these are linked together in a dialectical process which advances from abstract to concrete.

If we try to think the notion of pure being (the most abstract category of all), we find that it is simply emptiness; *i.e.,* nothing. Yet nothing is. The notion of pure being and the notion of nothing are opposites; and yet each, as we try to think it, passes over into the other. But the way out of the contradiction is at once to reject both notions separately and to affirm them both together; *i.e.,* to assert the notion of becoming, since what becomes both is and is not at once. The dialectical process advances through categories of increasing complexity and culminates with the absolute idea, or with the spirit as objective to itself.

"Nature".—Nature is the opposite of spirit. The categories studied in "Logic" are all internally related to one another; they grow out of one another. Nature, on the other hand, is a sphere of external relations. Parts of space and moments of time exclude one another; and everything in nature is in space and time and thds finite. But nature is created by spirit and bears the

mark of its creator. Categories appear in it as its essential structure, and it is the task of the philosophy of nature to detect that structure and its dialectic; but nature, as the realm of externality, cannot be rational through and through, though the rationality prefigured in it becomes gradually explicit when man appears. In man nature rises to self-consciousness. It is clear that the theory of the evolution of species fits in admirably with Hegel's conception of nature, but he rejected it because it had no justification in the science of his day.

"Mind".—Here Hegel follows the development of the human mind through the subconscious, consciousness and the rational will; then through human institutions and human history as the embodiment or objectification of that will; and finally to art, religion and philosophy, in which finally man knows himself as spirit, as one with God and possessed of absolute truth. It is thus then open to him to think his oan essence; *i.e.*, the thoughts expounded in "Logic." We have returned to the starting point of the system but en route have made explicit all that was therein implicit and discovered that "nothing but spirit is, and spirit is pure activity."

Hegel had an eye for detail; his system is not developed a *priori* or in *vacuo* but depends throughout on the results of scientific, historical, theological and philosophical inquiry. No reader of his lectures can fail to be impressed by the penetration and breadth of his mind or by the immense range of knowledge which in his view had to precede the work of philosophizing. "The owl of Minerva spreads her wings only with the falling of the dusk"; *i.e.*, a civilization must be mature and indeed in its death throes before, in the philosophic thinking which has implicitly been its substance, it becomes conscious of itself and its significance. When philosophy comes on the scene, some form of the world has grown old; and it rises into self-consciousness in the philosophy which it produces. The business of philosophy is to comprehend, not to construct.

Philosophy of Right.—Although Hegel's works on politics and history merely elaborate part of his system—that part in which human mind objectifies itself in its endeavour to find an object identical with itself—and are unintelligible in isolation, they deserve separate treatment because they have become so famous, if not notorious. The Philosophy of Right (or of Law) falls into three main divisions. In the first, Hegel is concerned with law and rights as such: persons. not individuals, are the subject of rights, and what is required of them by law is mere obedience, no matter what the motives of obedience may be. The law or a right is thus an abstract universal and therefore, though it is an embodiment of the human will, does justice only to the universal element in that will; all persons are equal before the law. My will, however. though universal as will and rational, is also mine, and this element of individuality demands recognition. The individual cannot be satisfied unless the act which he does accords, not merely with law or custom, but with his own conscientious convictions. Hegel points out that the claims of conscience are what distinguishes the modern world from, for instance, Plato's *Republic*. This distinction has its origin in Christianity. Thus the problem in the modern world is to construct a social and political order which satisfies the claims both of the universal law and of the individual conscience. This is a hard task. because conscience is intimately linked with freedom, the freedom of the rational will as vindicated by Kant. No political order in the modern world can satisfy the demands of reason unless it is organized so as to avoid on the one hand a centralization which would make men slaves or ignore the individual conscience and on the other hand an antinomianism which nould allow freedom of conviction to any individual, no matter what the conviction was. and so produce a licentiousness that would make social and political order impossible.

Hegel proceeds to describe a state in which this synthesis of universal and individual claims is achieved. It rests on the family and on the guild, tno institutions in which, in personal and in communal life. the individual is taught to find in co-operation with others the full satisfaction of his individual needs. Thus schooled, the individual can recognize the state not as something alien and oppressive but as something which, in so far as he participates in it, does satisfy him as an individual while at the same time it maintains peace and order.

The state so described is unlike any existing state in Hegel's day. It is a form of limited monarchy, with parliamentary government, trial by jury and toleration for Jews and dissenters. In all these respects it differed from the contemporary Prussia. It has often been said by Hegel's detractors that his book was nritten on the "dunghill of servility" and that his ideal state is identical with the monarchy of Frederick William. Little historical knowledge and little study of Hegel is required to see that this is nonsense.

Philosophy of History.—Hegel presupposes that the whole of human history is a process through which mankind has been making spiritual and moral progress; it is what human mind has done in the course of its advance to self-knowledge. In other words, history has a plot, and the philosopher's task is to discern it. Many eminent historians have been unable to discern any plot and have contented themselves with recording what has happened; others have found the key to history in the operation of natural laws of various kinds. Hegel's attitude rests on the faith that history is the carrying out of God's purpose and that by the beginning of the 19th century man had advanced far enough to descry what that purpose is. The purpose in question is the gradual realization of human freedom.

The first step was to make the transition from a natural life of savagery to a state of order and law. States had to be founded, and the heroes who founded them had to use force and violence. There is no other way to make men law-abiding before they have advanced far enough mentally to apprehend and to accept the rationality of an ordered life. This process cannot succeed all at once: there will be a stage at which some men have accepted the law and become free, while others must perforce be slaves. In the modern world we have come to appreciate that all men, as minds. are free in essence, and our task is to frame institutions under which they will be free in fact.

Hegel is careful to leave room for developments in the future. He did not believe, despite some critics, that history had ended in his lifetime. In particular, he maintained against Kant that to eliminate war was impossible. Each nation state was an individual, sovereign in its own sphere; and, so long as this remained true, disputes between sovereigns could be settled by violence alone. As Hobbes had said of relations between individuals in the state of nature, pacts without the sword were but words. Students of the history of Europe since Hegel's day may be the last to think him wrong. His reverence for fact prevented him from accepting Kant's idealism.

The Fate of Hegelianism.—Hegel's system is avowedly an attempt to unify opposites—spirit and nature, universal and particular, ideal and real—and to be a synthesis in which all the partial and contradictory philosophies of his predecessors are alike contained and transcended. It is thus both idealism and realism at once, and hence it is not surprising that his successors, emphasizing now one and now another strain in his thought, have interpreted him variously. Conservatives and revolutionaries, believers and atheists have professed alike to draw inspiration from him. In one form or another his teaching dominated German universities for some years after his death and spread to France and to Italy; but its very success produced, as he would himself have foretold, a reaction. Its influence, indeed, was almost dead when in the later part of the 19th century it blossomed anew in England and Scotland in the work of such writers as Benjamin Jowett, T. H. Green, John and Edward Caird. J. M. E. McTaggart and Bernard Bosanquet (see NEO-HEGELIANISM). This success led to a reaction in its turn; but when Hegelianism was dying in Great Britain, interest in Hegel suddenly revived in Germany under the influence of Georg Lasson, a clergyman, and of Wilhelm Dilthey (*q.v.*). These two studied Hegel's manuscripts in the University of Berlin; and on the basis of this study Lasson began a new critical edition of Hegel's works while Dilthey wrote Die *Jugendgeschichte Hegels* (Berlin, 1905) on the development of Hegel's thought prior to the date of his first publications. The

manuscripts on which Dilthey's work is based were then published as *Hegels theologische Jugendschriften,* ed. by H. Nohl (Tübingen, 1907).

Hitherto Hegel's philosophy had won either enthusiastic disciples or bitter opponents; in the 75 years since his death, however, passions had had time to cool, and, thanks to Dilthey and to Lasson and also to Benedetto Croce (*Ciò che è vivo e ciò che è morto della filosofia di Hegel,* Bari, 1907), the critical study of Hegel began. The early theological writings gave rise to an immense body of literature in Germany, in Italy and in France between 1925 and 1950, and an English translation of the more important of them appeared in Chicago in 1948. Interest in these writings and in the *Phenomenology* was increased by the rise of existentialism during the same period. At the same time the growing importance of Communism encouraged political thinkers to study Hegel's political works, as well as his "Logic," because of their influence on Karl Marx.

BIBLIOGRAPHY.—Hegel's collected works, ed. by his pupils, 18 vol. (Berlin, 1832–40), were reprinted in a new arrangement, with the 1st ed. of the *Encyclopaedia* added, as well as an analytical index and a biography, under the editorship of H. Glockner, 26 vol. (Stuttgart, 1927–40). A new edition, incorporating material hitherto unpublished, was begun by G. Lasson in 1907, but was suspended during World War II and then replanned under J. Hoffmeister to consist of 32 vol. (Hamburg, 1952 —); this was to include the *Theologische Jugendschriften.* English translations include: T. M. Knox, *Hegel's Early Theological Writings* (Chicago, 1948); J. B. Baillie, *Phenomenology of Mind,* 2nd ed. (London, New York, 1931); W. H. Johnston and L. G. Struthers, *Science of Logic,* 2 vol. (London, New York, 1929); H. S. Macran, *Hegel's Doctrine of Formal Logic* (Oxford, 1912) and *Hegel's Logic of World and Idea* (Oxford, 1929); W. Wallace, *The Logic of Hegel,* 2nd ed., 2 vol. (Oxford, 1892–94), and *Hegel's Philosophy of Mind* (Oxford, 1894); T. M. Knox, *Hegel's Philosophy of Right,* revised ed. (Oxford, 1943); J. Sibree, *Philosophy of History* (London, 1857; new issue, 1947); F. B. Osmaston, *Hegel's Philosophy of Fine Art,* 4 vol. (London, 1916–20); E. B. Spiers and J. B. Sanderson, *Philosophy of Religion,* 3 vol. (London, 1895); E. S. Haldane and F. H. Simson, *Lectures on the History of Philosophy,* 3 vol. (London, 1892–96; reissue, London, 1955).

HEGEMON OF THASOS, Greek writer of the old comedy, flourished during the Peloponnesian War. According to Aristotle (*Poetics,* ii, 5) he was the inventor of a kind of parody; by slightly altering the wording in well-known poems he transformed the sublime into the ridiculous.

Fragments in T. Kock, *Comicorum Atticorum fragmenta,* i (1880); B. J. Peltzer, *De parodica Graecorum poesi* (1855).

HEGEMONY, leadership, predominance and preponderance —originally the leadership of one particular state in a group of federated or loosely united states. The term was first applied in Greek history to describe the predominance, at different times, of individual Greek city-states; *e.g.,* Athens, Sparta and Thebes, over other city-states. Philip of Macedon claimed for Macedonia the "hegemony" of Greece. In the 19th century, hegemony, as leadership within a confederation, was similarly applied to the position of Prussia vis-à-vis the other German states. The term has come to assume a more general meaning as the predominance of a nation or group of nations within a given area. Thus, Great Britain is said to have enjoyed a position of over-all hegemony from the end of the Napoleonic wars (1815) to the advent of World War I.

With 20th-century advances in communications, making the remotest areas of the globe accessible to conquest, the "drive for hegemony" denotes the attempt by any nation to dominate. Hitler, for example, with the support of Italy and Japan, made a bid for global hegemony. (R. S.-HE.)

HEGESIAS OF MAGNESIA (in Lydia), Greek rhetorician and historian, flourished about 300 B.C. Strabo (xiv, 648) speaks of him as the founder of the florid "Asiatic" style (*see* TIMAEUS). Agatharchides, Dionysius of Halicarnassus and Cicero all speak of him in disparaging terms, although Varro seems to have approved of his work. He professed to imitate the simple style of Lysias, avoiding long periods and expressing himself in short, jerky sentences, but his vulgar affectation and bombast made his writings a mere caricature of the old Attic.

See C. W. Müller, *Scriptores rerum Alexandri Magni,* p. 138 (appendix to Didot ed. of Arrian, 1846); Norden, *Die antike Kunstprosa* (1898); J. B. Bury, *Ancient Greek Historians,* pp. 169–172 (1909), on origin and development of "Asiatic" style, with example from Hegesias. Fragments and references in ancient authorities in F. Jacoby, *Fragmente der griechischen Historiker,* vol. ii (1927).

HEGESIPPUS (*fl.* 4th century B.C.), Athenian orator and statesman, who may have been the author of an oration ascribed to Demosthenes, his contemporary, was the son of Hegesias of Sunium. In 343 B.C. he was sent on an embassy to Philip of Macedon, who subsequently wrote a letter to which the 7th oration (*Peri Halonnesou*) in the Demosthenes corpus is a reply. Libanius and some other early critics ascribed this oration to Hegesippus on grounds of style, but Photius suggested that it was one of Demosthenes' less typical pieces. No other works of Hegesippus are extant.

See G. Dindorf's ed. of Demosthenes in the "Teubner Series," vol. 1, pp. 114–126 (1885) and Pauly-Wissowa, *Real-Encyclopädie,* suppl. 4, col. 713–714 (1924).

HEGESIPPUS (*fl.* A.D. 150–180), early Christian writer, was of Palestinian origin, and lived under the emperors Antoninius Pius, Marcus Aurelius and Commodus. He belonged to that group of Judaistic Christians which, while keeping the law themselves, did not attempt to impose on others the requirements of circumcision and Sabbath observance. He was the author of a treatise in five books dealing with various aspects of the Christian religion, fragments of which are found in Eusebius. Hegesippus was also a great traveler, and like many other leaders of his time came to Rome about the middle of the 2nd century. His journeyings impressed him with the idea that the continuity of the church in the cities he visited was a guarantee of its fidelity to apostolic orthodoxy: "in each succession and in every city, the doctrine is in accordance with that which the Law and the Prophets and the Lord (*i.e.,* the Old Testament and the evangelical tradition) proclaim." To illustrate this opinion he drew up a list of the Roman bishops.

HEGESIPPUS, the supposed author of a free Latin adaptation of the *Jewish War* of Josephus under the title *De bello Judaico et excidio urbis Hierosolymitanae.* The seven books of Josephus are compressed into five, but much has been added from

the *Antiquities* and from the works of Roman historians, while several entirely new speeches are introduced to suit the occasion. Internal evidence shows that the work could not have been written before the 4th century A.D. The author, who is undoubtedly a Christian, describes it in his preface as a kind of revised edition of Josephus. Some authorities attribute it to Ambrose, bishop of Milan (340–397), but there is nothing to settle the authorship definitely. The name Hegesippus itself appears to be a corruption of Josephus, through the stages Ἰώσηπος, Iosippus, Egesippus, Hegesippus, unless it was purposely adopted as reminiscent of Hegesippus, the father of ecclesiastical history (2nd century).

See edition by C. F. Weber and J. Caesar (1864); E. Schurer, *History of the Jewish People* (Eng. trans.), i, 99 *seq.*

HEGIUS, ALEXANDER (c. 1433–1498), German humanist schoolmaster, was born at Heek (from which his name, in Latin form, is derived) in Westphalia. He was associated with the Brethren of the Common Life in the revival of learning in northern Europe. His long teaching career included the headship of schools in Wessel, Emmerich and Deventer, where Erasmus, Butzbach and the future Pope Adrian VI were among his pupils. At Deventer, Hegius put into practice the humanistic ideas of his youthful friend and teacher. Rudolph Agricola, who brought from Italy the new learning, stressing the liberal arts and the art of conduct. To this end Hegius reformed instructional methods to make Latin and Greek grammar subordinate to the appreciation of classical literature. New textbooks were introduced and the school was divided into eight classes. Hegius died at Deventer on Dec. 7, 1498. His writings were published in 1503 by his pupil Jacob Faber.

See William H. Woodward, *Studies in Education During the Age of the Renaissance, 1400–1600* (1906); D. Reichling, "Beitrage zur Charakteristik des Alex. Hegius," in the *Monatsschrift fur Westdeutschland* (1877). (*J. M.* Bk.)

HEHE, a Bantu tribe inhabiting the Tanganyika plateau, combining agriculture with animal husbandry. Sheep, goats and fowls are kept in addition to cattle, the care of which is almost exclusively man's province, while women are responsible for agricultural economics, raising millet, yams, maize and a variety of leguminous and other vegetable crops. While their characteristics are chiefly eastern they display certain lacustrian contacts and southern influences can be traced in their internal organization.

The most characteristic feature is the tembe, a long building partitioned into separate chambers for families. Each chamber is subdivided into two rooms, the outer one for boys, the inner for women and the head of the family. A tembe varies in size from one sufficient for a few families to the length of a kilometre, and a village may consist of anything from one small tembe to a number of large ones adjoining. The houses are made of palings neatly plastered with clay, with a slightly curved roof also constructed with palings covered with rushes and caulked with clay.

Kinship is mainly reckoned in the paternal line and the maternal kinship imposes obligations for one generation only, whereas any paternal relationship that can be proved in the remotest degree is important and is a bar to marriage. Marriage is arranged between a man and the bride's father and involves the payment of a dowry by the former. Polygyny is practised, but the first wife must be the mother's brother's daughter, and only after this statutory marriage may a man exercise his own choice. On marriage a boy or girl leaves the family chamber and builds anew. A peculiar system of totemism prevails, as every one possesses one or two totems inherited paternally. The totem may be an animal or part of an animal or a part of all animals, for instance a sheep's head or the heart of all animals. But though there is no prohibition against killing the totem, a dispensatory ceremony is required before it may be eaten. The possession of the same totem is no bar to marriage unless a common paternal ancestor can also be determined.

The weapons employed are the heavy-bladed thrusting spear, light throwing spears with barbed blades and a battle axe, showing an influence which is probably traceable to the Angoni. A large oval shield of oxhide is carried.

The Hehe believe in a vague deity *Nguruhe,* who controls things in general but to whom neither prayers nor sacrifices are offered. Their religion consists mainly of the worship of ancestor-spirits *(masoka),* to whom prayers are made for success and prosperity and the avoidance of evils. Offerings of grain, milk or flesh are made at the grave of an ancestor by the head of the family.

See E. Nigmann, *Die Wahehe* (1908). (J. H. D.)

HEIBERG, JOHAN LUDVIG (1791–1860), Danish dramatist and man of letters, originator of the Danish vaudeville, or ballad opera, was born in Copenhagen, Dec. 14, 1791, son of the playwright and political writer, P. A. Heiberg (1758–1841) and his wife Thomasine, later Baroness Gyllembourg-Ehrensvard (1773–1856), the novelist. He matriculated at Copenhagen university in 1809, and his first publication, *Marionettheater* (1813; dated 1814), comprising two romantic dramas, showed independence of outlook, elegance and clarity of thought. In 1817 he took his doctorate with a thesis on Calderón, to whose work he was attracted, though not himself a mystic, by its blend of sublime and "folk" elements. In 1819 he went to Paris with a government grant, and in 1822 was appointed lecturer in Danish at Kiel university. There he wrote the treatise *Om den menneskelige Frihed* ("On Human Freedom," 1824) which introduced Hegelian philosophy to Denmark.

He returned to Copenhagen in 1825 and his *Kong Salomon og Jprgen Hattemager* was produced there, with great acclamation, on Nov. 28. It was the first Danish vaudeville, with songs set to well-known melodies, and although derived from Parisian and Viennese models, the subject and the humour were national and topical. Heiberg exploited the new genre with verve and versatility in *Aprilsnarrene* (1826). *De Uadskillelige* (182;) and many others, and defended it on sound Hegelian principles in the treatise *Om Vaudevillen som dramatisk Digtart* ("On the Vaudeville as a Dramatic Form," 1826). More serious and poetical in intention and execution were the romantic dramas *Elverhøi* (performed 1828), *Alferne* (1834). *Fata Morgana* (1838) and *Syvsoverdag* (1840), which blend fantasy and realism and contain much of Heiberg's best lyrical poetry.

From 1827 to 1830 Heiberg edited the *Kjøbenhavns flyvende Post,* which, with its successors, exerted considerable influence by introducing new authors and criticizing Ohlenschlager and other romantics for deficiencies in taste. form and intellectual content. His polemics and his gift for pointed satire. of which the apocalyptic poem "En Sjæl efter Døden" (included in *Nye Digte,* 1841) and the satyr play *Nøddeknækkerne* (1845) are supreme examples, made Heiberg many enemies and he never fully recovered his popularity. From 1849 to 1856 he had some success as the director of the Royal theatre, but the last 20 years of his life were mainly spent in studying physical science. He died at Bonderup near Ringsted. Aug. 25, 1860. His prose works appeared in 11 vol. (1861–62), and his poetical writings in 11 vol. (1862).

In 1831 Heiberg married Johanne Luise Patges (1812–1890), the foremost Danish actress of her day and herself author of some good vaudevilles and of interesting memoirs *(Et Liv,* 4 vol.. 1891–92).

HEIDE, a town in the *Land* of Schleswig-Holstein, Germany, on a small plateau between the marshes and moors bordering the North sea, 35 mi. N.N.W. of Gluckstadt. Pop. (1950) 22,169. In 1447 it became the capital of the Ditmarsh peasant republic, but on June 13, 1559, it was the scene of the complete defeat of the peasant forces by the Danes.

HEIDEGGER, JOHANN HEINRICH (1633–1698), Swiss Reformed theologian, was born at Bärentschweil, in the canton of Zürich, Switz., on July 1, 1633. After studying in Germany he settled in 1665 in Zurich, where he was successively professor of moral philosophy and of theology. He died there on Jan. 18, 1698.

Heidegger was the principal author of the *Formula Consensus Helvetica* in 1675, which was designed to unite the Swiss Reformed

churches, but had an opposite effect.

Heidegger's autobiography appeared in 1698, under the title *Historia vitae J. H. Heideggeri.*

HEIDEGGER, MARTIN (1889–), German philosopher who exercised a major influence on 20th-century existentialism, was born at Messkirch in the Black Forest on Sept. 26, 1889. He studied philosophy at Freiburg, coming under the influence of Edmund Husserl, the founder of phenomenology. He was appointed professor of philosophy at Marburg in 1923. In 1927 he published *Sein und Zeit,* part i, the work on which his reputation chiefly rests. I-laving succeeded Husserl as professor at Freiburg in 1928, he was made rector of that university in 1933; in his rectorial address he expressed his hope for "a complete revolution of German existence." In 1934 he resigned this post and resumed his teaching.

While the second part of *Sein und Zeit* was not forthcoming, Heidegger published numerous essays and lectures, of which the following are particularly noteworthy: *Was ist Metaphysik?* (Bonn, 1929); *Vom Wesen des Grundes* (Halle, 1929); *Hölderlin und das Wesen der Dichtung* (Munich, 1937, previously printed in *Das Innere Reich,* 1936); *Vom Wesen der Wahrheit* (Frankfurt-am-Main, 1943); *Brief über den Humanismus* (Frankfurt-am-Main, 1947); *Holzwege* (Frankfurt-am-Main, 1949); *Einführung in die Metaphysik* (Tiibingen, 1953); and *Vorträge und Aufsätze* (Pfullingen, 1954).

In *Sein und Zeit* Heidegger sets out to discover "the meaning of being" *(Sein).* He holds that a necessary preliminary is an investigation of human being *(Dasein),* carried out. not in terms of sophisticated theoretical conceptions such as "substance" or "cause," but in terms of the tools with which men are practically concerned and of men's basic situation, aims and moods. When considered in this way human existence is seen to be grounded in care and dread and to consist in projects brought to nothingness in death. Although Heidegger acknowledges the influence of Soren Kierkegaard, he denies that he himself is an existentialist, but nevertheless *Sein und Zeit* mas important in the development of the atheistic forrn of existentialism. Heidegger continued to employ the method, prominent in *Sein und Zeit,* of basing metaphysical assertions on the literal meanings of the roots of German words and amplified it with parallel discussions based on the etymology of Greek philosophical terms. He holds that the basic metaphysical question is "Why is there something rather than nothing at all?", emphasizes fate and destiny and asserts that although Christian faith exists "here and there." in the 20th-century world "God is no longer a living God" ("Nietzsche's Wort 'Gott ist tot' " in *Holzwege,* pp. 234–235). Nevertheless he also says that in poetry the holy beings or the gods are "named" and communicated to the people.

HEIDELBERG, the name of two towns in the Union of South Africa:

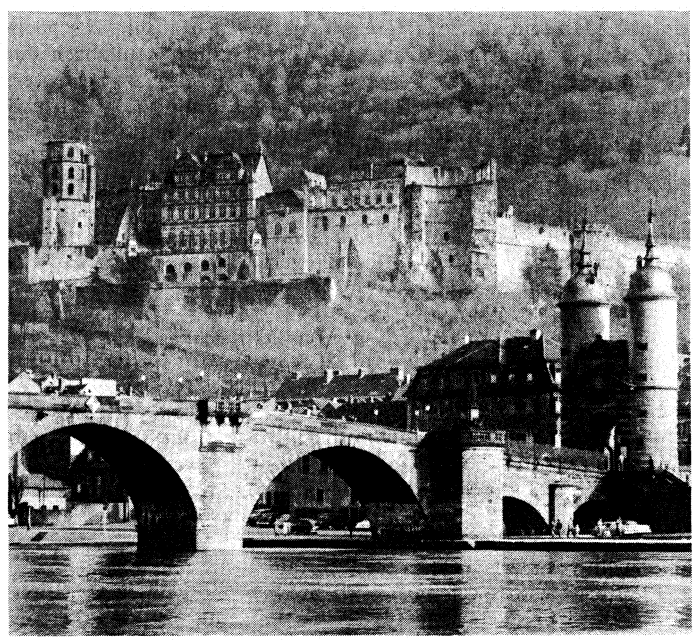
1. Situated in the Transvaal, 31 mi. S.E. of Johannesburg, and 390 mi. from Durban. Altitude, 5.026 ft. Pop. (1951) 7,677, including 2,896 Europeans. The town is built on the Blesbokspruit, just on the southeastern side of the Witwatersrand gold fields. The district of Heidelberg extends southward to the Vaal river and is part of the great maize triangle of South Africa.

2. Situated on the Duivenhoeks river in Cape Province, 230 mi. east of Cape Town by rail. Altitude, 250 ft. Pop. (1951) 2,898, including 1,259 Europeans. The principal productions of the region are wool, grain, aloes and tobacco.

HEIDELBERG, a town of Baden-Württemberg, Germany, on the south bank of the Neckar, 12 mi. above its confluence with the Rhine, 13 mi. S.E. from Mannheim and 54 mi. from Frankfurt-on-Main by rail. The town lies between hills covered with vineyards and forests, at the spot where the rapid Neckar leaves the gorge and enters the plains of the Rhine. The town itself consists practically of one long, narrow street—the Hauptstrasse—running parallel to the river. A number of smaller streets intersect the Hauptstrasse at right angles and run down to the river. Heidelberg is an important railway centre, and is connected by trunk lines with Frankfort, Mannheim, Karlsruhe. Spires and Wiirzburg.

Of the churches the chief are the Protestant Peterskirche dating from the 15th century and restored in 1873, to the door of which Jerome of Prague in 1406 nailed his theses; the Heilige Geist Kirche (Church of the Holy Ghost), an imposing Gothic edifice of the 15th century; and the Jesuitenkirche (Roman Catholic), nith a decorated interior.

Heidelberg castle. overhanging the east of the town, stands on the Jettenbuhl, a spur of the Konigsstuhl (1,857 ft.), 330 ft. above the Neckar. It is one of the chief monuments of Germany, begun in the 13th century and extended by addition of a wing, Ruprechtsbau, under the elector palatine and the German king



BY COURTESY OF THE GERMAN TOURIST INFORMATION OFFICE

THE TOWN OF HEIDELBERG FROM THE NECKAR RIVER IN THE FOREGROUND IS THE KARL-THEODORE BRIDGE (ERECTED IN 1786) WITH ITS TWO-TOWERED GATE: IN THE BACKGROUND IS THE CASTLE (CONSTRUCTION BEGUN IN THE 13TH CENTURY)

Rupert III (d. 1410). Otto Henry "the Magnanimous" (d. 1559), built the beautiful early Renaissance wing (1556–59); the fine late Renaissance wing called the Friedrichsbau was added (1601–07) under Frederick IV; and, on the west side, the Elisabethenbau or Englischebau (1618), named after his wife, the daughter of James I of Great Britain, built under Frederick V. At the peace of Westphalia, Heidelberg was given back to Frederick V's son, Charles Louis, who restored the castle. At the end of the 17th century it was despoiled by the French and finally, in 1764, it was struck by lightning and reduced to ruin. Apart from outworks, the castle is an irregular square with round towers at the angles, the principal buildings being grouped round a central courtyard containing the Alte Bau and the Bandhaus with the entrance from the south through a series of gateways. In this courtyard, besides the buildings already mentioned. are the oldest parts of the castle, the so-called Alte Bau (old building) and the Bandhaus. The Friedrichsbau was elaborately restored and rendered habitable between 1897 and 1903. The fountain in the courtyard is decorated with four granite columns from Charlemagne's palace at Ingelheim; the Elisabethentor is a beautiful gateway named after the English princess, there is a beautiful octagonal bell tower at the northeast angle; and the castle chapel and the museum of antiquities are in the Friedrichsbau. In a cellar entered from the courtyard is the famous vat built in 1751, which has been used only occasionally. Its capacity is 49,000 gal., and it is 20 ft.

high and 31 ft. long. Behind the Friedrichsbau is the Altan (1610), or castle balcony with a magnificent view.

The university of Heidelberg was founded by the elector Rupert I., the bull of foundation being issued by Pope Urban VI. in 1385. It was constructed after the type of Paris, and had four faculties; Otto Henry gave it a new organization, further endowed it and founded the library, first kept in the choir of the Heilige Geist Kirche, and consisting of 3500 mss. In 1623 it was sent to Rome by Maximilian I. of Bavaria, and stored as the Bibliotheca Palatina in the Vatican. It was afterwards taken to Paris, and in 1815 was restored to Heidelberg.

At the Reformation the university became a stronghold of Protestant learning. Damaged by the Thirty Years' War, it led a struggling existence for a century and a half and many of its endowments uere cut off by the peace of Lunéville (1801).

Heidelberg makes metalware, pianos, cigars, leather. cement, surgical instruments and beer, but is ordinarily concerned with catering for tourists and students. Pop. (1950) 116,488. In World War II the city suffered little damage.

HEIDELBERG CATECHISM, THE, the most attractive of all the catechisms of the Reformation, was drawn up at the bidding of Frederick III., elector of the Palatinate, and published on Tuesday the 19th of January 1563. The task was entrusted to two young men who have won deserved remembrance alike by their learning and their character: Zacharias Ursinus (1536–1583), a man of modest and gentle spirit, unwearied in study and well fitted to impart his learning to others; and Caspar Olevianus (1536–1587), whose ardour and enthusiasm made him the happy complement of Ursinus. The elector could have chosen no better men, young as they were, for the task in hand. As a first step each drew up a catechism of his own composition, that of Ursinus being naturally of a more grave and academic turn than the freer production of Olevianus, while each made full use of the earlier catechisms already in use. But when the union was effected it was found that the spirits of the two authors were most happily and harmoniously wedded, the exactness and erudition of the one being blended with the fervency and grace of the other. Thus the Heidelberg Catechism, which was completed within a year of its inception, has an individuality that marks it out from all its predecessors and successors. The Heidelberg synod unanimously approved of it; it was published in January 1563, and in the same year officially turned into Latin. The Heidelberg book, in spite of violent attacks on it by the extreme Lutherans, rapidly passed beyond the bounds of the Palatinate and gained an abundant success not only in Germany but also in the Netherlands and in the Reformed churches of Hungary, Transylvania and Poland. It was officially recognized by the synod of Dort in 1619, passed into France, Britain and America, and probably shares with the De *imitatione Christi* and *The Pilgrim's Progress* the honour of coming next to the Bible in the number of tongues into which it has been translated.

This wide acceptance and high esteem are due largely to an avoidance of polemical and controversial subjects, and even more to an absence of the controversial spirit. There is no mistake about its Protestantism, even when we omit the unhappy addition made to answer 80 by Frederick himself (in indignant reply to the ban pronounced by the Council of Trent), in which the Mass is described as "nothing else than a denial of the one sacrifice and passion of Jesus Christ, and an accursed idolatry"—an addition which is the one blot on the ἐπιείκεια of the catechism. The work is the product of the best qualities of head and heart, and its prose is frequently marked by all the beauty of a lyric. It follows the plan of the epistle to the Romans (excepting chapters ix.–xi.) and falls into three parts: Sin, Redemption and the New Life. This arrangement alone would mark it out from the normal Reformation catechism, which runs along the stereotyped lines of Decalogue, Creed, Lord's Prayer, Church and Sacraments. These themes are included, but are shown as organically related.

BIBLIOGRAPHY.—See *The Heidelberg Catechism,* the *German Text, with a Revised Translation and Introduction,* edited *by A* Smellie (London, 1900), and *The Hezdelberg Catechism* (New York, 1863), with introduction and German, Latin and English text; also Schaff, **Creeds** of *Christendom,* **vols.** i. 529 ff.and iii. 307 ff., and Müller, *Die Bekenntniss Schriften der Reformierten Kirche* **(Leipzig,** 1903).

HEIDENHEIM, a town of Germany, in the *Land* of Baden-Württemberg, 31 mi by rail N. by E. of Ulm. Pop. (1950) 40,142. The town, which received municipal privileges in 1356, is overlooked by the ruins of the castle of Hellenstein, standing on a hill 1,985 ft. high. Its industrial establishments include cotton, tobacco, machinery, metal and rubber factories, bleach-works, dyeworks and breueries. Heidenheim is also the name of a small place in Bavaria famous on account of the Benedictine abbey, founded in 748 by the bishop of Eichstatt, which formerly stood therein. It was plundered by the peasantry in 1525 and was closed in 1537.

HEIDENSTAM, (KARL GUSTAF) VERNER VON (1859–1940), Swedish poet and prose writer, who won the Nobel prize for literature in 1916 and whose reputation rests on his lyrical poetry. uas born. July 6. 1859, at the manor house of Olshammar, in the province of Närke, which inspired much of his poetry. A delicate boy, in 1876 he was sent to the middle east and after his first (of three) marriages, in 1880, lived in Italy, France and for several years in Switzerland, where he had an important meeting nith Strindberg. On return to Sweden, he published *Vallfart och Vandringsår* (1888), richly coloured poems based mainly on impressions of the east. early study of painting gave all his literary work a strong sense of colour. Original and imaginative, it formed a protest against naturalism and marked the beginning of the literary renaissance of the 1890s. Similar in effect were *Endymion* (1889), a novel set in Damascus. and *Hans Alienus* (1892), a fanciful epic describing a pilgrimage in search of beauty through various ages and countries, partly suggested by *Childe Harold.* Travel sketches, full of wit and psychological observation, were collected in *Från Col dt Tenda till Blocksberg* (1888).

Heidenstam's second collection of poems (1895), expressing personal feelings with great richness of texture, marks a transition to love of home and nationalism, which culminated in the famous *Karolinerna,* 2 vol. (1897–98; Eng. trans. *The Charles Men,* 1920). impressionistic stories of Charles XII and his followers. His historical writings were continued nith *Heliga Birgittas pilgrimsfard* (1901): *Folkungaträdet,* 2 vol. (1905–07) a powerful story of ancient and medieval Sweden, and a book for schools, *Svenskarna och deras hövdingar,* 2 vol. (1908–10; Eng trans. *The Swedes and thezr Chieftains,* 1925). His third and greatest collection of poetry, *Nya Dikter* (1915), contains lyrics comparable with those of Goethe. For the rest of his life he did not publish anything; after his death, at Övralid. May 20. 1940, some of his literary remains nere edited, the most notable being *Nar kastanjerna blommade* (1941), charming evocations of the Olshammar of his childhood. His collected works were edited by F. Book and K. Bang, 23 vol. (1943–44).

BIBLIOGRAPHY.—H. Kamras, *Den unge Heidenstam* (1942); F Böök, *V von Heidenstam* (2 vol., 1945–46; 2nd ed., 1 vol. 1959); K Bang, *Vagen till Ovralid* (1945) and *Övralid* **(1946)**; S. Björck, *Heidenstam och sekelskzjtets Sverige* **(1946)**; *G* Axberger, *Diktaren och elden* (1959) (H Ks.)

HEIJERMANS, HERMANN (1864–1924), Dutch writer, of Jewish origin, was born on Dec. 3, 1864, at Rotterdam. In the Amsterdam *Handelsblad* he published a series of realistic sketches of Jewish family life under the pseudonym of "Samuel Falkland," which were collected in volume form. His novels and tales include *Trinette* (1892), *Fles* (1893), *Kamertjeszonde* (2 vols., 1896), *Intérieurs* (1897), *Diamantstadt* (2 vols.. 1903). He created great interest by his play *Op Hoop van Zegen* (1900), represented at the Théâtre Antoine in Paris, and in English by the Stage Society as *The Good Hope.* His other plays include. *Dora Kremer* (1893), *Ghetto* (1898), *Ora et labora* (1901), *De Groote Vlucht* (1908), *Eva Bonheur* (1919). *A Case of Arson,* an English version of the one-act play *Brand in de Jonge Jan,* was notable for the impersonation (1904 and 1905) by Henri de Vries of all seven witnesses who appear as characters Heijermans lived for a few years in Berlin, but returned to the Netherlands in 1912 to manage a society of players. He died at Zandvoort on Nov. 22, 1924

HEILBRONN, a town of Germany, in the *Land* of Baden-Wurttemberg, on the Keckar, 33 mi. by rail N. of Stuttgart. and

at the junction of lines to Crailsheim and Eppingen. Pop. (1950) 139,332, administrative district; 64.643, town. It occupies the site of an old Roman settlement; it is first mentioned in 741, and the Carolingian princes had a palace there. It owes its name–+riginally Heiligbronn, or holy spring—to a spring of water which issued from under the high altar of the church of St. Kilian.

The older streets are narrow, and contain a number of high turreted houses with quaint gables. The principal public buildings are the church of St Kilian (restored 1886–1895) in the Gothic and Renaissance styles, begun about 1019 and completed in 1529, with a tower 210 ft. high, a beautiful choir. and a finely carved altar; the town hall (Rathaus), founded in 1540, and possessing a curious clock made in 1580; the house of the Teutonic knights (Deutsches Haus); the Roman Catholic church of St. Joseph, formerly the church of the Teutonic Order; and the tower (Diebsturm or Götzens Turm) on the Neckar. The town is commercially the most important in Württemberg, and possesses an immense variety of manufactures, of which the principal are gold, silver, steel and iron wares, machines, motor cars, sugar of lead, white lead, vinegar, beer, sugar, tobacco, soap, oil, chemicals, artificial manure, glue, soda, paper and leather.

HEILSBERG (after World War II, LIDZBARK WARMINSKI), a town in Olsztyn province, Poland, at the junction of the Simser and Alle, 38 mi. S. of Kaliningrad (Konigsberg). Pop. (1950) 7,200. It has a castle, founded by the Teutonic order in 1240, which was the seat of the bishops of Ermeland (1306–*c* 1800). In 1807 the French fought the Russians and Prussians nearby. Industries are tanning, dyeing and brewing, and there is trade in grain.

HEILSBRONN or KLOSTER-HEILSBRONN, a village of Germany, in the Land of Bavaria, on the railway between Nürnberg and Ansbach. Pop. (1950) 3,464. In the middle ages it possessed one of the great monasteries of Germany, which belonged to the Cistercian order and owed its origin to Bishop Otto of Bamberg in 1132, existing till 1555. Its sepulchral monuments are of exceptionally high artistic interest. It was the hereditary burial-place of the Hohenzollern family. The buildings of the monastery have mostly disappeared, with the exception of the fine church, a Romanesque basilica, restored between 1851 and 1866, and possessing paintings by Albert Durer.

HEILUNGKIANG (HEI-LUNG-CHIANG SHENG), northernmost of the three Manchurian provinces of China. It is named for the Amur river, which is known as Heilungkiang (Black Dragon river) in Chinese, and forms the northern border of the province. Heilungkiang has an area of 99,522 sq.mi. and a population of 11,897,309 (1953). Its capital is Harbin.

The black chernozem soils of Heilungkiang favour the growing of wheat, which is planted to a large extent in large mechanized state farms established by new settlers in the ndrthern virgin lands of the province. Other important crops are sugar beets, soybeans and flax. Timber is felled in the Little Khingan mountains around the lumber town of Ichun. The principal mineral resources are coal, which is mined at Hokang. Shwangyashan and Kisi, and gold, which occurs in placers along tributaries of the Amur river.

Most of the province's large cities are situated along the Chinese Eastern railroad, which crosses Heilungkiang from northwest to southeast, and along the Sungari river, a navigable tributary of the Amur. Harbin, with a population of 1,163,000 (1953 census), is the principal manufacturing and transportation centre, with machine building and agricultural processing industries. Other cities and their 1953 population are Tsitsihar (200,000), Mutankiang (250,000) and Kiamusze (146,000). (T. SD.)

HEIM, ALBERT VON ST. GALLEN (1849–1937), Swiss geologist, was born at Ziirich on April 12, 1849. He was educated at Zurich and Berlin universities, and became professor of geology at Zurich, and director of the geological survey of Switzerland. With E. Schmidt he prepared the geological map of Switzerland (2nd ed. 1912). His researches on the structure of the Alps threw light on the structure of mountain masses in general. He traced the plications from minor to major stages, and illustrated the remarkable foldings and overthrust faultings in numerous sections with the aid of pictorial drawings. His *Mechanismus* der Gebirgsbildung (1878) is a classic.

HEIMDAL (HEIMDALL), in Scandinavian mythology. keeper of the gates of Heaven, guardian of the rainbow bridge Bifrost, used by the gods between heaven and earth, son of Odin by nine virgins. He lives in the fort of Himinsbiorg at the end of Bifrost. Nothing can escape his vigilance, for he sleeps less than a bird, sees at night and in his sleep, can hear grass and the wool on a lamb's back grow. With Gjallarhorn he will summon the gods on the day of judgment.

HEINE, HEINRICH (originally HARRY) (1797–1856), one of the greatest German lyric poets and an outstanding satirist and publicist, was born at Dusseldorf on Dec. 13, 1797, the eldest of the four children of Jewish parents, Samson Heine and Betty (Peierche) van Geldern. He took the name Heinrich at his baptism in 1825. Owing to the French occupation of the Grand Duchy of Berg (1806–13), his education inspired in him an ardent love of liberty and hero worship for Napoleon (Die Grenadiere, Das Buch Le Grand and passim). Destined for a commercial career, he made a bad start at Frankfurt-on-Main and was sent to his millionaire uncle, the banker Solomon Heine, at Hamburg (1816–19), for his father's health had declined and his business had failed. Heine was set up on his own, but the firm Harry Heine & Co. went bankrupt within a year and thereafter relations between the millionaire and the poet were often strained. The latter's sufferings at Ottensen, his uncle's country seat, are described in the poem "Affrontenburg," written 30 years later; they were intensified by his unrequited passion for "Molly," presumably his cousin Xmalie Heine. Being unfit for commerce, Harry was sent to Bonn to read law; but he preferred to study literature under A. W. Schlegel, moving on to Gottingen in 1820. Rusticated for six months because he had challenged a fellow student to a duel, he went to Berlin where he sat at the feet of Hegel and the classical scholar Friedrich Wolf. He frequented the salon of Varnhagen and Rahel von Ense and other literary and intellectual circles, and belonged to the Society for the Culture and Learning of the Jews. In 1821 he published a volume of Gedichte and in 1823 *Tragödien nebst* einem lyrischen Intermezzo. The tragedies, Almansor and *Ratcliff*, showed no great promise; but the lyrical sequence contained a number of those songs made famous by the settings of Schubert, Schumann, Mendelssohn, Liszt, Brahms, Wagner, Hugo Wolf and others. Yet already in this collection the pure melodies of the love lyrics were mingled with ironical, flippant and even cynical strains in a deliberate effort at emotional truth.

In 1823 the civil disabilities against the Jews were again enforced; rather than accept baptism Heine decided to become a journalist in Paris. He went to Hamburg to obtain his uncle's consent, and found passion overwhelming him again, "grafting a new folly on to the old," as he put it. This has been plausibly interpreted by E. Elster to mean that he had fallen in love for the second time with a daughter of Solomon Heine, Amalie's younger sister Therese. He fled from Hamburg to Cuxhaven, where his first sight of the sea and his first experience of a storm aroused that feeling of kinship to which we owe his magnificent Nordsee cycles. An incensed letter from his uncle, threatening to cut off his meagre allowance because it had been anticipated, added to his emotional turmoil. The Paris scheme was dropped and Heine returned to Gottingen in January to prepare for his final examination. His excursion to the Harz mountains that autumn was to bring him fame, but his visit to Goethe in Weimar on Oct. 2 resulted in a snub and he was in very low spirits when, having passed the written examination, he was baptized privately on June 28, 1825, in order to proceed to the public disputation on July 20, at which he obtained the degree of doctor of laws. He felt this "apostasy" keenly, although he was neither a practising nor-a professing Jew, and it never procured him any practical advantage; but the striking success of Reisebilder I (Heimkehr, Harzreise, Nordsee I) in 1826, followed by *Reisebilder* 11 (Nordsee *II*, Nordsee III, Ideen oder das Buch Le Grand, Briefe aus Berlin) in 1827 and Buch der Lieder in the same year opened up literary prospects.

Buch der Lieder, which ran through 13 large editions in Heine's lifetime, placed him in the first rank of contemporary poets. As a ballad poet he is unrivaled; and the best of his love lyrics crystallize in a few short, exquisite verses his poignant personal emo-

tions, combining the charm and simplicity of the folksong with informal modern speech. Musical and magical, they are, as Benedetto Croce was to say, "pure and transparent as a dew-drop." The *Nordsee* cycles in free rhythms echo the stormy splendour, the ceaseless ebb and flow, the gentle murmuring and the breathless calm of the sea which harbours Heinesque Homeric divinities. A new note too mas struck in the prose sketches in the *Reisebilder,* written in a flexible, vivid and racy style. They are intensely subjective and multiple in mood, witty, captivating, exasperating, challenging, daring and provocative. Heine, who needed a courageous publisher for such works, had found one in Julius Campe; but this best-selling author was never remunerated adequately; so that, between his uncle and his publisher, the poet was perpetually on the rocks.

Things were rather easier in 1827, however, and Heine, attracted by the fame of George Canning, was in London from April to August. "Never send a poet to England," he moaned, aghast at English materialism. He saw all the sights and assiduously frequented the house of commons, admiring English liberal institutions and continuing to revere Canning. But what with England's treatment of Napoleon and Byron, its stiffness and coldness, its cooking and its climate, he returned to Germany a full-blown Anglophobe. Worse still, he returned in very bad odour with Solomon, having cashed a letter of credit on the London house of Rothschild which had been entrusted to him merely to serve as an introduction. Fortunately Baron J. F. Cotta, the well-known liberal publisher, offered him the joint editorship of *Neue politische Annalen,* and Heine went to Munich in the autumn of 1827 to take up this work. He found it uncongenial, and the news of Therese's marriage increased his depression. It was somewhat lightened when the minister for the interior, Eduard von Schenk, proposed him for the chair of German literature in Munich university. He left for a holiday in Italy in July, fully expecting to hear in Florence that Louis I of Bavaria had approved the appointment. But it did not go through owing to the machinations of the Catholic party in Munich and also, or so Heine believed, to the poet August von Platen, who brought out a vicious lampoon in 1829, *Der romantische Oedipus,* reviling Heine as a "baptised Jew." Heine retaliated in "Die Bader von Lucca" *(Reisebilder* 111, 1829) holding Platen up to ridicule as a pitiable poetaster and a sexual pervert. By this witty but scurrilous retort he incurred widespread odium; and his next publication, *Reisebilder IV* (1831) was banned in Prussia as pernicious, blasphemous, indecent and obscene, stock epithets at the time for anything liberal and unorthodox. *Persona non grata* in Germany, Heine now turned his eyes once more toward France. He had been profoundly stirred by the July Revolution in 1830 and believed that Saint-Simonism, which was daily gaining converts in the French capital, was the religion of the future. He took farewell of Germany in *Kahldorf über den Adel* (1831), in which he voiced his rage against the suppression of the Polish insurrection and against the reactionary governments of Germany, Austria and Russia, and saluted revolutionary France. Having shot this bolt, he left his native land and arrived in Paris on May 19, 1831, for what was to be a lifelong exile.

A curious state of affairs awaited him: the implacable enmity of the German refugees, with Ludwig Borne at their head. The latter, like Heine a baptized Jew, and a witty, singleminded and powerful publicist, was an out-and-out revolutionary, rigid and puritanical. He regarded his more moderate young compatriot as a traitor to the cause, took the darkest view of his private life and pursued him with unrelenting malice, whereas Heine was welcomed with open arms by the French literary and intellectual circles and was on intimate terms with many of the romantic poets. The historian Thiers, then the all-powerful president of the council, tried to persuade him to accept French nationality and place his brilliant gifts at the service of France. This would have assured his future; but he declined the offer, although in 1835 he accepted a *pension de secours* of 4,800 francs annually from the secret funds. This did not influence his political opinions, and he criticized the July monarchy sharply sometimes in his articles for Cotta's *Augsburg Allgemeine Zeitung* (1831–32 and 1840–43). These were collected and published under the titles *Franzosische Zustande* (1832) and *Lutezia* (1854), appearing almost simultaneously in German and French. His account of contemporary German literature *(Zur Geschichte der neueren schönen Literatur in Deutschland,* 1833; expanded into *Die romantische Schule,* 1835) also appeared in French in *L'Europe littéraire* in 1833; and his history of German religion and philosophy, published in *Salon* **11** (1835) was given in French in *La Revue des deux mondes* in 1834.

The two books about Germany are impregnated with Saint-Simonian ideals and expound the gospel of the new religion which aimed at establishing a perfect harmony between the spirit and the flesh. Heine preached it with a poetical fervour and an infectious enthusiasm which won him disciples in Germany and helped to precipitate the catastrophe which overtook him and his Young German followers in Dec. 1835, when both federal and Prussian edicts placed the works of the whole school under a perpetual ban. In 1836 this took the somewhat milder form of a special Prussian censorship; but for many years Heine and his fellow victims, Ludolf Wienbarg, Heinrich Laube, Karl Gutzkow and Theodor Mundt, were effectively muzzled by it.

This disaster coincided with Heine's devastating passion for Crescentia Eugénie Mirat, a young assistant in a little glove-and-shoe shop, whom he called Mathilde, and took to live with him. He married her in 1841 on the eve of a duel with Solomon Strauss, the result of a slanderous passage inserted at the eleventh hour into his self-justificatory book on Borne, who had died in 1837. Bitter polemics of one sort or another darkened the years 1836–41, during which Heine was mentally and physically at a low ebb. Mathilde had anything but a soothing influence, and the censorship inhibited free production, although two beguiling prose works, "Florentinische Nachte" and "Elementargeister" *(Salon III,* 1837), managed to slip through. His health, and especially his eyes, gave cause for alarm; he was in dire financial straits and once more estranged from his uncle. Happily a reconciliation was effected in 1838, and an allowance of 4,800 francs annually granted him for life. This, with his government pension, eased the situation, and a visit to Cauterets in the Pyrenees brought about a poetical resurgence which produced in 1843 the enchanting, half-romantic, half-satirical epic poem, *Atta Troll,* published in book form in 1847.

Heine was a devoted son and brother; and in 1843, risking arrest, he traveled to Hamburg after a 12 years' absence to see his mother and his sister Charlotte, returning for another visit in 1844. The renewed contact with his native land inspired *Deutschland, ein Wintermarchen* (1844), a scintillating, hard-hitting, topical and yet visionary satire, applauded by the liberal-minded and banned throughout Germany.

In Dec. 1844 Solomon Heine died. His will contained no mention of the pension he had promised his nephew; and the ensuing conflict with his son and heir, Carl Heine, aggravated the spinal disease which was already incapacitating the poet and which for the last eight years of his life (1848–56) confined him, half-blind and paralytic, to his "mattress-grave."

His mental and physical anguish resulted in an extraordinary flow of poetical inspiration, producing *Rornanzero* (1851), *Gedichte 1853 und 1854* (1854) and some remarkable posthumous poems. The prose works of the period also witness to unimpaired intellectual and imaginative powers: *Doktor Faust, ein Tanzpoem* (1851), *Nachwort zum Romanzero* (1851), "Gestandnisse" and "Gotter im Exil" (both in *Vermischte Schriften,* 1854). But his fiercest energies were bent on the revision and completion of his *Memoiren* which had occupied him at intervals most of his life. Only a mutilated but charming fragment has survived, and it is generally believed that the Solomon Heines destroyed what had been for many years a *casus belli* between the poet and his rich relations. The last months of Heine's life were lightened by Camille Selden (Elise Krinitz) whom he called "La Mouche." They were passionately attached to each other, and she inspired some wonderful poems, the last and one of the loveliest he ever wrote being based on a dream. She called it *The Passion Flower;* Alfred Meissner, who first published it, called it *Fur die Mouche.*

Heine's life was torn by conflicts, and his personal satire often

overstepped the bounds of decency; but he fought tyranny both in verse and in prose with such kindling wrath and such annihilating laughter as to justify his proud claim to have been a good soldier in the war of liberation. A passionate sense of justice and a deep prophetic instinct inform his political works; and in his mature prose his brilliant wit and poetical imagination counteract the innate tendency toward self-pity and self-display also apparent in his poetry. Religiously disorientated, he depicted in many striking mythological poems, prose monographs and sudden flights of fancy the conflict between paganism and Christianity in his own breast; these passages greatly influenced the English Neo-Hellenists, in particular Swinburne and Pater, while his more satanic moods were echoed in Baudelaire's *Les Fleurs du Mal.* His unfinished novel, *Der Rabbi von Bacherach,* as well as "Jehudah ben Halevy," in *Romanzero,* and several other poems, not to mention his short-lived mattress-grave "conversion," show him groping vainly after a shattered faith.

Heine's later poems are greater than those in *Buch der Lieder,* although they are more diffuse on the whole and suffer from lack of inner harmony to an even greater extent. The themes are often macabre; the satire is more searing, the tone is more tragic, the laments are more piercing, the compassion is profounder, the hatred more demonic, the love deeper and more intense. As for the humour, it is, said Havelock Ellis, "a modern development of the humour of the mad king and the fool in *Lear*—that humour which is the last concentrated word of the human organism under the lash of fate."

HEINECKEN, CHRISTIAN HEINRICH (1721–1725), a child prodigy, was born on Feb. 6, 1721, at Liibeck, Ger. Able to speak at the age of ten months, he knew by heart the principal incidents in the Pentateuch by the time he was one year old. At two years of age he is said to have mastered sacred history; at three he was intimately acquainted with history and geography, besides being able to speak French and Latin; and in his fourth year he began the study of religion and church history. Crowds of people flocked to Liibeck to see the wonderful child, who mas able to discuss what he had learned. He began to learn writing, but died on June 27, 1725, at the age of four.

See C. von Schoneich, *Ehren-Bedachtnis von . . . Christian Henrich Heineken* (1726).

HEINEMANN, WILLIAM (1863–1920), British publisher who introduced an international outlook into British publishing, mas born in Surbiton, Surrey, on May 18, 1863. In 1890 he set up in London without any previous experience and immediately made available for the first time direct English translations of Dostoevski, Turgenev and, in part, Tolstoy. Thus were the Russian masterpieces first adequately presented to the English reading public.

Heinemann also introduced to the English theatre the plays of Ibsen, translated by William Archer. and launched such series as the Ars Una and the surviving Loeb Classical Library. His literary activities did not only concern translations; at one time or another he published works by R. L. Stevenson, Henry James, H. G. Wells, Joseph Conrad, George Moore and many others and he "discovered" John Galsmorthy, Sir Max Beerbohm and Somerset Maugham. Heinemann died in London on Oct. 5, 1920.

HEINRICH VON MORUNGEN (d. 1222) was one of the few notable courtly poets from east central Germany. A native of Thuringia, he spent much of his later life in the service of Duke Dietrich of Meissen. He died in the monastery of St. Thomas, near Leipzig, in 1222. His poems, of which some 33 are to be found in the Heidelberg manuscript, are all devoted to the fashionable cult of love. While his outlook was influenced both by the classical schooling, consistent with his upbringing near the court of Hermann of Thuringia, and by courtly manners from Provence, his poems show more originality and spontaneity than those of his contemporaries, through his vivid imagination and the intensity of his emotion. As a result his poems appeal to the modern reader more than those of any other *Minnesänger* with the exception of Walther von der Vogelaeide.

See C. von Kraus (ed.), *Des Minnesangs Frühling,* 31st ed. (1954). (W. W. Cs.)

HEINRICH VON VELDEKE (*fl.* 1185) Middle High German poet, whose *Eneide* was the first German court epic to attain an artistic form worthy of the elevated subject matter, was born near Maastricht, Holland, of a noble family, and served at the court of Cleves. He attended Frederick I's famous *Hof-fest* at Mainz in 1184 and subsequently joined the court of the landgrave of Thuringia, in whose service he completed his greatest work *Eneide,* modeled on the French *Roman d'Énéas. Eneide* was written not in Veldeke's native Flemish but in the Franconian literary language of such works as Eilhart von Oberge's *Tristan.* Both Gottfried von Strassburg and Wolfram von Eschenbach testify to the value of the *Eneide* as an example. The language of the poem is simple and direct. if somewhat cramped and conventional, and the verse flows smoothly.

Veldeke also wrote a religious epic, *Servatius,* and a number of lyric poems. In these, as in his epics, he appears as the ideal transmitter to Germany of the new literary fashions of Romance courtly civilization.

See G. Ehrismann, *Geschichte der deutschen Literatur bis zum Ausgang des Mittelalters* II, 2, 1, pp. 79–95 (1954); and many articles by T. Frings and G. Schieb in *Beiträge zur Geschichte der deutschen Sprache und Literatur* (1945 ff.). (RD. J. T.)

HEINSE, JOHANN JAKOB WILHELM (1746–1803), German novelist and art critic who had a considerable influence on the romantic school. He was born near Ilmenau, Thuringia, Feb. 15, 1746. As a law student at Erfurt he met C. M. Wieland and through him J. W. L. Gleim (called "Father" Gleim because of his patronage of young poets), who in 1772 procured him the post of tutor in a family at Quedlinburg. In 1774 he went to Düsseldorf, where he helped J. G. Jacobi in editing the periodical *Iris.* He traveled in Italy between 1780 and 1783, and after returning to Germany became librarian to the archbishop of Mainz at Aschaffenburg. He died there on June 22, 1803.

Heinse's *Über einige Gemälde der Düsseldorfer Galerie* (1776–77) stressed the dependence of artistic production upon historical and national circumstances and appreciated Rubens. His famous novel *Ardinghello oder die Glückseeligen Inseln,* 2 vol. (1787) glorified eroticism in a kind of Utopia; *Hildegard von Hohentltal* (2 vol.; 1795–96) contained stimulating musical criticism. He also translated Tasso (1781). His *Sämtliche Schriften* were ed. by H. Laube, 10 vol. (1838) and by C. Schiiddekopf, 10 vol. (1902–25), and a selection by R. Benz (1944).

(1938). (A. Gs)

HEINSIUS (HEINS), **DANIEL** (1580–1655), one of the most famous scholars of the Dutch Renaissance, was born at Ghent on June 9, 1580, and died at The Hague on Feb. 25, 1655. The troubles of the Spanish war drove his parents to settle first at Veere in Zeeland, then in England, next at Ryswick and lastly at Flushing. In 1594 he was sent to the University of Franeker; six months later he went to Leyden, where he remained for the rest of his life, becoming professor and then librarian. There he studied under Joseph Scaliger, and there he found Marnix de St. Aldegonde, Janus Douza, Paulus Merula and others, and was soon taken into the society of these celebrated men as their equal. His proficiency in the classic languages won the praise of all the best scholars of Europe, and offers were made to him, but in vain, to accept honourable positions outside Holland The remainder of his life is recorded in a list of his productions. He published his original Latin poems in three volumes—Iambi (1602), *Elegiae* (1603) and Poemata (1605); his Emblemata amatoria, poems in Dutch and Latin, were first printed in 1604. In the same year he edited Theocritus, Bion and Moschus, having edited Hesiod in 1603. In 1609 he printed his Latin Orations. In 1610 he edited Horace, and in 1611 Aristotle and Seneca. In 1613 appeared in Dutch his tragedy of The Massacre of the Innocents; and in 1614 his treatise De *politica sapientia.* In 1616 he collected his original Dutch poems into a volume. He edited Terence in 1618, Livy in 1620, published his oration De *contemptu mortis* in 1621, and brought out the *Epistles* of Joseph Scaliger in 1627.

HEINSIUS, NIKOLAES (1620–1681), Dutch scholar, son of Daniel Heinsius, was born at Leyden on July 20, 1620. His boyish Latin poem of Breda *expugnata* was printed in 1637, and attracted much attention. In 1642 he began his wanderings with a visit to England in search of mss. of the classics. From 1644 to 1653 he travelled without cessation between the principal libraries of Europe, everywhere collating mss and taking philological and textual notes He collected his Latin poems into a volume in 1653. His latest labours were the editing of Velleius Paterculus in 1678, and of Valerius Flaccus in 1680. He died at The Hague on Oct. 7, 1681. Nikolaes Heinsius was one of the purest and most elegant of Latinists, and if his scholarship was not quite so perfect as that of his father, he displayed higher gifts as an original writer.

HEIR, in modern usage, tends to be synonymous with the'term "next of kin," that is, he who succeeds to property of a person who dies without a will. In Scotland and other countries whose law derives from Roman law, heir has always had this meaning. Technically, in Anglo-American law, heir refers to the person who succeeds by descent to an estate of inheritance in land (see ESTATES, ADMINISTRATION OF) in contradistinction to the person to whom personal property is distributed by the executor to the next of kin. A few **U.S.** jurisdictions retain some vestiges of this distinction which has been abolished in England and elsewhere in the United States. (See INHERITANCE; INTESTACY.) An heir apparent is he whose right of inheritance is indefeasible provided he outlives the ancestor; *e.g.,* the eldest son in such matters as titled (see PEERAGE). An expectant heir or heir presumptive is he whose right of inheritance is defeasible by the birth of a nearer heir or by the owner executing a will or by his death before that of the owner; *e.g.,* the brother of an owner childless but capable of having children. (A. DM.)

HEIRLOOM, strictly so called in English laa a chattel which by immemorial usage is regarded as annexed by inheritance to a family estate Any owner of such heirloom may dispose of it during his lifetime, but he cannot bequeath it by will away from the estate If he dies intestate it goes to his heir-at-lax and if he devises the estate it goes to the devisee At the present time such heirlooms are almost unknown and the word has acquired a secondary and popular meaning and is applied to furniture pictures etr . vested in trustees to hold on trust foi the person for the time being entitled to the possession of a settled house Such things are more properly called settled chattels An heirloom in the strict sense is mdde by family custom not settlement Under the Settled Land act 1882 a settled chattel might be sold under the direction of the court, the money arising under such sale being capital money. By the Lam- of Property act, 1925, pt. iv, settlements of realty and personal property were assimilated.

HEISENBERG, WERNER KARL (1901–), German physicist, who was awarded the 1932 Nobel prize for physics "for the creation of quantum mechanics," is best known as the formulator of the Uncertainty Principle (*q.v*). He was born on Dec. j, 1901, at Wurzburg, where his father was a professor. He studied theoretical physics at the University of Munich under Arnold Sommerfeld and obtained his doctor's degree in 1923. In the same year he became assistant to Max Born at Gottingen and was appointed lecturer there in 1924. He then worked for three years with Niels Bohr (*q.v.*) at Copenhagen, and from 1927 to 1941 he was professor of theoretical physics at Leipzig. From 1942 to 1945 he was director of the Max Planck Institute for Physics at Berlin and from 1946 was director of the Max Planck Institute for Physics at Gottingen. Heisenberg's work on the quantum theory profoundly influenced the development of atomic and nuclear physics. He wrote *Die physikalischen Prinzipien* der Quantentheorie (1930) and many other books and papers on quantum mechanics, atomic physics and cosmic rays. (W. J. BP.)

HEJAZ (AL-HIJAZ), a province of the independent kingdom of Saudi Arabia, formerly under King Husain and prior to 1916 a vilayet of the old Ottoman empire. It then extended from Ma'an and 'Aqaba in the north to Hali point on the Red sea coast on the south, and had its headquarters under a wali at Mecca. The northern part of this territory is now included in Jordan, the northern boundary running east from the Gulf of 'Aqaba in approximately 29° 35' N. as far as 38" E. The Hejaz is about 800 mi. long and forms a narrow strip varying in depth from about 100 to 200 mi. broad. An indeterminate frontier with the province of 'Asir forms the southern boundary, and the area is about 134,600 sq.mi. The population is probably about 2,000,000. The majority of the inhabitants are Bedouin, but the Moslem holy cities of Mecca (1956 est., 200,000), the birthplace of the Prophet, Medina (19jj est., 80,000), the tomb of the Prophet, and Jidda (1955 est., 160,000), the port of Mecca, form considerable urban areas, swollen by the annual influx of pilgrims, whose presence, much interrupted by the troublous events of two world wars, formed one of the most important parts of the commercial activities of the Hejaz. Medina produces dates, and Taif and the mountain oases fruit and honey; otherwise the products of the Hejaz are limited to camels, horses, sheep and donkeys, hides, wool and charcoal; also ore products from the one operating mine.

Geography. — The Hejaz is divided into two zones, a coastal and an inland, by a range of mountains whose highest peaks probably reach 8,600 ft. Along the coastal strip there are a few settlements where the wadis (stony valleys) run from the hills on to the coastal plains, the most important of these wadis being the Wadi Hamdh. which has three main sources. a northern, a central. on which Khaibar stands, and a southern. which supplies Medina. The valley of Medina can also be approached from the coast, either from Yenbo (Yanbu') or Jidda by the Wadi al-Safra. The wadis, though liable to heavy floods, are not permanent water supplies, but in places permanent springs are to be found, accompanied by the luxuriant vegetation of palm groves. Along the desolate coast of the Red sea there is a series of ports. of which Jidda the port for Mecca, and Yenbo (for Medina) are the most important. The others include Muwailih. Wajh. Rabigh, Laith and Qunfidha. Wajh was formerly of importance as a port for Egyptian pilgrims. while in Roman times it was a post and the port of the Nabataean town of al-Hijr.

The inland region consists of a series of basins. mostly aith internal drainage. but in one or tno cases, through the wadis mentioned above, the valleys communicate nith the coastal region. Over this barren mountain country runs the old pilgrim nay and the track of the Hejaz railway North of Tebuk there is a large arid sandstone plateau, much eroded and carved into fantastic forms whence it has been suggested the sands of the interior are derived. while along the western boundary of the Nejd plateau stretches the desolate volcanic lava bed of the Harrat ar Raha. There are few settlements apart from the oasis of Tebuk and el-

'Ala (Egra of Ptolemy). The southern Hejaz is more fortunate in its water supplies. The city of Medina lies in the broad plain between the coastal range and the Nejd plateau. There at an altitude of 2,500 ft. there is an abundance of water, and dates, wheat and barley flourish. There is also a string of small settlements down to the port of Yenbo along the Wadi al-Safra. Mecca (*q.v.*), the chief town of the Hejaz, lies to the south, about 48 mi. from Jidda. From the hot lowland in which Mecca is situated the country rises up steeply to the Taif plateau, which because of its altitude. about 5,200 ft., possesses a climate closely resembling the southern part of Arabia. On the northern edge of the plateau lies Jabal al-Kura, a fertile well-watered region. producing grain, fruit and dates. Taif itself lies in a gravel plain, surrounded by numerous granite and gneiss hills.

