GUIZOT TO HYDROXYLAMINE

GUIZOT, FRANÇOIS PIERRE GUILLAUME (1787–1874), French historian and statesman, was born at Nîmes, Oct. **4,** 1787, of Protestant parents His father perished on the scaffold (April **8,** 1794) and the boy was brought up by his mother in Geneva. In 1805 Guizot began the study of law in Paris, living in the house of M. Stapfer, formerly Swiss minister in France, as tutor. He contributed to the *Publiciste,* and marned (1812) Pauline de Meulan, who was also a contributor to Suard's journal. After her death, in **1827,** Guizot married her niece, Elisa Dillon (d. **1833).** Their son, Maurice Guillaume (1833–1892), became a ell-known scholar and writer. Under the Empire, Guizot devoted himself exclusively to literary works, including, a critical edition of Gibbon's *Decline and Fall.* This work led to his appointment (1812) to the chair of modern history at the Sorbonne. But, though he took no public part in politics, he was closely associated with leading Liberals, notably with Royer-Collard, who secured for him the position of secretary-general of the Ministry of the Interior at the first Restoration.

During the Hundred Days Guizot returned to his literary pursuits. He then went to see Louis XVIII at Ghent, and, in the name of the Liberal Party, told him frankly that the open adoption of a liberal policy was the essential condition of a permanent monarchy. The advice was ill-received by the king's advisers, and the visit itself brought him into disgrace with the Bonapartists.

After the second Restoration Guizot had two short spells of official work, as secretary-general of the Ministry of Justice (1815–16) and as a director at the Ministry of the Interior (1819–20). He was one of the leaders of the *Doctrinaires,* monarchists who desired a *juste milieu* between absolutism and democracy. Their motives were honourable. Their views were philosophical. But they were opposed alike to the democratic spirit of the age, to the military traditions of the empire, and to the bigotry and absolutism of the court. They lived by a policy of resistance; they perished by another revolution **(1830).** They are remembered more for their constant opposition to popular demands than by their undoubted services.

In **1820,** when the reaction was at its height after the murder of the duc de Berri and the fall of the ministry of the duc Decazes, Guizot was deprived of his offices. and from **1822** to **1828** even his course of lectures were interdicted. He was now one of the leaders of the Liberal opposition to the Government of Charles X. His numerous works at this period include: *Histoire des origines du gouvernement représentatif* (**1821–22,** 2 vol.; Eng. trans. 1852); *Histoire de la révolution d'Angleterre depuis Charles Ier à Clzarles II.* (2 vols., 1826–27; Eng. trans., 1838), revised by him in his later years; *Histoire de la civilisation en Europe* **(1828;** Eng. trans by W. Hazlitt, **3** vols., **1846);** and *Histoire de la civilisation en France* (4 vols., **1830).** In addition he published during this period two great collections of sources for English and French history, a revised translation of Shakespeare, essays and pamphlets.

Hitherto Guizot's fame rested on his merits as a writer on public affairs and as a lecturer on modern history. In Jan. **1830** he was elected by Lisieux to the Chamber of Deputies, and he retained that seat during the whole of his political life. His first speech in the chamber was in defence of the celebrated address of the **221,** in answer to the menacing speech from the throne, which was followed by the dissolution of the chamber, and was the precursor of another revolution. On July **27** Guizot was called upon by his friends Casimir-Périer, Laffitte, Villemain and Dupin to draw up the protest of the Liberal deputies against the royal ordinances of July, whilst he applied himself with them to control the revolutionary character of the late contest. Personally, Guizot deprecated a change in the hereditary line of succession. But once convinced that it was inevitable, he became one of the most ardent supporters of Louis-Philippe. From August to November Guizot was minister of the interior. He had now passed into the ranks of the Conservatives, and for the next **18** years was the most determined foe of democracy, the unyielding champion of "a monarchy limited by a limited number of bourgeois." In Marshal Soult's Government formed on Oct. 11, **1832,** Guizot was minister of public instruction. Guizot applied himself in the first instance to carry the law of June **28, 1833,** establishing and organizing primary education. The branch of the Institute of France known as the Académie des Sciences Morales et Politiques, suppressed by Napoleon, was revived by Guizot. Some of the old members of this learned body — Talleyrand, Siéyès, Roederer and Lakanal — again took their seats there, and new members were

elected. The "Société de l'Histoire de France" was founded for the publication of historical works; and a vast publication of mediaeval chronicles and diplomatic papers was undertaken at the expense of the state.

The object of the cabinet of Oct. 1832 was to organize a Conservative Party, and to resist the Republican faction, which threatened the existence of the monarchy. The real strength of the ministry lay not in its nominal heads, but in the fact that in this Government and this alone, Guizot and Thiers acted in cordial co-operation. But in 1840 parliamentary difficulties arose and Guizot was not sorry to accept the post of ambassador in London, which withdrew him for a time from parliamentary contests. This was in the spring of 1840, and Thiers succeeded shortly afterwards to the Ministry of Foreign Affairs.

Thiers' policy regarding the Syrian question led France to the brink of war, until the king put an end to the crisis by refusing his assent to the military preparations of Thiers, and by summoning Guizot from London to form a ministry and to aid his majesty in what he termed "ma lutte tenace contre l'anarchie." Thus began, under dark and adverse circumstances, on Oct. 29, 1840, the administration in which Guizot remained the master-spirit for nearly eight years. He himself took the portfolio of foreign affairs, to which he added some years later, on Soult's retirement, the ostensible rank of prime minister. His first care was the restoration of amicable relations with the other Powers of Europe. His success in calming the troubled elements and healing the wounded pride of France was due mainly to the indomitable courage and splendid eloquence with which he faced a raging opposition, gave unity and strength to the Conservative Party, and appealed to the thrift and prudence of the nation rather than to their vanity and their ambition. In his pacific task he was fortunately seconded by the formation of the Peel administration in England, in the autumn of 1841. Lord Palmerston held (as it appears from his own letters) that war between England and France was, sooner or later, inevitable. Guizot held that such a war would be the greatest of all calamities, and certainly never contemplated it. In Lord Aberdeen, the foreign secretary, Guizot found a friend and an ally. Both of them held the common interest of peace and friendship to be paramount; and when differences arose, as they did arise, in remote parts of the world—in Tahiti, in Morocco, on the Gold Coast—they were reduced by this principle to their proper insignificance.

The history of Guizot's administration is dealt with in the article FRANCE: *History*. It was the longest and the last which existed under the constitutional monarchy of France, and bears the stamp of the great qualities and the great defects of his political character, for he was throughout the master-spirit of that Government. He united and disciplined the Conservative Party, which had been broken up by previous dissensions and ministerial changes. No one ever doubted the purity and disinterestedness of Guizot's own conduct. He despised money; he lived and died poor; and though he encouraged the fever of money-getting in the French nation: his own habits retained their primitive simplicity. But some of his instruments were mean; he employed them to deal with meanness after its kind. Gross abuses and breaches of trust came to light, and under an incorruptible minister the administration was denounced as corrupt.

Of his parliamentary eloquence it is impossible to speak too highly. It was terse, austere, demonstrative and commanding—not persuasive, not humorous, seldom adorned, but condensed with the force of a supreme authority in the fewest words. He was essentially a ministerial speaker, far more powerful in defence than in opposition. Like Pitt he was the type of authority and resistance, unmoved by the brilliant charges, the wit, the gaiety, the irony and the discursive power of his great rival. Nor was he less a master of parliamentary tactics and of those sudden changes and movements in debate which, as in a battle, sometimes change the fortune of the day. His confidence in himself, and in the majority of the chamber which he had moulded to his will, was unbounded; and long success and the habit of authority led him to forget that in a country like France there was a people outside the chamber elected by a small constituency, to which the minister and the king himself were held responsible.

After the fall of the monarchy in 1848 Guizot found a temporary refuge in Paris and then escaped via Belgium to London, where he arrived on March 3.

He stayed in England about a year, devoting himself again to history. He published two more volumes on the English revolution, and in 1854 his *Histoire de la république d'Angleterre et de Cromwell* (2 vols., 1854), then his *Histoire du protectorat de Cromwell et du rétablissement des Stuarts* (2 vols., 1856). He also published an essay on Peel, and the extensive *Mémoires pour servir à l'histoire de mon temps* (9 vols., 1858–68). His speeches were included in his *Histoire parlementaire* de *la France* (5 vols., 1863).

Guizot survived the fall of the monarchy and the Government he had served 26 years. He was of no party, a member of no political body; no murmur of disappointed ambition, no language of asperity, ever passed his lips; it seemed as if the fever of oratorical debate and ministerial power had passed from him and left him a greater man than he had been before, in the pursuit of letters, in the conversation of his friends, and as head of the patriarchal circle of those he loved. The greater part of the year he spent at his residence at Val Richer, an Augustine monastery near Lisieux in Normandy, which had been sold at the time of the first Revolution. His two daughters, who married two descendants of the illustrious Dutch family of De Witt, kept his house. One of his sons-in-law farmed the estate. And here Guizot devoted his later years with undiminished energy to literary labour, which was in fact his chief means of subsistence. Proud, independent, simple and contented he remained to the last: and these years of retirement were perhaps the happiest and most serene portion of his life. He was a member of three of the five academies of the Institute of France. In these learned bodies Guizot continued for nearly 40 years to take a lively interest and to exercise a powerful influence. He continued to be the jealous champion of their independence. His voice had the greatest weight in the choice of the new candidates; the younger generation of French writers never looked in vain to him for encouragement; and his constant aim was to maintain the dignity and purity of the profession of letters. In the consistory of the Protestant church in Paris Guizot exercised a similar influence. He remained through life a firm believer in the truths of revelation, and a volume of *Meditations on the Christian Religion* was one of his latest works.

His last and not his least work, the *Histoire de France racontée à mes petits enfants*, which came down to 1789, was continued to 1870 by his daughter Madame Guizot de Witt from her father's notes (7 vol., 1870–80). Guizot died Sept. 12, 1874.

Thieme, *Guide bibliographique de la littérature française de 1800 à 1906* (*s.v.* Guizot, Paris, 1907).

GUJARAT (also GUJRAT or GUJERAT), a state of the Republic of India which came into existence under the Bombay Reorganization act on May 1, 1960. Before that, the term Gujarat was loosely applied to a region lying north of Bombay city where Gujarati is spoken. When India became independent in 1947 the British-Indian province long known as the Bombay Presidency became Bombay state (*q.v.*). In the years which followed there was a successive reorganization of former princely states, notably the rich state of Baroda and the numerous small units which made up the peninsulas of Kathiawar and Cutch (Kutch). From 1948 to 1956 the greater part of the Kathiawar peninsula formed the separate Rajpramukh's state of Saurashtra with capital at Rajkot. When the states of peninsular India were reorganized on a linguistic basis in 1956 there was difficulty in separating the Gujarati-speaking and the Marathi-speaking parts of Bombay state and the

separation was deferred till 1960. In broad terms Gujarat is that part of India nhere Gujarati is the dominant language. comprising Cutch, Kathiawar and the parts of the former Bombay state north of Damão (Daman). Although the boundary usually drann along the northern shore of the seasonal marsh known as the Rann of Cutch is now commonly accepted as the frontier with West Pakistan, the line is not finally agreed. Accepting this, the area is 72.-154 sq mi., bounded by West Pakistan and Rajasthan on the north. Madhya Pradesh. Maharashtra and Damão on the east and south.

Physical Geography. — The state of Gujarat is one of great contrasts; it stretches from the wet fertile rice-growing plains of the west coast north of Bombay city to the almost rainless salt deserts of Cutch. The state is best considered on a basis of its natural divisions. In the northwest. Cutch (*q.v.*) comprises a single district so arid as to be almost desert; it is bounded on the south by the Gulf of Cutch and on the north and east is separated from Pakistan and the mainland of India by the Great Rann of Cutch best described as a vast salt marsh covering about 8 000 sq mi. The Rann floods during the rainy season slight though the rains may be, and Cutch is converted into an island; in the dry season it is a sandy salty plain plagued by duststorms. To the south of Cutch is the large peninsula of Kathiawar lying betneen the Gulf of Cutch and the Gulf of Cambay. It also is arid and rises from the coasts to a low rolling area of hill land in the centre. covered with scrub or sparse woodland. The chief towns are found in the more fertile spots and mere formerly the capitals of small states; non six of them are headquarters of districts Soils are mostly poor being derived from a variety of the old crystalline rocks but among the products of value are the fine building stones of Porbunder. Rivers. except for seasonal streams, are absent. On the southern shores of the peninsula is the former Portuguese territory of Diu (q v.). Northern Gujarat, using the old regional name, occupies the northeastern part of the new state and is mainly a country of small plains and low hills through nhich runs the main line of the Western railway (formerly the Bombay, Baroda and Central Indian) from Bombay to Delhi Rainfall is low; January temperatures may drop almost to freezing point whilst 118° F has been recorded in the hot season. Dry zone crops of millet with some cotton are grown; Ahmedabad is an important cotton town.

Southward in central Gujarat the rainfall increases, temperature ranges are less, soils are more fertile being derived partly from the Deccan basalts. The focus of this area is the city of Baroda, formerly the capital of a rich and powerful state. South of what is now the Baroda district, the important river, the Narmada (formerly Narbada), empties into the Gulf of Cambay and it is the silt borne by this river and the Tapti which is responsible for the shallowing of the Gulf of Cambay and the decline of its former ports.

Southern Gujarat, the districts of Broach and Surat, are famed for their rich soils and fine crops of cotton. The great river Tapti, flowing in a deep trench from the east, cuts through Surat and in the eastern parts of south Gujarat the country is mountainous. This is indeed the northern extension of the Sahyadri mountains or Western Ghats, so important in Maharashtra state and which attract a heavy rainfall from the summer monsoon. Farther south, the mountains are forested and the small district of the Dangs (*q.v.*) lies here. Along the coastal plains conditions begin to approach the equable climate, with rainfall nearing 80 in., characteristic of Bombay city. Almost the only unifying factor in the varied state of Gujarat is the Gujarati language.

(L. D. S.)

History. — Rich in Paleolithic and microlithic finds, the area included in Gujarat state has been inhabited from prehistoric times. It is believed that there was contact with the Indus Valley civilization, for a cult of the Mother Goddess has been traced along with more characteristic Hindu faiths. Between the 4th and the 8th centuries A.D., Gujarat was ruled successively by the Mauryas, the Sakas. the Guptas and the Valabhis. It mas during the 8th century that the Parsees entered the country from Iran. The Chalukya (*q.v.*) dynasty reigned from the 10th to the 13th century. Their power was then usurped by the Vaghelas who ruled until the Muslim conquest in 1298. The imperial rule of the sultans of Delhi ended with the usurpation of the first sultan of Gujarat, whose capital was at Anhilvada (Patan) Sultan Ahmed I founded Ahmedabad in 1411. From 1515 to 1572–73, when Akbar conquered Gujarat, the sultans were constantly embroiled with their Hindu. Rajput neighbours. About that time Affonso de Albuquerque and other Portuguese leaders made strenuous efforts to establish trading posts and forts in the coastal areas. Diu was obtained in 1535 and Damão in 1558, but relations with the Muslim rulers were seldom easy. Bassein (Vasai) was founded in 1534–35, and became an important centre of Portuguese and missionary activity, but it was taken by the Marathas in 1739 Between 1719 and 1758 the Marathas infiltrated through Gujarat. After the collapse of Maratha pouer. the former princely states entered into treaty relations with the British. They included Cambay, Chota Udaipur, Bariya, Balasinor and numerous petty states The Gaekwar of Baroda was left as the principal representative of Maratha dominance, and his state was famed for enlightened administration. In 1937 the political agencies Rewa Kantha. Surat, Kaira, Nasik and Thana combined with Baroda to form the Gujarat States Agency with headquarters at Baroda city. In July 1947, on the eve of Indian independence, all the component states joined the union of India and were subsequently incorporated into the state of Bombay. The latter was reorganized in 1960 to form the states of Gujarat and Maharashtra.

Apart from the areas that were formerly under direct British control, much of the modern Gujarat state still auaits development and socially and (except for the textile industry) economically also it retains archaic features. Its architecture is exceptionally rich, particularly in elaborate tracery and highly ornate temples and sculpture. Jainism there reached a high pitch of intellectual development. being patronized lavishly by the wealthy, numerous and abstemious Hindu mercantile classes. (See also INDIA *History*.)

(J. D. M. D)

Population, Administration and Social Conditions. — At the 1961 census the population figure for Gujarat was 20.621 283, giving a density of 286 persons per square mile. Ahmedabad is the provisional capital; the projected new capital. 15 mi. N of Ahmedabad, is to be called Gandhinagar. There are about 250 towns and more than 18.700 villages in the state; the chief towns are Ahmedabad (pop., 1961, 1,149,852), Baroda (295,304), Surat (288,167), Rajkot (194,510), Bhavnagar (177,488), Jamnagar (147,420); all the others have fewer than 100.000 persons.

Gujarat comprises 17 districts. They are Cutch; six which make up most of the Kathiawar peninsula, Jamnagar (formerly Halar), Junagadh (Sorath), Rajkot (Madhya Saurashtra), Amreli. Bhavnagar (Gohilnad) and Surendranagar (Zalawad); and ten in the old Gujarat region. Surat, Dangs, Kaira, Mehsana, Sabarkantha, Banaskantha, Broach, Baroda, Panch Mahals and Ahmedabad.

By the early 1960s Gujarat. with more than 30% of the population literate, ranked fourth among the Indian states in literacy. There are more than 24.500 schools and educational institutions, including three universities (Gujarat in Ahmedabad, Sayajirao in Baroda and Sardar Vallabhbhai Vidyapeeth in Anand). Free and compulsory primary education for children aged 7 to 11 is provided in all districts of Baroda division. The Gujarati language (*q.v.*) is spoken by most people.

By the early 1960s about 900 hospitals and dispensaries were providing generally free medical treatment. There are a number of labour welfare centres which provide free recreational facilities and cultural activities for industrial workers. The state government spends about Rs. 56,000,000 annually on educational, housing, medical and cultural facilities for backward classes and tribal people.

(S. CH.; S. B. L. N.)

Economy. — The main products of the state are cotton, rice, wheat, jowar, bajri and pulses. Forests produce teak, bamboos and sandalwood The Gir forests contain the only lions' sanctuary in India Minerals include calcite and limestone in Jamnagar and manganese in Baroda Kaira has bauxite and limestone and Saurashtra has gypsum. When completed the Ukai project will irrigate 555 000 ac. of land and help the industrial development of southern Gujarat. There are cement works at Porbunder, Dwarka

and Sikka, and factories for drugs and medicines near Bulsar and in Raroda. Silk goods are produced and there is a smaller output of gold and silver thread, carved sandalwood, and leather goods.

The industrialization characteristic of the city of Bombay (*q.v.*) and especially the textile industry. extends northward into Gujarat with such centres as Surat. Broach. Baroda and Ahmedabad well served by rail and road. To relieve the pressure on this main railway and the port of Bombay, it has been the policy of the central government of India to develop railways and modern deep water ports in Cutch and Kathiawar since the Gulf of Cambay is too shallow. Okha at the western tip of the Kathiawar peninsula has proved too distant and involves a long rail haul; Port Kandla on the Gulf of Cutch has accordingly been developed. Gujarat is credited with 3.529 mi. of railway. and road construction in the drier parts is relatively easy. But Gujarat has less than half of the number of factories and of factory workers found in Maharashtra. (L. D. S.)

(1938–57); K. M. hlunshi, *Glory That Was Gurjaradesa,* vol. i (1943); A. K. Majumdar, *Chaulukyas of Gujarat* (1956); M. R. Majumdar (ed.), *Historical and Cultural Chronology of Gujarat* (1960). (J. D. M. D.)

GUJARATI LANGUAGE, spoken by about 16,000,000 people in the present states of Gujarat and Maharashtra and adjoining districts, is one of the Indo-Aryan languages (*q.v.*). Its neighbour east and northeast is the Rajasthani language (*q.v.*) into which it merges so gradually that it is difficult to assign border dialects to either language. Gujarati, one of the 14 regional languages specified in the Indian constitution, has a number of dialects and class variations; *e.g.,* Parsis make distinctions between cerebrals and dentals that are disregarded by Moslems. Both communities have borrowed Persian and Arabic words more freely than standard Gujarati, which, because of its maritime connections, has borrowed occasional words from other parts of Asia and from Europe, especially in the dialect of the Kathiawar sailors. There are differences in pronunciation among the Hindus, too, *e.g.,* variation between *ē* and i, k and c, kh and ch, *s* and *ch,* as well as loss of It, confusion of cerebrals and dentals and alternation of d, *r,* l and *l.* (For standard Gujarati grammar, *see* G. P. Taylor, *The* Student's *Gujarati Grammar,* 3rd ed., 1944.)

Gujarati has a long literary tradition with an almost unbroken evolution from Gaurjara Apabhramsa to Old Gujarati (or Old Western Rajasthani). the latter generally considered to begin with the Bhakta or devotional poems of Narasimha Mehta (15th century) and, in the same period, the writings of the great poetess Mira Bai. Premanand, the 17th-century master of narrative poetry, adapted themes from the Sanskrit epics "Mahābhārata" and "Rāmāyaṇa." The last great poet of Old Gujarati was Dayaram (1767–1852). Jain *bhaṇḍārs* or libraries are veritable storehouses of Old Gujarati manuscripts.

On the impact of European civilization Narmadashankar (1833–1886), in his prose and verse innovations, gave direction to a literary revival; he is justly termed the founder of modern Gujarati literature. Govardhanram Tripathi's (1855–1907) novel *Saraswaticandra* depicts Gujarati life; it marks a renaissance and gives a literary inspiration to the period. K. M. Munshi (1887–) captured a wide public with his historical novels. The Gujarati writings and speeches of Mohandas K. Gandhi (1869–1948) had a strong literary influence. Panalal Patel wrote novels about village life.

GUJRANWALA, a municipal town. a district and a *tehsil* in Lahore division, West Pakistan. The town, headquarters of the district, lies 42 mi. N. of Lahore. Pop. (1961), including refugee camp, 196,154. Originally a village founded, as the name shows, by Gujars, it was renamed Khanpur by some Sansi Jats of Amritsar who settled there, but its old name survived. Little is known about its early history till it rose to importance during the Sikh period. It owes its growth to the father (Mahan Singh) and grandfather (Charat Singh) of Maharaja Ranjit Singh (*q.v.*). whose capital it was during the early 19th century. the early period of Sikh power. The principal places of interest include the grave of Mahan Singh. Mahan Singh's garden and a lofty cupola covering part of the ashes of the great maharaja. There are two degree colleges, for men and women, both affiliated to the Punjab university, and an intermediate college and secondary schools.

Gujranmala lies on the railway line to Peshawar, and on the Grand Trunk road, and is the chief market of the district and an important industrial centre. Manufacturing of iron safes and aluminum, brass and copper utensils are the old industries for which it occupies an important position in Pakistan. New industries have grown since independence, including manufactures of textiles. hosiery, sanitary fittings and electric fans, and tanneries.

GUJRANWALA TEHSIL, area 936 sq.mi., had a population in 1961 of 745,393.

GUJRANWALA DISTRICT comprises an area of 2.312 sq.mi. Pop. (1961) 1,291,886. In 1847 the district came under British influence in connection with the regency at Lahore. In 1849 it was included in the territory annexed after the second Sikh War. and became a part of Pakistan in 1947. Located in the Rechna doab it consists of a featureless plain that naturally falls into two divisions: the low-lying lands fringing the Chenab and the Degh. and the upland between them. Wheat. rice and cotton are the chief crops. As a result of canal irrigation large areas have been affected by waterlogging and salinity. A number of factories have grown up along the Grand Trunk road. (K. S. AD.)

GUJRAT, a town, *tehsil* and district in Rawalpindi division. West Pakistan. The town stands about 5 mi. from the right bank of the Chenab river, 70 mi. N. of Lahore by rail. Pop. (1961) 59,608. It is built upon an ancient site formerly occupied, according to tradition,, by two successive cities, the second supposedly destroyed in 1303, the year of a Mongol invasion. More than 200 years later either Sher Shah or Akbar founded the existing town. Though standing in the midst of a Jat neighbourhood the fort was first garrisoned by Gujars, and took the name of Gujrat. The town has manufactures of furniture, brassware, boots, cotton goods and shawls. It is the site of the Zamindar college and the government college for women affiliated to Panjab university at Lahore. Gujrat *tehsil* covers an area of 565 sq.mi. Pop. (1961) 433,340.

GUJRAT DISTRICT comprises a narrow ridge of sub-Himalayan plain country, possessing few natural advantages. A range of low hills. known as the Pabbi, traverses the northern angle. They are destitute of vegetation and present a barren chaos of naked rock, deeply scored with ravines.

Numerous relics of antiquity stud the surface of the district. A mound occupied by the village of Moga (Mong) has been identified by some as the site of Nicaea, the city built by Alexander the Great on the field of his victory over Porus. In 1846 Gujrat first came under the supervision of British officials. Two years later the district became the theatre for the important engagements of the second Sikh war. After several battles in which the British were unsuccessful. the Sikh power was irretrievably broken at the battle of Gujrat in Feb. 1849. The Punjab then passed by annexation under British rule. At Chillianwalla, a village in the district situated on the left bank of the Jhelum river, an obelisk erected by the British government preserves the names of those who fell in the battle of that name on Jan. 13, 1849.

The district comprises an area of 2.264 sq.mi. In 1961 the population was 1,326,012. The district has a large export trade in wheat and other grains, oil, wool, cotton and hides. It is traversed by the Northern railway. The southern part of the district receives irrigation from the Upper Jhelam canal. and contains the headworks of the Lower Jhelam canal.

GULA, a Sumerian goddess, patroness of Medicine, the consort of Nin-urta. She is identical with another goddess, known as Bau, though it would seem that the two were originally independent. The name Bau is more common in the oldest period and gives way in the post-Khammurabic age to Gula. Other names borne by this goddess are Nin-Karrak. Ga-tum-dug and Nin-din-dug, the latter signifying "the lady who restores to life." The designation well emphasizes Bau-Gula's chief trait, which is that of healer. She is often spoken of as "the great physician," and accordingly plays a specially prominent role in incantations and incantation rituals intended to relieve those suffering from disease. She is, however, also invoked to curse those who trample upon the rights of rulers or those who do wrong with poisonous potions. As in the case of Nin-urta, the cult of Bau-Gula is prominent in Lagash and in Nippur, but her principal cult was at Isin. While generally in close association with her consort, she is also invoked by herself, and thus retains a larger measure of independence than most of the goddesses of Babylonia and Assyria. She appears in a prominent position on the designs accompanying the Kudurrus boundary-stone monuments of Babylonia, being represented by a statue attended by a dog when other gods and goddesses are merely pictured by their shrines, by sacred animals or by weapons. In neo-Babylonian days her cult continued to occupy a prominent position, and Nebuchadrezzar II speaks of no less than three chapels or shrines within the sacred precincts of E-Zida in the city of Borsippa, besides a temple in her honour at Babylon. Another deity (namely, the heaven god Anu) is often called Gula, for the word means "the great one"

GULBARGA, a city and district in Mysore, India. The city, headquarters of the district. lies about 100 mi. E. of Hyderabad. Pop. (1951) 77.189. Originally included in the territory of the Kakatiyas of Warangal. it was annexed to the kingdom of Delhi in the early 14th century by Ulugh Khan, afterward Mohammed Tughluq; after his death it fell to the Bahmani kingdom and, upon the breakup of that power, to Bijapur. With the conquest of the Deccan by Aurangzeb it was again included in the empire of Delhi, but was separated from it by the establishment of Hyderabad state in the early 18th century.

There are many ancient monuments. In the eastern quarter of the city are the tombs of the Bahmani kings; the most notable building is a mosque said to be modeled upon that of Córdoba in Spain. Gulbarga is also a centre of the cotton trade with ginning and pressing factories and spinning and weaving mills, and also flour and oil mills and paint factories. It is situated on the main line from Bombay to Madras.

GULBARGA DISTRICT (pop., 1961, 1,391,815; area 6.348 sq.mi.) lies on the north bank of the river Krishna and mainly in the valley of its tributary, the Bhima. The rainfall is low, seldom exceeding 30 in. The chief crops are millets, pulses, cotton and linseed. Limestone is quarried in places, but the majority of the population is engaged in agriculture. Formerly in Hyderabad state, the district became part of Mysore in 1956. (S. AH.)

GULBENKIAN, CALOUSTE SARKIS (1869–1955), Armenian oil financier, connoisseur and philanthropist, was born in Scutari, Turk., March 24, 1869. Educated in France and England, he became a naturalized British citizen in 1902, but assumed Iranian citizenship in 1926

He was a founder and constituent member of the Iraq Petroleum company in 1911. The following year, he admitted Royal Dutch Shell with a 25% interest to the combine; the British Petroleum company got 25% in 1914; the Compagnie Française des Pétroles received 22½% in 1920; and the U S.-owned Near East Development corporation obtained 23¾% in 1925. During this time, Gulbenkian reduced his personal holdings in Iraq Petroleum to 40% in 1911, to 15% in 1912 and to 5% in 1920. From 1925 until Gulbenkian's death, each group held 23¾% of the stock with Gulbenkian's holdings remaining at 5%. In 192; the government of Iraq entered into an equal ownership agreement with the company.

Gulbenkian died in Lisbon, Port., July 20, 195j, leaving the bulk of his vast fortune, including an art collection valued at approximately $15,000,000, to a charitable foundation he had established

See Ralph Hewins, *Mr Five Per Cent* (1958) (R A Hs)

GULDBERG, OVE HÖEGH- (1731–1808), Danish statesman, one of the principal ministers of Christian VII's reign, was born at Horsens on Sept. 1, 1731, the son of a shopkeeper. He grew up in straitened circumstances and norked for a time as a tutor before taking a degree in theology in 1753. He then occupied himself with historical studies. but became professor of rhetoric at Soro academy in 1761. In 1764, however, he was appointed tutor to Prince Frederick. half brother of the future King Christian VII (*q.v.*). He became Frederick's private secretary in 1771 and shared his indignation at the usurpation of power by J. F. Struensee (*q.v.*). After contributing to Struensee's fall in 1772. he began, in collaboration with Prince Frederick and the dowager queen Juliana Maria, to exert considerable influence over internal affairs; and in 1774 he was appointed confidential cabinet secretary. Mild in manner but ambitious, Guldberg gradually increased his power. From his office issued increasing numbers of cabinet orders which bypassed his colleagues and the council but were signed by the unbalanced christian VII. By this means the important law concerning citizenship, which reserved the holding of public office to Danish citizens, was passed. Guldberg concerned himself with educational and religious affairs, but was conservative in the matter of land reform and wished to preserve the landowners' authority over the peasants. When the foreign minister Andreas Peter Bernstorff (*q.v.*) opposed the influence of the cabinet and conducted a foreign policy of his own, Guldberg had him dismissed (1780) and tried to pursue a policy based exclusively on cooperation with Russia. A director of several companies, he also controlled Denmark's financial policy from 1782 and so could secure government support for his companies during the economic difficulties after the close of the American Revolution in 1783. In April 1784, just as he was about to be admitted to the privy council, Guldberg was overthrown by the crown prince Frederick's coup *d'état*. For the next 18 years Guldberg was a loyal and active provincial civil servant He also resumed the writing of works of scholarship. At his death on Feb. 7, 1808, in Hald, he was a landowner.

See Aage **Friis,** *Andreas Peter Bernstorff og Ove Hoegh Guldberg* (1899); *E.* Holm, *Danmark-Norges Historie* 1720–1814, vol. v–vi (1906–09). (F. SK.)

GULDEN, a term used synonymously with guilder and florin to denote the monetary unit of the Netherlands. The original Netherlands florin, a silver coin of about ten grams. became the unit of account with the adoption of the silver standard in 1847. When, as a result of the severe fall in the world price of silver, the silver standard was abandoned in 1873, the Netherlands had for a time no metallic standard of value. Then, in 1875, the florin was linked to gold, and the largest, the ten-florin piece, contained slightly more than six grams of fine gold. At the time, 12.107 florins were equal to £1 sterling and 1 florin equaled 40.196 U.S. cents.

As the florin was perhaps the most important of the neutral currencies during World War I, the exchange quotations in Amsterdam provided one of the few guides to the relative financial position of the belligerent countries. Nevertheless, nar pressures and postnar inflation undermined the florin and brought about the temporary suspension of its link with gold. In 1925 the Netherlands re-established the florin on the basis of prewar parity. Attempts to maintain this level long after the devaluation of sterling in 1931 failed; the gold standard was suspended and the foreign-exchange value of the currency was reduced in 1936.

The florin virtually ceased to operate as an international currency after the German occupation of the Netherlands in World War II, but 'transactions based on a stabilized florin or gulden (valued at 10.69 gulden to the pound sterling) were resumed in Sept. 1945. The devaluation of sterling as against the dollar in 1949 was followed by a similar adjustment in the guilder; its parity was established at .233861 grams of fine gold per unit, or 3.80 florins per U.S. dollar. From March 7, 1961, its par value was changed to 3.62 florins per U.S. dollar. (Jo. M. L.; C. G. T.)

GULF INTRACOASTAL WATERWAY, an improved navigable waterway along the Gulf of Mexico coast of the United States, extends from Apalachee bay, Fla., westward to the Mexi-

can border at Brownsville, Tex.. a distance of more than 1,100 mi. In part artificial, the waterway consists of a channel paralleling the coast behind barrier beaches, linked by a series of canals and maintained at a minimum depth of 12 ft. by the U.S. army corps of engineers.

The Gulf Intracoastal waterway is an important route for barges, and several sections of it furnish access to major gulf ports for ocean-going vessels. Among the major ports along the waterway are Panama City and Pensacola, Fla.; Mobile, Ala.; Gulfport, Miss.; New Orleans and Lake Charles, La.; and Port Arthur, Freeport, Beaumont, Galveston, Corpus Christi and Brownsville, Tex.

Although much of the traffic is short-haul, averaging about 170 mi., the waterway is connected with the Mississippi valley system of inland waterways; through barge traffic is handled between such ports as Chicago, Pittsburgh, St. Louis and Memphis and points on the Gulf Intracoastal waterway and its branches. Among the principal items moved on the waterway are petroleum and its products, industrial chemicals, pipe and other supplies for the oil fields, sulfur and seashells.

At its eastern end, the waterway is not directly connected with the Atlantic Intracoastal waterway, except via the open waters of the Gulf of Mexico; numerous studies and plans were made for a connection across Florida, to provide a continuous protected waterway from the northeastern United States to the Mexican border. Traffic is concentrated in that section of the waterway connecting the Warrior-Tombigbee system on the east at Mobile bay, Ala., with the Mississippi river system at New Orleans, La., and between the Mississippi river and the major Texas ports. A cut-off route. the Plaquemine waterway, provides direct connection west of New Orleans between the Gulf Intracoastal waterway and the Mississippi river. The waterway is at sea level. The Harvey lock at New Orleans provides entrance from the Mississippi river. Part of the route of the waterway at New Orleans consists of the Inner Harbor Navigation canal, an artificial waterway which is the axis of a major industrial district.

See also WATERWAYS, INLAND. (H. M. M.)

GULFPORT, a city and seat of Harrison county in southeastern Mississippi. U.S., on the Gulf of Mexico, is midway between Mobile, Ala., and New Orleans, La.. on the Old Spanish. trail. Gulfport was founded in 1887 by Capt. William H. Hardy, Confederate soldier and engineer. who selected the site for the southern terminus of his Gulf and Ship Island railroad. Its development. however, was made possible by Capt. Joseph T. Jones of the Bradford (Pennsylvania) Construction company, who completed the railroad, secured controlling interest and moved to the city in 1902. Jones and his family mere leaders in the building of the city, including its excellent harbour, transferred to the U.S. government in 1907.

Gulfport is in the centre of what has been called the world's longest man-made sand beach (28 mi. long and 300 ft. wide) which helped make the city a year-around resort.

Gulfport was incorporated as a city in 1904. (For comparative population figures see table in MISSISSIPPI: *Population.*)

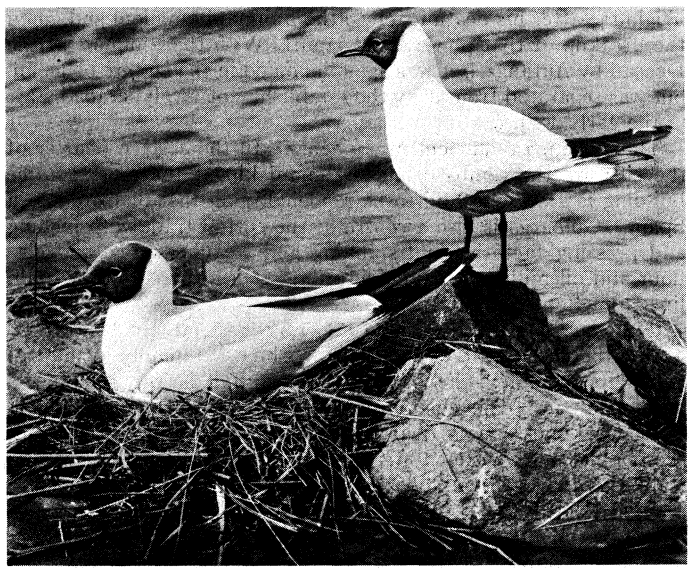
There is a frontage of 6 mi. on the Gulf which includes a modern deepwater port: consisting of two moles, separated by a harbour one-half mile long. The commerce of the port is chiefly in wood products, creosoted piling, cottonseed products. salt of potash, phosphate rock and fish. A number of industries produce a variety of goods, including textile products, concrete and building materials, fertilizers. small craft and drugs. There is also a U.S. Veterans hospital there. (J. T. D.)

GULF STREAM, the western and northern quadrants, extending from Florida to the Grand Banks of Newfoundland, of the current system which sets clockwise around the North Atlantic in mid-latitudes. Fed by water from the Gulf of Mexico and reinforced off Florida by some water from the trade-wind current. the initial Gulf stream is relatively narrow and deep. Maximum velocities exceed four knots, with a rate of flow about 1,000 times that of the Mississippi river. Beyond Cape Hatteras it broadens, slackens and breaks down into a meandering streaky pattern with countercurrents and eddies. Its deep blue colour and higher salinity and temperature distinguish it from the inshore countercurrent (Cold Wall) along the eastern coast of the United States, and from the Labrador current with which it mixes along the periphery of the Grand Banks. East of the Banks the continuing current is normally referred to as the North Atlantic current. The offshore boundary of the stream is generally difiuse and poorly defined: the result in part of the similarity of the stream and central Atlantic waters. See ATLANTIC OCEAN: Surface *Currents;* OCEAN AND OCEANOGRAPHY: *Movement* of Sen Water. (C. A. Bs.)

GULFWEED, a popular name given to a species of the brown seaweeds (Phaeophyta) belonging to the genus *Sargassum,* more particularly the species (*Sargassum natans*) that grows in free-floating masses in the Gulf stream and the Sargasso sea. It is remarkable among seaweeds for its form, which resembles branches bearing leaves and berries; the latter are hollow floats answering the same purpose as the bladders in another brown seaweed, *Fucus vesiculosus,* common around the British Isles between high and low water.

GULL, the common name for sea birds of the family Laridae, subfamily Larinae. Perhaps the most beautiful of all gulls is the ivory gull (Pagophila eburnea), which breeds in the high arctic. The plumage is pure white, the legs black. The well-known kittiwake (*q.v.*) (Rissa tridactyla) inhabits the seas of the northern hemisphere, breeding as far south as the coasts of Britain; in this species the hind toe is lacking. Of the 25 or more species of the genus Larus, the largest are the glaucous and greater black-backed gulls (L. hyperboreus and L. *marinus*), of which the former is circumpolar, the latter nearly so, not occurring, however, between Labrador and Japan. These species are more or less raptorial in their habits, eating the eggs, young and even adults of many other birds.

L. *minutus* of Europe is the smallest species. The black-headed gull. L. *ridibundus,* breeds in large colonies in marshes, but



ERIC HOSKING FROM NATIONAL AUDUBON SOCIETY

BLACK-HEADED GULL (LARUS RIDIBUNDUS)

most species prefer cliffs. The silvery gull (L. novae-hollandiae) has a southern habitat. The rare and beautiful roseate gull (*Rhodostethia rosea*), an arctic form, is recognized by the pink tinge in its plumage. Sabine's gull, Xema sabini, breeds in arctic America and Siberia; it has a forked tail. Franklin's gull (L. *pipixcan*) inhabits the interior of North America, breeding in marshes. It is the only bird with a monument to it—in Salt Lake City to commemorate its services in the destruction of grasshoppers. The herring gull (L. argentatus) is the commonest Atlantic species; a dozen races breed over northern parts of the northern hemisphere, two in North America. The laughing gull (L. atricilla) breeds on coasts from Maine to Texas and Venezuela, and southern California, robbing pelicans (*q.v.*). The ring-billed gull (L. *dominicanus*) is common in the interior United States and Canada, the California gull (L. *californicus*) also about inland lakes farther

west, the western gull (L. *occidentalis)* along the U.S. Pacific shores. The only gull with a strikingly forked tail is the swallow-tailed gull *(Creagrus furcatus)* of the Galapagos archipelago. The large Pacific gull (*Gabianus pacificus*) breeds about Tasmania and southern Australia, the medium-sized dolphin gull (*Gabianus scoresbii)* from Tierra del Fuego southnard. (G. F. Ss.)

GULLAH is the dialect of former slaves and their descendants (also called Gullahs and Geechees, West African tribal names) on the sea islands of South Carolina and Georgia and on the mainland nearby. It reveals characteristics of the speech of British settlers in that region during the 17th and 18th centuries and of several West African languages—including Vai, Mende, Twi, Ewe, Hausa, Yoruba, Ibo, Kikongo and others—spoken by slaves imported to the region during the 18th and 19th centuries. The influence of these languages upon Gullah is evident in its vocabulary, sounds, syntax, morphology, intonation and word formations.

Nearly 6,000 African words have been identified in Gullah, most of which are now used as personal names, such as *Abiona,* "born by the wayside" (Yoruba); *Adanse,* a place name in Ghana; *Anyika,* "she is beautiful" (Vai); *Pitipa,* a Mende name given children born during a rain; etc. Many African words in Gullah are fairly common in American English, such as *cooter,* "tortoise"; *goober,* "peanut"; *gumbo,* "okra"; *juke* as in "jukebox"; *voodoo,* "witchcraft"; etc. Gullah speakers simplify English words and constructions! speak rapidly with no southern drawl, and use an intonation unlike that of English. The following sentences reveal features of Gullah: *Dey fa* go *shum,* "They went to see her," literally, "They take go see her"; *Shishuh tall pass una,* "Sister is taller than you"; 'E *yedi wulisankpankpan, but cyan' shum,* "He hears the woodpecker, but can't see it"; *'Twix' me na una 'e duh badnzout 'em fuh trut, enti?,* "Between me and you he surely put a curse on them, didn't he?"; *Uma-chil' nyamnyam fufu an' t'ree roll-roun', but 'e ain' been satify,* "The girl ate mush and three biscuits, but she wasn't satisfied."

For an analysis of Gullah with illustrative texts, *see* Lorenzo D. Turner, "Notes on the Sounds and Vocabulary of Gullah," *Am. Dialect Soc.* (May 1941), "Problems Confronting the Investigator of Gullah," *Am. Dialect Soc.* (April 1948) and *Africanisms in the Gullah Dialect* (1949). For Gullah stories, *see* Ambrose E. Gonzales, *The Black Border* (1922); S. G. Stoney and G. Shelby, *Black Genesis* (1930). (L. D. T.)

GULLANE, a village in the parish of Dirleton, East Lothian, Scot., on the southern shore of the Firth of Forth, lies 17 mi. E. of Edinburgh. Pop. (1951) 1,182. The 12th-century kirk of St. Andrew (now disused) has a Norman chancel arch and a 15th-century north transept. Gullane's associations with Knights Templar are indicated in such names as Templar lane. The 16th century Saltcoats castle. ½ mi. S.W., belonged to the Livingston family, whose ancestor obtained a grant of land for killing a wild boar, the last in Scotland, which terrorized the neighbourhood. Gullane possesses three excellent golf courses. (W. Be.)

GULLSTRAND, ALLVAR (1862–1930), Swedish physician, was born on June 5, 1862, at Landskrona. In 1894 he became professor of diseases of the eye at Uppsala, and in 1913 was appointed professor of physiological and physical optics there. His investigations concerned the general laws of dioptrics, a new conception of the theory of optical images; the extrication of the optical images in the eye; and the eye's relation to the diffusion of light. In 1911 he was awarded the Nobel prize for medicine. Among Gullstrand's works are *Allgemeine Theorie der monochromatischen Aberrationen* (1900), *Die optische Abbildung in heterogenen Medien und die Dioptrik der Kristallinse des Menschen* (1908) and *Einführung in die Methoden der Dioptrik des Auges des Menschen* (1911). He received the honorary degree of doctor of science at Dublin in 1912.

GULLY, JOHN (1783–1863), British prize fighter, racing man and politician, a light of the 19th-century English sporting world, was born Aug. 21, 1783, at Wick near Bristol, the son of an innkeeper. In 1805, having failed as a butcher, he was in the king's bench prison when he was visited by his Bristol pugilist friend Henry Pearce, the "Game Chicken." As the result of an informal bout between them Gully's debts were paid and he was matched against Pearce. They met at Hailsham, before the duke of Clarence (afterward William IV), when Gully lost after 59 rounds. In 1807 he twice beat the huge Bob Gregson. He then retired from the ring. was landlord of "The Plough" in Carey street in London and took to horse racing. He executed betting commissions for important patrons including the prince regent. In 1827 he lost £40,000 in backing Mameluke (which he had bought for 4,000 guineas) in the St Leger. With Robert Ridsdale as his confederate in 1832 he won the Derby and St. Leger with St. Giles and Margrave respectively. In alliance with John Day he won the Two Thousand Guineas with The Ugly Buck in 1844 and two years later the Derby with Pyrrhus the First and the Oaks with Mendicant. In 1854 he non the Two Thousand Guineas with The Hermit and, in partnership with Henry Padwick, the Derby with Andover. For many years his horses were trained at Danebury in Hampshire, where he and his betting associates were called the Danebury confederacy. He bought Ackworth park, Yorkshire, and was member of parliament for the pocket borough of Pontefract from Dec. 1832 to July 1837. In 1862 he bought the Wingate estate and collieries in Durham. Gully married twice and had 24 children, 12 by each wife. He died on March 9, 1863, in Durham He was a fine figure, six feet tall and immensely strong He was a man of resolute character who lived in an age of dubious sporting ethics and scandal has not wholly spared him; he probably kept to his own reasonably high standard of honesty and was always ready to fly to arms if defamed. (B. Dn.)

GUMAL (Gomal) **PASS,** the route that leads along the valley of the Gumal river, through South Waziristan agency. connecting Ghazni in eastern Afghanistan with Tank and Dera Ismail Khan in West Pakistan, via Domandi. Gulkach (Gul Katch) post, Nilikach and Kot Murtaza near the entrance of the pass. The name is sometimes applied to the whole course of the Gumal river. The actual Gumal pass is a four-mile defile, and the most important pass between the Khyber and Bolan passes (*qq.v.*), providing the oldest of the trade routes in that area. It has been traditionally used by traders called Powindahs, nho carry all their goods on the hacks of camels or donkeys. They spend the summer in Afghanistan and on the approach of winter cross over to Pakistan in caravans The Powindahs are mostly of the Ghilzai clan (mainly Nasir and Sulaiman Khel tribes) who live on the Afghan side of the frontier. They trail their camels along the borders of the territory of the Mahsud Waziris, bringing fruits, skins and cloth for disposal in the frontier markets or in the plains of Dera Ismail Khan. The entry of Powindahs into Pakistan is no longer free.

Gumal River rises near Sarwandi on the Koh Nak range in Afghanistan. Between Waziristan and the highland plateau of Afghanistan there is a belt of hills, in more or less parallel lines, which forms the barrier through which the Gumal breaks before it enters West Pakistan near Domandi. where it is joined by the Kundar. It is joined by the Wana Toi (from the north) at Toi Khula and by the Zhob (from the south) at Khajuri Kach, and falls into the Indus a few miles south of Dera Ismail Khan cantonment. Almost all its water is used for irrigation.

In the early 1960s plans were in hand to construct a multipurpose dam at Khajuri Kach, below the junction of the Zhob and the Gumal, to form a reservoir with a storage capacity of 2,500,000 ac.ft. It was designed to provide irrigation to about 115,000 ac., to produce 73,000 kw, of hydroelectric power and also to control floods in the area. (K. S. Ad.)

GUM ARABIC, an exudation from various varieties of acacia, much used in the arts *(see* Gums. Plant).

GUMBINNEN (Gusev), a town in the Kaliningrad *oblast,* Russian Soviet Federated Socialist Republic, U.S.S.R., formerly in East Prussia, Ger., on the Pissa, 70 mi. E. of Konigsberg (Kaliningrad). Frederick William I in 1724 raised Gumbinnen to the rank of a town, and in 1732 brought to it a number of persons who had been driven from Salzburg by religious persecution. The manufacture of agricultural machinery, cotton and linen weaving, tanning, brewing and distilling are the chief industries. There are horse and cattle markets

GUMBO or Okra. a herbaceous hairy annual plant *(Hibiscus esculentus)* of the mallow family (Malvaceae), of the old world tropics and widely cultivated or naturalized in tropical and sub-

tropical countries. The leaves are heart shaped, three to five lobed, and the flowers yellow with a crimson centre. The fruit or pod. the *bendi-kai* of the Europeans of southern India, is a tapering, ten-angled capsule, 4 to 10 in. in length (except in the dwarf varieties) and contains numerous oval. dark-coloured seeds. hairy at the base. The unripe fruit is eaten either pickled or prepared like asparagus. It is also an ingredient in various dishes (*e.g.*, the gumbo of the southern Cnited States), and because of the large amount of mucilage it contains it is extensively used for thickening broths and soups. The fruit is grown on a large scale in the vicinity of Istanbul. The seeds of the gumbo are used as a substitute for coffee. From their demulcent and emollient properties. the leaves and immature fruit have long been in repute in the east for use in poultices and fomentations.

The musk mallow or abelmosk (*Hibiscus abelmoschus*), a related plant indigenous to India and cultivated in most warm regions of the globe, is a low, slightly woody plant. bearing a conical five-ridged pod about 3 in. in length. within which are numerous brown reniform seeds. smaller than those of H. *esculentus*. The seeds possess a musky odour caused by an oleoresin and are known to perfumers under the name of "ambrette," now mostly of synthetic origin.

The seeds are used in Africa as beads. The plant yields an excellent fibre and, being rich in mucilage, is employed in upper India for clarifying sugar. The best-perfumed seeds are reported to come from Martinique.

GUMMA, Japanese prefecture located in the western Kantō plain. Pop. (1935) 1,613,549; area 2,445 sq.mi. Gumma is mostly mountainous. with two-thirds of its territory over 1.640 ft. elevation with volcanic peaks towering over 6,560 ft. The capital Maebashi (*q.v.*) and most of the population are on a small segment of the Kantō plain in the southeastern corner. Sericulture and wheat growing are the most important activities in its predominantly agricultural economy. Mountain forests and mineral deposits (sulfur. manganese, limestone) are exploited. The silk-reeling industry. conducted on a small workshop scale. is centred in Maebashi. Tomioka, Kiryū (*q.v.*) and Isezaki.