History.— The Hejaz, together with the other provinces of Arabia, which on the overthrow of the Baghdad caliphate in 12 j8 by the Mongol invaders had fallen under Egyptian domination, became, after the conquest of Egypt by the Turks in 1517, a dependency of the Ottoman empire. Although the title caliph passed to Constantinople, the government remained for the most part in the hands of the sherifs of Mecca, until, in the religious upheavals at the beginning of the 19th century, the holy cities were pillaged by Wahhabis. The sultan accordingly entrusted to Mohammed Ali, viceroy of Egypt, the task of restoring peace. Eventually, in 1818, the Wahhabis were defeated but not destroyed and their capital Deraiyeh, in Nejd, was taken by Ibrahim Pasha. Egypt continued to administer the Hejaz until 1845 when the administration, under a wali, was taken over by Constantinople directly. Because of bad communications, however, it was difficult to control these distant and unruly parts and in 1900 Abdul Hamid began the construction of a railway, financed by Moslems throughout the world. which avoided the Suez canal and improved communications. The first part of the line from Damascus to Ma'an was opened in 1904 and four years later the last section, terminating at Medina. was finished, and the Turkish control of the whole region considerably strengthened. In that year (1908), however, Husain ibn Ali was appointed amir of Mecca, and this ambitious man at once began to oppose the Turkish plans, particularly in regard to the further extension of the railway to Mecca itself. The outbreak of World War I gave him further opportunities to satisfy his aspirations. So long as the railway was in the hands of the Turks. who had proclaimed a *jihad*, the sea route to the east was exposed to attack: Great Britain therefore negotiated with Husain, Jidda was bombarded hy British ships and that town and Mecca, and later Taif. were taken from the Turks. Medina, however, held out and was defended by Fakhri Pasha till Jan. 1919, when he surrendered on receiving explicit orders from Constantinople. Meanwhile Col. T. E. Lawrence and Husain's third son, Amir Faisal, organized a brilliant guerrilla warfare against the railway and the northern positions of the Turks. Tenbo, Wajh and 'Aqaba (1917) fell and after the capture of Ma'an, Shaubak and Hejaz they reached a northern frontier which was kept until 1925. Husain assumed the title of king in 1916. He was represented by the Amir Faisal at the peace conference in Paris in 1919, and the Hejaz was admitted as an original member of the League of Nations. but eventually he refused to ratify the peace treaties. In the summer of 1921 Lawrence visited Jidda on behalf of the British government to negotiate a treaty with Husain, but as the latter would not accept the de *facto* position in Palestine negotiations broke down. Meanwhile other factors were clouding the horizon. During the war Husain's reign had been mild. but he became more and more autocratic and alienated the sympathies both of his neighbours and of his own people. He had undertaken, by the terms of the peace treaties, to maintain the annual pilgrimage but his administration of the arrangements for the reception of the pilgrims was very unsatisfactory. Government departments were corrupt, even the army was not properly cared for and the air force which had been organized lapsed more than once until revived once more by his successor. On the other hand his transport fleet and system of wireless communication were satisfactory and proved of value. It was under such conditions that the Hashimite dynasty faced its new perils. Early in 1919 King Husain's relations with Ibn-Sa'ud became strained as a result of a dispute over Khurma oasis. His forces were defeated by the Wahhabis at Taraba and in 1922 Ibn-Sa'ud occupied Khaibar and Taima. Meanwhile negotiations with the British government were kept alive by Kaji al-Asil, the Hashimite representative in London, and were not finally abandoned till the outbreak of war between Nejd and Hejaz in 1924. King Husain. however, refused until it was too late to send a representative to the conference summoned by the British government at Kuwait. Early in 1924 he visited Transjordan. where he assumed the title of caliph (*khalifah*) and returned to Mecca to attempt to obtain recognition of his new position by the Moslem world. This brought matters to a head and Ibn-Sa'ud declared war on the Hejaz. Taif fell without any resistance and Husain abdicated in favour of his son Ali. The latter evacuated Mecca and attempted to raise an army. Jidda was organized for defense. Ibn-Sa'ud entered Mecca in Dec. 1924 and immediately attacked Jidda without any success. The siege was temporarily raised in June 192 j. In the meantime, however, considerable success attended his arms. the ports fell one by one, and at the beginning of December Medina. and shortly afterward Wajh, surrendered. The end was not far off. King Ali abdicated a fortnight later. Jidda and Yenbo surrendered and Ibn-Sa'ud was master of the Hejaz. He was crowned king at Mecca in Jan. 1926. Certain changes later took place in the actual political boundaries. 'Asir, the coastal strip to the south, was in a difficult position between its two powerful neighbours, Ibn-Sa'ud and the imam of the Yemen. In Oct. 1926 the former was definitely recognized as paramount sovereign. The annexation on the other hand by the British government, in July 1925, of the 'Aqaba-Xla'an region to the Transjordan mandated area deprived the Hejaz of territory won during the war. In this region alone was the Hejaz railway, which made this land so important during World War I, in working order. The southern section was put out of order during the Wahhabi siege of Medina and was not repaired. In May 1927 a treaty was signed between Great Britain and Ibn-Sa'ud at Jidda. Great Britain agreed to recognize Ibn-Sa'ud's independence. He therefore secured a dominant position in Arabia from his headquarters at Riyadh and became absolute ruler of the country which in Sept. 1932 became known as Saudi Arabia, comprising the three former divisions of Nejd, Hejaz and Hasa. and, after 1934, 'Asir. In Jan. 1928 the old currency was superseded by a silver currency of rials (about 10 rials = £1). (See also ARABIA; 'ASIR; IBN SA'UD, 'ABD UL-'AZĪZ IBN 'ABD UR-RAHMAN IBN FAISAL.)

HEJIRA or HEGIRA, the name of the Mohammedan era (Arab, *hijra*, flight). It dates from 622, the year in which Mohammed "fled" from Mecca to Medina to escape the persecution of his kinsmen of the Koreish tribe. The years of this era are distinguished by the initials A.H. (*anno hegirae*). The Mohammedan year is a lunar one. about 11 days shorter than the Christian. Although Mohammed himself appears to have dated events by his flight, it was not till later that the actual era was systematized by Omar, the second caliph, as beginning from the first day of Muharram (the first lunar month of the year) which in that year (639) corresponded to July 16. The term hejira is also applied in its more general sense to other "emigrations" of the faithful; *e.g.*, to that to Abyssinia (see MOHAMMED), and to that of Mohammed's followers to Medina before the capture of Mecca. These latter are known as *Muhajirun*.

HEL, in Korse mythology, was originally the name of the world of the dead; it came to be personified as the goddess of death. Hel was one of the children of Loki, and her kingdom was said to lie downward and northward. It was called Niflheimr, or "the world of darkness," and appears to have been divided into several sections, one of which was Nastrond, the shore of corpses. There stood a castle facing north and filled with the venom of serpents, in which murderers, adulterers and perjurers suffered torment, while the dragon Nidhoggr sucked their bodies. Mention is made in an early poem of the nine worlds of Niflheimr. It was said that those who fell in battle did not go to Hel, but to the god Ódin, in Valhalla, the hall of the slain. The name Hel is probably related to the verb *hylja*, "to cover, to hide." (G. T.-P.)

HELDENBUCH, DAS, the title under which a large body of German epic poetry of the 13th century has come down. The main subjects of the individual poems were drawn from sagas based on the struggles and conquests of the Germanic tribes during the epoch of the migrations (*Völkerwanderung*), although many other themes, doubtless based on the traditional allegorical interpretations of natural forces and phenomena, became, in the course of time, associated with the historical events. The poems of the *Heldenbuch* belong to two cycles: the Ostrogothic saga of Ermanrich, Dietrich von Bern (*q.v.*) (*i.e.*, Theodoric the Great) and Etzel (*i.e.*, Attila); and the cycle of Hugdietrich, Wolfdietrich (*q.v.*) and Ortnit (*q.v.*), which was probably of Franconian origin. Dietrich of Berne, the central figure of the more important group, was the ideal type, of German medieval hero. Of the romances of this group, the chief are *Biterolf und* Dietlirb, Der *Rosengarten* and *Laurin und* der kleine *Rosengarten.* Other episodes of the Dietrich saga are recounted in *Alpharts* Tod, *Dietrichs Flucht*, and Die *Rabenschlacht.* Of these, the first is the finest poem of the cycle. The other two, by an Austrian. Heinrich der Vogler, date from the end of the 13th century and show the decay that had by this time set in in Middle High German poetry. The second cycle of sagas is represented by several long "popular" romances, notably Ortnit, Hugdietrich and Wolfdietrich, but their literary value is not very high.

. BIBLIOGRAPHY.—This collection of romances was one of the first German books printed. The date of the first edition is unknown, but the second appeared in 1491. A reprint of 1590 forms the basis of the edition by A. von Keller for the Stuttgart *Literarische Verein* in 1867. In 1472 the Heldenbuch was remodeled in rough *Knittelvers* and this version was printed by F. von der Hagen and S. Primisser in their *Heldenbuch* (1820–25). A critical edition was published in 5 vol. by O. Janicke et al. (1866–73). 4 selection, ed. by E. Henriei, appeared in J. Kiirschner's Deutsche rational-literatur, vol. 7 (188;). All the poems have been translated into modern German by K. Simrock and others. The literature of the Heldensage is very extensive. See especiallv O. L. Jiriczek, *Deutsche Heldensage,* vol. i. (1898); and H. Schneider, *Germanische Heldensage,* 2 vol. (1928). (W. W. Cs.)

HELDER or DEN HELDER, seaport in North Holland province, Netherlands. 51 mi. by rail N.N.W. of Amsterdam. Pop. (1957 est.) 46,102 (mun.). It is on the Marsdiep, the channel separating the island of Texel from the mainland and the main entrance to the Zuider Zee. It is the terminus of the North Holland canal from Amsterdam. On the east side of the town is the harbour with naval wharves and magazines, wet and dry docks. The great sea dike stretches from Nieuwe Diep to Fort Erfprins, a distance of about ¡ mi. It descends at an angle of 40° for 200 ft. into the sea. The town is fortified and the province can be flooded from this point. The defenses were insufficient to prevent German capture of the town early in May 1940. Helder has a meteorological observatory, a zoological station and a lighthouse.

HELEN, in Greek mythology, daughter of Zeus by Leda (wife of Tyndareus, king of Sparta) or by Nemesis; sister of Polydeuces and Clytemnestra, and wife of Menelaus. She was the most beautiful woman in Greece, and indirectly the cause of the Trojan War. When a child she was carried off from Sparta by Theseus to Attica, but was recovered and taken back by her brothers. When she grew up, the most famous of the princes of Greece sought her hand in marriage and her father's choice fell upon Menelaus. During her husband's absence she was induced by Paris, son of Priam, with the connivance of Aphrodite, to flee with him to Troy. After the death of Paris she married his brother Deiphobus, whom she is said to have betrayed into the hands of Menelaus at the capture of the city (Aeneid, vi, 517 ff). Menelaus thereupon took her back, and they returned to Sparta. where they lived happily till their deaths and were buried at Therapnae in Laconia. According to another story, Helen survived her husband and was driven out by her stepsons. She fled to Rhodes, where she was hanged on a tree by her former friend Polyxo, to avenge the loss of her husband Tlepolemus in the Trojan War (Pausanias, iii. 19). After death, Helen was said to have married Achilles in his home in the island of Leuke. According to Stesichorus. Paris, on his voyage to Troy with Helen. was driven ashore on the coast of Egypt. where King Proteus detained the real Helen in Egypt, while a phantom Helen was carried off to Troy; the real one was recovered by her husband after the war (Herodotus. ii, 112–120; Euripides. *Helena*). Helen was worshiped as the goddess of beauty at Therapnae in Laconia, where a festival was held in her honour. At Rhodes she was worshiped under the name of Dendritis (the tree goddess), where the inhabitants built a temple in her honour. There are thus an epic heroine Helen and a goddess Helen; the relations between the two are a problem as yet unsolved. Like her brothers, the Dioscuri, she was a patron deity of sailors.

HELENA, SAINT (c. 248–*c.* 328), mother of the emperor Constantine I the Great, was the reputed discoverer of Christ's cross. She served in an inn at Drepanum in Bithynia before marrying Constantius I Chlorus, who in 293 divorced her so that he might on becoming Caesar marry Theodora. stepdaughter of the emperor Maximian. When Constantine became emperor at York in 306, he made his mother empress-dowager. She later became a Christian. Her devotion to her eldest grandson. Crispus, and grief at his execution in 326, perhaps impelled Constantine to execute Fausta, his empress, and the accuser of Crispus. This double tragedy in the imperial family was immediately followed by the aged empress' pilgrimage to the Holy Land. She caused churches to be erected on the sites of the Nativity and of the Ascension. Coins bearing her name or effigy cease from 330. She was buried in Constantinople.

Before 337 it was claimed in Jerusalem that. during the building of Constantine's church on Golgotha, Christ's cross had been found. Later in the century, Helena began to be credited with the discovery. There grew up a crop of legends, of which Ambrose's panegyric on Theodosius the Great in 395 is the earliest witness. The story of the "Invention of the Holy Cross." enhanced by subsidiary romances and confusions with other Helens, became a favourite throughout Christendom (*see* CROSS).

Eastern churches commemorate Constantine and Helena together, on May 21, as "equal to the Apostles." In the west, only St. Helena. popularized by the cross legend, is commemorated. on Aug. 18. Geoffrey of Monmouth (1147) spread the idea, already extant. that Helena was a British princess. The consequent popularity of her legend in the British Isles is attested by the many medieval church dedications there to St. Helen and to Holy Cross.

See H. Chadwick in Journal of Theological Studies, vol. xlix, pp. 32–33 (1948); H. Thurston and D. Attwater (eds.), Butler's Lives of the *Saints,* vol. iii, pp. 346–348 (1956). (W. TR.)

HELENA, a city in Arkansas, U.S., and seat of Phillips county, is on the Mississippi river about 55 mi. (airline) S.W. of Memphis, Tenn.

Hernando de Soto (in 1541) and other early explorers along the Mississippi visited the area: which became a part of the Louisiana Purchase. Settlers began to arrive in 1800 and built a warehouse for barge shipping. In 1811, the steamboat "New Orleans" called at Helena, opening a prosperous era of river traffic. The county was named after an early settler, Sylvanus Phillips (1766–1830) and Helena, which was named for his daughter, was incorporated as a town in 1833 and as a city in 1856. Streets and many homes were laid out in mid-19th century. Helena was the site of a Civil War battle July 4, 1863, and the county sent seven generals to the Confederate army. Long important as an agricultural and river shipping centre for cotton, cottonseed products and lumber, the area became increasingly industrialized after World War II, especially at West Helena (founded 1909, incorporated 1917). Manufactures include tires, sporting goods, luggage, ladies' clothing, wood products and fertilizer. For comparative population figures see table in ARKANSAS: *Population.* (K. W. P.)

HELENA, the capital city of Montana, U.S., the seat of Lewis and Clark county, is near the Missouri river and the centre of the western third or the mountainous portion of the state, about 50 mi. N.N.E. of Butte. It is picturesquely situated at the eastern foot of the continental divide, at an altitude of 3,955 ft., in Prickly Pear valley, a rich agricultural region surrounded by rolling hills and lofty mountains. Mt. Helena and Mt. Ascension form a background for the city.

The area was first visited by the expedition of Meriwether Lewis and William Clark (*qq.v.*) in 1805, and in 1862 a wagon train of

immigrants wintered in Prickly Pear valley. Gold was discovered in Last Chance gulch, now the official name of former Main street, in July 1864. On Oct. 30, 1864, the town was founded, and named Helena at the instigation of John Somerville for his home town in Minnesota, and within two years had a population of 7,500. Gold to the value of $16,000,000 was taken from the gravels of Last Chance gulch, much of it before 1868. Rich gold and silver deposits were found within a 20-mi. radius, which stimulated Helena's growth. In the 1880s and early 1890s, Helena's prosperity was reflected by a display of ornate mansions, built by the nouveaux riches, onetime prospectors. By 1893 when the price of silver dropped, the boom passed. Business waned, and prosperity came in cycles with the building of the Canyon ferry, Hauser and Holter dams on the Missouri river (1900–10), with the renewal of mining activities following the demand for metals in World War I, and with the piping of natural gas from surrounding fields. The damage caused by the series of earthquakes in 1935, 1936 and 1937 was rapidly repaired.

The town continued to be a regional centre for trade, finance and transportation with about 65% of Montana's population and most of the state's mining, agricultural and livestock enterprises located within a radius of 125 mi. Industries include concrete, ceramics, paints, brick and tile, and machine parts. At nearby East Helena there are quartz crushers and smelters and a large zinc reduction works. Helena was made the capital of the territory in 1875, was chartered as a city in 1881, and became state capital in 1894.

The capitol building and the state office buildings lie in the southeast section of the city. The Pioneers and Veterans Memorial building houses the Historical Society of Montana with an excellent library and museum, and a Charles M. Russell art collection valued at $500,000. The Veterans Administration centre and hospital is located at Fort Harrison, 3 mi. from the city. The State Vocational School for Girls is located in Helena, as is the Montana Children's home for crippled children and the Florence Crittenden home. The Deaconess home and St. Joseph's orphanage, both for children, and old people's homes operated by the Masons and the Independent Order of Odd Fellows are nearby. There are state offices of the Montana Education association, the Montana Physicians service, the Montana Stockgrowers association and many other state organizations and institutions.

Carroll college (Roman Catholic) established in 1909, has about 800 students. The Archie Bray foundation provides a nationally known centre for artists interested in ceramics. Helena has a number of buildings which are distinctive for their architectural design, including the Roman Catholic St. Helena cathedral (Gothic, modeled after the Cologne cathedral in Germany), the Episcopal procathedral (English Tudor) and the civic centre, formerly the Algeria Shrine temple (of Moorish design).

For comparative population figures see table in MONTANA: *Population.* (M. G. Bu.)

HELENIUM, a genus of the Compositae (*q.v.*) family comprising more than 30 species of North American hardy annual or perennial herbs, commonly known as sneezeweeds. Their stems are erect, usually branched above, with alternate leaves extending downward and flowers in yellow or brownish heads. either solitary or in flat clusters, opening from early summer to late autumn. All the species may be grown in gardens, but perhaps the common sneezeweed. H. *autumnale,* is used most frequently, while the orange sneezeweed, H. hoopeszi, is the most valuable species for general planting.

The bitter sneezeweed, H. *tenuifolium,* is a troublesome weed in pastures in many sections of the southern states because when eaten by dairy cows it imparts a bitter flavour to the milk and butterfat. (J. M. BL.)

HELENSBURGH, a small burgh in Dunbartonshire, Scot., on the north shore of the Firth of Clyde, opposite Greenock. 22 mi. N.W. of Glasgoa by road. Pop. (1951) 8.760. There is steamer communication from Craigendoran pier with Gourock, Dunoon, the Isle of Bute. Wemyss Bay and other Clyde resorts.

In 1776 the site began to be built upon, and in 1802 the town, named after Helen, sister of the earl of Sutherland and wife of Sir James Colquhoun of Luss, the ground landiord, was erected into a burgh of barony.

John Logie Baird (*q.v.*), the inventor and television pioneer, was born at the manse in Helensburgh.

HELENUS, in Greek legend, son of Priam and Hecuba and twin brother of Cassandra. In Homer, he appears as a seer and warrior. In later writers it is related that he and his sister fell asleep in the temple of Apollo Thymbraeus and that snakes came and cleansed their ears, whereby they obtained the gift of prophecy and were able to understand the language of birds. After the death of Paris, because Helen rejected him for Deiphobus, Helenus withdrew in indignation to Mt. Ida, where he was captured by the Greeks; in other accounts he was captured by a stratagem of Odysseus, or surrendered voluntarily in disgust at the treacherous murder of Achilles (q v.). He informed the Greeks of the "fates" of Troy (Palladium, arrows of Hercules, arrival of Neoptolemus) and advised the building of the wooden horse. (See TROY AND TROAD)

After the capture of Troy he and his sister-in-law Andromache accompanied Neoptolemus (Pyrrhus) as captives to Epirus, where Helenus persuaded him to settle. After the death of Neoptolemus, Helenus married Andromache and became ruler of the country. He was the reputed founder of Buthrotum and Chaonia, named after a brother or a companion whom he had accidentally slain while hunting. He was said to have been buried at Argos, where his tomb was shown.

See Homer, Iliad, vi, 76, vii, 44, xii, 94, xiii, 576; Sophocles, Philoctetes, 604, who probably follows the Little Iliad of Lesches; Pausanias. i, 11, ii, 23; Conon, *Narrationes,* 34; Dictys Cretensis, iv, 18; Virgil, Aeneid, iii, 294–490; Servius on Aeneid, ii, 166, iii, 334.

HELFFERICH, KARL (1872–1924), German financier and politician. was born in Neustadt-an-der-Haardt on July 22, 1872. In 1901 he became a professor of political science in Berlin. and in 1906 went to Constantinople as manager of the Anatolian railway. He returned to Berlin in 1908 to take up the chairmanship of the Deutsche bank. In 1913 he was the chief German delegate at the Paris conference for the settlement of Balkan financial affairs. In 1915 Helfferich was appointed secretary of state for the imperial treasury. where he followed the principle of defraying the cost of the war by borrowing rather than by fresh taxation, relying on a final German victory. In June 1916 he left the treasury for the home office. In June 1918 he was appointed to succeed Count Mirbach, who had been assassinated, as Germany's representative in Moscow. He remained in Moscow for three months, returning to Berlin in August to conduct the economic and industrial demobilization of Germany after the Armistice. He devoted himself thenceforward principally to financial questions. In 1923 he secured the currency of the Rentenmark, and then fought against the Government policy of fulfilment of treaty obligations. He was fatally injured April 23, 1924.

HELGAUD or **HELGALDUS** (d. *c.* 1048), French chronicler, was a monk of the Benedictine abbey of Fleury. Little else is known about him save that he was chaplain to the French king, Robert II. the Pious, whose life he wrote. The only extant ms. of this Epitoma vitae Roberti *regis* is in the Vatican. Editions have been printed by J. P. Migne in the Patrologia *Latina,* tome cxli. (Paris, 1844); and by M. Bouquet in the *Recueil* des *historiens* des Gaules, tome x. (Paris, 1760).

See *Histoire littéraire* de la France, tome vii. (1865–1869); and A. Molinier, Les Sources de l'histoire de France, tome ii. (1902).

HELIAND, a 9th-century alliterative epic poem in Old Saxon, relating the life and teaching of Christ; the name Heliand ("Saviour") was given to it in 1830 by J. A. Schmeller, its first editor. The poem totals almost 6.000 lines and has come down in one complete, one virtually complete and two fragmentary manuscripts. The Heliand, together with the Genesis fragments (see below), is all that remains of Old Saxon poetry. The only documentary evidence that bears on the composition of the poem consists of two Latin passages—a prose Praefatio in *librum* Antiquum lingua *Saxonica conscriptum,* and a *Versus* de poeta et *interprete huius* codicis in hexameters—included in a collection of documents published in 1562 by the Lutheran reformer Flacius Illyricus, who

gave no indication of their origin. Scholars are generally satisfied. however, both that these documents are in all essentials authentic 9th-century records and that they relate to the *Heliand*. The *Praefatio* states that the work was undertaken by an eminent Saxon poet (unnamed) at the instance of Louis the Pious. Since the emperor is referred to in the present tense, the poem must at least have been started during his reign, *i.e.*, between the years 814 and 840. Its precise origin remains uncertain.

The substance of the poem is drawn, not directly from the Vulgate, but from the pseudo-Tatian harmony of the Gospels. with additional matter apparently derived from the Gospel commentaries of Rabanus Maurus. Alcuin and Bede. The particular interest of the work lies in the way in which the religious narrative is assimilated to the form of the Germanic heroic epic. Biblical scenes and characters are portrayed against a Germanic background. cardinal elements in the Germanic code of ethics, such as the bond of service between lord and vassal: are drawn into the motivation, while the poetic language and form are those of Germanic alliterative verse. On the other hand the ideals which sustain the work as a whole are entirely Christian, and the poet's evangelical purpose requires that particular emphasis be laid on the didactic parts of the poem, above all, on the words of the Saviour himself. The most powerful literary influence bearing upon the poet is that of the Anglo-Saxon religious epic. in which certain specific and characteristic techniques used in the *Heliand* are already found.

The fragmentary Old Saxon *Genesis* was once thought to be the work of the poet of the *Heliand,* but it displays different attitudes of mind and different techniques, and is generally of an inferior quality. The relationship between the Old Saxon *Genesis* and the Junian Anglo-Saxon *Genesis* is an interesting and very early example of literary intercourse between Germany and England, for it has been shown that what had long appeared to be a somewhat incongruous passage of some 600 lines in the latter work is in fact a translation from the Old Saxon poem.

The hybrid poetic literature represented by the *Heliand* and the *Genesis* was forced to yield before the pressure of a severe and formal Christianity which denied all concessions to the pagan Germanic forces of history. Yet, for reasons still not properly understood, the High German literature which accompanied this stricter line of thought made no headway in Low German territory. and except for a few insignificant remnants of prose, the *Helinnd* and the *Genesis* remain the only literary documents in a Saxon dialect until the end of the 12th century.

BIBLIOGRAPHY.—The most convenient combined edition of *Heliand* and *Genesis* is that of O. Behaghel. 7th ed. (1958). For textual analysis E. Sievers' edition (1878) prints the tests of the complete Munich and Cotton manuscripts side by side. Bibliographies on specific problems are given in G. Ehrismann's *Geschichte der deutschen Literatur bis zum Ausgang des Mittelalters*, vol. i, pp. 150–171 (1918). (RD. J. T.)

HELICON, a mountain range in Greece, celebrated in classical literature as an abode of the Muses, is situated between Lake Copais and the Gulf of Corinth.

The highest summit, the present Palaeovouni (old hill), rises to the height of 5,735 ft. On the fertile eastern slopes stood a temple and grove sacred to the Muses and adorned with statues, which, taken by Constantine the Great to beautify his new city, were consumed there by a fire in A.D. 404. Near by were the fountains Aganippe and Hippocrene, the latter created by the tread of the winged horse Pegasus. At the neighbouring Ascra dwelt the poet Hesiod, a fact which probably enhanced the poetic fame of the region.

Pausanias describes Helicon as the most fertile mountain in Greece; neither poisonous plant nor serpent was to be found on it, while many of its herbs possessed miraculous virtue. His description makes it possible to reconstruct the classical topography and French excavators have discovered the temple of the Muses and a theatre.

See W. M. Leake, *Travels in Northern Greece,* vol. ii (1835); J. G. Frazer, *Pausanias,* rcl. v, p. 1jo.

HELICON, the circular form of the B-flat contrabass tuba used in military bands. worn round the body. with the enormous bell resting on the left shoulder and towering above the head of the performer. (Fr. *hélicon, bombardon circulaire;* Ger. *Helikon).*

The pitch of the helicon is an octave below that of the euphonium.

HELICONIA, a genus of large tropical American, banana-like herbs of the Musaceae family. but only one species, H. *bihai,* knonn as mild-plantain or baliser. is commonly cultivated. It requires the same cultural methods that are used for the banana.

HELICOPTER, a heavier-than-air aircraft with one or more power-driven horizontal propellers or rotors that enable it to take off and land vertically, to move in any direction or to remain stationary in the air. It is often described as a rotary-wing aircraft in contrast to conventional fixed-wing airplanes. A helicopter does not require a long runway but can land on, and take off from, small areas inaccessible to fixed-wing aircraft. It can land in a small clearing in the jungle. on the deck of a ship, or atop a large building. Its ability to hover motionless over a given area enables it to deliver or take on personnel or cargo without actually landing. In the event of power failure during flight, the rotor, if disengaged from the engine. will continue to turn freely (autorotate) and provide lift as the helicopter descends, thereby permitting safe landing in an emergency.

Because of its versatility the helicopter is used extensively by the military services for transportation of troops into inaccessible areas, for rescue and medical evacuation, and for communication, surveillance and search at sea and on land. It proved its military value during the Korean war (1950–53) when it was used to evacuate thousands of wounded men from the front lines. Commercial uses include short-haul transportation between city centres and outlying airports, transportation into undeveloped areas. crop dusting. surveying and exploration.

The helicopter gained widespread publicity as a result of its lifesaving activities in civil emergencies. particularly those resulting from floods and earthquakes. and from its use by President Eisenhower for commuting from the White House to his farm at Gettysburg. Pa.. and to Camp David. Md. With the increasing congestion of ground transportation. there may be a promising future for the helicopter in the field of commuter travel.

HISTORICAL DEVELOPMENT

To the early inventors vertical take-off appeared to be the logical approach to the problem of flying. Apart from the Chinese top, nhose origin is lost in antiquity, and Leonardo da Vinci's models. which are not knonn to have flown. the first successful flying models utilizing rotating wings appear to have been built by Launoy and Bienvenu in France in 1784 and George Cayley in England in 1796. In the 1840s, Cayley built a steam-powered model. But the helicopter as well as fixed-wing aircraft had to await the development of lightweight gasoline engines before full-scale flights became possible.

The year 1907 saw the first man-carrying flights in France with two gasoline-engine helicopters, one designed by Louis Charles Bréguet and one by Paul Cornu. These pioneers never successfully solved the problem of control and were not sufficiently encouraged to continue their efforts. The simpler flight techniques demonstrated by the Wright brothers utilizing fixed wings discouraged further attempts at direct lift although, in the interests of safety, many further attempts were made to develop aircraft whose lift would be independent of forward speed. Among these early developments was the Petroczy-von Kármán tethered coaxial helicopter intended for surveillance on the front lines by the Germans during World War I; it never progressed beyond the development stage, although flights as long as one hour were recorded. Emile and Henry Berliner in the United States developed, first a coaxial. and then a side-by-side version with large fixed wings for control which achieved limited flight success during 1923. George de Bothezat developed for the U.S. army signal corps a side-by-side helicopter with four large rotors; it flew in 1923 with three people on board lor short distances at moderate heights. However, controlled vertical and forward flight was not officially acknowledged to have been achieved until 1930 when d'Ascanio (Italian) flew a coaxial helicopter, whose rotors were controlled by means of small tabs on the trailing edges of the blades. In 1936 the Bréguet-

Dorand (French) and in 1937 the Focke-Achgelis (German) successively held the record for sustained flight. In 1939 Igor Sikorsky (United States) flew the VS-300, which had only one main rotor; in 1941 he broke all previous records by remaining in flight for 92 minutes. The helicopter from then on developed rapidly.

Autogiro. — During this period another type of rotary wing aircraft, the Autogiro or gyroplane, was developed by Juan de la Cierva of Spain. His first successful flight was made in Spain in 1923. Development of the Autogiro provided much of the technical background that made the evolution of the helicopter possible. "Autogiro" is a trade-name for a type of aircraft that is readily distinguished from the helicopter. Unlike the helicopter rotor, the Autogiro rotor is not powered; the forward movement of the aircraft, through the air causes the rotor to turn like a windmill and hence to produce rotor lift. A conventional propeller provides propulsion for forward motions of the machine. The Autogiro cannot hover or land vertically, as the helicopter can, although a technique was developed known as the jump take-off, in which the rotor was brought up to speed on the ground by mechanical means and the energy stored thereby in the rotor utilized to lift the aircraft off the ground to an altitude sufficiently high to permit a short dive and glide into forward speed. The greater utility of the helicopter has favoured its development over that of the Autogiro, although the principle is still used on certain compound aircraft concepts such as the McDonnell XV-I and the Fairey Rotodyne in which the rotor is powered by jets at the blade tips for vertical take-off or landing and the aircraft is propelled in forward flight by means of a conventional propeller with the rotor unpowered and autorotating. The autorotating rotor in forward flight has a more favourable angle of attack distribution than the powered rotor and consequently can operate at higher forward speeds. Also, by providing fixed wings, some of the lift can be unloaded from the rotor onto the wings and the forward speed further increased over that of the conventional helicopter up to values of the order of 300 m.p.h.

MODERN HELICOPTERS

Hinged Blade. — Juan de la Cierva was responsible for many major contributions of value to later helicopter development, among them the concept of hinging the blade at the root, first put into practice by him. This concept simplified the control problem and made possible the development of lightweight, flexible and structurally reliable rotor systems in which the rotor blades are maintained in equilibrium by centrifugal force. Highly flexible blades adjust readily by bending to the load distribution and its cyclic changes associated with forward speed. This bending allows the vertical loads to be carried by components of the tension in the blade arising from centrifugal force; it minimizes the high stresses that would otherwise be associated with a more rigid blade and thus averts failures due to structural fatigue.

The hinge is located near the root, where the structural material required to carry the tension load makes it difficult to provide sufficient bending flexibility to ensure low stresses. With a hinge located at the root the blade is restrained by centrifugal force but otherwise free to flap up or down as the applied loads change. "Blade flapping" is the basic means of control of the helicopter. Varying the applied load by means of cyclic pitch change or feathering as described below causes the rotor disk to tilt relative to the shaft. The thrust being substantially perpendicular to the rotor disk, tilting the rotor relative to the helicopter produces forces that move the helicopter in any desired direction. This tilt is achieved by changing the pitch of the blades once per revolution thereby forcing them to seek a new plane of rotation in which no cyclic pitch change occurs since, because of the hinge, no cyclic moments can exist. A swash plate, which tilts in response to pilot's controls, is used to change the pitch of each individually hinged blade through a mechanical linkage system. The tilt of the swash plate therefore establishes the tilt of the plane of no cyclic input of the rotor; hence, the tilt of the rotor follows the tilt of the swash plate. The same swash plate is moved up or down to change blade pitch in order to climb or descend.

In general, tilting the plane of rotation of the blades relative to the shaft, which is turning at constant speed, results in a periodic change in rotational speed of the blades once and twice per revolution. These changes in speed would produce large forces causing bending and consequently large blade stresses in the chordwise direction. Since the blade is relatively stiff in the chordwise direction, it is necessary to relieve these stresses by means of a vertical hinge, called the lag hinge, at the blade root. Motion about this lag hinge thus permits the blade to maintain substantially constant speed regardless of the tilt of the rotor disk and, in addition, provides a means of relieving the periodic forces in the plane of rotation due to cyclic changes in drag forces in forward flight.

These changes in drag forces and the periodic changes in lift distribution discussed previously exist because of the changes in velocity across the rotor disk as the helicopter moves forward. On one side of the rotor disk, the advancing side, the velocity due to blade rotation and that due to forward speed add and, on the other, retreating side, subtract. The lift at constant pitch setting would therefore vary cyclically around the rotor disk, if the rotor were rigid. However, such a lift variation would result in a tendency to roll, and, by virtue of the hinge at the root, such a tendency can evidently not exist. The blade therefore flaps cyclically, the vertical velocity of flapping combining with the horizontal speed of the blade in such a way as to cyclically change the angle of attack and maintain substantially constant lift and zero moment at the blade root.

Speed Limitation. — This change in angle of attack on the advancing and retreating sides of the rotor disk inherently limits the speed of the helicopter and represents one of the most serious practical limitations to its greater utility. As the forward speed increases, the angle of attack on the retreating side must increase until stalling occurs. The forward speed is thus limited to approximately 0.4 of the rotational speed, or, for typical values of the rotational speed, to approximately 200 m.p.h. Higher speeds may be achieved by increasing the blade area and thereby reducing the mean angle of attack, but there are practical considerations of blade weight and the additional power consumption associated with the increased drag of larger chord blades and the compressibility effects on the advancing side which would appear to set a limit to the high speeds of conventional helicopters.

Other Types. — Other configurations, which operate on the basic principles of the helicopter as described above but overcome the speed limitation have been developed. These include the many machines covered by the generic term VTOL (vertical take-off and landing) of which the helicopter is the best known example. In one such machine the wings and propellers tilt through 90°, with the axis of rotation vertical for take-off and landing and substantially horizontal in forward flight. In others, the wings and propellers remain horizontal, and the slipstream is deflected down by large flaps for vertical flight. In either case, more thrust must be provided in vertical than in forward flight and the final design is therefore a compromise between the hovering and forward-flight regimes. A typical helicopter is designed to lift approximately 12 lb. per installed horsepower but the smaller rotors suitable for use as propellers would produce only 6 lb. or less per horsepower; high forward speeds are therefore achieved at the expense of hovering efficiency. With the advent of lightweight gas turbine power plants, and since most of the additional power is required anyway for the higher forward speeds, this loss of efficiency becomes of lesser importance.

Aerodynamic Theory. — The increase in power required to produce a given thrust as the rotor diameter decreases is fundamental in the rotor aerodynamic theory. Thrust is produced by imparting a downward velocity to the mass of air flowing through the rotor. The lift is proportional to the change in momentum, $m \times v$, where m is the mass flow of air through the rotor and v is its change in velocity. The energy expended, or induced power, is proportional to the change in kinetic energy, $\frac{1}{2}mv^2$. Additional power is consumed in overcoming profile drag of the rotor blades. Considering only the induced power, which represents the major portion of power expended, the ratio of thrust to power is $\frac{mv}{\frac{1}{2}mv^2}$

or $\frac{2}{V}$. A large rotor handles a great mass of air, hence requires a lower value of v and therefore less power for a given thrust than a smaller rotor.

Similarly, in forward flight the flow of air passing through a rotor is increased when the rotor is inclined forward to propel the helicopter. The amount of power required therefore drops off as the speed increases. It reaches a minimum value of about half that required for hovering at about 50 m.p.h., then increases with increasing forward speed as the drag of the fuselage increases. This minimum power characteristic is of importance in considering the ability of multiengine helicopters to maintain altitude after failure of an engine during take-off.

Helicopter Types.—Many types of helicopters have been proposed. The single-rotor type, utilizing one main rotor and a small vertical tail rotor, is one of the best known. The tandem type in which two rotors rotate in opposite direction to provide torque balance, is popular for transportation of personnel or cargo because of its long fuselage and insensitivity to load distribution. Another type that is of interest, particularly for small, compact vehicles, is the synchropter in which two rotors are closely intermeshed.

Extensive engineering effort has resulted in the development of helicopters of great reliability and with useful loads of about 30% of the gross weight, which is still somewhat less than the 40% average for fixed-wing aircraft. The additional weight of the helicopter may be attributed to the necessity of providing reliable mechanical transmission systems, operating at low rotational speeds and hence high torques, to power the rotor.

The Sikorsky H-19, developed during 1949, was capable of carrying 10 passengers in addition to the pilot and copilot. It saw extensive service during the Korean war. The Vertol 107, a twin-engine, twin-rotor helicopter is designed to carry 23–30 passengers in airline operation.

The stability and control problem of the helicopter is more serious than that of the airplane because of the necessity for control at zero air speed where the usual stabilizing effects of a horizontal tail and wings are nonexistent. The helicopter in hovering flight is essentially neutrally stable and responds to the controls as would any system with inertia only, and with no damping or static stability. The pilot must therefore develop an anticipatory reaction in order to arrest the motion of the machine when it responds to the controls. However, the development of reliable and lightweight electromechanical control systems utilizing gyro signals for increased damping and static stability have provided a satisfactory solution to this problem.

Finally, the cyclic loads to which the rotor is subjected in forward flight, as discussed above, requires a careful evaluation of the aeroelastic properties of the highly flexible rotor blades in order to avoid vibration levels in the helicopter above the comfort level. Evidently if one of the natural frequencies of the rotor or fuselage is close to a critical harmonic of the rotor speed, an amplification of these forces will occur. Again, careful engineering design effort can avoid resonances and reduce to a negligible amount such vibratory inputs. See also AERODYNAMICS; AERONAUTICS.

HELIGOLAND (Ger. Helgoland), an island of Germany, in the North sea, lying off the mouths of the Elbe and the Weser, 28 mi, from the nearest point in the mainland. Area .35 sq.mi.

The generally accepted derivation of Heligoland (or Helgoland) is from Heiligeland, *i.e.,* "Holy Land." The original name of the island was Fositesland from a god called Fosite (Forseti). According to northern mythology, Forseti, a son of Balder and Nanna. the god of justice. had on the island a temple subsequently destroyed by St. Ludger. Another suggested etymology, however, is that of Hallaglun, or Halligland, *i.e.,* "land of banks, which cover and uncover."

There Hertha, according to tradition, had her great temple, and the Angles came from the mainland to worship at her shrine, and on this isle St. Willibrord in the 7th century first preached Christianity. For its ownership, before and after that date, many sea rovers fought until it finally became a fief of the dukes of Schleswig-Holstein. The island was a Danish possession in 1807, when the English seized and held it until it was formally ceded to them in 1814. A British possession until 1890, it was ceded in that year to Germany, and after 1892 formed part of the Prussian province of Schleswig-Holstein. It consists of two islets, the main, or Rock island, and the small Dunen-Insel, a quarter of a mile to the east, connected by a neck of land until 1720, when they were severed by a violent irruption of the sea. The former is nearly triangular in shape and is surrounded by steep red cliffs, the only beach being the sandy spit near the southeast point, with the landing stage.

The cliffs are worn into caves, arches and columns. The impression made by the red cliffs, fringed by a white beach and supporting the green Oberland, is commonly believed to have suggested the national colours, red, white and green, or, as the old Frisian rhyme goes:

"Grön is dat Land,
Rood is de Kant,
Witt is de Sand,
Dat is de Flagg vun't hillige Land."

The lower town of Unterland, on the spit, and the upper town, or Oberland, on the cliff above, were connected by a wooden stair and a lift. After cession by Great Britain to Germany, the main island was strongly fortified, but the fortifications were demolished under terms of the treaty of Versailles; they were rebuilt by Hitler before World War II. The island was heavily bombed in World War II. After the war the population (about 2,600) was removed temporarily and the island was razed and used as a target for bombing practice by the British.

Heligoland was returned to Germany in 1952, with plans to repatriate the population gradually. Pop. (1955) 542.

The greatest length of the main island is just a mile, and the greatest breadth less than a third of a mile, its average height 198 ft., and the highest point, crowned by the church. 216 ft. The Dunen-Insel is a sand bank protected by groynes. In 1892 a biological institute, with marine museum and aquarium (1900) attached, was opened.

The winters are stormy. May and the early part of June are wet and foggy, so that few visitors arrive before the middle of the latter month.

HELIGOLAND BIGHT. On Aug. 28, 1914, a sweep by the British light naval forces into the Heligoland bight brought about the first serious contact between the opposing naval forces during World War I. The action began at daylight, developed into a series of confused fights, in misty weather upon a glassy-smooth sea, and lasted until 1:30 P M., when, the sweep having been completed, Vice-Adm. Sir David Beatty withdrew his forces. The day ended to the distinct advantage of the British. who had one cruiser ("Arethusa") and three destroyers damaged with a total casualty list of 35 killed and 40 wounded. The Germans lost 1,242 officers and men, killed, wounded and prisoners; three cruisers ("Mainz," "Coln" and "Ariadne") and one destroyer (V. 187) were sunk; one cruiser ("Frauenlob") was badly crippled, and there was unreported damage to other cruisers and torpedo craft.

THE PLAN OF OPERATIONS

From the first days of the war a watching patrol, maintained by British submarines off the entrance to the German ports, had obtained an accurate kno ledge of the routine movements of the German patrols. Against these patrols the sweep was planned to be carried out by light forces, upon a day when the German heavy ships would be tide-bound until afternoon, inside the Jade river bar.

In the original plan of the operation, Comm. Roger Keyes, commanding the submarine flotilla (eight submarines of the "D"

and "E" class and the destroyers "Lurcher" and "Firedrake") was to place an inner line of three submarines close to Heligoland, with orders to remain submerged until after a certain hour. An outer line of three submarines was stationed 40m. to the westward, instructed to try and draw the enemy destroyers to sea. Two other submarines were to watch the entrance to the Ems river.

The destroyer force, under Comm. Reginald Tyrwhitt, consisted of the "Arethusa" with the 3rd flotilla (16 t.b.d's) and the "Fearless" (Capt. Blunt) with the 1st flotilla (15 t.b.d's). The battle-cruisers "Invincible" (Rear-Admiral Sir Archibald Moore) and "New Zealand" were to act in support and were to meet the destroyer force to the south-east of the Dogger Bank on the evening of the 27th. Whilst the submarines were taking up their positions the cruisers and destroyers were to steer for a point 75m. N.N.W. from Heligoland, so as to arrive there by daylight on the 28th. The flotillas were then to sweep south and west through the Bight to cut off the German destroyers on their return from their nightly patrol. The two battle-cruisers would be in support to seaward and, away to the west, off the Terschilling light, an armoured cruiser force under Rear-Admiral Christian was held in reserve.

Such was the original plan. It was modified at the last moment on account of the diversion at Ostende. A brigade of Royal Marines was landing at that place on the 26th, under cover of the ships of the channel squadron, and a countermove by the German high sea fleet seemed likely. Therefore, support from the grand fleet was arranged and Admiral Jellicoe sent Vice-Admiral Beatty south in command of a force consisting of the battle-cruisers "Lion," "Queen Mary," and "Princess Royal" and Comm. Goodenough's squadron of six light cruisers ("Southampton," "Falmouth," "Birmingham," "Nottingham," "Lowestoft," and "Liverpool"). Beatty joined the "Invincible" off the Dogger Bank on the evening of the 27th and Goodenough's cruisers were sent on towards the destroyers' daylight position. Unfortunately, a wireless message, informing Tyrwhitt and Keyes of the change of plan, miscarried and neither commodore was aware of the presence of the northern forces until after the operation had commenced.

At about 3.30 A.M. Goodenough's cruisers came into contact with Tyrwhitt's destroyers and were at first mistaken for an enemy: recognition signals, however, averted the danger of an attack and at 4.0 A.M. Tyrwhitt, with his destroyers, began his run to the south. Goodenough's six cruisers were eight miles astern of him, and 30m. away on his starboard quarter was Beatty with five battle-cruisers. Keyes, in the "Lurcher," had stationed his submarines, but was still unaware of the presence of the cruisers, a fact which, as will be seen later, complicated the situation during the forenoon, when, owing to the mist, the course of events was by no means clear. Meanwhile, intercepted wireless signals had warned the Germans that a considerable force was approaching the Bight and they altered their normal dispositions. Their patrol force was ordered to retire before the British destroyers and to try and entice them into the Bight, where the light cruisers would be ready to cut them off. Thus, at daylight, the position was an interesting one, the destroyer forces being each intent upon leading its opponent into the arms of its supporting cruisers.

THE FIRST PHASES

The morning broke dull and overcast, with a smooth sea. To seaward the horizon was clear, but inshore it was misty, with the visibility never exceeding three to four miles and sometimes much less. At 4.45 A.M. E.7 fired a torpedo at one of the German outer patrol (G. 194), and this brought the German 5th flotilla out from Heligoland to hunt the submarine. At this time Tyrwhitt, in the "Arethusa," with the 3rd flotilla, was steering S.S.E. into the Bight, followed by "Fearless" with the 1st flotilla. Shortly before 7.0 A.M. a German t.b.d. was sighted on the port bow, about 3½m. off, and "Laurel," with the 4th division, was sent in chase (see fig. 1). The enemy turned S.E. and "Laurel" soon sighted ten more destroyers; shots were exchanged at long range as the Germans made off towards Heligoland. Tyrwhitt turned to the eastward to support his chasing division and, just before 8 A.M., the "Stettin" came in sight to the N.E. Her arrival was opportune, for the German destroyer "V.1" had been hit and was dropping astern. A few minutes later "Frauenlob" was seen to the eastward and "Arethusa" for a short time came under a heavy fire from both German cruisers. "Stettin," which had not yet got steam for full speed, on sighting "Fearless" with her flotilla, turned away and disappeared into the mist. "Frauenlob" turned to the south-west-

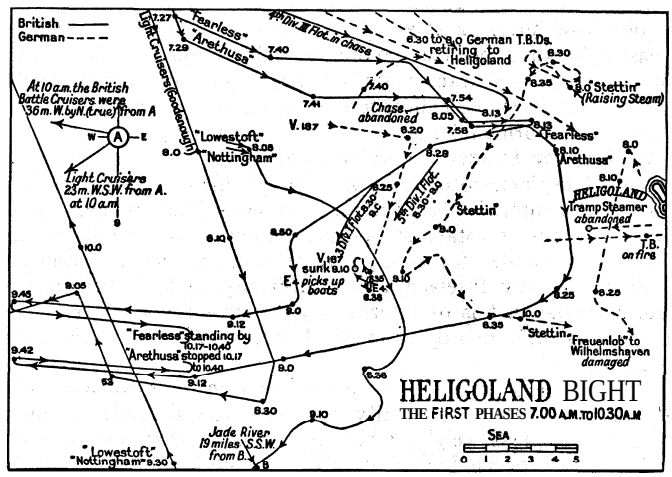

FIG. 1.— INITIAL MOVEMENTS IN BATTLE OF HELIGOLAND BIGHT, DURING WHICH ONE GERMAN CRUISER WAS DAMAGED, ONE DESTROYER SUNK AND H.M.S. "ARETHUSA" RECEIVED DAMAGE TO HER ENGINES

ward, and "Arethusa," turning to a converging course, a sharp fight ensued. "Arethusa," which had been commissioned only the day before, suffered heavily. She came under the fire of the forts of Heligoland and by 8.20 A.M. had only one 6in. gun remaining in action; but she continued her fight with "Frauenlob." At 8.25 A.M. the latter, heavily hit on her forebridge, broke off the action and retired. She reached Wilhelmshaven at noon with 50 killed and wounded on board. A tramp steamer, attempting to cross the bows of "Arethusa," was turned back by the British destroyers, who also chased and smashed up the torpedo boats D.8 and T. 33. After "Frauenlob" had retired S.E. Tyrwhitt turned W. He had, at 8.13 A.M., made the signal "Course W½S" (the course for the sweep), but delayed turning himself until he had finished with "Frauenlob." "Fearless," having lost sight of "Stettin," turned to the new course and recalled the chasing destroyers. The first phase thus closed at 8.30 A.M. with the British flotillas steering to the westward as planned, "Fearless" being about six m. to the north of "Arethusa."

THE SINKING OF "V.187"

The mist had now thickened, and soon after turning, "Fearless" sighted a destroyer coming in from seaward. At first she was mistaken for the "Lurcher," but soon identified as an enemy. "Goshawk" with the 5th and "Ferret" with the 3rd divisions were sent in chase. The enemy was "V.187," the leader of the German flotillas, and she attempted to escape to the southward. At 8.0 A.M. Goodenough had detached "Nottingham" and "Lowestoft" to Tyrwhitt's assistance and "V.187," sighting these two cruisers ahead at 8.38 A.M., was turned back by their 6in. guns into the arms of "Fearless" and eight destroyers. She was soon reduced to a wreck and she sank at 9.10 A.M. ."Fearless," leaving the destroyers to deal with "V.187," rejoined Tyrwhitt and together they resumed the westerly course by 9.0 A.M.

The survivors of the sinking German were rescued by boats from the British destroyers. Whilst the rescue work was in progress "Stettin" appeared from the north and, opening fire upon the destroyers, scattered them, herself receiving a few hits whilst doing so. In the confusion, five boats, full of German wounded and prisoners, were left behind. Submarine "E.4" (Lt.-Com. Leir), made an unsuccessful attack upon "Stettin," which caused that ship to withdraw; then, appearing suddenly on the surface, she went to the rescue of the British boat's crews. One German officer and three men were kept as prisoners; the remainder were left in the British boats, were supplied with bread and water, and given the course to Heligoland. "E.4" then submerged as dramat-

ically as she had appeared.

Goodenough, with four cruisers, turned westward at 8.30 A.M., being at that time ten m. ahead of the flotillas. "Nottingham" and "Lowestoft," after heading off "V.187," tried to rejoin Goodenough, but failing to regain touch, they steered N.W. for the battle-cruiser position. Keyes in "Lurcher," still unaware of the presence of the northern force, sighted and shadowed them, under the impression they were enemy ships. Through the mist, just before 9.0 A.M., Keyes sighted Goodenough's four other ships astern. He informed "Invincible" that he was being chased by four cruisers and was trying to lead them towards her. Goodenough followed "Lurcher" for about ten minutes and then turned back to the westerly course. This took his ships over the outer line of British submarines, who were still unaware of his presence. At 9.30 A.M. "Southampton" sighted "E 6" and promptly attempted to ram; the submarine escaped only by making a rapid dive. Towards 10.0 A.M., the weather to seaward becoming clearer, mutual recognition took place between Keyes and Goodenough and the latter went on to the westward, in order to give the submarines freedom of action.

Tyrwhitt had intercepted Keyes's message to "Invincible," and at 9 45 A.M. he gallantly turned back to his assistance with the crippled "Arethusa." "Fearless" turned back at the same time, and by 10.0 A.M. the 3rd and 5th divisions, having rejoined after sinking "V.187," the re-united flotillas turned once more to the westward. But by this time "Arethusa" could only steam at ten knots, and at 10.17 she was forced to stop to repair her engines. "Fearless" stood by her, and by 10.45 A.M. the two ships were under way again, steaming slowly W., with the destroyers spread out ahead of them.

THE MAIN ACTION

The German command, in the Jade river, had by now realized the situation and was endeavouring to concentrate the light cruisers to attack the British flotillas *(see* fig. 2). "Mainz" left the Ems river at 9.0 A.M. and was coming up from S.W., hoping to cut off the destroyers and to join "Strassburg." That ship left the Jade river at 9.30 A.M., followed at intervals by "Coln," "Ariadne," "Stralsund," and "Kolberg," while the "Stettin" was on her way W. from Heligoland. Thus six light cruisers were endeavouring to encompass the British flotillas, whose position

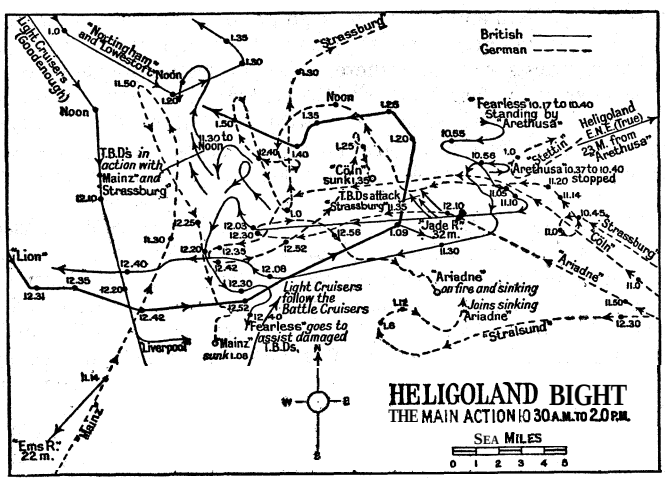

FIG. 2.— CHART SHOWING THE ATTEMPT OF GERMAN CRUISERS TO SURROUND BRITISH FLOTILLAS. THE MOVE WAS UNSUCCESSFUL, BRITISH BATTLE CRUISERS DASHING IN AND SINKING THREE GERMAN CRUISERS

from 11.0 A.M. onwards was precarious. Soon after "Arethusa" resumed her westerly course at 10.45 A.M. "Strassburg" appeared from S.E., and after firing a few salvoes at long range disappeared in the mist to the northward. She was followed at 11.5 A.M. by "Coln," which also passed on after exchanging a few salvoes. When "Coln" appeared Tyrwhitt asked Beatty for support. At 11.16 A.M. "Strassburg" reappeared to the northward and opened a heavy fire upon "Arethusa." A determined attack by the 1st and 2nd divisions of the 3rd and the 1st division of the 1st flotillas drove her off, and the stricken "Arethusa" continued her course to W., supported by "Fearless" and the destroyers. When "Strassburg" reappeared "Fearless" sent out an urgent call for help, and Beatty, at 11.20 A.M., ordered Goodenough to turn back to the assistance of the flotillas.

To Beatty, who had been steaming at high speed around a position about 50m. to the N. and W. of Heligoland, the course of events had by no means been clear. The urgent call from "Fearless," however, made it evident that she and the "Arethusa" were in action with two or more cruisers. The flotillas were still within 30m. of Heligoland, and at any time after noon there was a possibility of heavy enemy ships appearing from the Jade river. Goodenough was turned back, and Beatty, accepting the risk of mines and submarines, determined to take his whole force into the Bight to clear matters up and to extricate "Arethusa" and the flotillas. By 11.30 A M. the battle-cruisers were forming single line ahead on a S.E. course and were working up to full speed.

The Sinking *of the "Mainz."*—At 11.30 A.M. the and, 3rd, and 5th divisions of the 1st flotilla were about six m. to the westward of "Arethusa" when the "Mainz" appeared right ahead and chased them away to the north. At 11.50, after a 20 min. chase, "Mainz" sighted Goodenough's four cruisers coming out of the haze from N.W. and the whole aspect of affairs was at once changed. "Mainz" turned S., followed by the destroyers she had been chasing, and was hit twice by the cruisers before she could draw away in the mist. At 12.08, she met "Fearless" with the remainder of the 3rd flotilla, and in the sharp fight that followed her rudder and port engine were damaged and she was hit by a torpedo from one of the destroyers. Goodenough's cruisers were now closing up and the fate of "Mainz" was sealed. She turned and dealt savagely with the 4th division when they attacked. "Laurel" had her after-funnel blo n away and her captain severely wounded, "Laertes" was stopped dead by four hits from the same salvo, and "Liberty's" mast was shot away and her captain killed. But "Mainz," under the concentrated fire of the cruisers and destroyers, soon became a helpless wreck. She struck at 12.50, and 18 minutes later she rolled over and sank. Keyes, in the "Lurcher," went alongside and rescued 348 of her crew, narrowly escaping damage from her propellers as she sank.

The Battle-Cruisers in Action.—During the half-hour after noon the two British flotilla leaders were in grave danger of being overwhelmed. "Mainz" had appeared ahead, "Coln" and "Ariadne" were fast coming up astern, followed by "Stralsund" and "Stettin," and "Strassburg" was in action with the destroyers about five m. to the N.E. Goodenough's arrival and the sinking of the "Mainz" relieved the pressure and Tyrwhitt continued to limp slowly to the westward. At 12.30 "Arethusa" sighted a large ship in the mist ahead, and after a moment of breathless suspense recognized her as the "Lion," followed by the battle-cruiser squadron. Steaming at high speed, Beatty left the "Arethusa" to port and the sinking "Mainz" to starboard and swept on. Goodenough's cruisers joined in astern and "Fearless" turned away to the assistance of "Laurel" and her damaged consorts. The German cruisers fled. "Strassburg" turned N., disappeared into the mist, and was no more seen. "Coln," sighted on the port bow of the "Lion," made a desperate attempt to escape to N.E. but a few salvoes disabled her engines. "Ariadne" tried to pass ahead of "Lion" on a S E. course, but, hit by the first two salvoes fired at her, she disappeared to the southward, badly on fire and sinking. "Stralsund" and "Stettin" turned eastward and escaped. At 1.09 P.M. Beatty, being only 32m. from the mouth of the Jade river, made the general signal to retire. The battle-cruisers turned in a wide circle to the N. and W. and at 1 25 P.M. the "Coln" was seen again, steaming slowly to the S.E. Three salvoes caused her to list to port and at 1.35 P sr. she sank, taking with her the German cruiser admiral and all her ship's company.

Thus, in a brief hour, Beatty's bold stroke with the battle-cruisers had turned an awkward situation into a brilliant success. The British force withdrew homewards and all ships arrived safely at their ports. Two only, the "Arethusa" and "Laurel," had to be towed home. The German battle-cruisers were slow in getting to sea and did not leave the Jade river until 2.0 P.M. By 4.0 P.M., accompanied by destroyers and the remnants of the light cruiser

squadron, they reached a position close to where the "Cöln" had sunk, and, seeing no enemy, returned to the shelter of their base.

The success achieved in this operation exceeded all expectations and its effects were far-reaching. It came at a time when the British nation needed a success to dispel the dismay caused by the overwhelming advance of the German armies. Upon the British navy the effect was exhilarsting. The command of the North Sea had been asserted right up to the gates of the enemy and the young destroyer commanders had acquired a sense of superiority over their enemy and a trust in their leaders. Serious as was the material loss to the German fleet, it was not comparable to the effect upon its morale. Admiral Tirpitz stated that "August 28 was a day fateful, both in after effects and in incidental results, to the work of the German navy." Certainly, the marked disinclination shown by the German fleet throughout the war to be drawn from the protection of its bases is attributable to this early British success in the Bight of Heligoland.

(S. T. H. W.)

HELIOCENTRIC, *i.e.*, referred to the centre of the sun (ἥλιος) as an origin, a term designating especially co-ordinates of heavenly bodies referred to that origin.

HELIODORUS, of Emesa in Syria, Greek writer of romance. He was the author of the *Aethiopica*, the oldest and best of the Greek romances that have come down to us. It was first brought to light in modern times in a ms. from the library of Matthias Corvinus, found at the sack of Buda (Ofen) in 1526, and printed at Basle in 1534. Other codices have since been discovered. The story is that the daughter of Persine, wife of Hydaspes, king of Aethiopia, was born white. Fearing an accusation of adultery, the mother gives the babe to the care of a gymnosophist. The child is finally taken to Delphi, and made a priestess of Apollo under the name of Charicleia. Theagenes, a noble Thessalian, comes to Delphi and the two fall in love with each other. He carries off the priestess with the help of an Egyptian, employed by Persine to seek for her daughter. After many adventures the chief personages meet at Meroë at the very moment when Charicleia is about to be sacrificed to the gods by her own father. Her birth is made known, and the lovers are married. The rapid succession of events, the variety of the characters, the graphic descriptions of manners and of natural scenery, the simplicity and elegance of the style, give the *Aethiopicn* great charm. As a whole it offends less good taste and moral decency than other romances of its class. Homer and Euripides were the favourite authors of Heliodorus, who in his turn was imitated by French, Italian and Spanish writers. The early life of Clorinda in Tasso's *Jerusalem Delivered* (canto xii. 21 sqq.) is almost identical with that of Charicleia; Racine meditated a drama on the same subject; and it formed the model of the *Persiles* y *Sigismunda* of Cervantes. According to the ecclesiastical historian Socrates (*Hist. eccles.* v. 22), the author of the *Aethiopica* was a certain Heliodorus, bishop of Tricca in Thessaly. But it is now generally agreed that the real author was a sophist of the 3rd century A.D.

The best editions are: A. Coraes (1804), G. A. Hirschig (1856); *see* also *M.* Oeftering, *H. und seine Bedeutung für die Literatur,* with full bibliographies (1901); J. C. Dunlop, *History* of *Prose Fiction* (1888); and especially E. Rohde, *Der griechische Roman* (1900). There are translations in almost all European languages.

HELIOGABALUS: *see* ELAGABALUS.

HELIOMETER, an instrument originally designed for measuring the variation of the sun's diameter at different seasons of the year (named from Gr. ἥλιος, sun, and μέτρον, a measure). By subsequent improvements it became one of the most accurate astronomical instruments for measuring angular distances between stars, but its work is now done by photography and the heliometer is rarely used.

In the standard heliometer the object-glass is cut into two semi-circular segments. In the zero position the two halves form practically a single object-glass; they can be displaced by sliding their straight edges over one another, the amount of displacement being measured by a screw; a double image of each star is thus formed, *i.e.*, one by each half-lens. If the distance between two stars is being measured, the observation consists in turning the screw until the image from one star coincides with that from the other. For greater precision it is found desirable to move both segments an equal amount in opposite directions, so that the centre of the field of view where the observations of coincidence are made remains a centre of symmetry. Distances up to 2° are measured with these instruments.

The first use of a divided object-glass to give a double image is due to Servington Savary in 1743, but his segments were not movable. Pierre Bouguer (1748) invented an instrument used in the manner of a modern heliometer but employing two complete lenses instead of half-lenses to give the double image. In 1754 John Dollond combined Savary's idea of the divided object-glass with Bouguer's method and constructed the first really practical heliometer. The heliometer acquired a great reputation through the work of Bessel at Konigsberg, who used it to measure the parallax of 61 Cygni. Many instruments were made for the transit of Venus expeditions in 1874. The last great heliometer observer was Sir David Gill; his measurements of the parallax of southern stars remained for a long while unsurpassed; he used it also for his important determinations of the solar parallax by observations of Mars and certain minor planets.

See Bessel, *Astronomische Untersuchungen,* vol. i.; Gill, ***Annals*** of *Cape Observatory,* vol. vii., pp. 1–71.

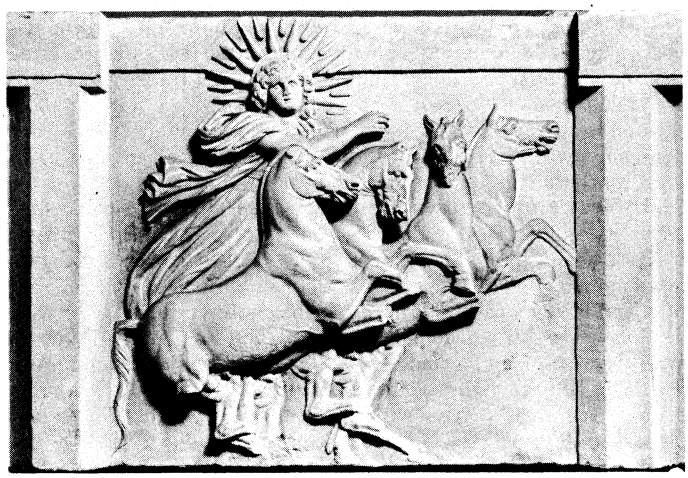
HELIOPOLIS, an ancient city of Egypt (the Biblical On). It stood 5 m. E. of the Nile at the apex of the Delta. It was the principal seat of sun-worship, and in historic times its importance was entirely religious. There appear to have been two forms of the sun-god at Heliopolis in the New Kingdom — namely, Ra-Harakht, or Rē'-Harmakhis, falcon-headed, and Etōm, human-headed; the former was the sun in his mid-day strength, the latter the evening sun. A sacred bull was worshipped here under the name Mnevis (Mreu), and was especially connected with Etōm. The sun-god RE' (*see* EGYPT: *Ancient Religion: Pantheon*) was the royal god, the ancestor of all the Pharaohs, who therefore held the temple of Heliopolis in great honour. Each dynasty might give the first place to the god of its residence — Ptah of Memphis. Ammon of Thebes, Neith of Sais, Bubastis of Bubastis, but all alike honoured Rē'. His temple became in a special degree a depository for royal records, and Herodotus states that the priests of Heliopolis were well informed in matters of history. The schools of philosophy and astronomy are said to have been frequented by Plato and other Greek philosophers; Strabo, however, found them deserted, and the town itself almost uninhabited, although priests were still there. The Ptolemies probably took little interest in their "father" RE', and Alexandria had eclipsed the learning of Heliopolis; thus with the withdrawal of royal favour Heliopolis quickly dwindled. In Roman times obelisks were taken from its temples to adorn Rome and the northern cities of the delta.

Finally, the growth of Fostat and Cairo! only 6 mi. S.W., caused the ruins to be ransacked for building materials. The site was known to the Arabs as *'Ayin esh shems,* "the fountain of the sun," later as Tel Hisn. It has been brought for the most part under cultivation, but the ancient city walls are to be seen in the fields on all sides, and the position of the great temple is marked by an obelisk and a few granite blocks bearing the name of Rameses II.

HELIOSTAT, an instrument containing a mirror driven by clockwork so as to reflect sunlight in a fixed direction; *e.g.*, onto the slit of a fixed spectroscope. It is of more complicated design than the coelostat (*q.v.*).

It has the advantage over the coelostat that the instrument fed by it need not be moved from day to day as the declination of the sun changes; the disadvantage is that only one point of the image remains fixed, the remainder rotating around it, so that unlike the coelostat it cannot be used for photographing an extended region.

HELIOS, the Greek word for the sun, always a god. He was, however, a minor mythological character and had no original Greek cult. He drove a chariot daily from east to west across the sky and sailed round the northerly stream of Ocean each night in a huge cup. In Homer he is invoked. as the all-seeing god, to witness oaths; his wrath when his cattle are killed by Odysseus'



STAATLICHE MUSEEN OF BERLIN

HELIOS IN HIS CHARIOT. RELIEF SCULPTURE, EXCAVATED AT TROY. 1872

companions, who had sworn to spare them, is one of the minor themes in the *Odyssey*. In classical Greece Helios was worshiped almost exclusively in Rhodes, where from at least the early 5th century B.C. he was regarded as the chief god, to whom the island belonged and from whom its first inhabitants sprang. His worship spread as he became increasingly identified aith other deities, often under eastern influence.

From the 5th century B C. Apollo (*q.v*), originally a deity of light, was more and more interpreted by thinkers as a sun-god; during the Roman empire the sun itself came to be worshiped as the Unconquered Sun.

HELIOTHERAPY: *see* LIGHT AND RADIATION IN RELATION TO HEALTH.

HELIOTROPE or TURNSOLE, a common name applied both to the garden'heliotrope *(see* VALERIAN) and the plants described below, which belong to the genus *Heliotropium.* The name indicates a plant which follows the sun with its flowers or leaves.