(J. D. Ee.)

GUMS, PLANT, are adhesive substances of plant origin that are carbohydrate in nature and are usually produced as exudates from the bark of trees or shrubs. The term plant gums does not normally include the so-called varnish gums which, although they are of natural origin. are in fact resins and quite different chemically (*see* Abietic Acid). Some plant gums. such as gum arabic. are soluble in water, dissolving to give clear solutions. Others including gum tragacanth give mucilages by the absorption of large amounts of water. When the water evaporates after the application of gum solutions, a film with considerable adhesive properties is formed.

Plant gums are produced by trees either after mechanical damage to the hark or atter a bacterial insect or fungal attach upon it It may thereiore be possible that the formation oi gums (a proc ess otten reierred to as gummosis) is associated with some protective mechanism However all reasons tor gummosis are not completely understood. Concerning this. it may be mentioned that the yield of gum acacia from the Acacia *senegal* tree is greatest when the trees are in an unhealthy condition, but methods of good culture reduce the yield of plant gum.

The production of plant gums for commercial use involves making an incision in the bark of the tree and after a month or so collecting the exudate. The collection is repeated throughout the season and the gums so obtained consist of small lumps, each about the size of a walnut, which are usually transparent and light-yellow in colour.

A number of plant gums are used on a considerable scale commercially. They come from many parts of the world: some originate in Africa and include Sudan gum and Kordofan gum from Sudan and Senegal gum from Senegal. These are varieties of gum arabic which is also collected in northern Nigeria, 'Tripoli. Tunisia and Tanganyika. Gum ghatti is collected in India. gum tragacanth comes from Asia Minor and Iran and wattle gum from Australia.

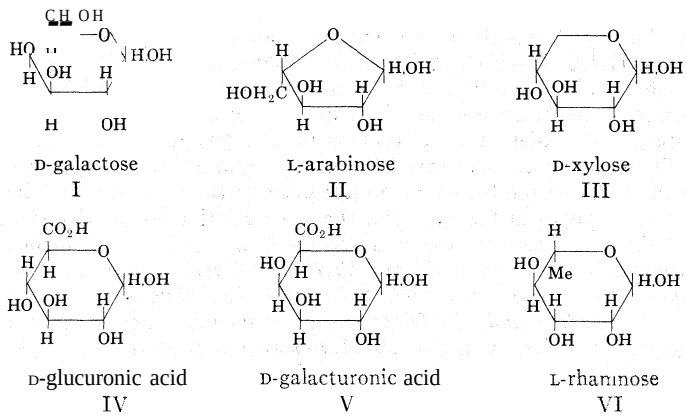
Gum arabic is the most widely used of the truly water-soluble gums. True gum arabic (gum acacia) is produced by species of Acacia only. but the term is sometimes used to include gum arabic suhstitutes obtained from other sources. Gum sudan and gum kordofan are names which refer to their geographical origin. but they are also a type of gum arabic in that they are produced from various Acacia trees.

Gum tragacanth is the second most important commercial gum and is produced by several shrubs which belong to the *Astragalus* genus. *Astragalus gummifer* is the source of most of the gum tragacanth and is endemic in the arid regions of Iran. Asia Minor and Greece. The exudate is produced spontaneously on the bark of the shrub. but the yield is often increased by making an incision and driving wooden wedges into it. Gum tragacanth is not totally soluble in water. but forms a mucilage on treatment with water. It is one of the oldest drugs known and its use has dated from pre-Christian times. It is still used pharmaceutically as a demulcent and as an adhesive agent in pill manufacture. It is also used in food manufacture as an emulsifying agent and as a thickener in sauces.

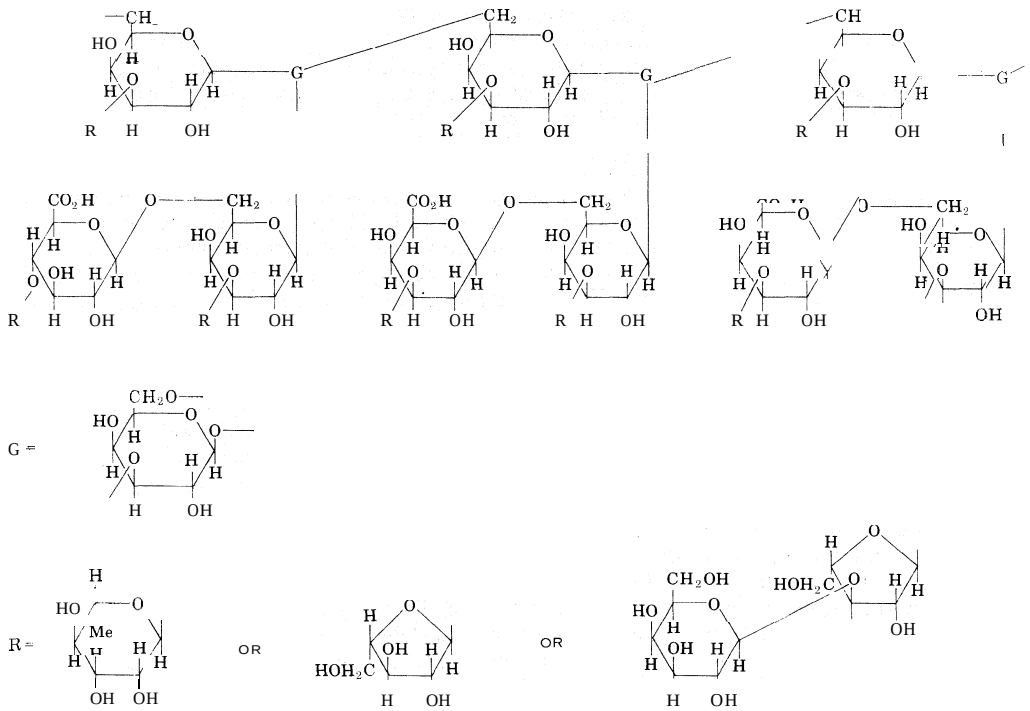
Other plant gums include gum ghatti which has been used as a gum arabic substitute. Gum karaya and carob gum have been used as substitutes for gum tragacanth, but their use is limited. Many cultivated trees yield plant gums including cherry (*Prunus cerasus*) and plum (P. *domestica*), while other miscellaneous sources yield cholla gum (*Cylindropuntia fulgida*) and mesquite gum (Prosopis species). Some of these gums are used in cosmetics. pharmaceuticals and food; an examination of their chemical nature (see below) has shown that they have a close relationship to other plant gums.

Chemical Investigations and Structure of Plant Gums.— The plant gums are complex carbohydrate derivatives which are polysaccharide in nature (see Carbohydrates). Their chemical study is complementary to the detailed study of the other polysaccharides that has been made. The polysaccharides are an important group of natural products and the chemistry of the plant gums has contributed to knowledge regarding their structure and function.

Plant gums are the neutral potassium. magnesium or calcium salts of acidic polysaccharides. whose acidity is due to the presence of uronic acid functions in their structure. Hydrolysis of plant gums gives a mixture of monosaccharides, including D-galactose (I) and L-arabinose (II) in all cases and D-xylose (III) fairly frequently. With the exception of gum tragacanth. which yields D-galacturonic acid (V), all plant gums yield D-glucuronic acid (IV) on acid hydrolysis. Thus the acidity of gum tragacanth is due to D-galacturonic acid residues. whereas the acidity of the other plant gums is due to D-glucuronic acid residues. Sugars such as L-rhamnose (VI) and L-fucose occur rather rarely as plant gum hydrolysis products.



The problem of determining the complete structure of a plant gum is really the determination of the order of the various monosaccharide residues in the parent polysaccharide molecule. The researches of E. L. Hirst. J. K. N. Jones and F. Smith have enabled substantial progress to he made with this problem and the determination of the structure of gum arabic is illustrative of the methods which have been used.



A possible repeating unit in the gum arabic molecule

The sugar units of which the gum arabic .molecule is composed are indicated by the acid hydrolysis products which are D-galactose (I), L-arabinose (11), L-rhamnose (VI), and D-glucuronic acid (IV) and the problem of structure determination is really (a) the identification of the repeating unit in the macromolecular polysaccharide structure and (b) the determination of the arrangement of the monosaccharide components within this repeating unit. Several formulae are possible for the gum arabic molecules and one of them is indicated. Comparison of this structure with the structures of the monosaccharide units (I, II, IV and VI) show the way in which they are linked together.

It can be seen therefore that gum arabic has a highly branched structure which is no doubt responsible for its special physical properties. Similar studies have been made of several different plant gums and an over-all similarity between their structures is detectable.

GUMTI, a river of northern India. It rises in Pilibhit district, Uttar Pradesh, and after a sinuous southeasterly course of 500 mi. past Lucknow and Jaunpur joins the Ganges in Ghazipur district. At Jaunpur it is spanned by a fine 16th-century bridge and is navigable. There is also a river of the same name rising in Tripura state, India, and falling into the Meghna in Tippera district, East Pakistan, after a 150-mi. course.

GUMULJINA or KOMOTINE, capital of the department of Rhodope in western Thrace, Greece. Pop. (1951 census) 29,734. Gumuljina is situated on the river Karaja-Su, south of the eastern extremity of the Rhodope range of mountains and 13 mi. inland from the Aegean sea. The district produces wheat, maize, barley and tobacco; sericulture and viticulture are both practised on a limited scale. A cattle fair is held annually on Greek Palm Sunday. Copper and antimony are found in the neighbourhood. The town went to Greece in 1918 and was occupied by Bulgaria in 1941.

GUMUSH-KHANEH or GUMUSANE, the chief town of a vilayet of the same name in Asiatic Turkey, situated on high ground (4,400 ft.) in the valley of the Kharshut Su, about ½ mi. S. of the Trebizond-Erzerum *chaussée*. The silver mines from which the place takes its name were noted in ancient times and are mentioned by Marco Polo. Pop. (1955) 4,197.

GUNCOTTON, a high-grade type of nitrocellulose (cellulose nitrate) resembling cotton in appearance. It contains more than 13% nitrogen and is prepared by the nitration of cotton fibres with a strong mixture of nitric and sulfuric acids. Commonly a batch process of nitration in iron or earthenware pots is used. After nitration care must be taken to hydrolyze unstable chemicals by boiling the final product in slightly acidified water (stabilization) and washing it free of all acid. Unless this is done the inherent instability associated with nitric esters of this type is enhanced even at ordinary temperatures.

Guncotton, like other forms of nitrocellulose, will decompose with time forming nitrogen dioxide in air which promotes further decomposition.

Guncotton is insoluble in water, alcohol and ether and will dissolve in acetone, nitrobenzene and ethyl acetate. The essential constituent of cotton is cellulose which is a long chain polymer of anhydroglucose units having the empirical formula of $C_6H_{10}O_5$. Cotton linters may have as many as 1,000 to 1,500 of these units in a single molecular chain. In the nitration process the three hydroxyl (OH) groups of each unit can be replaced by a nitrate (ONO_2) ion. If this replacement is complete the resulting guncotton would contain 14.14% nitrogen.

Actually complete nitration is not accomplished and the attached nitrate groups are believed to be distributed randomly along the chain among the three possible positions for each unit. For military purposes in the United States a minimum nitrogen content of 13.35% is used. This represents a somewhat more complete nitration of the cellulose than the *coton-poudre* no. 1 (CP_1) used in World War I.

A characteristic property of this highly nitrated cellulose is its low solubility in an ether-ethanol solution. This property distinguishes guncotton from the less nitrated celluloses which are referred to as collodion cotton or soluble nitrocellulose because of the fact that they dissolve in the ether-alcohol solvent. Guncotton has superior explosive properties to those of collodion and has been extensively employed in conjunction with nitroglycerin for the production of cordite, the British service propellant. The blending of the two ingredients is brought about by acetone, but by the use of collodion with a large proportion of nitroglycerin a cordite is obtainable without the employment of acetone.

During the mid-19th century numerous attempts were made, particularly in Austria, to employ guncotton alone and unmodified as a military propellant, the necessity for tempering its explosive violence by colloiding processes being as yet unrecognized. All ended in failure.

Moist guncotton has been used as a high explosive, but is quite unsatisfactory because of the hazards in handling. Dry guncotton is even more hazardous, being sensitive to all forms of initiation—friction, impact, heat, sparks, etc. Its sensitivity is comparable with other primary explosives such as mercury fulminate or lead azide. It propagates detonation and has a brisance (shattering effect) comparable with TNT. See NITROCELLULOSE.

See T. E. Thorpe, *Dictionary of Applied Chemistry*, vol. iii (1922); Tenney L. Davis, *The Chemistry of Powder and Explosives* (1943). (P. M. FE.)

GUN METAL, a variety of bronze (*q.v.*), formerly used for ordnance. Gun or "G" metals are copper-base casting alloys of the general type: 88% copper, 10% tin and 2% zinc or 86% copper, 10% tin and 4% zinc. Usually up to 1% nickel is present in the modern alloys to add strength, promote grain refinement and reduce segregation. The addition of 0.5% lead improves machinability without harming the cold mechanical properties. A small quantity (0.05% max.) of phosphorus may be used as a deoxidizer to promote metal fluidity and soundness of the casting.

The 88–10–2 alloys are used frequently for gears and bearings subjected to heavy loads and low speeds. They also withstand atmospheric, steam and sea-water corrosion, and thus are suitable for valves, pump parts and steam fittings. The mechanical properties of the "as cast" alloy are: tensile strength, 36,000–46,000 lb. per square inch (p.s.i.), yield point 18,000–26,000 (p.s.i.); elongation 15%–25% (in 2 in.), reduction of area 12%–26% and Brinell hardness 65–80. (D. S. E.)

GUNNERY, NAVAL. Naval gunnery is the art and science of using naval guns and rocket and missile launchers. It is distinguished from land-based military gunnery in that the naval gun fires from an unsteady and moving platform. The task of the military gunner is to fire at one fixed point from another fixed point. The naval gunner has a task comparable to firing at a fast automobile moving along a bumpy and twisting road from another fast automobile also moving along a bumpy and twisting road. In this respect it has points of similarity with aerial gunnery. (See also ARTILLERY: Technique.)

The principal developments in naval gunnery of modern times have been in fire control, automatic fire, antiaircraft guns and missiles. Fire control improvements included use of radar, greatly improved directors and more accurate ballistic computing devices. Automatic fire was improved by the introduction of more reliable ammunition as well as new and improved loading mechanisms. Antiaircraft gunnery was improved by the introduction of more accurate guns of larger calibre. Missile development greatly increased range and the probability of hits on high-speed air targets.

Types of Guns.—It is convenient to classify naval guns by the type of breech-operating mechanisms employed.

Automatic.—An automatic gun is one that uses part of the energy of explosion to eject the empty cartridge case and to energize a device which automatically loads another cartridge and continues to fire the gun as long as the firing circuit is closed and the ammunition supply is maintained. An example is the 40-mm. antiaircraft gun.

Semiautomatic.—A semiautomatic gun is one in which part of the energy of explosion is first stored and later used to open the breech, eject the empty cartridge case and close the breech after another round is loaded, either by hand or by auxiliary power. Most naval guns are of this type.

,?ionautomatic.—A nonautomatic gun is one in which none of the energy of the explosion is used to operate any part of the operating mechanism other than the salvo latch. The salvo latch is a device which prevents the unintentional opening of the breech of a loaded gun. The main battery guns of battleships and most heavy cruisers are of this type.

Gun Mounts.—The naval gun mount is the entire system of gun-supporting parts, elevating and training mechanisms, recoil and counterrecoil equipment. The two classes of mounts are deck mounts and turret mounts. Deck mounts may be worked either manually or by power; turret mounts are invariably worked by power, either electric, hydraulic or a combination of both.

The principal parts of the deck mount are the slide, carriage and stand. The slide is a hollow cylindrical support in which the slide cylinder of the gun is housed. During recoil and counterrecoil, the gun rides back and forth in this support. Two horizontal projections on the slide, called trunnions, provide the axis about which the gun is free to move in the vertical plane. The carriage supports the slide and rests on roller bearings. It is free to rotate in a horizontal plane and provides means for training the gun. The stand is the stationary part of the mount, bolted to the deck of the ship and containing the lower roller path on which the roller bearings rest. It supports the combined gun, slide and carriage. Movement of the gun in the horizontal and vertical planes is by a system of handwheels, shafting and gearing. Movement may also be accomplished by a power source through suitable shafting and gearing. Deck mounts may be partially or completely shielded by armour.

The turret mount consists of the barbette, the turret revolving structure, the gunhouse and the turret foundation. The barbette is a heavy fixed cylinder of armour extending from the gunhouse to the lowest armoured deck. Its sole function is to protect the turret revolving structure and the turret foundation. The gunhouse is a heavily armoured rotatable structure containing the guns. The turret revolving structure, which corresponds to the carriage of the deck mount, extends from the gunhouse down to the magazine handling rooms (located outside the barbette) and is composed of steel girders and bulkheads that form the various compartments for the turret machinery and personnel. The turret foundation is composed of steel girders built into the hull of the ship to support the turret revolving structure and the gunhouse. Training of the turret is accomplished by a system of power-driven gears and a toothed rack fitted inside, but not attached to, the barbette. Elevation is accomplished by means of a long, power-driven shaft and pinion.

Recoil and Counterrecoil.—In naval gun mounts the recoil mechanism is generally a hydraulic brake consisting of one or more cylinders secured to the slide of the mount; in the slide, pistons operate so that they move to the rear during recoil and forward during counterrecoil. The cylinders are filled with hydraulic fluid that must pass through orifices in the pistons which are so designed that the resistance to flow is approximately constant throughout the length of the piston's travel. The work done by the recoil in forcing the piston through the liquid absorbs the momentum of the gun in recoil.

The counterrecoil mechanism may be either mechanical, pneumatic, hydraulic or a combination of all three. The counterrecoil system must not only return the gun to firing position (battery), but must be able to hold it there at all angles of elevation.

Fire Control.—The practical application of exterior ballistics and the methods and devices used to control guns and other weapons are known as fire control. In the early days of naval gunnery and until well past Horatio Nelson's time, fire control was a simple matter. Each gunner peered along the barrel of his muzzle-loader and trained his gun by means of a lever; he also estimated the range and elevated his gun by means of a wedge under the breech or by a threaded shaft.

As guns became more powerful and ranges increased from a few hundred to several thousand yards, this hit-or-miss system was no longer effective. Range finders were introduced to determine the exact distance to the target, and guns were elevated according to the number of degrees required to shoot a given distance.

By World War I, battle ranges exceeded 10,000 yd. and additional problems arose: (1) It was no longer possible to fire at the target directly; allowance had to be made for movement of the target while the projectile was in flight. (2) Allowances were necessary for the wear of gun barrels (called bore erosion), temperature of the powder, effects of air density and upper air wind velocity. (3) Allowance had to be made for the ship's roll and pitch. Failure to allow for any one of these might change the range of the projectile by several thousand yards. To meet these problems, director firing was instituted. Director firing is essentially the firing of all guns in one battery by use of a director, a range-determining device and a computer.

The director itself is a master gun sight for all the guns in its battery. The director is trained continuously on the target, giving the line-of-sight bearing and elevation. These, and the distance to the target as given by the range-determining equipment, are fed directly to the computer. Other information sent to the computer includes: firing ship's motion with respect to the horizontal plane, from a stable element; firing ship's course and speed; surface wind velocity, projectile muzzle velocity loss through gun erosion and powder temperature; time; and certain other nonstandard variables such as air density and unavoidable errors in calculations. These data are combined by the computer and result

in a continuous output of the following: present target range and bearing; advance range, used in setting gun sights; gun and elevation orders to position the guns; and fuze orders or time of flight. (*See* SIGHTS, GUN.)

In earlier director systems, train and elevation orders were sent by electrical connections to indicators on the guns. The gun layers kept the gun trained and elevated by keeping pointers on the guns in coincidence with the director indications. Firing took place at a predetermined point of the ship's roll. In later director systems, the guns were trained and elevated automatically, and stabilizing devices discounted the roll and pitch of the firing ship. Antiaircraft fire presents a quite different problem. The antiaircraft battery must cope with high-speed targets that may attack from several directions simultaneously. To achieve the necessary flexibility, the battery is divided into four groups, each capable of independent operation in its own sector, or of combining with an adjacent group to defend a sector common to both. Each group has its own director system, and in cases where two groups fire together, one director handles the fire control problem for both groups.

The introduction of radar changed naval gunnery drastically. It permitted the automatic tracking of targets and accurate firing under adverse conditions. The effective range of large guns formerly had been limited to the visible range; haze, fog, smoke or darkness sometimes reduced this range to a few hundred yards. Radar not only permitted the ranging of targets under conditions of poor or limited visibility, but allowed effective firing at them. Battle ranges often exceeded 25,000 yd.

The introduction of high-speed aircraft and bombs with a large destructive radius also introduced new problems. It became necessary to destroy the most dangerous, not necessarily the nearest, target first. This destruction had to be accomplished quickly before the target could arrive at a position, such as the bomb release point, where it could damage the ship. This involved early detection of the target, rapid determination of the firing data and fast. accurate firing.

Before the end of World War II, it had become apparent that self-propelled, guided missiles were necessary to cope with the increased speed of aircraft. By the early 1950s, all major naval powers had operational antiaircraft missiles available for use in their fleets. These missiles were capable of rapid launching, of receiving post-launching guidance during the intermediate part of their flight and of automatically seeking the target at long range. Some of these antiaircraft or antimissile missiles were capable of destruction of the target at ranges up to 65 mi. from the launching ship. The use of such missiles combined with nuclear warheads seemed to be the answer to the problem of improving the range, accuracy and destructive effect of naval weapons. *See* MISSILES; ROCKETS.

(R. L. NE.; H. J. SL.)

GUNPOWDER (BLACK POWDER), generic names applied originally to a mechanical mixture of saltpetre (potassium nitrate), charcoal (carbon) and sulfur. Gunpowder is the older and more commonly used term but black powder is preferred in military circles in the United States. Prepared in approximately the correct proportions (74.6% saltpetre, 13.5% charcoal, 11.9% sulfur) it will, when ignited, burn rapidly and evolve a large volume of whitish gas. In a confined space this pent-up gas can be used for blasting or for propelling missiles. Black powder is a low explosive rather than a high explosive like TNT. It is easily ignited and is nidely used for primers, fuzes and blank fire charges in military ammunition. See AMMUNITION, ARTILLERY.

History. — Discovery of black powder and its adaptation to firearms marks one of the most important events in the history of civilization. The blasting power of black powder enabled men to do work that had formerly required brute force, and its use to propel missiles gave civilized men ascendancy over barbarians. On the other hand the introduction of siege artillery toward the end of the middle ages diminished the defensive value of feudal castles and other fortifications. Black powder was the sole explosive material available for about 600 years, from the time of its discovery to mid-19th century when nitroglycerin and nitrocellulose were discovered.

There is no certainty as to the actual date of the invention of black powder, but early experiments with such materials as oil, pitch, sulfur and other ingredients were all steps on the road to its discovery. These predecessors were of a sticky nature; they not only adhered to objects they hit, but their fire was difficult to extinguish, especially with water. Best known of these mixtures was Greek fire (*q.v.*), long a terror to the enemies of the ancient Byzantine empire.

There is some evidence that the Chinese possessed black powder in ancient times, but the evidence is not conclusive. It may be significant that saltpetre (or nitre), an essential ingredient of black powder. was mentioned for the first time in the writings of the Arabian Abd Allah, about A.D. 1200. Nevertheless, it may have been used in rockets or in "Roman candles" in the 10th century or even earlier.

Among the many claimants of the honour of discovering black powder are Chinese, Hindus, Greeks, Arabs, English (Roger Bacon) and Germans (Berthold Schwarz). The subject attained greater prominence when the first guns were invented to utilize black powder as a propellanf, early in the 14th century. The actual loading of the powder into cannon required considerable artistry to get uniform and maximum results, and therefore good gunners were in great demand. There had to be just the right density of loading for optimum propagation of the flame, since burning occurs mostly on exposed powder surfaces. (*See* ARTILLERY.) Other applications followed slowly. For example, no record is found of the use of black powder for blasting for nearly 300 years.

The original powdered form of black powder burned too rapidly and generated high pressures that often caused guns to burst. Successive steps to develop slower burning material that would create less extreme and longer lasting pressures include "corning" (pressing into grains of specific sizes and shapes) and the use of undercharred carbonaceous material. These developments are described more fully below.

Early Manufacture. — The preparation of black powder from solid ingredients requires fine particle sizes for uniform mixing and blending of the saltpetre, carbon and sulfur. In the earliest processes these were combined by simple mortar-and-pestle methods, often with improvised equipment — even to the point of using hollowed-out logs as mortars.

A little later methods were devised to raise the pestle mechanically. using horse or water power, and to drop it by the automatic tripping of a trigger. These rather violent blows increased the danger of spontaneous fires and explosions, so these "stamp mills" were banned in some quarters (notably England, in 1772).

One of the main problems at first was to secure sufficiently pure ingredients, especially important being the purity of the saltpetre. This material is found in many parts of India and in Spain and southern Andalusia. Various means of developing it from other sources, such as the decomposition of organic matter, were devised by governments of most European countries. Near the end of the 19th century the discovery in Chile of huge deposits of sodium nitrate (Chilean saltpetre), which could readily be converted to potassium nitrate by treatment with potassium chloride, improved the world supply situation.

As the powdered form of black powder burned too rapidly, 15th-century powder makers introduced a process for corning or graining the powder. The mixture of ingredients was moistened while being pounded in the pestle, using various fluids such as alcohol and urine. The paste so formed was beaten into a more or less coherent cake under the action of the pestle, then removed and broken into chunks. These chunks were broken down into smaller particles by agitation with metal balls in the mass; the resulting particles were "classified" by passing through various meshes of sieve. The final "grains" were irregular in shape and left ample space for the passage of flame throughout the charge. Particles of different sizes were readily adapted to varying sizes of cannon

to furnish burning rates that were effective ballistically but did not create excessive pressures.

As elongated projectiles replaced round balls and rifling of gun tubes was adopted to rotate and stabilize the projectile, ordnance specialists searched for slower burning propellants. Capt. (later Brig Gen.) Thomas J. Rodman, of the U.S. army, conducted many experiments in the 1850s and finally came up with grains of controlled shape and size. The shape was hexagonal with a number of perforations parallel to the edges. These perforations provided expanding burning surfaces, thus promoting progressive burning rates as the projectile traveled down the bore of the gun. These grains could be made in various sizes, by pressing the ordinary black ponder particles into specially designed dies.

For even slower burning in heavy ordnance, brown or "cocoa" ponder nas introduced in the late 19th century. Here the carbonaceous material was prepared from rye straw and was undercharred. For dependable burning the saltpetre content was increased from 75% to 80% and the sulfur reduced to 3%. This powder, made in the prism form devised by Rodman, proved to be the best evolved. With it the U.S. navy fought the Spanish-American War (1898) but that was the last great conflict in which black powder played an important role as a propellant.

Modern Manufacture. — Black powder is manufactured by pulverizing charcoal and sulfur together in a ball mill, whereby some of the sulfur is incorporated or worked into the cellular openings of the charcoal. The dampened material is mixed with finely ground nitrate and the moisture content is adjusted to approximately 4%. About 300 lb of the mixture is placed in a wheel mill having tno wheels, each 18 in. wide and weighing 8 or 10 tons. The milling operation, which is continued for 3 to 6 hours. increases the degree of incorporation.

The milled material is then pressed into cakes. using a pressure of approximately 6,000 p.s.i. The cake is broken up by means of adjustable rolls nith corrugated surfaces. The several rolls in the corning mill reduce the material to the desired grain size. Passage of the material over shaker screens removes dust and fines, which are returned to the wheel mill. The coarse material is passed through the rolls a second time and is rescreened.

In the blending house, the screened material is tumbled for about 8 hours in a rotating drum of hardwood. Because of friction the powder is heated to as much as 6j° C. and any moisture present is removed by evaporation. If the powder is to be glazed. graphite is added to the contents of the drum after the moisture has been reduced to a certain point but before the powder is too dry. The dried powder is separated into standard granulations by sieving and then packed in metal drums holding 20 to 2j lb. Manufacture of black powder is hazardous because of the sensitivity of the material to ignition by spark: the separate operations are conducted by remote control in widely spaced buildings. The corning mill operation is considered the most hazardous.

Properties and Variations. — The early composition of black powder saw little change in the proportions of ingredients for 400 years or more. Since then, however. the properties, and especially the burning rate. have been altered for various uses by changing the percentage of saltpetre, using different types of wood to make the charcoal, substituting powdered coal for the charcoal and substituting sodium nitrate for the saltpetre. The original material is no longer used as a propellant but still finds valuable application as an igniting medium. In an artillery shell. for example, it apparently projects almost an optimum mixture of hot gases and incandescent solid particles onto the surface of the propellant grains. In the absence of moisture, black ponder is quite stable chemically, its ingredients being essentially nonreactive with each other even at 120° C. Presence of moisture causes black powder to react with some metals such as steel, brass and copper. The high degree of accidental explosion hazard is attributable to its great sensitivity to ignition by flame, incandescent particles or electric spark.

In addition to use as an igniting material, black powder (with variations in compositions as described above) finds useful application in time fuzes, saluting charges. squibs, smoke-puff charges, "spotting" charges for practice bombs and, of course, many commercial applications such as fireworks and signals. For blasting purposes it is still employed in large quantities and is especially effective where a relatively slow "push" is required to avoid excessive break-up of the material being excavated. This property would be ideal for coal mining except for the fact that the resultant flames cannot be tolerated because of flammable gases present in many mines.

One may wonder at the sudden demise of black powder as a propellant, for centuries its most dramatic use. The question is partly answered by the terminology of its replacement, "smokeless" powder. Nitrocellulose propellants burn more completely and thus produce less smoke. because both the fuel (carbon and hydrogen) and the oxygen exist together in the same molecule. Furthermore, modern propellants deliver much more mechanical work per unit of weight, and from many weapons the undesirable muzzle flash can be prevented by addition of certain alkali metal salts (as K_2SO_4) or cooling agents (as dibutylphthalate) in the colloid. Curiously, the term "ponder" still is applied in some quarters to modern propellants, even though a single grain for rockets may have a diametre of many inches and a length measured in feet. Fortunately, the single word propellant is rapidly replacing the inaccurate terms gunpowder and smokeless powder.

Folloaing World War II the production rate of most types of black powder dropped off considerably as military requirements were reduced and substitute materials were utilized for special purpose application. For example, such metals as magnesium and aluminum. uith an oxidizer, give higher burning rates. much more heat energy and cleaner burning. Nevertheless, black powder has served mankind well for many centuries. It has acted as a most important tool and steppingstone in the rapid march toward the modern concept of civilization.

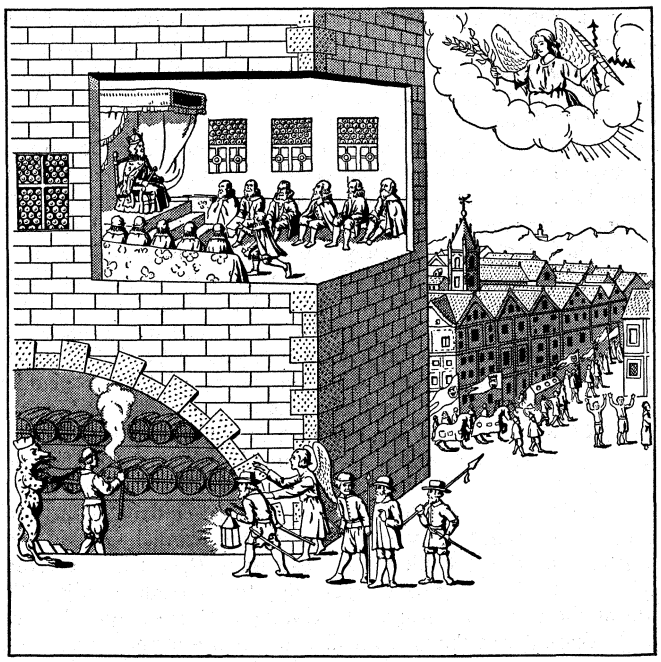
(B. E. AN.)

GUNPOWDER PLOT, the name given to a conspiracy for blowing up King James I and the parliament on Nov. 5, 1605. Organized as a reply to the anti-Roman Catholic laws, which: after a temporary relaxation, were being applied by James with renewed vigour, it originated at a meeting, probably in Jan. 1604. at a house in Lambeth. among Robert Catesby and his cousin Robert Winter and John Wright. Later: several other persons mere included in the plot, Winter's brother Thomas. Thomas Percy. John Grant. Ambrose Rokewood. Robert Keyes, Sir Everard Digby, Francis Treshani (a cousin of Catesby) and Catesby's servant Thomas Bates, all, with the exception of the last, being men of good family and all Roman Catholics. Father Greenway and Father Garnet, the Jesuits, mere both cognizant of the plot. Guy Fawkes was brought over from Flanders in 1604. In March 1605 a vault immediately under the house of lords was hired by Percy and 36 bbl. of gunpowder (amounting to about 1 ton 12 cwt.), concealed there under coal and faggots. The preparations were completed in May and the conspirators separated.

On Oct. 26 Lord Monteagle (a brother-in-law of Tresham), who had engaged in Romanist plots against the government, but who had given his support to the new king, was seated at supper at Haxton when the following letter was brought to him: "My lord, out of the love I bear to some of your friends, I have a care for your preservation. Therefore I would advise you, as you tender your life to devise some excuse to shift of your attendance of this Parliament, for God and man hath concurred to punish the wickedness of this time. And think not slightly of this advertisement, but retire yourself into your country. where you may expect the event in safety, for though there be no appearance of any stir, yet I say they shall receive a terrible blow, the Parliament. and yet they shall not see who hurts them. This counsel is not to be contemned, because it may do you good and can do you no harm, for the danger is past as soon as you have burnt the letter: and I



THE GUNPOWDER PLOT. 1605, AS REPRESENTED IN AN OLD PRINT

James I is seen opening parliament. Guy Fawkes stands below, at the entrance to the cellar, with lighted taper ready to fire the barrels of gunpowder. The Devil is at his side with bellows. An angel accompanies the discoverer of the plot, who is shown with lighted lantern. The scene is purely imaginative, since the plot was discovered two days before parliament opened

hope God will give you the grace to make good use of it, to whose holy protection I commend you."

The authorship of the letter has never been disclosed or proved, but all evidence seems to point to Tresham and to the probability that he had warned Monteagle and agreed with him as to the best means of making known the plot and preventing its execution; at the same time of giving the conspirators time to escape.

Monteagle at once showed the letter to Salisbury and other ministers, but the cellar under the house of lords was not searched until Nov. 4. The whole plot was then discovered; Fankes was arrested and tortured; Catesby and others fled into the country, rejoining each other in Warwickshire, as had been agreed in case the plot had been successful. Catesby with some others covered the distance of 80 mi. between London and his mother's house at Ashby St. Legers in eight hours. He informed his friends in Warwickshire of the failure of the plot, but succeeded in persuading Sir Everard Digby, by an unscrupulous falsehood, further to implicate himself in his hopeless cause by assuring him that both James and Salisbury were dead. They failed to rally any of the support that they had expected from the countryside. and their small party was run to earth by the sheriff at Hewell Grange on Nov. 8. Catesby, Percy and the two Wrights were killed, Winter and Rokewood wounded and taken prisoners with the men who still adhered to them. In all, eight of the conspirators including the two Winters, Digby, Fawkes. Rokewood, Keyes and Bates, were executed; Tresham died in the Tower. Of the priests involved. Garnet was tried and executed, Greenway and Gerard succeeded in escaping. The allegation that the whole affair was an *agent-provocateur's* plot for which Salisbury was responsible is regarded as baseless.

In England, the anniversary of the discovery of the Gunpowder plot is still celebrated on Guy Fawkes' day (Nov. 5) by bonfires, fireworks, and the carrying of "guys" through the streets.

GUNTER, EDMUND (1581–1626), English mathematician, invented several useful measuring devices. Of Welsh extraction. he was born in Hertfordshire in 1581. He was educated at Westminster school, and in 1599 was elected a student of Christ Church, Oxford. He was professor of astronomy at Gresham college from 1619 until his death on Dec. 10, 1626. Descriptions of some of his inventions were given in his treatises on the sector, cross-staff, bow, quadrant and other instruments. In 1620 he published his Canon *triangulorum*. There is reason to believe that Gunter was the first to discover (in 1622 or 1625) that the magnetic declination at one place varies (see GEOMAGNETISM). He introduced the words cosine and cotangent (see TRIGONOMETRY). and he suggested to Henry Briggs. his friend and colleague, the use of the arithmetical complement (see Briggs. *Arithmetica logarithmica,* ch. xv, and LOGARITHMS).

His practical inventions included Gunter's chain, the chain in common use for surveying. 22 yd. long and divided into 100 links; Gunter's line, a logarithmic line! the forerunner of the slide rule; Gunter's quadrant. used to find the hour of the day, the sun's azimuth, etc., and also to take the altitude of an object in degrees; and Gunter's scale, generally called by seamen the gunter, a large plane scale engraved with various lines of numbers and used to solve problems in navigation, trigonometry, etc., with the aid of a pair of compasses. (O. OE.)

GÜNTHER, (FRANZ) IGNAZ (1725–1775). German sculptor who specialized in the carving of great altarpieces in wood, full of rococo fantasy, vivacity and imagination, was born Nov. 22, 1725, in Altmannstein in the Gpper Palatinate. At first a pupil of his father, he went to Munich in 1743 and studied for seven years under J. B. Straub. As an independent master he worked in the tradition of wooden altar art of south Germany. In his later period signs of neoclassicism, beginning in the altar at Starnberg (1766–68), are to be seen. An extraordinary number of his works survive in south Germany, notably at Freising. Munich, Nenningen in Württemberg (late style) and Ingolstadt. Günther died in Munich on June 26. 1775. (A. K. McC.)

GÜNTHER, JOHANN CHRISTIAN (1695–1723). German poet, was born at Striegau, Lower Silesia, on April 8, 1695. In 1717 he went to Leipzig and was befriended by J. B. Mencke (1674–1732). A recommendation from Mencke to Frederick Augustus II of Saxony, king of Poland, proved worse than useless, as Giinther appeared at the audience drunk. He died at Jena, March 15, 1723. Goethe pronounces Gunther a poet in the fullest sense of the term. His lyric poems reveal fine imagination, clever wit and a true ear for melody and rhythm; but duil or vulgar witticisms are frequently found side by side with the purest inspirations of his genius.

Gunther's collected poems were published in 4 vol. (1723–35). They are also included in vol. vi. of Tittmann's *Deutsche Dichter des 17ten Jahrh.* (1874) and vol. xxxviii. of Kürschner's *Deutsche Nationalliteratur* (1883). *A* life by Siehrand appeared in 1738.

GÜNTHER OF SCHWARZBURG (1304–1349), German king, was a descendant of the counts of Schwarzburg and the younger son of Henry VII, count of Blankenburg. He was elected German king at Frankfort (Jan. 30, 1349) by four of the electors, partisans of the house of Wittelsbach and opponents of Charles of Luxemburg, afterward Charles IV. Charles defeated him at Eltville, and Giinther renounced his claims for 20,000 marks of silver. He died three weeks later at Frankfort.

GUNTRAM or GONTRAN (561–592), king of Burgundy, was a son of Clotaire I. On the death of his father (561) he and three brothers divided the Frankish realm. Guntram received as his share the valleys of the Saône and Rhône, together with Berry and the town of Orléans, which he made his capital. On the death of Charibert (567). he obtained the cioitates of Saintes. Angoulême and Périgueux. During the civil war between the kings of Neustria and Austrasia, he sought to maintain equilibrium. After the assassination of Sigebert (575), he took the youthful Childebert II under his protection. After the death of Chilperic (584) he protected the young Clotaire II, and prevented Childebert from seizing his dominions. The danger to the Frankish realm caused by the expedition of Gundobald (585), and the anxiety which was caused him by the revolts of the great lords in Xustrasia finally decided him in favour of Childebert. He adopted him as his son and recognized him as his heir at the treaty of Andelot (587). Guntram died in 592, and Childebert received his inheritance.

GUNTUR, city and district in Andhra Pradesh, India. The city (pop. [1961] 187,068) is 20 mi. S.W. of Bezwada, east of the Kondavid hills. Guntur appears to have been founded in the 18th century by the French. At the time of the cession of the Circars to the English in 1765, it was exempted during the life of Basalat Jang. whose personal *jagir* it was. In 1788 it came into British possession. the cession being confirmed in 1823. It has cotton factories, tobacco factories and oil and rice mills.

GUNTUR DISTRICT, constituted in 1904 from territory till then divided between Kistna and Nellore, has an area of 5.795 sq.mi.; pop. (1961) 3,009,997. It is bounded east and north by the Kistna river; in the west, part of the boundary is formed by the Gundlakamma river. Most of it is a fertile plain irrigated by canals from the Kistna, producing cotton, rice and other crops.

GURDASPUR, a municipality and district in the Jullundur division of Punjab, India. The town is 9 mi. S.E. of the West Pakistan frontier; pop. (1951) 22.677. It has a fort (now a Brahman monastery) which was famous for the siege it sustained in 1712 from the Moguls.

GURDASPUR DISTRICT (pop [1961] 984,152), has an area of 1.363 sq.mi., 480 sq.mi. having been allotted to Pakistan at the 1947 partition. Pathankot (pop.. 1951. 23,108), the neighbouring villages in the plain and all the hill country of Gurdaspur district, formed part of the area ceded by the Sikhs to the British after the first Sikh war in 1846. The largest town and chief commercial centre is Batala (55,850). There are woolen mills at Dhariwal, and the district exports cotton! sugar: grain and oilseeds.

GURGAN (GORGAN), formerly Xsterabad, a town of Mazandaran ostan (province), Iran, lies on a small tributary of the Kara Su, 23 mi. from the Caspian sea, at the foot of a steep wooded spur of the Elburz mountains. The population (1956) 28.525, has nearly trebled since 1900. Most of the houses are built of baked bricks, with tilted and tiled roofs, because of the frequent rains. Occupying a commercially and strategically important position, the town dates back to remote antiquity. Its surroundings are dotted with mounds or *tappeh,* the remains of Neolithic and Bronze Age settlements. During the disorders in Persia in the 18th century, Xsterabad was frequently ravaged but was reinforced by the Kajar dynasty. It was renamed Gurgan in the 1930s. The chief articles of trade are cotton; rice, wheat, salt, sesame oil, soap and carpets; trade was favourably affected by the trans-Iranian railway which ends at the nearby port of Bandar Shah.

The former province of Gurgan-Xsterabad had long suffered from the inroads of the Turkoman tribes who occupied the plain north of the Kara Su. In modern times this plain was settled by the tribesmen and turned into a flourishing granary. (H. Bo.)

GURGAON, a municipality and district in the Ambala division of Punjab, India. The town (pop., 1951, 18,613) is 17 mi. S.W. of Delhi.

GURGAON DISTRICT has an area of 2,368 sq.mi. It comprises the southernmost corner of Punjab state. Salt is processed and mineral products are iron ore, copper ore, plumbago and ochre. In 1803 Gurgaon district passed to the British. On the outbreak of the mutiny in 1857, the nawab of Farukhnagar rose in rebellion. After the fall of the rebel capital, the territory of the nawab was confiscated. Pop. (1961) 1,238,128. The chief trade centre is Rewari (pop., 1951, 34,082); trade is in cereals, and hardware.

The former principality of Pataudi (53 sq.mi.) was incorporated into the district in 1948.

GURKHA, the ruling Hindu caste in Nepal (*q.v.*). Courageous, faithful and self-reliant, they make excellent riflemen, at their best in hill warfare.

GURKB, VASILI (1864–1937), Russian general, was born in 1864. He was educated in the corps of pages, and in 1885 was given a commission in the Grodno Hussar regiment. In 1911 he was chief of the 1st cavalry division, which in Xug. 1914 advanced into eastern Prussia. In 1915 he was commander of the VI corps. At the end of 1917, during Gen. Mikhail Alexeyev's illness, he fulfilled the duties of chief of staff. Later, after the revolution, he was dismissed by Alexander Kerensky, because of his objections to risking an offensive with the army in a ferment, and of his outspoken opinions as to the causes of this condition. Gurko was imprisoned, released, imprisoned again and finally exiled.

GURNARD (Trigla), a genus of fishes forming a group of the family Triglidae, recognized by the three first fin rays of the pectoral fin being detached to form movable fingerlike appendages, serving as organs of touch and of locomotion along the bottom, and by their large, angular, bony head. Gurnards are coast fishes, generally distributed over the tropical and temperate areas. Although never found far from the coast, gurnards descend to several hundred fathoms; they are caught chiefly by the trawl. In young fishes, the pectorals are comparatively longer than in the adult, extending to the end of the body. These fins are beautifully coloured, especially in the young. When taken out of the water, gurnards emit a grunting noise produced by the vibrations of a perforated diaphragm across the cavity of the air bladder. Their flesh is white, firm and wholesome.

GURNEY, the name of an English family of bankers and merchants. In 1770 the brothers JOHN and HENRY GURNEY founded a banking house at Norwich, the business passing in direct line to SAMUEL GURNEY (1786–1856), who assumed control of the bank in 1809. At approximately the same time Samuel Gurney took over the control of the bill broker business of Richardson. Overend and Co., a London firm devoted entirely to the trade in bills. The title of the firm was changed to Overend, Gurney and Co., and for 40 years it was the greatest discount house in the world. The firm was known as "the banker's banker" and competed effectively with the Bank of England. In 1866, Overend, Gurney and Co., by then a joint stock company, suspended payment with liabilities amounting to £11,000,000. (J. R. LT.)

GUSTAVO A. MADERO, a town in Mexico's federal district whose name was changed from Guadalupe Hidalgo on Dec. 22, 1931. to honour the brother of Francisco Indalecio Madero (*q.v.*), revolutionary hero and former president of Mexico. Named the Villa de Guadalupe by royal decree in the 18th century for the Virgin of Guadalupe, the town became Guadalupe Hidalgo on Feb. 12, 1828, to honour Miguel Hidalgo y Costilla, hero of Mexican independence. (H. R. HY.)

GUSTAVUS I ERIKSSON (1496–1560), king of Sweden, was born at Lindholm on Ascension Day, 1496. His family was conspicuous in 15th century politics. Gustavus' youthful experiences gave him a lifelong distrust of everything Danish — strengthened by the fact that in 1516 King Christian, to whom he had been sent as a hostage, treacherously carried him prisoner to Denmark. Detained for 12 months in the island fortress of Kalö, he contrived to escape to Lubeck in Sept. 1519. On May 20, 1520, he chartered a ship to Kalmar, one of the few Swedish fortresses which held out against Christian II. While hunting near Lake Mälar, news of the Stockholm massacre was brought to him. Gustavus appealed to the sturdy yeomen of the dales, and finally drove the Danes out of Sweden (1521–23). After his coronation on June 6, 1523, order had to be evolved from the chaos in which Sweden had been plunged by the disruption of the union. The shortest way was to restore the royal authority, which had been in abeyance during 90 years. But an effective reforming monarchy must stand upon a sound financial basis; and the usual revenues of the crown were so diminished that they did not cover half the daily expenses of government. New taxes could only be imposed with extreme caution. The lack of capable, trustworthy administrators threw the burden of government on the shoulders of the young king. His time was taken up in traveling about the kingdom and doing purely clerical work for want of competent assistance. This lack of native talent compelled Gustavus to employ the services of foreign adventurers like Berent von Mehlen, John von Hoja, Konrad von Pyhy and others. Gustavus had constantly to watch the Swedish peasantry; he put down four rebellions between 1525 and 1542, but the strain upon his resources was damaging, and more than once he was on the point of abdicating.

He was compelled (1534–36) to take part in *Grevens* fejde (Counts' War) (see DENMARK: *History*), as the ally of Christian III, but his exaggerated distrust of the Danes was invincible. A fresh cause of dispute was generated in 1548, when Christian III's daughter was wedded to Duke Augustus of Saxony. On that occa-

sion, apparently by way of protest against the decree of the diet of Vesterås (Jan. 15, 1544), declaring the Swedish crown hereditary in Gustavus's family, the Danish king caused to be quartered on his daughter's shield not only the three Danish lions and the Norwegian lion with the axe of St. Olaf, but also "the three crowns" of Sweden. Gustavus, naturally suspicious, was perturbed by the innovation, and warned all his border officials to be watchful. In 1557 he even wrote a letter of protest to the Danish king, but Christian III. replied that "the three crowns" signified not Sweden in especial, but the three Scandinavian kingdoms, and that their insertion in the Danish shield was only reminiscent of the union of Kalmar. But Gustavus was not satisfied, and this was the beginning of "the three crowns" dispute which did so much damage to both kingdoms.

The rupture of Gustavus with the Holy See was a purely political act, as Gustavus, personally, had no strong dogmatic convictions. He not unnaturally expressed his amazement when Olavus Petri informed him that the pope was antichrist. He consulted the older and graver Laurentius Andreae, who told him how "Doctor Martinus had clipped the wings of the pope, the cardinals and the big bishops," which could not fail to be pleasing intelligence to a monarch who was never an admirer of episcopacy, while the rich revenues of the church were tempting to the impecunious ruler of an impoverished people. When the Protestant hierarchy was forcibly established in Sweden, matters were much complicated by the absolutist tendencies of Gustavus. The incessant labour, the constant anxiety, which were the daily portion of Gustavus Vasa during the 37 years of his reign, told at last even upon his magnificent constitution. In the spring of 1560, conscious of a decline of his powers, Gustavus summoned his last diet, to give an account of his stewardship. On June 16, 1560 the assembly met at Stockholm. Ten days later, supported by his sons, Gustavus greeted the estates in the great hall of the palace, when he took a retrospect of his reign. Four days later the diet passed a resolution confirming the hereditary right of Gustavus's son, Prince Eric, to the throne. The old king's last anxieties were now over and he could die in peace. He expired on Sept. 29, 1560.

Gustavus was thrice married. His first wife, Catherine, daughter of Magnus I, duke of Saxe-Lauenburg, bore him in 1533 his eldest son Eric. This union was neither long nor happy, but the blame for its infelicity is generally attributed to the lady, whose abnormal character was reflected and accentuated in her son. Much more fortunate was Gustavus's second marriage with his own countrywoman, Margaret Lejonhufvud, who bore him five sons and five daughters, of whom three sons, John, Magnus and Charles, and one daughter, Cecilia, survived their childhood. Queen Margaret died in 1551; and a twelvemonth later Gustavus wedded her niece, Catharine Stenbock, a handsome girl of 16, who survived him more than 60 years.

Gustavus's outward appearance in the prime of life is thus described by a contemporary: "He was of the middle height, with a round head, light yellow hair, a fine long beard, sharp eyes, a ruddy countenance . . . and a body as fitly and well proportioned as any painter could have painted it." Learned he was not, but he had naturally bright and clear understanding, an unusually good memory, and a marvellous capacity for taking pains. He was also very devout, and his morals were irreproachable. On the other hand, Gustavus had his full share of the family failings of irritability and suspiciousness, the latter quality becoming almost morbid under the pressure of adverse circumstances. His energy too not infrequently degenerated into violence, and when crossed he was apt to be tyrannical.

(R. N. B.; X.)