Heliotropium is a genus of usually more or less hairy herbs or undershrubs of the family Boraginaceae, having alternate, rarely almost opposite leaves; small white, lilac or blue flowers, in terminal or lateral one-sided simple or once or twice forked spikes, with a calyx of five deeply divided segments, a salver-shaped, five-lobed corolla, and entire four-celled ovary; fruit two- to four-sulcate or lobed, at length separable into four one-seeded nutlets or into two hard two-celled carpels. The genus contains 220 species indigenous in the temperate and warmer parts of both hemispheres, but commonest in the old world. A few species are natives of Europe, as *H. europaeum.* This, as well as four or five other species, is naturalized along the Atlantic seaboard of North America.

The common heliotrope. *H. arborescens,* popularly known as cherry pie, is a great favourite with florists because of the delicious odour of its flowers. It was introduced into Europe by the younger Jussieu, who sent the seed of it from Peru to the royal garden at Paris. About the year 1757 it was grown in England by Philip Miller from seed obtained from St. Germain, near Paris. *H. corymbosum* (probably a native of Peru), which was grown in Hammersmith nurseries as early as 1812. has larger but less fragrant flowers than *H. arborescens.* It is from these two species that most of our garden heliotropes have been derived. Some of them are known as turnsole. The species commonly grown in Russia is *H. suaveolens,* which has fragrant white flowers.

The fragrant butterbur, better known as sweet coltsfoot, *Petasites fmgrans,* a perennial plant of the family Compositae, is sometimes called winter heliotrope because of the perfume of its flowers.

Heliotrope also is a name given to the mineral called bloodstone (*q.v.*) and sometimes girasol—a name applied also to fire opal. The mineral is a green variety of chalcedony, flecked and streaked with spots of red jasper. *See* also SILICA. (X.; N. TR.)

HELIOZOA, an order of single-celled animals (protozoa; *q.v.*) mostly spherical in form, distinguished by numerous, somewhat stiff, protoplasmic processes (axopodia), which serve primarily for capturing food and also are of some use in locomotion.

HELIUM (chemical symbol, He), aside from hydrogen the lightest substance known, is a member of a family of normally gaseous elements, called the noble or inert gases because of their complete lack of chemical activity. Helium was first used in large quantities for lifting airships (see *Uses* below).

History. — Helium was discovered in 1868 in the gaseous atmosphere surrounding the sun. Several scientists, including P. Janssen, a prominent French astronomer, observed in India an eclipse of the sun which occurred on Aug. 18,1868. They noted a number of bright lines in the spectrum of the solar chromosphere and thus recognized the gaseous nature of the prominences, but they were uncertain as to the exact position of the lines in the spectrum. The number of lines seen by several of the scientists differed from the number of lines noted by others in the group. Janssen continued his observations of the unobscured sun for 17 days after the eclipse and reported his findings by telegram to the French Academy of Sciences. If he observed the helium D_3 line. it made no special impression on him. for it was not mentioned in either the telegram or the letter report that followed.

The following October. J. Norman Lockyer, a brilliant English astrophysicist, observed the chromosphere through a special telescope that he had designed in 1866, and he showed conclusively that the prominences of the sun gave a bright-line spectrum and were, therefore, immense volumes of gas, shooting out from a gaseous solar envelope; and, furthermore, that they were composed in part of hydrogen. Lockyer noted also a yellow line in the spectrum that did not correspond to the two already known D lines of sodium. These findings were reported to the Royal society on the day of their discovery, Oct. 20, 1868. They were reported also to the French Academy of Scitnces by Warren de la Rue, who introduced a letter from Lockyer dated Oct. 23. Strangely enough, the announcement by De la Rue of Lockyer's discovery and Janssen's letter report to the academy were received only a few minutes apart.

Thus a problem of proper apportionment of credit for the discovery of the gaseous nature of the prominences was presented. Janssen actually observed the bright lines in the spectrum of the chromosphere two months before Lockyer, but Lockyer conceived the idea of investigating the chromosphere with the spectroscope in 1866 and actually originated the method for doing it. The coincidence of their separate investigations served to cement a close friendship between the two scientists, however, and a medallion bearing the profiles and names of both Janssen and Lockyer was struck by the French Academy of Sciences to commemorate their discovery.

Lockyer continued his investigations and on Nov. 15, 1868, he fixed the yellow line that he had noted previously in the spectrum of the chromosphere at a position which he called D_3. After subsequent exhaustive experiments in co-operation with Edward Frankland, who thought the line might be due to hydrogen at solar temperature and pressure, Lockyer became convinced that the D_3 line was caused by a substance then unknown on earth. He called the substance helium, deriving the word from *helios,* the Greek name for the sun.

Probably the first terrestrial helium mas observed in a laboratory by W. F. Hillebrand, of the U.S. geological survey, in 1891. when he experimented with an inert gas which he obtained by heating uraninite, a uranium oxide. This gas consisted mainly of nitrogen, but its spectrum was unusual because it contained strange lines not identifiable with any elements known to exist on earth. Hillebrand attributed the strange lines to variations of pressure in the spectrum tube and failed to investigate the matter further, rejecting the suggestion by one of his colleagues that a new element might be present.

It remained, therefore, for Sir William Ramsay, a London professor. to discover the existence of helium on earth. When informed of Hillebrand's work. Ramsay obtained a sample of the mineral cleveite (a uranium-bearing mineral). and in March 1895 he duplicated Hillebrand's experiments in an effort to produce

argon, an element which he and Lord Rayleigh had discovered in the air in the summer of 1894. Upon intestigating the resultant gas with the spectroscope, Ramsay found argon as he had hoped; but, to his astonishment, he also found in the spectrum the bright yellow line of helium. At Ramsay's request, Sir William Crookes measured the wave length of the yellow line and confirmed its identity with the line found in the spectrum of the sun. Ramsay's discovery of helium as a constituent of the earth was announced in simultaneous communications to the British Royal society and the French Academy of Sciences on March 26, 1895. In the same year, Ramsay discovered helium in a specimen of meteoric iron from Augusta county, Va., and H. Kayser found helium to be a component of the atmosphere. Later, Ramsay and Frederick Soddy discovered that helium is a product of the spontaneous disintegration of radioactive substances. In 1905 H. P. Cady and D. F. McFarland found that natural gas produced from a shallow well near Dexter, Kan., contained 1.84% helium, and when helium-bearing natural gas was found in other fields large sources of helium became available.

Occurrence. — Although helium occurs in the atmosphere to the extent of 1 part in 186,000, and small amounts occur in radioactive minerals, meteoric iron and mineral springs, by far the greatest volumes of helium are in natural gases produced over widely distributed areas in the Cnited States. In only a few localities, however, is helium present in enough quantity to permit economic extraction.

The best-known sources of supply are in the Texas Panhandle, northwestern New Mexico. Kansas and Utah. The Cliffside gas field near Amarillo, Tex., is perhaps the best-known source because it supplies helium-bearing natural gas to the U.S. bureau of mines Amarillo helium plant where most of the world's supply of helium was produced prior to World War II. The helium content of gas produced from the Cliffside field is about 1.8%. A noncombustible gas containing 7.6% helium was found in 1942 in the Rattlesnake field of northwestern New Mexico. The best natural-gas sources in Kansas contain 1% to 1.5% helium, which is slightly higher than the helium content of gas from the Channing area of the large Panhandle gas field, north of Amarillo, Tex.; however, the volume of helium in the Panhandle field is very great. Helium occurs also in several Canadian provinces, but these occurrences, like all others known to exist outside the United States, are of minor importance.

Production. — The production of helium on a large scale was born of military necessity. The use of lighter-than-air craft filled with hydrogen is exceedingly hazardous in military operations because incendiary bullets easily ignite the gas.

The federal government is the only producer of helium in the United States. There has been a tremendous increase in the amount of helium produced by the U.S. bureau of mines since 1938. In that year the government produced 5,830,750 cu.ft. of helium. Production soared during World War II and reached 137,000,000 cu.ft. in 1944. The output amounted to 81,000,000 cu.ft. in 1950 and then rose rapidly to 235,000,000 cu.ft. in 1955. The increase in production after 1950 is mainly due to the use of helium for welding.

The helium contents of natural gases processed in the bureau of mines plants ranged from 1% to 7½%. Carbon dioxide, other acidic gases and water vapour are removed from the natural gas by washing it with a solution of monoethanolamine and glycol, and it is dried further with activated alumina before it is transmitted to the main separation cycle. The gas then is cooled to approximately −300° F. by a nitrogen refrigeration cycle and counterflow heat exchangers. At that temperature, and under a pressure of more than 600 lb. per square inch, all of the constituents of the gas, except helium and some nitrogen, are liquefied. The liquid is drawn off the bottom of the apparatus, and crude helium composed of about 50% helium and 50% nitrogen is removed from the top of the apparatus for further purification. The crude helium is compressed to 2,500 lb. per square inch pressure and cooled by a cycle similar to that used in the initial separation. Most of the remaining nitrogen is liquefied and the purity of the helium is increased to 98.2%.

This is the grade of helium that was produced until recent developments in welding and other metallurgical processes required that purer helium be made available. The 98.2% pure helium now is purified further by passage through activated coconut charcoal surrounded by a bath of liquid nitrogen. This helium: which contains only a trace of impurity, is conveyed into clean, dry high-pressure containers for shipment.

Physical and Chemical Properties. — Helium is a colourless, odourless and tasteless gas with a density of 0.1785 g. per litre at 0° C. Chemically it is completely inert (zero valence) and forms no compounds. It is a monatomic element with an atomic number of 2, and it exists naturally in two stable isotopic forms, He^3 with an atomic mass of 3.0170 and He4 with an atomic mass of 4.0039. With the exception of a trace (10^{-5}%) of He^3, all of the naturally occurring helium is He^4. The unstable isotope He^6 with atomic mass 6.0208 is radioactive with a half-life of 0.8 sec. The liquid phases of He^4 and He^3 are quite remarkable fluids and have become of considerable scientific interest as macroscopic demonstrations of quantum effects. The detailed understanding of their unusual properties is still a challenge to science. Both He^4 and He^3 do not solidify without the help of an external pressure of at least 25 atmospheres and they stay liquid to the lowest temperatures attained experimentally, and there is no indication that they will form solid crystals at even lower temperatures. This unusual behaviour is a consequence of the zero point energy postulated by quantum mechanics (*q.v.*) which is intimately related to the uncertainty principle (*q.v.*). The momentum and position of a particle cannot be fixed simultaneously with arbitrary accuracy. If the helium atoms have to be localized on the points of a crystal lattice their momentum and therefore their kinetic energy would be so great that they would overcome the forces holding the crystal together. Nature compromises in this dilemma by letting helium stay liquid where the atoms are not so narrowly confined in space. reducing in this way the zero point energy sufficiently so that a condensed phase can be formed. Zero point energy is also responsible for the extremely low liquid density, boiling points and critical points of helium, as shown in the table.

Boiling Points and Critical Points of Helium

	Boiling point				Critical point	
	°C.	°F.	Absolute temperature, °K.	Liquid density, g. per c.c.	Temperature, °K.	Pressure atmosphere
He^4	−268.9	−452.0	4.2	.13	5.2	2.3
He^3	−269.9	−453.8	3.2	.08	3.4	1.2

Other strange properties of helium are due to more subtle features of quantum mechanics. Liquid He^4 undergoes a transition at 2.19° K. called the λ-point. The modification above 2.19° K. is called He I, the modification below this temperature He II. There is no change in density or any latent heat connected with this transition, in contrast to the freezing of a liquid. Specific heat and expansion coefficient change abruptly, and especially striking are the changes in transport phenomena. The heat conductivity of He II is about 100,000,000 times that of He I, and more than 100 times better even than that of copper. The viscosity of He II diminishes rapidly with decreasing temperature to fractions of micropoise (the viscosity of water being about 10,000 micropoise) when measured with a viscometer. The flow through narrow channels of less than 0.001 cm. nidth takes place without any measurable friction at all. A certain amount of liquid He II passes through such a slit in a fraction of a second; the same amount of helium as gas needs several days to pass the slit.

If a temperature difference arises between two chambers filled with liquid He II and connected by such a narrow slit or a diaphragm an appreciable difference in pressure is produced. the warmer side showing the higher pressure. This can be demonstrated by a simple glass tube extending above the level of the liquid, part of which is filled with a fine powder acting as a diaphragm. Heating the ponder by shining a light upon it causes the liquid He II to spout out of the top of the tube up to a height of 10 in. due to the pressure differences created by this strange effect. which earns it the name "fountain effect."

All these extraordinary properties of liquid He II are due to superfluidity. Near the absolute zero of temperature, liquid He^4 can move up to certain critical velocities of several centimeters per second without any friction, a state which is called superfluid. At temperatures between absolute zero and 2.19° K., He II is considered as consisting of a mixture of this superfluid and a normal fluid. the latter behaving more or less like ordinary fluids in showing the usual resistance to mechanical motion or heat flow. At 2.19° K. the whole liquid helium consists only of the normal part of the fluid and becomes He I which has properties similar to those of the other condensed rare gases.

The physical properties of isotopes are usually quite similar, but not in the case of the helium isotopes. The relative difference in mass between He^3 and He^4 is considerable, and as the mass determines the zero point energy it causes also the appreciable differences in boiling points, critical points, etc. of the two isotopes. Moreover, liquid He^3 does not show a A-transition or superfluidity. He" consists of an uneven number of nucleons and obeys therefore the Pauli principle which requires that every quantum state be only singly occupied. He^4 consists of an even number of nucleons and is not subject to this restriction; at very low temperatures all particles can condense into the lowest quantum state, a phenomenon often called Bose-Einstein condensation. It seems rather certain that superfluidity is intimately related with the Bose-Einstein condensation and therefore only possible for He^4. Furthermore a liquid mixture of He^3 and He^4 breaks up into two separate phases containing more or less pure isotopes below $\frac{1}{2}$° K.

uses.—Helium is still used as a lifting gas, the purpose for which it was originally produced in large volumes. It is the ideal gas for this purpose because it will provide 92.64% as much lift as will hydrogen and it is completely safe to handle. Helium-filled U.S. navy blimps played an important part in defeating the axis submarine campaign in the Atlantic ocean in World War II. Smaller, but important, volumes of helium are used by the U.S. weather bureau to carry radiosonde balloons aloft for weather observations.

In addition to this basic use, many medical and industrial applications for helium have been found since the bureau of mines was authorized in 1937 to sell helium for medical, scientific and commercial use. Helium is used to provide inert atmospheres in the welding of light metals and in other metallurgical operations. Because of its low refractive index, helium is used to fill the spaces between multiple optical lenses arranged in series. It is employed as a tracer, especially in the determination of oil and gas migration in underground geologic structures. In 1925 the bureau of mines issued a report by R. R. Sayers, W. P. Yant and J. H. Hildebrand, who recognized that helium is less soluble in body tissues than nitrogen and studied the use of helium-oxygen mixtures in mitigating caisson disease. Resulting developments by the bureau of mines and the navy department proved that divers can go to greater depths and work longer if a breathing mixture of helium and oxygen is supplied to them.

Helium has a low density and can be mixed with oxygen in suitable proportions for medical use. The mixture can be moved through relatively small airways more freely than air. It is useful in partial obstructions and spasms of the air passages. Reports by A. L. Barach. A. R. Benke. P. A. Neal and other physicians state that less effort is required to breathe helium-oxygen mixtures than to breathe air and that such mixtures may be used effectively in the treatment of respiratory diseases. especially acute cases of asthma. G. W. Jones and G. J. Thomas reported also that helium may be used as a diluent with various anaesthetics, especially cyclopropane, to prevent explosions in operating rooms, and in the treatment of certain operative complications with helium-oxygen mixtures.

As a result of the wartime expansion of helium production facilities, and the decline in military requirements which occurred at the end of hostilities in World War II, large volumes of helium became available to private enterprise at moderate cost. This caused the demand to increase so much that at the International Meeting on Low Temperature Physics in Madison, Wis., in Xug. 19j;, an immediate conservation program was unanimously urged.

(H. P. WR.; L. MR.)

HELIX, a line which rises as it twists, such as the line of a screw thread. In architecture, the term helix is sometimes given to the spirally twisted stalks or volutes under the corners of the abacus of the Corinthian capital (*see* ORDER). The helix form is also found most commonly in architecture in those curving stairways which are popularly known as spiral.

HELL, used in English both of the place of departed spirits and of the place of torment of the wicked after death (O. Eng. *hel,* a Teutonic word from a root meaning "to cover"). In the O.T. it translates the Hebrew *Sheol,* in the N.T. the Greek "Hades," and Hebrew *Gehenna.*

See ESCHATOLOGY; HEAVEN.

HELLANICUS OF LESBOS (fl. late 5th century B.C.), Greek historian, whose work marks an advance in the development of historiography. According to the Suda lexicon, he lived for some time at the court of one of the kings of Macedon and died at Perperene, a town in Asia Minor near the gulf of Adramyttium.

Some 30 works (of which only fragments survive) are attributed to him, including *Hiereiai tes Heras en Argei* ("Priestesses of Hera at Argos"), a chronological compilation; *Karneonikai,* a list of the victors at the Carnean festival with notices of literary events; *Phoronis,* a mainly genealogical work covering the period up to the return of the Heracleidae; and *Atthis* which gives the history of Attica from 683 to the end of the Peloponnesian War (404). Thucydides says that in this work the events of 480 to 431 were treated briefly and superficially, with little regard to chronology.

Hellanicus was not content to repeat the traditions that had gained general acceptance through the poets, but tried to give them as they were locally current. By using the few national or priestly lists that presented something like contemporary registration, he attempted to lay the foundations of a scientific chronology, based primarily on the list of the Argive priestesses of Hera, and secondarily on genealogies, lists of magistrates (*e.g.,* the archons at Athens) and oriental dates, in place of the old reckoning by generations. But as his materials were insufficient he often fell back on the older methods. Because he deviated so much from common tradition he was thought untrustworthy by the ancients themselves.

Hellanicus appears to have made no systematic use of inscriptions, and unlike his contemporary Herodotus, never rose to the conception of a single current of events wider than local and ethnical distinctions. A remark of Dionysius of Halicarnassus that Herodotus was not deterred from a theme already handled by Hellanicus and Charon of Lampsacus refers only to their raw material and not to their historical viewpoint.

HELLBENDER, common name for the aquatic salamander *Cryptobranchus alleganiensis* of the eastern United States. The hellbender and the giant salamanders (*Megalobatrachus*) of Japan and China are the only survivors of a primitive family (*Cryptobranchidae*) that was more widely distributed through the northern hemisphere in the Tertiary period, which began about 70,000,000 years ago.

The major part of the range of the thoroughly aquatic hellbender is within the larger, swift-flowing streams of the Ohio river system, but it is also found in other tributaries of the central Mississippi and in the Susquehanna river in New York.

This grotesque salamander has a flat head and body, compressed tail and wrinkled fleshy folds on the sides. Although the adult is lung-breathing, a gill slit persists on each side behind the head. The back colour is gray or brown with darker blotches. Maximum size is 27 in.

The hellbender feeds on small fish, crayfish and other inverte-

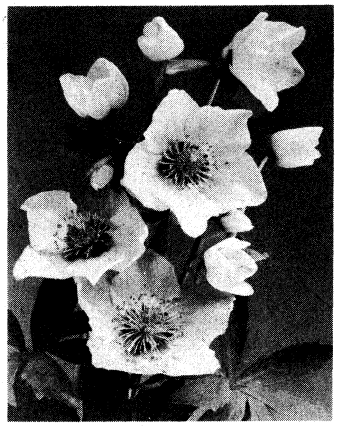
brates and is occasionally caught taking bait off fishing lines.

Mating takes place during August and September. Each female deposits 300–400 eggs in rosarylike strings in a nest scooped out beneath a stone or other shelter in the stream bed. The male fertilizes the eggs as they are laid and guards the nest during incubation, which takes 10 to 12 weeks. Young lose their external gills in a year or two but do not mature until three to four years old.

See AMPHIBIA. (*G.* B, R.)

HELLEBORE, any of a genus *Helleborus,* of plants of the family Ranunculaceae (*q.v.*), natives of Europe and western Asia. They are coarse, perennial, poisonous-juiced herbs with lobed leaves. The flowers have five persistent petaloid sepals, within the circle of which are placed the minute honey-containing tubular petals of the form of a horn with an irregular opening. The stamens are very numerous and are spirally arranged. The carpels are variable in number, sessile or stipitate and slightly united at the base; they dehisce by ventral suture.

Helleborus niger, black hellebore or Christmas rose (so-called because it blooms in midwinter) is found in southern and central Europe, and with other species was cultivated in English gardens as early as the 16th century. Its knotty rootstock is blackish-brown externally and poisonous. The leaves spring from the top of the rootstock, and are smooth, distinctly pedate, dark green above and lighter below, with seven to nine segments and long petioles.



J. HORACE MCFARLAND CO.

BLACK **HELLEBORE** OR **CHRISTMAS ROSE** (HELLEBORUS NIGER)

The scapes, which end the branches of the rhizome, have a loose entire bract at the base and terminate in a single flower with two bracts from the axis of one of which a second flower may be developed. The flowers have 5 broad white or pale rose, eventually greenish sepals; 8 to 13 tubular green petals containing honey; and 5 to 10 free carpels. There are several forms, the best being H. *niger altifolius.*

The Christmas rose is extensively grown in many English and American gardens to provide white flowers about Christmas time for decorations. A related species. H. *orientalis,* blooms in early spring, it is usually called the Lenten rose. H. *niger altifolius* grows to two feet, half a foot taller than the typical form, has red-spotted stalks and a pink-tinged flower nearly four inches wide. Because its roots are brittle, it should be carefully planted, preferably in the shade where the soil is moist and rich. It may be planted either by roots or seeds. The best time for planting is in the months of August and September.

H. orientalis has given rise to several fine hybrids with *H. niger,* some of the best forms being clear in colour and distinctly spotted. H. *foetidus,* stinking hellebore or bear's-foot, is found in England where, like *H. viridis,* it is confined chiefly to limestone districts; it is common in France and the south of Europe. Its leaves have 7- to 11-toothed divisions, and the flowers are in panicles, numerous. cup-shaped and drooping, with many bracts and green sepals tinged with purple alternating with the five petals.

H. viridis is probably indigenous in some of the southern and eastern counties of England and occurs also in central and southern Europe. It has bright yellowish-green flowers, two to four on a stem, with large leaflike bracts.

H. viridis is usually, but unfortunately, called green hellebore, and was thought by some to be the black hellebore. Confusion still exists because green hellebore is properly applied to *Veratrum viride,* an equally poisonous herb. White or false hellebore also belongs to the genus *Veratrum* (*q.v.*), of the family Liliaceae.

The rhizome of H. *niger* occurs in commerce in irregular and nodular pieces, from about one to three inches in length, white and of a horny texture within. Cut transversely, it presents internally a circle of 8 to 12 wedge-shaped ligneous bundles, surrounded by a thick bark. It emits a faint odour when cut or broken and has a bitter and slightly acrid taste. The drug is sometimes adulterated with the rhizome of baneberry, *Actaea rubra,* which however, may be recognized by the distinctly cruciate appearance of the central portion of the attached roots when cut across. *H. niger, viridis,* and *foetidus* contain the glucosides helleborin. helleborem and hellebrin. These compounds are extremely poisonous and in sufficient doses lead to cramps, vomiting, convulsions and sometimes death.

In medical preparations the drug was once employed as a purge in dropsy but is now considered more dangerous than beneficial. It is occasionally used in veterinary medicine. (N. TR.)

HELLENISM. The term Hellenism is ambiguous. It is derived from Gr. ἑλληνίζειν, "to speak the language of the Greeks." who called themselves Ἕλληνες, after Hellen, the son of Deucalion. In late Greek Ἑλληνισμός means "imitation of the Greeks" (Septuagint. II Macc iv, 13). It may be used to denote ancient Greek culture in all its phases. The German historian J. G. Droysen introduced the fashion of using it to describe particularly the latter phases of Greek culture from the conquests of Alexander to the end of the ancient world. when those over whom this culture extended were largely not Greek in blood: *i.e* , Hellenes but peoples who had adopted the Greek speech and nay of life. *Hellenistai.*

While using the term in the larger sense, this article will devote its principal attention to Hellenism as it appeared in the norld after spread of Greek culture which followed the Macedonian conquests

THE EXPANSION OF HELLENISM BEFORE ALEXANDER

In the 5th century B.C. Greek cities dotted the coasts of the Mediterranean and the Black sea from Spain to Egypt and the Caucasus, and already Greek culture was beginning to pass beyond the limits of the Greek race. As early as the 7th century B.C., when Hellenism was still in a rudimentary stage. Greek mercenaries came to be in request throughout the nearer east. But as Hellenism developed, its social and intellectual life began to exercise a power of attraction. The proud old civilizations of the Euphrates and the Nile might ignore it, but the ruder barbarian peoples came in various degrees under its spell. In some cases an outlying colony would coalesce with a native population, and a fusion of Hellenism with barbarian customs take place.

The great developments of the century and a half before Alexander set the Greek people in a very different light before the world. In the sphere of material power the repulse of Xerxes greatly enhanced Greek military prestige. The kings of the east leaned more than ever upon Greek mercenaries. whose superiority to barbarian levies was further brought home to them by the expedition of Cyrus. But the developments within the Hellenic sphere itself were also of great consequence for its expansion outward. The political disunion of the Greeks was to some extent neutralized by the rise of Athens to a leading position in art, literature and philosophy. and by the fact that the Attic dialect attained a classical authority; if Hellenism was to be propagated in the world at large. it was obviously convenient that it should have some one definite form of speech to be its medium.

The Persians. — The ruling race of the east. the Persian, was but little open to the new culture. The military qualities of the Greeks were appreciated. and so, too, was Greek science, where it touched the immediately useful: a Greek architect bridged the Bosporus for King Darius; Greek physicians were retained at the Persian court. Exactly how far Greek influence can be traced in the remains of Persian art. such as the palaces of Persepolis and Susa. may be doubtful, but it is certain that the engraved gems for which there was a demand in the Persian empire were largely the work of Greek artists.

The **Phoenicians**.—As early as the first half of the 4th century communities of Phoenician traders were established in the Peiraceus. In Cyprus, on the frontier between the Greek and

Semitic worlds! a struggle for ascendancy went on. The Phoenician element seems to have been dominant in the island, when Evagoras made himself king of Salamis in 412 and restored Hellenism with a strong hand. Even into the original seats of the Phoenicians Hellenism began to intrude. Abdashtart, king of Sidon (374–362 B.C.), called Straton by the Greeks. entered into close relations with the Greek states and imitated the Hellenic princes of Cyprus.

The Carians and **Lycians.**—The seats of the Greeks in the east touched peoples more or less nearly related to the Hellenic stock. with native traditions not so far remote from those of the Greeks in a more primitive age, the Carians and the Lycians. The Carian princes of the 4th century B.C.. Hecatomnus and especially Mausolus, modelled themselves upon the pattern of the Greek tyrant. The capital of Mausolus was a Greek city, Halicarnassus, and all that can still be traced of his great works of construction shows conformity to the pure Hellenic type. His famous sepulchre, the Rlausoleum (the remains of it are in the British Museum), was a monument upon which eminent Greek sculptors worked in rivalry. In Lycia Greek influence is more limited. There the native language maintains itself against Greek. The proper names are (if not native) mainly Persian. But the Greek language makes an occasional appearance; the coins are Greek in type; above all, the monumental remains of Lycia show strong Greek influence, especially the well-known "Nereid monument" in the British Museum, the date of which is held to go hack to the jth century.

South Russia and the Danube **Lands.**—A brisk trade. which reached its highest point of development in the 4th century B.C., sprang up between the Scythian chieftains and the Greek colonists. The finds of Greek pottery, and still more of gold and silver ware. in the tombs of southern Russia have been very considerable. But in Scythia Greek influence appears to have been limited to the material sphere (see SCYTHIA). A similar trade connection, which also flourished most in the 4th century. sprang up between Greek merchants from the Black sea or the Adriatic and the inhabitants of the Danube lands. But in these regions the Greeks did less than the Celts and the Italians to introduce a higher civilization.

Egypt.—From the time of Psammetichus (d. 610 B.C.) Greek mercenaries had been used to prop Pharaoh's throne, and Greek merchants had begun to find their way up the Nile and even to the oases. A Greek city, Naucratis (*q.v.*), was allowed to arise at the Bolbitinic mouth of the Nile. But the racial repugnance to the Greek probably kept the soul of the people more shut against Hellenic influences than were those of the other orientals.

Macedonia.—In Macedonia the native chiefs had been attracted by Hellenic life. at any rate from the beginning of the 5th century, when Alexander I persuaded the judges at Olympia that his house was of good Argive descent (Herodotus, v, 22). It was probably not until the reorganization of the kingdom by Archelaus (413–399) that Greek culture found any abundant entrance into Macedonia. Archelaus' palace was decorated by Zeuxis; Euripides spent the end of his days there. From that time a certain degree of literary culture was general among the Macedonia nobility; their names in the days of Philip are largely Greek; the Macedonian service was full of men from the Greek cities within Philip's dominions, and Philip chose Aristotle to be the educator of his son. How far the country generally might be regarded as Hellenized is a problem which involves the vexed question whether Macedonian is to be considered a dialect of Greek.

The West.—The process of Hellenization was carried out most completely in Sicily, where the distinction between native Sicels and Greek settlers faded out in the 4th century B.C.

In Italy the peoples of the south, who came into direct contact with the Greek colonists, showed some proficiency in their imitations of Greek ceramic art and coinage, and they derived their alphabets, directly or indirectly, from Greek script. In central Italy the Romans at first remained comparatively impervious to Greek influence. but the Etruscans in the 6th and 5th centuries became partially Hellenized. It is a moot point how far their alphabet was copied from Greek models, but the dependence of their art (architecture, sculpture, pottery, coins) is unmistakable.

In Gaul the native culture was little affected by Greek civilization until the end of the 4th century B.C. But by 300 B.C. the Greek colony of Massilia had become an important focus of Hellenism. The druids of Gaul adopted the Greek alphabet and scraps of Greek philosophic lore. Imitations of Greek coins (especially the pieces of Philip II of Macedon) were struck even in the remote parts of the country. and rude copies of the Gallic pieces were in turn produce'd in southern Britain.

In Spain the native art of the eastern districts came under Greek influence in the jth and 4th centuries B.C.. but the growing political ascendancy of Carthage in the peninsula proved unfavourable to the spread of this influence.

In north Africa the Carthaginians. albeit political enemies of the Greeks. did not remain untouched by Greek culture. By the 4th century they had begun to copy Greek architecture, sculpture and coinage. and to use Greek as a subsidiary tongue.

AFTER ALEXANDER THE GREAT

By 350 B.C. Hellenism had not seriously affected any but the more primitive races which dwelt upon the borders of the Hellenic lands, and there. with the doubtful exception of the Macedonians, was rather for the courts than for the people. Everything was changed when by the conquests of Alexander (334–323) Hellenism rose to material supremacy in all the east as far as India, and when cities of Greek speech and constitution were planted at the cardinal points of intercourse within those lands. The Macedonian chiefs found their pride in being champions of Hellenism. Their courts were Greek in language and atmosphere. All kings liked to win the good word of the Greeks. All of them in some degree patronized Greek art and letters, and some sought fame for themselves as authors. Even the barbarian courts, their neighbours or vassals. were swayed by the dominant fashion. But by the courts alone Hellenism could never have been propagated far. Greek culture had been the product of the city-state, and Hellenism could not be dissevered from the city. It n-as upon the system of Greek and Macedonian cities, planted by Alexander and his successors. that their work rested. Rome. when it stepped into their place, safeguarded its continuance, and acted as a Hellenistic power.

The Character of the New Greek Cities.—The citizen bodies at the outset were really of Greek or Macedonian blood—soldiers who had served in the royal armies, or men attracted from the older Greek cities to the new lands thrown open to commerce. The cities, of course, drew in numbers beside of the people of the land. The cities were Hellenic in their political organs and functions. with boule and demos and popularly elected magistrates. Life was filled with the universal Hellenic interests, which centred in the gymnasium and the religious festivals, these last including, of course, not only athletic contests but performances of the classical dramas or later imitations of them. The wandering sophist and rhetorician would find a hearing no less than the musical artist. The language of the upper classes was Greek; and the material background of building and decoration, of dress and furniture, was of Greek design. A greater regularity in the street plans distinguished the new cities from the older, slowly grown cities of the Greek lands.

Sometimes the Greek city was not an absolutely new foundation. but an old oriental city recolonized and transformed. And in such cases the old name was often replaced by a Greek one. Even where there was no new foundation the older cities of Phoenicia and Syria became transformed by the overwhelming prestige of Hellenic culture. In Tyre and Sidon. no less than in Antioch or Alexandria. Greek literature and philosophy were seriously cultivated, as may be seen by the great names which they contributed.

CHARACTERISTICS OF HELLENISM AFTER ALEXANDER

Hellenism had been the product of the free life of the Greek city-state, and after the Macedonian conquest the great days of the city-state were past. Not that all liberty was everywhere

extinguished. In the history of the next two or three centuries the cities are by no means ciphers. Rhodes takes a great part in Weltpolitik, as a sovereign ally of one or another of the royal courts. In Greece itself the overlordship to which the Macedonian king aspires is imperfect in extent and only maintained'by continual wars. The Greek states on their side show that they are capable even of progressive political development, the needs of the time being met by the federal system. The Achaean and Aetolian leagues are independent powers, which keep a field clear for Hellenic freedom within their borders. As to the cities outside Greece, within or around the royal realms. Seleucid, Ptolemaic or Attalid, their degree of freedom probably differed widely according to circumstances. At one end of the scale, cities of old renown could still make good their independence. At the other end of the scale the cities which were royal capitals, *e.g.*, Alexandria, Antioch and Pergamum, mere normally controlled altogether by royal nominees. Between the two extremes there was variation not only between city and city, but, no doubt, in one and the same city at different times. With the extension of the single strong rule of Rome over this Hellenistic world. the conditions were changed. Just as the Macedonian conquest, while increasing the domain of Greek culture, had straitened Greek liberty, so Rome, while bringing Hellenism finally into secure possession of the nearer east, extinguished Greek freedom altogether. Even now the old forms were long religiously respected. Formally, the most illustrious Greek states. Athens. for instance, or Marseilles or Rhodes, were not subjects of Rome, but free allies. Even in the case of tribute-paying states, municipal autonomy, subject indeed to interference on the part of the Roman governor, was allowed to go on. But during the first centuries of the Christian era, this municipal autonomy decayed. The demos first sank into political annihilation and the council: no longer popularly elected but an aristocratic order. concentrated the whole administration in its hands. After Diocletian and under the eastern empire the Greek world was organized on the principles of a vast bureaucracy.

Social **Changes.**—With this long process of political decline correspond the inner changes in the temper of the Hellenistic peoples. When the vast field of the east was opened to Hellenic enterprise and the bullion of its treasuries flung abroad, fortunes were made on a scale before unparalleled. A new standard of sumptuousness and splendour was set up in the richest stratum of society. This material elaboration of life was furthered by the existence of Hellenistic courts, where the great ministers amassed fabulous riches. and of huge cities like Alexandria. Xntioch and the enlarged Ephesus. With the mingling of Greeks of all sorts in the newly conquered lands, a generalized Greek culture, in which the old local characteristics were merged, overspread the world. The gradual supersession of the old dialects by the koine, the common speech of the Greeks, was one obvious sign of the new order of things. (See GREEK LANGUAGE.)

Art and Literature. — In its artistic. its literary. its spiritual products the age after Alexander gave evidence of change. In no department did activity immediately stop; but the old freshness and creative exuberance was gone. Artistic pleasure, grown less delicate, required the stimulus of a more sensational effect or a more striking realism. Artists and men of letters were now addressing themselves not to their fellow citizens in a free city, but to kings and courtiers or the educated class generally of the Greek world.

In the study of the world of fact, the centuries immediately following Alexander witnessed notable advance. Scientific research might prosper under the patronage of kings, and such research had now a vast amount of new material at its disposal and could profit by the old Babylonian and Egyptian traditions. The medical schools, especially that of Alexandria, really enlarged knowledge of the animal frame. Knowledge of the earth gained immensely by the Macedonian conquests.

The literary schools of Alexandria and Pergamum built up grammatical science. and brought literary and artistic criticism to a fine point. The classical products were registered, studied and commented upon. Libraries became a feature of the age; the one attached to the museum at Alexandria is said to have contained 700,000 rolls.

With the general decay of ancient civilization under the Roman empire, even scientific research ceased, and though there were literary revivals, like that connected with the new Atticism under the Antonine emperors, these were mainly imitative and artificial, and learning became under the Byzantine emperors a formal tradition. (See GREEK LITERATURE.)

Religion and Philosophy.—The mingling of citizens of many cities and the close contact between Greek and barbarian in the conquered lands had made the old sanctions of civic religion and morality of less account. New guides of life mere needed. The Stoic philosophy, with its cosmopolitan note. its fixed dogmas and plain ethical precepts came into the world to meet the needs of the new age. Its ideas became popular among ordinary men as the older philosophies had never been.

Although the cults of the old Greek deities in the new cities might still hold the multitude with their splendid apparatus, men turned in ever larger numbers to alien religions, and the various gods of Egypt and the east began to find larger entrance in the Greek world. Before the end of the 2nd century B.C. there were temples of Serapis in Athens, Rhodes. Delos and elsewhere. Under the Roman empire the cult of Isis became popular in the Hellenistic world. Other religions of oriental origin penetrated far, the worship of the Phrygian Great Mother (see GREAT MOTHER OF THE GODS) and, in the 2nd century A.D.. the religion of Mithras (*q.v.*). The Jews, too, by the time of Christ were discovering in many quarters an open door. Besides those who were ready to accept circumcision, numbers adopted particular Jewish practices, observing the Sabbath, for instance, or turned from polytheism to the doctrine of the One God. The synagogues in the Gentile cities had generally attached to them a multitude of those "who feared God" and frequented the services.

Christianity. — Among the religions which penetrated the Hellenistic world from an eastern source. Christianity ultimately overpowered all the rest and made that world its own. The teaching of Christ Himself contained. as it is given to us, no Hellenic element; so far as He built with older material. that material was exclusively the sacred tradition of Israel. As soon, however, as the Gospel was carried in Greek to Greeks, Hellenic elements began to enter into it; in the writings of St. Paul the appeal to what "nature" teaches would be generally admitted to be a Greek mode of thought. There was, at the same time, in the early church a powerful current of feeling hostile to Greek culture. What the attitude of the New People should be to it, whether it was all bad or whether there were good things in it which Christians should appropriate was a vital question to them. The School of Alexandria represented by Clement and Origen effected a durable alliance between Greek education and Christian doctrine. In proportion as the Christian Church had to go deeper into metaphysics in the formulation of its beliefs, the Greek philosophical terminology. which was the only vehicle then available for precise thought, had to become more and more an essential part of Christianity. At the same time Christian ethics incorporated much of the current popular philosophy, especially Stoical elements. In this way the church itself became a propagator of Hellenism.

EFFECT UPON NON-HELLENIC PEOPLES

India. — In India (including the valleys of the Kabul and its northern tributaries, then inhabited by an Indian, not, as now, by an Iranian. population) Alexander planted a numher of Greek towns. Soon after 321 B.C. Macedonian supremacy beyond the Indus collapsed before the advance of the native Maurya dynasty, and about 303 B.C. large districts west of the Indus were ceded by Seleucus. But the Maurya dynasty broke up about 180 B.C., and at the same time the Greek rulers of Bactria began to lead expeditions across the Hindu Kush. Menander. in the middle of the 2nd century B.C., extended his rule to the Ganges. Then "Scythian" peoples from central Asia gradually squeezed within ever-narrowing limits the Greek power in India. The last Greek prince. Hermaeus. seems to have succumbed about 30 B.C. Under the Roman empire, though Greek rule in India had disappeared,

active commercial intercourse went on between India and the Hellenistic lands. How far, through these changes, did the Greek population settled by Alexander or his successors in India maintain its distinctive character? What influence did Hellenism, during the centuries in which it was in contact with India, exert upon the native mind? Only extremely qualified answers can be given to these questions. Capital data are possibly waiting underground—the Kabul valley, for instance, is almost virgin soil for the archaeologist—and any conclusion arrived at is merely provisional. If certain statements of classical authors were true, Hellenism in India flourished exceedingly. But the philhellenic Brahmins in Philostratus' life of Apollonius had no real existence, and the statement of Dio Chrysostom that the Indians were familiar with Homer in their own tongue is a traveller's tale. India has yielded no Greek inscription except on the coins of the Greek kings and their Scythian successors. If it is argued by probability from what is known of the conditions. it must be considered that the Greek rule in India mas all through fighting for existence, and can have had little time or energy left for such things as art, science and literature. Perhaps the Hellenic colonists should rather be thought of as resembling the Greeks found in modern times dispersed over the nearer east. with interests mainly commercial. easily assimilating themselves to their environment. As to what India derived from Greece there has been a good deal of erudite debate. That the Indian drama took its origin from the Greek is still maintained by some scholars, though hardly proved. There is no doubt that Indian astronomy shows marked Hellenic features, including actual Greek words borrowed. But by far the most signal borrowing is in the sphere of art. The stream of Buddhist art which went out eastward across Asia had its rise in northwest India, and the remains of architecture and sculpture unearthed in this region allow its development to be traced back to pure Greek types. How far to the east the distinctive influence of Greece went is shown by the seal impressions with Athena and Eros types, the stucco reliefs and antefixes and the frescoes found by Sir Aurel Stein in the buried cities of Khotan. These remains belong to the period of the early and middle Roman empire. and were probably the work of Hellenized orientals rather than of Greeks: but their Hellenic character is unmistakable. According to E. B. Havell, there exist "paintings treasured as the most precious relics and rarely shown to Europeans, which closely resemble the Graeco-Buddhist art of India" in some of the oldest temples of Japan (Studio, vol. xxvii, p. 26, 1903).

Iran and Babylonia.—The colonizing activity of Alexander and his successors found a large field in Iran. Cities arose in all its provinces. Media was defended by a chain of Greek cities from barbarian incursion. In eastern Iran the cities which are its chief places today then bore Greek names, and looked upon Alexander or some other Hellenic prince as their founder. Khojend, Herat, Kandahar were Alexandrias, Merv was an Alexandria till it changed that name for Antioch. One document from Antioch in Persis (about 206 B.C.) shows the normal organs of a Greek city in full working. It also throws a remarkable light upon the solidarity of the Hellenic dispersion. The citizen body had been increased several generations before by colonists from Magnesia-on-Meander, and in this decree Antioch determines to take part in the new festival being started in honour of Artemis at Magnesia.

Greek *Kingdoms*.—About 250 B.C. Bactria and Sogdiana broke away from the Seleucid empire; independent Greek kings reigned there till the country was conquered by nomads from central Asia a century later. Alexander had settled large masses of Greeks in these regions. In estimating the amount and quality of Hellenism in Bactria during the 180 years or so of Macedonian and Greek rule. hypotheses must be built upon the scantiest data. W. W. Tarn's careful survey leads to the conclusion that palpable evidences of an active Hellenism have not been found; he inclines to think that the Greek kingdoms mainly took on the native Iranian colour. The coins, of course: are adduced on the other side, being not only Greek in type and legend but (in many cases) of a peculiarly fine execution. (See BACTRIA and works there quoted.)

The west of Iran slipped from the Seleucids in the course of the 2nd century B.C., to be joined to the Parthian kingdom or fall under petty native dynasties. Soon after 130 B.C. Babylonia, too, was conquered by the Parthian. and Mesopotamia before 88. Then the reconquest of the nearer east by oriental dynasties was checked by the advance of Rome. Asia Minor and Syria remained substantial parts of the Roman empire until the Mohammedan conquests of the 7th century A.D. began a new process of recoil on the part of the Hellenistic power. The greatest of all the Hellenic colonies stood there—almost on the site of Bagdad—Seleucia on the Tigris. It superseded Babylon as the industrial focus of Babylonia and counted about 600,000 inhabitants. In Mesopotamia, Pliny especially notes how the character of the country was changed when the old village life was broken in upon by new centres of population in the cities of Macedonian foundation.

Hellenic Iranian *Culture*.—When the Parthians rent away provinces from the Seleucid empire, the Greek cities did not cease to exist by passing under barbarian rule. Gradually, no doubt, the Greek colonies were absorbed, but the process was a long one. Seleucia on the Tigris is spoken of by Tacitus as being, in A.D. 36. "proof against barbarian influences." How important an element the Greek population of their realm seemed to the Parthian kings can be seen by the fact that they claimed to be themselves champions of Hellenism. From the reign of Artabanus I (128/7–123 B.C.) they bear the epithet of "Phil-Hellen" as a regular part of their title upon the coins. That the Parthian court itself was to some extent Hellenized is shown by the story that a Greek company of actors was performing the Bacchae before the king when the head of Crassus was brought in. Artavasdes, king of Armenia (54?–34 B.C.), composed Greek tragedies and histories. The Parthian princes were in many cases the children of Greek mothers who had been taken into the royal harems. Many of the Parthian princes resided temporarily, as hostages or refugees, in the Roman empire; but the nation at large looked with anything but favour upon too liberal an introduction of foreign manners at the court.

Such slight notices in western literature do not give any penetrating view into the operation of Hellenism among the Iranians. As an expression of the Iranian mind there are the Avesta and the Pehlevi theological literature. Unfortunately. in a question of this kind the dating of documents is the first matter of importance; and dates can only be assigned to the different parts of the Avesta by processes of fine-drawn conjecture. And even if the Avesta could be dated securely, borrowing could only be proved by more or less close coincidences of idea. a tempting but uncertain method of inquiry. It is enough here to observe that Iran and Babylonia do, as a matter of fact, continually yield the explorer objects of workmanship either Greek or influenced by Greek models. belonging to the age after Alexander, and that hence. at any rate. such an influence of Hellenism upon the tastes of the richer classes as would create a demand for these things may be inferred.

Sassanian Empire.—If any vestige of Hellenism still survived under the Sassanian kings, the records do not show it. At the court a limited recognition might be given, as fashion veered, to the values prevalent in the Hellenistic world. Chosroes I interested himself in Greek philosophy and received its professors from the west with open arms; according to one account, he had his palace at Ctesiphon built by Greeks. But the account of Chosroes' mode of action makes it plain that the Hellenism once planted in Iran had withered away; representatives of Greek learning and skill had all to be imported from across the frontier.

Asia Minor.—Greek Cities of the *Diadochi*.—Very different were the fortunes of Hellenism in those lands which became annexed to the Roman empire. In Asia Minor it has been seen how, even before Alexander, Hellenism had begun to affect the native races and Persian nobility. During Alexander's own reign progress in the Hellenization of the interior cannot be traced, nor can his activity as a builder of cities be proved here. But under the dynasties of his successors a great work of colonization

went on as each rival dynasty of Greek or Macedonian kings endeavoured to secure its hold on the country by founding fresh Greek settlements.

While new Greek cities were rising in the interior, the older Hellenism oi the western coast grew in material splendour under the munificence of Hellenistic kings. Its centre of gravity to some extent shifted. Ephesus grew in greatness and wealth, and Smyrna rose again after an extinction of four centuries. The great importance of Rhodes belongs to the days after Alexander. when it received the riches of the east from the trade routes which debouched into the Mediterranean at Alexandria and Antioch. In Aeolis the centre of gravity moved to the Attalid capital, Pergamum. But the irruption of the Celts. beginning in 278–277 B.C., checked the Hellenization of the interior. Not only did the Galatian tribes take large tracts of the plateau in possession, but they were an element of perpetual unrest which hampered and distracted the Hellenistic monarchies.

Native Dynasties.—The minor dynasties of non-Greek origin, the native Bithynian and the two Persian dynasties in Pontus and Cappadocia. were Hellenized before the Romans drove the Seleucid out of the country. In Bithynia the upper classes seem to have followed the fashion of the court; the dynasty of Pontus was philhellenic by ancestral tradition; the dynasty of Cappadocia dated its conversion to Hellenism from the 2nd century B.C.

Hellenism Under Rome.—When Rome began to interfere in Asia Minor, its first action was to break the power of the Gauls (189 B.C.). In 133 Rome entered formally upon the heritage of the Attalid kingdom and became the dominant power in the Anatolian peninsula for 1,200 years. Under Rome the process of Hellenization, which the divisions and weakness of the Macedonian kingdoms had checked. went forward. The coast regions of the west and south the Romans found already Hellenized. In Lydia not a trace of the old language was left in Strabo's time; in Lycia, the old language became obsolete in the early days of Macedonian rule. But inland, in Phrygia. Hellenism had as yet made little headway outside the Greek cities. It mas not until the reign of Hadrian that city life on the Phrygian plateau became rich and vigorous. with its material circumstances of temples, theatres and baths. The lower classes at Lystra in St. Paul's time spoke Lycaonian (Acts xiv. 11). In Galatia the larger towns seem to have become Hellenized by the time of the Christian era, while the Celtic speech maintained itself in the country villages until the 4th century A.D. Cappadocia at the beginning of the Christian era was still comparatively townless. a country of large estates with a servile peasantry. Even in the 4th century its Hellenization was still far from complete; but Christianity had assimilated so much of the older Hellenic culture that the church was now a main propagator of Hellenism in the backward regions. The native languages of Asia Minor all ultimately gave way to Greek. The effective Hellenization of Armenia did not take place until the jth century.

Syria.—In Syria the work of planting cities was pursued effectively north of the Lebanon by the house of Seleucus, and, less energetically south of the Lebanon by the house of Ptolemy.

Seleucid *Empire.*—The whole of Syria was brought under the Seleucid sceptre, together with Cilicia, by Antiochus III (223–187 B.C.). Under his son, Antiochus IV (175–164), a fresh impulse was given to Syrian Hellenism. In 1 Maccabees he is represented as writing an order to all his subjects to forsake the ways of their fathers and conform to a single prescribed pattern, and though in this form the account can hardly be exact, it does no doubt represent the spirit of his action. Many cities exchanged their existing name for that of Antioch. With the ever-growing weakness of the Seleucid dynasty, the independence and activity of the cities increased. although they were less protected against military adventures and barbarian chieftains.

Roman *Period.*—When Pompey annexed Syria in 64 B.C. as a Roman province, he found it a chaos of city-states and petty principalities. The Nabataeans and the Jews above all had encroached upon the Hellenistic domain; in the south the Jewish raids had spread desolation and left many cities practically in ruins. Under Roman protection Hellenism was secured from the barbarian peril, and Greek city life, with its political forms, its complement of festivities, amusements and intellectual exercise, went on more largely than before. The great majority of the Hellenistic remains in Syria belong to the Roman period. Such local dynasties as were suffered by the Romans to exist had, of course, a Hellenistic complexion. Especially was this the case with that of the Herods. Not only were such marks of Hellenism as a theatre introduced by Herod the Great (37–4 B.C.) at Jerusalem, but in the work of city building this dynasty showed itself active. Sebaste (the old Samaria). Caesarea, Antipatris were built by Herod the Great. Tiberias by Herod Antipas (4 B.C.–A.D. 39). In Syria: too, Hellenism under the Romans advanced upon new ground. Palmyra, of which nothing is heard before Roman times. is a notable instance.

Greek *Culture in* Syria.—In Syria the same disappearance of native languages and racial characteristics as in Asia Minor are not found. Still less was this the case in Mesopotamia. At Doura-Europus on the middle Euphrates excavations presented the picture of a Seleucid foundation, built and decorated in good Greek style. but unable to resist Semitic encroachments. By A.D. 300 even the people of the wealthier classes usually bore Semitic names. The lower classes at Antioch and no doubt in the cities generally were in speech Aramaic or bilingual. The villages. of course. spoke Aramaic. The richer natives, on the other hand, would become Hellenized in language and manners, and the "Syrian code" of civil laws shows how far the social structure was modified by the Hellenic tradition. Of the Syrians who made their mark in Greek literature; some were of native blood; *e.g.*, Lucian of Samosata, and several later poets and philosophers.

On the other hand there was a Syriac-speaking church as early as the 2nd century, and with the spread of Christianity Syriac asserted itself against Greek. The extant Syriac literature is all Christian. But where Greek gave place to Syriac, Hellenism was not thereby effaced. It was to some extent the passing over of the Hellenic tradition into a new medium. There was an extensive translation of Greek works into Syriac during the next centuries, chiefly handbooks of philosophy and science.

Hellenism and the Jews.—In the first century and a half of Macedonian rule the relation of the Jews to Hellenism is very obscure, since the statements made by later writers. like Josephus, as to the privileges conferred upon the Jews in the new Macedonian realms are justly suspected of being fiction. It has been maintained that Greek influence is to be traced in parts of the Old Testament assigned to this period, as, for instance, the Book of Proverbs; but even in the case of Ecclesiastes, the canonical writing whose affinity with Greek thought is closest. the coincidence of idea need not necessarily prove a Greek source. The one solid fact in this connection is the translation of the Jewish Law into Greek in the 3rd century B.C., implying a Jewish Diaspora at Alexandria, so far Hellenized as to have forgotten the speech of Palestine.

Early in the and century B.C. the priestly aristocracy of Jerusalem had, like the well-to-do classes everywhere in Syria, been carried away by the Hellenistic current. its strength being evidenced no less by thc intensity of the conservative opposition embodied in the party of the "Pious" (Assideans, Hasidim). Under Antiochus IV (176–165) the Hellenistic aristocracy contrived to get Jerusalem converted into a Greek city; the gymnasium appeared, and Greek dress became fashionable with the young men. Rut when Antiochus, for political reasons, interfered violently at Jerusalem, the conservative opposition carried the nation with them. The revolt under the Hasmonaean family (Judas Maccabaeus and his brethren) followed, ending in 143–142 in the establishment of an independent Jewish state. Hut the Hasmonaean state was of the nature of a compromise. The Mosaic Law was respected, but Hellenism still found an entrance in various forms. The first Hasmonaean king, Aristobulus I (104–103), was known to the Greeks as Phil-Hellen. He and all later kings of the dynasty bear Greek names as well as Hebrew ones, and after Iannaeus Alexander (103–76) the Greek legends are' common on the coins beside the Hebrew. Herod, who supplanted the Hasmonaean dynasty (37–4 B.C.), made, outside

Judaea, a display of philhellenism, building new Greek cities and temples. His court, at the same time, welcomed Greek men of letters like Nicolaus of Damascus. Even in the neighbourhood of Jerusalem, he erected a theatre and an amphitheatre. Meanwhile a great part of the Jewish people were living dispersed among the cities of the Greek world. speaking Greek as their mother tongue. These are the Jews who are found contrasted as "Hellenists" with the "Hebrews" in Acts. A large Jewish literature in Greek had grown up since the translation of the Law in the 3rd century. Besides the other canonical books of the Old Testament. it included translations of other Hebrew books (Ecclesiasticus, Judith, etc.); works composed originally in Greek but imitating to some extent the Hebraic style (like Wisdom); works modelled more closely on the Greek literary tradition, either historical, like II Maccabees, or philosophical, like the productions of the Alexandrian school, represented by Aristobulus and Philon; or Greek poems on Jewish subjects, like the epic of the elder Philon and Ezechiel's tragedy, *Exagógé*. It included also a number of forgeries contrived for the heathen public. as a means of propaganda, calculated to inspire them with respect for Jenish antiquity or turn them from idols to God.

Through the Hellenistic Jews, Greek influences reached Jerusalem itself, though their effect upon the Aramaic-speaking rabbinical schools was naturally not so pronounced The large number of Greek words, however, in the language of the Mishnah and the Talmud is a significant phenomenon. The attitude of the rabbinical doctors to a Greek education does not seem to have been hostile until the time of Hadrian. The sect of the Essenes probably shows an intermingling of the Greek with other lines of tradition among the Jews of Palestine.

Egypt and Ethiopia.—In Egypt the Ptolemies were hindered by special considerations from building Greek cities after the manner of the other Macedonian houses. Even at Alexandria Hellenism was not allowed full development. In its population, too. Alexandria was only semi-Hellenic; for besides the proportion of Egyptian natives in its lower strata, its commercial greatness drew in elements from every quarter; the Jews, for instance, formed a majority of the population in two out of the five divisions of the city. At the same time the prevalent tone of the populace mas, no doubt, Hellenistic, as is shown by the fact that the Jews who settled there acquired Greek in place of Aramaic as their mother tongue, and in its upper circles Alexandrian society under the Ptolemies was not only Hellenistic, but notable among the Hellenes for its literary and artistic brilliance. The state university, the "museum," was in close connection with the court, and gave to Alexandria the same pre-eminence in natural science and literary scholarship which Athens had in moral philosophy. Probably in no other country, except Judaea, did Hellenism encounter as stubborn a national antagonism as in Egypt. Yet the papyri show habitual marriage of Greeks and native women, and a frequent adoption by natives of Greek names. In Egypt, too, the triumph of Christianity brought into being a native Christian literature, and if this was in one way the assertion of the native against Hellenistic predominance, it must be remembered that Coptic literature, like Syriac, necessarily incorporated those Greek elements which had become an essential part of Christian theology.

From the Ptolemaic kingdom Hellenism early travelled up the Nile into Ethiopia. Ergamenes, the king of the Ethiopians in the time of the second Ptolemy, who had received a Greek education and cultivated philosophy, broke with the native priesthood, and from that time traces of Greek influence continue to be found in the monuments of the upper Nile. When Ethiopia became a Christian country in the 4th century, its connection with the Hellenistic world became close.

Hellenism in the West.—While in the east Hellenism had been sustained by the political supremacy of the Greeks, in Italy *Graecia capta* had only the inherent power and charm of its culture wherewith to nin its way. Even before Alexander. Hellenism had affected the peoples of Italy. but it was not until the Greeks of south Italy and Sicily mere brought under the supremacy of Rome in the 3rd century B.C. that the stream of Greek influence entered Rome in any volume It was now that the Greek freedman L. Livius Andronicus laid the foundation of a new Latin literature by his translation of the *Odyssey*, and that the Greek dramas were recast in a Latin mould. The first Romans who set about writing history wrote in Greek. At the end of the 3rd century there was a circle of enthusiastic philhellenes among the Roman aristocracy, led by Titus Quinctius Flamininus. who in Rome's name proclaimed the autonomy of the Greeks in 196. In the middle of the 2nd century B C. Roman Hellenism centred in the circle of Scipio Aemilianus, which included men like Polybius and the philosopher Panaetius. The visit of the three great philosophers, Diogenes, Critolaus and Carneades, in 155 was an epoch-making event in the history of Hellenism at Rome. Opposition there could not fail to be, and in 161 a *senatus consultum* ordered all Greek philosophers and rhetoricians to leave the city. The effect of such measures was, of course, transient. Even though the opposition found so doughty a champion as the elder Cato (censor in 184), it was ultimately of no avail. The Italians did not indeed surrender themselves passively to the Greek tradition In different departments of culture the degree of their independence was different. The mere fact that they produced a literature in Latin argues a power of creation as well as receptivity. The great Latin poets were imitators indeed, but mere imitators they were no more than Petrarch or Milton On the other hand. even where the creative originality of Rome was most pronounced. as in the sphere of law, there were elements of Hellenic origin. It has been often pointed out how the Stoic philosophy especially helped to shape Roman jurisprudence.

While the upper classes in Italy absorbed Greek influences by their education, the lower strata of the population of Rome became largely Hellenized by the actual influx on a vast scale of Greeks and Hellenized Asiatics, brought in for the most part as slaves and coalescing as freedmen with the citizen body. The early Christian Church in Rome, to which St. Paul addressed his epistle. was Greek-speaking, and continued to be so until far into the 3rd century. In the western Mediterranean a Greek element was introduced wherever the Romans iosiered town life and thus invited the Greek trader and professional man. This later process of Hellenization is especially noticeable in north Africa. where the native king Juba (under Augustus) actively encouraged it. But in the west the Latin language everywhere ousted the Greek as a spoken tongue, and the prevalent culture was Italian rather than Hellenic.

LATER HISTORY

It remains only to glance at the ultimate destinies of Hellenism in west and east. In the Latin west, knowledge of Greek. firsthand acquaintance with the Greek classics. became rarer and rarer as general culture declined, until in the dark ages (after the jth centuryj it existed practically nowhere but in Ireland. In Latin literature. however, a great mass of Hellenistic tradition was maintained in currency wherever culture of any kind continued to exist. Then the stream began to rise again, first with the influx of the learning of the Spanish Moors, then with the new knowledge of Greek brought from Constantinople in the 14th century. With the Kenaissance and the new learning. Hellenism came in again in flood. to form a chief part of that great river on which the modern world is being carried forward, In the east it is popularly thought that Hellenism, as an exotic. withered altogether away. This view is superficial. Ultimately the Greek east was absorbed by Islam; the popular mistake lies in supposing that the Hellenistic tradition thereby came to an end. The Mohammedan conquerors found a considerable part of it taken over by the Syrian Christians. and Greek philosophical and scientific classics were now translated from Syriac into Arabic. These were the starting points for the Mohammedan schools in these subjects. Accordingly the Arabian philosophy (*q.v.*), mathematics, geography, medicine and philology are all based professedly upon Greek works. Aristotle in the east no less than in the west was the "master of them that know"; the geography and astronomy of Claudius Ptolemaeus had canonical authority in Isiam and in Christendom alike; and Moslem physicians to this day invoke the

names of Hippocrates and Galen. The Hellenistic strain in Mohammedan civilization has. it is true. flagged and failed, but only as that civilization as a whole has declined.

HELLER, STEPHEN (1814–1888), Austrian pianist and composer. was born at Pest on Slay 1j. For several years he played as a *Wunderkind,* but in 1838 settled in Paris where he became intimate with Liszt. Chopin, Berlioz and their circle.

Heller later visited England. where he performed with Sir Charles Hallé. He composed many elegant short pieces for the piano, and was much esteemed as a teacher in Paris. where he died on Jan. 14. 1885.

HELLESPONT (*i.e.,* "Sea of Helle"; variously named in classical literature Hellespontos. Hellespontum Pelagus and Fretum Hellesponticum). the ancient name of the Dardanelles (*q.v.*). It was so-called from Helle, the daughter of Athamas (*q.v.*), who was drowned there. *See* ARGONAUTS.

HELLMAN, LILLIAN (1905–), U.S. playwright whose dramas bitterly and forcefully attacked injustice, exploitation and selfishness, was born June 20. 1905, in New Orleans, La., attended New York public schools, and received degrees from New York university and Columbia university. Her marriage (1925–32) to playwright Arthur Kober ended in divorce. After working variously as book reviewer, press agent and play reader, she began writing plays.

Her dramas exposed various forms in which evil appears—a malicious child's lies about two schoolteachers (The Children's *Hour,* 1934); a ruthless family's exploitation of fellow townspeople and of one another (The Little Foxes, 1939, and Another Part of the Forest, 1946); and the irresponsible selfishness of the Versailles treaty generation (Watch on *the* Rhine, 1941, and The Searching *Wind,* 1944). Criticized at times for her doctrinaire views and characters, she nevertheless kept her characters from becoming merely social points of view by credible dialogue and realistic intensity matched by few of her contemporaries. These plays exhibit the tight structure and occasional overcontrivance of what is known as the "well-made play." In the 1950s she showed her skill in handling the looser structure of Chekhovian drama (The *Autumn* Garden, 1951) and in translating and adapting (Anouilh's *The* Lark, 1955). She returned to the well-made play with *Toys* in the Attic (1960). (Js. T. N.)

HELL'S CANYON, a mile-deep gorge in the central section of the grand canyon of the Snake river, runs along the Idaho-Oregon boundary. Reaching a maximum depth of 7,900 ft. on its Idaho mall, it is the deepest canyon in North America. Two 19th-century steamboats sailed down the canyon with extreme difficulty, but the river is navigable only for small craft.

Excellent hydroelectric power sites. including an incomparable one for a high dam, are numerous in the canyon. When the devastating Columbia river flood of 1948 focused attention upon control of the Snake river, the bureau of reclamation and the U.S. army engineers recommended a high Hell's canyon multiple-purpose dam for flood control (4,400,000 ac.-ft. storage). navigation and power. In 1950 the Idaho Power company applied for private development through three lower dams; after a hearing of four and one-half years, the Federal Power commission granted a licence to the company on Aug. 4. 1955. A national controversy, pitting public against private power advocates, grew out of the hearing, and in 1957 the United States senate approved federal construction of a high dam that would flood the Idaho Power sites. The house did not concur, however, and in 1958 power production commenced at the initial private dam. (M. D. B.)

HELMET, a defensive covering for the head, one of the most universal forms of body armour. Helmets are usually thought of today as items of military equipment for soldiers, sailors or airmen. but modified types are worn by firemen, miners, civil-defense workers. race drivers and others engaged in hazardous occupations or sports.

Although there were earlier protective head coverings, most studies of helmets begin with those worn in ancient Greece and Rome. Made of hard leather or bronze, these helmets ranged from simple caps to highly developed forms with crests projecting before and behind. On some of these types the neck was protected in back; on others there were also hinged plates to guard the ears, and even a rudimentary visor. The most effective of the Greek helmets, and perhaps the best in the ancient world, was the so-called Boeotian or Corinthian form. the helmet usually portrayed on statues of Athena. It covered the entire head with only the narrowest of openings in front for vision and breath. A specialized Roman form different from the rest was the gladiator's helmet with its broad brim and pierced visor 'covering the face.

FIG. 1.— PARTS OF THE HELMET (CLOSED HELMET OF SIR HENRY LEE. BY JACOB TOPF. 1530–97)

In northern and western Europe the first helmets were made of leather reinforced with bronze or iron straps. Usually they took the form of conical or hemispherical skullcaps. Gradually the amount of metal increased until entire helmets of iron were fashioned, still following the same forms. About the year 1000 a bar projecting below the rim in front, called a nasal, was added to protect the nose. When the owner could afford it, these helmets were worn over a hood of chain mail which protected the cheeks and neck.

The desire for still further protection led to the development of the helm, or heaume, about 1200. At first almost a straight flat-topped cylinder, it was worn over the iron or steel skullcap and hood of mail, usually being put on at the last minute before the beginning of an engagement. Warriors soon discovered that the flat top and perpendicular sides transmitted the full force of any blon to the wearer and that the loose helm could easily be knocked off. Helms then gradually assumed rounded contours that would cause blows to glance off and were extended downward so

FIG 2 —DEVELOPMENT OF THE HELMET FROM AD. 600 TO THE 17TH CENTURY

that they could be attached directly to the breastplate. As such they became for many years the favoured headpiece for tournaments. (See ARMOUR, BODY.)

Meanwhile the skullcap itself was developing. The point grew higher, and the back was extended downward to protect the neck. In this form it became the bascinet (basinet). Shortly after 1300 a movable visor was added to cover the face. Usually these visors were sharply pointed, and the name "dog faced" or "pig faced" has been given to them. A cape of mail, called a camail, was attached to the lower edges of the helmet to guard the neck. About the year 1400 this camail was superseded by additional plates, and the so-called "great bascinet" had appeared.

The 11th century, which witnessed the appearance of the great bascinet, also brought forth three other types of helmet, all deriving from the same simple bascinet. These were the salade, the barbute and the armet. In the salade the pointed crown was rounded off. and a long graceful tail protecting the neck was added. As time passed, the rim was lowered in front, covering the upper half of the face with a narrow slot cut through for vision. Still later, the portion below the slot was hinged to provide a movable visor. This helmet protected the upper portion of the head but left the chin and front of the neck bare. If a defense for the chin and neck was desired, it was provided by a separate plate or plates called a beavor, or buffe, that could be strapped around the neck or attached to the breastplate but did not form an integral part of the helmet. The barbute also had a rounded crown, but the tail was missing. Instead, the lower borders were extended almost straight down to protect the neck and cheeks, leaving in some instances only a narrow T-shaped opening in front. In this form it closely resembled the classical Corinthian helmet of Greece.

The real advance in helmet design, however, came with the armet, and later the close helmet. All other helmets had been put on directly over the head, thus requiring that a large opening be provided at the bottom for the head to enter. This made them susceptible to being knocked off and caused many difficulties in protecting the neck. The armet and close helmet changed all that. By hinging the cheek pieces, as on the armet, or pivoting, as on the close helmet, armourers produced a helmet that could fit tightly under the chin and base of the skull. This design fully protected the neck and made it impossible for a blow to dislodge the helmet in battle. The evolution of the armet began shortly after 1400. The close helmet appeared about 1500. Both were truly closed helmets and continued in use as long as full helmets were worn.