GUSTAVUS II. ADOLPHUS (1594–1632), king of Sweden, the eldest son of Charles IX. and of Christina, daughter of Adolphus, duke of Holstein-Gottorp, was born at Stockholm castle on Dec. 9, 1594. From the first he was carefully nurtured to be the future prop of Protestantism by his austere parents. Gustavus was well grounded in the classics, and his linguistic accomplishments were extraordinary. He may be said to have grown up with two mother-tongues, Swedish and German; at twelve he had mastered Latin, Italian and Dutch; and he learnt subsequently to express himself in Spanish, Russian and Polish. But his practical father took care that he should grow up a prince, not a pedant. So early as his ninth year he was introduced to public life; at 13 he received petitions and conversed officially with the foreign ministers; at 15 he administered his duchy of Vestmanland and opened the Örebro diet with a speech from the throne; indeed from 1610 he may be regarded as his father's co-regent. In all martial and chivalrous accomplishments he was already an adept; and when, a year later, he succeeded to supreme power, his superior ability was as uncontested as it was incontestable.

The first act of the young king was to terminate the fratricidal struggle with Denmark by the peace of Knäred (Jan. 28, 1613). Simultaneously, another war, also an heritage from Charles IX., had been proceeding in the far distant regions round lakes Ilmen, Peipus and Ladoga, with Great Novgorod as its centre. It was not, however. like the Danish War, a national danger, but a political speculation meant to be remunerative and compensatory, and was concluded very advantageously for Sweden by the peace of Stolbova on Feb. 27, 1617 (see SWEDEN: *History*). By this peace Gustavus succeeded in excluding Muscovy from the Baltic. "I hope to God," he declared to the Stockholm diet in 1617. when he announced the conclusion of peace, "that the Russians will feel it a bit difficult to skip over *that* little brook." The war with Poland which Gustavus resumed in 1621 was a much more difficult affair. It began with an attack upon Riga as the first step towards conquering Livonia Riga was invested on Aug. 13 and surrendered on Sept. 15; on Oct. 3 Mitau was occupied; but so great were the ravages of sickness during the campaign that the Swedish army had to be reinforced by no fewer than 10,000 men A truce was thereupon roncluded and hostilities were suspended till the summer of 1625, in the course of which Gustavus took Kokenhusen and invaded Lithuania. In Jan. 1626 he attacked the Poles at Walhof and scattered the whole of their army after slaying a fifth part of it. This victory, remarkable besides as Gustavus's first pitched battle, completed the conquest of Livonia. As, however, it became every year more difficult to support an army in the Dvina district, Gustavus now resolved to transfer the war to the Prussian provinces of Poland with a view to securing the control of the Vistula, as he had already secured the control of the Dvina. At the end of 1626, the Swedish fleet, with 14,000 men on board, anchored in front of the chain of sand-dunes which separates the Frische-Haff from the Baltic. Pillau, the only Baltic port then accessible to ships of war, was at once occupied, and Konigsberg shortly afterwards was scared into an unconditional neutrality. July was passed in conquering the bishopric of Ermeland The surrender of Elbing and Marienburg placed Gustavus in possession of the fertile and easily defensible delta of the Vistula, which he treated as a permanent conquest, making Axel Oxenstjerna its first governor-general. Communications between Danzig and the sea were cut off by the erection of the first of Gustavus's famous entrenched camps at Dirschau. From the end of August 1626 the city was blockaded, and in the meantime Polish irregulars, under the capable Stanislaus Koniecpolski, began to harass the Swedes. But the object of the campaign. a convenient basis of operations, was won; and in October the king departed to Sweden to get reinforcements He returned in May 1627 with 7,000 men. which raised his forces to 14,000 against which Koniecpolski could only oppose 9,000. But his superior strategy frustrated all the efforts of the Swedish king, who in the course of the year was twice dangerously wounded and so disabled that he could never wear armour again. Gustavus had made extensive preparations for the ensuing campaign and took the field with 32,000 men But once again, though far outnumbered, and unsupported by his own government, the Polish grand-hetman proved more than a match for Gustavus, who, on Sept. 10, broke up his camp and returned to

Prussia; the whole autumn campaign had proved a failure and cost him 5,000 men. During the ensuing campaign of 1629 Gustavus had to contend against the combined forces of Koniecpolski and 10,000 of Wallenstein's mercenaries. The Polish commander now showed the Swedes what he could do with adequate forces. At Stuhm, on June 29, he defeated Gustavus, who lost most of his artillery and narrowly escaped capture. The result of the campaign was the conclusion of the six years' truce of Altmark, which was very advantageous to Sweden.

And now Gustavus turned his attention to Germany. The motives which induced the Swedish king to intervene directly in the Thirty Tears' War are told us by himself in his correspondence with Oxenstjerna. Here he says plainly that it was the fear lest the emperor should acquire the Baltic ports and proceed to build up a sea-power dangerous to Scandinavia. For the same reason, the king rejected the chancellor's alternative of waging a simply defensive war against the emperor by means of the fleet, with Stralsund as his base. He was convinced by the experience of Christian IV. of Denmark that the enemies' harbours could be wrested from them only by a successful offensive war on land; and, while quite alive to the risks of such an enterprise in the face of two large armies, Tilly's and Wallenstein's, each of them larger than his own, he argued that the vast extent of territory and the numerous garrisons which the enemy was obliged to maintain, more than neutralized his numerical superiority. Merely to blockade all the German ports with the Swedish fleet was equally impossible. The Swedish fleet was too weak for that; it would be safer to take and fortify the pick of them. In Germany itself, if he once got the upper hand, he would not find himself without resources. It is no enthusiastic crusader, but an anxious and far-seeing if somewhat speculative statesman who thus opens his mind to us. No doubt religious considerations largely influenced Gustavus. He had the deepest sympathy for his fellow-Protestants in Germany; he regarded them as God's peculiar people, himself as their divinely appointed deliverer. But his first duty was to Sweden; and, naturally and rightly, he viewed the whole business from a predominantly Swedish point of view. Lutherans and Calvinists were to be delivered from a "soul-crushing tyranny"; but they were to be delivered by a foreign if friendly power; and that power claimed as her reward the hegemony of Protestant Europe and all the political privileges belonging to that exalted position.

On May 19, 1630 Gustavus solemnly took leave of the estates of the realm assembled at Stockholm. He appeared before them holding in his arms his only child and heiress, the little princess Christina, then in her fourth year, and tenderly committed her to the care of his loyal and devoted people. Then he solemnly took the estates to witness, as he stood there "in the sight of the Almighty," that he had begun hostilities "out of no lust for war, as many will certainly devise and imagine," but in self-defence and to deliver his fellow-Christians from oppression. On June 7, 1630 the Swedish fleet set sail, and two days after midsummer day, the whole army, 16,000 strong, was disembarked at Peenemiinde. Gustavus's plan was to take possession of the mouths of the Oder Haff, and, resting upon Stralsund in the west and Prussia in the east, penetrate into Germany. In those days rivers were what railways now are, the great military routes; and Gustavus's German war was a war waged along river lines. The opening campaign was to be fought along the line of the Oder. Stettin, the capital of Pomerania, and the key of the Oder line, was occupied and converted into a first-class fortress. He then proceeded to clear Pomerania of the piebald imperial host composed of every nationality under heaven, and officered by Italians, Irishmen, Czechs, Croats, Danes, Spaniards and Walloons. Gustavus's army has often been described by German historians as an army of foreign invaders; in reality it was far more truly Teutonic than the official defenders of Germany at that period. Gustavus's political difficulties (see SWEDEN: History) chained him to his camp for the remainder of the year. But the dismissal of Wallenstein and the declaration in Gustavus's favour of Magdeburg, the greatest city in the Lower Saxon Circle, and strategically the strongest fortress of north Germany, encouraged him to advance boldly. But first, honour as well as expediency moved him to attempt to relieve Magdeburg, now closely invested by the imperialists, especially as his hands had now been considerably strengthened by a definite alliance with France (treaty of Bärwalde, Jan. 13, 1631). Magdeburg, therefore. became the focus of the whole campaign of 1631; but the obstructive timidity of the electors of Brandenburg and Saxony threw insuperable obstacles in his way, and, on the very day uhen John George I. of Saxony closed his gates against Gustavus the most populous and prosperous city in north Germany became a heap of smoking ruins (May 20). Gustavus. still too weak to meet the foe, entrenched himself at Werben, at the confluence of the Havel and Elbe. Only on Sept. 12 did the elector of Saxony, alarmed for the safety of his own states, now invaded by the emperor, place himself absolutely at the disposal of Gustavus; and, five days later, at the head of the combined Swedish-Saxon army, though the Swedes did all the fighting, Gustavus routed Tilly at the famous battle of Breitenfeld, north of Leipzig.

The question now was. In what way should Gustavus utilize his advantage? Should he invade the Austrian crown lands, and dictate peace to Ferdinand II. at the gates of Vienna? Or should he pursue Tilly westwards and crush the league at its own hearth and home? Oxenstjerna was for the first alternative; Gustavus decided in favour of the second. His decision has been greatly blamed. More than one modern historian has argued that if Gustavus had done in 1631 what Napoleon did in 1805 and 1809, there would have been a fifteen instead of a thirty years' war. But it should be borne in mind that, in the days of Gustavus. Vienna was by no means so essential to the existence of the Habsburg monarchy as it was in the days of Napoleon; and even Gustavus could not allow so dangerous an opponent as Tilly time to recover himself. Accordingly, he set out for the Rhine, taking Marienberg and Frankfort on his way, and on Dec. 20 entered Mainz, where he remained throughout the winter of 1631–32. At the beginning of 1632, in order to bring about the general peace ne so earnestly desired, he proposed to take the field with an overwhelming numerical majority. The signal for Gustavus to break up from the Rhine was the sudden advance of Tilly from behind the Danube. Gustavus pursued Tilly into Bavaria, forced the passage of the Danube at Donauuorth and the passage of the Lech, in the face of Tilly's strongly entrenched camp at Rain, and pursued the flying foe to the fortress of Ingolstadt where Tilly died of his wounds a fortnight later. Gustavus then liberated and garrisoned the long-oppressed Protestant cities of Augsburg and Ulm, and in May occupied Munich. The same week Wallenstein chased John George from Prague and manoeuvred the Saxons out of Bohemia. Then, armed as he was with plenipotentiary power, he offered the elector of Saxony peace on his own terms. Gustavus suddenly saw himself exposed to extreme peril. If Tilly had made John George such an offer as Wallenstein was now empowered to make. the elector would never have become Gustavus's ally; would he remain Gustavus's ally now? Hastily quitting his quarters in upper Swabia, Gustavus hastened towards Kuremberg on his way to Saxony. but finding that Wallenstein and Maximilian of Bavaria had united their forces, he abandoned the attempt to reach Saxony. and both armies confronted each other at Yuremberg which furnished Gustavus with a point of support of the first order He quickly converted the town into an entrenched and fortified camp. Wallenstein followed the king's example, and entrenched himself on the western bank of the Regnitz in a camp twelve English miles in circumference. His object was to pin Gustavus fast to Nuremberg and cut off his retreat northwards. Throughout July and August the two armies faced each other immovably. On Aug. 24 after an unsuccessful attempt to storm Alte Veste, the key of Wallenstein's position, the Swedish host retired southwards

Towards the end of October, Wallenstein, after devastating Saxony, was preparing to go into winter quarters at Lutzen, when the king surprised him as he was crossing the Rippach (Nov. 1) and a rearguard action favourable to the Swedes ensued. Indeed, but for nightfall, Wallenstein's scattered forces might have been routed. During the night, however, Wallenstein re-collected his host for a decisive action, and at daybreak on Nov. 6, while an autumn mist still lay over the field, the battle began. It was obviously Gustavus's plan to drive Wallenstein away from the Leip-

zig road, north of which he had posted himself, and thus, in case of success, to isolate, and subsequently, with the aid of the Saxons in the Elbe fortresses, annihilate him. The king, on the Swedish right wing, succeeded in driving the enemy from the trenches and capturing his cannon. What happened after that is mere conjecture, for a thick mist now obscured the autumn sun, and the battle became a colossal mêlée the details of which are indistinguishable. It was in the midst of that awful obscurity that Gustavus met his death—how or where is not absolutely certain; but it would seem that he lost his way in the darkness while leading the Småland horse to the assistance of his infantry, and was despatched by a hostile horseman as he lay severely wounded on the ground.

By his wife, Marie Eleonora, a sister of the elector of Brandenburg, whom he married in 1620, Gustavus Adolphus had one daughter, Christina, who succeeded him on the throne of Sweden.

GUSTAVUS **III.** (1746–1792), king of Sweden, the eldest son of Adolphus Frederick, king of Sweden, and Louisa Ulrica of Prussia, sister of Frederick the Great, was born on Jan. 24, 1746. Gustavus was educated under the care of two eminent Swedish statesmen, Carl Gustaf Tessin and Carl Scheffer; but he owed most, perhaps, to the poet and historian Olof von Dalin. His teachers were amazed by the brilliance of his natural gifts, and, while still a boy, he possessed that charm of manner which was to make him so fascinating and so dangerous in later life, coupled with the strong dramatic instinct which won for him his honourable place in Swedish literature. There was scarce a French author of his day with whose works he was not intimately acquainted; while his enthusiasm for the new French ideas of enlightenment was as sincere as his mother's. On Nov. 4, 1766, Gustavus married Sophia Magdalena, daughter of Frederick V. of Denmark. The match was an unhappy one.

Gustavus first intervened in politics in 1768, at the time of his father's interregnum, when he compelled the dominant Cap faction to summon an extraordinary diet from which he hoped for the reform of the Constitution in a monarchical direction. But the Hats refused to redeem the pledges which they had given before the elections. "That we should have lost the constitutional battle does not distress us so much," wrote Gustavus, "but what does dismay me is to see my poor nation so sunk in corruption as to place its own felicity in absolute anarchy." From Feb. 4 to March 2j, 1771, Gustavus was in Paris, where the poets and the philosophers paid him enthusiastic homage. But his visit to the French capital was a political mission. The duc de Choiseul, weary of Swedish anarchy, had resolved to discuss with him the best method of bringing about a revolution in Sweden. Before he departed, the French Government undertook to pay the outstanding subsidies to Sweden unconditionally, at the rate of one and a half million livres annually; and the comte de Vergennes was transferred from Constantinople to Stockholm. On his way home Gustavus visited his uncle, Frederick the Great, at Potsdam. Frederick bluntly informed his nephew that, in concert with Russia and Denmark, he had guaranteed the integrity of the existing Swedish constitution, and advised the young monarch to play the part of mediator and abstain from violence.

On his return to Sweden Gustavus made a sincere attempt to mediate between the Hats and Caps who were ruining the country between them *(see* **SWEDEN**: ***History)***. On June 21, 1771, he opened his first parliament in a moving speech. Addressing the diet in the Swedish tongue, he laid stress on the necessity of sacrifice for the common weal and offered to mediate between contending factions. A composition committee was actually formed, but it proved illusory from the first. The subsequent attempts of the dominant Caps still further to limit the prerogative, induced Gustavus at last to consider the possibility of a revolution. Of its necessity there could be no doubt. Under the sway of the Cap faction, Sweden, already the vassal, could not fail to become the prey of Russia. Only by a swift coup *d'état* could the independence of a country isolated from the rest of Europe by a hostile league, be saved from absorption into that northern system, the invention of Count Nikita Panin. At this juncture Gustavus was approached by Jakob Magnus Sprengtporten, a Finnish nobleman of determined character, with the project of a revolution. He undertook to seize the fortress of Sveaborg, and, Finland once secured, to embark for Sweden, meet the king and his friends near Stockholm, and surprise the capital by a night attack, when the estates were to be forced to accept a new constitution from the king.

The plotters were reinforced by an ex-ranger from Scania (Skåne), Johan Kristoffer Toll, also a victim of Cap oppression. Toll proposed that a second revolt should break out in the province of Scania, to confuse the Government still more, and undertook to secure the southern fortress of Kristianstad. It was finally arranged that, a few days after the Finnish revolt had begun, Kristianstad should declare against the Government. Prince Charles was thereupon to mobilize the garrisons of all the southern fortresses, ostensibly to crush the revolt at Kristianstad; but on arriving before the fortress he was to make common cause with the rebels, and march upon the capital from the south, while Sprengtporten attacked it simultaneously from the east. On Aug. 6, 1772, Toll succeeded in winning the fortress of Kristianstad, and on the 16th Sprengtporten successfully surprised Sveaborg. But contrary winds prevented him from crossing to Stockholm, and in the meanwhile events had occurred which made his presence there unnecessary.

On Aug. 16, the Cap leader, Ture Rudbeck, arrived at Stockholm with the news of the insurrection in the south, and Gustavus, finding himself isolated in the midst of enemies, resolved to strike the decisive blow without waiting for the arrival of Sprengtporten. On the evening of the 18th all the officers whom he thought he could trust received instructions to assemble in the square facing the arsenal on the following morning. At ten o'clock on the 19th Gustavus rode to the arsenal, joined on the way by his adherents, so that by the time he reached his destination he had about 200 officers in his suite. After parade he reconducted them to the guard-room of the palace and unfolded his plans. He then dictated a new oath of allegiance, absolving them from their allegiance to the estates, and binding them to obey their lawful king, Gustavus III. Meanwhile the senate and the governor-general, Rudbeck, had been arrested and the fleet secured. On the evening of the 20th heralds proclaimed that the estates were to meet in the Rikssaal on the following day; every deputy absenting himself would be regarded as the enemy of his country and his king. On the 21st, a few moments after the estates had assembled, the king in full regalia appeared, and taking his seat on the throne, delivered that famous philippic in which he reproached the estates for their unpatriotic venality in the past. A new constitution was recited by the estates and accepted by them unanimously. The diet was then dissolved.

Gustavus was inspired by enthusiasm for the greatness and welfare of Sweden, and worked in the same reformatory direction as the other contemporary sovereigns of the "age of enlightenment." He took an active part in every department of business, but relied far more on extra-official counsellors of his own choosing than upon the senate. The effort to remedy the corruption which had been fostered by the Hats and Caps engaged a considerable share of his time and he even found it necessary to put the whole of a supreme court of justice (Gota Hofratt) on its trial. Measures were taken to reform the administration and the judicial procedure, and torture as an instrument of legal

investigation was abolished. In 1774 an ordinance providing for the liberty of the press was issued, the national defences were developed on a "Great Power" scale, and the navy was so enlarged as to become one of the most formidable in Europe. The finances were set in good order by the "currency realization ordinance" of 1777, and in 1775 free trade in corn was promoted and a number of oppressive export-tolls abolished.

The poor law was amended, absolute religious liberty was proclaimed, and he even succeeded in inventing and popularizing a national costume which was in general use from 1778 till his death. His one economic blunder was the attempt to make the sale of spirits a government monopoly, which was an obvious infringement upon the privileges of the estates. His foreign policy, on the other hand, was at first both wise and wary. Thus, when the king summoned the estates to assemble at Stockholm on Sept. 3, 1778, he could give a brilliant account of his six years' stewardship. Never was a parliament more obsequious or a king more gracious. Yet, short as the session was, it was long enough to open the eyes of the deputies to the fact that their political supremacy had departed. They had changed places with the king, who for all his gentleness, guarded his prerogative jealously. Even the few who were patriotic enough to acquiesce in the change by no means liked it. The diet of 1778 had been obsequious; the diet of 1786 was mutinous. The consequence was that nearly all the royal propositions were either rejected outright or so modified that Gustavus himself withdrew them.

The diet of 1786 marks a turning-point in Gustavus's history. Henceforth we observe a determination on his part to rule without a parliament; a passage, cautious and gradual, yet unflinching, from semi-constitutionalism to semi-absolutism. His opportunity came in 1788, when the political complications arising out of his war with Catherine II. of Russia enabled him by the Act of Unity and Security (on Feb. 17, 1789) to override the opposition of the rebellious gentry, and, with the approbation of the three lower estates, establish a new constitution, in which, though the estates still held the power of the purse, the royal authority largely predominated. Throughout 1789 and 1790 Gustavus gallantly conducted the unequal struggle with Russia, finally winning in the Svensksund (July 9–10) the most glorious naval victory ever gained by the Swedish arms, the Russians losing one-third of their fleet and 7,000 men. A month later, on Aug. 14, 1790, peace was signed between Russia and Sweden at Varala. The peace of Varala saved Sweden from humiliating concessions, and in Oct. 1791 Gustavus took the bold step of concluding an eight years' defensive alliance with the empress, who thereby bound herself to pay her new ally annual subsidies amounting to 300,000 roubles.

Gustavus now aimed at forming a league of princes against the Jacobins, and every other consideration was subordinated thereto. His profound knowledge of popular assemblies enabled him accurately to gauge from the first the scope and bearing of the French Revolution. But he was hampered by poverty and the jealousy of the other European Powers, and, after showing once more his unrivalled mastery over masses of men at the brief Gefle diet (Jan. 22–Feb. 24, 1792), he fell a victim to a widespread aristocratic conspiracy. Shot in the back by Anckarstrom at a midnight masquerade at the Stockholm opera-house, on March 16, 1792, he died on the 29th.

Although he may be charged with many foibles and extravagances, Gustavus III. was indisputably one of the greatest sovereigns of the 18th century. Unfortunately his genius never had full scope, and his opportunity came too late. Gustavus was, moreover, a most distinguished author. He may be said to have created the Swedish theatre, and some of the best acting dramas in the literature are by his hand. His historical essays, notably the famous anonymous eulogy on Torstenson crowned by the Academy, are full of feeling and exquisite in style,—his letters to his friends are delightful. Every branch of literature and art interested him, every poet and artist of his day found in him a most liberal and sympathetic protector. (R. N. B.; X.)

GUSTAVUS IV. (1778–1837), king of Sweden, the son of Gustavus III. and Queen Sophia Magdalena, was born at Stockholm, on Nov. 1, 1778. Carefully educated under the direction of Nils von Rosenstein, he grew up serious and conscientious. In 1797 he married Frederica Dorothea, daughter of Charles Frederick, grand-duke of Baden, a marriage which might have led to a war with Russia but for the hatred of the French republic shared by the emperor Paul and Gustavus IV., which served as a bond of union between them. Indeed the king's morbid horror of Jacobinism drove him to adopt all sorts of reactionary measures and to postpone his coronation for some years, so as to avoid calling together a diet; but the disorder of the finances, caused partly by the continental war and partly by the almost total failure of the crops in 1798 and 1799, compelled him to summon the estates to Norrkoping in March 1800, and on April 3, Gustavus was crowned.

The change which now took place in Sweden's foreign policy and its consequences are elsewhere set forth (see SWEDEN: History). By the end of 1808 it was obvious that the king was insane. His violence had alienated his most faithful supporters, while his obstinate incompetence paralysed the national efforts. To remove a madman by force was the one remaining expedient; and this was successfully accomplished by a conspiracy of officers of the western army, headed by Adlersparre, the Anckarsvards, and Adlercreutz. On March 13, 1809 seven of the conspirators broke into the royal apartments unannounced, seized the king, and conducted him to the château of Gripsholm; Duke Charles was persuaded to accept the leadership of a provisional Government, which was proclaimed the same day; and a diet, hastily summoned, approved the revolution.

On March 29, Gustavus, in order to save the crown for his son, voluntarily abdicated; but on May 10, the estates, dominated by the army, declared that his whole family had forfeited the throne. On June 5, the duke regent was proclaimed king under the title of Charles XIII., after accepting the new liberal constitution, which was ratified by the diet the same day. In December Gustavus and his family were transported to Germany. Gustavus now assumed the title of count of Gottorp, but subsequently called himself Colonel Gustafsson, under which pseudonym he wrote most of his works. Separated from his family, he led an erratic life for some years; was divorced from his consort in 1812; and finally settled at St. Gall in Switzerland in great loneliness and indigence. He died on Feb. 7, 1837, and, at the suggestion of King Oscar II. his body was brought to Sweden and interred in the Riddarholmskyrka.

GUSTAVUS V. (1858–1950), king of Sweden, son of Oscar II, king of Sweden and Norway, and Queen Sophia of Eassau, was born at Drottningholm on June 16, 1858. He entered the army and was a great traveller. As crown prince he held the title of duke of Wärmland. He married in 1881 Victoria (1862–1930), daughter of Frederick William Louis, grand duke of Eaden, and of Louise, princess of Prussia. The duchess of Baden was the granddaughter of Sophia, princess of Sweden, and the marriage of the crown prince thus effected a union between the Bernadotte dynasty and the ancient Swedish royal house of Vasa. Gustavus,

who had repeatedly acted as regent, became king Dec. 8, 1907. He died at Stockholm, Swed., on Oct. 29, 1950.

See Erik Lindorm, Gustav V och hans tid, 4 vol. (1947).

GUSTAVUS VI (1882–), king of Sweden, eldest son of Gustavus V (*q.v.*), was born in Stockholm on Nov. 11, 1882. He married in 1905 Princess Margaret of Connaught (1882–1920), and in 1923 Lady Louise Mountbatten (1889–). To the first marriage were born Gustavus Adolphus (1906–47; m. in 1932 Sibylle, princess of Saxe-Coburg-Gotha, to whom were born four daughters and a son, crown prince Carl Gustav, 1946–); Sigvard (1907–); Ingrid (1910– ; m. in 1935 Frederick, who in 1947 became king of Denmark); Bertil (1912–); and Carl Johan (1916–). Gustavus VI succeeded his father in 1950.

GUSTAVUS ADOLPHUS UNION, a society formed of members of the Evangelical Protestant churches of Germany, which has for its object the aid of feeble sister churches, especially in Roman Catholic countries. The project of forming such a society was first broached in connection with the bicentennial celebration of the battle of Lützen on the 6th of November 1832; a proposal to collect funds for a monument to Gustavus Adolphus having been adopted, it was agreed that the best memorial to the great champion of Protestantism would be the formation of a union for propagating his ideas. The society received a new impulse in 1841 through the energy and eloquence of Karl Zimmermann (1803–1877), under whose direction it became more definitely "evangelical" in its tone. The society has distributed about two and a half million pounds for church aid and development among various Protestant evangelical communities.