While these closed helmets were being brought to perfection, a series of light open helmets also appeared. As early as the 14th century a broad-brimmed helmet with a domed or pointed bowl known as a chapel-de-fer, or "iron hat," had become popular. Aside from the skullcap and small versions of the salade; it was almost the only light open helmet worn throughout the 11th century. About 1110, however, two new types, the morion and the cabasset, became popular. The cabasset had a pointed, keeled bowl or crown and a narrow brim. The morion had a round bowl with a high comb and a crescent-shaped brim rising to points at the front and back. Both helmets sometimes had ear defenses of overlapping plates covering straps that could be fastened under the chin; and sometimes the brim of the morion and the crown of the cabasset were combined to form a morion-cabasset. They were worn by nearly all infantry, by ceremonial guards and by almost everyone who desired a light helmet. Their period of popularity lasted roughly a century, until about 1650, though the Papal Swiss guard continues to wear them in the 20th century.

In England a variant form of helmet for pikemen was developed and worn from about 1600 to 1680. It had a broad straight brim, a hemispherical crown with a low comb, and was generally known as a "pikeman's pot."

During the 16th century there appeared also a very versatile helmet known as a burgonet. This helmet was characterized by a peak over the eyes similar to that found on modern baseball caps and by the fact that it protected the nape of the neck. Usually it also had a comb or combs and ear pieces. Sometimes protection for the face was added in the form of a sliding nasal, a pivoted cage of bars, or even a visor similar to those used on armets. though usually flatter. In the 17th century a particular form of a burgonet with a neck defense of overlapping plates became popular and was called a lobster-tail burgonet because of the supposed resemblance to the plates of a lobster's abdomen or "tail." Light-horsemen were particularly fond of the burgonet, and it became almost standard equipment for them throughout Europe until nearly the end of the 17th century. A very heavy bulletproof bur-

gonet was used by engineers besieging fortresses from at least 1600 until well after 1800.

With the decline of the full helmet late in the 17th century, attention was focused on the light metal skullcap that could be worn under the regular cloth hat. Such caps became standard for dragoons. heavy cavalry and for many officers, and were worn throughout the succeeding century. Some infantry officers wore them as late as World War I. About 1750 it became the custom to equip the newly developed light cavalry with helmets of hard leather in both England and America and with brass helmets in England, France and other European nations. During the 19th century, leather, brass and even steel helmets became fashionable for various types of cavalry. Many of these units retained them for dress use long after they ceased to be worn in the field.

Although some infantry regiments, notably those of Germany, wore leather helmets bound with metal, the steel helmet did not reappear as a regulation item of equipment until the opening years of World War I. The French first adopted the helmet as standard in 1914, the British in 1915, followed quickly by the Germans and then by the rest of Europe and the United States. All were designed to present glancing surfaces so that a bullet or shell fragment would bounce off without imparting its full impact. Many resembled the light helmets of the 15th century, notably the Italian salade and the chapel-de-fer. The performance of these headpieces in action was so successful that they became standard equipment, not only for infantry, but also for other branches and arms of the service. During World War I, Americans used helmets of British design, but in World War II, after continued research by armour specialists, several new models were brought forth and issued for soldiers, sailors and airmen. By and large, other nations retained the helmets they had used in World War I with only slight modifications.

The helmets described above are only a few of the many types developed and used in Europe and the United States during the last 3,000 years. Other cultures in Asia and Africa have also produced and worn them. The ancient Assyrians and Persians had helmets of leather and of iron before the era of the battle of Marathon (490 B.C.).

FIG. 5.—MORION OF THE MUNICH CIVIC GUARD, 17TH CENTURY

In later years, the conical steel helmets of Persia. Turkey and India have been valued as works of art because of their fine forging and delicate damascening. In Tibet and China helmets of bronze, leather and horn have been made and worn for untold centuries, and the highly developed Japanese helmets with detachable face guards. finely forged and lacquered, have also been recognized as fine examples of the armourer's craft.

The primitive cultures of Africa and the South seas also produced distinctive helmets which cannot even be listed in a brief article.

HELMHOLTZ, HERMANN LUDWIG FERDINAND VON (1821–1894), German philosopher and man of science, made important contributions in a wide range of scientific areas, but is best known for his statement of the law of conservation of energy. He was born on Aug. 31. 1821, at Potsdam, near Berlin. In 1849 he became professor of physiology in Konigsberg. There he remained until 1855. when he removed to the chair of physiology in Bonn. In 1858 he became professor of physiology in Heidelberg, and in 1871 he occupied the chair of physics in Berlin. To this professorship was added in 1887 the post of director of the physico-technical institute at Charlottenburg. near Berlin, and he held the two positions together until his death on Sept. 8, 1894.

His investigations occupied almost the whole field of science, from physiology to mechanics. In 1847 Helmholtz read to the Physical Society of Berlin a famous paper, *Über die Erhaltung der Kraft* ("On the Conservation of Force"), which became one of the epoch-making papers of the century; indeed, along with J. R. Mayer, J. P. Joule and W. Thomson (Lord Kelvin), he may be regarded as one of the founders of the law of the conservation of energy. In 1851, he invented the ophthalmoscope.

Helmholtz' contributions to physiological optics are of great importance. He investigated the optical constants of the eye, measured by his invention, the ophthalmometer, the radii of curvature of the crystalline lens for near and far vision. explained the mechanism of accommodation by which the eye can focus within certain limits. discussed the phenomena of colour vision and gave a clear account of the movements of the eyeballs so as to secure single vision with two eyes. In particular he revived and gave new force to the theory of colour vision associated with the name of Thomas Young, showing the three primary colours to be red, green and violet, and he applied the theory to the explanation of colour blindness. His great work on *Physiological Optics* (1856–66) was by far the most important book to have appeared on the physiology and physics of vision. Equally distinguished was his research in physiological acoustics. He explained accurately the mechanism of the bones of the ear, and he discussed the action of the cochlea on the principles of sympathetic vibration.

Perhaps his greatest contribution in this area, however, was his attempt to account for our perception of quality of tone. He showed. both by analysis and by synthesis, that quality depends on the order, number and intensity of the overtones or harmonics that may, and usually do, enter into the structure of a musical tone. He also developed the theory of differential and of summational tones. His work on *Sensations of Tone* (1862) may well be termed the principia of physiological acoustics. He may also be said to be the founder of the fixed-pitch theory of vowel tones,. according to which it is asserted that the pitch of a vowel depends on the resonance of the mouth, according to the form of the cavity while singing it, and this independently of the pitch of the note on which the vowel is sung.

For the later years of his life his work may be summed up under the following heads: (1) on the conservation of energy; (2) on hydrodynamics; (3) on electrodynamics and theories of electricity; (4) on meteorological physics; (5) on optics; and (6) on the abstract principles of dynamics. In all these fields of labour he made important contributions to science and showed himself equally great in all.

Helmholtz continued his study of the phenomena of electrical oscillations from 1869 to 1871, and in the latter year he announced that the velocity of the propagation of electromagnetic induction was greater than 314,000 m. per second. This work is interesting in view of the fact that Heinrich Hertz was a pupil of Helmholtz at this time and that later he demonstrated the existence of electromagnetic waves while studying a problem suggested to him by Helmholtz. This was followed by a series of papers on electrodynamics which were published from 1870 onward. Helmholtz started with a formula of F. E. Neuman *for* the potential of two current elements. and investigated the terms which must be added to give a general expression which agreed with the phenomena of closed circuits. There followed a controversy on the relative merits of the work of Helmholtz. Weber and J. Clerk Maxwell on this problem. In his paper on the "equations of motion of

electricity in conductors at rest" (1874), Helmholtz applied his generalized formula to the propagation of electric and magnetic disturbances through bodies capable of electric or magnetic polarization. He contributed papers on the theory of the electrical double layer and on electrolysis. Toward the end of his life he wrote on the physical meaning of the principle of least action and applied the principle to electrodynamics; he also wrote and lectured on philosophical and aesthetic problems. His position was that of an empiricist, denying the doctrine of innate ideas and holding that all knowledge is founded on experience, hereditarily transmitted or acquired.

See L. Konigsberger, *Hermann von Helmholtz,* Eng. trans. by F. A. Welby (1906); J. G. McKendrick, H. L. F. *von Helmholtz* (1899).

HELMINTHOLOGY, the study of parasitic worms. *See* NEMATODA; PARASITISM AND PARASITOLOGY; PLATYHELMINTHES; TREMATODES; TAPEWORMS.

HELMOLD, a historian of the 12th century, was a priest at Bosau near Plön. He was a friend of the two bishops of Oldenburg, Vicelin (d. 1154) and Gerold (d. 1163), who did much to Christianize the Slavs. At Bishop Gerold's instigation Helmold wrote his *Chronica Slavorum,* a history of the conquest and conversion of the Slavonic countries from the time of Charlemagne. For the life and times of Henry the Lion, duke of Saxony, Helmold's chronicle: as that of a contemporary who had exceptional means for gaining information. is of first-rate importance. The history was continued down to 1209 by Abbot Arnold of Liibeck.

The *Chronica* were first edited by Siegmund Schorkel (Frankfurt-on-Main, 1556). The best edition is by J. M. Lappenberg in *Mon. Germ. hist. scriptores,* xxi (1869). For critical works on the *Chronica* see A. Potthast, *Bibliotheca hist. med. aevi,* s. "Helmoldus."

HELMOND, town in the province of North Brabant, Netherlands. on the Aa river and the Zuid-Willems Vaart canal between 'sHertogenbosch and Maastricht. 24½ mi. W N.W. of Venlo by rail. It is connected by tramway with 'sHertogenbosch (21 mi. N.W.). Pop. (1957 est.) 40,888 (mun.).

The castle of Helmond. built in 1402, is the seat of the town hall. Helmond is an industrial centre with factories for textiles, iron founding, soap, margarine and tobacco dressing, as well as having an engine works

HELMONT, JAN BAPTISTA VAN (1577–1644), Belgian chemist, physiologist and physician, identifier of carbon dioxide and discoverer of the existence of gases, was born at Brussels in 1577. He was educated at Louvain and, after ranging from one science to another, turned to medicine. in which he took his doctor's degree in 1599. In 1609 he settled at Vilvorde, near Brussels, where he occupied himself with chemical experiments and medical practice until his death on Dec. 30, 1644.

Helmont presents curious contradictions. On the one hand he was a mystic with strong leanings to the supernatural, an alchemist who believed in the philosopher's stone; on the other hand he was touched with the new learning of William Harvey, Galileo and Francis Bacon, and was a careful observer and an exact experimenter. He was the first to understand that there are gases distinct in kind from atmospheric air. The very word "gas" he claims as his oan invention, and he perceived that his "gas sylvestre" (carbon dioxide) given off by burning charcoal is the same as that produced by fermenting must. He believed that water was the chief if not the only ultimate constituent of all matter. He showed that plants could grow though they apparently received nothing but pure water, and so he argued that the wood. bark and roots had been formed from nater alone.

Van Helmont considered that digestion, nutrition and even movement are due to ferments, nhich convert dead food into living flesh in six stages. But having got so far with the application of chemical principles to physiological problems, he introduces a complicated system of supernatural agencies. nhich preside over and direct the affairs of the body. At the same time chemical principles guided him in the choice of medicines—undue acidity of the digestive juices, for example, was to be corrected by alkalies and vice versa; he was thus a forerunner of the iatrochemical school.

His works were collected and published at Amsterdam as *Ortus medicinae, vel opera et opuscula omnia* in 1648 by his son Franz Mercurius (b. 1618 at Vilvorde, d. 1699 at Berlin), in whose own writings, *e.g., Cabbalah denudata* (1677) and *Opuscula philosophica* (1690), mystical theosophy and alchemy appear in still wilder confusion.

BIBLIOGRAPHY.—F. Strunz, essay in G. Bugge's *Buch der grossen Chemiker* (1930); F. Giesecke, *Die Mystik J. B. van Helmonts* (1908); J. R. Partington, essay in *Annals of Science,* vol i, iv (1936).

HELMSTEDT, or, more rarely, HELMSTADT, a town of Germany, in the *Land* of Lower Saxony, 30 mi. W.N.W. of Magdeburg on the main railway line to Brunswick. Pop. (1950) 28.041. Helmstedt was probably founded about 900, and obtained civic rights in 1099. In 1457 it joined the Hanseatic league. and in 1490 it came into the possession of Brunswick. In 1576 Julius, duke of Brunswick, founded a university there, and throughout the 17th century it was one of the chief seats of Protestant learning. It nas closed by Jerome, king of 'Cl'estphalia, in 1809. The principal buildings are the Juleum, the former university, in Renaissance style (late 16th century), and the Stephanskirche dating from the 12th century. The principal manufactures are furniture, yarn, soap. tobacco, machinery, glass and earthenware.

HELMUND, a river of Afghanistan, about 600 mi. long, the ancient Etymander, the most important river in Afghanistan next to the Kabul river, which it exceeds both in volume and length. It rises in the recesses of the Koh-i-Baba to the west of Kabul, its infant stream parting the Unai pass from the Irak, the two chief passes on the well-known road from Kabul to Bamian. About the parallel of 33° N. it enters the Zamindawar province which lies to the northwest of Kandahar, and thenceforward it is a well-mapped river to its termination in the lake of Seistan. Until about 40 mi. above Girishk the character of the Helmund is that of a 'mountain river, flowing through valleys which in summer are the resort of pastoral tribes. On leaving the hills it enters a flat country, and extends over a gravelly bed. There also it begins to be used in irrigation. At Girishk it is crossed by the principal route from Herat to Kandahar. Forty-five miles below Girishk the Helmund receives its greatest tributary. the Arghandab, from the high Ghilzai country beyond Kandahar, and becomes a very considerable river, with a width of 300 or 400 yd. and an occasional depth of 9 to 12 ft. Even in the dry season it is never without a plentiful supply of water. The course of the river is more or less southwest from its source until in Seistan it crosses meridian 62°, when it turns nearly north and so flows for 70 or 80 mi. until it falls into the Seistan hamuns, or swamps. by various mouths. In this latter part of its course it forms the boundary between Afghan and Iranian Seistan. and because of constant changes in its bed and the swampy nature of its borders it has been a fertile source of frontier squabbles. Iranian Seistan was once highly cultivated by means of a great system of canal irrigation; but, since the country was devastated by Timur, it has been a barren, treeless waste of flat alluvial plain. In years of exceptional flood the Seistan lakes spread southward into an overflow channel called the Shelag which, running parallel to the northern course of the Helmund in the opposite direction. finally loses its waters in the Gaod-i-Zirreh swamp. Throughout its course from its confluence with the Arghandab to the ford of Chahar Burjak. where it bends northward, the Helmund valley is a narrow green belt of fertility sunk in the midst of a wide alluvial desert, with many thriving villages interspersed among the remains of ancient cities, relics of Kaiani rule.

HELOTS (Gr. Εἵλωτες or Εἵλωται), the serfs of the ancient Spartans. They were probably the aborigines of Laconia who had been enslaved by the Achaeans before the Dorian conquest. After the second Messenian War *(see* SPARTA), the conquered Messenians were reduced to the status of Helots. The Helots were state slaves bound to the soil and assigned to individual Spartiates to till their holdings (Gr. *klēroi*); their masters could neither emancipate them nor sell them off the land, nor raise the rent payable yearly in kind by the Helots. In time of war, they served as light-armed troops or as rowers in the fleet; from the Peloponnesian War onward they were occasionally employed as heavy infantry (Gr. *hoplitai),* distinguished bravery being re-

warded by emancipation. The general attitude of the Spartans toward them was one of distrust and cruelty. The ephors of each year. on entering office, declared war on the Helots so that they might be put to death at any time without violating religious scruple. and there is a well-attested record of 2,000 Helots being freed for service in war and .then secretly assassinated. (Thuc., iv, 80.) (See CRYPTEIA.)

Intermediate between Helots and Spartiates were the neodamodes and mothones. The former were emancipated Helots, or their descendants, and were much used in war; they served especially on foreign campaigns. as that of Agesilaus (396–394 B.C.) in Asia Minor. The mothones, or mothakes, were the sons of Spartiates and Helot mothers; they were free men sharing the Spartan training. but not full citizens.

HELSINGBORG (HÄLSINGBORG), a seaport of Sweden in the *län* of Malmohus, 35 mi. N.E. of Copenhagen by rail and water. Pop. (1960) 76,504. The original site of the town is marked by the tower of the old fortress, first mentioned in 1135, the ruins of which stand on a hill above the town. From 1370, along with other towns in the province of Skane. it was united for 1j years with the Hanseatic league. The fortress was destroyed by fire in 1418, and about 1425 Eric XIII built another near the sea and caused the town to be transported thither. bestowing upon it important privileges. Until 1658 it belonged to Denmark. and in 1684 its fortifications were dismantled. It was retaken by the Danes several times but in 1710 the town came finally into the possession of Sweden. It stands on the narrowest part of Oresund (the Sound), there only 3 mi. wide. opposite Helsingor (Elsinore) in Denmark. On the outskirts are the Oresund park, containing iodide and bromide springs, and sea baths. On the coast to the north is the royal chhteau of Sofiero; to the south, the small spa of Ramlosa. North and east of Helsingborg lies the only coal field in Sweden, extending into the Kullen peninsula. Potter's clay is also found. Helsingborg ranks among the first manufacturing towns of Sweden, having copper works. using ore from Sulitelma in Norway, indin-rubber works. sugar refineries, superphosphate works and breweries. The new harbour has a depth of 32 ft., and there are extensive docks. The chief exports are timber, dairy produce, paper. rubber wares, iron ore.

HELSINKI (Swedish *Helsingfors*), the capita1 and leading seaport of the republic of Finland. on the Gulf of Finland. Pop. (1960) 452,800. Helsinki is well laid out. with wide streets, parks and gardens. The principal square contains the cathedral known as the Great Church designed by C. L. Engel (completed by E. Lohrmann in 1852) who also created other distinguished buildings in classical style such as the old senate house, now the state council building. and the university. In varied styles are the post office building (1938), the National museum (1906–10), the diet building (1931) and Eliel Saarinen's railway station (1916). Many of the buildings have acquired a certain national character through the use of local granite. As the seat of the country's government. Helsinki contains the president's palace, the administrative offices and the supreme courts of justice. The municipality, administered by a city council. spends about 40% of its budget on social services. The fine port, divided into two parts by a promontory and protected at its entrance by a group of small islands. includes five harbours. The port accommodates the largest vessels, but is usually closed by ice from January to May, except for a channel kept open by an icebreaker. Helsinki imports coal. machinery, sugar. grain and clothing. Its main industries are metal goods, foodstuffs. luxury goods and printed matter. Most of Finland's cultural institutions are located in the capital: the university (transferred from Abo (Turku) after the fire of 1827) and technical school, the Athenaeum and its picture gallery, the Swedish theatre and opera house. the Finnish theatre and the archives.

The city was founded by Gustavus Vasa. king of Sweden, in 1550 as a trading centre on the estuary of the Vantaa river. It received its first charter from John III in 1569; but the site proved ill-chosen and in 1640 it was moved to its present position on Vironniemi peninsula. The inhabitants continued to suffer from fire, famine and plague, and in May 1713 were evacuated from the town before its capture by Peter the Great's fleet during the Russian campaign against Sweden. Before retreating. Swedish troops razed the town, and after the treaty of Nystad in 1721 reconstruction was begun only to be destroyed by subsequent Russian invasions. When the fortifications at Suomenlinna were commenced in 1748 however. Helsinki's trade and shipping flourished. Finland having been ceded by Sweden to Russia in 1809, a decree of Alexander I in 1812 appointed Helsinki the capital city instead of Xbo. With the establishment of the republic in 1919 it was at last freed from foreign occupation. It was repeatedly bombed during the Russo-Finnish war of 1939–40 and suffered again in the subsequent world conflict which Finland entered in 1941.

HELST, BARTHOLOMEUS VAN DER (c. 1613–1670), Dutch artist, who enjoyed a successful practice as one of the leading portrait painters of Amsterdam. was born at Haarlem. His first known picture. "Four Regents of the Walenweeshuis" (Amsterdam, Walenweeshuis; signed and dated 1637). is closely related to the work of Nicolas Elias. generally assumed to have been his master. Helst's success was rapid. Influential sitters and important commissions came to him at an early age. In 1642 he painted the Amsterdam burgomaster Andries Bicker and his wife and son. and in the following year he completed a great portrait group, "Captain Roelof Bicker's Company." which formed part of the same scheme of decoration as Rembrandt's "Night Watch." Another of these huge portrait groups. "Captain Cornelis Witsen's Company." followed in 1648. Of the less ambitious portraiture that flowed from his facile brush. many of the official and family groups remain in Holland. Many of these may be seen in the Rijksmuseum in Amsterdam. He died in Amsterdam. Dec. 16. 1 0 . Heist was prone to be too complaisant toward the vanities of his sitters, and the force and insight that in some of his early portraits reflect his study of Rembrandt and Frans Hals tend later to lose themselves in mechanical facture, empty rhetoric or spurious elegance. Yet by his direct approach and solid mastery some achieve genuine distinction. (D. KG.; X.)

HELSTON, a market town and municipal borough in the Falmouth and Camborne parliamentary division of Cornmall, Eng.. 13 mi. W.S.W. of Falmouth by road. Pop. (1961) 7,085. Helston is the nearest railway station to the Lizard peninsula. May 8 is Furry (Flora) day, an old festival when church bells are rung early in the morning and processions dance through the streets and in and out of the houses to traditional music. As the capital of the Meneage district of Cornwall, the place was held by Earl Harold in the time of the Confessor and by William I at the Domesday survey. From 1298 to 1885 it returned two members to parliament. although in 1790 the electorate had dwindled to one person only. The town obtained its first charter (1201) from King John and in the 13th century it was the most important town in west Cornwall, having a harbour on the Cober, which now expands into Loe pool (2 mi. S.W.) banked up by Loe bar at the mouth. In Elizabeth I's time it was one of the four Cornish stannary towns and its main street is still called Coinagehall street. The mining industry is extinct, but agriculture and dairy farming flourish. There is a weekly cattle market. The small port of Porthleven, 3 mi. S.W., was included in the borough in 1034.

HELVETIC CONFESSIONS are two documents officially adopted as expressing the common belief of the Reformed Church in Switzerland. The First Helvetic Confession (less aptly called the Second Confession of Basel), consisting of 27 brief articles, was composed in 1536 by Heinrich Bullinger and delegates from several Swiss cities, with the participation of Martin Rucer of Strasbourg. Viewed favourably by Luther and sometimes criticized as too Lutheran for Keformed tastes, it nonetheless was the first Reformed creed of national authority. In 1562 Bullinger wrote for his private use a lengthy theological statement of 30 articles, which he later revised and attached to his will. This document, known as the Second Helvetic Confession, was published in 1566 as the official creed of the Swiss cantons (superseding the first. except in Basel) and was adopted also in the Palatinate where it had served the elector Frederick 111 the Pious as a defense against Lutherans. It was recognized in Scotland (1566), Hungary (1567), France (1571) and Poland (1578); was favourably

received in Holland and England, and was subsequently recognized as one of the most authoritative statements of Reformed theology.

The Second Helvetic Confession is a comprehensive and detailed statement of the ancient dogmas of the Trinity (art. 3) and Christology (11), as well as more specifically Reformation elaborations of Scripture as the sole norm of belief (1, 2), condemnation of the use of images in worship (4), discussions of law (12), gospel (13) and faith (15, 16). It contains in addition a more especially Reformed (*i.e.*, of the Calvinist rather than the Lutheran type) doctrine of providence (6), predestination (10) and the church. ministry and sacraments (17–21). By constant biblical citation, occasional reference to Augustine and other early writers and repeated assertion, the confession represents itself as at one with the earliest and purest form of Christian theology. Heresies, ancient and contemporary, are condemned by name. *See* also CONFESSIONS OF FAITH, PROTESTANT: *Reformed Churches.*

See Philip Schaff, *Creeds of Christendom,* vol iii (1919), for the Latin texts of both and the German text of the first. (E. A. DY.)

HELVETII, a Celtic people, whose original home was situated in the country between the Hercynian forest, the Rhine and the Main. In Caesar's time their boundaries were the Jura on the west, the Rhône and the Lake of Geneva on the south, the Rhine as far as Lake Constance on the north and east. They thus inhabited the western part of modern Switzerland. They were divided into four cantons *(pagi).* common affairs being managed by the cantonal assemblies. They possessed the elements of a higher civilization (gold coinage and the Greek alphabet), and, according to Caesar, were the bravest people of Gaul. The reports of gold and plunder spredd by the Cimbri and Teutones (*qq.v*) on their way to southern Gaul induced the Helvetii to follow their example. In 107 B.C., two of their tribes, the Tougeni and Tigurini, crossed the Jura and defeated the Romans under L. Cassius Longinus. In 102 B C. the Helvetii joined the Cimbri in the invasion of Italy, but after the defeat of the latter by Marius they returned home. In 58 B C.. hard pressed by the Germans and incited by one of their princes, Orgetorix, they resolved to found a new home west of the Jura. Joined by the Rauraci, Tulingi, Latobrigi and some of the Boii they agreed to meet at Geneva and to advance through the territory of the Allobroges. They were overtaken by Caesar at Bibracte, defeated and forced to submit.

Under Augustus, Helvetia *(ager Helvetiorum)* proper was included under Gallia Belgica. Two Roman colonies were founded at Noviodunum (Nyon) and at Augusta Rauracorum (Augst near Basle) to keep watch over the inhabitants. who were treated nith generosity by their conquerors. Under the name of *foederati* they retained their original constitution and division into four cantons. They were under an obligation to furnish a contingent to the Roman army for foreign service, but were allowed to maintain garrisons of their own, and their magistrates had the right to call out a militia; they managed their own local affairs and kept their own language, although Latin was used officially. Their chief towns were Aventicum (Avenches) and Vindonissa (Windisch). Under Tiberius, the Helvetii were separated from Gallia Belgica and made part of Germania Superior. After the death of Galba (A.D. 69). as they refused submission to Vitellius their land was devastated by Alienus Caecina. Under Vespasian they attained the height of their prosperity. He greatly increased the importance of Aventicum, where his father had carried on business. Its inhabitants obtained the *ius Latinum,* had a council of *decuriones,* flamens of Augustus, etc. *(see* MUNICIPIUM). After the extension of the eastern frontier. the troops were withdrawn, and Helvetia became completely romanized. Aventicum had an amphitheatre, a public gymnasium and an academy with Roman professors. Roads were made wherever possible, and commerce developed rapidly. The west of the country was more susceptible to Roman influence, and hence preserved its independence against barbarian invaders longer than its eastern portion. During the reign of Gallienus (A.D. 260–268) the Alamanni overran the country and it never regained its former prosperity. Under Honorius (A.D. 395–423) it was occupied by the Alamanni, except in the west, where the small portion remaining to the Romans was ceded in A.D. 436 by Aetius to the Burgundians.

HELVÉTIUS, CLAUDE ADRIEN (1715–1771), French philosopher, noted for his emphasis on physical sensations, was born at Paris, Fr., on Jan. 26, 1715, the son of J. C. A. Helvetius, chief physician to Queen Maria Leszczynska, the wife of Louis XV of France. In 1738, at the queen's request, Helvétius was appointed farmer-general, a post of great responsibility and dignity. In 1751 he married, resigned his post and retired to his estate at Voré in Perche.

Helvétius proceeded to enjoy his leisure, producing a poem, *Le Bonheur* (published posthumously, with an account of Helvétius' life and works, by C F. de Saint-Lambert, 1772), and his famous philosophical study, *De l'esprit* (1758; Eng. trans. by W. Mudford, 1807), intended to be the rival of Montesquieu's *L'Esprit des Lois.* This attracted immediate attention and aroused the most formidable opposition, especially from the dauphin Louis, son of Louis XV. The Sorbonne condemned it as full of the most dangerous doctrines, and the author's three retractations did not save it from being publicly burned. Voltaire said that it was full of commonplaces and that what was original was false or problematical; Rousseau declared that the very benevolence of the author gave the lie to his principles. Helvétius visited England in 1764 and Berlin, on the invitation of Frederick the Great, in 1765. Returning to France. he passed the remainder of his life at Voré. He died on Dec. 26, 1771. In 1773 was published *De l'homme* (Eng. trans. by W. Hooper, 1777). in which he argues against Rousseau's *Émile* and holds that education can do everything.

The four chief contentions of Helvétius' hedonistic philosophy are: (1) all man's faculties may be reduced to physical sensation, even memory, comparison, judgment; (2) self-interest, founded on the love of pleasure and the fear of pain. is the spring of judgment, action, affection (self-sacrifice is prompted by the fact that the sensation of pleasure outweighs the accompanying pain); (3) all intellects are equal, their apparent inequalities are due to the unequal desire for instruction, and this desire springs from passions, of which all men commonly well-organized are susceptible to the same degree ("one becomes stupid as soon as one ceases to be passionate"); and (4) philosophical rulers may achieve an artificial identification of interests by suitably contrived legislation.

HELVIDIUS PRISCUS (d. between A.D. 70 and 79), a Roman Stoic who, though the son of a centurion, rose to the senate in the reign of Nero. Nero banished him in 66 when his father-in-law, Thrasea Paetus (*q.v.*), was put to death. On Nero's fall (68) he returned and is recorded as demanding the punishment of Eprius Marcellus, who had encompassed Thrasea's death, openly opposing the emperor Vitellius in the senate (69) and later urging that the senate mark out the men it thought worthy of the emperor Vespasian's confidence and assume responsibility for rebuilding the Capitol and meeting the financial crisis of 70. His uncompromising freedom of speech brought him into conflict with Vespasian, perhaps because he opposed dynastic succession, and he was put to death; it later earned the admiration of the Stoics Epictetus and. significantly, Marcus Aurelius.

Helvidius can hardly have been a republican (as is often said); he accepted office as praetor in 70 and spoke of Vespasian with

honour. But he was a Stoic and. unlike most Stoics, did not seek refuge in retirement but was strengthened by his creed in adherence to political principles; he clearly held that the senate should discharge in reality the functions that it nominally possessed and that the emperor should act only with its consent and co-operation.

His son HELVIDIUS THE YOUNGER, a friend of the younger Pliny, became consul (date unknown) but in 93 or 94 was executed by order of the emperor Domitian, whose amours he had allegedly burlesqued.

See E. Groag and A. Stein, *Prosopographia Imperii Romani,* H 59, *60,* 2nd ed. (1958); C. Wirszubski, *Libertas as a Political Idea at Rome,* pp. 147 ff. (1950). (P. A. BR.)

HELWAN, a well-known health resort in the United Arab Republic, 16 mi S. of Cairo and connected with it by rail. Standing 150 ft. above the Nile level and surrounded by desert, it enjoys a dry equable climate especially suitable for invalids; it possesses strong sulfur and salt springs with a natural temperature of 91° F.

The Egyptian government opened a fully equipped thermal establishment in 1900, and the station was provided with hotels and all the usual forms of amusement familiar at European spas. An astronomical observatory was built there in 1903–04 to replace the former observatory at Al Abbasiyah. On the opposite bank of the river lie the ruins of Memphis and the famous pyramids of Saqqarah.

HELWYS, THOMAS (*c.* 1550–c. 1616), leader of the first General Baptist church in London, was born at Broxtowe hall in Nottinghamshire of a well-connected family and was a student of law at Gray's Inn. On his return home he showed strong Puritan sympathies. which ultimately led to his joining the separatist church in Gainsborough, of which his friend John Smyth (*q.v.*), an ordained clergyman, had become pastor. Helwys took a leading part in the migration of this church to Amsterdam in 1607 or 1608 and in 1609 followed Smyth in opposing infant baptism and in starting the first Baptist church. When Smyth entered into negotiation with the Mennonites. Helwys broke with him, refusing to repudiate the earlier steps they had taken together. Regretting their flight from persecution, he and a small group of followers returned to London in 1611 or 1612 and established themselves at Spitalfields. In Holland Helwys had published in 1612 A *Short Declaration of the Mistery of Iniquity,* which contains the first printed plea in English for complete religious freedom and toleration Appeal was made to King James I, but Helwys was imprisoned in Newgate and it was probably there that he died about 1616. He and his associates rejected the current Calvinist doctrines of election and original sin and became known as General or Arminian Baptists. *See* also BAPTISTS: *History.*

See W H Burgess, *John Smith, Thomas Helwys and the First Baptist Church in England* (1911); *A. C.* Underwood, *A History of the English Baptists* (1947). (E. A. PA)

HELY-HUTCHINSON, JOHN (1724–1794), Irish politician, was celebrated for his accumulation of offices and for his stormy tenure of the provostship of Trinity college, Dublin. He was the son of Francis Hely of County Cork and was educated at Trinity college, Dublin. Called to the Irish bar in 1748, he built up a large practice. He married Christiana Nickson in 1751 and when his wife inherited the estates of her uncle. Richard Hutchinson, he added the name of Hutchinson to his own. He entered the Irish house of commons in 1759 and remained a member until his death, representing first Lanesborough and then for almost 30 years, Cork city. Hely-Hutchinson held the offices of prime sergeant (1761–74), alnager (1762–75), provost of Trinity college, Dublin (1774–94), and secretary of state (1777–94).

An able debater, self-assured, alert and indefatigable. Hely-Hutchinson possessed a mastery of economic fact and parliamentary procedure. He often had an intelligent approach to political problems, advocating free trade and the removal of disabilities imposed on the Irish Catholics. He was also distinguished for the blatant persistence aith which he pressed his personal claims. Immediately after entering parliament he showed his mettle as a critic of the government. but he soon became a supporter of the administration and was for years one of the government's mainstays in debate.

On a few occasions, however, he showed signs of joining the opposition. When Viscount Townshend introduced his unpopular augmentation scheme in 1767, Hely-Hutchinson at first opposed it but was enticed back to the government ranks. In 1779, when nationalist sentiment was mounting, Hely-Hutchinson, who was genuinely concerned for Ireland's economic interests, published *Commercial Restraints of Ireland,* an able pamphlet against the trade restrictions in which he displayed an intelligent awareness of Adam Smith's theory of free trade. Finally he gambled in political futures by supporting the Whigs in the regency dispute of 1788–89. The lord lieutenant urged his dismissal but Hely-Hutchinson joined a strong group of officeholders who had chosen the wrong side in the crisis but who, by hanging together, managed to elbow their way back into the government's ranks.

As provost of Trinity college he was severely handicapped. He had no pretensions to scholarship and his appointment was bound to be resented by many of the fellows. Moreover he used his statutory powers in a very overbearing fashion. He uas determined to obtain one of the university seats for his family and at the elections of 1776 and 1790 he put forward a son as one of the candidates. These contests led to bitter electioneering and to some sensational and unedifying episodes. In addition he quarreled with the majority of the fellows over academic policy, contending (in the event unsuccessfully) that he had the right to veto the decisions of the governing body of the college. The controversial dust stirred up by these disputes has obscured his real services to the college. He was anxious to widen the curriculum. He instituted prizes at entrance for composition. was responsible for the foundation of professorships in modern languages, secured the act of parliament which marked the effective foundation of the medical school and obtained the grants which enabled the college to complete Parliament square and erect the public theatre.

He died at Buxton on Sept. 4, 1794, having obtained a peerage for his wife as Baroness Donoughmore, in 1783. His son Richard became Lord Donoughmore on his mother's death in 1788 and 1st Earl Donoughmore in 1800. (R. B. McD.)

HELYOT, PIERRE (1660–1716), Franciscan friar and historian, was born at Paris in Jan. 1660, and in 1683 entered the third order of St. Francis at Picpus, near Paris. During his travels to many parts of Europe on monastic business he collected materials for his great work, *L'Histoire des ordres monastiques, religieux, et militaires, et des congrégations séculières* (8 vol., 1714–21). Helyot died on Jan. 5, 1716, before the fifth volume appeared, but his friend Maximilien Bullot completed the edition.

The *Histoire* is a work of great historical importance, and is profusely illustrated by plates exhibiting the dress of the various orders. The material has been arranged in dictionary form in J. P. Migne's *Encyclope'die the'ologique,* under the title "Dictionnaire des ordres religieux" (4 vol., 1858). Helyot's only other noteworthy work is *Le Chre'tien mourant* (1695).

HEMANS, FELICLA DOROTHEA (1793–1835), English poetess, was born in Duke street, Liverpool, on Sept. 25, 1793, the daughter of George Browne, a Liverpool merchant of Irish extraction. Her mother seems to have been of Austrian origin. In 1806 the family moved to Gwrych, Denbighshire, and there Felicia grew up by the Welsh mountains and the seashore. When she was only 14, her *Juvenile Poems* were published by subscription, and were harshly criticized in the *Monthly Review.* Her *Domestic Affections and Other Poems* appeared in 1812, on the eve of her marriage to Capt. Alfred Hemans, adjutant of the Northamptonshire militia. While they lived at Bronwylfa, a house near St. Asaph, she published *The Restoration of Works of Art to Italy* (1816), *Modern Greece* (1817) and *Translations From Camoens and Other Poets* (1818).

Husband and wife separated in 1818, and though letters were interchanged concerning their five children, they never met again. Her next productions were *Tales and Historic Scenes in Verse* (1819), *The Sceptic* and *Stanzas to the Memory of the Late King* (1820), a volume of poems containing "The Siege of Valencia," "The Last Constantine" and "Belshazzar's Feast" (1823), and

The Forest Sanctuary and *Lays of Many Lands* (1825), which were two of her favourite works.

In 1828 Mrs. Hemans moved to Wavertree, near Liverpool. In the following summer she visited the Hamiltons of Chiefswood, where she enjoyed "constant. almost daily. intercourse" with Sir Walter Scott. who had written an epilogue for her play; *The Vespers of Palermo,* produced at Edinburgh in April 1824. It had been acted at Covent Garden on Dec. 12, 1823, but was withdrawn after the first performance. In 1830 she visited Wordsworth and the Lake country. and went again to Scotland. Her publications of this period include *Songs of the Affections* (1830), *Hymns for Childhood* (1834; had appeared in America in 1827), *National Lyrics* (1834), *Scenes and Hymns of Life* (1834) and a series of sonnets. *Thoughts During Sickness.* She died in Dublin on May 16, 1835.

Mrs. Hemans' poetry is the outcome of a beautiful hut singularly circumscribed life, a life spent in romantic seclusion. without much worldly experience. and warped by domestic unhappiness and physical suffering. Scott complained that it contained "too many flowers" and "too little fruit." Her reputation rests on her short poems, such as "The Treasures of the Deep," "The Better Land," "The Homes of England," "Casabianca," "The Palm Tree," "The Graves of a Household," "The Wreck," "The Dying Improvisatore," "The Lost Pleiad" and the "Landing of the Pilgrims," beginning:

The breakinc waves dashed high on a stern and rock bound coast.

Mrs. Hemans' *Poetical Works* were collected in 1832 (last ed., Oxford. 1914); her *Memorials,* etc., by *H.* F. Chorley (1836).

HEMATITE (HAEMATITE), a mineral consisting of ferric oxide. Fe_2O_3, containing 70% of iron. Hematite is the most important iron ore. both because of its high iron content and its abundance. The world's greatest production of hematite (nearly 100,000,000 tons in a single year) has been from the Lake Superior district. including Minnesota. Michigan, Wisconsin and Ontario. Enormous deposits of high-grade hematite have been found in Minas Gerais. Braz.; Cerro Bolivar, Venez.; Labrador; and Quebec. Other important localities are Yorkshire. Eng.; Lorraine, Prance; Birmingham. Ala.; Krivoi Rog. Donets basin. C.S.S.R.; India; Newfoundland; and Cuba.

The crystals of hematite are hexagonal with rhombohedra1 symmetry. The hardness is 5.5–6 and the specific gravity 5.26. The steel-gray crystals and coarse-grained varieties have a brilliant metallic lustre, and are known as specular iron ore. Thin scaly types are called micaceous hematite. Both have a characteristic red-brown streak. Much hematite occurs in a fine-grained earthy form (red ochre). and is nonmetallic in lustre and apparently soft. Intermediate between these types are conipact varieties. often with a reniform surface (kidney ore! and many times with a fibrous structure (pencil ore). Red ochre is used as a paint pigment, and a purified form. rouge, is used to polish plate glass. *See* also IRON; IRON AND STEEL: *Iron Ove.* (L. *S.* RL.)

HEMBYZE, JAN VAN (1513–1584). Calvinist leader of Ghent during the revolt of the Netherlands against Spain, was born in Ghent on July 9, 1513. of a patrician family. After adhering to the cause of the Gueux (*q.v.*), he supported William I the Silent, prince of Orange. in the negotiations for the Pacification of Ghent (*see* NETHERLANDS), but then together with Frans van de Kethulle. lord of Ryhove. took the lead of the combined factions of radical Calvinists and reactionary democrats in their native town. On Oct. 28. 1577, they arrested, among others, the stadholder of Flanders. Philippe de Croy, duke of Aerschot. The democratic form of municipal government that had prevailed beiore 1540 was then restored, hut the real power came to be wielded by a revolutionary committee of 18. set up on Nov. 1. William of Orange caused the stadholder to he released. but otherwise upheld the committee. Soon, however, excesses began. Monasteries were looted. images broken, monks and priests expelled and finally Roman Catholic worship was prohibited. True to its trnditions. Ghent tried to dominate the whole of Flanders. These activities. in contravention of the pacification. roused the Catholics and conservatives, especially in the Walloon provinces. and caused a rift in the national unity advocated by William. A civil war broke out. By playing the more moderate Ryhove off against Hembyze, William in Dec. 1578 secured religious freedom for the Catholics. but after a few months Hembyze and the fanatical Calvinist minister Petrus Dathenus again got the upper hand. Finally, but too late to conciliate the Walloons, William, with Ryhove's help, succeeded in removing Hembyze and his fellow radicals (Aug. 1579). Hembyze left the country, but was recalled in Aug. 1583 when Ghent needed a resolute leader against the threatening advance of Alessandro Farnese (*q.v.*). Hembyze fell short of expectations. Accused of corresponding with the enemy, he was executed in Ghent as a traitor on Aug. 4, 1584.

HEMEL HEMPSTEAD, a market town and municipal borough in the Hemel Hempstead parliamentary division of Hertfordshire, Eng., 23 mi. N.N.W. of London by road. Pop. (1961) 55.165.

Settlements in the neighbourhood of Hemel Hempstead, which is on the Gade and Bulbourn rivers near the Grand Junction canal. date from pre-Roman times, and a Roman villa has been discovered at Boxmoor. The manor, held by the count of Mortain in 1086, was granted by Edmund, earl of Cornwall. in 1285 to the house of Ashridge, and the town developed under monastic protection. In 1539 it was raised by charter to a bailiwick and other charters were granted in 1572, 1609, 1656, 1666 and 1693; it was recreated a borough in 1898. St. Mary's church, of clunch stone and flint, is Norman with Decorated additions. Part of Hemel Hempstead is being developed as a New Town (formed 1947) in the Greater London plan (see NEW TOWNS).

Great quantities of watercress are grown commercially in the rivers. Once a big market for wool and corn, Hemel Hempstead has modern industries including the manufacture of paper, fireworks and electrical and light engineering products.

HEMEROBAPTISTS: see JEWISH SECTS DURING THE SECOND COMMONWEALTH.

HEMEROCALLIS: see DAY LILY.

HEMICHORDATA, a subphylum of the Chordata, of which the vertebrates or Craniata are another subphylum. The term was introduced by W. Bateson in 1884. The Hemichordata are marine animals and include two classes, the Enteropneusta (see BALANOGLOSSUS) and the Pterobranchia (*q.v.*).

Vertebrates are distinguished by the presence of a notochord or dorsal supporting rod, separated from the roof of the embryonic gut, which gives the name to the phylum, by gill slits in the wall of the pharynx and by a dorsal tubular nervous system. Hemichordates possess all these characters in some measure. The notochord is a short tubular diverticulum of the fore-gut. The dorsal nerve cord is tubular for part of its length in the Enteropneusta, but is solid in the Pterobranchia. The gill slits are numerous in the Enteropneusta, few or absent in the 'Pterobranchia. (F. W. R. B.)

HEMIMORPHITE. This mineral is a hydrous zinc silicate and an important ore of zinc (*q.v.*), of which it contains 54.4%. Hemimorphite occurs as a secondary mineral formed from the alteration of sphalerite (zinc sulfide) and is associated with other zinc ores (smithsonite and sphalerite) in veins and beds in limestone. It is found in many zinc mines throughout the world. Well crystallized specimens have been found in Siberia, Rumania, Sardenia and Belgium. In the United States fine crystals have come from Sterling Hill, N.J.. and Elkhorn, Mont.

The mineral was formerly called calamine or electric calamine in the United States. It is orthorhombic and the name hemimorphite is given because of the hemimorphic development, that is, different terminations at the two ends of the prismatic crystals. Because of this polarity, the crystals, when subjected to changes in temperature, become positively charged at one end and negatively charged at the other (pyroelectricity). There is perfect cleavage parallel to the faces of the vertical prism. Crystals are usually colourless and transparent but may be yellowish or greenish; they have a vitreous lustre. The composition is $Zn_4Si_2O_7(OH)_2.H_2O$. The hardness is j, and the specific gravity 3.45. The mineral also occurs as stalactitic or botryoidal masses with a

fibrous structure, or in massive, cellular or granular aggregates intermixed with smithsonite and clay. It resembles smithsonite (zinc carbonate) but can be distinguished from it by a test with hydrochloric acid. Smithsonite readily effervesces in the cold acid, hemimorphite does not. (C. S. H.)

HEMINGBURGH, WALTER OF, also commonly. but erroneously, called Walter Hemingford, a Latin chronicler of the 14th century. was a canon regular of the Austin priory of Gisburn in Yorkshire. Hence he is sometimes known as Walter of Gisburn (Walterus Gisburnensis). Bale. seems to have been the first to give him the name by which he became more commonly known. His chronicle embraces the period of English history from the Conquest (1066) to the 19th year of Edward III, with the exception of the years 1316–26. In compiling the first part, Hemingburgh apparently used the histories of Eadmer, Hoveden, Henry of Huntingdon and William of Newburgh; but the reigns of the three Edwards are original.

There are several manuscripts of the history extant, the best, perhaps, being that presented to the College of Arms by the earl of Arundel.

The first three books were published by Thomas Gale in 1687, in his *Historiae Anglicanae scriptores quinque,* and the remainder by Thomas Hearne in 1731. The first portion was again published in 1848 by the English Historical society, under the title *Chronicon Walteri de Hemingburgh, vulgo Henzingford nuncupati, de gestis regum Angliae,* edited by *H.* C. Hamilton.

HEMINGE (HEMING. HEMMINGE, HEMMINGS, etc.). **JOHN** (*c.* 1556–1630), English actor and long-time colleague of William Shakespeare. He was an important and prosperous member of the theatrical company that eventually became the King's Men in 1603, apparently serving as business manager for over a quarter of a century. He was one of the original "housekeepers" of the Globe and Blackfriars theatres. Heminge, Henry Condell (*q.v.*), and Richard Burbage (*q.v.*) were closely associated with Shakespeare throughout his career. They are listed among the 26 "principal actor's" in his plays, and he left them token remembrances in his will. Heminge and Condell prepared and oversaw the *First Folio* (1623), and their prefatory letters of dedication make it clear that this was in part a gesture of love and respect toward their dead friend. (FK. C. B.)

HEMINGWAY, ERNEST MILLER (1899–1961). U.S. novelist and short-story writer, was born in Oak Park, Ill., on July 21, 1899. Educated in the local public schools, he skipped college to begin writing as a cub reporter on the *Kansas City Star.* Entering World War I with a U.S. ambulance unit. he was attached to the Italian infantry, until severely wounded by shrapnel near the village of Piave in northern Italy on the night of July 8. 1918. Following a period of recuperation in Milan, of trade-journal editing back home in Chicago, and of serious writing practice in northern Michigan, he resumed newspaper work and sailed for France on Dec. 8, 1921, as a foreign correspondent for the *Toronto Star.* Five hardworking apprentice years. during which he supported himself through journalism in France, Italy, Spain, Switzerland, Germany and Greece were enough to develop the succinct and lucid style which would subsequently exert so powerful an influence on American fiction.

Three Stories and Ten Poems (1923) and *in our time* (1924), published in Paris, prepared the way for the short-story collection In *Our Time* (New York, 1925). But his first notable success came in 1926 with *The Sun Also Rises,* a poignant fictional reminiscence of so-called "lost generation" expatriates in and out of a Pamplona fiesta. *The Torrents of Spring,* a parody of Sherwood Anderson's *Dark Laughter,* also appeared in 1926. Two more short-story collections, *Men Without Women* (1927) and *Winner Take Nothing* (1933), advanced Hemingway's reputation in this genre. His fame as a novelist was consolidated by *A Farewell to Arms* (1929) which incarnated his sense of war's immorality through the tragic story of a U.S. officer and a British nurse in wartime Italy and neutral Switzerland. Experimental works in nonfiction followed: *Death In the Afternoon* (1932), a bible of the Spanish bullfight which had fascinated Hemingway for ten years; and *The Green Hills of Africa* (1935). which employed certain fictional techniques to give a true account of the author's safari of 1933–34 in the big-game region of Tanganyika. To *Have and Have Not* (1937) is a novel about a Caribbean desperado, set against a background of low-class violence and upper-class decadence in Key West, Fla. Despite powerful passages. this is perhaps the least successful of Hemingway's experiments during the period of the 1930s.

Meantime the Spanish Civil war attracted Hemingway's interest. For *Whom the Bell Tolls* (1940), his greatest novel. tells of a U.S. volunteer who joins a guerrilla band behind the rebel lines in the vastness of the Guadarrama mountains. The story masterfully embodies Hemingway's sense of the tragic betrayal of the Spanish people by foreign Fascist and Communist forces, as well as by reactionary elements within Spain itself. (A stage melodrama, *The Fifth Column,* written under fire in wartime Madrid, had already appeared with the collected short stories in 1938.) He also edited. with a revealing introduction, *Men at War* (1942), an anthology of war stories both historical and fictional, including three of his own, *Across the River and Into the Trees* (1950) provides an account of the last three days in the life of a C.S. army officer in Venice and environs; the hero's comments partially summarize the author's sardonic reactions to World War II. in which he had participated at many levels. His short novel. *The Old Man and the Sea* (1952), is the heroic story of an aged Cuban fisherman's lone expedition after a great marlin in the Gulf stream north of the island. Following an extended and spirit-straining struggle. Santiago brings his huge quarry to the gaff. only to have it eaten by voracious sharks during the long voyage home. The novel won the Pulitzer prize in fiction for 1953, and was instrumental in winning Hemingway the Nobel prize for literature in 1954. The Nobel prize award committee praised his "forceful and style-making mastery of the art of modern narration."

Hemingway's death, the result of a self-inflicted gunshot wound, took place at his home in Ketchum, Ida.. on July 2. 1961. Whether the shooting was intentional or accidental was not determined.

Along with his achievement as a stylist, Hemingway's career as a writer was distinguished throughout by his ability to produce swift-moving narratives of action supported by complex structures of natural symbolism, a fact which, without sacrifice of dramatic verisimilitude, gave his best works the force of parables.

HEMIPTERA (Gr. *emi,* half, and *pteron,* a wing), the name applied in zoological classification to that order of insects (*q.v.*) which includes true bugs. cicadas, aphides and scale insects. The name was first given by Linnaeus (1735), who applied it in allusion to the half-coriaceous and half-membranous character of the forewings in many species of the order. This expression, however. is not very well suited, as the forewings in many members are of a uniform texture; the most characteristic feature is afforded by the mouth parts, which form a beaklike proboscis with piercing and sucking stylets. This latter feature led J. C. Fahricius (1775) to substitute the name Rhynchota (Rhyngota), which is still used by some authorities. Hemiptera number about 51,000 described species; the great majority are plant feeders and rank among the most destructive of all insects. Two pairs of wings are generally present, the anterior pair being most often of harder consistency than the posterior pair! or with the apical region more membranous than the remainder. The mouth parts always are adapted for sucking and piercing. and the palpi are atrophied. Metamorphosis is incomplete (fig. 6) in most cases but. more rarely, complete in certain others (fig. 13). The insects comprising this order are mostly small or moderate in size although a few, such as the giant water bugs and cicadas, may be very large.

In general the colour patterns are not conspicuous, but some of the tropical forms especially are strikingly colourful.

General Structure.—The head is very variable in form and in most cases the sclerites are compactly fused with few noticeable sutures. As a rule the antennae have only 4 or 5 segments,

but in exceptional cases 10 (Psyllidae) or even 25 segments (males of a few Coccidae) may be present. The mouth parts are of an exceptionally uniform character throughout the order, a feature that is correlated with the universal habit of feeding by means

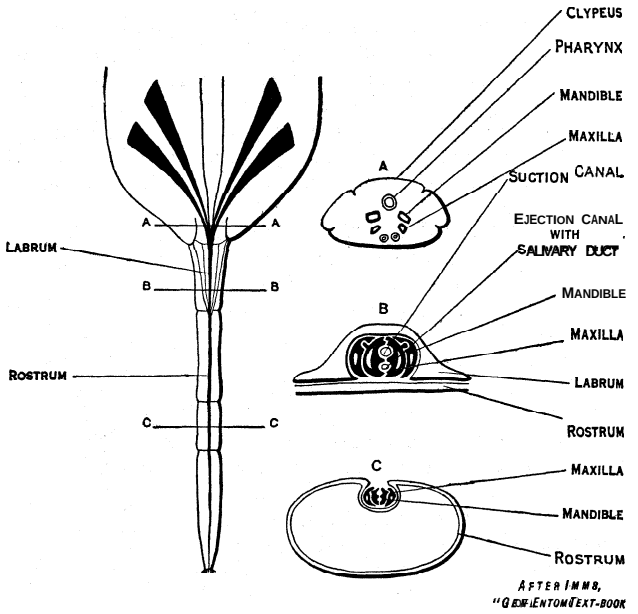

FIG. 1.—DIAGRAM OF MOUTH PARTS AND ADJACENT REGIONS OF HEAD OF HEMIPTERAL INSECT. AT RIGHT ARE TRANSVERSE SECTIONS ACROSS REGIONS BEARING CORRESPONDING LETTERING ON LEFT-HAND FIGURE. (THE MAGNIFICATION OF THESE SECTIONS IS NOT UNIFORM)

of piercing and sucking. The mandibles and maxillae are in the form of needlelike stylets and are held together intimately so as to function almost as one organ (fig. 1). Each maxilla bears two grooves separated by a longitudinal ridge, and the two maxillae are locked together so that the grooves form a pair of minute tubes. The upper tube so formed is the suction canal through which the food is imbibed, while the lower tube allows for the flow of the saliva into the plant and hence is termed the ejection canal. The labium takes the form of a segmented sheath or rostrum which is grooved above to form a slot in which the other mouth parts repose when at rest. The labium takes no part in feeding, and both pairs of palpi are wanting. In many members of the order the pronotum is a large, conspicuous shield as in beetles, the legs have three or fewer segments to the tarsi and the wings are exceedingly variable in character with relatively scanty venation. In the suborder Heteroptera the forewings are termed

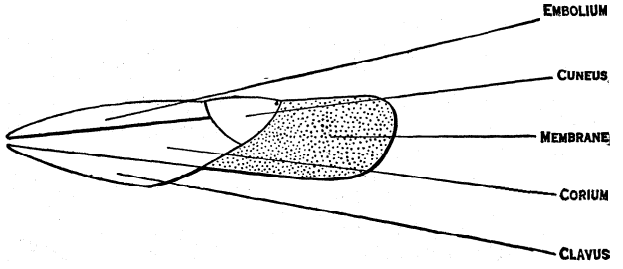

FIG. 2.—DIAGRAM OF THE FOREWING, OR HEMELYTRON, OF A HETEROPTEROUS BUG, SHOWING AREAS INTO WHICH IT IS DIVIDED

hemelytra (hemi-elytra) and their proximal area is horny or leathery, resembling an elytron, only the distal portion remaining membranous. The hind wings are always membranous and in repose are folded beneath the hemelytra. The hardened basal portion of the hemelytron is divided into a narrow posterior area or clavus and a broader main portion or corium. In some cases a narrow strip of the corium is marked off along the anterior margin to form the embolium, and in mirid bugs there is a triangular apical area to the corium which is termed the cuneus (fig. 2). In the suborder Homoptera the forewings are of uniform texture and frequently of harder consistency than the hind pair. Many species of Hemiptera are wingless, especially in aphides and the females of all scale insects. In other cases there are several degrees of wing development within a single species—wingless, fully winged and half-winged individuals being present. The meaning of this wing polymorphism is obscure. The abdomen sometimes exhibits indications of 11 segments, but reduction or suppression of one or more is the rule. In some Hemiptera a true ovipositor is well developed but in other groups it is inconspicuous or wanting.

Classification.—The order is divided into a large number of families which are grouped under two suborders as given below:

SUBORDER I. HETEROPTERA

Wings generally overlapping on the body when at rest, the forepair usually hardened, the apex only being membranous. Pronotum large; tarsi generally three-segmented. The Heteroptera include both terrestrial and aquatic families the most important of which are the following:

Series I. GYMNOCERATA.—Antennae conspicuous; terrestrial or in some cases living on the surface of water. The Pentatomidae or shield bugs are rather large and often brightly coloured insects, with five-segmented antennae and a large scutellum which sometimes covers the abdomen (fig. 3). The Coreidae have a smaller scutellum and the antennae are placed high upon the head; the squash bug (*Anasa tristis*) of the U.S. is a well-known example. The Lygaeidae are related to them, but the antennae are placed lower on the head; the American chinch bug (*Blissus* leucopterus) is well known and the family includes about 50 British species. The Pyrrhocoridae or red bugs differ from Lygaeidae in having no ocelli; most species have bright red, or green, and black coloration and the injurious cotton stainers (Dysdercus) are well-known examples. The Tingidae or lacebugs are small creatures, whose integument exhibits a beautiful netlike pattern and the tarsi are two-segmented. The Gerridae are a large family of pond skaters which are clothed below with silvery pubescence; the genus Halobates (fig. 4) occurs far out on the ocean in warm latitudes. The Reduviidae are a family of more than 2,500 species, with a prominently curved rostrum; they mostly live on the blood of other insects, while species of the Triatominae suck the blood of vertebrates. The Cimicidae (fig. 5) are the well-known bedbugs (*Cimex*), which are bloodsuckers of mammals and birds, and the Polyctenidae are curious parasites living on bats. The Miridae (Capsidae) are a large family in which the hemelytra have a cuneus and a linear undifferentiated embolium. More than 180 species are British and some are serious enemies of fruit trees.

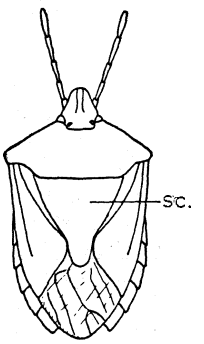

FIG. 3.—SOUTHERN GREEN STINKBUG (NEZARA VIRIDULA), A TYPICAL SHIELD BUG. SC = SCUTELLUM

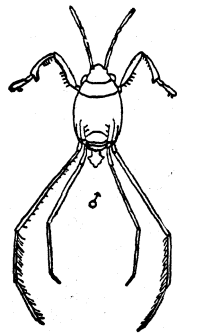

FROM F. BUCHANAN WHITE, "SCIENTIFIC RESULTS OF THE VOYAGE OF H.M.S. CHALLENGER"

FIG. 4.—PELAGIC HEMIPTERON (HALOBATES SERICEUS) TAKEN IN MID-OCEAN IN BOTH ATLANTIC AND PACIFIC

Series II. CRYPTOCERATA.—Aquatic species with concealed antennae. Included here are the Belostomatidae or giant water bugs of the tropics which may exceed four inches in length. They feed upon small fish, tadpoles and other insects. but often take to the wing and are attracted to lights at night. The Nepidae or water scorpions (fig. 7) have an apical breathing tube at the extremity of the abdomen, raptorial forelegs and three-segmented antennae. The Notonectidae or back swimmers: also called water boatmen (*q.v.*), swim on their backs and when diving carry a supply of air on their abdominal venter. They are markedly predaceous and can inflict painful punctures when handled. The Corixidae or

FIG. 5.— DORSALAND VENTRAL VIEWS OF THE FEMALE BEDBUG (CIMEX LECTULARIUS), WITH STRUCTURAL DETAILS

water boatmen (*q.v.*) are numerous in most countries and are largely bottom dwellers, notable for their lack of a typically segmented rostrum and their herbivorous feeding habits.

SUBORDER II. HOMOPTERA

Wings usually sloping roofwise over the sides of the body when at rest, the forepair of uniform consistency, but wingless forms are frequent. Pronotum small, tarsi one- to three-segmented. The greater number of the Hemiptera belong to this suborder and, with the exception of the cicadas and lantern flies, they are mostly small or very small, fragile insects. The Cicadidae or cicadas (*q.v.*) include more than 2,000 species of large insects with ample membranous wings and toothed femora to the forelegs. The males almost always have a sound-producing apparatus on each side of the base of the abdomen (fig. 8) and are very powerful stridulators. The nymphs live below ground at the roots of plants. The family is mainly tropical; 200 species occur in North America but there is only a single representative in Britain, where it is rarely found. The Fulgoroidea are an assemblage of about 18 families, the members of many of which secrete wax in various forms; the best-known examples are the large tropical lantern flies which, however, are not luminous. The Membracidae are remarkable on account of the development of the pronotum into variably shaped processes which extend far backward over the body. The Cercopidae comprise the cuckoo spit (*q.v.*) insects or froghoppers and the Cicadellidae include the leaf hoppers (fig. 9). Both families are exceedingly large groups of small insects, numerous in Britain and most parts of the world. The Psyllidae or jumping lice include the apple and pear suckers; they have usually ten-segmented antennae, and the forewings are of somewhat firmer consistency than the hind pair. The Aphididae (fig. 10) are the large and very important families of aphides (*q.v.*), which include many injurious species and undergo a highly complex life cycle; among the best-known forms are the woolly aphis of the apple and the vine *Phylloxera* (*q.v.*). The Aleyrodidae or white flies are minute fragile creatures dusted with a waxy powder; the greenhouse white fly (Trialeurodes *vaporariorum*) is the only species likely to attract notice. The Coccidae (fig. 12) form one of the most noxious groups of all insects and include the scale insects (*q.v.*) and mealy bugs. The females are degenerate wingless insects and cause most of the damage entailed by this family, while the males are very fragile creatures with a single pair of wings and no mouth parts.

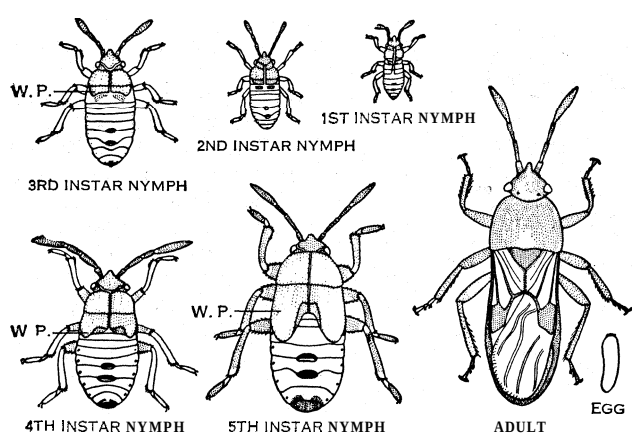

FIG. 6.— CHINCH BUG (BLISSUS LEUCOPTERUS), ILLUSTRATING GRADUAL OR INCOMPLETE METAMORPHOSIS CHARACTERISTIC OF HETEROPTERA. WING PADS (W.P.) INDICATED IN THIRD INSTAR NYMPH

Reproduction and Development.— In most Hemiptera the nymphs resemble the parents except for the absence of wings, and they are active through all stages of growth, feeding in a manner similar to the adults. The number of moults undergone is very variable and the wing rudiments appear among Heteroptera about the third instar (fig. 6). Cicadas are remarkable because the young insects are adapted for burrowing, and suck the sap from roots, while the adults are aerial. In male Coccidae an incipient pupal stage is passed through (fig. 13) and the same occurs in both sexes of Aleyrodidae; these families, therefore, afford a transition toward insects with complete metamorphosis.

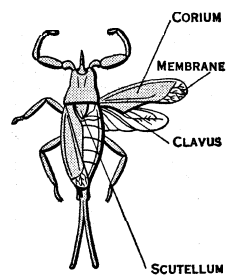

FIG. 7.— WATER SCORPION (NEPA CINEREA), NATURAL SIZE

Geographical Distribution.— Though very widely distributed, Hemiptera have not penetrated so far into remote and inhospitable regions as have some of the other orders. The Fulgoroidea and Cicadidae are more especially tropical groups and the Membracidae attain their greatest development in Central and South America, but many of the other large families are well represented in most countries. Some species such as the bedbug (*Cimex lectularius*) and the shield bug *Nezara* viridula are nearly world-wide, and a number of European species have found their way into North America.

Geological **Distribution.**—Hemiptera first appear in geological times in Lower Permian rocks of Kansas and Germany. The remarkable German fossil Eugeron has the typical Hemipterous mouth parts except that the labium is paired and unfused, while the wing venation is more like that of an early cockroach type. On these characters Eugeron has been referred to a separate extinct order, the Protohemiptera. In the Kansas rocks undoubted Homoptera occur, belonging to extinct families, and the first Heteroptera appear in the Upper Trias of Ipswich (Australia), where they are represented by forms possibly ancestral to shield bugs and Notonectidae. In Jurassic times both suborders are well represented and some of the dominant existing families differentiated. After the Jurassic period Hemiptera become more abundant as fossils, notably in the Miocene of Florissant and in Baltic amber.

(A. D. I.; H. B. HD.)

Natural History.— Most of the Heteroptera or true bugs attach their eggs to the plant host or some other support in their environment. However, the Miridae, the Nabidae, the Mesoveliidae, the Nepidae, some Notonectidae, some Tingidae and a few others insert their eggs in plant tissues. The toad bugs (Gelastocoris) and ground-inhabiting Reduviidae place their eggs in the ground. The females

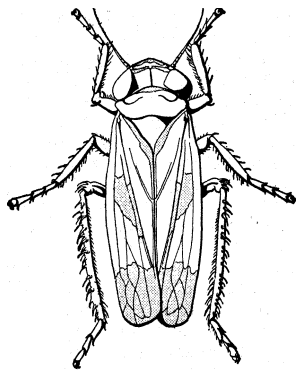
FIG. 8.— THE 17-YEAR CICADA (MAGICICADA SEPTENDECIM), SHOWING EGG PUNCTURES IN TWIG. FIRST INSTAR NYMPH, LAST-STAGE NYMPH AND ADULT MALE SHOWING TYMPANA (TM.)

of the Coreid genus *Phyllomorpha* deposit their eggs on the concave, spine-protected dorsal surface of the males, while the Belostomatid females of the genera Belostoma, Abedus, *Sphaerodema* and *Diplonychus* glue their egg batches to the backs of the males. The curious Corixid Ramphocorixa attaches its eggs to crayfish. A few Pentatomidae are said to guard their eggs and newly hatched offspring. The Polyctenidae, which are peculiar ectoparasitic bugs on bats, bring forth their young relatively advanced in development, while all other true bugs or Heteroptera lay eggs. The hatching nymphs are enclosed in a diaphanous membrane which often is equipped with an egg burster. This membrane is shed upon the nymphs' emergence. There are usually five nymphal stages with the last three possessing wing pads. In most families of terrestrial Heteroptera the nymphs possess scent or stink glands that open on the abdominal dorsum. Some aquatic bugs, the Corixidae for example, possess such glands. In the adults these abdominal glands are replaced by thoracic glands that open on the venter. These produce the characteristic buggy odour of the Heteroptera so well known in the bedbug, chinch bug, squash bug and stinkbugs (Pentatomidae). While nearly all Hemiptera imbibe only food of a liquid nature, the water bugs of the family Corixidae may ingest long filaments of algae and other solid matter. Most families of terrestrial Heteroptera are plant feeders although some of them may include species that are predaceous upon other insects. Some terrestrial families, such as Reduviidae and Nabidae, are typically predaceous as are all the families of semiaquatic and aquatic Hemiptera except the Corixidae. Some Reduviidae and the families Cimicidae and Polyctenidae suck the blood of vertebrates.



FROM "MEMOIRS OF THE DEPARTMENT OF AGRICULTURE AFTER MISRA (HIGH COMMISSIONER FOR INDIA)

FIG. 9.—THE LEAF HOPPER (NEPHOTETTIX APICALIS)

In various Heteroptera sound is produced by some method of stridulation which is the rubbing of some portion of the body against another. Some Reduviidae scrape the beak against a roughened groove on the thoracic venter; notonectid males of the genera Buenoa and Anisops have stridulatory patches on the front legs that are rubbed over scrapers on the base of the beak to produce a chirping sound. Certain corixid males have patches of pegs on the bases of the femora of the front legs that are rasped over a sharp edge on the side of the head below the eyes to produce sounds that can be heard at some distance from these aquatic stridulators.

Some pentatomids, naucorids, nabids and veliids rub their legs against certain areas of the abdomen to produce sound, while one Naucorid scrapes the margin of one abdominal segment over a roughened area of the next. In most cases only the males possess stridulatory organs.

In the Homoptera are the familes Fulgoridae, Cicadidae, Membracidae, Cicadellidae and Cercopidae which, with few exceptions, insert their eggs in the tissues of plants. They have active nymphs, the most interesting of which are those of the Cicadidae, which burrow in the ground, feeding on the roots of plants, and those of the Cercopidae, which produce masses of spittle in which they live. All the families mentioned above have at least one generation a year except the Cicadidae, which may require several years to complete a cycle. The famous 17-year locust or periodical cicada Magicicada septendecim of the middle and eastern United States completes its life cycle in 17 years over most of its range but in the south requires only 13 years.

The mating calls of male cicadas are often loud, shrill and monotonous and more or less characteristic for the species. As a rule the females are mute but the sound-producing devices of the males are the most complicated organs of sound found in the animal kingdom.

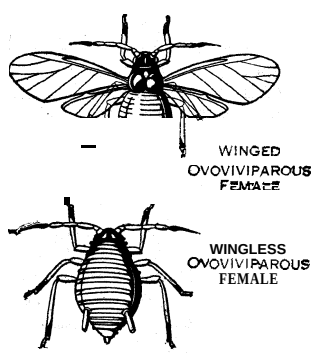
Other well-known families are the Psyllidae (jumping plant lice), Aleyrodidae (white flies), Aphididae (plant lice) and Coccidae (scale insects). These are all very small insects that may occur in astonishing numbers. The jumping plant lice and the white flies lay eggs that are attached to the host plant by a short stipe or a pedicel, and the nymphs are often so flattened that they are mistaken for scale insects. Some of the psyllid nymphs are gall formers, such as the one that makes galls on the leaves of hackberry in America. Others are naked or wax-covered and excrete quantities of honeydew. The sugar lerp insect of Australia produces enough of this material to warrant its being gathered by the natives for food. The Aleyrodidae nymphs upon hatching are motile, but with the first moult shed their legs and antennae, settle upon the leaves of the host plant and resemble soft, unarmoured scale insects. They may be naked or covered with waxy excretion or white cottony material, often with a fringe of white waxy plates or filaments about the margin. These young should be called larvae rather than nymphs. Beneath the last larval skin the larva changes to a pupa. The wing pads and legs which have been developing within the larva become external as in exarate pupae (fig. 13). The adult emerges through a T-shaped slit in the dorsum of the last larval skin or puparium. Both sexes are four-winged little insects with compound eyes, two ocelli and rostrum.

The superfamily Aphidoidea or plant lice present quite an array of forms within a species. They often have complex life histories involving a primary host and secondary hosts, or migrations from leaves to roots of the same plant or unrelated plants. In temperate regions a typical life history includes in the annual cycle one generation of males and females, called sexuales, which mate, the iemales then laying one or more eggs on the primary host. Many species pass the winter in the egg stage. The eggs then hatch into stem mothers (fundatrices) which may be winged but are usually apterous, usually ovoviviparous, parthenogenetic iemales. These give rise to a series oi generations of ovoviviparous, parthenogenetic females which may be wingless or include migrants or winged forms. Since each female may give birth to many young, each of which is mature in a week or two, the biotic potential is enormous. Late in the season sexuales are again produced. Under tropical conditions species that normally produce sexuales may not do so. Some aphides form galls on plants or cause extensive leaf curling. Many excrete honeydew that has led to their care and protection by ants. Some produce an abundant white waxy material that covers the whole colony.

The superfamily Coccoidea or scale insects are mostly small to minute insects that embrace some of the most highly specialized of all Hemiptera. The males are fragile insects without functional mouth parts. The adult females are always wingless; the males though usually with one pair of delicate wings, the second pair being greatly reduced, are sometimes wingless.

Scale insects may infest fruit, leaves, twigs, trunks or roots of plants. Some occur in the nests of ants and termites. A few live in galls, as does the giant Australian *Apiomorpha* duplex on eucalyptus. The mature female of this species may be 1½ in. long and its gall 3 in. in length.

The female is sometimes ovoviviparous, as in the San José scale and some mealy bugs, but she usually lays her eggs beneath her body, under her scale covering, or in a waxy ovisac behind her. The newly hatched young are active crawlers. Some, like the mealy bugs, may be able to move throughout life, but the majority soon settle down and become fixed. Some of them are naked scales, heavily sclerotized, while others are covered by a tough scale and are soft, delicate creatures beneath it. In the young six-legged crawlers the males and females are similar. Usually after the second moult the males form cocoons or remain under their scales, which are smaller and often different in shape and colour from the iemale scales, where they undergo a more complete metamorphosis. In the armoured scales the young lose their legs and antennae with their first moult and secrete wax to form the covering scale, which may be circular, linear or oystershell shaped, around or at the end of the moulted skin or exuvium (figs. 11 and 12).



FROM DAVIDSON, "BULLETIN ON ENTOMOLOGICAL RESEARCH" BY COURTESY OF THE IMPERIAL BUREAU OF ENTOMOLOGY

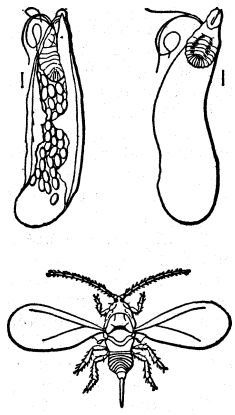
FIG. 10.— BEAN APHID (APHIS RUMICIS), A MEMBER OF THE APHIDIDAE

During the spring and summer a number of generations of virgin females are produced, some winged, some wingless. These individuals bring forth living young, and in autumn the true males and females appear

Many scale insects, as well as plant lice, Cicadellidae, Membracidae and others, void quantities of honeydew and, like them, are attended by ants which sometimes build shelters or sheds over them as they do over aphides. Among the Homoptera there appears to be an excess of sugars in the diet which is repeatedly voided from the anus in fluid drops. They possess a modification of the midgut, called a filter chamber, which is supposed to be associated with their habit of feeding on the copious watery juices of plants. This enables the excess fluid in the food to pass directly from the first part to the last part of the midgut, thus by-passing the main digestive section which receives only the necessary constituents of the plant juices.

Economic Importance. — Since the great majority of Hemiptera feed upon the juices of plants, their over-all damage to grasslands, trees, shrubs and agricultural crops is difficult to estimate. Neverthe-

less, nearly every species of plant is the host of plant lice, scale insects or true bugs that may occur in tremendous numbers and seriously weaken the plant host. This has led to the statement that the Hemiptera are more directly concerned with human welfare than any other insect order. In the Heteroptera the well-known chinch bug (*q.v.*) (*Blissus* leucopterus) causes vast losses to wheat, oats, barley and maize in the United States; the squash bug (Anasa *tristis*) on cucurbits and the harlequin bug (*q.v.*) (Murgantia *histrionica*) on cabbage are very destructive and difficult to control; the cotton stainers (Dysdercus spp.) injure cotton in various parts of the world; the lace bugs (Tingidae) damage trees, shrubs and some garden crops, including eggplants; the Miridae include destructive pests of rice, cotton, sugar cane, fruit trees and garden plants. The latter family also includes the genus Helopeltis, the species of which damage tea in eastern Asia. The famous tea mosquito (H. theivara) of India is one of these.



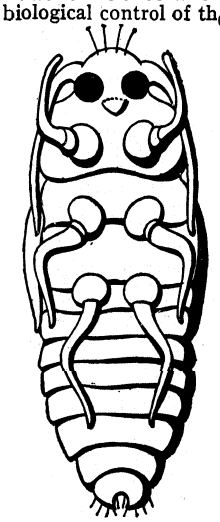
"YEAR BOOK," AFTER HOWARD (U.S. DEPARTMENT OF

FIGS. 11 AND 12.—THE APPLE SCALE INSECT (LEPIDOSAPHES ULMI) Above: female and eggs seen from beneath (left) and from above (right). Below: male apple scale. Magnified

In the Homoptera there is a host of destructive species. The leaf hoppers (Cicadellidae or Jassidae) include such pests as the grape, apple and potato leaf hoppers; the plant lice or aphides (Aphidoidea) are seriously destructive to trees, shrubs, field and garden crops, and include such well-known pests as the woolly aphis of the apple, the grape *Phylloxera* (*q.v.*) and the green bug (*Toxoptera graminum*) of wheat, oats, etc. The scale insects (Coccoidea) are most harmful and comprise many noxious species such as the mealy bugs, the cottony cushion scale, the oystershell scale and the San José scale. The white flies (Aleyrodidae) include the greenhouse white fly and the citrus white fly which share with the scale insects the major insect problems of the greenhouse and citrus crops. In fact, all families of Homoptera contain some injurious species. A considerable number of species of Homoptera are vectors of plant diseases. The Triatominae of the Heteropterous family Reduviidae are vectors of Chagas' disease of humans, and Triatoma sanguisuga has been found naturally infected by the virus of equine encephalomyelitis in Kansas. The Cimicidae, including the bedbug (*q.v.*), are blood suckers, and the predaceous families, such as some of the Reduviidae, Notonectidae, Naucoridae and Belostomatidae, can inflict painful wounds on humans. On the other hand, there are some Hemiptera that are beneficial. In the families Reduviidae, Nabidae, Anthocoridae. some Pentatomidae (*Brochymena* and Perillus, *e.g.*), and other families containing predaceous forms, there are many that feed upon destructive insects. The marsh treaders (Hydrometra) in Panama and in New Caledonia destroy many mosquito larvae, and the little mirid *Cyrtorhinus mundulus*, which feeds upon the eggs of the sugar-cane kaf hopper, was transported from Queensland and Fiji in 1920 by F. Muir to the Hawaiian Islands where it proved to be a highly successful factor in the biological control of the sugar-cane leaf hopper.

The Hemiptera have served as food of man in many places. The giant water bugs are eaten in Thailand, while the eggs of the water boatman (Corixidae) are eaten in Mexico, and cicadas are used as food by natives of Malaya and elsewhere. The biblical "manna of the wilderness" was produced by the tamarisk manna scale insect. The females of this species (Trabutina *mannipara*) secrete quantities of honeydew that in arid regions of Iraq and Asia Minor accumulates and solidifies to form the sweet food which was called "manna" or "gift of God" by the Israelites wandering in the wilderness of Sinai. This material is still used as sugar by the natives. Many Homoptera secrete wax that man has used. The Indian lac scale insect Laccifer *lacca* produces a wax or lac which is refined and marketed as shellac at the rate of about 50,000,000 lb. a year, while the Chinese wax scale Ericerus pela has provided wax for making candles for centuries. The province of Szechwan alone produces about 5,600,000 lb. annually.

Other Homoptera, especially scale insects, have provided dyes. The cochineal *Dactylopius* coccus of the western United States and Mexico feeds upon Opuntia cacti and produces a crimson dye now largely replaced by aniline dyes but still used for colouring cosmetics and some foods.



FROM RILEY AND H "INSECT LIFE" (U S DEPARTMENT OF AGRICULTURE)

FIG. 13.—PASSIVE NYMPH, OR PUPA, OF MALE SCALE INSECT (ICERYA)

The root-feeding Margarodes scales form wax cysts that are metallic gold in colour and which are worn as beads by natives in areas where they occur.

A few Hemiptera have been used in the folk medicine of various peoples. The idea that the common bedbug (Cimex *lectularius*) constitutes a sovereign remedy for malaria still persists in some places, and one of the older pharmacopoeias gives directions for making a tincture of Cimex for this purpose. The chuki or "blistering cicada" of China, now believed to be the fulgorid Lycroma delicatula, has long been thought to have therapeutic value.

The use of xenodiagnosis in the detection of chronic Chagas' disease became a standard practice. The difficulty of finding the causal organism of this disease (*Trypanosoma cruzi*) in the blood of the human host at such times, and the ease with which it can be cultured in the insect host, led to feeding uninfected clean Triatominae bugs (Reduviidae) upon the patient suspected of having Chagas' disease and ten days later examining the faeces of the bugs for trypanosomes. The multiplication of the trypanosomes in the digestive tract of the insect makes their detection in its faeces a relatively simple matter, and their presence gives a positive diagnosis. The common practice is to feed five hungry clean bugs on the patient, and it is quite usual to find all the bugs infected when they have fed on a person with Chagas' disease.

HEMLOCK is the name commonly applied in North America to trees of the genus *Tsuga*, of the pine family (Pinaceae). The genus comprises ten species, six native to eastern Asia and four to temperate North America. They are tall, pyramidal evergreen conifers with cinnamon-red bark; slender horizontal or drooping branches; flat, narrowly linear, two-ranked leaves; and small, pendulous, persistent-scaled cones bearing winged seeds.

The eastern hemlock (*T. canadensis*), called also Canadian hemlock and hemlock spruce, grows in upland forests from Nova Scotia to Minnesota and south to Maryland, Indiana, Wisconsin and the mountains of Georgia and Alabama. It is a handsome tree, usually 60 to 80 ft. tall but sometimes 100 ft. tall, 4 ft. in diameter. The dark green leaves, to three-quarters of an inch long, are grooved above and marked with two whitish bands beneath. The bark contains tannin used in tanning; the soft, coarse-grained, splintery wood, though inferior to pine or spruce, is used for building purposes. Young eastern hemlocks, introduced into England in 1736, are ornamental and several varieties are cultivated. The smaller Carolina hemlock (T. caroliniana), sometimes 70 ft. tall, a beautiful but local tree in the southern Alleghenies from Virginia to Georgia, is used also as an ornamental. The mountain hemlock (*T.* mertenszana), 20 to rarely 90 ft. tall, with leaves crowded densely around the branchlets, occurs on high mountains from southern Alaska to Montana and California.

The western hemlock (T. *heterophylla*), called also hemlock fir and Prince Albert's fir, is often 200 ft. tall, with a trunk 6 to 10 ft. in diameter. It grows from southeastern Alaska to California and Montana. The wood of the western hemlock is superior to that of all other hemlocks, comparing favourably with that of pine and spruce. Over 75% of the total cut of hemlock in the U.S. is this species, with Oregon and Washington supplying 95% of the hemlock lumber cut in the U.S. Huge timbers, some 24 in. square and

up to 20 ft. long, come from the better stands of western hemlock.

Siebold's hemlock (T. *sieboldii*) attains 100 ft. in height, and the Japanese hemlock (T. diversifolia) grows to 80 ft. in height on good sites. Both are natives of Japan and are used as ornamentals in North America and Europe.

Various poisonous plants of the parsley family (Umbelliferae) also are called hemlock; *e.g.*, poison hemlock and the water hemlock. The fool's-parsley (Aethusa *cynapium*) is known as small hemlock (*see* UMBELLIFERAE). American yew (*Taxus canadensis*) is called ground hemlock because its foliage resembles that of the eastern hemlock (see YEW).

See W. Dallimore and A. B. Jackson, *A Handbook of Coniferae* (1948); W. M. Harlow and E. S. Harrar, *Textbook of Dendrology* (1958). (I. L. W.)

HÉMON, LOUIS (1880–1913), French author of the best-known novel of French-Canadian pioneer life, Maria *Chapdelaine*, was born in Brest, France, on Oct. 12, 1880. Educated in Paris, Hémon moved in 1903 to England, uhere he wrote numerous short stories and articles for French sporting and automotive magazines; he also composed three novels, which were published posthumously. Seeking new surroundings. Hémon sailed for Canada in Oct. 1911. After spending the winter in Montreal, he went north to Lac Saint-Jean. becoming a hired man on the farm of Samuel Bédard near Péribonka. There he found the materials for Maria *Chapdelaine*. First published as a serial in *Le* Temps (Paris) in 1914, the novel had hundreds of editions and was translated into all the major languages. Hémon did not live to see its success: he was killed by a train near Chapleau, Ont., on July 8, 1913.

Despite some resentment over Hémon's failure to idealize French-Canadian life, Maria *Chapdelaine* soon became a model for Canadian regionalistic writers, and Hémon's influence was apparent for more than a generation. It reached its peak in Abbé F.-A. Savard's novel Menaud, *maître-draveur* (*Boss of the River*) in 1937, and later declined as French-Canadian novelists turned to urban settings in the 1940s.

See Allan McAndrew, *Louis Hémon, sa vie et son oeuvre* (1936); Louvigny de Montigny, *La revanche de Maria Chapdelaine* (1937); Damase Potvin, *Le roman d'un roman* (1950). (D. M. HE.)

HEMORRHOIDS: see HAEMORRHOIDS.

HEMP. Although there is but one species of true hemp (Cannabis sativa), there is much confusion about its common name because many other fibre-producing plants, and the commercial fibres obtained from them, have been incorrectly termed "hemp"; among these are Manila hemp, sisal hemp, New Zealand hemp, Mauritius hemp, bowstring hemp, sunn hemp and ambari hemp, none of which is true hemp or has any botanical relationship to true hemp.

Description of the Hemp Plant.— The *Cannabis sativa* plant is an annual propagated by seed, is cross-pollinated, has a deep taproot system and is adapted to many countries throughout the temperate zones. The seed-producing flowers are borne on separate plants from those which produce pollen. The plants which produce seed are termed pistillate or "female" plants and those that produce pollen are termed staminate or "male" plants. There are rare variants which produce both kinds of flowers on the same plant. When the crop is produced under natural conditions the proportion of female to male plants is about equal. The male plants die soon after the pollen is shed, but the female plants continue to live until the seed is mature or until killed by frost.

When seeded broadcast or in close drills for the production of fibre, the fibre varieties produce relatively tall, slender, whiplike plants that are free from branches except at the tops. When spaced in rows or hills for seed production, the plants produce long, coarse branches from nearly every node, and the main stem (stalk) becomes very thick. The tallest-growing varieties, when spaced for seed production and when grown under favourable soil and climatic conditions, may reach a height of 16 ft. When seeded thickly for commercial fibre production the usual height is from five to ten feet. The varieties used primarily for producing oilseed in northeastern U.S.S.R. and northern China are relatively short and much branched; likewise the so-called drug-producing strains in India, Arabia and northern Africa are short-stemmed and extremely branched.

The stem of the hemp plant is hollow except at the base and tip. The thickness of the tissues that surround the hollow varies greatly among the different types, varieties and strains. The cells which produce the fibre of commerce are formed in the stems between the cambium and the epidermis, and specifically occur in the phloem and pericycle. In other words, the fibre is in that part of the stem which is commonly called bark. The staminate flowers are readily seen, while the pistillate flowers are so small that they are very difficult to observe. The male plants cannot be distinguished from the female plants, either in the seed or in the seedling plants, until the flower buds are considerably developed. The seeds are about the size of wheat grains but more nearly round and are produced in clusters at the top of the main stem or at the tips of branches or at the nodes along the branches. Some strains produce seed much more abundantly than others, and there is a wide variation as to the time required to mature seed; some kinds will mature as much as 60 days earlier than others.

Origin and Distribution.— It is thought that hemp originated in the general region just north of the Himalayas, and ancient writings indicate that in 2800 B.C. the plant was used for fibre in China. Evidently hemp is one of the first fibre plants used by man, and it is probable that both hemp and flax fibre were used long before man learned to write. It is supposed that hemp spread from Asia to eastern and southern Europe and that it reached western Europe in about A.D. 500. It is known that it was introduced into Chile about 1545 and into New England and Virginia about 100 years later. By the 20th century it was known as either a wild or cultivated plant in practically every country in the north temperate zone and also in several countries of the south temperate zone. As a cultivated fibre crop it is grown in the U.S.S.R., Italy, China, Yugoslavia, Rumania, Korea, Poland. Turkey, Hungary, Japan, Germany, Czechoslovakia, France, Bulgaria, Chile and the U.S.

Cultivation for Fibre Production.— There is wide variation in the methods used in growing and handling hemp in the many producing countries, but there are some general procedures that are common to nearly all. Thus it is common practice to seed the crop early in the growing season; to use a well-prepared and firm seed bed; to select the most fertile soil available; and to seed thickly by broadcasting or drilling. The rate of seeding varies perhaps as much within any one country as it does from one country to another and usually ranges from 33 lb. (three pecks) to fully 66 lb. (six pecks) per acre. The use of as much as 88 lb. (eight pecks) has been reported in Belgium and northern France. In all producing countries shallow seeding is practised (½ to 1 in. deep); no subsequent cultivation (intertillage) is given, and except for a few areas in Europe no weeding by hand or machines is practised. In nearly every producing country it is thought that when grown for fibre, hemp is ready for harvesting as soon as the male plants are in full blossom and are freely shedding pollen. It is generally believed that the softest and finest (though weakest) fibre is obtained from plants harvested immediately after the shedding of pollen begins and that the greatest yield of strongest fibre (though more coarse and harsh) is obtained from the more completely matured plants. In some areas in Europe hemp is pulled (uprooted) by hand, but in nearly all producing countries the crops are harvested by cutting a few inches above the ground—either with a hand sickle, a self-rake reaper or a special hemp harvesting machine.

Retting Hemp Straw.— After the hemp stalks are harvested they must be retted. which means that they must be subjected to a partial decomposition or rotting in order to make possible the separation of the fibre. Methods of retting vary greatly among the producing countries; in some areas water retting is practised, while in others the dew retting method is used.

Much of the Soviet crop and all of that grown in the United States is dew retted. In most other countries water retting is common. In dew retting, the harvested hemp straw is spread in thin layers on the stubble of the fields where it grew. The straw remains there until the moisture from rain and dew (and sometimes snow) has made it possible for micro-organisms (bac-

teria and fungi) partially to decompose those plant tissues which surround the fibres. Such partial decomposition permits the mechanical separation of the fibre from the other tissues. The time required for dew retting is determined by weather conditions and may vary from a week to many weeks and in some instances several months. When retting is completed, the straw is lifted and set up in open shocks (stooks) to dry.

In water retting, the freshly harvested straw is allowed to become thoroughly dry and is then immersed in water, where it is left until the combined action of bacteria and the water have partially decomposed and dissolved the tissues and substances which surround the fibre. The time necessary for water retting is determined by the temperature of the water and usually varies from 10 to 20 days, but in temperature-controlled tank retting the process may be completed in 3 to 5 days (using temperatures of around 90° F.). Both natural and artificially constructed pools and ponds are used, as well as small streams, rivers and tanks of varicus kinds.

In some countries the dew-retted straw is not bundled, but in the northern United States it is picked up and tied into bundles with a specially designed machine termed a gather binder. The shocks are so built that the air circulates freely through them. No drying other than that which occurs during shocking in the fields is practised except in the United States, where drying is accomplished by artificial methods.

Separating and Cleaning the Fibre.—When the retted hemp straw is sufficiently dried, it is subjected to one of many mechanical methods for separating the fibre from other parts of the straw. The mechanical devices are termed brakes (because they break or crush the woody part of the straw), and the process itself is called breaking. After breaking, the crushed mass must be so handled as to separate the fibre from the broken woody core (termed hurds). This shaking, brushing and combing process is called scutching.

Hand brakes are used in some European countries. However, power-driven mechanical breaking machines are in common use in most countries where hemp is grown as a commercial crop. Nearly all the various kinds of mechanical brakes consist essentially of pairs of fluted rolls through which the retted straw is fed (usually lengthwise) and by means of which the woody portion (core) of the stalks is broken in short pieces (hurds).

The broken material (fibre and hurds) is either shaken by hand or subjected to a mechanical scutching machine, of which many kinds hdve been developed. Such machines separate the hurds from the fibre and in doing so also remove a considerable proportion of short, tangled and broken fibre which is termed tow. The long, reasonably straight fibre from which the hurds and tow have been removed is termed line.

Yields.—Acre yields of total fibre (line and tow) vary greatly among the producing countries but may be approximated as ranging from about 500 lb. to as much as 1,800 lb. Lowest average yields are obtained in the U.S.S.R. and highest yields in northern Italy. In the United States acre yields of fully 1,600 lb. frequently have been reported, but the average over a ten-year period is probably not more than 850 lb.

Uses as a Fibre Plant.—In Asia and Europe hemp fibre at one time or another has been used for making a wide range of textile products, from fine fabrics to coarse ropes. Such general uses of hemp continued to be made in those countries where peasants did their own spinning and weaving. In North America the only hemp products of commercial importance manufactured in the period between World Wars I and II aere hemp twines, but during the actual war periods hemp fibre was used extensively for making a variety of threads, twines and ropes; after 1950 considerable hemp fibre was used in the United States for making artificial sponges.

Hemp as an Oil and Feed Crop.—Hemp oil (of which the seed contains about 30%) is usable for making paints, varnishes and soaps; but the commercial use of hempseed oil has never been of any considerable importance. Hempseed was much used in ready-mixed feed for caged birds and continued to be used to some extent for that purpose.

Hemp as a Drug Plant.—The leaves and other tissues of the hemp *(Cannabis)* plant produce a resin from which the cannabis drug is obtainable. This drug is not recognized as a medicine in either the British or the United States pharmacopoeia, yet, if stable preparations of the drug could be obtained, it might be worthy of attention in medicine. As a narcotic, it is either smoked or eaten and is known as bhang, charas or ghanga in India, as hashish in Egypt and Asia Minor, as kif in northern Africa and as marijuana in the western hemisphere. After 1938 outstanding research was done on the chemistry of hemp drugs and their biological activity. While such research clarified the subject, much still remained unknown in the latter 1950s. It appears that the primary action of the drug is on the central nervous system; that it produces such symptoms as a "feeling of well-being" and various hallucinations; that it is not physically habit forming; that it is not an alkaloid; and that it is not a single substance but a complex mixture. There are no proved chemical tests for measuring the potency of the drug, and biological assays by the use of animals, though used, are not considered entirely reliable. Probably the potency varies in different regions and the most potent preparations may be from plants grown in hot, relatively dry climates.

HEMPSTEAD, a village in Nassau county, Long Island, N.Y., U.S., 5 mi. E. of New York city limits and a terminal of a branch of the Long Island railroad. The area, known as the Hempstead plains, was first settled in the 1640s and experienced slow but steady rural grouth until the mid-19th century. The village was incorporated in 1853 and is now primarily residential. Hempstead is the hub of a large retail trade area of populous Nassau county. It is the home of Hofstra college, founded in 1935 and named for William S. Hofstra, a lumber merchant, whose widow willed the Hofstra estate for-such a general use. Once an affiliate of New York university but independent since 1939, its enrollment is more than 8.000. A reservoir known as Hempstead Lake State park (903 ac.) is located nearby.

For comparative population figures *see* table in *NEW YORK: Population.* *(M. H. LE.)*

HEMSTERHUIS, FRANÇOIS (1721–1790). Dutch writer on aesthetics and moral philosophy, was born at Franeker on Dec. 27, 1721. Educated at the University of Leiden, he was for many years secretary to the state council of the United Provinces. He died at The Hague, July 7, 1790. His philosophy, strongly Platonic. was founded on the desire for self-knowledge and truth. His chief works are *Lettre sur la sculpture* (1769), in which occurs the well-known definition of the Beautiful as "that which gives us the greatest number of ideas in the shortest space of time"; its continuation, *Lettre sur les désirs* (1770); *Lettre sur l'homme et ses rapports* (1772); *Sopyle* (1778), an attack on materialism; *Aristée* (1779), the "theodicy" of Hemsterhuis; *Simon* (1787), discussing the will, the imagination, the moral principle; *Alexis* (1787); *Lettre sur l'athéisme* (1787).

HENAULT, CHARLES JEAN FRANÇOIS (1685–1770), French man of letters, was born in Paris on Feb. 8, 1685. He became a councillor of the *parlement* of Paris (1705), president of the chamber of *enquêtes* (1710) and superintendent of the household of the queen (1753). But he became most famous as a man of varied literary talents and attended the salon of Mme. du Deffand over a period of 40 years. He wrote tragedies, comedies, ballets, poetry and *Mémoires* (published 1855). His highly original *Abrégé chronologique de l'histoire de France* (1744) ran through eight editions during his lifetime and uas translated into several languages, including Chinese. He died on Nov. 24, 1770.

HENBANE, the common name of the plant *Hyoscyamus niger*, a member of the family Solanaceae (*q.v.*), indigenous to Great Britain. It is found growing uild in waste places and on rubbish heaps. It occurs also in central and southern Europe and in western Asia extending to India and Siberia, and has long been naturalized in the United States. There are two forms of the plant,

an annual and a biennial. The annual grows during the summer to a height of one to two feet, then flowering and seeding. The biennial produces during the first season only a tuft of radical leaves, which disappear in winter, leaving underground a thick fleshy root, from the crown of which arises in spring a branched flowering stem, usually much taller and more vigorous than the flowering stems of the annual plants.

The biennial form is that which is of pharmaceutical interest. The radical leaves of this biennial plant spread out flat on all sides from the crown of the root; they are ovate-oblong, acute, stalked and more or less incisely toothed, of a grayish-green colour, and covered with sticky hairs; these leaves perish at the approach of winter. The flowering stem pushes up from the root crown in spring, ultimately reaching from three to four feet in height. As it grows it becomes branched and furnished with alternate sessile leaves, which are stem-clasping, oblong, unequally lobed, clothed with glandular clammy hairs and of a dull gray-green. The whole plant has a powerful nauseous odour. The flowers are short-stalked, the lower ones growing in the fork of the branches; the upper ones sessile in one-sided leafy spikes which are rolled back at the top before flowering, the leaves becoming smaller upward and taking the place of bracts. The flowers have an urn-shaped calyx which persists around the fruit and is strongly veined, with five stiff, broad, almost prickly lobes. The corollas are obliquely funnel-shaped, of a dirty yellow or buff, marked with a close netaork of purple veins. The capsule opens transversely by a convex lid and contains numerous seeds.

JOHN MARKHAM

HENBANE (HYOSCYAMUS NIGER), SOURCE OF A POISONOUS ALKALOID

Commercial henbane, which consists of the dried leaves of *Hyoscyamus niger,* and sometimes of *H. muticus* of Egypt, is the source of two dangerous narcotics, atropine and hyoscyamine (*qq.v.*). Atropine is also produced by the belladonna (*q.v.*), but the chief source is henbane. The major sources of supply of these leaves are Hungary, the U.S.S.R., Egypt and the United States, in all of which it is grown commercially. In France another species of henbane, H. *albus,* is used for the same purpose.

The dangerous alkaloid hyoscyamine, besides being used for the extraction of atropine, is a potent narcotic used in illicit preparations of smoking mixtures and, in India, as a beverage. Also in India the seeds (which contain more alkaloid than the foliage) are employed as a somewhat dangerous remedy for toothache.

Medical use of henbane, as an extract, fluid extract and tincture, is complicated by the fact that the leaves also contain scopolamine (*q.v.*), another dangerous alkaloid. The isolated and purified drugs derived from henbane are valuable remedies for spasmodic muscular contractions, nervous irritation and hysteria. See also ALKALOIDS. (N. TR.)

HENCH, PHILIP SHOWALTER (1896–), U.S. physician and Nobel laureate, was born in Pittsburgh, Pa., Feb. 28, 1896. He studied at Lafayette college, Easton, Pa., and at the University of Pittsburgh (M.D., 1920). In 1921 he became a fellow in medicine in the Mayo foundation, Rochester, Minn., and in 1923 first assistant and member of the staff of the Mayo clinic. In 1926 he became a consultant in the division of medicine and head of a new section on rheumatic diseases at the Mayo clinic.

Hench noticed that during pregnancy and in the presence of jaundice, the severe pain of arthritis has a tendency to abate, and in some cases to disappear. This fact was well known to other workers, but Hench, in association with Edward C. Kendall (*q.v.*), also of the Mayo clinic, pursued studies of endocrinologic factors in rheumatic diseases. Together, they evolved and applied cortisone to the treatment of rheumatoid arthritis late in 1948 and early in 1949. For this work Hench and Kendall, in company with Tadeus Reichstein of Switzerland, were awarded the 1950 Nobel prize in physiology and medicine. (J. R. EN.)

HENDERSON, ALEXANDER (1583–1646), Scottish ecclesiastic, born at Criech. Fifeshire, graduated at the University of St. Andrews in 1603, and in 1610 was appointed professor of rhetoric and philosophy and questor of the faculty of arts. Shortly after this he was presented to the living of Leuchars. As Henderson was forced upon his parish by Archbishop George Gladstanes, and was known to sympathize with episcopacy. his settlement was at first extremely unpopular; but he subsequently became a presbyterian in doctrine and church government, and one of the most esteemed ministers in Scotland. He was one of the petitioners against the "five acts" and later against the introduction of a service book and canons drawn up on the model of the English prayer book. On March 1. 1638, the public signing of the National Covenant began in Greyfriars church. Edinburgh. Henderson was mainly responsible for the final form of this document. He was moderator of the famous assembly which met in Glasgow on Nov. 21, 1638. Henderson was then transferred to Edinburgh.

In the negotiations for peace at Birks after the "First Bishops' War" Henderson was one of the Scottish commissioners. In 1640 he was elected by the town council rector of Edinburgh university—an office to which he was annually re-elected till his death. The Pacification of Birks had been wrung from the king: and the Scots, seeing that he was preparing for the "Second Bishops' War," took the initiative, and pressed into England so vigorously that Charles had again to yield everything. The maturing of the treaty of peace took time, and Henderson again took part in the negotiations. first at Ripon (Oct. 1) and afterward in London. During Charles's second state visit to Scotland, in the autumn of 1641, Henderson acted as his chaplain, and managed to get the funds. formerly belonging to the bishopric of Edinburgh, applied to the metropolitan university.

At the meeting of the general assembly held in Xug. 1643, Henderson was again elected moderator. He presented a draft of the famous Solemn League and Covenant. which was received with enthusiasm. Unlike the National Covenant of 1638, which applied to Scotland only. this document was common to the two kingdoms. Henderson, Baillie, Rutherford and others were sent to London to represent Scotland in the assembly at Westminster. The Solemn League and Covenant passed the two houses of parliament and the Westminster assembly. and thus became law for the two kingdoms. As Scottish commissioner to the Westminster assembly. Henderson was in England from Aug. 1643 till Xug. 1646; his principal work was the drafting of the directory for public worship. In Aug. 1646. failing in health. he sailed to Scotland, where he died Aug. 19. eight days after his arrival. A document was published in London purporting to be Henderson's death bed declaration. and although this paper was disowned, denounced and shown to be false in the general assembly of Aug. 1648, the document was used by Clarendon as giving the impression that Henderson had recanted. Its foundation was probably certain expressions lamenting Scottish interference in English affairs.

Henderson is one of the greatest men in the history of Scotland and. next to Knox, is certainly the most famous of Scottish ecclesiastics. He is justly considered the second founder of the Reformed Church in Scotland.

See J. Aiton, *Life and Times of Alexander Henderson* (1836); *T.* McCrie, *Life of Alexander Henderson* (1836); *J.* P. Thornson, *Alexander Henderson, the Covenanter* (1912); *R.* L. Orr, *dlexaader Henderson, Churchman and Statesman* (1919); also *The Letters and Journals of Robert Baillie* (1841–42), an exceedingly valuable work from an historical point of view; J. H. Burton, *History of Scotland,* 2nd ed., 8 vol. (1873); D. Masson, *Drummond of Hawthornden* (1873) and *Life of Milton,* 7 vol. (1859–94); Andrew Lang, *History of Scotland,* vol. iii (1907). Henderson's own works are chiefly contributions to current controversies, speeches and sermons.

HENDERSON, ARTHUR (1863–1935), British politician, was born in Glasgow, Scot. Sept. 15, 1863, but his work and interests subsequently lay at Nencastle and in the county of Durham. He became prominent in the trade-union movement. He nas for some years a member of the Newcastle city council and the Darlington borough council. He was mayor in 1903, and was made

a magistrate for the county of Durham. He entered parliament for Barnard Castle, as a Labour member. at a by-election in 1903, and soon made his mark. In 1908 he was elected chairman of the party, a post which he held for two years and to which he was re-elected after the outbreak of war in 1914, when the then chairman. Ramsay MacDonald, had to resign because of his pacifist views.

When the first coalition ministry was formed by H. H. Asquith in 1915, Henderson was included in the cabinet mainly as adviser of the government on labour questions arising out of World War I. with the office first of president of the board of education and afterward of paymaster general. He showed himself resolved on a strenuous prosecution of the war. strongly advocating the Munitions bill. the Registration bill and compulsory service. He followed up this action by urging the Labour party to rally in Dec. 1916 to Lloyd George. and by accepting himself the position of an original member of the war cabinet of four without portfolio. In 1917 he visited Russia. just after the Revolution, on behalf of the British government, and found the provisional government strongly in favour of an international labour and socialist conference, which was to meet at Stockholm under the auspices of the International Socialist bureau. It mas Henderson's view that, provided the conference were merely consultative, it would be better for British representatives to attend than to permit Russian representatives to meet German representatives alone. He could not obtain the endorsement of his fellow cabinet members to his proposal. however, and he therefore resigned.

Henderson espoused the Labour decision of the latter part of 1918 to take the Labour men out of the government and to appeal for support on a purely Labour platform. This cost him his seat in parliament at the general election of Dec. 1918. Indeed. ill luck pursued him also at the next two general elections, in 1922 and 1923; but in all three cases he returned to the house of commons a few months later at a by-election. In the parliament of 1923–24 he had the satisfaction of having two sons as fellow members, though they were both defeated in the autumn of 1924. In MacDonald's ministry he was secretary of state for home affairs. He actively endorsed the policy of his party in 1925–26 in severing themselves definitely from the Communists. In the Socialist government of 1929–31 Henderson was secretary of state for foreign affairs; but on the formation of the National government in 1931 he went into opposition. He was defeated in the general election of that year, but was elected for the Clay Cross division in 1933. He was president of the World Disarmament conference at Geneva. 1932–33. He was awarded the Nobel peace prize for 1934. He died October 20, 1935.

HENDERSON, LAWRENCE JOSEPH (1878–1942), U.S. physiologist, biochemist and sociologist. He attended Harvard college and medical school, then studied in Strasbourg. Returning to Harvard university as instructor in biological chemistry in 1904, he remained on the medical faculty until 1911 when he transferred to the arts and sciences faculty. There he pioneered a famous course in the history of science and one in biochemistry. In 1920 he founded the laboratory of physical chemistry in the medical school. In 1927 he organized the fatigue laboratory in the business school as another means of interdisciplinary study.

Henderson's initial investigations of acid-base equilibria in blood plasma led him to recognize physical properties of matter uniquely related to the existence of life. His first book was *The Fitness of the Environment* (1913). In *The Order of Nature* (1917) he stressed the uniqueness of organisms. In 1919 he began to synthesize the reciprocal interrelations of oxygen, carbon dioxide and other components in blood. His Silliman lectures at Yale university summarized these researches in *Blood* (1928). In 1927 he first read the work of V. Pareto on social equilibriums. In it he found general concepts concerning multivariate systems. He thereupon extended his thinking to social phenomena. He lectured on Pareto at the University of California, Berkeley, in 1931, and in subsequent years conducted the Pareto seminar at Harvard, which resulted in his *Pareto's General Sociology* (1935).

Henderson admired French culture and British science, and frequently visited Europe. In 1932 he organized the Society of Fellows at Harvard; 24 junior fellows are thereby freed for independent studies. Henderson stimulated colleagues and students to exactitude and depth of concepts.

See Biographical *Memoirs,* National Academy of Sciences, 23:31–58 (1945). (E. F. AH.)

HENDERSON, SIR NEVILE MEYRICK (1882–1942), British diplomat, who, as British ambassador in Berlin from 1937 to 1935, was closely associated with Neville Chamberlain's policy of appeasement toward Hitler's Germany, was born on June 10, 1882. He was educated at Eton college and joined the diplomatic service in 1905.

After serving in various subordinate posts, Henderson became British minister in Egypt (1924–28), France (1928–29) and Yugoslavia (1929–35). At this point he was recommended to the then foreign secretary, Sir Samuel Hoare (afterward Lord Templewood), as "the coming young diplomat in the foreign service." Promoted ambassador to Argentina in 1935, he was transferred in 1937 to Germany, where he stayed until the start of World War II in 1939. In Berlin he worked under severe nervous strain and was seriously ill in the winter of 1938. Some observers considered that he supported the appeasement policy even more vehemently than Chamberlain himself. Afterward he published his own account of the final phase of Nazi aggression in *Failure of a Mission* (1940). *He* was knighted in 1932 and made a privy councilor in 1937. He died in London on Dec. 30, 1942. His autobiography, *Water Under the Bridges,* was published posthumously in 1945. (J. F. B.)

HENDERSON, WILLIAM JAMES (1855–1937), U.S. music critic and author, who with Richard Aldrich, James Huneker and Henry E. Krehbiel established himself as one of the foremost critics of his day, was born at Newark, N.J., on Dec. 4, 1855. Graduating from Princeton (1876), he was on the *New York Times* (1883–1902) and the *New York Sun* (1902–37) as music critic. His works include: *The Story of Music* (1889); *The Elements of Navigation* (1892); *Richard Wagner* (1901); *Pipes and Timbrels* (1905); and *The Art of the Singer* (1906).

HENDIADYS, a rhetorical figure in which two words connected by a conjunction are used of a single idea; usually the figure takes the form of two substantives instead of a substantive and adjective, as in the classical example *pateris libamus et auro* (Virgil. *Georgics,* ii, 192), "we pour libations in cups and gold" for "cups of gold."

HENDON, a municipal (1932) and parliamentary borough (returning two members) of Middlesex, Eng.. on the Brent. 8 mi. N.W. of St. Paul's cathedral. London. Served by electric trains of the London Passenger Transport board, Hendon grew rapidly as a residential area in the period after World War I. Pop. (1961) 15'1,500. Hendon airfield was bought by Claude Grahame-White in 1910 and there he founded the London Flying club. In 1511 the first United Kingdom airmail service was flown from there. In 1923 the air ministry took it over and during both world wars it was used for military purposes. It was closed to flying in 1957. The Metropolitan Police college was established at Hendon in 1934; there is a large technical college (1937) and a local history museum at Chalk Farm house. For nearly six centuries Hendon belonged to the abbot and monks of Westminster and they acquired for it two charters of liberty from Edward the Confessor and William the Conqueror. St. Mary's parish church is partly Norman. David Garrick lived at Hendon hall (now a hotel) when he was lord of the manor.

Industries include the making of motor bodies and aircraft products. By the mid-1950s there were about 1.600 ac. of open spaces including a part of Hampstead heath and Golders Hill park (with deer) and green-belt land. In the northern part of the borough is Mill Hill. with a Roman Catholic missionary college, and a large boys' school founded by Nonconformists in 1660 and refounded in 180;. The borough also contains Edgware, Temple Fortune, Burnt Oak, C'olindale (with the British Museum's newspaper section). Golders Green with its Hippodrome and part of Hampstead Garden suburb, founded in 1906.

HENDRICKS, THOMAS ANDREWS (1819–1885), U.S. political leader, vice-president of the United States in 1885, was

born near Zanesville, O., on Sept. 7, 1819. He graduated at Hanover college, Hanover, Ind., in 1841, and began in 1843 a successful career at the bar. Identifying himself with the Democratic party, he served in the state house of representatives in 1848, and was a prominent member of the convention for the revision of the state constitution in 1850–51, a representative in congress (1851–55), commissioner of the C.S. general land office (1855–59), a U.S. senator (1863–69) and governor of Indiana (1873–77). From 1868 until his death he was put forward for nomination for the presidency at every national Democratic convention save in 1872. Both in 1876 and 1884 after his failure to receive the nomination for the presidency. he was nominated by the Democratic convention for vice-president. In 1876. with S. J. Tilden, he lost the disputed election by the decision of the electoral commission, but he was elected with Grover Cleveland in 1884. He died at Indianapolis on Nov. 25, 1885.

HENGELO, a town in the province of Overyssel. Neth.. and a junction station 5 mi. N.W. of Enschede hy rail. Pop. (1947) 43,431. The town is the centre of the flourishing industries of the Twente district. The manufacture of cotton is carried on. and there are dye works. railway works and breweries. Five miles from Hengelo is the superb mediaeval castle of Twickel, seat of the baronial family Van Heeckeren van Wassenaer.

HENGEST AND HORSA, the brother chieftains who led the first Saxon bands which settled in England. They were apparently called in by the British king Vortigern (*q.v.*) to defend him against the Picts. Their landing place is said to have been Ebbsfleet in Kent. Its date is not certainly known, 450–455 being given by the English authorities. 428 by the Welsh (*see* KENT). The settlers of Kent are described by Bede as Jutes (*q.v.*), and there are 'traces in Kentish custom of differences from the other Anglo-Saxon kingdoms. Hengest and Horsa were given the island of Thanet as a home, but soon quarrelled with their British allies, and gradually acquired what became the kingdom of Kent. In 455 the *Saxon Chronicle* records a battle between Hengest and Horsa and Vortigern at a place called Aegaels threp. in which Horsa was slain. Thenceforward Hengest reigned in Kent. together with his son Aesc (Oisc). Both the *Saxon Chronicle* and the *Historia Brittonum* record three subsequent battles, though they disagree as to their issue. There is no doubt, however, that the net result was the expulsion of the Britons from Kent. According to the *Chronicle*, probably based on a lost list of Kentish kings, Hengest died in 488, while his son Aesc continued to reign until 512.

Bede, *Hist. Eccl.* (Plummer, 1896), i, 15, ii, 5; *Saxon Chronicle* (Earle and Plummcr, 1899), s.a. 449, 455, 457, 465, 473; Nennius, *Historia Brittonum* (San Marte, 1844), §§ 31, 37, 38, 43-46, 58.

HENGSTENBERG, ERNST WILHELM (1802–1869), German Lutheran divine and theologian, was born at Fröndenberg, Westphalia, on Oct. 20, 1802. He studied at the universities of Bonn and Berlin. and in 1826 became professor extraordinarius and in 1828 professor of theology at Berlin. In July 182; he started the *Evangelische Kirchenzeitung*, a strictly orthodox journal. In 1830 an anonymous article (by E. L. von Gerlach) appeared in this journal which charged Wilhelm Gesenius and J. A. L. Wegscheider with infidelity and profanity. and advocated the interposition of the civil power, thus giving rise to the *Hallische Streit*. He died on May 28, 1869.

His principal work is *Christologie des Alten Testaments* (1829–35; 2nd ed.. 1854–57; Eng. trans. by R. Keith, 1835–39, also in Clark's "Foreign Theological Library," by T. Meyer and J. Martin, 1854–58). Of his other works, the chief are: *Beiträge zur Einleitung in das Alte Testament* (1831–39; Eng. trans. 1848); *Commentar über die Psalmen* (1842–47; Eng. trans. 1844–48); *Die Offenbarung Johannis erlazrtert* (1849–51; Eng. trans.? 1851–52) and *Das Evangelium Johannis erläutent* (1861–63).

See J. Bachmann's *Ernst Wilhelm Hengstenberg*, 3 vol. (1876–92); also his article in Herzog-Hauck, *Realenzyklopädie* (1899); and F. Lichtenberger, *History of German Theology in the Nineteenth Century* (1889).

HENKE, HEINRICH PHILIPP KONRAD (1752–1809), German theologian, was born at Hehlen. Brunswick, on July 3, 1752. He studied at Helmstädt, and from 1778 to 1809 he was professor, first of philosophy, then of theology, in that university. He died on May 2, 1809. Henke belonged to the rationalistic school. His principal work *(Allgemeine Geschichte der christl. Kirche*, 6 vol., 1788–1804; 2nd ed., 1795–1806) is commended by F. C. Baur for fullness, accuracy and artistic composition.

HENLE, FRIEDRICH GUSTAV JAKOB (1809–1885), German pathologist and anatomist, was the first to treat physiology and pathology as branches of one science. He was born in July 1809, at Fürth, in Franconia. After studying medicine at Heidelberg and at Bonn, where he took his doctor's degree in 1832, he became prosector in anatomy to Johannes Müller at Berlin. He published three monographs on new species of animals, and papers on the structure of the lacteal system, the distribution of epithelium in the human body, the structure and development of the hair, the formation of mucus and pus, etc. In 1840 he became professor of anatomy at Zurich. in 1844 he was called to Heidelberg, where he taught not only anatomy! but physiology and pathology. About this period he was engaged on his complete system of general anatomy, which formed the sixth volume of the new edition of S. T. von Sömmerring's treatise. He published a zoological monograph on the sharks and rays, in conjunction with his teacher, Müller. His famous *Manual of Rational Pathology*, 2 vol. (1846–55) marked the beginning of a new era in pathological study. The facts of disease were systematically considered with reference to their physiological relations. *The Handbook of Systematic Human Anatomy*, 3 vol. (1855–76) was of great scientific merit and of epoch making importance. During the latter half of his life Henle's researches were mainly histological in character, his investigations embracing the minute anatomy of the blood vessels, serous membranes, kidney, eye, nails, central nervous system, etc. Henle died at Gottingen on May 13. 188j.

See F. H. Garrison, *Introduction to the History of Medicine*, 4th ed. (Philadelphia, 1929); N. Robinson, *The Life of Jacob Henle* (1921).

(A. L. A.)

HENLEY, JOHN (1692–1759), English eccentric, commonly called "Orator Henley," rebelled against orthodox ways of preaching. The son of a curate, he was born at Melton Mowbray on Aug. 3, 1692. Educated at St. John's college, Oxford. and ordained (1716), he held several cures before opening his own "oratory chapel" in London (1726). Sir Robert Walpole paid him £100 a year (1730–41) to edit the weekly *Hyp-doctor* in answer to attacks by the *Craftsman*. Alexander Pope satirized Henley in the *Dunciad* and William Hogarth portrayed him in prints.

See I. Disraeli, *Calamities of Authors*, (ed.) *B.* Disraeli (London, 1881).

HENLEY, WILLIAM ERNEST (1849–1903), British poet, critic and editor, was born at Gloucester and educated at the Crypt grammar school where he had the good fortune to have T. E. Brown (*q.v.*) as headmaster for a time. Henley contracted tuberculosis as a child, and one foot had to be amputated. He was placed in Edinburgh infirmary in 1874, to be under Lister's care, and from his bed there he sent to the *Cornhill Magazine* poems in irregular rhythms, describing with poignant force his experiences in hospital. Leslie Stephen, then editor, being in Edinburgh, took Robert Louis Stevenson: another recruit of the *Cornhill*, to see him in hospital. This meeting was the beginning of a famous friendship.

In 1877 Henley went to London and began a long and distinguished journalistic career. He edited *London* (1877–82), the *Magazine of Art* (1882–86), and in 1888 became literary editor and in 1889 editor of the *Scots Observer*, transferred to London as the *National Observer*. In this paper appeared Kipling's *Barrack Room Ballads*. In 1880 appeared Henley's own *Book of Verse*, which included the verses written in hospital at Edinburgh, and in 1890 *Views and Reviews*. The criticisms, covering a wide range of authors (except Heine and Tolstoy, all English and French), though wilful and often one-sided were terse; trenchant and picturesque. There followed *The Song of the Sword* (1892), another volume of verse renamed in 1893 *London Voluntaries;* three plays in 1892 written with Stevenson—Beau *Austin, Deacon Brodie* and *Admiral Guinea;* and *Macaire* (1895). In 1898 Henley published a collection of his *Poems* and in 1901 a second volume of collected

poetry with the title *Hawthorn and Lavender.* He projected the excellent series of "Tudor Translations" and was engaged on the preface to the Authorized Version of the Bible in that edition when he died. He also prepared, with T. F. Henderson, the centenary edition of the poems of Robert Burns, contributing an essay on the poet to the last volume. He died on July 11, 1903. A portrait-bust of him by Rodin was presented by his widow to the National Portrait Gallery in 1913. His fame rests on his poetry. He excelled alike in his delicate experiments in complicated metres, and the strong impressionism of *Hospital Sketches* and *London Voluntaries.* The influence of Heine may be discerned in these "unrhymed rhythms"; but he was perhaps a truer and more successful disciple of Heine in his snatches of passionate song, the best of which should retain their place in English literature.

See also references in *Stevenson's Letters; Cornhill Magazine* (1903) (Sidney Low); *Fortnightly Review* (Aug. 1892) (Arthur Symons); and for bibliography, *English Illustrated Magazine,* vol. xxix, p. 548.

HENLEY-ON-THAMES, a market town and municipal borough in the Henley parliamentary division of Oxfordshire, Eng., on the left bank of the Thames, 35 mi. W. of London by road and 57½ mi. by river. Pop. (1951) 7,982. Area 2.2 sq.mi. It lies at the foot of the Chiltern hills where the river is crossed by a stone bridge of five arches built in 1786. Henley is celebrated for the annual Henley Royal regatta, the principal gathering in England of amateur oarsmen from all over the world, first held in 1839 and usually taking place in the first week of July. The parish church (Decorated and Perpendicular) has a tower of intermingled flint and stone. attributed to Cardinal Wolsey but more probably erected by Bishop John Longland; next to it is the 14th-century Chantry house.

Henley-on-Thames was a manor of the crown in Domesday Book and was granted (1337) to John de Molyns, whose family held it for about 250 years. It was incorporated in 1526. Henley suffered from both parties in the Civil War; later. in 1688, William III in his march on London received there a deputation from the lords. The prosperity of the 17th and 18th centuries was attributable to glass, lace and malt and to the corn and wool trade. Modern Henley is mainly a riverside resort, with market gardening, brewing and engineering industries. There is considerable river fishing.

The Thursday market was granted by King John and the Corpus Christi fair by Henry VI. At Shiplake-on-Thames, 3½ mi. upstream, is the Andrew Duncan convalescent home for boys, opened in 1950.

HENNA is the Persian name for a small shrub found in India, Iran and along the African coasts of the Mediterranean, where it is frequently cultivated. It is the *Lawsonia inermis* of botanists, so called because young trees are spineless, while older ones have the branchlets hardened into spines. It forms a slender shrubby plant of from 8 ft. to 10 ft. high, with opposite lance-shaped smooth leaves. which are entire at the margins, and bears small white four-petaled sweet-scented flowers disposed in panicles. Its Egyptian name is *Khenna,* its Arabic name *Al Khanna,* its Indian name *Mendee,* while in England it is called *Egyptian privet,* and in the West Indies, where it is naturalized, *Jamaica mignonette.*

Henna or Henné is of ancient repute as a cosmetic. This consists of the leaves of the *Lawsonia* powdered and made up into a paste; it has been used by Egyptian and Indian women to dye their fingernails and other parts of their hands and feet an orange-red colour, which is considered to add to their beauty. The colour lasts for three or four weeks, when it requires to be renewed. It is moreover used for dyeing the hair and beard, and even the manes of horses; and the same material is employed for dyeing skins and morocco leather a reddish yellow, but it contains no tannin. The practice of dyeing the nails was common among the Egyptians, and not to conform to it would have been considered indecent. It has descended from very remote ages, as is proved by the evidence afforded by Egyptian mummies, the nails of which are most commonly stained a reddish hue. Henna is also said to have been held in repute among the Hebrews. considered to be the plant referred to as camphire in the Bible (Song of Solomon i, 14; iv. 13). "The custom of dyeing the nails and palms of the hands and soles of the feet of an iron-rust colour with henna," observed Dr. J. Forbes Royle, "exists throughout the East from the Mediterranean to the Ganges, as well as in northern Africa. In some parts the practice is not confined to women and children, but is also followed by men, especially in Persia. In dyeing the beard the hair is turned to red by this application, which is then changed to black by a preparation of indigo. In dyeing the hair of children, and the tails and manes of horses and asses. the process is allowed to stop at the red colour which the henna produces." Mohammed, it is said, used henna as a dye for his beard, and the fashion was adopted by the caliphs. The preparation of henna consists in reducing the leaves and young twigs to a fine powder, catechu or lucerne leaves in a pulverized state being sometimes mixed with them. When required for use, the powder is made into a pasty mass with hot water, and is then spread upon the part to be dyed, where it is generally allowed to remain for one night. The distilled water from the flowers is used as a perfume.

HENNEBONT, a town of western France, in the *département* of Morbihan, 6 mi. N.E. of Lorient. Pop. (1954) 5,913. Hennebont is famed for the resistance which it made, under the widow of Jean de Montfort, when besieged in 1342 by the armies of Philip of Valois and Charles of Blois during the War of the Succession in Brittany *(see* BRITTANY). It is near the mouth of the Blavet, which divides it into the Ville Close, the medieval military town, and the Ville Neuve on the left bank and the Vieille Ville on the right bank. The Ville Close, surrounded by ramparts and entered by a massive gateway flanked by machicolated towers, consists of narrow streets bordered by 16th- and 17th-century houses. The Ville Neuve, nearer the river, developed during the 17th century. The Gothic church of Notre Dame de Paradis (16th century) has a tower with ornamented stone spire. There are scanty remains of the old fortress.

Hennebont has a small but busy river port accessible for small vessels. Hennebont is a market town for grain, cheese and agricultural produce and has an important foundry manufacturing tin plate. Other industries are tanning, distilling and the manufacture of earthenware. Granite is worked in the neighbourhood.

HENNEPIN, LOUIS *(c.* 1640–after 1701), Franciscan missionary and explorer, was born at Ath, in Hainaut. While quite young he joined the Franciscan order. In 1675 he went to Canada in company with a Recollet mission, crossing in the same ship with R. Cavelier de la Salle, whose chaplain he became. From Quebec he carried on his missionary work (in 1678 among the Iroquois). In 1679 he accompanied La Salle on his expedition to the west. They reached the site of Peoria (Jan. 1, 1680), when La Salle was compelled to return to Fort Frontenac for supplies; Hennepin and the remainder of the party were dispatched to explore the upper Mississippi. They were captured by Sioux Indians in April and accompanied them on several hunting expeditions, during the course of which they reached the falls of St. Anthony, where the modern Minneapolis stands. Hennepin was rescued by Graysolon du Lhut (Duluth) in July 1680 and went to Quebec. Returning to France in 1682, he published his *Description de la Louisiane* (Paris, 1683; new Eng. trans., Minneapolis. 1938), a full account of his exploits; but after La Salle's death (1687) he brought out a revised account, *Nouvelle de'couverte d'un trks grand pays situé dans l'Amérique* (Utrecht, 1697; Eng. trans., 1698, ed. by R. G. Thwaites, Chicago, 1903), in which he claimed to have explored the Mississippi to its mouth. This bold assumption was soon discredited, and Hennepin's otherwise valuable contributions to the history of New France and to American ethnology are looked upon with suspicion. He incurred his order's displeasure by refusing to return to America and spent his last years in obscurity.

See Justin Winsor, *Narrative and Critical History of America (1889);* Hugolin *(i.e.,* Stanislas le May), *Bibliographie du Père Louis Hennepin* (1937).

HENNER, JEAN JACQUES (1829–1905), French painter, best known for his rather sensuous pictures of nymphs and naiads in vague landscape settings, and of idealized, almost symbolist, heads of young women and girls. He also painted a number of

portraits in a straightforward naturalistic manner. Henner was born on March 5, **1829,** at Bernweiler, Alsace, and studied at Strasbourg and at the École des Beaux Arts in Paris under Michel Drolling. In 1858 he won the Prix de Rome, and he spent the years 1859–65 in Italy where the chiaroscuro, colour and sentiment of the paintings of Correggio and Giorgione made a lasting impression on him.

Henner exhibited regularly at the Paris salon and was one of the most successful artists of his day, but his reputation was already in decline at the time of his death in Paris on July 23, 1905.

See **L.** Benedite, articles in Gazette des ***Beaux*** *Arts,* i and ii (1906), ii (1907) and i and ii (1908). **(A. Bs.)**

HENOGAMY, a term used to denote the custom by which one, and only one. member of a family or stock is permitted to marry, or is required to marry according to definite rules which are not binding on other members of the family. Thus, among the Nambutiri Brahmins of Malabar "the eldest son alone marries. The accepted practice, as well as the recognized principle among them! seems to be in consonance with the directions expounded by Manu, viz., immediately on the birth of his firstborn male child, a man is the father of a son, and is free from the debt to the Manes. That son is, therefore. worthy to receive the whole estate. That son alone. on whom he throws his debt. is begotten for (the fulfillment of) the law. And the next they consider the offspring of desire. . . . Should a Nambutiri eldest son die. the next marries and so on." (E. Thurston, *Tribes and Castes of Southern India,* 1909, vol. **V,** p. 175.)

This custom, it is observed, has long been in force to keep the family property intact and to prevent its disintegration by partition which the marriage of the younger sons might necessitate (A. N. Krishna Iyer, *The Cochin Tribes and Castes,* **1912,** vol. ii, p. **183).** Polygamy "is often indulged in by the Nambutiris, owing partly to their desire to have a son to perform funeral and other ceremonies for the spirits of the departed. and partly to dispose of the superfluous number of girls." *(Ibid.,* p. 210.) The younger males contract alliances with Nayar women. Their children belong to the *Tarwad,* a matrilineal group of their mothers and pollute their Brahmin fathers. This dislocation of the social order extends far down in Malabar society, and is ultimately traceable to the practice of henogamy among the patrilineal Brahmins.

The belief in direct and specific reincarnation which is embodied in the teaching of Manu is connected with customs in the Punjab, where "the position of the firstborn is probably due to the fact that, if a son, his father is born again in him, so that the father is supposed to die at his birth, and in certain Khatri sections, *e.g.,* the Kochhar. his funeral rites are actually performed—in the fifth month of the mother's pregnancy. Probably herein lies the explanation of the *dev-kaj,* or divine nuptials, a ceremony which consists in a formal remarriage of the parents after the birth of their first son" (*Punjab. Census Report,* 1901, part *I,* **p.** 215).

Among the matrilineal Garos *(see* GARO HILLS) the youngest daughter is reserved for marriage with her father's brother's son, after he has married her own mother who, under the dual system. is also his paternal aunt (A. Playfair. *The Garos,* 1909, **p.** 67; *Assam Census Report,* **1891,** p. **229).** The elder daughters make their own arrangements for marriage.

There are other instances in India and elsewhere of rules by which special status—as regards inheritance and succession—is conferred by marriage betneen specified persons, as if one mode or set of rites gave peculiar dignity and validity. These devices mark decisively a change from a social order in which inheritance and succession are determined by the principle of social equivalence. as in the levirate (*q.v.*) or sororate (q *v.*), which is expressed in terms of a classificatory system. to that order in which one line is selected, one son preferred, for transmission. The economic results which in history have accrued from the emergence of the principle of unilinealism have been, and still are, considerable.

The custom of henogamy, if extended to cover the case where special rites and conditions are used for the marriage of the eldest son, is of wide occurrence, and the survival in India of the strict logical form has, therefore, special interest.

HENRI, ROBERT (1865–1929), U.S. painter, the leader of the Ash Can school and one of the most influential teachers in the history of American art, was born in Cincinnati, O., June 25, **1865.** He studied at the Pennsylvania Academy of Fine Arts, Philadelphia, and in Paris, and on returning to the United States became in **1891** an instructor at the Women's School of Design in Philadelphia. His vigorous ideas attracted a group of young illustrators for the Philadelphia press: J. Sloan, E. Shinn, G. Luks and W. Glackens. From **1896** to 1900 he was again in Paris, and exhibited at the salon. He settled in New York city. where in 1908 he was among the painters who exhibited together and came to be known as The Eight. During an extremely active life as an artist. Henri exercised considerable influence as a portrait painter. From 191**j** to 1923 he taught at the Art Students' league, New York city.

Henri's book, *The Art Spirit,* embodying his conception of art as an expression of love for life. was first published in 1923, and maintained a continuing popularity among artists and art students. He died in New York city, July 12, 1929.

HENRIETTA MARIA (1609–1669), queen of Charles I of England, daughter of Henry IV of France. was born on Nov. 15, **1609.** The first serious overtures for her hand were made in the spring of **1624.** on behalf of Charles, prince of Wales. Her brother. Louis XIII. consented to the marriage on the condition that the English Roman Catholics were relieved from the operation of the penal laws. On May 1. 162**j.** in Paris, she was married by proxy to Charles. who was non- king, and set out for England in June.

The early years of their married life were unhappy. Charles soon broke his promise to relieve the English Catholics and his young wife was deeply offended. The favourite Buckingham stirred the flames of his master's discontent. After the assassination of Buckingham (1628) the barrier between the married pair was broken down, but Charles caused much discontent by his favourable treatment of the Catholic subjects whom he had formerly persecuted. The children of the marriage were Charles II (b. 1630), Mary, princess of Orange (b. 1631), James II (b. 1633), Elizabeth (b. **1635).** Henry, duke of Gloucester (b. 1639), and Henrietta. duchess of Orléans (b. **1644).**

For several years Henrietta Maria's chief interests lay in the amusements of a brilliant court, and she took no part in politics. Her participation in the private rehearsals of the *Shepherd's Pastoral* probably drew down upon her the savage attack of William Prynne. Her coreligionists found little aid from her till **1636.** She had then recently opened a diplomatic communication with the see of Rome, and under the influence of a papal agent. a Scotsman named George Conn, accredited to her, thwarted Archbishop William Laud's proclamation against the Catholic recusants. Her court became the centre of a Catholic revival.

When the Scottish troubles broke out in **1639,** she raised money from her fellow Catholics to support the king's army on the borders. During the session of the Short Parliament in the spring of **1640** the queen urged the king to oppose himself to the house of commons in defense of the Catholics. She was generally believed to be the instigator of the army plot to bring the forces in the north to London, hut she was probably acting on the suggestion of her adviser Henry Jermyn.

She threw herself heart and soul into this scheme for rescuing Strafford and coercing the parliament. and the impeachment of the five members on the charge of treason was brought about partly by her influence over the king.

In Feb. **1642** the queen went to the continent to try to raise arms and money. Her intrigues to introduce foreign armies into England lasted throughout the Civil War and being discovered had no small share in her husband's execution. In Feb. **1643** she landed at Bridlington quay with a large sum of money but no foreign troops. She joined the king near Oxford. which they entered together on July 14. By July **1644,** however. her position had become so insecure that she again took refuge in France, where she received a pension of 12.000 crowns a month from the queen regent. As long as her husband was alive the queen never ceased to encourage his resistance. and she continued to hope for success

until his execution in 1649.

She brought up her youngest child, Henrietta, in her own faith, but failed to convert her youngest son. the duke of Gloucester. When after the Restoration (Oct. 1660) she returned to England, she found that she had no place in the new uorld. She received from parliament a grant of £30,000 a year, and the king added a similar yearly sum. In Jan. 1661 she returned to France for the marriage of her daughter Henrietta to the duke of Orléans. She set out again for England in July 1662, but in 1665 she returned to France, and died on August 21, 1669, at Colombes, not far from Paris. Rumours that she married Jermyn some time after 1649 are probably unfounded.

See I. A. Taylor, *The Life* of *Queen Henrietta Maria* (London, 1905); and Carola Oman, *Henrietta Maria* (New York, London, 1936), which has a bibliography. Her letters have been edited by M. A E Green (London, 1857). (G. Ds.)

HENRY, "prince of the house" (Fr. *Henri;* Span. *Enrique;* Ger. *Heinrich*). The name of many European sovereigns.