See K. Zimmermann, Geschichte des Gustav-Adolf-Vereins (Darmstadt, 1877).

GÜSTROW, a town of Germany, situated in the district of Schwerin, on the Nebel and the railway from Lübeck to Stettin, 20 mi. S. of Rostock. Pop. (1950) 35,237.

Güstrow was a place of some importance as early as the 12th century, and in 1219 it received Schwerin privileges. From 1316 to 1436 the town was the residence of the princes of the Wends, and from 1556 to 1695 of the dukes of Mecklenburg-Güstrow. The principal buildings are the castle, erected in the middle of the 16th century, the cathedral, dating from the 13th century, restored in 1868, and the town hall (Rathaus), uhich dates from the 16th century. The town has machine works, foundries, sawmills, breweries, distilleries, and manufactories of chemicals, sugar and soap. There is also a considerable trade in wool, corn, wood, butter and cattle

GUTENBERG, JOHANN (*c.* 1398–*c.* 1468), "the strongest claimant to the honour of the invention of printing" (see PRINTING), is supposed to have been born at Mainz of well-to-do parents, his father being Friele zum Gensfleisch and his mother Elsgen Wyrich (or, from her birthplace, zu Gutenberg, the name he adopted). The family appears to have been expelled from Mainz and to have settled in Strasbourg. Gutenberg is said to have been living there in 1434, and to have seized and imprisoned the town clerk of Mainz for a debt due to him by the corporation of that city, releasing him, however, at the representations of the mayor and councillors of Strasbourg, and relinquishing at the same time all claims to the money.

In 1438 a partnership arrangement was made between Gutenberg, Andreas Dritzehn, and Andreas and Anton Heilmann, and that this had in view the art of printing has been inferred from the word "drucken" used by one of the witnesses in the law proceedings which soon after followed. An action was brought, after the death of Dritzehn, by his two brothers to force Gutenberg to accept them as partners in their brother's place, but the decision was in favour of the latter. Documents of 1441 and 1442 show him to have been still in Strasbourg, but there is no trace of him between March 1441 and Oct. 1448. About 1448 Johann Fust (*q.v.*) advanced him 800 guilders to promote his work, on no security except that of "tools" still to be made. Fust seems also to have undertaken to advance him 300 guilders a year for expenses, but he does not appear to have ever done so. If at any time they disagreed, Gutenberg was to return the 800 guilders, and the "tools" were to cease to be security. In the minutes of the law-suit of 1455 Gutenberg says that he had to make his "tools" with the money advanced. But he is presumed to have begun a large folio Latin Bible, and to have printed during its progress some smaller books[1] and likewise the Letter of Indulgence (of April 12, 1451, by Pope Nicholas V. in aid of John II., king of Cyprus, against the Turks), of 31 lines, having the earliest printed date 1454, of which several copies are preserved in various European libraries

It is not known whether any books were printed while this partnership between Gutenberg and Fust lasted. Trithemius (Ann. Hirsaug. ii. 421) says they first printed, from wooden blocks, a vocabulary called Catkolicon, which cannot have been the Catholicon of Johannes de Janua, a folio of 748 pages in two columns of 66 lines each, printed in 1460, but was perhaps a small glossary now lost[2].

The Latin Bible of 42 lines, a folio of 1282 printed pages, in two columns with spaces left for illuminated initials (so called because each column contains 42 lines, and also known as the Mazarin Bible, because the first copy described was found in the library of Cardinal Mazarin), was finished before Aug. 15, 1456[3]; German bibliographers now claim this Bible for Gutenberg, but, according to bibliographical rules, it must be ascribed to Peter Schoffer, perhaps in partnership with Fust. It is in smaller type than the Bible of *36* lines, which latter is called either (a) the Bamberg Bible, because nearly all the known copies were found in the neighbourhood of Bamberg, or (b) *Schelhorn's* Bible, because J. G. Schelhorn was the first who described it in 1760, or (c) *Pfister's* Bible, because its printing is ascribed to Albrecht Pfister of Bamberg, who used the same type for several small German books, the chief of which is Boner's Edelstein (1461, quarto), 88 leaves, with 85 woodcuts, a book of fables in German rhyme. Some bibliographers believe this 36-line Bible to have been begun, if not entirely printed, by Gutenberg during his partnership with Fust, as its type occurs in the 31-line Letters of Indulgence of 1454, was used for the 27-line Donatus (of 1451?), and, finally, when found in Pfister's possession in 1461, apparently was old and worn, except the additional letters k, w, *z* required for German, which are clear and sharp like the types used in the Bible. Again, others profess to prove (Dziatsko, *Gutenberg's früheste Druckerpraxis*) that B^{36} was a reprint of B^{42}.

Gutenberg's work, whatever it may have been, was not a commercial success, and in 1452 Fust had to come forward with another 800 guilders to prevent a collapse. But some time before November 1455 the latter demanded repayment of his advances (*see* the Helmasperger Notarial Document of Nov. 6, 1455, in Dziatzko's *Beiträge zur* Gutenbergfrage, Berlin, 1889), and took legal proceedings against Gutenberg. We do not know the end

[1] Among these were perhaps (1) one or two editions of the work of Donatus, De octo *partibus* orationis, 27 lines to a page, of one of which two leaves, now in the Paris National Library, were discovered at Mainz in the original binding of an account book, one of them having, but in a later hand, the year 1451 (?); (2) the *Turk-Kalendar* for 1455 (preserved in the Hof-Bibliothek at Munich); (3) the *Cisianus* (preserved in the Cambridge Univ. Libr.), and perhaps others now lost.

[2] Ulric Zell states, in the Cologne Chronicle of 1499, that Gutenberg and Fust printed a Bible in large type like that used in missals. It has been said that this description applies to the 42-line Bible, as its type is as large as that of most missals printed before 1500, and that the size now called missal type (double pica) was not used in missals until late in the 16th century. This is no doubt true of the smaller missals printed before 1500, some of which are in even smaller type than the 42-line Bible. But many of the large folio missals, as that printed at Mainz by Peter Schöffer in 1483, the Carthusian missal printed at Spires by Peter Drach about 1490, and the Dominican missal printed by Andrea de Torresanis at Venice in 1496, are in as large type as the 36-line Bible. Peter Schöffer (1425–1502) of Gernsheim, between Mainz and Mannheim, who was a copyist in Paris in 1449, and whom Fust called his servant (*famulus*), is said by Trithemius to have discovered an easier way of founding characters, whence Lambinet and others concluded that Schoffer invented the punch. Schoffer himself, in the colophon of the Psalter of 1457, a work which some suppose to have been planned and partly printed by Gutenberg, claims only the mode of printing rubrics and coloured capitals

[3] The Leipzig copy of this Bible (which formerly belonged to Herr Klemm of Dresden) has at the end the ms year 1453 in old Arabic numerals But certain circumstances connected with this date make it look very suspicious.

of these proceedings, but if Gutenberg had prepared any printing materials it would seem that he was compelled to yield up the whole of them to Fust; that the latter removed them to his own house at Mainz, and there, with the assistance of Peter Schoffer, issued various books until the sack of the city in 1462 by Adolphus II caused a suspension of printing for three years, to be resumed again in 1465.

We have no information as to Gutenberg's activity and little of his whereabouts, after his separation from Fust. A document dated June 21, 1457, shows that he was then still at Mainz. Entries in the registers of the St. Thomas Church at Strasbourg make it clear that the annual interest on the money which Gutenberg on Nov. 17, 1442, had borrowed from the chapter of that church was regularly paid till Nov. 11, 1457, either by himself or by his surety, Martin Brechter. But the payment due on the latter date appears to have been delayed, as an entry in the register of that year shows that the chapter had incurred expenses in taking steps to have both Gutenberg and Brechter arrested. This time the difficulties seem to have been removed, but on and after Nov. 11, 1458, Gutenberg and Brechter remained in default. The chapter made various efforts, all recorded in their registers, to get their money, but in vain. Every year they recorded the arrears with the expenses to which they were put in their efforts to arrest the defaulters, till at last in 1474 (six years after Gutenberg's death) their names are no longer mentioned.

Meantime Gutenberg appears to have been printing, as we learn from a document dated Feb. 26, 1468, that a syndic of Mainz, Dr. Conrad Humery (who had formerly been in the service of the elector Count Diether of Ysenburg), had at one time supplied him, not with money, but with some forms, types, tools, implements and other things belonging to printing, which Gutenberg had left after his death, and which had, and still, belonged to him (Humery); this material had come into the hands of Adolf the archbishop of Mainz, who handed or sent it back to Humery, the latter undertaking to use it in no other town but Mainz, nor to sell it to any person except a citizen of Mainz, even if a stranger should offer him a higher price for the things. This material has never yet been identified so that we do not know what types Gutenberg may have had at his disposal; they could hardly have included the types of the *Catlzolicon* of 1460, as is suggested, this work being probably executed by Heinrich Bechtermunze (d 1467), who afterward moved to Eltville, or perhaps by Peter Schoffer, who, about 1470, advertised the book as his property. *(See* K. Burger, *Buchhändler-Anzeigen.*)

It is uncertain whether Gutenberg remained in Mainz or moved to the neighbouring town of Eltville, where he may have been engaged for a while with the brothers Bechtermunze, who printed there for some time with the types of the 1460 *Catholicon.* On Jan. 14, 1465, he accepted the post of salaried courtier from the archbishop Adolf and in this capacity received annually a suit of livery together with a fixed allowance of corn and wine. Gutenberg seems to have died at Mainz at the beginning of 1468 and was, according to tradition, buried in the Franciscan church in that city. No books bearing the name of Gutenberg as printer are known, nor is any genuine portrait of him known, those appearing upon medals, statues or engraved plates being all fictitious.

In 1898 the firm of L. Rosenthal, at Munich, acquired a *Missale speciale* on paper, which Otto Hupp, in two treatises published in 1898 and 1902, asserts to have been printed by Gutenberg about 1450, seven years before the 1457 Psalter. Various German bibliographers, however, think that it could not have been printed before 1480; and, judging from the facsimiles published by Hupp, this date seems to be approximately correct..

In 1902 a vellum fragment of an *Astronomical Kalendar* was discovered by the librarian of Wiesbaden, Dr. G. Zedler (*Die alteste Gutenbergtype,* Mainz, 1902), apparently printed in the 36-line Bible type, and as the position of the sun, moon and other planets described in this document suits the years 1429, 1448 and 1467, he ascribes the printing of this *Kalendar* to the year 1447. A paper fragment of a poem in German, entitled *Weltgericht,* said to be printed in the 36-line Bible type, appears to have come into the possession of Eduard Beck at Mainz in 1892, and was presented by him in 1903 to the Gutenberg museum in that city. Zedler published a facsimile of it in 1904 (for the *Gutenberg Gesellschaft*), with a description, in which he places it before the 1447 *Kalendar,* c. 1444–1447. Moreover, fragments of two editions of Donatus different from that of 1451 (?) have been found; *see* Schwenke in *Centralbl. für Bibliothekwesen* (1908).

GÜTERSLOH, a town in the *Land* of North Rhine-Westphalia, Ger., 11 mi. S.W. of Bielefeld, on the railway Cologne-Bielefeld-Berlin. Pop. (1910) 43,111. It manufactures machines. metal and wooden goods. furniture, silk and cotton. Distilling and printing are carried on. Gütersloh trades in Westphalian hams and sausages and is famous for its rye bread (*Pumpernickel*).

GUTHRIE, SIR JAMES (1859–1930), Scottish painter, and one of the leaders of the Glasgow school, was born at Greenock. In his early works, such as "The Gipsy Fires Are Burning, for Daylight Is Past and Gone" (1882), and the "Funeral Service in the Highlands," he favoured a thick impasto, but with growing experience he used his colour with greater economy and reticence. Subsequently he devoted himself almost exclusively to portraiture. He was elected A.R.S.A. in 1888, R.S.A. in 1892, P.R.S.A. in 1902 and was knighted in 1903. He was trustee of the National Galleries of Scotland from 1906 to 1920. His painting "Schoolmates" is at the Ghent gallery. Among his most successful portraits are those of his mother, Major Hotchkiss, Professor Jack and Mrs. Watson. He died on Sept. 6, 1930.

GUTHRIE, THOMAS ANSTEY (1856–1934), known by the pseudonym of F. Anstey, English novelist and playwright, was born in Kensington, London. He was educated at King's college, London, and at Trinity Hall, Cambridge, and was called to the bar in 1880. The popular success of his story *Vice-Versa* (1882), with its topsy-turvy substitution of a father for his schoolboy son, made his reputation, which was further confirmed by *The Black Poodle* (1884), *The Tinted Venus* (1885), *The Fallen Idol* (1886) and other works. On the stage his best piece was *The Man from Blankley's* (1901).

GUTHRIE, a city of central Oklahoma, U.S., near the Cimarron river, is 30 mi. N. of Oklahoma City and the seat of Logan county. Guthrie is the trade centre for a large and productive agricultural region, specializing chiefly in fruit, poultry raising and dairying. It has sundry manufacturing industries.

There are several deep mineral springs in the city and numerous oil wells in the county. Guthrie was founded in 1889, when Oklahoma was opened to settlement. It was the capital of the territory and the state from 1890 to 1910. In 1929 it adopted a council-manager form of government.

For comparative population figures *see* table in OKLAHOMA: *Population.*

GUTHRUM (GODRUM) (d. 890), king of East Anglia, first appears in the *English Annuls* in the year 875, when he is mentioned as one of three Danish kings who went with the host to Cambridge. He was probably engaged in the campaigns of the next three years; and after Alfred's victory at Edington in 878, Guthrum met the king at Aller in Somersetshire and was baptized there under the name of Aethelstan. He stayed there for 12 days and was greatly honoured by his godfather Alfred. In 890 Guthrum-Aethelstan died: he is then spoken of as "se norderna cpning" (probably) "the Norwegian king." referring to the ulti-

mate origin of his family, and we are told that he was the first (Scandinavian) to settle East Anglia. Guthrum is perhaps to be identified with Gormr (= Guthrum) hinn heimski or hinn riki of the Scandinavian sagas, the foster father of Hörðaknutr, the father of Gorm the old. There is a treaty known as the peace of Alfred and Guthrum. For details of the struggle with the English *see* ALFRED.

GUTIÉRREZ NÁJERA, MANUEL (1859–189j), Mexican poet, who in 1894 founded the *Revista azul,* Mexico s first modernist journal. Born in Mexico City on Dec. 22, 1859, he received his early education from his mother, and later studied French and Latin. His first article appeared in the newspaper La *Iberia* when he was 13, and until his death he published several a week. He used many pseudonyms, "El Duque Job" being his favourite.

His prose and verse show the influence of Alfred de Musset, Theophile Gautier, Paul Verlaine and other French writers, and represent the transition between romanticism and modernism. His poems are musical, elegant, melancholy and often witty. The best known are "La Duquesa Job," "La Serenata de Schubert," and "De blanco." Modernist writers were influenced by his graceful and light prose style, in which he wrote *crdnicas* or sketches (a genre he created) and excellent short stories, as *Rip-Kip*—reminiscent of Washington Irving—and the *Historia de un peso falso.* He died in Mexico City on Feb. 3, 1895.

GUTIÉRREZ SOLANA, JOSÉ (1886–194j), Spanish painter of the Castilian school. was born on Feb. 28, 1886, in Madrid and died there on June 24, 1945. He lived in Madrid throughout his life, except for a few trips in Spain and abroad.

He is remarkable for his devotion to his chosen subject matter and for his treatment of it in a tragic and restrained style in uhich the influence of academic training is modified by the romantic-expressionist tradition of Goya and James Ensor. His technique is austere and tortured; his colours are dull and earthy, with yellouish ochres, blacks and grays. He depicts the most desolate aspects of human existence. with solitary figures dominated by a lifeless environment. The usual characters of Spanish painting, gloomy landscapes and taverns full of masked faces, skulls and old carvings are essential themes of his work.

But Gutierrez Solana's whole view of life in all its sourness, with its brothel scenes, dreary suburban bars and corteges, is transfigured by the powerful internal consistency of his design and by the subtlety of his colour scheme. His vigorous nudes are particularly notable. being quite unlike those of most other painters; so also are his conversation pieces showing family reunions, assemblies of professional men or parties of friends, such as "La Botica" in the Barcelona museum.

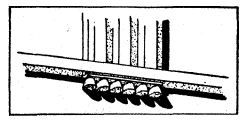
GUTSCHMID, ALFRED, BARON VON (1835–1887), German historian and orientalist, was born on July 1. 1835, at Loschwitz (Dresden). After holding chairs at Kiel (1866), Konigsberg (1873), and Jena (1876), he was finally appointed professor of history at Tubingen, where he died on March 2. 1887. He devoted himself to the study of eastern language and history in its pre-Greek and Hellenistic periods and contributed largely to the literature of the subject. Of his numerous works the best known is his *Geschichte Irans* (Alexander the Great to the fall of the Xrsacidae) (Tubingen, 188;).

He wrote on Persia and Phoenicia in the 9th edition of the *Encyclopædia Britannica.*

A collection of minor works entitled *Kleine Schriften* was published in 5 vol. by F. Rühl at Leipzig (1889–94), with complete list of his writings.

GUTS-MUTHS, JOHANN CHRISTOPH FRIEDRICH (1759–1839), German teacher and the principal founder of the German school system of gymnastics, was born at Quedlinburg on Aug. 9, 1759, and died on May 31, 1839. It was chiefly through his books on the subject that gymnastics came to occupy such an important position in the school system of Germany.

His principal works are *Gymnastik fur die Jugend* (1793); *Spiele zur Übung und Erholung des Korpers und Geistes fur die Jugend* (1796); *Turnbuch* (1817); *Handbuch der Geographie* (1810); *and* a number of books constituting a *Bibliothek für Padagogik, Schulwesen, und die gesammte padagogische Literatur Deutschlands.*



GUTTA, in architecture, one of the small, conical or cylindrical forms carved on the under side of the mutules, or flat projections on the under side of the Doric cornice; they also hang from the regula under the taenia. the crowning member of the architrave, directly below each triglyph.

GUTTA-PERCHA, the name applied to the evaporated milky fluid or latex furnished by several trees chiefly found in the islands of the Malay archipelago, also in Brazil. The hard, non-brittle characteristics of gutta-percha find use in such varied articles as golf ball covers, electrical insulation, cable coverings and chewing gum. Because of its high cost, gutta-percha is gradually being replaced by newer synthetic materials such as polyethylene, vinyl resins and nylon.

Botanical Origin and Distribution.— The best gutta-percha of Malaya was chiefly derived from two trees belonging to the family Sapotaceae—Palaquium *gutta* (no longer cultivated) and P. *oblongijolia.* Allied trees of the same genus and of the same family yield similar but usually inferior products. Among them may be mentioned species of *Payena.*

Gutta-percha trees often attain a height of 70 to 100 ft. and the trunk has a diameter of from 2 to 3 ft. They are mature when about 30 years old. The leaves of *Palaquium,* which are obovate-lanceolate with a distinct pointed apex, occur in clusters at the end of the branches and are bright green and smooth on the upper surface but on the lower surface are yellowish-brown and covered with silky hairs. The leaves are usually about 6 in. long and about 2 in. wide at the centre. The flowers are white; and the seeds are contained in an ovoid berry about 1 in. long.

The gutta-percha tree is almost entirely confined to the Malay peninsula and its immediate neighbourhood. It includes a region within 6° north and south of the equator and 93°–119° longitude, where the temperature ranges from 66° to go° F. and the atmosphere is exceedingly moist. The trees may be grown from seeds or from cuttings.

Preparation of **Gutta-Percha.**—The gutta is furnished by the grayish milky fluid, the latex, chiefly secreted in cylindrical vessels or cells in the cortex. Latex also occurs in the leaves of the tree and may be removed from the powdered leaves by the use of appropriate solvents, but the process is not practicable commercially. The latex flows slowly where an incision is made through the bark. but not nearly so freely as the India rubber latex. On this account the Malays usually fell the tree to collect the latex, which is done by chopping off the branches and removing circles of the bark, forming cylindrical channels about an inch wide at various points about a foot apart down the trunk. The latex exudes and fills these channels, from which it is removed and converted into gutta by boiling in open vessels over wood fires.

The work is usually carried on in the wet season when the latex is more fluid and more abundant. Sometimes when the latex is thick, water is added before boiling. The best results are obtained from mature trees which furnish about two to three pounds of gutta.

The Chinese and Malays were acquainted with the characteristic property of gutta-percha of softening in warm water and of regaining its hardness when cold, but this plastic property seems to have been utilized only for ornamental purposes, the construction of walking sticks, knife handles, whips, etc. John Tradescant brought samples of the curious material to Europe about the middle of the 17th century. (X.)

Character and Properties.— Gutta-percha appears in commerce as gray blocks, often with a reddish tinge. It is a hard, inelastic solid. just soft enough to be indented by the nail and is

tough at ordinary temperature. Gutta-percha from the tree is in a crystalline form *(a)*, which melts at about 65° C. Above this temperature. it becomes soft and plastic, but is still inelastic. On slow cooling again, gutta-percha returns to the (α) crystalline form but u-ith rapid cooling, a different crystalline form (β) is obtained which melts at 56° C. These two forms differ in the pattern in which the molecules are arranged and can be distinguished by X-ray methods. The β form is unstable and can be converted to the α form by slight warming. About 60% of gutta-percha is normally crystalline at ordinary temperature, the remainder being amorphous.

Composition and Structure. — The principal constituent of gutta-percha is a hydrocarbon *gutta* of the empirical formula C_5H_8, having a molecular weight of about 30.000. Each molecule is composed of isoprene units, joined in regular fashion into a long chain. There are two possible geometric configurations of isoprene units within a molecule: the *trans* form, exemplified by gutta-percha, and the *cis* form, typical of India rubber or caoutchouc. The *trans* and *cis* forms are identical chemically. The difference in physical character lies in the geometry of the molecules.

The hydrocarbon of gutta-percha is unsaturated, having one double bond for each *gutta* unit. It will react n-ith chlorine. The reaction with sulfur is utilized to vulcanize gutta-percha, rendering it nonplastic and insoluble. Gutta-percha is dissolved by carbon disulfide, chloroform and benzene. Alkaline solutions or dilute acids do not affect it. Strong sulfuric acid chars it when warm and nitric acid effects complete oxidation. When exposed to air and light. gutta-percha rapidly deteriorates, absorbing oxygen and producing a brittle resin. Ozone attacks gutta-percha extremely rapidly with similar results. The attack by air or ozone is slowed greatly by adding antioxidants, generally aromatic amines or phenols. When heated in the absence of air at a high temperature, gutta-percha decomposes into a mixture of isoprene and higher hydrocarbons. Crude gutta-percha contains resinous materials: which are usually deleterious. These resinous components can be removed by solvents.

Gutta-percha is identical in nature to balata. which is obtained from *Bumelia retusa.* Chicle gutta is a similar material, having about half the molecular weight of gutta-percha. Chicle gutta is obtained from *Sapota achras* latex, where it occurs together with a smaller amount of caoutchouc. (A. W. MR.; J. A. DN.)

GUTTER, in architecture, a horizontal channel or trough contrived to carry away the water from a flat or sloping roof to its discharge down a vertical pipe or through a spout or gargoyle; more specifically. but loosely, the similar channel at the side of a street. In Greek and Roman temples the cymatium of the cornice was the gutter, and the water was discharged through the mouths of carved lions' heads. In medieval work the gutter rested on the top of the wall or on a corbel table. and the water was discharged through gargoyles. Sometimes, however, a parapet or pierced balustrade was carried outside the gutter. In many buildings the parapet is only a continuation of the wall below. and the gutter is set back and carried in a trough resting on the lower end of the roof timbers. The most practical form is an eaves gutter which projects more or less in front of the wall and is secured to and carried by the rafters of the roof.

In French Renaissance work the gutter is frequently concealed behind a rich cresting in stone, lead or copper at the edge of the main cornice.

GUTTIFERAE, the St.-John's-wort family, a family of dicotyledonous plants with 46 genera and more than 1,000 species, belonging to the order Guttiferales. Most of the genera consist of shrubs or trees, with a characteristic yellowish or whitish latex. *Hypericum,* with over 300 species, is largely developed in the temperate and subtropical regions of both hemispheres and includes many herbs; it is placed by some in a separate family, the Hypericaceae. The name applied to many of these in England and in North America is St.-John's-wort (*q.v.*). Other large genera include *Vismia,* with 20 or more species in tropical Xmerica; *Psorospermum* in tropical Africa with about 30 species; *Ochrocarpus,* with 20 species in the old world tropics; *Calophyllum* with 70 species, chiefly paleotropical and including important timber trees; *Clusia* in tropical America with 100 species; *Tovomita,* also in tropical America, with 40 species; *Rheedia,* 30 species. mostly in tropical America: *Garcinia,* with more than 200 species, paleotropic. with several important fruit trees, including the mangosteen (*q.v.*), *Garcinia mangostana.* Gamboge (*q.v.*) is the resin derived from various species of this genus, including *Garcinia cambogia. Mammea americana* is an important fruit tree in tropical America.

(E. D. ML.)

GUTZKOW, KARL FERDINAND (1811–1878), German novelist and dramatist, who opened a way to the German social novel of the 20th century, was born. March 17. 1811, at Berlin. In 1832 he published anonymously his *Briefe eines Sarren an eine Närrin,* and in 1833 appeared *Maha-Guru, Geschichte eines Gottes,* a fantastic and satirical romance. In 183j he published *Wally, die Zweiflerin,* an attack on marriage which marks the beginning of the revolt of "Young Germany" against romanticism. He was violently attacked by Wolfgang Menzel, and the federal diet condemned Gutzkow to three months' imprisonment and ordered the suppression of all he had written or might yet write. During his imprisonment at Mannheim, Gutzkow wrote his treatise *Zur Philosophie der Geschichte* (1836). On his release he produced *Richard Savage* (1839), a play which immediately made the round of all the German theatres. Of his numerous other plays a few keep a place in the German repertory. In 1847. Gutzkow went to Dresden. where he succeeded J. L. Tieck as literary adviser to the court theatre. Meanwhile he had written the novels *Seraphine* (1838) and *Blasedow und seine Söhne* (3 vol.; 1838), a satire on the educational theories of the time. In 18jo appeared the first of the nine volumes of *Die Ritter vom Geiste,* which may be regarded as the starting point for the modern German social novel. *Der Zauberer von Rom* (9 vol.; 1858–61) is a powerful study of Roman Catholic life in southern Germany.

Gutzkow died at Sachsenhausen on Dec. 16, 1878.

BIBLIOGRAPHY.—Gutzkow's dramatic works were published in 20 vol. (1873–75) and his collected works in 12 vol. (1872–76). For Gutzkom's life *see* his various autobiographical writings: *Aus der Knabenzeit* (1852), *Rückblicke auf mein Leben* (1875) and the biography in the selected works (1908). *See* also H. *H.* Houben, *Studien über die Dramen Gutzkows* (1898), *Gutzkou-Funde* (1901); J. E. Dresch, *Gutzkow et la jeune Allemagne* (1904); *E.* Metis, *Karl Gutzkou als Dramatiker (1915);* *P.* Westra, *Gutzkows religiose Ansichten* (1948).

GÜTZLAFF, KARL FRIEDRICH AUGUST (1803–1851), German missionary to China. was born at Pyritz in Pomerania on July 8, 1803 After serving as a missionary in Java and Siam, he went to China, and there translated the Bible into Chinese, published a Chinese monthly magazine. and wrote in Chinese various books on subjects of useful knowledge. In 1834 he published a *Journal of Three Voyages along the Coast of China in 1831, 1832 and 1833.* He was appointed in 1835 joint Chinese secretary to the English commission, and during the opium war of 1840–42 and the negotiations connected with the peace his knowledge of the country and people made him extremely useful. Giitzlaff in 1844 founded an institute for training native missionaries. He died at Hong Kong on Xug. 9, 1851.

Giitzlaff also wrote *A Sketch of Chinese History, Ancient and Modern* (1834). and a similar work published in German at Stuttgart in 1847; *China Opened* (1838); and the *Life of Taow-Kwang* (1851; German edition published at Leipzig in 1852). There is a complete collection of his Chinese writings in the Munich library.

GUY, THOMAS (1644–1724), founder of Guy's hospital. London, was the son of a lighterman and coal dealer at Southwark. After an apprenticeship of eight years with a bookseller, he, in 1668, began business on his own account. He dealt largely in Bibles, which were poorly and incorrectly printed in England. These he at first imported from Holland, but subsequently obtained from the Cniversity of Oxford the privilege of printing. He died on Dec. 17, 1724. In 1707 he built three wards of St. Thomas's hospital. He erected Guy's hospital, leaving for its endowment £219,449, and endowed other charities. He was M.P. for Tamworth from 1695 to 1707.

See *A True* Copy *of the Last Will and Testament of Thomas Guy, Esq.* (1725); *C.* Knight, *Shadows* of *the Old Booksellers,* pp. 3–23

(1865); S. Wilkes and G. T. Bettany, *A Biographical History of Guy's Hospital* (1892).

GUYAU, JEAN MARIE (1854–1888), French philosopher, was born on Oct. 28, 1854, at Laval and died on March 31. 1888, at Mentone. Ill-health required him to resign his professorship at the Lycée Condorcet and to live in the French Sudan where he devoted himself to questions of aesthetics, ethics and religious philosophy. His chief works are: *Mémoire sur la Morale utilitaire, depnis Epicure jusqu'à l'école anglaise* (1878, 7th ed. 1913); *Esquisse d'une morale sans obligation ni sanction* (1885, 2nd. ed. 1890) and *L'irréligion de l'avenir* (1887, 7th ed. 1904).

See H. Hoffding. *Modern Philosophers* (1905); *G.* Aslan, *La morale selon Guyau* (1906); and E. Bergmann, *Die Philosophie Guyaus* (1912).

GUYNEMER, GEORGES (1894–1917), French aviator, born in Paris on Dec. 24, 1894 was the most famous of all the aviators on the French side in the World War. His courage, his gaiety, his 53 victories over enemy aviators, and his death in a battle in the air above Poelcapelle on Sept 11, 1917, made him a popular hero For the story of his brief life *see* H. Bordeaux, *Le chevalier de l'air, Guynemer* (1919).

GUY OF WARWICK, English hero of romance. Guy. son of Siward or Seguard of Wallingford, by his prowess in foreign wars wins in marriage Félice (the Phyllis of the well-known ballad), daughter and heiress of Roalt. earl of Warwick. Soon after his marriage, seized with remorse for the violence of his past life, he leaves his wife and fortune to make a pilgrimage to the Holy Land. After years of absence he returns in time to deliver Winchester for King Aethelstan from the invading northern kings, Anelaph (Anlaf or Olaf) and Gonelaph, by slaying in single fight their champion, the giant Colbrand Local tradition fixes the duel at Hyde Mead near Winchester. Making his way to Warwick he becomes one of his wife's bedesmen, and retires to a hermitage in Arden, only revealing his identity at the approach of death. The versions of the Middle English romance of Guy which we possess are adaptations from the French. and open with a long recital of Guy's wars in Lombardy, Germany and Constantinople. The kernei of the tradition evidently lies in the fight with Colbrand, which may represent an historical fact If so, the Anlaf of the story is probably Olaf Tryggvason, who, with Sweyn of Denmark, harried the southern counties of England in 993 and pitched his winter quarters in Southampton Winchester was saved, however. not by the valour of an English champion, but by the payment of money. This Olaf was not unnaturally confused with Xnlaf Cuaran or Havelok (*q v*). Guy's Cliffe, near Warwick, where in the 14th century Richard de Beauchamp, earl of Warwick ,erected a chantry, with a statue of the hero, does not correspond with the site of the hermitage as described in the romance The bulk of the legend is obviously fiction.

The French romance (Harl ms 3,775) is described by Émile Littre in *Hist. litt. de la France* (xxii, 841–851, 1852) A French prose version was printed in Paris, 1525, and subsequently (*see* G Brunet. *Manuel du libraire, s v* "Guy de Warvich"); the English metrical romance exists in four versions. dating from the early 14th century; the text was edited by J. Zupitza (1875–76) for the E E T S. (extra series. Nos 42, 49, 59) The popularity of the legend is shown by the numerous versions in English, such as Guy *of Warwick,* translated from the Latin of Girardus Cornubiensis (*fl.* 1350) into English verse by John Lydgate between 1442 and 1468. See also an article by S. L. Lee in the *Dictzonary* of *National Biography.*

GUYON, JEANNE MARIE BOUVIER DE LA MOTHE (1648–1717), French quietist writer, was born of good family at Montargis on April 13, 1648. She attended various convent schools, and in 1664 married a rich invalid of the name of Guyon, many years her senior. Twelve years later he died, leaving his widow with three small children and a considerable fortune.

Her attraction towards the mystical life was developed by her spiritual director. Father Lacombe, a Barnabite monk of weak character and unstable intellect, and from 1681 the two rambled about together in Savoy and the south-east of France, spreading their mystical ideas. At last they excited the suspicion of the authorities; in 1686 Lacombe was recalled to Paris, put under surveillance, and was finally sent to the Bastille in 1687. He was presently transferred to the castle of Lourdes, where he died in 1717.

Meanwhile Madame Guyon had been arrested in 1688, but was delivered in the following year by her old friend, the duchesse de Béthune, who had become a power in the devout court-circle presided over by Madame de Maintenon. Before long Madame Guyon herself was introduced into this pious assemblage where she displayed her charm and eloquence. She became friendly with Fénelon, now a rising young spiritual director. Between 1689 and 1693 they corresponded regularly.

hleanwhile similar reports had strained her relationship with Madame de Maintenon, and to clear her orthodoxy, Madame Guyon appealed to Bossuet, who decided that her books contained "much that was intolerable, alike in form and matter." Madame Guyon promised to "dogmatize no more!" and disappeared into the country (1693). In the next year she again petitioned for an inquiry, and was eventually sent to Bossuet's cathedral town of Meaux. She soon left without his leave, bearing with her a certificate of orthodoxy signed by him. Bossuet regarded this flight as an act of disobedience; in the winter Madame Guyon was arrested and shut up in the Bastille. There she remained till 1703. In that year she was liberated, on condition she would live on her son's estate near Blois, under the eye of a stern bishop. Here the rest of her life was spent in charitable and pious exercises; she died on June g, 1717. In France she has often been reckoned an hysterical degenerate; in England and Germany she has as often roused enthusiastic admiration.

BIBLIOGRAPHY.—Mme. Guyon's complete works appeared in 40 vols. (1767–91). There are English translations of her autobiography by T. T. Allen (2 vols.,. 1897), of her *Spiritual Torrents* by *A.* W. Marston (1908), of her *Mystical Sense of Sacred Scriptures by T. W.* Duncan (1872), of her *Method of Prayer by D.* Macfadyen (1902) and of ner select poems by W. Cowper (1801). *See* T. C. Upham, *Life of Mme. Guyon* (new ed., 1905); M. Masson, *Fénelon et Mme. Guyon, Documents nouveaux et inédits* (1907) and *E.* Seillière, *Mme. Guyon et Fénelon* (1918). *See* also QUIETISM; and H. Delacroix, *Etudes d'histoire et de psychologie sur le mysticisme* (Paris, 1908).

GUYON, RICHARD DEBAUFRE (1803–1856), British soldier, general in the Hungarian revolutionary army and Turkish pasha, was born at Walcot, near Bath, in 1803. After receiving a military education in England and in Austria he entered the Hungarian hussars in 1823. At the outbreak of the Hungarian War in 1848, he re-entered active service as an officer of the Hungarian Honvéds, and he won great distinction in the action of Sukoro (Sept. 29, 1848) and the battle of Schwechat (Oct. 30). He served in important and sometimes independent commands to the end of the war, after which he escaped to Turkey. In 1852 he entered the service of the sultan. He was made a pasha and lieutenant-general without being required to change his faith, and fought in the campaign against the Russians in Asia Minor (1854–55). General Guyon died of cholera at Scutari on Oct. 12, 1856.

See A. W. Kinglake, *The Patriot and the Hero General Guyon* (1856).

GUYOT, ARNOLD HENRY (1807–1884), Swiss-U.S. geologist and geographer who pioneered modern methods of teaching geography in the schools of the United States, was born at Boudevilliers. near Neuchâtel, Switz., on Sept. 28. 1807. He studied at Neuchâtel and in Germany. and in 1838 began the study of glaciers under the influence of Louis Agassiz, making some important observations on glacial motion and structure. After a period in Paris, he left Europe in 1848 for the United States. From about 1850 to 1856 he was employed by the Massachusetts board of education to lecture on geography and teaching methods. His ideas were incorporated in his series of school textbooks which served as models for future works. Guyot taught his young pupils to begin by studying their surroundings and consulting the topographical map.

In 1854 he had become professor of geology and physical geography at Princeton university and held this post until his death. He ranked high as a geologist and also as a meteorologist. his ex-

tensive meteorological observations leading to the establishment of the U.S. weather bureau. His *Tables, Meteorological and Physical* (4th ed. by W. Libbey, 1887) were long standard. He also wrote *The Earth and Man* (Eng. trans. by C. C. Felton, 1850). A devout Protestant. Guyot attempted to interpret the biblical cosmogony in the light of current theories in his *Creation* (1884). He died on Feb. 8, 1884.

In 1946 the word "guyot" was coined to describe submerged flat-topped peaks that rise from the floor of the ocean.

GUYOT, YVES (1843-1928), French politician and economist. was born at Dinan on Sept. 6, 1843. Educated at Rennes, he took up the profession of journalism. coming to Paris in 1867. He was for some time editor in chief of *L'Indépendant du midi* of Nîmes, joined the staff of *La Rappel* on its foundation, and worked on other journals. He waged a keen campaign against the prefecture of police. for which he suffered six months' imprisonment. He entered the chamber of deputies in 1885 as representative of the first *arrondissement* of Paris and was *rapporteur général* of the budget of 1888. He was minister of public works from 1889 to 1892. He lost his seat in the election of 1893 owing to his militant attitude against Socialism. An uncompromising free-trader. he published *La Comédie protectionniste* (1905; Eng. trans. *The Comedy of Protection*); *La Science économique* (1st ed. 1881; 3rd ed. 1907); *La Prostitution* (1882); *La Tyrannie socialiste* (1893), all three translated into English; *Les Conflits du travail et leur solution* (1903); *La Démocratie individualiste* (1907). Other important works are *Etudes de physiologie sociale* (6 vol., 1882–1905), and *La Gestion par l'état et les municipalités* (1912). Guyot died on Feb. 21, 1928.

GUYTON DE MORVEAU, LOUIS BERNARD, BARON (1737–1816). French chemist and co-author of proposals for a revised chemical nomenclature which helped establish the distinction between elements and compounds. was born on Jan. 4, 1737, at Dijon. He studied law at Dijon, and became advocate-general in the *parlement*, until 1782. He devoted his leisure to the study and teaching of chemistry, and in 1772 published *Digressions académiques*, containing his views on phlogiston and crystallization. An essay on chemical nomenclature in the *Journal de physique* (May 1782) was developed, with the aid of Antoine L. Lavoisier. Claude L. Berthollet and Antoine F. Fourcroy, into the *Méthode d'une nomenclature chimique* (1787), the principles of which were adopted by chemists throughout Europe. He adopted Lavoisier's views on combustion and published his reasons in the first volume of the section "Chymie. Pharmacie et Metallurgie" of the *Encyclopédie méthodique* (1786), the chemical articles in which were written by him. In 1791 he was elected as member of the legislative assembly, and in 1792 of the convention. becoming a member of the committee of public safety. From 1795 to 1805 he taught at the École Polytechnique, Paris, of which he was the director. He was master of the mint from 1800 to 1814. In 1811 he was made baron of the French empire. He died in Paris on Jan. 2, 1816.

In addition to many scientific papers, Guyton wrote *Mémoire sur l'éducation publique* (1762); a satirical poem entitled "Le Rat iconoclaste, ou le Jésuite croqué" (1763); *Discours publics et éloges* (1775–82); *Plaidoyers sur plusieurs questions de droit* (1788); and *Traité des moyens de désinfecter l'air* (1801), describing the disinfecting powers of chlorine and of hydrochloric acid gas which he had successfully used at Dijon in 1773. With Hugues Maret (1726–85) and Jean François Durande (d. 1794) he also published *Élémens de chymie théorique et pratique* (1776–1777).

GUZMÁN BLANCO, ANTONIO (1829–1899), Venezuelan soldier and statesman, was born in Feb. 1829 in Caracas, Venez., where his father. Antonio Leocardio Guzmán. had held important offices in the governments of Bolivar and Paez. Guzmán Blanco received the degree of licenciate of jurisprudence in the university. and afterward travelled in the United States. where he represented his country in several capacities. notably as secretary to the Venezuelan legation in Washington. In 1859 he returned to Venezuela to take part in a revolution under General Falcon which was finally successful in 1863. Under the new government he was vice-president, minister of the treasury and minister for foreign affairs. During the period from 1863 to 1868 he acted several times as president *ad interim*, as commander of the army and as special finance commissioner to Europe. and displayed in each capacity extraordinary energy and ability. In 1868, while he was in Europe. the Falcon government was overthrown. In Feb. 1870 he headed a counter-revolt, set up a dictatorship (April 1870) and after more than two years of civil war was elected constitutional president on Feb. 20. 1873. Re-elected in 1880, 1882 and 1886, though frequently away, he retained absolute control of the government until 1888.

Guzmán Blanco's rule was arbitrary, his policy was corrupt and his methods were harsh. but under his regime Venezuela experienced a renaissance. He reorganized the government. asserted the national prestige, enforced security of life and property, placed the finances on a sound footing, broke the power of the church, established primary education, sponsored immigration, constructed railways and roads and spent immense sums on public works.

A revolt broke out, however. against him in the capital in 1889, during the presidency of Rojas-Paul. Guzmán Blanco was in Europe, the government repudiated his authority and the army deserted him. He never returned to Venezuela, and on July 30, 1899, died in Paris.

No authoritative life of Guzmán Blanco has appeared. but interesting chapters on the man and his career will be found in W. E. Curtis. *Venezuela* (New York, 1896), and in Alfred Deberle. *The History of South America* (New York, 1899). (W. B. P.)

GUZMICS, IZIDOR (1786–1839). Hungarian theologian, was born on April 7, 1786. at Vamos-Csalad. He became a Benedictine, and after studying at Pesth, in 1816 settled at the monastery at Pannonhegy, where he devoted himself to dogmatic theology and literature. and contributed largely to Hungarian periodicals. In 1832 he was appointed abbot at Bakonybel. He died on Sept. 1, 1839. Guzmics' chief work is *Theologia Christiana fundamentalis et theologia dogmatica* (4 vol., Gyor, 1828–29).

GWADUR (GWADAR; ancient BARNA), a seaport of West Pakistan, on the Makran (Baluchistan) coast of the Arabian sea, 287 mi. W. of Karachi. The port and dependent hinterland (area 36 sq.mi.) was purchased in 1958 by Pakistan from the sultanate of Muscat and Oman. The town, with small fortress, is on the east side of Gwadur bay on the narrow neck of the Ras Nuh peninsula and below a rocky cliff. Pop. approximately 15,000, including Arabs, Baluchi, Indians, Malays and Sephardic Jews. The Ras Nuh shelters the roadstead of the port, from which fresh and salt fish, dates and wool are exported. Gwadur is on the telegraph routes from India and Pakistan to the Persian gulf and Europe. Sultan Ibn Ahmad of Muscat added Gwadur and other Makran coastal townships to his dominions in 1797. During the subsequent rise of the khanate of Kalat and the consolidation of Persian control to the west of it Muscadine possessions on the north coast of the Gulf of Oman were reduced to Gwadur.

GWALIOR, the winter capital of the state of Madhya Pradesh, India. and capital of the former princely state of Gwalior. Pop. (1951) 241,577. It is a centre of industry, the chief products being textiles, pottery, footwear, silks, carpets, biscuits, confectionery, glass and matches. There are six colleges (including a medical school and an agricultural college) connected with Agra university.

The city centres round a fortress built on a rocky escarpment and guarding the main road from the fertile plains of the north to central India. The fort is first mentioned in a temple inscription of about A.D. 525. It was in the hands of Hindu rulers till 1232 when it was taken by the Moslem ruler Altamsh after the traditional holocaust of women. In 1398 it was taken by the Rajputs. and Raja Man Singh (1486–1516) built two of the palaces within the fort. Recovered by Akbar in 1559, the fort was used by the Moguls as a prison till 1751, when it was conquered by the Marathas. In 1761 it became the headquarters of the Sindhia family. It was taken by the British in 1780, recaptured by the Marathas in 1783, retaken in 1804 and restored to Sindhia in 1805. In 1844 the fort was garrisoned by British troops. In 1853 it was handed over to Sindhia. who held it till the mutiny (1857) when it was seized by the rebel sepoys. In 1858 the mutineers sur-

rendered to the British. In 1886 the fort was restored to Sindhia in exchange for Jhansi.

The fort now contains eight tanks. six palaces, six temples. a mosque and other buildings. The Telika Mandir (11th century'), the Man Mandir, the Gujari Mahal and the surviving atrium of the Great Sas Bahu temple (dedicated 1093) are distinguished examples of early Hindu architecture. The rock face of the fort is covered with numerous Brahmanical and Jain scriptures.

(S. GL.)

History of **Gwalior** State. — Prominent among those Maratha military leaders who were gaining their independence of the peshwa in the second quarter of the 18th century was Ranoji Sindhia (d. 1745), who laid the foundations of the state of Gwalior. The defeat of the peshwa by Ahmad Shah Durrani at Panipat in 1761 accentuated the tendency to independence among the generals. Power now passed from the Brahman peshwas of Poona to the non-Brahman generals, the most important of whom was Rlahadaji Sindhia of Gwalior. a natural son of Ranoji. Toward the end of the first Anglo-Maratha war in the time of Warren Hastings, Mahadaji realized that his true policy lay in throwing in his lot with the British. and his influence at Poona led to the treaty of Salbai (1782). From this date until his death in 1794 Mahadaji strove to consolidate his position in Hindustan and to control the peshwa, primarily in his own interests. This necessitated undermining the Brahman ascendancy at Poona, since the aim of Nana Phadnavis mas to preserve the peshwa's supremacy over the confederacy. In 1785 Mahadaji re-established Shah Alam on the imperial throne at Delhi. In 1788 he took advantage of the cruelties practised by Ghulam Kadir on Shah Alam to occupy Delhi, where he established himself as the protector of the aged emperor. Though nominally a deputy of the peshwa he was the ruler of a vast territory. including parts of central India and Hindustan proper, while his officers exacted tribute from the chiefs of Rajputana.

Mahadaji was succeeded in 1794 by his adopted nephew. Daulat Rao. The death of Kana Phadnavis in 1800 and dissensions in the confederacy were followed by the flight of the peshwa to Bassein, where in 1802 he entered into a subsidiary alliance with the British. This was resented by the other members of the confederacy and brought on the Anglo-Maratha war of 1803 in which Daulat Rao's forces were defeated. By the treaty of Surji Arjangaon (Dec. 30, 1803) his territories were considerably reduced. In 1816 he was called upon to assist in the suppression of the Pindaris, but his conduct was so equivocal that in 1818 he mas forced to sign a fresh treaty by which his territories were further reduced. During the governor-generalship of Lord Ellenborough the growth of turbulence and misrule necessitated British intervention in Gwalior, and the Marathas were defeated at Maharajpur and at Punniar in Dec. 1843. In the 1857 mutiny the maharaja of Gwalior remained loyal to the British even after his troops had joined the mutineers. From that time on Gwalior remained faithful to the British connection. This was maintained through a British resident stationed at Morar. 4 mi. E. of Gmalior city. (This officer in 1936 also became responsible for imperial relations with the United Provinces states of Benares *[see* VARANASI] and Rampur [*q.v.*].) The former Gwalior state (26,367 sq.mi.; pop., 1941, 4,006.159) was divided as follows: (1) large northern tract southeast of the Chambal river and extending southward to the Bhopal border; (2) a large tract about the headwaters of the Kali Sind river, north of the Vindhya hills; (3) three smaller areas west of this, the southernmost containing Ujjain, the original Sindhia capital; (4) a further division to the southeast, north of the Narbada river. The state administrative headquarters were at Lashkar, founded *c.* 1800, 4 mi. S. of old Gwalior. (C. C. D.)

GWATKIN, HENRY MELVILL (1844–1916), English theological scholar, was born at Barrow-on-Soar, Leicestershire, on July 30. 1844, and was educated at Shrewsbury and St. John's college, Cambridge. In 1868 he became a fellow of St. John's and in 1874 theological lecturer. He succeeded Creighton as Dixie professor of ecclesiastical history at Cambridge (1891). He died at Cambridge on Nov. 14. 1916.

His chief works were *Studies of Arianism* (1882); *The Knowledge of God,* the published version of his Gifford lectures (1906); and *Early Church History* (1909).

GWEDUC: see CLAM.

GWILT, JOSEPH (1784–1863), English architect and writer, was born in Southwark, London. Jan. 11. 1784, and died at Henley-on-Thames. Oxfordshire. Sept. 14, 1863. He designed St. Thomas's. Charlton. Greenwich (1846), in the revived Italian Romanesque style then fashionable; also the mansion of Markree castle. County Sligo. But he was best known as a translator of Vitruvius (1826) and author of an *Encyclopaedia of Architecture* (1842). His brother GEORGE GWILT (1775–1856) restored the tower. choir and lady chapel of St. Mary Overy, Southwark (now cathedral,. in 1822–25, using cast iron extensively.

GWINNETT, BUTTON (*c.* 1735–1777), American merchant, patriot and signer of the Declaration of Independence, was born in Gloucester. Eng., probably in 1735, and moved to the colony of Georgia in America some time before 176j. On Feb. 2, 1776, he was elected a delegate from that colony to the .continental congress, and as such signed the Declaration of Independence. His name is known today chiefly because his autographs are of extreme rarity, and collectors of the signers have forced their value to a high figure. Returning to Georgia he was a member of the convention to frame a new constitution for the state and speaker of the assembly. He was mortally wounded in a duel with Gen. Lachlan McIntosh, and died at his home on St. Catherine's Island on May 19, 1777.

See C. F. Jenkins, *Button Gwinnett* (1926).

GWYN, NELL (ELEANOR GWYN, GWYNNE OR GWYNN) (1650–1687), English actress and mistress of Charles II, whose frank recklessness, generosity, invariable good temper, ready wit, infectious high spirits and amazing indiscretions appealed irresistibly to a generation that welcomed in her the living antithesis of Puritanism, was born on Feb. 2, 1650, probably in an alley near Covent Garden, London. Her father's name is unknown; according to tradition he died in a debtors' prison in Oxford during Nell's infancy. Her mother, Helena Gwyn, kept a bawdyhouse in the Covent Garden district, where Nell was brought up "to fill strong waters [brandy] to the guests" (Pepys, *Diary,* Oct. 26. 1667). In 1664. through the influence of her older sister, Rose, Nell became an orange-girl in the King's theatre. Quickly attracting the attention of the leading actor, Charles Hart (whose mistress she became), Nell mounted to the stage, making her first appearance as Paulina, a courtesan, in Thomas Killigrew's *Thomaso,* probably in Dec. 1664. From 1666 to 1669 Nell was the leading comedienne of the King's company, playing continuously save for a brief absence in the summer of 1667 when she lived at Epsom as the mistress of Lord Buckhurst, afterward 6th earl of Dorset (*q.v.*). She created such popular roles as Florimel in Dryden's *Secret Love,* Mirida in James Howard's *All Mistaken* and Jacinta in Dryden's *An Evening's Love.* An excellent singer and dancer, and much in demand as a speaker of impudent prologues and epilogues, "pretty, witty Nell" was ill-suited to serious parts, yet she was often cast for roles in romantic dramas.