HENRY (HENRY BENEDICT MARIA CLEMENT STUART) (1725–1807), usually known as Cardinal York, the last prince of the royal house of Stuart, younger son of James Stuart, was born in the Palazzo Muti at Rome on March 6, 1725. He was created duke of York by his father soon after his birth, and by this title he was always alluded to by Jacobite adherents of his house. In support of the Young Pretender's campaign in Scotland, Henry was despatched in the summer of 1745 to France, where he was placed in nominal command of French troops at Dunkirk, with which the marquis d'Argenson had some idea of invading England. Seven months after Charles's return from Scotland Henry, who had joined his brother in Paris, secretly left for Rome and, with his father's approval, but to his brother's disgust, was created a cardinal deacon under the title of the cardinal of York by Pope Benedict XIV. on July 3, 1747. In the following year he was ordained priest, and nominated arch-priest of the Vatican Basilica. In 1759 he was consecrated archbishop of Corinth *in partibus,* and in 1761 bishop of Frascati (the ancient Tusculum) in the Alban Hills near Rome, where he founded an ecclesiastical seminary. In 1763 he became vice-chancellor of St. Peter's. Henry Stuart held sinecure benefices in France, Spain and Spanish America, so that he became one of the wealthiest churchmen of the period, his annual revenue being said to amount to £30,000 sterling. On the death of his father, James Stuart, Henry tried unsuccessfully to induce Pope Clement XIII, to acknowledge his brother Charles as legitimate king of Great Britain. On Charles's death in 1788 Henry issued a manifesto asserting his hereditary right to the British crown. At the outbreak of the French Revolution he lost two rich French livings and his pension from Spain, and in Feb. 1798, at the approach of the invading French forces, he was forced to fly to Naples, whence he sailed to Messina. At this time he disposed of his family heirlooms to help the pope raise the tribute demanded by Napoleon. From Messina he proceeded by sea in order to be present at the expected conclave at Venice, where he arrived in the spring of 1799, aged, ill and almost penniless. George III., on the recommendation of Prince Augustus Frederick, duke of Sussex, gave a pension of £4,000 a year to the last of the royal Stuarts. Henry received this assistance gratefully, and subsequently left by his will certain British crown jewels in his possession to the prince regent. In 1800 Henry was able to return to Rome, and in 1803, being senior cardinal bishop, he became *ipso facto* dean of the sacred college and bishop of Ostia and Velletri. He died at Frascati on July 13, 1807, and was buried in the *Grotte Vaticane* of St. Peter's in an urn bearing the title "Henry IX."; he is also commemorated in Canova's well-known monument to the royal Stuarts *(see* JAMES). The Stuart archives, once the property of Cardinal York, were presented by Pope Pius VII. to the prince regent, who placed them in the royal library at Windsor Castle.

See B. W. Kelly, *Life of Cardinal York;* H. *M.* Vaughan, *Last* of *the Royal Stuarts; A.* Shield, *Henry Stuart, Cardinal of York, and his Times* (1908); *T.* F. Henderson, *The Royal Stuarts* (1914).

HENRY II. (973–1024), surnamed the "Saint," Roman emperor, son of Henry II., the Quarrelsome, duke of Bavaria, and Gisela, daughter of Conrad, king of Burgundy, or Arles (d. 993), and great-grandson of the German king Henry I., was born on May 6, 973, and was educated at Hildesheim and at Regensburg. He became duke of Bavaria on his father's death in 995, and about 1001 married Kunigunde (d. 1037), daughter of Siegfried, count of Luxemburg. When Otto III. died childless in 1002, Henry was chosen German king by the Franks and Bavarians on June 7, 1002, and subsequently crowned by Willigis, archbishop of Mainz. He purchased the allegiance of the Thuringians and the Saxons; and when shortly afterwards the nobles of Lorraine did homage and Hermann of Swabia, his rival, submitted, he was generally recognized as king. An incipient war with Boleslaus I., the Great, king of Poland, who had extended his authority over Meissen and Lusatia, seized Bohemia, and allied himself with some discontented German nobles, including the king's brother, Bruno, bishop of Augsburg, was abandoned in favour of an expedition into Italy, where Arduin, margrave of Ivrea, had been elected king. Crossing the Alps Henry met with no resistance from Arduin, and in May 1004 was crowned king of the Lombards at Pavia. He then freed Bohemia from the rule of the Poles, led an expedition into Friesland, and compelled Boleslaus to sue for peace in 1005. A struggle with Baldwin IV, count of Flanders, in 1006 and 1007 was followed by trouble with the king's brothers-in-law, Dietrich and Adalbero of Luxemburg, who had seized respectively the bishopric of Metz and the archbishopric of Trier (Treves). In 1013, peace was made with Boleslaus and later in the year, the king went to Rome where, having recognized Benedict VIII. as the rightful pope, he was crowned emperor on Feb. 14, 1014. But the struggle with the Poles broke out afresh, and in 1015 and 1017 Henry led formidable armies against Boleslaus. On Jan. 30, he made peace at Bautzen, Boleslaus retaining Lusatia. As early as 1006 Henry had concluded a succession treaty with his uncle Rudolph III., the childless king of Burgundy, or Arles; but when Rudolph desired to abdicate in 1016 Henry's efforts to secure possession of the crown were resisted by the nobles. In 1020 the emperor was visited at Bamberg by Pope Benedict, in response to whose entreaty for assistance against the Greeks of southern Italy he crossed the Alps in 1021 for the third time. With the aid of the Normans he crippled the Greeks, but was compelled by pestilence among his troops to return to Germany in 1022. He died on July 13, 1024 at Grona near Gottingen.

Henry was an enthusiast for church reform, and under the influence of his friend Odilo, abbot of Cluny, sought to further the principles of the Cluniacs, and seconded the efforts of Benedict VIII. to prevent clerical marriage and the sale of spiritual dignities. Nevertheless he appointed bishops without the formality of an election, and sometimes attacked clerical privileges. He held numerous diets and issued frequent ordinances for peace, but feuds among the nobles were common, and the frontiers of the empire were insecure. Henry, who was the last emperor of the Saxon house, was the first to use the title "King of the Romans." He was canonized in 1146 by Eugenius III.

Matthaei, *Die Klosterpolitik Kaiser Heinrichs II.* (Gottingen, 1877). Further bibliography in *Camb. Mediaeval Hist.* **vol.** iii.

HENRY III. (1017–1056), surnamed the "Black," Roman emperor, only son of the emperor Conrad II., and Gisela, widow of Ernest I., duke of Swabia, was born on Oct 28, 1017, designated as his father's successor in 1026, and crowned German king at Aix-la-Chapelle on April 14, 1028. In 1027 he was appointed duke of Bavaria, where he had been educated under Bruno, bishop of Augsburg and under Egilbert, bishop of Freising. In 1032 he took part in a campaign in Burgundy; in 1033 led an expedition against Ulalrich, prince of the Bohemians; and in June 1036 married Gunhilda, afterwards called Kunigunde, daughter of Canute, king of Denmark and England. In 1038 the emperor

formally handed over to him the kingdom of Burgundy, or Arles, and appointed him duke of Swabia.

When Conrad died in June 1039, Henry became sole ruler of the empire. A struggle soon broke out with Bretislaus, prince of the Bohemians, who revived the idea of an independent Slavonic state, and conquered various Polish towns. After suffering two defeats in 1040, in the following year Henry was able to compel Bretislaus to sue for peace and to do homage for Bohemia. In 1042 he received the homage of the Burgundians and his attention was then turned to the Hungarians, who had driven out their king Peter, and set up one Aba Samuel, or Ovo, who attacked eastern Bavaria. During 1043–45 Henry restored Peter, and brought Hungary completely under the German king.

In 1038 Queen Kunigunde had died and in 1043 the king married Agnes, daughter of William V., duke of Guienne. In 1044 Gothelon (Gozelo), duke of Lorraine, died, and some disturbance arose over Henry's refusal to grant the whole of the duchy to his son Godfrey, called the Bearded. Godfrey took up arms, but after a short imprisonment was confirmed in the possession of Upper Lorraine in 1046 which, however, he failed to secure. About this time, the rival popes were deposed, and the king secured the election of Suidger, bishop of Bamberg, who crowned Henry emperor on Dec. 25, 1046. He was immediately recognized by the Romans as *Patricius,* an office which carried with it at this time the right to appoint the pope. Supreme in church and state alike, ruler of Germany, Italy and Burgundy, overlord of Hungary and Bohemia, Henry occupied a commanding position. He made a victorious progress in southern Italy, where he restored Pandulph IV. to the principality of Capua, and asserted his authority over the Normans in Apulia and Aversa. Returning to Germany in 1047 he appointed two popes, Damasus II. and Leo IX., in quick succession, and faced a threatening combination in the west of the empire, where Godfrey of Lorraine was again in revolt, and with Baldwin V., count of Flanders and Dirk IV., count of Holland, who had previously caused trouble, was ravaging the emperor's lands in Lorraine. Assisted by the kings of England and Denmark, Henry subdued the rebels in 1050. Godfrey was deposed; but Baldwin in 1054 again revolted.

Meanwhile a reaction against German influence had taken place in Hungary. King Peter had been replaced in 1046 by Andreas I., and inroads into Bavaria followed. A brief peace was secured in 1053, but the emperor, occupied elsewhere, soon lost his authority in the east. On pope Leo's death, Henry nominated Gebhard, bishop of Eichstadt, to the vacant chair. In 1055 the emperor went a second time to Italy, where his authority was threatened by Godfrey of Lorraine, who had married Beatrice, widow of Boniface III., margrave of Tuscany, and was ruling her vast estates. Godfrey fled, however, on the appearance of Henry, who only remained a short time in Italy, during which he granted the duchy of Spoleto to the pope. During his absence, the deposed Conrad III., duke of Bavaria, Welf, duke of Carinthia, and Gebhard III., bishop of Regensburg, formed an unsuccessful conspiracy against him. The emperor died at Bodfeld on Oct. j, 1056. He was a peace-loving prince, who favoured church reform and sought to suppress private warfare. But he alienated the sympathies of the nobles as a class, and, by allowing the southern duchies to pass into other hands, restored a power which was not always friendly to the royal house. Henry was a patron of learning, a founder of schools, and completed cathedrals at Spires, Worms and Mainz.

HENRY IV. (1050–1106), Roman emperor, son of the emperor Henry III. and Agnes, daughter of William V., duke of Guienne, was born on Nov. 11, 1050, chosen German king at Tribur in 1053, and crowned at Aix-la-Chapelle on July 17, 1054. In 1055 he was appointed duke of Bavaria, and on his father's death in 1056 inherited the kingdoms of Germany, Italy and Burgundy. These territories were governed in his name by his mother, who was compelled in 1062 to hand over her control to Anno, archbishop of Cologne, and to Adalbert, archbishop of Bremen. In March 1065 Henry was declared of age, and in the following year married Bertha, daughter of Otto, count of Savoy.

In 1069 the king led expeditions against the Liutii, and against Dedo or Dedi II., margrave of a district east of Saxony; and soon afterwards quarrelled with Rudolph, duke of Swabia, and Berthold, duke of Carinthia. His struggle with Otto of Nordheim, duke of Bavaria, who was accused in 1070 of being privy to a plot to murder the king, ended in the duke's submission in 1071. Henry aroused the hostility of the Thuringians by supporting Siegfried, archbishop of Mainz, in his efforts to exact tithes from them, and the enmity of the Saxons by ordering a restoration of all crown lands in Saxony, by ravaging the country to supply the needs of his courtiers, and by holding its duke Magnus a prisoner. In 1073 the Thuringians joined the Saxons, and the war, which lasted with slight intermissions until 1088, exercised a potent influence upon Henry's fortunes elsewhere *(see* SAXONY). For Henry's dispute with Hildebrand (Pope Gregory VII.), his excommunication and his famous visit to Canossa *see* GREGORY VII.

Henry left Italy to find that in his absence Rudolph, duke of Swabia, had been chosen German king; and although Hildebrand had taken no part in this election, Henry sought to prevent the pope's journey to Germany, and tried to recover his former position. Though supported by most of the German bishops and by the Lombards and recognized in Burgundy, Bavaria and Franconia, Henry suffered defeat at Mellrichstadt in 1078 and at Flarchheim in 1080. Gregory's attitude remained neutral, in spite of appeals from both sides, until March 1080, when he again excommunicated Henry. At Henry's initiative, Gregory was declared deposed on three occasions, and an anti-pope was elected in the person of Wibert, archbishop of Ravenna, who took the name of Clement III.

The death of Rudolph, the rival German king, in Oct. 1080, left the king at liberty to go to Italy early in 1081. He found considerable support in Lombardy; placed Matilda, marchioness of Tuscany, the faithful friend of Gregory, under the imperial ban; took the Lombard crown at Pavia; and secured the recognition of Clement by a council. After two unsuccessful attacks he took Rome in 1082, and a treaty was concluded with the Romans. who agreed that the quarrel between king and pope should be decided by a synod, and secretly bound themselves to induce the pope to crown Henry as emperor, or to choose another pope. The synod was a failure, and in March 1084 Gregory was declared deposed and Clement was recognized by the Romans. On March 31, 1084 Henry was crowned emperor by Clement, and received the patrician authority. His next step was to attack the fortresses still in the hands of the pope, but the advance of Robert Guiscard, duke of Apulia, compelled him to return to Germany.

hfeanwhile the German rebels had chosen a fresh anti-king, Hermann, count of Luxemburg. In 1086 Henry was defeated near Würzburg, but in 1088 Hermann abandoned the struggle and the emperor was generally recognized in Saxony. Although Henry's power was in the ascendent, a few powerful nobles adhered to the cause of the new pope, Urban II. Among them was Welf, son of the deposed duke of Bavaria, whose marriage with Matilda of Tuscany rendered him formidable. The emperor accordingly returned to Italy in 1090, where Mantua and Milan were taken, and Pope Clement was restored to Rome.

Henry's first wife had died in 1087, and in 1089 he had married a Russian princess Praxedis, afterwards called Adelaide. Her conduct soon aroused his suspicions, and his own eldest son, Conrad, who had been crowned German king in 1087, was thought to be a partner in her guilt. Adelaide fled to Henry's enemies and brought charges against him; and the papal party induced Conrad to desert his father and to be crowned king of Italy at Monza in 1093. After five years of inactivity Henry returned to Germany where his position was stronger than ever. Welf had submitted

and had been restored to Bavaria; the diet assembled at Mainz in 1098 declared Conrad deposed, and chose the emperor's second son, Henry, afterwards the emperor Henry V., as German king, and the crusade of 1096 had freed Germany from many turbulent spirits. But the younger Henry, in 1104, encouraged by the adherents of the pope, declared he owed no allegiance to an excommunicated father. Saxony and Thuringia were soon in arms and in 1105, the emperor became a prisoner in the hands of his son. A diet at Mainz in December compelled him to abdicate, but contrary to the conditions, he was detained at Ingelheim and denied his freedom. Escaping to Cologne, he entered into negotiations with England, France and Denmark, and was engaged in collecting an army when he died at Liége on Aug. 7, 1106.

After a licentious youth, Henry displayed much diplomatic ability, and his abasement at Canossa may fairly be regarded as a move of policy to weaken the pope's position at the cost of a personal humiliation to himself. He was a friend of the lower orders, was capable of generosity, and sho ed considerable military skill. Unfortunate in the troubles with which he had to contend, he ably resisted the pretensions both of the papacy and of the ambitious feudal lords of Germany.

Mediaeval Hist.*, vol. 5.

HENRY **V.** (1081–1125), Roman emperor, son of the emperor Henry IV., was born on Jan. 8, 1081, and after the deposition of his elder brother, the German king Conrad (d. 1101), was chosen as his successor in 1098. In spite of his oath to take no part in the business of the empire during his father's lifetime, Henry was induced by his father's enemies to revolt in 1104, and some of the princes did homage to him at Mainz in Jan. 1106. In August of the same year the elder Henry died, when his son became sole ruler. In 1107 a campaign to restore Bofiwoj II. to the dukedom of Bohemia was partially successful, and in the year following the king led his forces into Hungary, where he failed to take Pressburg. In 1109 he was unable to compel the Poles to renew their accustomed tribute, but in 1110 he succeeded in securing the dukedom of Bohemia for Ladislaus I.

The main interest of Henry's reign centres in the controversy over lay investiture which had been thrice prohibited by Paschal II. In 1110 Henry went to Italy with a large army, and at Sutri concluded an arrangement with Paschal by which he renounced the right of investiture in return for a promise of coronation, and the restoration to the empire of all lands given by kings, or emperors, to the German church since the time of Charlemagne. The king presented himself at St. Peter's on Feb. 12, 1111, for his coronation and the ratification of the treaty. The words commanding the clergy to restore the fiefs of the Crown to Henry were read amid a tumult of indignation, whereupon the pope refused to crown the king, who in return declined to renounce the right of investiture. Henry then left the city carrying the pope with him; and Paschal's failure to obtain assistance drew from him a confirmation of the king's right of investiture and a promise to crown him emperor.

In 1112 Lothair, duke of Saxony, rose against Henry, but was easily quelled. In 1113, however, a quarrel over the succession to the counties of Weimar and Orlamünde gave occasion for a fresh outbreak on the part of Lothair, whose troops were defeated at Warnstadt. Having been married in 1114 to Matilda, or Maud, daughter of Henry I. of England, the emperor was confronted with a further rising, initiated by the citizens of Cologne, who were soon joined by the Saxons and others. Henry's forces were defeated at Welfesholz in 1115, and complications in Italy compelled him to leave Germany to the care of Frederick II. of Hohenstaufen, duke of Swabia, and his brother Conrad. After the departure of Henry from Rome in 1111 a council declared the privilege of lay investiture, which had been extorted from Paschal, to be invalid, and Guido, archbishop of Vienne, excommunicated the emperor, but the pope refused to ratify this sentence. The quarrel entered upon a new stage in 1115 when Matilda, daughter and heiress of Boniface, margrave of Tuscany, died leaving her vast estates to the papacy. Crossing the Alps in 1116, Henry took possession of Matilda's lands. By this time Paschal had withdrawn his consent to lay investiture and the excommunication had been published. The pope was compelled to fly and the emperor was crowned a second time by Burdinas, archbishop of Braga. Paschal was succeeded by Gelasius II. in Jan. 1118, but Henry secured the election of an antipope who took the name of Gregory VIII. Finally in the concordat of Worms (Sept. 1122) Henry renounced the right of investiture with ring and crozier, recognized the freedom of election of the clergy and promised to restore all church property. The new pope Calixtus II. agreed to allow elections to take place in presence of the imperial envoys, and the investiture with the sceptre to be granted by the emperor as a symbol that the estates of the church were held under the Crown. Henry was received again into the communion of the church, after he had abandoned his nominee, Gregory, to defeat. The emperor's concluding years were occupied with a campaign in Holland, and with a quarrel over the succession to the margraviate of Meissen. In 1124 he led an expedition against King Louis VI. of France and turned his arms against the citizens of Worms. He died at Utrecht on May 23, 1125.

HENRY **VI.** (1165–1197), Roman emperor, son of the emperor Frederick I. and Beatrix, daughter of Renaud III., count of upper Burgundy, was educated under Conrad of Querfurt, afterwards bishop of Hildesheim and Wiirzburg. Chosen German king at Bamberg in June 1169, he was crowned at Xix-la-Chapelle on Aug. 15, 1169, and invested with lands in Germany in 1179. In 1184 his father sought to procure his coronation from Pope Lucius III., but the pope refused because of the marriage arranged between Henry and Constance, daughter of the late king of Sicily, Roger II., a step which threatened to unite Sicily with Germany. This marriage took place at Milan in Jan. 1186, and soon afterwards Henry was crowned king of Italy. Having been recognized by the pope as Roman emperor elect, Henry returned to Germany, where a campaign against Henry the Lion, duke of Saxony, was followed by a peace made at Fulda in July 1190.

A promise of his coronation from Pope Clement III. led Henry to cross the Alps in the winter of 1190. He purchased the support of the cities of northern Italy, but on reaching Rome found Clement was dead and his successor, Celestine III., disinclined to carry out the coronation. However, the strength of the German army and a treaty made between the king and the Romans induced him to crown Henry on April 14, 1191. Meanwhile a party in Sicily had chosen Tancred, an illegitimate son of Roger, son of King Roger II., as king. Henry marched to Naples, but was compelled to raise the siege and return to Germany. There the Welfs and their earlier opponents were united against the emperor, vacancies in various bishoprics added to the confusion, and Henry was suspected of being implicated in the murder of Albert, bishop of Liége. His salvation came from the captivity of Richard I., king of England, and the skill with which he used this event to make peace with his foes. When Henry the Lion came to terms in March 1194, order was restored to Germany.

In the following May, Henry went again to Italy, where Pope Celestine had espoused the cause of Tancred. When he reached Sicily he found Tancred dead, and, meeting with little resistance, entered Palermo, where he was crowned king on Dec. 25, 1194. Leaving his wife, Constance, as regent, he returned to Germany in June 1195.

Having established his position in Germany and Italy, Henry began to cherish ideas of universal empire. Richard of England had already owned his supremacy, and declaring he would compel the king of France to do the same Henry sought to stir up strife between France and England. Nor did the Spanish kingdoms escape his notice. Tunis and Tripoli were claimed, and when the eastern emperor, Isaac Angelus, asked his help, he demanded in return the cession of the Balkan peninsula. The kings of Cyprus and Armenia asked for investiture at his hands. To complete his scheme two steps were necessary, a reconciliation with the pope and the recognition of his young son, Frederick, as his successor in the empire. The first was easily accomplished; the second was more difficult.

Henry met the princes at Worms in Dec. 1195 and by threats or negotiations won the consent of about 50 of them; but though the diet which met at Wurzburg in April **1196** agreed to the scheme, the vigorous opposition of Adolph, archbishop of Cologne, and others rendered it inoperative. In June **1196** Henry went again to Itaiy to persuade the pope to crown his son who had been chosen king of the Romans at Frankfort. Celestine refused, and the emperor then went to the south, where the oppression of his German officials had caused an insurrection, which was put down with terrible cruelty. At Messina on Sept. **28,** 1197, Henry died from a cold caught whilst hunting.

Henry's poems appeared in F. H. von der Hagen's *Minnesinger* (Leipzig, 1838). The chief authorities for his life are Otto of Freising, *Chronicon,* continued by Otto of St. Blasius; Godfrey of Viterbo, *Gesta Frzdericz I.* and *Gesta Heinrici VI.;* Giselbert of Mons, *Chronicon Hanoniense,* all of which appear in the *Monum. Germ. hist. Scriptores,* Bde. xx., xxi., xxii. (1826–92). *See* also W. von Giesebrecht, *Geschichte der deutschen Kaiserzeit,* Bd. iv. (Brunswick, 1877); T. HENRY VII. (c. 1269–1313), Roman emperor, son of Henry III., count of Luxemburg, passed his early days under French influences. In **1288** he succeeded his father, and four years later married Margaret (d. 1311), daughter of John I., duke of Brabant. After the death of the German king, Albert I., he was elected to the vacant throne on Nov. **27, 1308.** The Rhenish archbishops were pacified by the restoration of the Rhine tolls, negotiations were begun with Philip IV., king of France, and with Robert, king of Naples, and the Habsburgs were confirmed in their possessions. At this time Bohemia was ruled by Henry V., duke of Carinthia, but the prevailing disorder induced some of the Bohemians to offer the crown, together with the hand of Elizabeth, daughter of the late king Wenceslas II., to John, the son of the German king. Henry accepted the offer, and in Aug. 1310 John was invested with Bohemia and his marriage was celebrated.

Meanwhile Henry had crossed the Alps, with the hope of reuniting Germany and Italy, and of restoring the empire of the Hohenstaufen. Having entered Milan he placed the Lombard crown upon his head on Jan. **6,** 1311. But trouble soon showed itself. His poverty compelled him to exact money from the citizens; the peaceful professions of the Guelphs were insincere, and Robert, king of Naples, watched his progress with suspicion. Risings took place and, after the capture of Brescia, Henry marched to Rome only to find the city in the hands of the Guelphs and the troops of King Robert. The king, unable to obtain possession of St. Peter's, was crowned emperor on June **29,** 1312, in the church of St. John Lateran by some cardinals who declared they acted under compulsion. Failing to subdue Florence, the emperor allied himself with Frederick III., king of Sicily, and, with the Venetians, set out to attack Robert of Naples. On the march he was taken ill, and died at Buonconvento near Siena on Aug. **24,** 1313. Henry was hailed by Dante as the deliverer of Italy, and in the *Paradiso* the poet reserved for him a place marked by a crown.

Many of the contemporary documents for the life of Henry VII. are found in the *Rerum Italicarum scriptores,* ed. L. *A.* Muratori (Milan; 1723–51), in *Fontes rerum Germanicarum,* ed. *J.* F. Bohmer (Stuttgart, 1843–68), and in *Die Geschichtsschreiber der deutschen Vorzeit,* Bde. 79 and 80 (Leipzig, 1884). *See* also *Acta Henrici VII. imperatoris Romanorum,* ed. G. Donniges (1839); F. HENRY (c. 1174–1216), emperor of Romania, or Constantinople, was a younger son of Baldwin, count of Flanders and Hainaut (d. **1195).** Having joined the Fourth Crusade about 1201, he distinguished himself at the siege of Constantinople in 1204 and elsewhere, and soon became prominent among the princes of the new Latin empire of Constantinople. When his brother, the emperor Baldwin I., was captured at the battle of Adrianople in April **1205,** Henry was chosen regent of the empire, succeeding to the throne when the news of Baldwin's death arrived. He was crowned on Aug. **20, 1205.** Henry was **a** wise ruler, whose reign was largely passed in successful struggles with the Bulgarians and with his rival, Theodore Lascaris I., emperor of Nicaea. Henry appears to have been brave but not cruel, and tolerant but not weak; possessing "the superior courage to oppose, in a superstitious age, the pride and avarice of the clergy." He died, poisoned, it is said, by his Greek wife, on June 11, 1216.

See Gibbon's *Decline and Fall of the Roman Empire,* vol. vi. (ed. J. B. Bury, 1898).

HENRY I. (1207?–1217), king of Castile, son of Alphonso VIII. of Castile and Eleanor of Aquitaine, daughter of Henry II. of England, born c. 1207. He was killed by the fall of a tile.

HENRY II. OF TRASTAMARA (1333–1379), king **(1369)** of Castile, eldest son of Alphonso XI. and his mistress, Leonora de Guzman. His father endowed him with great lordships in northern Spain, and made him count of Trastamara. After the accession of Alphonso's legitimate son, Peter the Cruel, Henry fled **(1356)** to France. In **1366** he persuaded the mercenary soldiers paid off by the kings of England and France to join him on an expedition to drive out Peter. The expedition was successful, but the Black Prince intervened on behalf of Peter and defeated Henry at Nájera (April **3, 1367).** Henry fled to Aragon, returned with French soldiers of fortune under du Guesclin, besieged Peter in Montiel (La Mancha), tempted him out and killed him on March **23, 1369.** Through his ten years' reign Henry remained a strong ally of the French king in his wars with the English, who supported the claims of Peter's natural daughters. To support his own, he made vast grants and concessions to nobles and cities, hence his title *El de las Mercedes* —he of the largesse.

HENRY III. (1379–1406), king **(1390)** of Castile, "El Doliente" (the Sufferer), was the son of John I., of Castile and Leon, and Eleanor, daughter of Peter IV of Aragon. Though delicate and a minor, he succeeded, by the generous support of the cities, in regaining (1393) his crown lands from the nobles. In 1394 he summoned the Cortes at Madrid, and established a practically despotic royal authority, based on the consent of the commons. His marriage with Catherine, granddaughter of Peter the Cruel, united the rival claims of the descendants of Peter and of Henry of Trastamara. He died on Dec. **25, 1406.**

HENRY IV. (1425–1474), king of Castile, "the Impotent," was the son of John II. of Castile and Leon and of Mary. daughter of Ferdinand I. of Aragon and Sicily. Born at Valladolid on

Jan. 6, 1425, he was weak and vacillating in character, and his reign was marked by incidents of the most ignominious kind. He divorced (1453) his wife Blanche of Navarre on the ground of mutual impotence, married Joan of Portugal in 1468, repudiated the daughter that she bore him, then claimed her for his own. Deposed in favour of his brother Alphonso in 1468, he was restored at the latter's death in the same year. He died at Madrid on Dec. 12, 1474.

HENRY I. (1068–1135), king of England, nicknamed Beauclerk, the fourth and youngest son of William I. by his queen Matilda of Flanders, was born in 1068 on English soil. Of his life before 1086, when he was solemnly knighted by his father at Westminster, we know little. He was his mother's favourite, and she bequeathed to him her English estates, which, however, he was not permitted to hold in his father's lifetime. Henry was given an excellent education, of which in later life he was proud. His attainments included Latin, which he could both read and write; he knew something of the English laws and language, and it may have been from an interest in natural history that he collected, during his reign, the Woodstock menagerie which was the admiration of his subjects. But from 1087 his life was one of action and vicissitudes which left him little leisure. Receiving, under the Conqueror's last dispositions, a legacy of 5,000 pounds of silver, but no land, he traded upon the pecuniary needs of Duke Robert of Normandy, from whom he purchased, for the small sum of £3,000, the district of the Cotentin. He negotiated with Rufus to obtain the possession of their mother's inheritance, but only incurred thereby the suspicions of the duke, who threw him into prison. In 1090 the prince vindicated his loyalty by suppressing, on Robert's behalf, a revolt of the citizens of Rouen which Rufus had fomented. But when his elder brothers were reconciled in the next year they combined to evict Henry from the Cotentin. He dissembled his resentment for a time, and lived for nearly two years in the French Vexin in great poverty. He then accepted from the citizens of Domfront an invitation to defend them against Robert of Belesme; and subsequently, coming to an agreement with Rufus, assisted the king in making war on their elder brother Robert. When Robert's departure for the First Crusade left Normandy in the hands of Rufus (1096) Henry took service under the latter, and he was in the royal hunting train on the day of Rufus's death (Aug. 2, 1100).

Had Robert been in Normandy the claim of Henry to the English crown might have been effectually opposed. But Robert only returned to the duchy a month after Henry's coronation. In the meantime the new king, by issuing his famous charter, by recalling Anselm, and by choosing the Anglo-Scottish princess Edith-Matilda, daughter of Malcolm III., king of the Scots, as his future queen, had cemented that alliance with the church and with the native English which was the foundation of his greatness. Anselm preached in his favour, English levies marched under the royal banner both to repel Robert's invasion (1101) and to crush the revolt of the Montgomeries headed by Robert of Belesme (1102). The alliance of crown and church was subsequently imperilled by the question of Investitures (1103–1106). Henry was sharply criticized for his ingratitude to Anselm (*q.v.*), in spite of the marked respect which he showed to the archbishop. At this juncture a sentence of excommunication would have been a dangerous blow to Henry's power in England. But the king's diplomatic skill enabled him to satisfy the church without surrendering any rights of consequence (1106); and he skilfully threw the blame of his previous conduct upon his counsellor, Robert of Meulan. Although the *Peterborough Chronicle* accuses Henry of oppression in his early years, the nation soon learned to regard him with respect. William of Malmesbury, about 1125, already treats Tinchebrai (1106) as an English victory and the revenge for Hastings. Henry was disliked but feared by the baronage, towards whom he showed gross bad faith in his disregard of his coronation promises. In 1110 he banished the more conspicuous malcontents, and from that date was safe against the plots of his English feudatories.

With Normandy he had more trouble, and the military skill which he had displayed at Tinchebrai was more than once put to the test against Norman rebels. His Norman, like his English administration, was popular with the non-feudal classes, but doubtless oppressive towards the barons. The latter had abandoned the cause of Duke Robert, who remained a prisoner in England till his death (1134); but they embraced that of Robert's son William the Clito, whom Henry in a fit of generosity had allowed to go free after Tinchebrai. The Norman conspiracies of 1112, 1118 and 1123–24 were all formed in the Clito's interest. Both France and Anjou supported this pretender's cause from time to time; he was always a thorn in Henry's side till his untimely death at Alost (1128), but more especially after the catastrophe of the White Ship (1120) deprived the king of his only lawful son. But Henry emerged from these complications with enhanced prestige. His campaigns had been uneventful, his chief victory (Brémule, 1119) was little more than a skirmish. But he had held his own as a general, and as a diplomatist he had shown surpassing skill. The chief triumphs of his foreign policy were the marriage of his daughter Matilda to the emperor Henry V. (1114) which saved Normandy in 1124; the detachment of the pope, Calixtus II., from the side of France and the Clito (1119), and the Angevin marriages which he arranged for his son William Aetheling (1119) and for the widowed empress Matilda (1129) after her brother's death. This latter match, though unpopular in England and Normandy, was a fatal blow to the designs of Louis VI., and prepared the way for the expansion of English power beyond the Loire. After 1124 the disaffection of Normandy was crushed. The severity with which Henry treated the last rebels was regarded as a blot upon his fame; but the only case of merely vindictive punishment was that of the poet Luke de la Barre, who was sentenced to lose his eyes for a lampoon upon the king, and only escaped the sentence by committing suicide.

Henry's English government was severe and grasping; but he "kept good peace" and honourably distinguished himself among contemporary statesmen in an age when administrative reform was in the air. He spent more time in Normandy than in England. But he showed admirable judgment in his choice of subordinates; Robert of Meulan, who died in 1118, and Roger of Salisbury, who survived his master, were statesmen of no common order; and Henry was free from the mania of attending in person to every detail, which was the besetting sin of mediaeval sovereigns. As a legislator Henry was conservative. He issued few ordinances; the unofficial compilation known as the *Leges Henrici* shows that, like the Conqueror, he made it his ideal to maintain the "law of Edward." His itinerant justices were not altogether a novelty in England or Normandy. It is characteristic of the man that the exchequer should be the chief institution created in his reign. The eulogies of the last *Peterborough Chronicle* on his government were written after the anarchy of Stephen's reign had invested his predecessor's "good peace" with the glamour of a golden age. Henry was respected and not tyrannous. He showed a lofty indifference to criticism such as that of Eadmer in the *Historia novorum*, which was published early in the reign. He showed, on some occasions, great deference to the opinions of the magnates. But dark stories, some certainly unfounded, were told of his prison-houses. Men thought him more cruel and more despotic than he actually was.

Henry was twice married. After the death of his first wife, Matilda (1080–1118), he took to wife Adelaide, daughter of Godfrey. count of Louvain (1121), in the hope of male issue. But the marriage proved childless. and the empress Matilda was designated as her father's successor, the English baronage being compelled to do her homage both in 1127, and again, after the Angevin marriage, in 1131. He had many illegitimate sons and daughters by various mistresses. Of these bastards the most important is Robert, earl of Gloucester, upon whom fell the main burden of defending Matilda's title against Stephen.

Henry died near Gisors on Dec. 1, 1135, in the 36th year of his reign, and was buried in the abbey of Reading which he himself had founded.

HENRY II. (1133–1189), king of England, son of Geoffrey Plantagenet, count of Anjou, by Matilda, daughter of Henry I., was born at Le Mans on March 2j, 1133. He was brought to England during his mother's conflict with Stephen (1142), and was placed under the charge of a tutor at Bristol He returned to Normandy in 1146. He next appeared on English soil in 1149[1] when he came to court the help of Scotland and the English baronage against King Stephen. The second visit was of short duration. In 1150 he was invested with Normandy by his father, whose death in the next year made him also count of Anjou In 1152 by a marriage with Eleanor of Aquitaine, the divorced wife of the French king Louis VII., he acquired Poitou, Guienne and Gascony; but in doing so incurred the ill-will of his suzerain from which he suffered not a little in the future. Lastly in 1153 he was able, through the aid of the Church and his mother's partisans, to extort from Stephen the recognition of his claim to the English succession; and this claim was asserted without opposition immediately after Stephen's death (Oct. 25, 1154).

The first years of the reign were largely spent in restoring the public peace and recovering for the crown the lands and prerogatives which Stephen had bartered away. Amongst the older partisans of the Angevin house the most influential were Archbishop Theobald, whose good will guaranteed to Henry the support of the Church, and Nigel, bishop of Ely, who presided at the exchequer. But Thomas Becket, archdeacon of Canterbury, a younger statesman whom Theobald had discovered and promoted, soon became all-powerful. Becket lent himself entirely to his master's ambitions, which at this time centred round schemes of territorial aggrandizement. In 1155 Henry asked and obtained from Adrian IV. a licence to invade Ireland, which the king contemplated bestowing upon his brother, William of Anjou. This plan was dropped; but Malcolm of Scotland was forced to restore the northern counties which had been ceded to David; North Wales was invaded in 1157; and in 1159 Henry made an attempt, which was foiled by the intervention of Louis VII., to assert his wife's claims upon Toulouse. After vainly invoking the aid of the emperor Frederick I., the young king came to terms with Louis (1160), whose daughter was betrothed to Henry's namesake and heir. The peace proved unstable, and there was desultory skirmishing in 1161. The following year was chiefly spent in reforming the government of the continental provinces. In 1163 Henry returned to England, and almost immediately embarked on that quarrel with the Church which is the keynote to the middle period of the reign.

Henry had good cause to complain of the ecclesiastical courts, and had only awaited a convenient season to correct abuses which were admitted by all reasonable men. But he allowed the question to be complicated by personal issues. He was bitterly disappointed that Becket, on whom he bestowed the primacy, left vacant by the death of Theobald (1162), at once became the champion of clerical privilege; he and the archbishop were no longer on speaking terms when the Constitutions of Clarendon came up for debate. The king's demands were not intrinsically irreconcilable with the canon law, and the papacy would probably have allowed them to take effect *sub silentio,* if Becket (*q.v.*) had not been goaded to extremity by persecution in the forms of law. After Becket's flight (1164), the king put himself still further in the wrong by impounding the revenues of Canterbury and banishing at one stroke a number of the archbishop's friends and connections. He showed, however, considerable dexterity in playing off the emperor against Alexander III. and Louis VII., and contrived for five years, partly by these means, partly by insincere negotiations with Becket, to stave off a papal interdict upon his dominions. When, in July 1170, he was forced by Alexander's threats to make terms with Becket, the king contrived that not a word should be said of the Constitutions. He undoubtedly hoped that in this he would have his way when Becket should be once more in England and within his grasp. For the murder of Becket (Dec. 29, 1170) the king cannot be held responsible, though the deed was suggested by his impatient words. It was a misfortune to the royal cause; and Henry was compelled to purchase the papal absolution by a complete surrender on the question of criminous clerks (1172). When he heard of the murder he was panic-stricken; and his expedition to Ireland (1171), although so momentous for the future, was originally a mere pretext for placing himself beyond the reach of Alexander's censures.

Becket's fate, though it supplied an excuse, was certainly not the real cause of the troubles with his sons which disturbed the king's later years (1173–1189). But Henry's misfortunes were largely of his own making. Queen Eleanor, whom he alienated by his faithlessness, stirred up her sons to rebellion; and they had grievances enough to be easily persuaded. Henry was an affectionate but a suspicious and close-handed father. The titles which he bestowed on them carried little power, and served chiefly to denote the shares of the paternal inheritance which were to be theirs after his death. The excessive favour which he showed to John, his youngest-born, was another cause of heart-burning; and Louis, the old enemy, did his utmost to foment all discords. It must, however, be remembered in Henry's favour, that the supporters of the princes, both in England and in the foreign provinces, were animated by resentment against the soundest features of the king's administration; and that, in the rebellion of 1173, he received from the English commons such hearty support that any further attempt to raise a rebellion in England was considered hopeless. Henry, like his grandfather, gained in popularity with every year of his reign. In 1183 the death of Prince Henry, the heir-apparent, while engaged in a war against his brother Richard and their father, secured a short interval of peace. But in 1184 Geoffrey of Brittany and John combined with their father's leave to make war upon Richard, now the heir-apparent. After Geoffrey's death (1186) the feud between John and Richard drove the latter into an alliance with Philip Augustus of France. The ill-success of the old king in this war aggravated the disease from which he was suffering; and his heart was broken by the discovery that John, for whose sake he had alienated Richard, was in secret league with the victorious allies. Henry died at Chinon on July 6, 1189, and was buried at Fontevraud. By Eleanor of Aquitaine the king had five sons and three daughters. His eldest son, William, died young; his other sons, Henry, Richard, Geoffrey and John, are all mentioned above. His daughters were: Matilda (1156–1189), who became the wife of Henry the Lion, duke of Saxony; Eleanor (1162–1214), who married Alphonso VIII., king of Castile; and Joanna, who, after the death of William of Sicily in 1189, became the wife of Raymund VI., count of Toulouse, having previously accompanied her brother, Richard, to Palestine. He had also three illegitimate sons: Geoffrey, archbishop of York; Morgan; and William Longsword, earl of Salisbury.

Henry's power impressed the imagination of his contemporaries, who credited him with aiming at the conquest of France and the acquisition of the imperial title. But his ambitions of conquest were comparatively moderate in his later years. He attempted to secure Maurienne and Savoy for John by a marriage-alliance, for which a treaty was signed in 1173. But the project failed through the death of the intended bride; nor did

[1] For a supposed visit in 1147, *see* J. H. Round in *English Historical Review,* v, 747.

the marriage of his third daughter, the princess Joanna (1165–1199), with William II., king of Sicily (1177) lead to English intervention in Italian politics. Henry once declined an offer of the empire, made by the opponents of Frederick Barbarossa; and he steadily supported the young Philip Augustus against the intrigues of French feudatories. The conquest of Ireland was carried out independently of his assistance, and perhaps against his wishes. He asserted his suzerainty over Scotland by the treaty of Falaise (1175), but not so stringently as to provoke Scottish hostility. This moderation was partly due to the embarrassments produced by the ecclesiastical question and the rebellions of the princes. But Henry, despite a violent and capricious temper, had a strong taste for the work of a legislator and administrator. He devoted infinite pains and thought to the reform of government both in England and Normandy. The legislation of his reign was probably in great part of his own contriving. His supervision of the law courts was close and jealous; he transacted a great amount of judicial business in his own person, even after he had formed a high court of justice which might sit without his personal presence. To these activities he devoted his scanty intervals of leisure. His government was stern; he over-rode the privileges of the baronage without regard to precedent; he persisted in keeping large districts under the arbitrary and vexatious jurisdiction of the forest-courts. But it is the general opinion of historians that he had a high sense of his responsibilities and a strong love of justice; despite the looseness of his personal morals, he commanded the affection and respect of Gilbert Foliot and Hugh of Lincoln, the most upright of the English bishops.

ORIGINAL AUTHORITIES.—Henry's laws are printed in W. Stubbs's *Select Charters* (Oxford, 1895). The chief chroniclers of his reign are William of Newburgh, Ralph de Diceto, the so-called Benedict of Peterborough, Roger of Hoveden, Robert de Torigni (or de Monte), Jordan Fantosme, Giraldus Cambrensis, Gervase of Canterbury; all printed in the Rolls Series. The biographies and letters contained in the 7 vols. of *Materials for the History of Thomas Becket* (ed. J. C. Robertson, Rolls Series, 1875–85) are valuable for the early and middle part of the reign. For Irish affairs the *Song of Dermot* (ed. Orpen, Oxford, 1892), for the rebellions of the princes the metrical *Histoire de Guillaume le Maréchal* (ed. Paul Meyer, 3 vols., Paris, 1891, etc.) are of importance. Henry's legal and administrative reforms are illustrated by the *Tractatus de legibus* attributed to Ranulph Glanville, his chief justiciar (ed. G. Phillips, Berlin, 1828); by the *Dialogus de scaccario* of Richard fitz Nigel (Oxford, 1902); the *Pipe Rolls*, printed by J. Hunter for the Record Commission (1844) and by the Pipe-Roll Society (1884, etc.) supply valuable details. The works of John of Salisbury (ed. Giles, 1848), Peter of Blois (ed. Migne), Walter Map (Camden Society, 1841, 1850) and the letters of Gilbert Foliot (ed. J. A. Giles, 1845) are useful for the social and Church history of the reign.

Hardegen, *Imperialpolitik König Heinrichs II. von England* (Heidelberg, 1905). (H. W. C. D.)

HENRY III (1207–1272), king of England, was the eldest son of King John by Isabella of Angoulême. Born on Oct. 1, 1207, the prince was but nine years old at the time of his father's death. The greater part of eastern England being in the hands of the French pretender, Louis, afterward Louis VIII, and the rebel barons, Henry was crowned at Gloucester, the western capital, on Oct. 28, 1216. John had committed his son to the protection of the Holy See; and a share in the government was accordingly allowed to the papal legares. Gualo and Pandulph, both during the civil war and for some time afterward. But the title of regent was given by the loyal barons to William Marshall, the aged earl of Pembroke (d. 1219); and Peter des Roches, the Poitevin bishop of Winchester, received the charge of the king's person. The cause of the young Henry was fully vindicated by the end of 1217. Defeated both by land and sea, the French prince renounced his pretensions and left England, leaving the regency to deal with the more difficult questions raised by the lawless insolence of the royal partisans. Henry remained a passive spectator of the measures by which Marshall and his successor, the justiciar Hubert de Burgh, asserted the royal prerogative against native barons and foreign mercenaries. In 1223, Pope Honorius III declared the king of age, but this was a mere formality, intended to justify the resumption of the royal castles and demesnes which had passed into private hands during the civil war.

The personal rule of Henry III began in Jan. 1227, when lie proclaimed himself of age. Even then he remained for some time under the influence of Hubert de Burgh, whose chief rival, Peter des Roches, found it expedient to quit the kingdom for four years. But Henry was ambitious to recover the continental possessions which his father had lost. Against the wishes of the justiciar he planned and carried out an expedition to the west of France (1230) and, when it failed, laid the blame upon his minister. Other differences arose soon afterward. Hubert was accused, with some reason, of enriching himself at the expense of the crown, and of encouraging popular riots against the alien clerks for whom the papacy was providing at the expense of the English church. He was disgraced in 1232; and power passed for a time into the hands of Peter des Roches, who filled the administration with Poitevins (Poitou having been acquired through Henry II's marriage with Eleanor of Aquitaine). So began the period of misrule by which Henry III is chiefly remembered. The Poitevins fell in 1234; they were removed at the demand of the barons and the primate Edmund Rich, who held them responsible for the tragic fate of the rebellious Richard Marshall. But the king replaced them with a new clique of servile and rapacious favourites. Disregarding the wishes of the great council, and excluding all the more important of the barons and bishops from omce, ne acted as his own chief minister and never condescended to justify his policy except when he stood in need of subsidies. When these were refused. he extorted aids from the towns, Jews or clergy. Always in straits through his extravagance, he pursued a foreign policy which would have been expensive under the most careful management. He hoped not only to regain the French possessions but to establish members of his own family as sovereigns in Italy and the empire. These plans were artfully fostered by the Savoyard kinsmen of Eleanor, daughter of Raymond Berenger, count of Provence, whom he married at Canterbury on Jan. 14, 1236, and by his half brothers, the sons of Queen Isabella and Hugo, count of la Marche. These favourites, not content with pushing their fortunes in the English court! encouraged the king in the wildest designs. In 1242 he led an expedition to Gascony which terminated disastrously with the defeat of Taillebourg; and hostilities with France were continued intermittently for 17 years. The Savoyards encouraged his natural tendency to support the, papacy against the empire; early in the period of misrule he entered into a close alliance with Rome, which resulted in heavy taxation of the clergy and gave great umbrage to the barons. A cardinal legate was sent to England at Henry's request, and during four years (1237–41) administered the English church in a manner equally profitable to the king and the pope. After the recall of the legate Otho the alliance was less open and less cordial. Still the pope continued to share the spoils of the English clergy with the king, and the king to enforce the demand; of Roman tax collectors.

Circumstances favoured Henry's schemes. Archbishop Edmund Rich was timid and inexperienced; his successor, Boniface of Savoy, was a kinsman of the queen; Robert Grosseteste, the most eminent of the bishops, died in 1253, when he was on the point of becoming a popular hero. Among the lay barons. the first place naturally belonged to Richard of Cornwall who, as the king's brother. was unwilling to take any steps which might impair the royal prerogative; while Simon de Montfort, earl of Leicester, the ablest man of his order, was regarded with suspicion as a foreigner, and linked to Henry's cause by his marriage with the princess Eleanor. Although the great council repeatedly protested against the king's misrule and extravagance, their remonstrances came to nothing for want of leaders and a clear-cut policy. But between 1248 and 1252 Henry alienated Montfort from his cause by taking the side of the Gascons, whom the earl had

provoked to rebellion through his rigorous administration of their duchy. A little later. when Montfort was committed to opposition, Henry foolishly accepted from Pope Innocent IV the crown of Sicily for his second son Edmund Crouchback (1255). Sicily was to be conquered from the Hohenstaufen at the expense of England; and Henry pledged his credit to the papacy for enormous subsidies, although years of comparative inactivity had already overwhelmed him with debts. On the publication of the ill-considered bargain the baronage at length took vigorous action. They forced upon the king the Provisions of Oxford (q v.) (1258), which placed the government in the hands of a feudal oligarchy; they reduced expenditure, expelled the alien favourites from the kingdom, and insisted upon a final renunciation of the French claims. The king submitted for the moment, but at the first opportunity endeavoured to cancel his concessions. He obtained a papal absolution from his promises; and he tricked the opposition into accepting the arbitration of the French king, Louis IX, whose verdict was a foregone conclusion. But Henry was incapable of protecting with a strong hand the rights he had recovered by his double-dealing. Ignominiously defeated by Montfort at Lewes (1264) he fell into the position of a cipher, equally despised by his opponents and supporters. He acquiesced in the earl's dictatorship; left to his eldest son, Edward, the difficult task of reorganizing the royal party; marched with the Montfortians to Evesham; and narrowly escaped sharing the fate of his jailer. After Evesham (1265) he is hardly mentioned by the chroniclers. The compromise with the surviving rebels was arranged by his son in concert with Richard of Cornwall and the legate Ottobuono; the statute of Marlborough (1267), which purchased a lasting peace by judicious concessions, was similarly arranged between Edward and the earl of Gloucester. Edward was king in all but name for some years before the death of his father, by whom he was alternately suspected and adored.

Henry had in him some of the elements of a fine character. His mind was cultivated; he was a discriminating patron of literature, and Westminster abbey is an abiding memorial of his artistic taste. His personal morality was irreproachable, except that he inherited the Plantagenet taste for crooked courses and dissimulation in political affairs. His reputation has suffered unduly at the hands of Matthew Paris, whose literary skill is only equaled by his malice. The ambitions which Henry cherished. if extravagant, were never sordid. Some of his worst actions as a politician were due to a sincere. though exaggerated, gratitude for the support which the papacy had given him during his minority. But he had neither the training nor the temper of a statesman. Many of his civil servants, such as John Mansel and Robert Waleraund, were men of great competence, but he could not control the complex administrative machine created by his predecessors. Matthew Paris said that he had a heart of wax, Dante relegated him to the limbo of ineffectual souls; and later generations have endorsed these scathing judgments.

Henry died at Westminster on Nov. 16. 1272; his widow, Eleanor, took the veil in 1276 and died at Amesbury on June 25, 1291. Their children were: the future king Edward I; Edmund, earl of Lancaster; Margaret (1240–75), wife of Alexander III, of Scotland; Beatrice; and Katherine.

(H. W C D.; N. D-Y.)

HENRY IV. (1367–1413), king of England, son of John of Gaunt, by Blanche, daughter of Henry, duke of Lancaster, was born on April 3, 1367, at Bolingbroke in Lincolnshire. As early as 1377 he is styled earl of Derby, and in 1380 he married Mary de Bohun (d. 1394) one of the co-heiresses of the last earl of Hereford. In 1387 he supported his uncle Thomas, duke of Gloucester, in his armed opposition to Richard II. and his favourites. Afterwards, probably through his father's influence, he changed sides. He was already distinguished for his knightly prowess, and for some years devoted himself to adventure. He thought of going on the crusade to Barbary; but instead, in July 1390, went to serve with the Teutonic knights in Lithuania. He came home in the following spring, but next year went again to Prussia, whence he journeyed by way of Venice to Cyprus and Jerusalem. After his return to England he sided with his father and the king against Gloucester, and in 1397 was made duke of Hereford. In Jan. 1398 he quarrelled with the duke of Norfolk, who charged him with treason. The dispute was to have been decided in the lists at Coventry in September; but at the last moment Richard intervened and banished them both.

When John of Gaunt died in Feb. 1399 Richard, contrary to his promise, confiscated the estates of Lancaster. Henry then felt himself free, and made friends with the exiled Arundels. Early in July, whilst Richard was absent in Ireland, he landed at Ravenspur in Yorkshire. He was at once joined by the Percies; and Richard, abandoned by his friends, surrendered at Flint on Aug. 19. On Richard's abdication Henry claimed the crown by right of blood from King Henry III., and through his right to recover the realm which was in point to be undone for default of governance and good law. Parliament formally accepted him, and thus Henry became king, "not so much by title of blood as by popular election" (Capgrave). The new dynasty had consequently a constitutional basis. But though the revolution of 1399 was popular in form, its success was due to an oligarchical faction. From the start Henry was embarrassed by the power and pretensions of the Percies. Nor was his hereditary title so good as that of the Mortimers. To domestic troubles was added the complication of disputes with Scotland and France. The first danger came from the friends of Richard, who plotted prematurely, and were crushed in Jan. 1400. During the summer of 1400 Henry made a not over-successful expedition to Scotland. The French court would not accept his overtures, but in the summer of 1401 a truce was patched up by the restoration of Richard's child-queen, Isabella of Valois. Meantime in 1400 and again in each of the two following autumns Henry tried in vain to subdue the revolt of Owen Glendower (*q.v.*). The success of the Percies over the Scots at Homildon Hill (Sept. 1402) was no advantage. Henry Percy (Hotspur) and his father, the earl of Northumberland, thought their services ill-requited, and finally made common cause with the partisans of Mortimer and the Welsh. The plot was frustrated by Hotspur's defeat at Shrewsbury (July 21, 1403); and Northumberland for the time submitted. Henry had, however, no one on whom he could rely outside his own family, except Archbishop Arundel. The Welsh were unsubdued; the French were plundering the southern coast; Northumberland was fomenting trouble in the north. In 1405 a plot to carry off the young Mortimers was defeated; but Mowbray, the earl marshal, who had been privy to it, raised a rebellion in the north supported by Archbishop Scrope of York. Mowbray and Scrope were taken and beheaded; Northumberland escaped into Scotland. For the execution of the archbishop Henry was personally responsible, and he could never free himself from its odium. Popular belief regarded his subsequent illness as a judgment for his impiety. Apart from ill-health and unpopularity Henry had succeeded—relations with Scotland were secured by the capture of James, the heir to the crown; Northumberland was at last crushed at Bramham Moor (Feb. 1408); and a little later the Welsh revolt was mastered.

Henry, stricken with sore disease, was unable to reap the advantage. His necessities had all along enabled the Commons to extort concessions in parliament, until in 1406 he was forced to nominate a council and govern by its advice. However, with Archbishop Arundel as his chancellor, Henry still controlled the government. But in Jan. 1410 Arundel had to give way to the king's half-brother, Thomas Beaufort. Beaufort and his brother Henry, bishop of Winchester, were opposed to Arundel and supported by the prince of Wales. For two years the real government rested with the prince and the council. Under the prince's influence the English intervened in France in 1411 on the side of Burgundy. In this, and in some matters of home politics, the king disagreed with his ministers. There is good reason to suppose that the Beauforts had gone so far as to contemplate a forced abdication on the score of the king's ill-health. However, in Nov. 1411 Henry showed that he was still capable of vigorous action by discharging the prince and his supporters. Arundel again became chancellor, and the king's second son, Thomas, took his brother's place. The change was further marked by the sending of an expedition to France in support of Orleans. But Henry's health was failing steadily. On March 20, 1413, whilst praying in Westminster Abbey he was seized with a fainting fit, and died that same evening in the Jerusalem Chamber. He was buried at Canterbury.

By Mary de Bohun Henry had four sons: his successor Henry V., Thomas, duke of Clarence, John, duke of Bedford, and Humphrey, duke of Gloucester; and two daughters, Blanche, who married Louis III., elector palatine of the Rhine, and Philippa, who married Eric XIII., king of Sweden. Henry's second wife was Joan, or Joanna (c. 1370–1437), daughter of Charles the Bad, king of Navarre, and widow of John IV. or V., duke of Brittany, who survived until July 1437. By her he had no children.

BIBLIOGRAPHY.—The chief contemporary authorities are the *Annales Henrici Quarti* and T. Walsingham's *Historia Anglicana* (Rolls Series), Adam of Usk's *Chronicle* and the various *Chronicles of London*. The life by John Capgrave (*De illustribus Henricis*) is of little value. Some personal matter is contained in *Wardrobe Acrounts of Henry, Earl of Derby* (Camden Soc.). For documents consult T. Rymer's *Foedera;* Sir N. H. Nicolas, *Proceedings and Ordinances of the Privy Council;* Sir H. Ellis, *Original Letters illustrative of English History* (1825–46); *Rolls of Parliament; Royal and Historical Letters, Henry IV.* (Rolls Series) and the *Calendars of Patent Rolls*. Of modern authorities the foremost is J. H. Wylie's minute and learned *Hist. of England under Henry IV.* (4 vols., 1884–1898). See also W. Stubbs, *Constitutional History;* Sir J. Ramsay, *Lancaster and York* (2 vols., Oxford, 1892), and C. W. C. Oman, *The Political History of England*, vol. iv.

(C. L. K.)

HENRY V. (1387–1422), king of England, son of Henry IV. by Mary de Bohun, was born at Monmouth, in Aug. 1387. On his father's exile in 1398 Richard II. took the boy into his own charge, and treated him kindly. Next year the Lancastrian revolution forced Henry into precocious prominence as heir to the throne. From Oct. 1400 the administration of Wales was conducted in his name; less than three years later he was in actual command of the English forces and fought against the Percies at Shrewsbury. The Welsh revolt absorbed his energies till 1408. Then through the king's ill-health he began to take a wider share in politics. (See HENRY IV.) In Nov. 1411 the king discharged the prince from the council. The quarrel of father and son was political only. It may be to that political enmity that the tradition of Henry's riotous youth, immortalized by Shakespeare, is partly due. To that tradition Henry's strenuous life in war and politics is a sufficient general contradiction. The most famous incident, his quarrel with the chief-justice, has no contemporary authority and was first related by Sir Thomas Elyot in 1531. The story of Falstaff originated partly in Henry's early friendship for Oldcastle (*q.v.*). That friendship, and the prince's political opposition to Archbishop Arundel, perhaps encouraged Lollard hopes. If so, their disappointment may account for the statements of ecclesiastical writers, like Walsingham, that Henry on becoming king was changed suddenly into a new man.

Henry succeeded his father on March 20, 1413. He had to deal with three main problems—the restoration of domestic peace, the healing of schism in the Church and the recovery of English prestige in Europe. Henry grasped them all together, and gradually built upon them a yet wider policy. From the first he made it clear that past differences were to be forgotten. Richard II. was honourably re-interred; the young Mortimer was taken into favour; the heirs of those whc had suffered in the last reign were restored gradually to their titles and estates. With Oldcastle Henry used his personal influence in vain, and the gravest domestic danger was Lollard discontent. But the king's firmness nipped the movement in the bud (Jan. 1414), and made his own position as ruler secure. Save for the abortive Scrope and Cambridge plot in favour of Mortimer in July 1415, the rest of his reign was free from serious trouble at home.

Henry could now turn his attention to foreign affairs. Old commercial disputes and the support which the French had lent to Glendower gave a pretext for war with France. The campaign of 1415, with its brilliant conclusion at Agincourt (Oct. 25), was only the first step. Two years of patient preparation followed. The command of the sea was secured by driving the Genoese allies of the French out of the Channel. A successful diplomacy detached the emperor Sigismund from France, and by the Treaty of Canterbury paved the way to end the schism in the Church. In 1417 the war was renewed on a larger scale. Lower Normandy was quickly conquered, Rouen cut off from Paris and besieged. The French were paralysed by the disputes of Burgundians and Armagnacs. Henry skilfully played them off one against the other, without relaxing his warlike energy. In Jan. 1419 Rouen fell. By August the English were outside the walls of Paris. The intrigues of the French parties culminated in the assassination of John of Burgundy by the dauphin's partisans at Montereau (Sept. 10, 1419). Philip, the new duke, and the French court threw themselves into Henry's arms. After six months' negotiation Henry was, by the Treaty of Troyes, recognized as heir and regent of France, and on June 2, 1420, married Catherine, the king's daughter. He was now at the height of his power. His eventual success in France seemed certain. He shared with Sigismund the credit of having ended the Great Schism by obtaining the election of Pope Martin V. All the states of western Europe were being brought within the web of his diplomacy. The headship of Christendom was in his grasp, and schemes for a new crusade began to take shape. He actually sent an envoy to collect information in the East; but his plans were cut short by death. A visit to England in 1421 was interrupted by the defeat of Clarence at Baugé. The hardships of the longer winter siege of Meaux broke down his health, and he died at Bois de Vincennes on Aug. 3, 1422.

Henry's last words were a wish that he might live to rebuild the walls of Jerusalem. They are significant. His ideal was founded consciously on the models of Arthur and Godfrey as national king and leader of Christendom. So he is the typical mediaeval hero. For that very reason his schemes were doomed to end in disaster, since the time was come for a new departure. Yet he was not reactionary. His policy was constructive: a firm central government supported by parliament; church reform on conservative lines; commercial development; and the maintenance of national prestige. His aims in some respects anticipated those of his Tudor successors, but he would have accomplished them on mediaeval lines as a constitutional ruler. His success was due to the power of his personality. He could train able lieutenants, but at his death there was no one who could take his place as leader. War, diplomacy and civil administration were all dependent on his guidance. His dazzling achievements as a general have obscured his more sober qualities as a ruler, and even the sound strategy, with which he aimed to be master of the narrow seas. If he was not the founder of the English navy he was one of the first to realize its true importance. Henry had so high a sense of his own rights that he was merciless to disloyalty. But he was scrupulous of the rights of others, and it was his eager desire to further the cause of justice that impressed his French contemporaries. He has been charged with cruelty as a religious persecutor; but in fact he had as prince opposed the harsh policy of Archbishop Arundel, and as king sanctioned a more moderate course. Lollard executions during his reign had more often a political than a religious reason. To be just with sternness was in

his eyes a duty. In his personal conduct Henry was chaste, temperate and sincerely pious. He delighted in sport and all manly exercises. He was cultured with a taste for literature, art and music. Henry lies buried in Westminster Abbey. His tomb was stripped of its splendid adornment during the Reformation. The shield, helmet and saddle, which formed part of the original funeral equipment, still hang above it.

BIBLIOGRAPHY.—Of original authorities the best on the English side is the ***Gesta Henrici Quinti*** (down to 1416), printed anonymously for the English Historical Society, but probably written by Thomas Elmham, one of Henry's chaplains. Two lives edited by Thomas Hearne under the names of Elmham and Titus Livius Forojuliensis come from a common source; the longer, which Hearne ascribed incorrectly to Elmham, is perhaps the original work of Livius, who was an Italian in the service of Humphrey of Gloucester, and wrote about 1440. Other authorities are the Chronicles of Walsingham and Otterbourne the ***English Chronicle*** or ***Brut,*** and the various ***London Chronicles.*** On the French side the most valuable are Chronicles of Monstrelet and St. Rémy (both Burgundian) and the ***Chronique du religieux de S. Denys*** (the official view of the French court). For documents and modern authorities ***see*** under HENRY IV. ***See*** also C. ***L.*** Kingsford, ***Henry*** V., ***the Typical Mediaeval Hero*** (New York, 1901); and J. H. Wylie, ***The Reign of Henry V.*** (2 vols. 1914–19).

HENRY VI. (1421–1471), king of England, son of Henry V. and Catherine of Valois, was born at Windsor on Dec. 6, 1421. He became king of England on Sept. 1, 1422, and a few weeks later, on the death of his grandfather Charles VI., was proclaimed king of France also. Henry V. had directed that Richard Beauchamp, earl of Warwick (*q.v.*), should be his son's preceptor. As early as 1423 the baby king was made to appear at public functions and take his place in parliament. He was knighted by his uncle Bedford at Leicester in May 1426, and on Nov. 6, 1429, was crowned at Westminster. Early in the next year he was taken over to France, and after long delay crowned in Paris on Dec. 16, 1431. His return to London Feb. 14, 1432 was celebrated with a great pageant devised by Lydgate.

During these early years Bedford ruled France wisely and at first with success, but he could not prevent the mischief which Humphrey of Gloucester caused both at home and abroad. Even in France the English lost ground steadily after the victory of Joan of Arc before Orleans in 1429. The climax came with the death of Bedford, and defection of Philip of Burgundy in 1435. This closed the first phase of Henry's reign. There followed 15 years of vain struggle in France, and growing disorder at home. The determining factor in politics was the conduct of the war. Cardinal Beaufort, and after him Suffolk, sought by working for peace to secure at least Guienne and Normandy. Gloucester courted popularity by opposing them throughout; with him was Richard of York, who stood next in succession to the crown. Beaufort controlled the council, and it was under his guidance that the king began to take part in the government. Thus it was natural that as Henry grew to manhood he seconded heartily the unpopular and difficult peace policy. Henry was unfortunate in his advisers. The cardinal was old, his nephews John and Edmund Beaufort were incompetent, Suffolk was tactless. Suffolk, however, achieved a great success by negotiating the marriage of Henry to Margaret of Anjou (*q.v.*) in 1445. Humphrey of Gloucester and Cardinal Beaufort both died early in 1447. Suffolk was now all-powerful in the favour of the king and queen. But his home administration was unpopular, whilst the incapacity of Edmund Beaufort ended in the loss of all Normandy and Guienne. Suffolk's fall in 1450 left Richard of York the foremost man in England. Henry's reign then entered on its last phase of dynastic struggle. Cade's rebellion suggested first that popular discontent might result in a change of rulers. But York, as heir to the throne, could bide his time. The situation was altered by the mental derangement of the king, and the birth of his son in 1453. York after a struggle secured the protectorship, and for the next year ruled England. Then Henry was restored to sanity, and the queen and Edmund Beaufort, now duke of Somerset, to power. Open war followed (see ROSES, WARS OF THE), with the defeat and death of Somerset at St. Albans on May 22, 1455. Nevertheless a hollow peace was patched up, which continued during four years with lack of all governance. In 1459 war broke out again. On July 10, 1460 Henry was taken prisoner at Northampton, and forced to acknowledge York as heir, to the exclusion of his own son. Richard of York's death at Wakefield (Dec. 29, 1460), and the queen's victory at St. Albans (Feb. 17, 1461), brought Henry his freedom and no more. Edward of York had himself proclaimed king, and by his decisive victory at Towton on March 29, put an end to Henry's reign. For over three years Henry was a fugitive in Scotland. He returned to take part in an abortive rising in 1464. A year later he was captured in the north, and brought a prisoner to the Tower. For six months in 1470–1471 he emerged to hold a shadowy kingship as Warwick's puppet. Edward's final victory at Tewkesbury was followed by Henry's death on May 21, 1471, certainly by violence, perhaps at the hands of Richard of Gloucester.

Henry was the most hapless of monarchs. He was so honest and well-meaning that he might have made a good ruler in quiet times. But he was crushed by the burden of his inheritance. He had not the genius to find a way out of the French entanglement or the skill to steer a constitutional monarchy between rival factions. Henry's very virtues added to his difficulties. He was so trusting that any one could influence him, so faithful that he would not give up a minister who had become impossible. Thus even in the middle period he had no real control of the Government. Religious observances and study were his chief occupations. For education he was really zealous. The planning of his great foundations at Eton (1440) and King's college, Cambridge (1441), was the one thing which absorbed his interest. To both he was more than a royal founder, and the credit of the whole scheme belongs to him.

Henry's only son was Edward, Prince of Wales (1453–1471), who, having shared the many journeys and varying fortunes of his mother, Margaret, was killed after the battle of Tewkesbury (May 4, 1471) by some noblemen in attendance on Edward IV.

BIBLIOGRAPHY.—There is a life of Henry by his chaplain John Blakman (printed at the end of Hearne's edition of Otterbourne); but it is concerned only with his piety and patience in adversity. English chronicles for the reign are scanty; the best are the ***Chronicles of London*** (ed. ***C. L.*** Kingsford), with the analogous ***Gregory's Chronicle*** (ed. J. Gairdner for Camden Soc.) and ***Chronicle of London*** (ed. Sir H. N. Nicolas). ***The Paston Letters,*** with James Gairdner's valuable introductions, are indispensable. Other useful authorities are Joseph Stevenson's ***Letters and Papers illustrative of the Wars of the English in France during the Reign of Henry VI.;*** and ***Correspondence of*** T. ***Bekynton*** (both ***in*** the "Rolls" series). For the French war the chief sources are the ***Chronicles*** of Monstrelet, D'Escouchy and T. Basin. For other documents and modern authorities ***see*** under HENRY IV. For Henry's foundations ***see*** Sir H. ***C.*** Maxwell-Lyte, ***History*** of ***Eton College*** (1899), and J. B. Mullinger, ***History of the University of Cambridge*** (1888). (C. L. K.)

HENRY VII (1457–1509), king of England, son of Edmund Tudor, earl of Richmond, and Margaret Beaufort, only daughter of John, duke of Somerset, was born at Pembroke castle on Jan. 28, 1457, two months after his father's death. His father was half-brother of Henry VI, being the son of Owen Tudor. who had married Catherine, daughter of Charles VI of France and widow of Henry V of England. His mother was the granddaughter of John of Beaufort, duke of Somerset, son of John of Gaunt, duke of Lancaster, and Catherine Swinford. John Beaufort had been born before his parents' marriage but legitimated by act of parliament under Richard II. This legitimation was confirmed by a patent of Henry IV which, however, professed to exclude the Beauforts from the succession to the throne. Henry of Richmond's fortunes were thus bound up from birth with the fortunes of the Lancastrian party in the Wars of the Roses. Until he was 11 he lived in Wales under the protection of his uncle, Jasper Tudor, earl of Pembroke. Then with the surrender of Harlech castle, the last Lancastrian stronghold, in 1468, he fell into the hands of the Yorkist William, Lord Herbert, until the brief restoration of Henry VI in 1470 restored him to Jasper's care. Next year the murders of Henry VI and Prince Edward, after the Yorkist triumph at Tewkesbury, left him head of the house of Lancaster. He was still a mere boy, and his claim was weakened by the fact that few—apparently not even he himself—knew that the clause in Henry IV's patent barring the Beauforts from the throne was an interpolation not found in the original act legitimating them, Nevertheless, the

final victory of Edward IV (May 4, 1471) made England, and even Wales, unsafe for him, and his uncle took him to Brittany. Duke Francis II readily gave him asylum. and there he remained until the usurpation of Richard III split the I orkist party and at length opened the way for new attempts to assert the Lancastrian claim.

The first attempt, in 1483, was planned in concert with the duke of Buckingham's rebellion *(see* BUCKINGHAM, HENRY STAFFORD, 2nd duke of), but failed. largely because of bad weather. But the conspiracy continued. The coalition betu-een Lancastrians and malcontent Yorkists was confirmed by Henry's sworn undertaking to marry Elizabeth of York. eldest daughter and (since the murder of her tno young brothers) heiress of Edward IV. On the basis of this coalition and with French support, Henry in 1485 tried again and, thanks largely to the Stanleys' desertion to him, succeeded in defeating and slaying Richard at Bosworth on Aug 22 *(see* BOSWORTH FIELD, BATTLE OF). After his coronation (Oct. 30). followed by formal recognition from parliament, had manifested his claim to be king in his own right. he fulfilled his bargain with his Yorkist allies by marrying Elizabeth on Jan. 18. 1486.

Opposition from Yorkists who had adhered to Richard III was, however, by no rneans at an end. They were hampered by lack of a suitable claimant, for Henry, besides marrying Elizabeth, had imprisoned the boy Edmard, earl of Warwick, the duke of Clarence's son. Nevertheless, they could always rely upon support from the dowager duchess of Burgundy, Edward IV's sister Margaret; they could hope for ready help from Yorkist Ireland; and they knew that France and Scotland were not eager to see Henry VII or any English king, too firmly settled upon his throne. With the iorces that such sympathizers might provide, the malcontents could still hope to succeed in an England grown weary of wars and inclined to stand by until the issue of the first battle clearly indicated the probable victor. So, ior 12 years after Bosworth, Henry was troubled and sometimes endangered by Yorkish conspiracies. The ill-concerted and aimless rising of Lord Lovell and the young Staffords in 1486 was dangerous only because it took Henry by surprise. But more threatening plots mere then organized around the impostors Lambert Simnel, who impersonated Warwick, in 1487, and Perkin Warbeck, who impersonated Richard of York, the younger oi the princes in the Tower, between 1492 and 1497. Simnel was partly financed by Margaret of Burgundy; John de la Pole, earl of Lincoln, whom Richard III had named as his heir, deserted Henry to join him; Ireland welcomed him as king; the queen dowager was apparently suspected of a hand in the plot; and Simnel's invasion of England was defeated only after three hours' hard fighting at Stoke (June 16).

Warbeck iound still wider support abroad, at first probably from France, then in the Netherlands from the regent Maximilian, as well as irom Margaret, and finally from James IV of Scotland. Thanks to Sir Edward Poynings' work as lord deputy, Ireland would not declare for him as it had ior Simnel, and the execution of Sir William Stanley damped any English ardour in his cause. Yet for five years he gravely complicated Henry's foreign policy even if he never seriously menaced his throne. Warbeck's execution, along with the uniortunate Warwick, in 1499 seems to have been part of the price paid by Henry for cementing his alliance with Spain by the marriage of his eldest son, Arthur, to Catherine of Aragon. For hitherto he had been surprisingly lenient toward pretenders and had made their supporters pay for their rebellions more often with their property than with their lives. At all events, aiter 1497 there were no more Yorkist insurrections, though the activities of the younger De la Poles occasionally troubled Henry's mind and even deflected his policy.

Henry, however, was not content merely to detect conspiracies and suppress rebellions. He sought also to remedy the weaknesses in government that made such things possible; to give strength to royal justice, authority and efficiency to royal administration, and above all riches to the royal coffers. He was not afraid to choose able men to serve him; and generally they served him well, for powerful as his councillors became, they drew their power from him and he remained always their master. Among them were noblemen such as the earls of Derby, Surrey and Oxford; but he trusted most ecclesiastics such as Archbishop John Morton, his lord chancellor, and Bishop Richard Fox, his lord privy seal, or officials of middling fortune such as Reginald Bray, Thomas Lovell and later Richard Empson and Edmund Dudley. The power of the council to deal promptly and efficiently with riot and unlawful practices such as maintenance were reasserted by the so-called Star Chamber act of 1487. By that act and in other ways special responsibility was placed upon particular councillors for particular aspects of the council's work; groups of councillor mere again, as in Yorkist times, sent to York and Ludlow to invigorate royal authority in the north and in the Welsh marches; and a series of measures placed new responsibilities upon the local justices of the peace, while at the same time bringing them more closely under the council's control It is not possible to say how far these improvements in justice and administration were Henry's own idea and how far they originated uith his councillors. However, it may be said at least that their effectiveness was attributable not to any intrinsic novelty but to the persistence with which they were applied, and ior that the credit must go chiefly to the king himself.

In the work of enriching the royal coffers, on the other hand, it is clear that Henry took a detailed and constant interest. That enrichment came quite as much from careful administration as from spectacular measures such as the Act of Resumption of 1485 And Henry's hand is constantly apparent in the development of speedier, less iormal methods of receiving and issuing money and of auditing accounts that grew up outside the old exchequer around the treasurer of the chamber and the general surveyors He himself audited the treasurer's books almost daily and exercised a direct control in matters of finance which none of his predecessors had equalled and none of his successors was to imitate Yet here again there was no great novelty in the methods used. Success was chiefly attributable to the king's own persistent application to business The success was remarkable By 1490 Henry had become a lender rather than a borrower; after 1497 he had no need oi grants from parliament; and he died one oi the richest kings in Christendom Many of his acd his ministers' devices for raising money were not popular, and Empson and Dudley in his later years aroused much resentment. Yet he knew how to appear magnificent, e\en if he was seldom generous; and his court, though modest by comparison with his son's, maintained the state expected oi a king He knew when to spend as well as how to save, but he never forgot that his power depended upon his saving and could easily he undermined by lavish spending

For this reason he avoided foreign wars. He did go to war with France early in his reign to preserve the independence oi Brittany, and when his allies, Spain and Maximilian, failed him, he made a show of invading France. But in Nov. 1492 he readily came to terms, wisely preferring to leave the French in Brittany rather. than overstrain his resources by renewing the Hundred Years' War. The preoccupation of the French with the Italian wars made friendly relations possible thereafter, but the activities of Perkin Warbeck and fear lest French ambition might turn back toward Flanders prevented Henry from relapsing into an isolationist policy. The support which first Maximilian and then James IV gave to Warbeck led to sharp quarrels with the Netherlands and Scotland. By economic measures Henry was able to induce Maximilian and the Netherlands government to abandon the pretender and make a treaty of peace and friendship in 1496. This, and the alliance with Spain which he had made in 1489, gave him an insurance not only against continental support of Yorkist conspiracies but also against any revival of French designs upon Flanders. He was thus able to concentrate upon Scotland and by threats oi war combined with generous offers to obtain in 1499 a peace which was consolidated in 1503 by the marriage of his eldest daughter, Margaret, to James IV. The marriage of his eldest son, Arthur, to Catherine of Aragon in 1501 seemed to set the seal of success on his ioreign policy. The death of Arthur (1502) and of Catherine's mother, Isabelia of Castile (1504), with the resultant rivalry for control of Castile between her father, Ferdinand of Aragon, and her brother-in-law the archduke Philip of Burgundy, jeopardized Henry's system oi alliances and involved him in new and sometimes strange combinations. Yet, as the rivalry oi the powers oi Europe remained centred upon Italy, he could still avoid any deep commitments. Indeed, the skill with which he had all along taken advantage oi thi's situation to give England a breathing space from foreign wars was in no small measure responsible ior his success in rebuilding the strength of the monarchy at home. The success was all the greater because, when dynastic interests did not overrule it, he used his diplomacy vigorously to further the prosperity of English overseas trade. For, as Francis Bacon wrote of him, "he could not endure to see trade sick."

He was, indeed, to quote Bacon again, "a wonder for wise men." The judicious moderation of his policies at home and abroad, his grasp oi essentials and his persistence in concentrating upon them made him perhaps the greatest, if also the least heroic, of the Tudor sovereigns. He had the presence and personality to command respect; he chose his servants wisely and was notably well served. He had a pleasantly sardonic humour and though cool-headed was not cold-blooded. He lacked the popular appeal of a bluff king Henry VIII or an artful Elizabeth I, but he possessed in full measure the solid virtues that his times required.

Gairdner, *Henry VII* (London, 1889); G. Temperley, *Henry VII* (London, 1914); J. D. Mackie, *The Earlier Tudors* (Oxford, 1951); G. R. Elton, *England Cnder the Tudors* (London, 195j). (R. B. WM.)

HENRY VIII (1491–1547), king of England and Ireland, the third child and second son of Henry VII and Elizabeth of York, was born at Greenwich on June 28. 1491. He was the first English monarch to be educated under the influence of the Renaissance, and his tutors included the poet John Skelton. He became an accom-

plished scholar, linguist, musician and athlete. The death of his elder brother, Arthur, in 1502 made him heir apparent, and in 1503 he mas betrothed to Arthur's widow, Catherine of Aragon. His father, however, delayed the marriage and even made him enter a protest against it, while some doubts were expressed about its validity in canon law *(see* ENGLISH HISTORY). Nevertheless one of Henry VIII's earliest acts after his accession (April 22, 1509) was to marry Catherine.

The young king at first displayed little of his father's application to business, and for two years and more affairs were managed by the pacific Richard Fox and Archbishop William Warham. Yet, although preoccupied with sport and other amusements. he showed a keen interest in learning and in the navy, while his inborn pride and thirst for fame soon made him listen to the warlike counsels of his father-in-law, Ferdinand of Aragon, and of his almoner Thomas Wolsey. In Nov. 1511 he committed himself to a, policy of war with France and in 1513 crossed the channel with an army and took part in the successful sieges of Thérouanne and Tournai and in the battle of Guinegate. Then. deserted by Ferdinand. he made peace with Louis XII. who married his sister Mary (1514). It was even reported from Paris that he would divorce Catherine, whose issue had so far been attended with fatal misfortune, and take a French wife. It seems unlikely that he had in fact yet thought of such a course, and, in any case, the renewed antagonism between England and France upon the accession of Francis I (1515) led to a *rapprochement* with Ferdinand, while the birth of Princess Mary to Catherine (1516) held out hopes of the male issue which Henry so much desired. Rforeover, Ferdinand died in 1516 and the emperor Maximilian in 1519. Their grandson Charles V succeeded .them both in all their realms and dignities, in spite of Henry's hardly serious candidature for the empire; and a lifelong rivalry broke out between Charles and Francis. Both monarchs courted England's favour in 1520, Francis at the Field of Cloth of Gold and Charles more quietly in Kent. At the conference of Calais in 1521 English influence reached its zenith. but the resulting alliance with Charles destroyed the balance on which that influence depended. Charles. sure of English help, concentrated his efforts on Italy, while English campaigns in northern France, lacking adequate imperial support. bore little fruit. Parliament's refusal of Wolsey's demands for money (1523) put an end to these campaigns and drove Henry into underhand negotiations with France (1524). Nevertheless Francis was overweighted by the Anglo-imperial alliance, and his defeat at Pavia (1525) left the emperor supreme. Henry at once urged Charles to join him in partitioning France. However, violent popular resistance to the "amicable grant," which Henry demanded from his subjects in order to prosecute the war against France, again prevented any English invasion of France, and Charles, satisfied with his victory, not only rejected the English proposals but also asked to be released from his promise, made in 1521, to marry Princess Mary.

This brought the question of the succession to the fore and gave Henry an urgent personal interest in politics. He had shown. at least as early as 1519, his anxiety about his lack of a son. and each succeeding year made it more certain that he could not hope for more children by Catherine. There was. of course. Mary; hut no queen regnant had yet ruled in England. Margaret Beaufort had been passed over in favour of her son in 1485 and there was a popular impression that women were excluded from the throne. Mary's marriage to the emperor might have solved the problem, but now that Charles had broken his engagement. her accession (or that of any other living candidate) seemed likely to mean a recurrence of civil war. Henry's first reaction (1525) was to bring out of obscurity his only illegitimate son. create him duke of Richmond and Somerset and give him precedence over Mary. Soon, however, he adopted a more drastic policy. The unexampled fatality which had attended his issue revived the theological scruples about his marriage to Catherine; the quarrel with Charles sharpened them; and all these considerations were magnified by Henry's passion for Anne Boleyn, though she nas not the sole or the main cause of the divorce. That the succession was the main point is proved by the fact that Henry's efforts were all directed to securing a wife and not a mistress. Wolsey persuaded him that the necessary divorce could be obtained irom Rome, as it had been in the cases of Louis XII of France and Margaret of Scotland. A French alliance was made, to increase the pressure on the pope; for a time Clement VII seemed inclined to concede the demand, and in 1528 Lorenzo Cardinal Campeggio mas given ample powers to try the case in England. But the prospect of French success in Italy, which had encouraged the pope, proved delusive, and in 1529 he had to submit to the emperor's yoke. This made it difficult for him to grant the divorce, for Charles mould not readily allow the casting aside oi his aunt, the disinheriting oi his cousin and perhaps the eventual succession of the son of a French princess to the English throne. Campeggio was therefore recalled in July 1529.

Wolsey fell when Campeggio was recalled, and his iall meant the triumph of the antiecclesiastical party in England (see WOLSEY, THOMAS). Laymen who had resented their exclusion irom power mere now promoted to offices such as those oi lord chancellor and lord privy seal which they had rarely held beiore, and parliament was encouraged to propound lay grievances against the church. Henry relied on the support of the laity to abolish papal jurisdiction and reduce clerical privilege and property in England. and by a close alliance with Francis I he insured himself against the enmity of Charles V. But it was only gradually that the breach with Rome was completed. Henry had defended the papacy against Luther in 1521 and had received in return the title "deiender oi the faith." He never liked Protestantism, and he was prepared ior peace with Rome on his own terms. Those terms were impossible of acceptance by a pope in Clement VII's position, but beiore Clement had made up his mind to reject them, Henry had discovered that the papacy was hardly worth conciliating. His eyes mere opened to the extent of his own power as the exponent of national antipathy to papal jurisdiction and ecclesiastical privilege, and his appetite ior power grew. With Thomas Cromwell's help he secured parliamentary support, and its useiulness led him to extend parliamentary representation to Wales and Calais, to defend the privileges of parliament and to yield rather than forfeit its confidence (see CROMWELL, THOMAS). He had little difficulty in securing the Acts of Annates, Appeals and Supremacy which completed the separation irom Rome, or the dissolution of the monasteries, which, by transferring enormous wealth irom the church to the crown, really, in Cecil's opinion, ensured the reformation (*see* ENGLISH HISTORY).

The abolition of the papal jurisdiction removed all obstacles to the divorce irom Catherine and to the legalization oi Henry's marriage with Anne Boleyn (1533). But the recognition of the royal supremacy could only be enforced at the cost of the heads of Sir Thomas More, Bishop Fisher and a number of monks and others among whom the Carthusians signalized themselves by their devotion (1535–36). Anne Boleyn iared no better than the Catholic martyrs; she failed to produce a male heir to the throne, and her conduct afforded a jury of peers. over which her uncle, the duke of Noriolk, presided, sufficient excuse for condemning her to death on a charge of adultery (1536). Henry then married Jane Seymour, who was obnoxious to no one, pave birth to Edward VI, and then died (1537). The dissolution of the monasteries had meanwhile evoked a popular protest in the north, and it was only by skilful and unscrupulous diplomacy that Henry mas enabled to suppress the Pilgrimage of Grace (Feb. 1537). Foreign intervention was avoided through the renewal of mar between Francis and Charles, and the insurgents were hampered by having no rival candidate for the throne and no means of securing the execution of their program.

Nevertheless their rising warned Henry against further doctrinal charges. He had authorized the English Bible and some approach toward Protestant doctrine in the Ten Articles. He had also considered the possibility oi a political and theological alliance with the Lutheran princes of Germany. But in 1538 he definitely rejected their theological terms, while in 1539–40 they rejected his political proposals. By the Act oi Six Articles (1539) he took his stand on Catholic doctrine; and when the Lutherans had rejected his alliance, and Cromxvell's nominee, Anne of Cleves, had proved both distasteful on personal grounds and unnecessary because Charles and Francis were not really projecting a Catholic crusade against England, Anne mas divorced and Cromwell beheaded (1540). The new queen. Catherine Howard, represented the triumph oi the reactionary party under Gardiner and Noriolk; but there was no idea oi returning to the papal obedience, and even Catholic orthodoxy as represented by the Six Articles was enforced only by spasmodic outbursts of persecution.

The secular importance of Henry's activity has been somewhat obscured by his achievements in the sphere of ecclesiastical politics; but no small part of his energies was devoted to the task of expanding the royal authority at the expense of temporal competitors. Feudalism was not yet dead, and in the north and nest there were mediaeval iranchises in which the royal writ and common law hardly ran at all. Wales and its marches were brought into legal union with the rest of England by the statutes oi Wales (1534–36), and after the Pilgrimage of Grace the council of the north was reorganized to bring into subjection the extensive jurisdictions of the northern earls. Neither they nor the lesser chiefs who flourished on the lack of common law and order could be reduced by ordinary methods, and the councils of Wales and of the north mere given summary powers derived irom the Roman civil law similar to those exercised by the Star Chamber at Westminster and the court oi Castle Chamber at Dublin. Ireland had been leit by Wolsey to wallow in its own disorder; but disorder was

anathema to Henry's mind, and in 1534 Sir William Skeffington was sent to apply English methods and artillery to the government of Ireland. Sir Anthony St. Leger continued his policy irom 1540; Henry, instead of being merely lord of Ireland dependent on the pope, was made by an Irish act of parliament king and supreme head of the Irish church. Conciliation was also tried with some success; plantation schemes were rejected in favour of an attempt to Anglicize the Irish; their chieftains were created earls and endowed with monastic lands, and so peaceiul mas Ireland in 1542 that the lord deputy could send Irish kernes and gallow-glasses to fight against the Scots.

Henry, however, seems to have believed as much in the coercion of Scotland as in the conciliation of Ireland. Margaret Tudor's marriage had not reconciled the realms; and as soon as James V became a possible pawn in the hands of Charles V, Henry bethought himself of his old claims to suzerainty over Scotland. At first he was willing to subordinate them to an attempt to win over Scotland to his antipupal policy, and he made various efforts to bring about an interview with his nephew. But James V was held alooi by Cardinal Beaton and by his two French marriages; and France was alarmed by Henry's growing friendliness with Charles V, who was mollified by his cousin Mary's restoration'to her place in the .succession to the throne. In 1542 James madly sent a Scottish army to ruin at Solway Moss; his death a few weeks later left the Scottish throne to his infant daughter Mary Stuart, and Henry set to work to secure her hand ior his son Edward and the recognition of his own suzerainty. A treaty n-as signed with the Scottish estates, but it was torn up a few months later under the influence of Beaton and the queen dowager Mary of Guise, and the earl of Hertford was sent in 1544 to punish this breach of promise by sacking Edinburgh.

Perhaps to prevent French intervention in Scotland Henry joined Charles V in invading France, and captured Boulogne (Sept. 1544). Rut Charles left his ally in the lurch and concluded the peace of Crêpy that same month, and in 1545 Henry had to face alone a French invasion of the Isle oi Wight. This attack proved abortive, and peace between England and France was made in 1546. Charles V's desertion inclined Henrv to listen to the yroyosals or the threatened Lutheran princes, and the last two years of his reign were marked by a renewed tendency to advance in a Protestant direction. Catherine Howard had been brought to the block (1542) on charges in which there was probably a good deal of truth, and her successor, Catherine Parr, was a patroness of the new learning. An act oi 1545 dissolved chantries, colleges and other religious foundations, and in the autumn of 1546 the Spanish ambassador was expecting further antiecclesiastical measures. Gardiner had almost been sent to the Tower, and Norfolk and Surrey were condemned to death, while Cranmer asserted that it was Henry's intention to convert the mass into a communion service. An opportunist to the last, he would readily have sacrificed any theological convictions he may have had in the interests of national uniformity. He died on Jan. 28, 1547, and was buried in St. George's chapel, Windsor.

The atrocity of many of Henry's acts, the novelty and success of his religious policy, the apparent despotism of his methods, or all combined, have made it difficult to estimate calmly the importance of Henry's, work or the conditions which made it possible. Henry's egotism was proiound, and personal motives underlay his public action. While political and ecclesiastical conditions made the breach with Rome possible—and in the view of most Englishmen desirable—Henry VIII was led to adopt the policy by private considerations. He worked ior the good of the state because he thought his interests were bound up with those of the nation; and it was the real coincidence of this private and public point of view that made it possible for so selfish a man to achieve so much for his country. The royal supremacy over the church and the means by which it was eniorced were harsh and violent expedients, but it was of the highest importance that England should be caved irom religious civil war, and it could be saved only by a despotic government. It mas necessary for the iuture development of England that its governmental system should be centralized and unified, that the authority oi the monarchy should be more firmly extended over Wales and the western and northern borders, and that the still existing ieudal franchises should be crushed; and these objects were worth the price paid in the methods oi the Star Chamber and of the councils of the north and of Wales. Henry's work on the navy requires no apology; without it Elizabeth's victory over the Spanish Armada, the liberation of the Netherlands and thy development of English colonies would have been impossible; and "of all others the year 1545 best marks the birth of the English 'naval power" (Sir J. S. Corbett. *Drake and the Tudor Navy,* vol. i, p. 59). His judgmrnt mas more at fault when he sought by violence to bring Scotland into union with England. Rut at least Henry appreciated the necessity of union within the British Isles, and his work in Ireland relaid the foundations of English rule. No less important mas his development of the parliamentary system. Representation was extended to Wales, Cheshire, Berwick and Calais; and parliamentary authority was enhanced, largely that it might deal with the church, until men began to complain oi this new parliamentary infallibility. The privileges of the two houses mere encouraged and expanded, and parliament mas led to exercise ever wider powers. This policy was not attributable to any beliei on Henry's part in parliamentary government but to opportunism, to the circumstance that parliament was willing to do most of the things which Henry desired, while competing authorities, the church and the old nobility, were not. Nevertheless, to the encouragement given by Henry VIII parliament owed not a little of its iuture growth, and to the aid rendered by parliament Henry owed his success.

He has been described as a "despot under the forms of law"; and it is apparently true that he committed no illegal act. His despotism consists not in any attempt to rule unconstitutionally but in the extraordinary degree to which he was able to use constitutional means in the iurtherance of his own personal ends. His industry, his remarkable political insight, his lack oi scruple and his combined strength of will and subtlety of intellect enabled him to utilize all the forces which tended at that time toward strong government throughout western Europe. The monarchy alone seemed capable of guiding the state through the social and political anarchy which threatened all nations in their transition from mediaeval to modern organization. The king was the emblem, the iocus and the bond oi national unity; and to preserve unity men were ready to put up with vagaries which to other ages seem intolerable. Henry could thus behead ministers and divorce wives with comparative impunity, because the individual appeared to be of little importance compared with the state. This impunity provoked a licence which is responsible for the unlovely ieaturcs of Henry's reign and character. The elevation and the isolation of his position iostered a detachment from ordinary virtues and compassion, and he was a remorseless incarnation of Machiavelli's *Prince.* He had an elastic conscience which was always at the beck and call oi his desire, and he cared little ior principle. But he had a passion for efficiency and for the greatness of England and himself. His mind, in spite of its clinging to the outward forms of the old faith, was intensely secular, and he was as devoid of a moral sense as he was of a genuine religious temperament. His greatness consists in his practical aptitude, in his political perception and in the seli-restraint which enabled him to confine within limits tolerable to his people an insatiable appetite ior power.

BIBLIOGRAPHY.—Most of the original materials for Henry VIII's biography are incorporated in the monu'mental *Letters and Papers of the Reign of Henry VIII,* ed. by J. S. Brewer and J. Gairdner, 21 vol. (London, 1862–1910), vol. i, 2nd ed. by R. H. Brodie (London, 1920), addenda (London, 1929–32). The best biography is A. F. Pollard, *Henry VIII* (London, 1902 and 1905). *See* also H. A. L. Fisher, *Political History of England, 1485–1547* (London, 1906); J. D. Mackie, *Early Tudors* (Oxford. 1952); J. .4. Froude, *History of England,* 12 vol. (London, 1862–70, etc.); A. F. Pollard, *Wolsey* (London, 1929) and *Cranmer* (London, 1904); G. Mattingley, *Catherine of Aragon* (London, 1942); G. Constant, *Reformation* in *England; Henry VIII* (London, 1936); G. R. Elton, *The Tudor Revolution in Government* (Cambridge, 1952); Conyers Read, *Bibliography of English History: Tudor Period* (Oxford, 1933).

Of the numerous paintings of Henry none is by Holbein, who, however, executed the striking chalk drawing of Henry's head, now at Lugano, and the famous but decaying cartoon at Chatsworth. The well-known three-quarter length at Windsor usually attributed to Holbein is by an inferior artist. Several good portraits are reproduced in the 1902 edition of A. F. Pollard's *Henry VIII.* Henry composed numerous state papers still extant; his only book was his *Assertio septem sacramentorum contra M. Lutherum* (1521), a copy of which, signed by Henry himself, is at Windsor. His songs and ballads were edited (London, 1912) by Lady M. Trefusis for the Roxburghe club. (A. F. Po.; R. B. WM.)

HENRY I (1008–1060), king of France, son of King Robert and his queen, Constance of Aquitaine, and grandson of Hugh Capet, succeeded his father in 1031, although in 1027 he had already been anointed king at Reims and associated in the government with his father. His mother formed a powerful league with her younger son. Robert, against him, and he was forced to take refuge with Robert II, duke of Normandy. In the civil war which resulted. Henry finally defeated his opponents in 1032. Constance died in 1034, and Robert was given the duchy of Burgundy, thus founding that great collateral line which was to rival the kings of France for three centuries. From 1033 to 1043 Henry was involved in a life and death contest with those nobles whose territory adioined the roval domains. especiallv with the house of Blois and the counts of Champagne. Henry's success was largely attributable to the help given him by Robert of Normandy, but upon the accession of Robert's son William (the Conqueror), Normandy itself became the chief danger. From 1047 until his death Henry was almost constantly at war with William. Henry's reign marks the height of feudalism. Normandy, Champagne and Burgundy being only nominally subject to royal authority. Yet Henry maintained the independence of the clergy against the pope Leo IX, and claimed Lorraine from the emperor Henry III. In 1059 he had his eldest son Philip crowned as joint king, and died the following year. Henry married in 1043 Maud, niece of the emperor Henry III, who died childless in 1044. In 1051 Henry married the Rus-

sian princess Anne, daughter of Yaroslav I., grand duke of Kiev. She bore him two sons, Philip, his successor, and Hugh, count of Vermandois.

Sochnée, *Catalogue des actes d'Henri Ier* (1907); de Caiz de Saint Aymour, *Anne de Russie, reine de France* (1896); *E.* Lavisse, *Histoire de France,* tome ii. (1901), and the article on Henry I. in *La Grande Encyclopédie* by *M.* Prou.

HENRY II. (1519–1559), king of France, the second son of Francis I. and Claude, succeeded to the throne in 1547. When only seven years old he was sent by his father, with his brother the dauphin Francis, as a hostage to Spain in 1526, whence they returned after the conclusion of the peace of Cambrai in 1530. Henry was perhaps young to have carried away abiding impressions, yet throughout his life his character, dress and bearing were far more Spanish than French. In 1533 his father married him to Catherine de' Medici, and he became dauphin by the death of his elder brother Francis in 1536. From that time he was under the domination of Catherine, of Diane de Poitiers, and also of Duke Anne de Montmorency, his mentor. His younger brother, Charles of Orleans, was his father's favourite; and the rivalry of Diane and the duchesse d'fitampes widened the breach between the king and the dauphin. Henry supported the constable Montmorency when he was disgraced in 1541; protested against the treaty of Crépy in 1544; and at the end of the reign held himself completely aloof. After his accession in 1547 Diane, Montmorency and the Guises were all-powerful, and dismissed Cardinal de Tournon, de Longueval, the duchesse d'fitampes and all the late king's friends and officials. At that time Henry was twenty-eight years old. He was a robust man, and inherited his father's love of violent exercise; but his character was weak and his intelligence mediocre, and he had none of the superficial and brilliant gifts of Francis I. He was cold, haughty, melancholy and dull. He was a bigoted Catholic, and showed to the Protestants even less mercy than his father. During his reign the royal authority became more severe and more absolute than ever. Resistance to the financial extortions of the government was cruelly chastised, and the "Chambre Ardente" was instituted against the Reformers. Abroad, the struggle was continued against Charles V. and Philip II., which ended in the much-discussed treaty of Cateau-Cambrésis. Some weeks afterwards high feast was held on the occasion of the double marriage of the king's daughter Elizabeth with the king of Spain, and of his sister Margaret with the duke of Savoy. On June 30, 1559, when tilting with the count of Montgomery, Henry was wounded in the temple by a lance; he died on July 10. By his wife Catherine de' Medici he had seven children living: Elizabeth, queen of Spain; Claude, duchess of Lorraine; Francis (II.), Charles (IX.) and Henry (III.), all of whom came to the throne; Marguerite, who became queen of Navarre in 1572; and Francis, duke of Alençon and afterwards of Anjou, who died in 1584.

The bulk of the documents for the reign of Henry II. are unpublished, and are in the Bibliothèque Nationale, Paris. Of the published documents, *see* especially the correspondence of Catherine de' Medici (ed. by de la Ferrière, Paris, 1880), of Diane de Poitiers (ed. by Guiffrey, Paris, 1866), of Antoine de Bourbon and Jeanne d'Albret (ed. by Rochambeau, Paris, 1877), of Odet de Selve, ambassador to England (ed. by Lefevre-Pontalis, Paris, 1888) and of Dominique du Gabre, ambassador to Venice (ed. by Vitalis, Paris, 1903); Ribier, *Lettres et mémoires d'estat* (Paris, 1666); *Relations des ambassadeurs vénitiens,* etc. *See* also H. Lemonnier, "La France sous Henri II." (Paris, 1904), in the *Histoire de France,* by *E.* Lavisse, which contains a fuller bibliography of the subject.

HENRY III. (1551–1589), king of France, third son of Henry II. and Catherine de' Medici, was born at Fontainebleau on Sept. 19, 1551. As duke of Anjou, he won, under the direction of Tavannes, the battles of Jarnac and Moncontour over Condé and Coligny in 1569, and he assisted his mother in organizing the massacre (1572) of St. Bartholomew. He was Catherine's favourite son, and she now (1573) secured his election to the throne of Poland. But next year the death of his brother, Charles IX., brought him back post-haste to assume the crown of France. His accession meant a fresh lease of power for Catherine, from whose authority he never emancipated himself. His indolence and his vicious and corrupt life scandalized both the Huguenots and the Catholic party. For the civil conflicts of his reign, see **FRANCE: *History.***

A revolt (May 12, 1588) in Paris, the "day of the barricades," forced Henry to take refuge at Chartres. He then secured the murder of Henry of Guise and his brother, the cardinal, at Blois (Dec. 23, 1588). Early in January, Catherine de' Medici died. "Now I am king," cried Henry. But Paris was in the hands of the partisans of Guise, many of the provinces were in revolt, and Henry was driven into alliance with Henry of Navarre. Together they were investing Paris, when the Leaguers avenged the Guise murders through the instrumentality of a fanatic monk, Jacques Clément, who stabbed the king at an audience on Aug. 1, 1589. Henry died a few hours later, naming Henry of Navarre as his successor. By his wife, Louise de Mercoeur, he left no children, and with him the male line of the house of Valois became extinct.

See Correspondence of Catherine de' Medici and of Henry IV. (in the *Collection de documents inddits),* and of the Venetian ambassadors, etc.; P. Matthieu, *Histoire de France,* vol. i. (1631); Scipion Dupleix, *Histoire* de *Henri III.* (1633); Robiquet, *Paris et la Ligue* (1886); and J. H. Mariéjol, "La Réforme et la Ligue," in the *Histoire de France,* by E. Lavisse (Paris, 1904), which contains a more complete bibliography.

HENRY IV. (1553–1610), king of France, the son of Antoine de Bourbon, duke of Vendôme, head of the younger branch of the Bourbons, descendant of Robert of Clermont, sixth son of St. Louis, and of Jeanne d'Albret, queen of Navarre, was born at Pau (Basses Pyrénées) on Dec. 14, 1553. He was educated as a Protestant, and in 1557 was sent to the court at Amiens. In 1561 he entered the Collège de Navarre at Paris, returning in 1565 to Béarn. During the third war of religion in France (1568–1570) he was taken by his mother to Gaspard de Coligny, leader of the Protestant forces since the death of Louis I., prince of Condé, at Jarnac, and distinguished himself at the battle of Arnay-le-Duc in Burgundy in 1569. On his mother's death in 1572 Henry became king of Navarre and married Margaret de Valois (*q.v.*) sister of Charles IX. of France. He escaped the massacre of St. Bartholomew by a feigned abjuration. On Feb. 2, 1576, after several vain attempts, he escaped from the court, joined the combined forces of Protestants and of opponents of the king, and obtained by the treaty of Beaulieu (1576) the government of Guienne. In 1577 he secured the treaty of Bergerac, which foreshadowed the edict of Nantes. As a result of quarrels with his wife, and the unwelcome intervention of Henry III., he undertook the seventh war of religion, seized Cahors on May 5, 1580, and signed the treaty of Fleix on Nov. 26, 1580. The death (1584) of the duke of Anjou, brother of King Henry III., made Henry of Navarre heir presumptive to the throne of France. Excluded from it by the treaty of Nemours (1585) he began the "war of the three Henrys" by a campaign in Guienne (1586) and defeated Anne, duc de Joyeuse, at Coutras on Oct. 20, 1587. Then Henry III., driven from Paris by the League on account of his murder of the duke of Guise at Blois (1588), sought the aid of the king of Navarre to win back his capital, recognizing him as his heir. The assassination of Henry III. on Aug. 1, 1589 left Henry king of France; but he had to struggle for ten more years against the League and against Spain before he won his kingdom. The main events in that long struggle were the victory of Arques (1589) over Charles, duke of Mayenne; of Ivry (1590); the siege of Paris (1590); of Rouen (1592); the meeting of the Estates of the League (1593), which the *Satire Ménippée* turned to ridicule; and finally the conversion of Henry IV. to Catholicism in July 1593—an act of political wisdom, since it brought about the collapse of all opposition. Paris gave in to him on March 22, 1594 and province by province yielded to arms or negotiations; while the victory of Fontaine-Française (1595) and the capture of Amiens forced Philip II. of Spain to sign the peace of Vervins on May 2, 1598. On April 13 of that year Henry IV. had promulgated the Edict of Nantes.

Then Henry set to work to pacify and restore prosperity to his kingdom. Convinced by the experience of the wars that France needed an energetic central power, he pushed at times his royal prerogatives to excess, raising taxes in spite of the Estates, interfering in the administration of the towns, reforming their consti-

tutions, and holding himself free to reject the advice of the notables if he consulted them. Aided by his faithful friend Maximilien de Béthune, baron de Rosny and duc de Sully (*q.v.*), he reformed the finances, repressed abuses, suppressed useless offices, extinguished the formidable debt and realized a reserve of eighteen millions. To alleviate the distress of the people he undertook to develop both agriculture and industry: planting colonies of Dutch and Flemish settlers to drain the marshes of Saintonge, issuing prohibitive measures against the importation of foreign goods (1597), introducing the silk industry, encouraging the manufacture of cloth, of glass-ware, of tapestries (Gobelins), and under the direction of Sully—named *grand-voyer de France*—improving and increasing the routes for commerce. A complete system of canals was planned, that of Briare partly dug. New capitulations were concluded with the sultan Ahmed I. (1604) and treaties of commerce with England (1606), with Spain and Holland. Attempts were made in 1604 and 1608 to colonize Canada (see CHAMPLAIN, SAMUEL DE). The army was reorganized, its pay raised and assured, a school of cadets formed to supply it with officers, artillery constituted and strongholds on the frontier fortified. While lacking the artistic tastes of the Valois, Henry beautified Paris, building the great gallery of the Louvre, finishing the Tuileries, building the Pont Neuf, the Hôtel-de-Ville and the Place Royale.

The foreign policy of Henry IV. was directed against the Habsburgs. Without declaring war, he did all possible harm to them by alliances and diplomacy. In Italy he gained the grand duke of Tuscany—marrying his niece Marie de' Medici in 1600—the duke of Mantua, the republic of Venice and Pope Paul V. The duke of Savoy, who had held back from the treaty of Vervins in 1598, signed the treaty of Lyons in 1601; in exchange for the marquisate of Saluzzo, France acquired Bresse, Bugey, Valromey and the bailliage of Gex. In the Low Countries, Henry sent subsidies to the Dutch in their struggle against Spain. He concluded alliances with the Protestant princes in Germany, with the duke of Lorraine, the Swiss cantons (treaty of Soleure, 1602) and with Sweden. In 1609, the opening of the question of the succession of John William the Good, duke of Cleves, of Jülich and of Berg, led Henry, in spite of his own hesitations and those of his German allies, to declare war on the emperor Rudolph II. But he was assassinated by Ravaillac (*q.v.*) on May 14, 1610, upon the eve of his great enterprise, leaving his policy to be followed up later by Richelieu. Sully in his *Économies royales* attributes to his master the "great design" of constituting, after having defeated Austria, a vast European confederation of fifteen states—a "Christian Republic"—directed by a general council of sixty deputies reappointed every three years. But this "design" has been attributed rather to the imagination of Sully himself than to the more practical policy of the king.

No figure in France has been more popular than that of "Henry the Great." He was affable, quick-witted, good-hearted and generally indulgent. His courage amounted almost to recklessness. He was a better soldier than strategist. Although at bottom authoritative he surrounded himself with admirable advisers (Sully, Sillery, Villeroy, Jeannin) and profited from their co-operation. His numerous love affairs (of which the most famous are those with Gabrielle d'Estrées and Henriette d'Entragues), did not affect his policy, in which he was guided only by an exalted ideal of his royal office, and by a certain sympathy—perhaps exaggerated in popular tradition—for the common people.

Henry IV. had no children by his first wife, Margaret of Valois. By Marie de' Medici he had Louis, later Louis XIII.; Gaston, duke of Orleans; Elizabeth, who married Philip IV. of Spain; Christine, duchess of Savoy; and Henrietta, wife of Charles I. of England. Among his bastards the most famous were the children of Gabrielle d'Estrées—Caesar, duke of Vendôme, Alexander of Vendôme, and Catherine Henriette, duchess of Elbeuf. Several portraits of Henry are preserved at Paris, in the Bibliothèque Nationale (cf. Bouchot, Portraits au crayon, p. 189), at the Louvre (by Probus, bust by Barthélemy Prieur) at Versailles, Geneva (Henry at the age of fifteen), at Hampton Court, at Munich and at Florence.

For the sources of the history of his reign see the *Recueil des lettres missives de Henri IV.*, published from 1839 to 1853 by B. de Xivrey, in the Collection de documents *inédits relatifs à* l'histoire de France, and the various researches of Galitzin, Bautiot, Halphen, Dussieux and others. Besides their historic interest, the letters written personally by Henry, whether love notes or letters of state, reveal a charming writer. Mention should be made of Auguste Poirson's *Histoire du règne* de Henri *IV.* (2nd ed., 4 vols., Paris, 1862–67) and of J. H. Mariéjol's volume (vi.) in the *Histoire de France*, edited by Ernest Lavisse (Paris, 1905), where main sources and literature are given with each chapter. A Revue Henri IV. has been founded at Paris (1905). Finally, a complete survey of the sources for the period 1494–1610 is given by Henri Hauser in vol. vii. of Sources de l'histoire de France (Paris, 1906), in continuation of A. Molinier's collection of the sources for French history during the middle ages.

HENRY I. (876?–936), surnamed the "Fowler," German king, son of Otto the Illustrious, duke of Saxony, shared in early life in various campaigns for the defence of Saxony. He married Hatburg, a daughter of Irwin, count of Merseburg, but as she had taken the veil on the death of a former husband this union was declared illegal by the church, and in 909 he married Matilda, daughter of a Saxon count named Thiederich, and a reputed descendant of the hero Widukind. On his father's death in 912 he became duke of Saxony, which he defended against the Slavs (see SAXONY). In 918 the German king Conrad I. advised the nobles to make the Saxon duke his successor. The Franks and the Saxons met at Fritzlar in May 919 and chose Henry as German king. The new king refused to allow his election to be sanctioned by the church. His authority, save in Saxony, was merely nominal; but he secured a recognition of his sovereignty from the Bavarians and the Swabians. In 921 Charles III. of France recognized Henry as king of the East Franks, and when in 923 the French king was taken prisoner by Herbert, count of Vermandois, Lorraine came under Henry's authority, and Giselbert, who married his daughter Gerberga, was recognized as duke. Henry reduced various Slavonic tribes in the east to subjection, took Brennibor, the modern Brandenburg, from the Hevelli, and secured both banks of the Elbe for Saxony. In 923 he had bought a truce for ten years with the Hungarians, by a promise of tribute, and on its expiration he gained two great victories over them in 933 at Jechaburg and Riade. The Danes were defeated, and territory as far as the Eider secured for Germany; and the king sought further to extend his influence by entering into relations with the kings of England, France and Burgundy. He died at Memleben on July 2, 936. By his first wife, Hatburg, he left a son, Thankmar, who was excluded from the succession as illegitimate; and by Matilda he left three sons, the eldest of whom, Otto (afterwards the emperor Otto the Great), succeeded him, and two daughters. Henry undertook only such enterprises as he was able to carry through. Laying more stress on his position as duke of Saxony than king of Germany, he conferred great benefits on his duchy. The founder of her town life and the creator of her army, he ruled in harmony with her nobles and secured her frontiers from attack.

See Widukind of Corvei, "Res gestae Saxonicae," ed. G. Waitz in the Monumenta Germaniae historica. *Scriptores*, Band iii. (Hanover and Berlin, 1826 *seq.*); "Die Urkunde des deutschen Konigs Heinrichs I.," edited by T. von Sickel in the Monumenta *Germaniae* historica. *Diplomata* (Hanover, 1879); W. von Giesebrecht, *Geschichte* der *deutschen Kaiserzeit*, Bände i., ii. (Leipzig, 1881); G. Waitz, *Jahrbücher* des deutschen Reichs unter *König Heinrich* I. (Leipzig, 1885); and F. Löher, Die deutsche Politik *König Heinrich* I. (Munich, 1857).

HENRY VII. (1211–1242), German king, son of the emperor Frederick II. and his first wife Constance, daughter of Alphonso II., king of Aragon, was crowned king of Sicily in 1212 and made duke of Swabia in 1216. Pope Innocent III. had favoured his coronation as king of Sicily in the hope that the union of Sicily with the Empire would be dissolved, and had obtained a promise from Frederick to this effect. Nevertheless Henry was chosen king of the Romans, or German king, at Frankfort in April 1220, and crowned at Aix-la-Chapelle on May 8, 1222 by his guardian Engelbert, archbishop of Cologne. He appears to have spent most of his youth in Germany, and in 1225 was married to Margaret (d. 1267), daughter of Leopold VI., duke of Austria. The murder of Engelbert in 1225 was followed by an increase of disorder in Germany, and in 1227 Henry took part in a quarrel which had

arisen on the death of Henry V., the childless count palatine of the Rhine. Relations between Frederick and his son began to be strained. The emperor had favoured the Austrian marriage because Margaret's brother, Duke Frederick II., was childless; but Henry took up a hostile attitude towards his brother-in-law and wished to put away his wife and marry Agnes, daughter of Wenceslaus I., king of Bohemia. In 1231 Henry refused to appear at the diet at Ravenna, and opposed the privileges granted by Frederick to the princes at Worms. In 1232 he submitted to his father, but in 1233 he issued a manifesto to the princes, and in 1234 raised the standard of revolt at Boppard. He succeeded in forming an alliance with the Lombards in December 1234, but his few supporters fell away when the emperor reached Germany in 1235, and, after a vain attack on Worms, Henry submitted and was kept for some time as a prisoner in Germany. His formal deposition as German king was not considered necessary, as he had broken the oath taken in 1232. He was removed to San Felice in Apulia, and afterwards to Martirano in Calabria, where he died, probably by his own hand, on Feb. 12, 1242. His two sons, Frederick and Henry, died in Italy about 1251.

See J. Rohden, *Der Sturz Heinrichs VII.* (Göttingen, 1883); F. W. Schirrmacher, *Die letzten Hohenstaufen* (Gottingen, 1871); E. Winkelmann, *Kaiser Friedrich II.* (Leipzig, 1889); P. Reinhold, *Die Empörung Konig Heinrichs gegen seinen Vater* (1911).

HENRY I (c. 1210–1274), surnamed THE FAT, king of Navarre and count (as Henry III) of Champagne, was the youngest son of Theobald I of Navarre by Margaret of Foix and succeeded his eldest brother, Theobald II, as king of Navarre and count of Champagne in Dec. 1270. His proclamation at Pamplona, however, did not take place till March of the following year, and his coronation was delayed until May 1273. At his death in 1274 the male line of the counts of Champagne and kings of Navarre became extinct. He married in 1269 Blanche, daughter of Robert. count of Artois, and niece of King Louis IX, and was succeeded by his only legitimate child, Joan, by whose marriage to Philip the Fair (afterward king of France) in 1284 the crown of Navarre was united to the French.

HENRY II. (1503–1555), titular king of Navarre, was the eldest son of Jean d'Albret (d. 1516) by his wife Catherine de Foix, sister and heiress of Francis Phoebus, king of Navarre, and was born at Sanquesa in April 1503. When Catherine died in exile in 1517 Henry succeeded her in her claim on Navarre, which was disputed by Ferdinand I. king of Spain; and under the protection of Francis I. of France he assumed the title of king. After ineffectual conferences at Noyon in 1516 and at Montpellier in 1518, an active effort was made in 1521 to establish him in the *de facto* sovereignty; but the French troops which had seized the country were ultimately expelled by the Spaniards. In 1525 Henry was taken prisoner at the battle of Pavia, but he contrived to escape, and in 1526 married Margaret, the sister of Francis I. and widow of Charles, duke of Alençon. By her he was the father of Jeanne d'Albret (d. 1572), and was consequently the grandfather of Henry IV. of France. Henry, who had some sympathy with the Huguenots, died at Pau on May 25, 1555.

HENRY I. (1512–1580), king of Portugal, third son of Emanuel the Fortunate, was born in Lisbon on Jan. 31, 1512. In 1532 he was made archbishop of Braga. In 1542 he received the cardinal's hat, and in 1578 when he was called to succeed his grandnephew Sebastian on the throne, he held the archbishoprics of Lisbon and Coimbra as well as that of Braga, in addition to the wealthy abbacy of Alcobazar. As a sovereign he proved weak, timid and incapable. On his death in 1580, the male line of the royal family which traced its descent from Henry, first count of Portugal (c. 1100), came to an end

HENRY, PRINCE OF BATTENBERG: *see* BATTENBERG and MOUNTBATTEN.

HENRY II. (1489–1568), duke of Brunswick-Wolfenbüttel, son of Duke Henry I., was born on Nov. 10, 1489. He began to reign in 1514, but his brother William objected to the indivisibility of the duchy which had been decreed by the elder Henry, and it was only in 1535, after an imprisonment of 11 years, that William recognized his brother's title. In 1525 he assisted Philip, landgrave of Hesse, to crush the rising of the peasants in north Germany, and in 1528 took help to Charles V. in Italy, where he narrowly escaped capture. He joined the Catholic princes in concerting measures for opposing the Reformation. Henry was attacked by Luther with unmeasured violence in a writing *Wider Hanns Worst*. The duke soon came into collision with the Protestant towns of Goslar and Brunswick, against the former of which a sentence of restitution had been pronounced by the imperial court of justice (*Reichskammergericht*). Charles V. had suspended the execution of this sentence, a proceeding which Henry declared was *ultra vires*. The league of Schmalkalden, led by Philip of Hesse and John Frederick, elector of Saxony, took up arms to defend the towns; and in 1542 Brunswick was overrun and the duke forced to flee. In September 1545 he tried to regain his duchy, but was taken prisoner by Philip, and only released in April 1547. After his return to Brunswick he quarrelled with his subjects on political and religious questions, while his duchy was ravaged by Albert Alcibiades, prince of Bayreuth. Henry joined the league of princes against Albert, and after the death of Maurice, elector of Saxony, at Sievershausen in July 1553, he commanded the allied troops and defeated Albert in two engagements. In his later years he was reconciled with his Protestant subjects. He died at Wolfenbüttel on June 11, 1568. The duke was twice married, firstly in 1515 to Maria (d. 1541), sister of Ulrich of Wiirttemberg, and secondly in 1556 to Sophia (d. 1575) daughter of Sigismund I., king of Poland. He had a romantic attachment to Eva von Trott, whom he represented as dead and afterwards kept concealed at Staufenburg. He was succeeded by his only surviving son, Julius (1528–1589).

See F. Koldewey, *Heinz von Wolfenbüttel* (Halle, 1883); and F. Bruns, *Die Vertreibung Herzog Heinrichs von Braunschweig durch den Schmalkaldischen Bund* (Marburg, 1889).

HENRY (1108?–1139), surnamed the "Proud," duke of Saxony and Bavaria, second son of Henry the Black, duke of Bavaria, and Wulfhild, daughter of Magnus Billung, duke of Saxony, was a member of the Welf family. His father and mother both died in 1126, and as his elder brother Conrad had entered the church, Henry became duke of Bavaria and shared the family possessions in Saxony, Bavaria and Swabia with his younger brother, Welf. In 1127 he married Gertrude, the only child of the German king, Lothair the Saxon, and at once took part in the warfare between the king and the Hohenstaufen brothers, Frederick II., duke of Swabia, and Conrad, afterwards the German king Conrad III. Simultaneously he suppressed a rising in Bavaria, led by Frederick, count of Bogen, during which both duke and Count sought to establish their own candidates in the bishopric of Regensburg. Frederick submitted in 1133, and two years later the Hohenstaufen brothers made their peace with Lothair. In 1136 Henry accompanied Lothair to Italy, and taking command of one division of the German army marched into southern Italy, devastating the land as he went. It was probably about this time that he was invested with the margraviate of Tuscany and the lands of Matilda, the late margravine. After the Italian campaign Henry was appointed by the emperor as his successor in the dukedom of Saxony. When Lothair died in 1137 Henry's wealth and position made him a formidable candidate for the German throne; but his ambition aroused the jealousy of the princes, and prevented his election. The new king, Conrad III., demanded the imperial *insignia* which were in Henry's possession, and the duke in return asked for his investiture with the Saxon duchy. Conrad refused to assent on the pretext that it was unlawful for two duchies to be in one hand. Attempts at a settlement failed, and in July 1138 the duke was placed under the ban, and Saxony was given to Albert the Bear, afterwards margrave of Brandenburg. War broke out in Saxony and Bavaria, but was cut short by Henry's sudden death, whether by poison or not cannot be ascertained, at Quedlinburg on Oct. 20, 1139. Henry was a man of great ability, and his early death alone prevented him from playing an important part in German history.

See S. Riezler, *Geschichte Bayerns*, Band i. (Gotha, 1878); W. Bernhardi, *Lothar von Supplinburg* (Leipzig, 1879); W. von Giesebrecht, *Geschichte der deutschen Kaiserzeit*, Band iv. (Brunswick, 1877); and A. L. Poole in *Cambridge Mediaeval History*, vol. v.

HENRY (1129–1195), surnamed the "Lion," duke of Saxony and Bavaria, only son of Henry the Proud, duke of Saxony and Bavaria, and Gertrude, daughter of the emperor Lothair the Saxon, was born at Ravensburg, and was a member of the family of Welf. In May 1142 Henry was invested as duke of Saxony at Frankfort, and Bavaria was given to Henry II., Jasomirgott, margrave of Austria, who married his mother. In 1147 Henry married Clementia, daughter of Conrad, duke of Zahringen (d. 1152). He made an expedition against the Abotrites, or Obotrites, in 1147, and won much land beyond the Elbe, in which were re-established the bishoprics of Mecklenburg, Oldenburg and Ratzeburg. Henry maintained, against Hartwig archbishop of Bremen, his right to invest these bishops, a privilege afterwards confirmed by the emperor Frederick I. In 1147 he made a formal claim on the duchy of Bavaria, and in 1151 made an unsuccessful attempt to take possession. The situation was changed in his favour when Frederick I. succeeded Conrad as German king in 1152. In 1154 he recognized the claim of Henry, who accompanied him on his first Italian campaign and suppressed a rising at Rome. Henry's formal investiture as duke of Bavaria took place in 1156. Two years later, Adolph II., count of Holstein, was compelled to cede Liibeck to him; campaigns in 1163 and 1164 broke the resistance of the Abotrites; and Saxon garrisons were established in the conquered lands. He had also helped Frederick I. in his expedition of 1157 against the Poles, and in 1159 had gone to his assistance in Italy.

In 1166 a coalition was formed against Henry at Merseburg under the leadership of Albert the Bear, margrave of Brandenburg. and Archbishop Hartwig. After indecisive fighting Frederick intervened, and made peace in 1168. Having obtained a divorce from his first wife in 1162, Henry was married in 1168 to Matilda (1156–89), daughter of Henry II. of England, and mas soon afterwards sent by the emperor Frederick I. on an embassy to England and France. A war with Valdemar of Denmark, caused by a quarrel over the booty from the conquest of Riigen, lasted until 1171, when, in pursuance of a peace treaty Henry's daughter, Gertrude, married the Danish prince, Canute. During his pilgrimage to Jerusalem in 1172, Henry was received with great respect by the eastern emperor Manuel Comnenus at Constantinople.

A variety of reasons were leading to a rupture between Frederick and Henry, who showed little inclination to sacrifice his interests in Germany to help the imperial cause in Italy. He was displeased when his uncle, Welf, bequeathed his Italian and Swabian lands to the emperor, and the crisis came after Frederick's check before Alessandria in 1175. Henry declined to help the emperor in 1176, and though the peace of Venice provided for the restoration of Ulalrich to his see of Halberstadt, Henry refused to give up the lands which he had seized belonging to the bishopric. This provoked a war in which Ulalrich was joined by Philip, archbishop of Cologne. The dispute was to be settled at Worms, but Henry's failure to appear to answer the charges preferred against him, led to his being placed under the imperial ban at Wiirzburg in 1180, and deprived of his lands.

Meanwhile the war with Ulalrich continued, but after his victory at Weissensee Henry's cause began to decline. When Frederick took the field in 1181, Henry sought peace. He was granted the counties of Liineburg and Brunswick, but was banished under oath not to return without the emperor's permission. He went to Normandy, and afterwards to England, returning to Germany with Frederick's permission in 1185. He was soon regarded once more as a menace to peace, and of the three alternatives offered by the emperor in 1188 he rejected the idea of making a formal renunciation of his claim, or of participating in the crusade, and chose exile, going again to England in 1189. A few months later, he returned to Saxony, asserting that his lands had not been defended according to the emperor's promise. He found many allies, won Lubeck, and soon almost the whole of Saxony was in his power. King Henry VI. took the field against him, and in 1190 a peace was arranged at Fulda, by which he retained Brunswick and Liineburg, received half the revenues of Liibeck. and gave two of his sons as hostages. In 1193 he revolted against Henry VI., but the captivity of his brother-in-law Richard I., king of England, led to a reconciliation. Henry passed his later years in intellectual and artistic pursuits at Brunswick, where he died on Aug. 6, 1195. One of his sons was Otto, afterwards the emperor Otto IV., and another was Henry (d. 1227) count palatine of the Rhine.

Henry won his surname of "Lion" by his intrepidity. His influence on the fortunes of Saxony and northern Germany was considerable. He colonized the whole of northern Germany down to the Elbe; he founded numerous towns in Germany and sought to spread Christianity by introducing the Cistercians, founding bishoprics, and building churches and monasteries. Lane Poole, in the *Cambridge Medieval Hzstory* says of him, "He ruled an *imperium in imperio,* but he did not abuse his privileged position; his rule for the 20 years which followed the settlement of Ratisbon was beneficial to Germany, if it was detrimental to the interests of individual princes. Henry threw himself with all his energy into the work of German expansion, the promotion of commercial enterprise, the development of municipal life."

The authorities for the life of Henry the Lion are those dealing with the reign of the emperor Frederick I., and the early years of his son King Henry VI. The chief modern works are G. Prutz, *Heinrich der Löwe* (Leipzig, 1866); M. Philippson, *Geschzchte Heinrichs des Löwen* (Leipzig, 1867, 2nd ed. 1918); and L. Weiland, *Das sächsische Herzogthum unter Lothar und Heinrich dem Löwen* (Greifswald 1866); F. Guterbock, *Der Prozess Heinrichs des Lowen* (1909); A. L. Poole, *Henry the Lzon* (1912) and *E.* Gronen, *Die Machtpolitik H. des Löwen* (1919).

HENRY, JOSEPH (1797–1878), U.S. physicist and scientific administrator, who had a great influence on the development of science in the United States, was born in Albany, N.Y., on Dec. 17, 1797, of Scottish ancestry. Henry attended a country district school to the age of 13; showing little interest in study, he was apprenticed to a watchmaker.

When Henry was 16, a popular book on natural history awakened his ambition, so that he resumed his education, attending Albany academy, teaching in country schools and tutoring to pay his way. Completing the prescribed course, he continued his studies in chemistry, anatomy and physiology with a view to practising medicine. An unexpected appointment in 1825 to survey a route for a state road from the Hudson river to Lake Erie changed his goal to engineering, and it was with some reluctance that in 1826 he accepted an appointment to teach mathematics and natural philosophy in the Albany academy.

But his decision proved a most happy one. Beginning experiments in electromagnetism, Henry was the first to insulate wire for the magnetic coil; he invented the "spool" or "bobbin" winding; he discovered the necessary law of proportion between the electromotive force in the battery and the resistance of the magnet. He thus worked out for the first time the differing functions of two entirely different kinds of electromagnets; the one surrounded by numerous coils of no great length revolutionized the feeble electromagnet of William Sturgeon. The other surrounded by a continuous coil of great length made possible for the first time the transmission of a current over a great distance with little loss. Every electrical dynamo or motor uses the electromagnet in practically the form in which it was left by Henry in 1829. The principles involved in the "intensity" magnet constitute the indispensable basis of every form of the electromagnetic telegraph since invented, and Henry himself invented and demonstrated what appears to have been the first practical electromagnetic telegraph in 1830–31 at Albany. It consisted of a mile of copper bell wire interposed in a circuit between a small Cruickshanks battery and an "intensity" magnet of continuous fine coil. A permanent magnet pivoted to swing horizontally like the compass needle, was arranged so that one end remained in contact with a leg of the soft iron core, while the other end was near an office bell. At each excitation of the electromagnet the suspended magnet was repelled from one leg and attracted by the other, so that its free end tapped the bell. This was the first instance of magnetizing iron at a great distance, or of a suitable combination of magnet and battery being so

arranged as to be capable of such action. Reporting his achievements in *Silliman's Journal* in **1831** Henry pointed out that the way was now clear for the invention of the commercial electromagnetic telegraph. In **1835,** after his transfer to the College of New Jersey (later Princeton university), he added a step in the invention of the "relay" by which a relatively feeble current operated an electromagnet which in turn controlled the local circuit of a more powerful magnet. This invention is extensively used in the field of electrical control, known as distant control. It was also in **1835** that Henry first used the earth as a return conductor. But in **1829** he had devised and constructed the first electromagnetic motor, an oscillating machine with automatic pole changer, publishing a description of it in **1831.** This machine was the forerunner of all electric motors. In the same period he made two other fundamental discoveries. The honour for the discovery of self-induction which he announced in **1832** has been universally conceded to him, and it was chiefly in recognition of this achievement that the International Congress of Electricians in Chicago, Ill., in **1893** gave his name to the standard unit of inductive resistance. The other discovery, that of electromagnetic induction, was made independently and at the same period by both Henry and Michael Faraday, and since the latter published first, the credit is rightfully given to him.

Professorship at Princeton. — After Henry's appointment to fill the chair of natural philosophy at Princeton in **1832** he taught physics and mathematics and lectured in chemistry, mineralogy, geology; later adding astronomy and architecture. Continuing his physical researches, he discovered that a current of low potential could induce a current of high potential by a suitable arrangement of the coils. He elucidated the laws upon which the electrical transformer of modern times is constructed. He found, also, that a second induced current could induce a third; the third a fourth; and so on, indefinitely; and that these currents could be induced at a distance. Some of his experiments in induction involved the transmission of electric force without wires through the floors and walls of buildings, and in one case he magnetized a needle by the transmission from a lightning flash **8** mi. away. This appears to be the earliest record of the action of ether waves of the type employed in radio telegraphy and telephony in modern times. The discovery of the oscillatory character of the electrical discharge came in **1842.** Outside the field of electricity, Henry showed that liquids and solids generally have the same amount of cohesion. He showed, by means of a thermogalvanometer, that sun spots radiate less heat than the general solar surface. He invented a new method for determining the velocity of projectiles. And in **1844** he presented a theoretical paper foreshadowing the principle of the conservation of energy.

Secretaryship at Smithsonian Institution. — In Dec. **1846** the second great period of Henry's life began with his election as first secretary of the newly formed Smithsonian institution. The plan of organization which he drew up for it was so far beyond the average intelligence of his day as to meet with bitter opposition. But scientific men turned to the institution as a rallying and guiding centre. Under his leadership branches of science hitherto unworked in the United States were taken up; activity in all fields was tremendously stirred; scientific exploration was made a beneficiary of the military exploration and commercial exploitation of the west; the government's support of scientific activity was enlisted and given direction.

Creation of **U.S.** Weather Service. — While at Albany he had devoted much attention to meteorology, realizing the need for much more data, and one of his first acts at the Smithsonian was to organize a corps of volunteer observers spread over the continent. He introduced standard instruments from abroad. prepared tables of instructions, and for **30** years maintained the investigations, collecting, reducing and publishing results which now form a considerable portion of the foundation of meteorological science. In this connection he was the first to use the telegraph to transmit weather reports; the first to indicate daily atmospheric conditions on a map; the first to embrace a continent under a single system; the first to make weather forecasts from the data obtained. The success of the Smithsonian meteorological work resulted in the creation of the U.S. weather bureau.

A second main achievement while at the Smithsonian was to supply American science with the first great agency for free publication of results. Of almost equal importance was the system Henry inaugurated of distribution of these publications to libraries and scientific bodies throughout the world. This soon developed into the system of international exchanges by which scientific and later government publications were exchanged between the rest of the world and the United States through the Smithsonian.

Other Scientific Work. — In **1852** Henry became a member of the lighthouse board, serving as chairman from **1871** until his death. This gave him the incentive to make his classical researches on sound in relation to fog signaling which provided his country with the most serviceable system of fog signals known to maritime powers. His researches also enabled the government to change from sperm oil to lard oil and later from lard oil to mineral oil as an illuminant, greatly increasing the efficiency of light beacons. He directed the mobilization of scientific effort during the Civil War and was a prime mover in the organization of the National Academy of Sciences of which he was the second president. He also took a leading part in the organization of the American Association for the Advancement of Science and of the Philosophical Society of Washington.

Henry was by general consent the foremost of U.S. physicists of his day; his influence upon the development of scientific work in the United States and upon its character cannot be overestimated. He was a man of varied culture, of large breadth and liberality of views, of generous impulses, of great gentleness and courtesy of manner, combined with equal firmness of purpose and energy of action, He died in Washington. D.C., on May **13, 1878.**

BIBLIOGRAPHY. — **A** *Memorial of Joseph Henry,* published by order of Congress (Washington, 1880), included also in *Smithsonian Misc. Colls.,* vol. xxi (1881); J. **G.** Crowther, *Famous American Men of Science* (New York, 1937); Thomas Coulson, *Joseph Henry, His Life and Work* (Princeton, 1950). (C. G. A.)

HENRY, MATTHEW (1662–1714), English Nonconformist divine, was born on the confines of Flintshire and Shropshire. on Oct. **8, 1662.** He was the son of Philip Henry. who had, two months earlier, been ejected by the Act of Cniformity. In **1687** Matthew Henry became minister of a Presbyterian congregation at Chester, removing in 1712 to Mare street. Hackney. He died suddenly on June 22, 1714, at Nantwich. Henry's well-known *Exposition of the Old and New Testaments* (1708–10) is a commentary of a practical and devotional rather than of a critical kind.

HENRY, O. (WILLIAM SIDNEY PORTER) (1862–1910), U.S. short-story writer, romanticized the commonplace and expressed the effect of coincidence on character through humour, grim or ironic; despite contrived plots and occasional clowning, his stories are significant social documents, artistically told. Born in Greensboro, N.C., Sept. 11, **1862,** he was christened William Sidney Porter. (In **1898** he dropped the first name and changed his middle name to Sydney.) He attended a school taught by his aunt, then clerked in his uncle's drugstore. In **1882** he went from a gloomy home to Texas with friends. On a ranch managed by Lee Hall, famous Texas ranger, Porter absorbed the robust life of La Salle county, but served only as a sheepherder or mail carrier. Within two years he was in Austin, working in the general land office and later as teller in the First National bank. He began writing free-lance sketches at about the time of his marriage to Athol Estes in **1887,** and in **1894** he started a humorous weekly, The *Rolling Stone.* When this venture failed, Porter joined the *Houston Post* as reporter, columnist and occasional cartoonist.

On Feb. 10, **1896,** he was indicted for embezzlement of bank funds. Friends aided his flight to New Orleans, where he worked as a reporter and felt the spell of the old French quarter before reaching safety in Honduras. Soon news of his wife's fatal illness brought him back to Austin, but lenient authorities did not press the case until after her death. When convicted, Porter received the lightest sentence possible and was allowed to appeal his case. In April **1898** he entered the penitentiary at Columbus, O.; his sentence was shortened to three years and three months

for good behaviour. As night druggist in the prison hospital he could write to earn money for support of his daughter Margaret His stories of adventure in the southwest and Central America were immediately popular with magazine readers. and nhen he emerged from prison W. S. Porter had become O. Henry.

In 1902 O. Henry arrived in New York—his "Bagdad on the Subway"—to begin a career as brief as it was brilliant. From Dec. 1903 to Jan. 1906 he produced a story a week for the *New York World,* writing also for syndicated magazines. His first book. *Cabbages and Kings* (1904), depicted fantastic characters against exotic Honduran backgrounds. *The Four Million* (1906) revealed the lives of the multitude of New York in their daily routines and searchings for romance and adventure. *The Trimmed Lamp* (1907) also explored metropolitan life, and *Heart of the West* (1907) presented accurate and fascinating tales of the Texas range. Then in rapid succession came *The Voice of the City* (1908), *The Gentle Grafter* (1908), *Roads of Destiny* (1909), *Options* (1909), *Strictlv Business* (1910) and *Whirligigs* (1910).

Despite his popularity, O. Henry's final years were marred by ill health, a desperate financial struggle and addiction to alcohol A second marriage in 1907 was unhappy. After his death on June j, 1910, three more collected volumes appeared: *Sixes and Sevens* (1911), *Rolling Stones* (1912) and *Waifs and Strays* (1917). Later seven fugitive stories and poems, *O. Henryana* (1920), *Letters to Lithopolis* (1922) and two collections of his early work on the *Houston Post, Postscripts* (1923) and *O Henry Encore* (1939), were published. Foreign translations and adaptations for other art forms attest his universal applicaticn and appeal (E. H. LG.)

O. Henry's varied life is reflected in his stories. The genial magic of his fine imagination. humour and brilliant narrative skill triumph over the occasional journalism of his method, and he remains endlessly and enchantingly rereadable. His New York stories are the most famous. but it is probable that some of the southern and western tales, in which there is less strain for glittering effect, are of more lasting value. The tragedy of his own life taught him a chivalrous tenderness for the unlucky. Some of the greatest native endowments a writer can have were undeniably his; of him, as much as of any modern writer, it can be said that he had "no talent. only genius." (C. M.)

HENRY, PATRICK (1736–1799), American politician and orator, was born at Studley, Hanover county, Va., on May 29, 1736. He was the son of John Henry, a well-educated Scotsman, who served in Virginia as county surveyor, colonel and judge of a county court. His mother was one of a family named Winston of Welsh descent, noted for conversational and musical talent. A mediocre student in the country school and under his father's tutorship, Patrick proved equally unsuccessful in business. In seven years he failed twice as a storekeeper and once as a farmer. In the meantime he acquired a taste for reading history and decided to study law. After a brief period of preparation he was admitted to the bar at the age of 24 and rapidly acquired a considerable practice. Then in 1763 was delivered his speech in "The Parson's Cause," a suit brought about by the custom of paying the clergy in money or tobacco according to the state of the market, which made Henry the idol of the common people of Virginia and procured for him an enormous clientele. In 1765 he was elected a member of the Virginia legislature, where he became in the same year the author of the "Virginia Resolutions," which, being no less than a declaration of resistance to the Stamp Act and an assertion of the right of the colonies to legislate for themselves independently of the control of the British parliament, gave a most powerful impetus to the movement resulting in the American Revolution. In a speech urging their adoption appear the often-quoted words, said to have been uttered in tones of thrilling solemnity, "Caesar had his Brutus, Charles the First his Cromwell, and George the Third (here he was interrupted by cries of 'Treason') and George the Third may profit by their example! If this be treason, make the most of it."

In the House of Burgesses he was prominent as a radical in all measures in opposition to the British Government, and was a member of the first Virginia committee of correspondence. In 1774 and 1775 he was a delegate to the continental congress. In 1775, in the second revolutionary convention of Virginia, Henry, regarding war as inevitable, presented resolutions for arming the Virginia militia, supporting them in a speech with the dramatic peroration, "I know not what course others may take, but as for me, give me liberty or give me death!" The resolutions were passed and their author was made chairman of the committee for which they provided. The chief command of the forces of Virginia was also given to him, but he was so checked by the Committee of Public Safety, that he resigned on Feb. 28, 1776. In the Virginia convention of 1776 he favoured the postponement of a declaration of independence until a firm union of the colonies and the friendship of France and Spain had been secured. In the same convention he served on the committee which drafted the first constitution for Virginia, and was elected governor of the State, being re-elected in 1777 and 1778, thus serving as long as the new constitution allowed any man to serve continuously. As governor he gave Washington able support and sent out the expedition under George Rogers Clark (*q.v.*) into the Illinois country.

In 1778 he was chosen a delegate to Congress, but declined to serve. From 1780 to 1784 and from 1787 to 1790 he was again a member of his State legislature; and from 1784 to 1786 was again governor. Until 1786 he was a leading advocate of a stronger central government, hut when chosen a delegate to the Philadelphia constitutional convention of 1787, he declined to serve and he led the opposition to ratification in Virginia, contending that the proposed Federal Constitution was dangerous to the liberties of the country. This change of attitude is thought to have been due chiefly to his suspicion of the North aroused by John Jay's proposal to surrender to Spain for 25 or 30 years the navigation of the Mississippi. From 1794 until his death he declined in succession the following offices: U.S. senator (1794), secretary of State in Washington's cabinet (1795), chief justice of the U.S. Supreme Court (1795), governor of Virginia (1796), to which office he had been elected by the assembly, and envoy to France (1799). In 1799, however, he consented to serve again in his State legislature, where he wished to combat the Virginia Resolutions; he never took his seat, since he died, on his Red Hill estate, on June 6 of that year. Henry was twice married, first to Sarah Shelton and second to Dorothea Dandridge.

HENRY, VICTOR (1850–1907), French philologist, was born at Colmar in Alsace on Aug. 17, 1850. Having held appointments at Douai and Lille, he was appointed professor of Sanskrit and comparative grammar in the University of Paris. A prolific and versatile writer, he is probably best known by the English translations of his *Pre'cis de Grammaire comparée de l'anglais et de l'allemand* and *Prkcis . . . du Grec et du Latin.* Important works by him on India and Indian languages are. *Manuel pour étudier le Sanscrit vkdique* (with A. Bergaigne, 1890); *Eldments de Sanscrit classique* (1902); *Pre'cis de grammaire Pâlie* (1904); *Les Litte'ratures de l'Inde: Sanscrit, Pâli, Prâcrit* (1904); *La Magie dans l'Inde antique* (1904); *Le Parsisme* (190j); *L'Agnistoma* (1906). Obscure languages (such as Innok, Quichua, Greenland) and local dialects (*Lexique étymologique du Brdton moderne; Le Dialecte Alaman de Colmar)* also claimed his attention. *Le Langage Martien* is a curious book. It contains a discussion of some 40 phrases (amounting to about 300 words), which a certain Mademoiselle Hélène Smith (a spiritualist medium of Geneva, Switz.) was said to have learned while on a hypnotic visit to the planet Mars.

HENRY, WILLIAM (1775–1836), English physician and chemist, author of "Henry's law" that the amount of gas absorbed by a liquid is proportional to the pressure of the gas upon the liquid, was the son of Thomas Henry (1734–1816), apothecary, translator of Lavoisier's *Opuscules* and writer on chemistry. William Henry was born at Manchester on Dec. 12, 1775, and was educated at Edinburgh (M.D., 1807). He devoted himself to

industry and scientific studies. One of his best known papers *(Philosophical Transactions of the Royal Society,* 1803) describes experiments on the quantity of gases absorbed by water under different pressures; the conclusion he reached being that "water takes up of gas condensed by one, two or more additional atmospheres. a quantity which, ordinarily compressed, would be equal to twice, thrice, etc., the volume absorbed under the common pressure of the atmosphere." His *Elements of Experimental Chemistry* went through 11 editions. In a fit of melancholia, he committed suicide at Pendlebury, Sept. 2, 1836. (R. E. O.)

HENRY FITZ HENRY (1155–1183), second son of Henry II., king of England, by Eleanor of Aquitaine, became heir to the throne on the death of his brother William (1156), and at the age of five was married to Marguerite, the infant daughter of Louis VII. In 1170 he was crowned at Westminster by Roger of York. The protests of Becket against this usurpation of the rights of Canterbury were the ultimate cause of the primate's murder. The young king soon quarrelled with his father, who allowed him no power and a wholly inadequate revenue, and headed the great baronial revolt of 1173. He was assisted by his father-in-law, to whose court he had repaired; but, failing to shake the old king's power either in Normandy or England, made peace in 1174. Despite the generous terms which he received, he continued to intrigue with Louis VII., and was in consequence jealously watched by his father. In 1182 he and his younger brother Geoffrey took up arms, on the side of the Poitevin rebels, against Richard Coeur de Lion, apparently from resentment at the favour which Henry II. had shown to Richard in giving him the government of Poitou while they were virtually landless. Henry II. took the field in aid of Richard; but the young king and Geoffrey continued to aid the Aquitanian rising until the young king died (June 11, 1183). His death was bitterly regretted by his father.

HENRY OF ALMAIN (1235–1271), so called from his father's German connections, was the son of Richard, earl of Cornwall and king of the Romans. As a nephew of both Henry III. and Simon de Montfort he wavered between the two at the beginning of the Barons' War, but finally took the royalist side and was among the prisoners taken by Montfort at Lewes (1264). In 1268 he took the cross with his cousin Edward, who, however, sent him back from Sicily to pacify the unruly province of Gascony. Henry took the land route with the kings of France and Sicily. While attending mass at Viterbo (March 13, 1271) he was attacked by Guy and Simon de Montfort, sons of Earl Simon, and foully murdered. This revenge was the more outrageous since Henry had personally exerted himself on behalf of the Montforts after Evesham. The deed is mentioned by Dante, who put Guy de Montfort in the seventh circle of hell.

HENRY OF BLOIS, bishop of Winchester (1101–1171), was the son of Stephen, count of Blois, by Adela, daughter of William I., and brother of King Stephen. Educated at Cluny, he was brought to England by Henry I. and made abbot of Glastonbury. In 1129 he was given the bishopric of Winchester and allowed to hold his abbey in conjunction with it. His hopes of the see of Canterbury were disappointed, but he obtained in 1139 a legatine commission which gave him a higher rank than the primate. Indeed, one of the ecclesiastical councils over which he presided formally declared that the election of the king in England was the special privilege of the clergy. Stephen owed his crown to Henry (1135), but they quarrelled when Stephen refused to give Henry the primacy; and the bishop took up the cause of Roger of Salisbury (1139). After the battle of Lincoln (1141) Henry declared for Matilda; but finding his advice treated with contempt, rejoined his brother's side, and his successful defence of Winchester against the empress (Aug.–Sept. 1141) was the turning-point of the civil war. The expiration of his legatine commission in 1144 deprived him of much of his power. At the accession of Henry II. (1154) he retired from the world. He died in 1171.

HENRY OF GHENT (HENRICUS DE GANDAVO) (d. 1293), scholastic philosopher, known as "Doctor Solemnis," was born in Ghent, where he studied before going to Cologne. In 1267 he was a canon of Tournai and in 1276 archdeacon of Bruges. By 1277 he was a master of theology at Paris, where he strongly opposed the mendicants.

Henry's philosophy, with its strong Augustinian colouring of peripatetic elements, closely resembles that of the early Franciscans. Thus, like them, he maintains that matter has its own actuality and by the Divine power could exist apart from form, that there is no real distinction between essence and existence or between the soul and its faculties, that a *forma corporeitatis* in man must be assumed if the independent natures of body and soul are to be ensured, that divine illumination is necessary for true knowledge, and that an eternal creation is impossible. Duns Scotus, whose formal distinction and voluntaristic leanings Henry anticipates, attacks his more original contributions, including his theory of negation as the principle of individuation, his rejection of the *species intelligibiles* in cognition, his stress on the activity of the intellect, his philosophy of conscience, and his theories that the Divine essence under a *relatio rationis* to *a* creature is the form in which God knows things and that creatures existed *secundum esse essentiae* in the Divine mind from all eternity.

BIBLIOGRAPHY.—Henry's *Quodlibeta* was published at Paris (1518) and at Venice (1608 and 1613), and his *Summa theologzae* at Paris (1520) and at Ferrara (1646). His *Comm. on the Physics,* his *Quaestiones on the Metaphysics* and a logical treatise are still in manuscript. The *De Scriptoribus ecclesiasticis* is probably not by him. *See* F. Ehrle, "Beitr. zu den Biographien beriihmter Scholastiker" in *Auchiv. fur Lit. u. Kirchengeschichte des Mittelalters* (1885); *H.* Delehaye, *Nouvelles Recherches sur Henri de Gand* (1886); *C.* Werner, *Heinrich von Gent als Reprasentant des christlichen Platonismus* (Vienna, 1878); De Wulf, *Hist. de la phil. scholastique dans les Pays-Bas* (1895); *G.* Hagemann, *De Henrici Gandavensis quem vocant ontologismo* (1898); *J.* Lichterfeld, *Die Ethik Heinrichs v. HENRY OF HUNTINGDON *(c.* 1080/90–*c.* 1155), English chronicler whose *Historia Anglorum,* from 55 B.C. to A.D. 1154, is interesting historically for the light it throws on the *Anglo-Saxon Chronicle,* on which the earlier part is based. Born sometime between 1080 and 1090, probably in Lincolnshire, Henry entered the household of Robert Bloet, bishop of Lincoln, at an early age. and in 1110 was appointed by him archdeacon of Hertford and Huntingdon. He was on familiar terms with his patron and also, apparently, with Bloet's successor. Alexander of Blois, who encouraged him to undertake the writing of his history. The first text, dealing with the period to 1129, appeared in 1130; four subsequent recensions brought it down to the accession of Henry II in 1154, made the occasion of a verse panegyric showing all the writer's loftiness of style. Henry must have died soon after, for a new archdeacon was appointed in 1155. The only recorded event of his later life is that in 1139 he accompanied Theobald, archbishop of Canterbury, to Rome.

The *Historia Anglorum,* formerly much esteemed, is now regarded as being of little independent value for the period before 1126, being largely a compilation or translation of such sources as Bede and the *Chronicle,* interspersed with passages of rhetoric. The later part, disappointingly. does little to illuminate contemporary events. More interesting for its sidelights on famous personalities of the day is the minor moralizing tract *Epistola ad Walterum de contemptu mundi,* written probably about 1135. Henry also wrote *De Miraculis,* a book of extracts from Bede, and two other Latin epistles, appended to later recensions of the *Historia.* He is known to have composed eight books of Latin epigrams, of which two books survive in a manuscript copy of the *Historia* (Lambeth manuscript, no. 118).

BIBLIOGRAPHY.—The *Historia Anglorum* was first printed in Sir Henry Savile's *Rerum Anglicarum scriptores post Bedam* (1596) The standard edition is by T. Arnold in the Rolls Series (1879), with appendix containing the *Epistola ad Walterum.* There is a translation by T. Forester in Bohn's *Antiquarian Library* (1853).... *See* also *F.* Liebermann, *Forschungen zur deutschen Geschichte,* XVIII (1878); R. R. Darlington, *Anglo-Norman Historians* (1947).

HENRY OF LAUSANNE (variously known as OF BRUYS, OF CLUNY, OF TOULOUSE, and as THE DEACON), French heresiarch of the first half of the 12th century. Practically nothing is known of his origin or early life, but if St. Bernard's reproach (*Ep.* 241) be true, Henry was an apostate monk.

In 1134 Henry appeared before Innocent II at the council

of Pisa, where he was compelled to abjure his errors and was imprisoned. Towards 1139, Peter the Venerable, abbot of Cluny, wrote his *Epistola seu tractatus adversus Petrobrusianos* (Migne, *Patr. Lat.* 189) against the disciples of Peter of Bruys and Henry of Lausanne, whom he calls Henry of Bruys, and whom, at the moment of writing, he accuses of preaching heresy in the south of France. In 1145, at the instance of the legate Alberic, St. Bernard set out for the heretical towns of Bergerac, Périgueux, Sarlat, Cahors and Toulouse. At his approach Henry quitted Toulouse, leaving Bernard by his eloquence and miracles to make many converts and to restore Toulouse and Albi to orthodoxy. After inviting Henry to a disputation, which he refused to attend, St. Bernard returned to Clairvaux. Soon afterwards the heresiarch was arrested, brought before the bishop of Toulouse, and probably imprisoned for life.

See E. Vacandard, "Les Origines de l'hérésie albigeoise," *Revue des questions historiques* (1894), and *Vie de S. Bernard* (vol. ii., 1895).

HENRY OF PORTUGAL, surnamed the "Navigator" (1394–1460), duke of Viseu, governor of the Algarve, was born at Oporto on March 4, 1394. He was the third surviving son of John (João) I., the founder of the Aviz dynasty, under whom Portugal, victorious against Castile and against the Moors of Morocco, began to take a prominent place among European nations; his mother was Philippa, daughter of John of Gaunt. When Ceuta, the "African Gibraltar," was taken in 1415, Prince Henry performed the most distinguished service of any Portuguese leader, and received knighthood; he was now created duke of Viseu and lord of Covilham, and about the same time began his explorations, which, however, limited in their original conception, certainly developed into a search for a better knowledge of the western ocean and for a sea-gay along the unknown coast of Africa to the supposed western Nile (our Senegal), to the rich negro lands beyond the Sahara desert, to the half-true, half-fabled realm of Prester John, and so ultimately to the Indies.

In 1415, the year of Ceuta, the prince sent out one John de Trasto on a voyage which brought the Portuguese to Grand Canary. There was no discovery here, for the whole Canarian archipelago was now well known to French and Spanish mariners. But in 1418 Zarco rediscovered Porto Santo, and in 1420 Madeira, which had originally been discovered in the 14th century. In 1424–25 Prince Henry attempted to purchase the Canaries, and began the colonization of the Madeira group, both in Madeira itself and in Porto Santo, for which he obtained charters (1430 and 1433) from the Portuguese Crown. In 1427, again, with his father King John, he sent out the pilot Diogo de Sevill, followed in 1431 by Gonçalo Velho Cabral, to explore the Azores. This rediscovery of the far western archipelago suggests that Henry had in mind the possibility of such a western route to Asia as Columbus attempted in 1492. Meantime, in 1418, Henry had gone in person to relieve Ceuta from an attack of Morocco and Granada Mussulmans; had accomplished his task, and had planned, though he did not carry out, a seizure of Gibraltar. At this time, it is probable that he was gathering information from the Moors with regard to the coast of "Guinea" and the interior of Africa. In 1419, after his return to Portugal, he was created governor of the "kingdom" of Algarve, the southernmost province of Portugal; and his connection now began with what afterwards became known as the "Infante's Town" (*Villa* do *Iffante*) at Sagres, close to Cape St. Vincent; where, before 1438, a *Tercena Nabal* or naval arsenal grew up and where, from 1438, after the Tangier expedition, the prince often resided.

In 1433 King John died; exhorting his son not to abandon his schemes; and in 1434 one of Henry's ships, commanded by Gil Eannes, at length doubled Cape Bojador. In 1435 Baldaya, the prince's cup-bearer, passed 50 leagues beyond; and by 1436 the Portuguese had almost reached Cape Blanco. Plans of further conquest in Morocco, resulting in 1437 in the disastrous attack upon Tangier, and followed in 1438 by the death of King Edward (Duarte) and the domestic troubles of the minority of Affonso V., now interrupted Atlantic and African exploration down to 1441, except in the Azores, where rediscovery and colonization progressed, as is shown by the royal licence of July 2, 1439, to people "the seven islands" of the group then known. In 1441 exploration began again in earnest with the venture of Antam Gonçalvez, who brought to Portugal the first slaves and gold-dust from the Guinea coasts beyond Bojador; while Nuno Tristam in the same year pushed on to Cape Blanco. These successes produced a great effect; the cause of discovery became popular; and many volunteers, especially merchants and seamen from Lisbon and Lagos, came forward. In 1442 Nuno Tristam reached the Bay or Bight of Arguim, where the infante erected a fort in 1448, and where for years the Portuguese carried on vigorous slave-raiding. Meantime the prince, who was now a knight of the Garter of England, proceeded with his Sagres buildings, which formed the nucleus of the "Infante's Town," and which had been begun about 1437.

In 1444–46 there was a burst of maritime and exploring activity; more than 30 ships sailed with Henry's licence to Guinea; and several of their commanders achieved notable success. Thus Diniz Diaz, Nuno Tristam, and others reached the Senegal in 1445; Diaz rounded Cape Verde in the same year; and in 1446 Alvaro Fernandez pushed on almost to our Sierra Leone, to a point 110 leagues beyond Cape Verde. This was perhaps the most distant point reached before 1461. In 1444, moreover, the island of St. Michael in the Azores was sighted (May 8), and in 1445 its colonization was begun. During this latter year also Juan Fernandez (*q.v.*) spent seven months among the natives of the Arguim coast, and brought back the first trustworthy first-hand European account of the Sahara hinterland. Slave-raiding continued ceaselessly; by 1446 the Portuguese had carried off nearly a thousand captives from the newly surveyed coasts; but between this time and the voyages of Cadamosto (*q.v.*) in 1455–1456, the prince altered his policy, forbade the kidnapping of the natives and endeavoured to promote their peaceful intercourse with his men. In 1445–46, again, Dom Henry renewed his earlier attempts to purchase or seize the Canaries, which brought Portugal to the verge of war with Castile; but the home Government refused to support him, and the project was again abandoned. Azurara's narrative ceases in 1448; one of the latest expeditions noticed by him is that of a foreigner in the prince's service, "Vallarte the Dane," which ended in destruction near the Gambia, after passing Cape Verde in 1448. After this the chief matters in Dom Henry's life are, first, the progress of discovery and colonization in the Azores; secondly, the rapid progress of civilization in Madeira, evidenced by its timber, sugar, corn and honey, and above all by its wine; and thirdly, the explorations of Cadamosto and Diogo Gomes (*q.v.*).

Cadamosto in 1455 and 1456, explored part of the courses of the Senegal and the Gambia, discovered the Cape Verde islands (1456), named and mapped more carefully than before a considerable section of the coast beyond Cape Verde, and gave much new information on the trade-routes of north-west Africa and on the native races; while Gomes, in his first important venture (after 1448 and before 1458), though not accomplishing the full Indian purpose of his voyage (he took a native interpreter with him for use "in the event of reaching India"), explored and observed in the Gambia valley and along the adjacent coasts with fully as much care and profit. As a result of these expeditions the infante seems to have sent out in 1458 a mission to convert the Gambia negroes. Gomes' second voyage, resulting in another "discovery" of the Cape Verde islands, was probably in 1462, after the death of Prince Henry; it is likely that among the infante's last occupations were the necessary measures for the equipment and despatch of this venture, as well as of Pedro de Sintra's important expedition of 1461.

The infante's share in home politics was considerable, especially in the years of Affonso V.'s minority (1438, etc.) while his elder brother Pedro was regent. When Dom Pedro rose in revolt (1447), Henry stood by the king and allowed his brother to be crushed. In the Morocco campaigns of his last years, especially at the capture of Alcazar the Little (1458), he restored his military fame which brought him invitations from the pope, the emperor and the kings of Castile and England, to take command of their armies. The prince was also grand master of the Order of Christ, the

successor of the Templars in Portugal; and most of his Atlantic and African expeditions sailed under the flag of his order, whose revenues were at the service of his explorations, in whose name he asked and obtained the official recognition of Pope Eugenius IV. for his work, and on which he bestowed privileges in the new lands. As "protector of Portuguese studies," Dom Henry founded a professorship of theology, and perhaps also chairs of mathematics and medicine, in Lisbon. To instruct his captains, pilots and other pioneers more fully in the art of navigation and the making of maps and instruments he procured the aid of one Master Jacome from Majorca, together with that of certain Arab and Jewish mathematicians. One Master Peter also inscribed and illuminated maps for the infante; the mathematician Pedro Nunes declares that the prince's mariners were well taught and provided with instruments and rules of astronomy and geometry "which all map-makers should know"; Cadamosto says that the Portuguese caravels in his day were the best sailing ships afloat; while, from several matters recorded by Henry's biographers, it is clear that he devoted great attention to the study of earlier charts and of any available information he could gain upon the trade routes of northwest Africa. Even if there were never a formal "geographical school" at Sagres, or elsewhere in Portugal, founded by Prince Henry, it appears certain that his court was the centre of active and useful geographical study, as well as the source of the best practical exploration of the time.

The prince died on Nov. 13, 1460, and was buried in the church of St. Mary in Lagos, but a year later his body was removed to the monastery of Batalha.

HENRY RASPE (1202?–1247), German king and landgrave of Thuringia, was the second surviving son of Hermann I, landgrave of Thuringia. When his brother, the landgrave Louis IV, died in Italy in 1227, Henry seized the government of Thuringia and expelled his brother's widow St. Elizabeth of Hungary and her son Hermann. Henry made good his position, although his nephew Hermann II was nominally the landgrave until his death in 1242. In 1236 Henry accompanied the emperor Frederick II on a campaign against Frederick II, duke of Austria, and took part in the election of his son Conrad as German king at Vienna in 1237. But he did not appear at the diet of Verona in 1238; possibly he disliked the betrothal of his nephew Hermann to the emperor's daughter Margaret. At all events, when the projected marriage had been broken off the landgrave supported the emperor in 1239 in opposition to a plan formed by various princes to elect an anti-king. In 1241 Henry's loyalty again wavered, and he was himself mentioned as a possible antiking. Frederick's visit to Germany in 1242 prevented this step for a time. In April 1246 Pope Innocent IV wrote to the German princes advising them to choose Henry as their king in place of Frederick, who had just been declared deposed. Henry was elected at Veitshochheim on May 22, 1246, and became known as the *Pfaffenkönig,* or parsons' king. He defeated King Conrad near Frankfort on Aug. j, 1246, and, after holding a diet at Niirnberg, undertook the siege of Ulm. He died at the Wartburg on Feb. 17, 1247.

HENRYSON, ROBERT (fl. 1475), one of the foremost of the Scottish Chaucerians. He is described on some early title pages as schoolmaster of Dunfermline—probably at the Benedictine abbey school—and he appears among the *morts* in William Dunbar's *Timor mortis conturbat me,* which was printed about 1508. Otherwise, the only detail known of his life is a circumstantial account of his deathbed wit in Sir Francis Kynaston's manuscript translation of Chaucer's *Troilus* into Latin (1635).

Henryson's longest work is *The Morall Fabillis of Esope the Phrygian, Compylit in Eloquent & Ornate Scottis,* a version of 13 fables based mainly on John Lydgate and William Caxton and running to over 400 seven-lined stanzas. The collection, made "be requeist and precept of ane Lord," has a prologue; and each tale is adorned with a *moralitas.* Some of the tales may have been written with some oblique political intention but their virtue lies in the freshness of the narrative, the sly humour and sympathy of Henryson's animal characterization and in his miniatures of the Scottish countryside. Not all the fables are written, as he modestly says, in "hamelie language and in termes rude," for he rises easily into an aureate style for comic effect or instruction; but his fundamental style is excellently colloquial.

In *The Testament of Cresseid,* a narrative and "complaint" in 86 stanzas, Henryson completes the story of Chaucer's Criseyde. He describes how he settled down on a winter night with *Troilus and Criseyde* and, questioning "gif all that Chauceir wrait was trew," turned to another version of the tale. From this he describes Criseyde's rejection by Diomede, her decline into prostitution, her rebuke to the gods, her punishment in leprosy and her death. The "uthir quair" is usually explained as a conventional fiction; but it may have been *The Spectakle of Luf,* a Latin work containing a hint of Criseyde's fate among a series of *exempla,* which was translated at St. Andrems in 1492 *(see* J. Kinsley in the *Times Literary Supplement,* Nov. 14, 1952). The *Testament* is more than a splendid piece of rhetorical craftsmanship; blended with Henryson's unwavering concern for justice are an aesthetic attraction to the repulsive and grotesque, and a refined sense of the "variance" of human love.

Among the shorter poems ascribed to Henryson are the lovely *Orpheus and Eurydice,* based on Boethius and akin to the *Testament* in mood and style; the "pastourelle" *Robene and Makyne,* in which a traditional French *genre* assimilates the speech and humour of the Scottish peasantry; and a number of fine moral narratives and meditations. Henryson is a slighter and less volatile figure than Dunbar; but in a narrower range he is as exquisite an artist.

BIBLIOGRAPHY.—*Manuscripts: The Morall Fabillis* is contained in four manuscripts: (1) the Asloan ms. (early 16th century), now in the possession of the Talbot de Malahide family in Dublin (ed. by W. A. Craigie for the Scottish Text society, 2 vol., 1923–5); (2) the Bannatyne ms. (1568), in the National Library of Scotland (ed. by W. T. Ritchie ior the Scottish Text society, 4 vol., 1928–34); (3) British museum Harleian ms. 3865 (1571; the most complete ms. version); and (4) the Makculloch ms., in the Edinburgh university library (one fable only). Early printed editions are dated 1570 (published by H. Charteris, Edinburgh, and surviving in a unique copy), 1571 (published by Bassandyne, Edinburgh, and surviving in a unique copy) and 1577 (London). There are no early manuscripts of *The Testameizt of Cressezd.* The earliest printed text is included in W. Thynne's *Chaucer* (1532). Later surviving editions are dated 1593 and 1663; at least two other 17th-century editions are lost. *Orpheus and Eurydice* was printed at Edinburgh by W. Chepman and A. Myllar c. 1508, and survives in a unique but incomplete copy. It is also included in the Asloan and Bannatyne mss. The shorter poems are preserved in the Bannatyne and other early mss.

Editioits: The standard collected edition is by G. Gregory Smith, for the Scottish Text society, 3 vol. (1906–14). There is a useful students' edition by H. Harvey Wood, 2nd ed. (1958).

Moore, "Robene and Makyne," in *Modern Language Review,* vol. xliii (1948); E. Muir in *Essays on Literature and Society* (1949); J. Kinsley in *Scottish Poetry: a Critical Survey* (19jj); C. Elliott, on the *Testament,* in *The Journal of English and Germanic Philology,* vol. liv (1955). (J. KY.)

HENSCMEL, SIR GEORGE (ISIDOR GEORG) (1850–1934), English musician (naturalized 1890), of German family, was born at Breslau, and educated as a pianist, making his first public appearance in Berlin in 1862. He subsequently, however, took up singing, having developed a fine baritone voice. In 1577 he began a successful career in England and in 1881 he married the American soprano, Lillian Bailey (d. 1901), who was associated with

him in a number of vocal recitals. He was also prominent as a conductor, started the London symphony concerts in 1886 and both in England and America (where he was the first conductor of the Boston symphony concerts, 1881) he did admirable work in this way, giving programs always of the highest type. In 1907 he married as his second wife Amy Louis, also a musician, of New York. He continued singing and teaching until long past his 70th year. Among his compositions may be mentioned a fine *Stabat Mater* (Birmingham Festival. 1894), an opera *Nubia* (Dresden, 1899) and many admirable songs.

HENSELT, ADOLF VON (1814–1889), German pianist. a follower of Liszt. Born at Schwabach. Bavaria. May 12. 1814. he studied the piano under J. N. Hummel at Weimar and composition under Simon Sechter in Vienna. He toured Germany as a pianist in 1836, and in 1838 settled in St. Petersburg, where he acquired a great position as teacher and performer and received a title. His manner of playing was similar to that of Liszt, except that. whereas Liszt relied on the pedals for maintaining sonorify, Henselt developed an exceptionally large stretch of the hand, which enabled him to hold down widely spaced notes. His method is illustrated in his *Études*, his *Exercices préparatoires* and his edition of the studies of J. B. Cramer for which he provided a second piano part. He also edited the piano works of Weber and made piano transcriptions of his overtures. His compositions include a piano concerto (Op. 16), some smaller piano pieces, a duo for piano and horn, a piano trio and two sets of choral pieces. *Maienzeit* and *Morgenständchen*. He died at Warmbrunn, Silesia, Ocr. 10, 1889.

See W. von Lenz, *Die grossen Pianoforte-Virtuosen unserer Zeit* (1872).

HENSLOW, JOHN STEVENS (1796–1861), English clergyman. botanist and geologist who popularized botany at the University of Cambridge and largely inspired Charles Darwin's taste for natural history. was born at Rochester, Kent. on Feb. 6, 1796. He graduated in mathematics at St. John's college, Cambridge, in 1818 and then turned to natural history. making geological expeditions to the Isle of Wight and the Isle of Man with Adam Sedgwick. They founded the Cambridge Philosophical society in 1821. In 1822 Henslow became professor of mineralogy at Cambridge, and was ordained in 1824. In 1827 he was made professor of botany, and enlivened its teaching, especially through excursions. He obtained for Darwin, his pupil and friend, the position of naturalist to H.M.S. "Beagle" (1831–36), and. in Darwin's own words. "took charge of the collections I sent home, and by his correspondence directed my endeavours." In 1837 Henslow was made rector of Hitcham, Suffolk, living there from 1839. Despite opposition. he fostered among his parishioners an interest in the economic and practical aspects of botany. greatly to the improvement of local farming practice. Henslow died at Hitcham on May 16. 1861. He formed many collections. and helped Sir W. J. Hooker with the botanical museums at Kew. His publications include *A Catalogue of British Plants* (1829; 2nd ed.. 1835); *Principles of Descriptive and Physiological Botany* (1835). He contributed to E. Skepper's *Flora of Suffolk* (1860).

HENSLOWE, PHILIP (d. 1616). English theatre proprietor and manager, the most important of the Elizabethan age. was born in Lindfield. Sussex. and apparently settled in Southwark. London. before 1577. He married the widow of Viscount Montague's bailiff, in whose service he had been; and with her money became an owner of much Southwark property. including inns and lodging houses. At various times he had interests in dyeing. starch-making and wood selling, as well as pawnbroking. moneylending and theatrical enterprises. He was a churchwarden and held some minor court offices. becoming a Groom of the Chamber. In 1587 Henslowe and a partner built the Rose playhouse on the Bankside near Southwark bridge. and under Henslowe's financial management various companies acted there from 1592 to 1603. He had an interest in the suburban Newington Butts theatre in 1594 and later in the Swan playhouse in Paris garden, at the western end of the Bankside. With the actor Edward Alleyn, who had married Henslowe's stepdaughter. he presented bearbaiting and bullbaiting in an old arena near the Swan. In 1610 Henslowe built a new theatre, the Hope. designed for plays as well as bearbaiting, on this site. The most sumptuous of Henslowe's theatres was the Fortune, built just north of London for the Admiral's Men in 1600.

Henslowe's theatres saw the first production of many important Elizabethan dramas; he was associated in one way or another with most of the famous playwrights for a quarter of a century, and his Admiral's Men were the chief rivals of Shakespeare's company. Henslowe was a shrewd. crotchety man of business who kept a tight hand on his theatrical companies. his players and his playwrights. "Should these fellowes come out of my debt I should have no rule over them." In the year before his death his players brought an indictment of "oppression" against him. The famous "Henslowe's diary" is really a manuscript book of miscellaneous accounts and memoranda. playhouse receipts, payments to playwrights, loans or advances to players, payments for ,materials, costumes! etc. It is one of the most important sources for the theatrical history of the time. For example! fully two-thirds of the plays mentioned in the diary are now otherwise lost. This book and other important theatrical papers were left by Edward Alleyn as part of his benefaction to Dulwich college. J. P. Collier edited the diary for the Shakespeare society in 1845, but unfortunately inserted a number of forged interpolations.

(FK. C. B.)

HENSON, HERBERT HENSLEY (1863–1947), English priest. was born in London on Nov. 8, 1863. As an unattached student at Oxford he graduated in 1884 and was elected a fellow of All Souls college. He was ordained in 1887; and. after being head of Oxford house at Bethnal Green for a year, he was given the living of Barking. Essex. He was incumbent of St. Mary's hospital, Ilford, 1895–1900, canon of Westminster and rector of St. Margaret's. 1900–12, and dean of Durham, 1912–18, when he was promoted to the bishopric of Hereford in succession to Percival. Because of his pronounced liberal opinions in theology, and his insistence on the validity of Nonconformist orders. his appointment aroused some controversy. From 1920 to 1939 he was bishop of Durham. He died on Sept. 27, 1947, at his home near Ipswich.

HENTY, GEORGE ALFRED (1832–1902), English war correspondent and author, was born at Trumpington, near Cambridge, and educated at Westminster school and Caius college, Cambridge. He served in the Crimea in the purveyor's department, and after the peace filled various posts in the department in England and Ireland, but drifted into journalism for the *London Standard*. He volunteered as special correspondent for the Austro-Italian War of 1866, accompanied Garibaldi in his Tirolese campaign, followed Lord Napier through the mountain gorges to Magdala, and Lord Wolseley across bush and swamp to Kumasi. Eext he reported the Franco-German War, starved in Paris through the siege of the Commune and then turned south to rough it in the Pyrenees during the Carlist insurrection. He was in Asiatic Russia at the time of the Khiva expedition, and later saw the desperate hand-to-hand fighting of the Turks in the Serbian war. In middle life he began to write excellent books of adventure for boys, many of which had a good historical background. His first boys' book *Out on the Pampas* dates from 1868; the last two, posthumously published, were *With Kitchener to the Sudan* (1903), and *With the Allies to Pekin* (1904). There are some 80 of these stories. Henty died on Nov. 16, 1902.

HENZADA, a town and district of Lower Burma, formerly in the Pegu. but now in the Irrawaddy division. Area, 2.782 sq.mi. Pop. (1941) 693.271. The district lies to the west of the Irrawaddy and stretches to the crest of the Arakan Yomas which form the boundary between Henzada and the Sandoway district of Arakan. The district thus comprises a tract of hilly, forested country on the west and a portion of the plain of the Irrawaddy on the east. The town of Henzada itself is usually regarded as lying at the southern end of the Irrawaddy valley proper and at the head of the delta. The low-lying eastern portions of the district are protected from inundation by immense embankments, so

that almost the whole is suitable for rice cultivation. Tobacco is also an important crop. The hills in the western part are forested. The chief town of the district is Henzada, which had in 1953 a population of 61,972. Other towns in the district are Myan-aung, with a population of 11,155; and Kyangin with a population of 6.073 according to the 1953 census. The river towns are served by the steamers of the Irrawaddy Flotilla company and a branch of the Burma railway runs from Kyangin to Henzada and from Henzada to Bassein.

The district was once a portion of the Talaing kingdom of Pegu, afterward annexed to the Burmese empire in 1753, and has no history of its own.

HEPATICA (Hepatica americana), a North American plant of the buttercup family (Ranunculaceae), called also liverleaf, liverwort and squirrel cup, native in woods from Nova Scotia to Manitoba and south to Florida and Missouri. It is a low, almost stemless perennial. about 3 in. high, often growing in tufts, with thick, evergreen, three-lobed basal leaves on very hairy stalks, and delicate blue, purple or white flowers. about $\frac{7}{8}$ in. broad, composed of 6 to 12 sepals, and borne singly on hairy stalks. Immediately beneath the flower are three leaflets (involucre) simulating a calyx. The very similar sharp-lobed hepatica (H. acutiloba), with pointed instead of rounded leaf lobes, found from Quebec to Minnesota and south in the Alleghanies to Georgia and in the interior to Missouri, is rare or absent near the Atlantic coast.

J. HORACE MCFARLAND CO.
OLD WORLD HEPATICA (H. TRILOBA)

The hepaticas are among the earliest and best-known woodland wild flowers of eastern North America, the two species occurring together in many localities. The leaves that last over winter are deep olive green or bronzy above and reddish-purple or liver-coloured beneath. According to some botanical authorities the genus Hepatica is included in the genus Anemone. The Old World hepatica or liverleaf (Hepatica triloba or Anemone Hepatica), widely distributed in Asia and Europe, and often cultivated, is not found native in the British Isles. (See ANEMONE; RANUNCULACEAE.)

HEPATITIS, CANINE VIRAL, is an acute viral infection, common in young dogs. affecting the liver and inner lining of blood vessels. It is usually characterized by fever, lack of appetite, vomiting, intense thirst, abdominal tenderness and hemorrhages. This disease has long been confused with canine distemper, next to which it is the most important disease of dogs in the United States. It also infects foxes, timber wolves, coyotes and bears.

In 1930 Richard Green of the United States published information indicating that the cause of infectious canine hepatitis in foxes was a virus. The disease as produced experimentally in dogs was first described by Green in 1934. In 1947 Sven Rubarth of Sweden published a comprehensive paper on the disease as it occurred both naturally and experimentally. Rubarth suggested that the virus producing infectious canine hepatitis was the same as Green's virus, and his theory was tested further by William Carlson and Harold Siedentopf, who confirmed it.

Symptoms and Treatment. — This disease is usually seen in young dogs; it does occur in older dogs. Puppies seem most susceptible, and in this group the mortality rate is highest. The infection may occur at any time during the year. The severity of the illness varies from an unnoticeable disease to a fatal infection. Usually, a susceptible dog becomes ill six to nine days after exposure to a dog discharging the virus. The first sign of infectious hepatitis is an elevation of the dog's temperature, the fever lasting from one to six days. A fever of short duration is sometimes the only sign of canine infectious hepatitis, but if the fever persists for more than two days, other symptoms become apparent.

In addition to the general signs of distress, the primary indication of infectious hepatitis is an attitude of apathy, followed by a partial or complete loss of appetite, combined with intense thirst. A watery exudate is occasionally discharged from the eyes. Fiery redness of the mouth lining is considered an important sign. Complications, such as tonsillitis, are sometimes noticed, but the degree of severity varies. Abdominal tenderness is frequently observed, and pain is evidenced by pressure on the abdomen in the region of the liver and gall bladder. Vomiting is occasionally seen. Swellings, causing disfigurement, are sometimes found in the region around the neck, head and trunk. Skin hemorrhages may result from a bodily injury: and these bleed profusely from the site of the wound; control of hemorrhage is difficult because of the prolonged blood clotting time. Sometimes jaundice is reported. Nervous disorders in dogs have been observed in a few natural cases. but never in experimentally infected dogs.

Approximately 25% of the dogs that recover from infectious hepatitis develop temporary bluish-white discolorations of one or both corneas. These may develop between seven and ten days after disappearance of acute illness.

Treatment of symptoms by a veterinarian is desirable to prevent the complications that may occur as a result of secondary bacterial infection. Careful nursing also is needed. Unfortunately there is no therapeutic substance that affects the disease course resulting from direct virus action, once symptoms are observed.

Lesions.--In fatal cases the primary destruction occurs in the blood vessels and in the liver cells. Multiple hemorrhages and excessive fluid in tissues and body cavities occur as a result of blood vessel damage. The liver is slightly enlarged and is usually tan-coloured with darker mottled streaks. A characteristic change is the thickened gall bladder wall. A definite diagnostic aid is the presence of intranuclear inclusion bodies in liver cells and the cells of the inner lining of blood vessels.

Transmission and Immunization. — In 1951 George Poppensiek and James Baker reported a finding that explains the transmission and survival of the canine infectious hepatitis virus. It persists for months in the urine of most dogs that recover from the infection and serves therefore as a constant source of infection to susceptible dogs. Thus prevention becomes the most important aspect in protecting the dog population from this highly contagious infection, and vaccination is the practical solution.

Various vaccines are available to immunize dogs against canine hepatitis. One, an inactivated virus vaccine, is extremely safe since the virus is treated chemically to inhibit its disease-producing properties. However, protection by this method is of limited duration. By contrast, a live virus vaccine produces a dependable immunity of longer duration. The live virus vaccine is desirable since it elicits no unfavourable reaction in the dog, having been modified by laboratory procedure through transfer in tissue-cultured dog kidney cells and then in tissue-cultured pig kidney cells.

In 1952 James Gillespie, James Robinson and Baker found that dogs could be infected simultaneously with canine infectious hepatitis and another important disease of dogs, canine distemper. After recovery, the dogs were immune to both diseases. Later in the same year, Poppensiek and Baker proved that immunity against both diseases can be produced in dogs by the administration of distemper virus modified by culture in hen's eggs in combination with canine hepatitis virus derived from infected dogs. When given simultaneously with antiserum, no clinical signs of illness resulted from the vaccination procedure. By use of canine hepatitis virus modified by tissue culture transfer, serum is no longer necessary to immunize dogs against canine distemper and infectious canine hepatitis. The dual vaccine has proved to be a safe and effective method for immunization of dogs.

HEPHAESTION, a Macedonian general, celebrated as the friend of Alexander the Great, who called Hephaestion his Patro-

clus. In the later campaigns in Bactria and India, he superintended the founding of cities and colonies and built the fleet intended to sail down the Indus. He was rewarded with a golden crown and the hand of Drypetis, the sister of Alexander's wife Stateira (324 B.C.).

In the same year he died suddenly at Ecbatana. Mourning was ordered throughout Asia; at Babylon a funeral pile was erected and temples were built in his honour (see ALEXANDER III, THE GREAT).

HEPHAESTION (?2nd century A.D.), Greek metrist of Alexandria. author of a work on metre in 48 books which was reduced to form a manual (Gr. enchiridion) by successive abridgments. The manual became a popular schoolbook and it alone survives. It is the only complete ancient work on metrics extant (see PROSODY. CLASSICAL). Appendixes dealing with poetic structure and with metrical notations may not be by Hephaestion. Important scholia have independent value.

BIBLIOGRAPHY.—Manual ed. by M. Consbruch in the "Teubner Series" (1906); Eng. trans. by T. F. Barham (1843). *See* also Pauly-Wissowa, *Realencyclopadie der classischen Altertumswissenschaft*, vol. *8*, col. 296–309 (1913); J. E. Sandys, *History of Classical Scholarship*, vol. i, 3rd ed. (1921). (G. B. KD.)

HEPHAESTUS (Gr. *Hēphaistos*), in Greek mythology, the god of fire. As the distribution of his shrines testifies, he was originally a deity of that Anatolian population known to the Greeks as Carians. The home of his worship seems to have been the Lycian Olympus, where a quantity of natural gas still escapes from the soil. This was in antiquity "at once the sanctuary and the image" of the god (Max. Tyr. Dissert. ii., 8). Hence the cuit spread to other places in Asia Minor and to some islands, especially Lemnos and Moschylus, which it reached very early. Hephaestus became the god of fire in general, and consequently the divine smith and patron of craftsmen. His cult reached Athens not later than about 600 B.C., and was carried at an early but unknown date to the volcanic Liparaean Islands off Sicily, whence it spread sporadically to Sicily and Campania. Crete it never reached, and Greece proper, with the exception of Attica, hardly at all. Natural fires, volcanic or gaseous, were often considered to be the workshops of Hephaestus.

In Homer the fire-god was the son of Zeus and Hera, cast out from heaven, either by Zeus, when he fell on Lemnos, or by Hera, who threw him down immediately after his birth in disgust at his lameness, when he was received by the sea-goddesses Eurynome and Thetis (Iliad, i. 590; xviii. 395).

The subsequent return of Hephaestus to Olympus is a favourite theme in early art. His wife was Charis, (in the Iliad) or Aphrodite (in the Odyssey). The connexion of the rough Hephaestus with these goddesses is curious; it may be due to the beautiful works (χαριέντα ἔργα) of the smith-god, but it is possibly derived from the supposed fertilizing and productive power of fire, in which case Hephaestus is a natural mate of Charis, a goddess of spring, and Aphrodite, the goddess of love. In Homer, the skill of Hephaestus in metallurgy is often mentioned; his forge was on Olympus, where he was served by images of golden handmaids that he had animated. Similar myths are found in relation to the Finnish smith-god Ilmarinen and the Teutonic Wieland; a belief in the magical power of metal-workers is a common survival from an age in which their art was new and mysterious., In epic poetry Hephaestus is rather a comic figure, and his limping gait provokes "Homeric laughter" among the gods. It has been suggested that in an early stage of society the trade of a smith would be suitable for the lame; Hephaestus and the lame Wieland would thus conform to the type of their human counterparts.

At Athens, with its large industrial population, Hephaestus was an important god. He finds a place in the local myths (see ERECHTHEUS). His temple has been identified, not improbably, with the so-called "Theseum." It contained a statue of Athena, and the two deities are often associated, in literature and cult, as the joint givers of civilization to the Athenians. The class of artisans was under their special protection; and the joint festival of the two divinities — the Chalceia — commemorated the invention of bronze-working by Hephaestus. In the *Hephaisteia* (the particular festival of the god) there was a torch race, a ceremonial not indeed confined to fire-gods like Hephaestus and Prometheus, but probably in its origin connected with them, whether its object was to purify and quicken the land, or (according to another theory) to transmit a new fire with all possible speed to places where the fire was polluted. The relation between Hephaestus and Prometheus is in some respects close, though the distinction between these gods is clearly marked. The fire, as an element, belongs to the Olympian Hephaestus; the Titan Prometheus, a more human character, steals it for the use of man. Prometheus resembles the Polynesian Maui, who went down to fetch fire from the volcano of Mahuika, the fire-god. Hephaestus is a culture-god mainly in his secondary aspect as the craftsman, whereas Prometheus originates all civilization with the gift of fire. But Prometheus despite his Greek name, in actual cult, was largely superseded by Hephaestus.

In archaic art Hephaestus is generally represented as bearded, though occasionally a younger beardless type is found, as on a vase (in the British Museum), on which he appears as a young man assisting Athena in the creation of Pandora. At a later time the bearded type prevails. The god is usually clothed in a short sleeveless tunic and wears a round close-fitting cap. His face is that of a middle-aged man, with unkempt hair. He is in fact represented as an idealized Greek craftsman, with the hammer, and sometimes the pincers. In art no attempt was made, as a rule, to indicate the lameness of Hephaestus; but one sculptor (Alcamenes) is said to have suggested the deformity without spoiling the statue.

HEPHTHALITES (EPHTHALITES). This many-named and enigmatic tribe was of considerable importance in the history of India and Persia in the 5th and 6th centuries and was known to the Byzantine writers. who call them Ephthalitoi, Euthalitoi. Nephthalitoi or Abdeloi. The last of these resembles the name Haital used by Arab chroniclers. They were also called Leukoi Hounnoi or Chounoi. White (that is. fair-skinned) Huns. The earliest information about the Hephthalites comes from the Chinese chronicles. in which it is stated that they were originally a tribe of the great Yue-Chi (*q.v.*), living to the north of the Great Wall and in subjection to the Jwen-Jwen, as were also the Turks at one time. Their original name was Hoa or Hoa-tun.

Before the 5th century A.D. they began to move westward, for about 420 they were in Transoxiana and for the next 130 years they were a menace to Persia. which they continually and successfully invaded. though they never held it as a conquest. The Sassanid king Bahram V fought several campaigns with them and succeeded in keeping them at bay, but they defeated and killed Firuz, A.D. 484. The Persians were not quit of the Hephthalites until 557. when Khosrau I Xnushirvan destroyed their power with the assistance of the Turks.

The Huns who invaded India appear to have belonged to the same stock as those who molested Persia. The headquarters of the horde were at Bamian and at Balkh. and from these points they raided to the southeast and southwest. Skandagupta repelled an invasion in 455, but the defeat of the Persians in 484 probably stimulated their activity. and at the end of the 5th century their chief Toramana penetrated to Malwa in central India and succeeded in holding it for some time. His son Mihiragula (*c.* 510–540) made Sakala in the Punjab his Indian capital, but the cruelty of his rule provoked the Indian princes to form a confederation and revolt against him *c.* 528. He took refuge in Kashmir. where after a few years he seized the throne. He died (*c.* 540). and shortly afterward the Hephthalites collapsed under the attacks of the Turks. They were probably gradually absorbed in the surrounding populations.

Another theory concerning the racial origin of the Hephthalites is that they were one branch of the Chionites (also known as Hunas or White Huns). This branch is said to have settled in Bactria (*q.v.*) whence they invaded Persia. while a second branch, the Zavula. moved south and settled round Kabul and Ghazni. It was the Zavula. according to this theory. who invaded India.

The accounts of the Hephthalites. especially those of the Indian Hunas, dwell on their ferocity and cruelty. Their invasions shook

Indian society and institutions to the foundations but, unlike the earlier Kushans, the Hephthalites do not seem to have introduced new ideas into India nor to have acted as other than a destructive force. Many of Mihiragula's coins bear the Nandi bull (Siva's emblem); and the king's name is preceded by the title *sahi* (shah). which had previously been used by the Kushan dynasty. Toramana's coins are found plentifully in Kashmir, which, therefore, probably formed part of the Huna dominions before Mihiragula's time.

Greek writers give a more flattering account of the Hephthalites; Procopius says they were far more civilized than the Huns of Attila. The Chinese writers say their customs were like those of the Turks: that they had no cities, lived in felt tents, were ignorant of writing and practised polyandry. Nothing whatever is known of their language, but some scholars explain the names Toramana and Jauvla as Turkish.

HEPPLEWHITE, GEORGE (d. 1786), English cabinet-maker and furniture designer whose name is famous for a graceful style rather than for the work of his own hand. Little is known of his life except that he was apprenticed to Robert Gillow of Lancaster, went to London and opened a shop in Redcross street. St. Giles, Cripplegate. He died in 1786, and administration of his estate was granted to his widow, Alice, who carried on the business. The *Cabinet-Maker and Upholsterer's Guide* was published in 1788, with nearly 300 designs "from drawings by A. Hepplewhite and Co. Cabinet-makers." A second edition, almost unchanged, appeared in 1789, and a third edition was published in 1794, the section on chairs being brought up to date, notably by the inclusion of chairs with square backs. The plates in the *Guide* are unsigned, but ten designs signed "Hepplewhite" or "Heppelwhite" are included in the *Cabinet-Makers' London Book of Prices* (1788).

Pieces of furniture based on designs in the *Guide* are rare, and no piece can be definitely attributed to Hepplewhite's firm. Nor can Hepplewhite's personal responsibility for the designs in the *Guide* be established. In a note on a chair design incorporating the three feathers, it is claimed that it "has been executed with good effect for the prince of Wales," but the firm is not mentioned in the royal accounts, nor is there any other evidence to show that Hepplewhite's was a fashionable firm. The achievement of the *Guide* was to translate into simple yet elegant terms the more extravagant furniture of the neoclassical style as seen in the designs of Robert Adam. This purpose is expressed in the preface, "to unite elegance and utility, and blend the useful with the agreeable."

That the designs are not an original creation but rather the expression of the best in current taste is again confirmed in the preface, "we designedly followed the latest or most prevailing fashion only. purposely omitting such articles, whose recommendation mas mere novelty, and perhaps a violation of all established rule."

Simplicity, elegance and utility are characteristic of all the designs in the *Guide*. Many of them were intended to be made in inlaid satinwood, others in mahogany or with japanned decoration. Chairs. with straight tapered legs, have shield-, heart- and oval-shaped backs, incorporating urns. festoons, cornhusk chains and other typical motifs of the neoclassical style. Upholstered settees of serpentine form, window seats with scrolled arms small square- and circular-topped inlaid tables, bookcases with delicate tracery in the glazed doors and serpentine fronted chests of drawers are all characteristic of the graceful style to which Hepplewhite has given his name.

HEPTARCHY, a word used by historians to designate the period between the setting up of Anglo-Saxon kingdoms in England toward the end of the 5th century and the destruction of most of them by the Danes in the second half of the 9th century. It is derived from the Greek words for "seven" and "rule" and appears first to have been used by William Lambarde in 1576. The seven kingdoms were Northumbria, Mercia, East Anglia, Essex, Kent, Sussex and Wessex. The term is inaccurate, however, for in sqme periods Northumbria consisted of the two kingdoms of Deira and Bernicia, and Lindsey also had a royal line of its own. while Sussex ceased to be a separate kingdom in the late 8th century.

(D. WK.)

HERA, in Greek mythology a daughter of the Titans Cronus and Rhea, sister-wife of Zeus and queen of the Olympian gods. The Romans identified her with their Juno (*q.v.*). The derivation of Hera's name is obscure, but it probably means simply "lady"; it is likely that she was a pre-Hellenic deity. Hera plays an important part in literature from the time of Homer and Hesiod, appearing most frequently as the jealous and rancorous wife of Zeus and pursuing with vindictive hatred the heroines, such as Alcmene, Leto and Semele. who were beloved by Zeus, as also their children. In cult, however, her dignity and power are naturally more emphasized.

Hera was worshiped throughout the Greek world, and especially in the ancient centres of Argos, Mycenae and Sparta, which she claims in the *Iliad* as her three dearest cities—although her Spartan cult subsequently somewhat declined. She was particularly honoured on the island of Samos, off the coast of Asia Minor, and worshiped also extensively in Magna Graecia, as witness her temple at Crotona on the south Italian coast.

Hera was held to be the sole lawful wife of Zeus from an early time; she soon supersedes Dione, who shares with him his ancient oracle shrine at Dodona in Epirus. He and Hera therefore often share altars and sacrifices, and also a dramatic representation of their sacred marriage. For instance, at Plataea in Boeotia, an effigy of Hera was made from an oak tree, dressed in bridal attire and carried in procession on a cart.

This conveyed a story to the effect that Hera had left Zeus in anger; that Zeus, to win her back through jealousy, announced that he was about to marry and dressed up a puppet to imitate a bride; and that Hera, meeting the wedding procession and tearing off the "bride's" veil, discovered the ruse and was reconciled to her husband. Every sixth year this mime was performed with numerous images, which were then burned on the top of Mt. Cithaeron together with animals and the sacrificial altar The rite thus appears to be a charm designed to quicken the growth of vegetation; the marriage of Zeus and Hera would, in this case, represent the union of the king and queen of May. Legends also often mention how the pair had anticipated marriage.

But Hera and Zeus need not for all that have had anything originally to do with the earth or with vegetation. The ceremony of the solemn concealment and discovery of Hera's image on the seashore at Samos suggests a marriage neither of heaven and earth nor of two vegetation spirits but rather a reflection of certain local marriage customs. It is to be noted that Hera had little to do with agriculture except at Argos, and that she was not closely associated with such earth and vegetation deities as Cybele, Demeter. Persephone and Dionysus.

In general Hera was worshiped in two main capacities: as consort of Zeus and queen of heaven; and as goddess of marriage and of the life of women. This latter sphere naturally made her the protectress of women in childbed. and she bore the title of Eileithyia (q v.), the birth-goddess, at Argos and Athens. In Homer and Hesiod she is the mother of Eileithyia. Her cult title of "maiden," "wife," "widow" or "divorced" express her worshipers' different conditions of life.

At Argos and Samos, however, Hera was more even than queen of heaven and marriage-goddess. She was patron of those cities, which gave her a position corresponding to that of Athena at Athens. Her Argive ritual was markedly agricultural; the first plow oxen were hers as "lady of the yoke," and the sprouting ears of corn were "the flowers of Hera." Girls called "flower-bearers" served in her temple, and a spring flower festival was celebrated by Peloponnesian women. She also had a celebration called the

Shield, and there was an armed procession in her honour at Samos. All this resulted from the breadth of functions attributed to the patron deity of a Greek state: a city-goddess must be chief in peace and war alike, and her interests reflect those of her people.

The animal especially sacred to Hera was the cow. The Homeric epithet *boopis* may have meant "cow-faced" to her earliest worshipers—the heifer-goddess Io (*q.v.*) was her first Argive priestess — although it was later understood as "large-eyed" (like a cow). Oxen drew her car in processions, and cows were sacrificed to her Her sacred bird was first the cuckoo. under whose form Zeus wooed her. and later.the peacock.

Hera's first primitive cult images consisted of a log, a plank or a pillar. Later came statues. of nhich the most celebrated was the work of gold and ivory made by the elder Polyclitus for the Heraion at Argos soon after 423 B.C. He seems to have fixed her type as the majestic, rather severe but youthful matron that she subsequently appears. *See* also references under "Hera" in the Index volume

See M. P. Nilsson, *Geschichte* der *griechischen Religion,* 2nd ed., vol. i, pp. 427–433 (1955).

HERACLEIA or, in the Latin form. HERACLEA. the name of a large number of ancient cities founded by the Greeks.

1. HERACLEA, an ancient city of Lucania. near the modern Policoro. Italy; 3 mi. from the coast of the Gulf of Tarentum, between the Aciris (Xgri) and Siris (Sinni) rivers about 13 mi. S.S.W. of Metapontum. It was a Greek colony founded by the Tarentines who had been deieated by the Thurians in 433 B.C. There Pyrrhus, king of Epirus, defeated the consul Laevinus in 280 B.C., after he had crossed the Siris river. In 278 B.C., probably in order to detach it from Tarentum, the Romans made a special treaty with Heraclea, on such favourable terms that in 89 B.C. the Roman citizenship given to the inhabitants by the Lex Plautia Papiria was only accepted after considerable hesitation. Having accepted Roman citizenship, it became a municipium; part of a copy on bronze of the Lex Iulia Municipalis of 46 B.C., found between Heraclea and Metapontum, is of the highest importance for knowledge of that law. It was still of importance under the empire; a branch road from Venusia joined the coast road there. Its medieval representative was Anglona, once a bishopric.

There was another Heraclea to which Herodotus refers. near Mt. Eryx. founded by Dorieus not. long after 500 B.C. and soon destroyed by the Carthaginians and Egesteans.

2. HERACLEA MINOA. an ancient town on the south coast of Sicily, at the mouth of the Halycus river (modern Platani) about 20 mi. W.N.W. of Girgenti. It was founded by Selinus and was always a border town between Carthaginian and Greek territory. It was taken by the Lacedaemonian colonists under Euryleon shortly before 500 but must have iallen into Carthaginian hands before Acragas (406). They lost it temporarily to Agathocles and Pyrrhus. but used it as a base in the first Punic War.

3. HERACLEA PONTICA (mod. Eregli), an ancient city on the coast of Bithynia in Asia Minor, at the mouth of the Kilijsu. It was founded by a Megarian colony. which soon subjugated the native Mariandynians and extended its power over a considerable territory. The prosperity of the city was utterly destroyed in the Mithridatic War. It was the birthplace of Heracleides Ponticus. The modern town is known for its coal mines.

4. HERACLEA SINTICA, a town in Thracian Macedonia, to the south of the Strymon, the site of which was sought by Leake at the village of Zervokhori, and identified by the discovery of local coins. while other authorities place it farther north.

5. HERACLEA, a tom-n on the borders of Caria and Ionia. near Mt. Latmus. A temple and a rock-cut theatre were once visible. In its neighbourhood was the burial cave of Endymion.

6. HERACLEA-CYBISTRA (mod. Eregli in the vilayet of Konia), under the name Cybistra, had some importance in Hellenistic times owing to its position near the point where the road to the Cilician Gates enters the hills. It lay in the way of armies and was more than once sacked by the Arab invaders of Asia Minor (A.D. 805 and 832) It becàme Turkish (Seljuk) in the 11th century.. Modern Eregli grew from a large village to a town after the railway reached it from Konia and Karaman in 1904. South, at Ivriz. is a Hittite rock relief: representing a king adoring a god. This was the first Hittite monument discovered in modern times (early 18th century, by an emissary of Louis XIV).

7. HERACLEA LYNCESTIS (mod. Monastir) was a town in Macedonia. on the Via Egnatia.

For Heraclea Trachinia *see* TRACHIS, and for Heraclea Perinthus *see* PERINTHUS.

HERACLEA was also the name of one of the Cyclades, between Kaxos and Ios, which is still called Iraklia, and bears traces of a Greek township with temples to Tyche and Zeus Lophites.

HERACLEIDES PONTICUS (d. after 322 B.C.). Greek philosopher. an eminent member of the Greek Academy (see ACADEMY, GREEK). was born at Heracleia in Pontus. Some authorities count him among the Peripatetics; but he was certainly a pupil of Plato. who left the Academy temporarily in his charge; and he was nearly elected to succeed Speusippus as the head of the Academy. His writings are lost except for a few fragments. We know that he taught the axial rotation of the earth, that he anticipated either the geoheliocentric or the geocentric hypothesis (Copernicus expressed his indebtedness to him, but the interpretation of the details of Heracleides' astronomic theories is controversial) and that he taught some kind of (teleologicalj atomism. Several works of his were devoted to literary criticism, musicology, etc. Besides these (more scientific) interests, he dealt with occult phenomena (trances. cosmological visions. prophecies, portents) and cataclysms, proving or illustrating by them the existence of gods, divine retribution, reincarnation, etc.. thus exemplifying the supranaturalistic tendencies of Platonism and foreshadowing some aspects of Neoplatonism.

See F. Wehrli (ed.). *Herakleides Pontikos* (Basel, 1953); P. Duhem, *Le Système du monde,* i, iii (Paris, 1913, 1915). (PP. M.)

HERACLEON, a Gnostic who flourished *c.* A.D. 125, probably in the south of Italy. He appears to have regarded the divine nature as a vast abyss in whose *pleroma* were aeons of different orders — emanations from the source of being. Midway between the supreme God and the material world was the Demiurgus, who created the latter, and under whose jurisdiction the animal soul of man proceeded after death. while his celestial soul returned to its origin. Origen. who treats Heracleon as a notabie exegete, has preserved fragments of his commentary on the fourth Gospel (brought together by Grabe in vol. ii of his *Spicilegium*), while Clement of Alexandria quotes what appears to be a passage from a commentary on Luke. These writings are intensely mystical and allegorical.

HERACLEONAS, East Roman emperor (Feb.–Sept. 641), was the son of Heraclius (*q.v.*) and Martina. At the end of Heraclius' reign he obtained through his mother's influence the title of Xugustus (638), and after his father's death was proclaimed joint emperor with his half-brother Constantine III. The premature death of Constantine. in May 641, left him sole ruler. But suspicion that he and Martina had murdered Constantine led to a revolt and to the mutilation and banishment of the supposed offenders. Nothing is known of him after 641.

HERACLIDAE, the general name for the numerous descendants of Heracles (Hercules); the name is especially used in antiquity for Hyllus and his descendants, the leaders of the Dorian invasion of the Peloponnese. The Dorian invasion and the collapse of the Heroic civilization is represented in Greek tradition as the "return of the Heraclids," seeking their father's inheritance. primarily Argos, oi which he had been defrauded by Eurystheus. The legend appears to have been reduced to order by Ephorus. and the date fixed at 1104 B.C.

The two main traditions may be summarized thus — chiefly from Herodotus and Pindar. The first centres round Echemus, king of Arcadia. who defeated the Heraclidae at the Isthmus before the Trojan War. They covenanted to stay away for three generations. At the end of this period the three sons of Xristomachus returned to Peloponnesus. captured it and divided the territory. Temenus taking .Argus. the sons of Xristodemus Sparta and Cresphontes Messene. The second. implicit in Herodotus' account of the coming of the Dorians, tells of the adoption by Xegimius, the Thessalian ancestor of the Dorians, of Hyllus as coheir with his own

sons (hence the Dorian tribes, Hylleis, Pamphyloi and Dymanes); and of the subsequent conquest of Peloponnesus by the three and their followers. It is difficult to reconcile these traditions, and, considered separately, each presents problems. It is probable that Messene was never Dorian until its conquest by Sparta.

There are further complications in addition to the confusion introduced by later writers; for instance, there is a Heraclid called Aletes ("the wanderer") who appears in Peloponnesus in one of the stories; he may have come from Rhodes. And Herodotus has a story of a Heraclid dynasty in Lydia. which ruled for the 505 years before the Mermnadae dynasty (685), the last being Candaules, who was killed by Gyges the founder of the Mermnad house.

(See DORIANS.)

The main ancient authorities in addition to Herodotus *(passim* and esp. i, 56; ix, 26) are Pindar, *Pyth,* ix, *Olymp.* vii.

HERACLITUS (c. 540–*c.* 480 B.C.), Greek philosopher, of Ephesus, was descended from the earlier kings of the city but surrendered his family privileges to his brother. He was a violent critic of his fellow citizens, of other thinkers and of mankind in general. Most of the stories about his life and death (*e.g.,* that he buried himself in dung to cure dropsy) are malicious embroideries on some of his well-known sayings, by Hellenistic biographers writing in the 3rd century B.C. and later. More than 100 short fragments survive as quotations in later writers; his style, vivid, gnomic and often cryptic, rapidly earned Heraclitus the name "the obscure."

According to Heraclitus the most important thing for men was the understanding of the logos, the universal formula of things in accordance with which all natural events occur and which all men should be able to assimilate. The majority, he complained, ignored the logos, even when he himself explained it, and relied like dreamers on a private and therefore false view of the world. An important manifestation of the logos was the underlying connections betueen opposites. This was illustrated by Heraclitus with many concrete examples; *e.g.,* sea water is both harmful (for men) and beneficial (for fishes). The connection between opposites—apparently the most divergent of all things—meant that the world was not just an indeterminate agglomeration of essentially distinct components, but a coherent and discoverable system in which changes in one direction are ultimately balanced by corresponding ones in the other; there is a hidden attunement or connection between things which means that what is apparently "tending apart" is actually "being brought together." The apprehension of the formal unity of the world of experience, rather than the genetic unity sought in the theogonic and Milesian tradition, together with the conviction that man's first task is to understand the principles that control both himself and his environment, was perhaps Heraclitus' main philosophical contribution.