Her last appearance was as Almahide to the Almanzor of Hart in Dryden's two-part heroic play The *Conquest of Granada* (Dec. 1670–Jan. 1671), the production of which had been postponed several months for her return to the stage after the birth of her first son by the king (May 14. 1670).

Established in a fine house in Pall Mall and admitted to the inner circles of the court, Nell spent the rest of her life entertaining the king and his friends, living extravagantly and intriguing against her rivals. She persuaded the king to create her son Charles Beauclerk, Baron Hedington and earl of Burford and, subsequently, duke of St. Albans. Her second son, James, Lord Beauclerk (b. Dec. 25, 1671), died in 1680. Nell settled her mother in a house in Chelsea, where, in July 1679, overcome by brandy, Madam Gwyn fell into a nearby brook and was drowned.

Of all the mistresses of Charles II, Nell was the only one beloved by the public. Her popularity was due partly, no doubt. to the disgust inspired by her rival. Louise de Kéroualle, duchess of Portsmouth, and to the fact that, while the Frenchwoman was a Catholic, Nell was a Protestant. But very largely it was the

result of exactly those personal qualities that appealed to the monarch himself. She was small, slender and shapely, with a heart-shaped face. hazel eyes and chestnut-brown hair. She was illiterate, and with difficulty scrawled an awkward "E. G." at the bottom of her letters, written for her by others. "A true child of the London streets," she never pretended to be superior to what she was, nor to interfere in matters outside the special sphere assigned to her; she made no ministers, she appointed to no bishoprics, and for the high issues of international politics she had no concern. She never forgot her old friends and, as far as is known, remained faithful to her royal lover from the beginning of their intimacy until his death and, after his death, to his memory.

When Charles II died in Feb. 1685, Nell was so deeply in debt that she was outlawed by her creditors. However, the king's deathbed request to his brother, "Let not poor Nelly starve," was faithfully carried out by James II, who paid off enough of her debts to re-establish her credit, gave her sizable amounts in cash and settled on her a pension of £1,500 a year. In March 1687 Nell was stricken by apoplexy and partial paralysis. She died Nov. 14, 1687, and on Nov. 17 was buried, according to her request, in the church of St. Martin's-in-the-Fields. Her funeral sermon was preached by the vicar, Thomas Tennison (afterward archbishop of Canterbury), who took as his text, "Joy shall be in Heaven over one sinner that repenteth, more than over ninety and nine just persons who need no repentance."

GWYNIAD, a species of the salmonid genus *Coregonus,* inhabiting Bala lake in Wales, nearly identical with the powan of Loch Lomond and the schelly of Ullswater and Haweswater. The snout is truncated and the lower jaw included. as in related species from Scandinavia and central Europe. *(See* SALMON AND SALMONIDAE; WHITEFISH.)

GWYNN, STEPHEN LUCIUS (1864–1950), Irish public official and man of letters. was born in County Dublin on Feb. 13, 1864. After studying at St. Columba's college. Dublin. and Brasenose college. Oxford, he taught classics at various places from 1887 to 1596. In the latter year he went to London, where he became a journalist.

In 1904 he returned to Ireland. He was Nationalist member for Galway city in the Westminster parliament, 1906–18, and a member of the Irish convention. 1917–18.

Gwynn published a considerable number of histories, essays, guides and biographies, including lives of Jonathan Swift, Oliver Goldsmith, Sir Walter Scott and Robert Louis Stevenson.

Other books include *Decay of Sensibility* (1900), *The Queen's Chronicler* (verses) (1901j, *Collected Poems* (1923), *The History of Ireland* (1923), *In Praise of France* (1937), *Irish Literature and Drama* (1936), *Memories of Enjoyment* (essays) (1946) and *Aftermath* (verses) (1946). Gwynn died in Dublin on June 11, 1950. His son Denis Rolleston Gwynn (1893–) also became a journalist, and a professor in modern Irish history at Cniversity college. Cork, and wrote biographies and a number of books on Catholic and Irish history. His books include *A Hundred Years of Catholic Emancipation* (1929), *The Inner History of Ireland's Partition* (1950) and *Father Luigi Gentili and His Mission* (1951).

GWYNNE, HOWELL ARTHUR (1865–1950), English journalist arid editor. was born at Kilvey, Swansea. He began his career as correspondent for the *Times* in the Balkans and served that newspaper and the Reuters agency in many areas, including the Sudan, the far east and South Africa, and was foreign director of Reuters in 1904. He was editor of the *Standard* (1904–11) and of the *Morning Post* until it ceased publication (1911–37). A lifelong opponent of sensational journalism. he resisted it to the end, even after the *Morning Post* became a penny paper. Politically he was an uncompromising Conservative. and as such had a part in the deposing of Lord Balfour as party leader and in the overthrow of David Lloyd George's coalition. He was created C.H. in 1938, and died at Little Easton. Essex, on June 26, 1950.

GYANTSE, one of the large towns of Tibet. It lies southeast of Shigatse, 130 mi. from the Indian frontier and 145 mi. from Lhasa. Its central position at the junction of the roads from India and Bhutan with those from Ladakh and central Asia leading to Lhasa made it a considerable distributing trade centre. Its market became one of the largest in Tibet, after Lhasa and Shigatse, especially celebrated for its woollen cloth and carpet manufactures. Caravans arrived there from Ladakh, Nepal and upper Tibet, bringing gold, borax, salt, wool, musk and furs to exchange for tea, tobacco, sugar, cotton goods, broadcloth and hardware. In the British expedition of 1904 Gyantse was one of the first towns occupied. Pop. (1953 est.) 10,000.

GYGES, king of Lydia (*q.v.*) and founder of the Mermnad dynasty, began the transformation of his country into an empire. The dates of his reign are uncertain, H. Gelzer giving 687–652 B.C. and H. Winckler 690–657 B.C. The historical facts of Gyges' accession to power are hidden in a cloud of legends. All agree that in gaining the throne Gyges killed the last of the Heraclid dynasty, variously called Sadyattes, Candaules and Myrsilus, and that he then married the widowed queen to consolidate his power. According to Herodotus in his *History* (7-13), Sadyattes set in motion the events that led to his murder because he was inordinately proud of his wife's beauty. He invited Gyges, a member of his bodyguard. to hide in the royal bedchamber to see the queen naked. Despite Gyges' stealth in leaving after he had seen her; the queen was aware of his presence and the next day summoned him, pleaded that she had been dishonoured and gave Gyges the choice of killing the king and taking his place on the throne or of himself dying. Gyges chose to murder the king.

In Plato's *Republic* (359) the story of Gyges is told as an allegory of how public knowledge of men's acts impel them to act justly. There Gyges was a shepherd who found a ring on a corpse in a hole in the earth made by an earthquake. While talking with other shepherds, Gyges discovered that by turning the ring he could make himself invisible. He then contrived to have himself appointed by the shepherds as a messenger to the king, and when he came to court used his power of invisibility to enter the royal bedchamber, seduce the queen and enlist her aid in killing the king and seizing the throne. Yet another story made Gyges the son of Dascylus, an exiled Lydian. who sent him to the court of Sadyattes where he became a favourite. The king sent him to fetch the daughter of Arnossus of Mylasa, whom he was to marry, and on the way back Gyges fell in love with her. She complained of his conduct to the king. Forewarned of the king's intention to punish him with death, Gyges enlisted the help of the Carian captain of the bodyguard. Arselis of Mylasa, killed the king, seized the throne and married the queen. The civil war which followed was ended only by Gyges' successful appeal to the oracle at Delphi (Herodotus says he was the first barbarian to do so) for confirmation of his right to the throne. Sir James Frazier in *The Golden Bough* theorized that the constant allusion to Gyges' ensuring his power by marrying the widowed queen was evidence that the Delian crown may have descended matrilineally.

The knowledge of Gyges' reign after his confirmation in power is somewhat more factual historically than the stories of how he gained power. He devoted himself to establishing Lydia as a maritime and military power. He is variously credited with successful attacks on the Troad, Miletus, Colophon. Magnesia ad Sipylum and possibly Smyrna. The attacks were probably raids rather than conquests. Whether Gyges was successful in securing the aid of Assur-bani-pal of Assyria when Lydia was invaded by the Cimmerii is uncertain, but the fact that he sent two captured chieftains of the Cimmerii to the court of Assur-bani-pal after successfully repelling the invasion would seem to make Assyrian aid probable. At any rate. Gyges later allied himself with Psammetichus of Egypt. sending him his faithful Carian troops and Ionian mercenaries when Egypt overthrew Assyrian rule. Gyges died in battle during another invasion of the Cimmerii and was succeeded by his son Ardys.

Gyges is said to be the first ruler to be called tyrant (*q.v.*). It was also during his reign that the minting and use of coins is said to have begun.

GYLIPPUS, a Spartan general of the 5th century B.C.; he was the son of Cleandridas, who had been expelled from Sparta for accepting Athenian bribes (446 B.C.) and had settled at Thurii. When Alcibiades urged the Spartans to send a general to take charge of the defense of Syracuse, Gylippus was appointed, and his arrival was undoubtedly the turning point of the struggle (414–413).

When he arrived the Syracusans were on the point of negotiating for a surrender, but Gylippus at once took vigorous measures. His first move was to block the completion of the Athenians' encircling wall. Later he organized assistance among the other Sicilian cities, and was responsible for the decisive step of attacking the Athenian fleet in the harbour. Persisting in this policy in spite of an early reverse, he turned defense into attack. According to Thucydides. who is probably right, he wished to spare the Athenian commanders when they were captured, in order to take them to Sparta. Later, entrusted with a large sum by Lysander to deliver to the ephors, he embezzled it, and went into exile when discovered.

See also SYRACUSE (for the siege operations), commentaries on Thucydides and the Greek histories.

GYLLEMBOURG-EHRENSVARD, THOMASINE CHRISTINE, BARONESS (1773–1856), Danish author, was born on Nov. 9, 1773, at Copenhagen. Her maiden name was Buntzen. Before she was 17 she married the famous writer P. A. Heiberg. Their son was afterward illustrious as the poet and critic J. L. Heiberg. In 1800 her husband was exiled, and she obtained a divorce, marrying in Dec. 1801 the Swedish Baron K. W. Ehrensvard, himself a political fugitive. Her second husband, who presently adopted the name of Gyllembourg, died in 1815. In 1822 she followed her son to Kiel, where he was professor, returning with him to Copenhagen in 1825. Her most famous work is *En* Hverdegs *historie* ("An Everyday Story"). On July 2, 1856, she died in her son's house at Copenhagen. For English readers no closer analogy can be found than between her and Mrs. Gaskell, and *Cranford* might well have been written by the witty Danish authoress.

See J. L. Heiberg, *Peter Andreas Heiberg og Thomasine Gyllembourg (1882)*; L. Kornelius-Hybel, *Nogle Bemaerkninger om P. A. Heiberg og Fru Gyllembourg* (1883).

GYLLENBORG, GUSTAF FREDRIK, COUNT (1731–1808), Swedish poet, a friend of G. Ph. Creutz and Hedvig Charlotta Nordenflycht (*qq.v.*), known for his satirical and reflective poetry, was born on Nov. 25, 1731, in Svinstad (Bankekind), Östergötland. Although his family were prominent in political life, he refused to engage in party battles, and attacked the weaknesses of modern society in the spirit of Rousseau in such poems as "Verldsforaktaren" ("The Misanthrope," 1762). A pessimism typical of the late 18th century is expressed in his most famous poem, "Menniskjans Elände" ("Misery of Man," 1762). After parting with Creutz and Mrs. Nordenflycht in 1763, Gyllenborg wrote little of importance, but devoted himself to a career in the civil service. He died in Stockholm, March 30, 1808.

Gyllenborg's poems were published in *Vitterhetsarbeten af Creutz och Gyllenborg* (1795); his memoirs, *Mitt lefverne 1731–1775,* appeared in 1885.

See M. Lamm, *Upplysningstidens romantik,* vol. 1, pp. 263–308 (1918); G. Sahlberg, *G. F. Gyllenborg* (1943). (L. G. Bz.)

GYLLENSTJERNA, JOHAN, COUNT (1635–1680), Swedish statesman, began his political career at the diet which assembled on the death of Charles X (1660). An aristocrat by birth and inclination, he was nevertheless a true patriot and demanded the greatest sacrifices from his own order in the national interests. He laboured zealously for the recovery of the crown lands, and in the upper house he was the spokesman of the gentry against the magnates. whose inordinate privileges he would have curtailed or abolished.

Gyllenstjerna's adversaries vainly endeavoured to gain him by favour, for as court marshal and senator he was still more hostile to the patricians who followed the policy of Magnus de la Gardie. Thus he opposed the French alliance which De la Gardie carried through in 1672, and consistently advocated economy in domestic and neutrality in foreign affairs.

On the outbreak of the war in 1675 he loyally supported the young Charles XI, whose indispensable counselor he became. Indeed. it may be said that the political principles which he instilled into the youthful monarch were faithfully followed by Charles during the whole of his reign.

In 1679 Gyllenstjerna was appointed the Swedish plenipotentiary at the peace congress of Lund. The alliance which he then concluded with Denmark bound the tno northern realms together in a common foreign policy. and he sought besides to facilitate their harmonious co-operation by every means in his power. In 1680, after bringing home Charles XI's Danish bride from Copenhagen, he was appointed governor general of Scania (Skane), but died a few weeks later.

See M. Hojer, *Ofversigt af Sveriges yttre politik under aren 1676–1680* (1875). (R. N. B.; X.)

GYMKHANA is a display of athletics and equestrian events originated at the military stations of India. The word apparently is derived from the Hindustani *gend-khana,* "ball house" or "racquet court," and the Persian *khana,* "house." The first syllable of "gymnastics" is substituted for gend, implying athletic competition.

Outside India amusing races were added. Thus gymkhanas now include varied competitions, some serious and some funny, on foot, on horseback and on bicycles.

"Gymkana," introduced at the University of Illinois in 1933 and continued at Florida State university after 1949, is a group-recreational activity combining gymnastics with showmanship. (H. D'O. P.)

GYMNASIUM. The history of the gymnasium dates back to ancient Greece where the literal meaning of the word was "school for naked exercise." The gymnasiums were of great significance to the ancient Greeks and every important city had at least one. These were usually built by the state and from a humble beginning of merely a gathering place where exercises were performed grew to imposing structures with dressing rooms: baths, training quarters and special areas for contests.

Originally these gymnasiums were public institutions where only male athletes over the age of 18 received training for competition in the public games of that time as opposed to the palestrae which were private schools where boys were trained in physical exercises. The supervision of the gymnasiums was entrusted to "gymnasiarchs." who were public officials responsible for the conduct of sports and games at public festivals and who directed the schools and supervised the competitors. The "gymnastae" were the teachers, coaches and trainers of the athletes.

Gradually, the gymnasiums developed into institutions of learning and schools of intellectual culture (see SCHOOLS, ANCIENT). In the German speaking countries, the term "Gymnasium" is still applied to the higher grades in secondary schools and has no association with athletics or sports; the name *"Turnverein"* is used to designate a site for physical exercise. However, in the English speaking countries the gymnasium's connection with philosophy and mental culture has been dropped and it ordinarily designates a room or building for the practice of physical culture. Although the Greeks attempted to establish their gymnasiums in the Roman empire, the Romans had little regard for the institution as they felt it was too effete and contributed little to the military training which was paramount for their youth.

One of the first gymnasiums of modern times was the Berlin *Turnverein* (*q.v.*) established by Frederich Ludwig Jahn (*q.v.*) in 1811. A military gymnasium was established at the United States Military academy at West Point in 1817, and in 1822 Capt. P. H. Clias, a Swiss army officer, was appointed gymnastics instructor in the English army and instructed at the gymnasium established at Aldershot, Eng.

Round Hill school at Northampton, Mass.. first offered systematic instruction in a gymnasium in 1823 arid the first German *Turnverein* in the United States was built in 1848 in Cincinnati. O. Princeton erected the first college gymnasium building in the U.S. in 1856 and in 1879 Harvard university built the Hemenway gymnasium which was considered the finest of its time.

Gymnastic instruction at a college for women was first offered in 1862 by Mount Holyoke college, South Hadley. Mass. in a storeroom over the wood and coal shed; a gymnasium was erected in 1865.

The famous Czech (Bohemian) gymnastic society, the *Sokol* established its first gymnasium in Prague in 1862, and its first gymnasium in the United States at St. Louis, Mo.. in 1865. The first Y.M.C.X. gymnasium was opened in 1869, in San Francisco, Calif.

The main purpose of these early institutions was to provide a suitable place for physical exercise and the practice of the sport of gymnastics on the various apparatus *(see* GYMNASTICS). Gradually, however, the scope of the activities carried on in gymnasiums broadened so that 20th-century gymnasiums have facilities for a great many other sports and games such as basketball, volleyball, tennis, handball, etc

(For special equipment. dimensions of playing areas, etc., *see* separate articles on the various sports.)

In addition, most gymnasiums are equipped with dressing and locker rooms, shower rooms and swimming pools, special exercise rooms for remedial gymnastics, boxing, arestling, weight-lifting and fencing rooms, running tracks. etc.

A typical list of standard gymnasium equipment includes the following:

1. Apparatus specified by the Federation of International Gymnastics (F.I.G.) for international gymnastic competitions, *i.e.,* pommelled or side horses, long (vaulting) horses; parallel bars, horizontal bars, stationary rings, balance beams (for detailed description *see* GYMNASTICS: *Men's Events and Apparatus; Women's Events and Apparatus.*
2. Climbing ropes, 1) to 2 in. in diameter (competitive climbing for time is for a distance of 20 ft. under U.S. collegiate and Amateur Athletic union rules).
3. Swinging (flying) rings, similar to the stationary rings, except that they are suspended from a height of 23 to 24 it. and the rings may be made of wood, metal or metal covered with seamless rubber or leather, weighing not less than 4 and not more than 6 lb. per ring. Exercises are performed on the swinging rings while they are in motion, maintaining an angle of at least 40° on each side of vertical (making a total swing of 80°).
4. Elementary apparatus such as low horizontal and parallel bars, vaulting bucks, wall bars and horizontal and oblique ladders.
5. High-jump and pole vaulting standards, together with the necessary sticks and poles ior indoor practice of these activities.
6. Mats, provided for safety when exercising on the apparatus and also large sized, single piece mats for wrestling and tumbling.
7. Necessary equipment for games such as volleyball and tennis nets, basketball goals and backstops. Cabinets provide for the neat and protective storing of equipment-such as basketballs, medicine balls, volleyballs and the portable hand apparatus such as Indian clubs, wands. dumbbells, etc.
8. Special exercise rooms contain such equipment as pulleys, chest weights and weightlifting equipment Boxing and iencing rooms are equipped with the accessaries for these sports.
9. Handball and squash courts, requiring specially constructed walls, are often included in a modern gymnasium.

In design, the recommended dimensions of a gymnasium are a minimum nidth of 60 ft., with a ratio of width to length of 3 to j. Height should be a minimum of 23 ft., and running tracks or galleries should be not less than 10 ft. above the floor. The space required for each person exercising is 40 to 50 sq ft. The floor, usually of maple, should have a hard, clear finish and may be permanently marked to designate boundary lines for basketball, volleyball, tennis courts. etc.

Accommodations for spectators at sporting events may be provided by bleachers — a series of tiered benches — which may be permanent in nature or portable, in that they may be folded up against the walls when not in use.

Gymnasiums often provide the facilities for holding social functions such as dances, receptions, bazaars, fairs, etc. Many gymnasiums include meeting rooms, lounges, auditoriums, theatres, cafeterias, workshops and other facilities to provide recreational and leisure time activities for an entire community. *See* also STADIUM. *(J. F. HY)*

GYMNASTICS. A system of physical exercises practised either to promote physical development or as a sport. The history of gymnastics dates back to the public games of ancient Greece, where the general term included activities which have since developed as separate sports, for example, track and field athletics, fencing, wrestling, boxing, etc. A primitive form of modern gymnastics was practised as training for the more strenuous combative sports and later developed into a competitive sport of its own to the extent of forming part of the ancient Olympic games (*q.v.*). With the termination of the ancient Olympic games all sports fell into a decline. In the middle ages jousts and various field sports were popular, but the systematic training of the body which the Greeks had associated with gymnastics fell into neglect.

The modern development of gymnastics started in the 19th century when there was a revival of interest in all sports, and gymnastics early came to be recognized as a systematized form of physical exercise having not only recreational but therapeutic value, and offering a means of developing a high degree of discipline of both mind and body.

Gymnastic societies were founded first in Germany (*Turnvereins*) and in the Bohemia of the Austro-Hungarian empire *(Sokols)*. followed by France and Suitzerland (where a system of gymnastics performed in unison by groups was developed) then gradually spread throughout western Europe. Gymnastics was one of the first sports to recognize that its recreational and therapeutic advantages were as valuable to women as to men and by the middle of the 18th century provided for the participation of women. The European gymnastic societies also provided children's classes starting youngsters as early as the age of five.

While interest in gymnastics in England and Canada has been mainly in its remedial and physical training qualities, particularly in connection with the military, its recreational and competitive aspects have slowly gained recognition.

The original impetus to gymnastics in the United States came in the 1880s with the advent of the great tide of immigrants from the European countries. who brought with them the ideas of their gymnastic societies and founded these wherever they settled. For additional historical details *see* GYMNASIUM.

COMPETITIVE GYMNASTICS

As a competitive sport gymnastics is akin to diving and figure skating in that it is a "demonstration" sport and the effectiveness of the competitor is assessed solely by the judgment of officials who have a knowledge of the technical rules and regulations governing the competition.

In international competition these rules and regulations are promulgated by the Fédération Internationale de Gymnastique (F.I.G.). The F.I.G. prescribes international standards for the apparatus to be used, the types of exercises to be performed and the conduct of the competition. It is charged with the conduct of the gymnastic competition at the Olympic games and holds world championships in gymnastics every four years (two years after each Olympic games).

Governing bodies in the different countries (such as the amateur athletic unions of England, the Cnited States, Canada, etc.) hold membership in the F.I.G. and conduct gymnastic competitions under F I.G rules.

The men's competition in the international program of competitive gymnastics consists of seven events: the horizontal bar, parallel bars, side or pommelled horse, long or vaulting horse, stationary rings, floor exercises or calisthenics and the all-around event consisting of the combined scores in the first six events (international rules require that a gymnast perform in all events, similar to the decathlon event in track and field).

The women's competition consists of the balancing beam, uneven parallel bars, vaulting horse, floor exercises or calisthenics and the all-around event.

On the apparatus and in calisthenics each competitor performs two exercises, one is a prescribed exercise which all competitors must perform. This prescribed exercise is composed by the governing administrative body of the sport (the amateur athletic unions of the different countries, and the F.I.G. for international competitions). The performance of this exercise is judged solely on its execution, that is, the form of the gymnast, the fluency of his performance, the correctness of the execution and the beauty of combining the component parts of the exercise.

In addition, an optional exercise, composed by the gymnast himself, must also be performed. The element of difficulty of the component movements of the exercise enters into the evaluation of the optional exercise. Beside difficulty, other elements of the optional exercise are originality, beauty of combining of the various movements and the fluency and perfection of its execution.

Four judges, supervised by a "superior judge" evaluate and score each exercise on a one-tenth basis, *i.e.* 8.8, 9.3, etc.. with 10.0 for a perfect exercise. For the prescribed exercise the entire 10.0 points are confined to the execution of the exercise inasmuch as all competitors perform the same exercise. In the evaluation of the optional exercise, 3.0 points are allotted for the difficulty of the exercise: 2.0 points for the element of combination of the various movements and 5.0 points for the execution of the exercise as a whole. All four judges evaluate and score each exercise independently. Then, in order to eliminate gross errors of judgment, the scorers delete the highest and the lowest marks of the four judges, and the two middle marks are averaged for the score of the exercise. For example, if the four judges' marks are 9.6, 9.2, 9.1, 8.7, the 9.6 and 8.7 are deleted and the 9.2 and 9.1 are averaged, giving the final score of 9.15. The average score of the prescribed exercise is added to that of the optional exercise to determine the final score of the competitor in the event and his standing as compared with the other competitors. To obtain the all-around score, the final scores of the six events (four in the case of women) are added and the total comprises the score of the gymnast in the all-around competition.

Since the diinensions and specifications of the apparatus used in the Olympic games and other international gymnastic competitions; as well as the type of exercises performed thereon, are standardized by the F.I.G., when gymnasts from all parts of the world gather for an international competition they have all trained on the same type of apparatus and have a common knowledge of the conditions and requirements of the competition. The F.I.G. delegates the task of prescribing these rules and regulations to two technical committees: one for the men's and one for the women's program, composed of experts who have made a study of the technical aspects of the sport and are alert to changes in the trend of gymnastics and change the programs accordingly.

It should be noted that there was a gradual change in the trend of competitive gymnastics from its earlier concept of emphasizing strength and the holding of classical poses to a more liberal interpretation, and the phrase "artistic gymnastics" came to describe perfection of execution and fluency of movement. Ballet movements, particularly in calisthenics, gained approval and on the apparatus fluent movement; and swinging exercises requiring changes of grasps and position were encouraged to the extent of limiting movements requiring strength and pressing.

Any changes in the rules by its technical committees are published by the F.I.G. and are disseminated to the governing bodies of the sport in the various countries holding membership so that they in turn may keep the gymnasts under their jurisdiction currently informed.

The following is a description of the apparatus as specified by the F.I.G. and the types of exercises to be performed thereon. Inasmuch as most of the countries use the metric system of measurement, the dimensions are so stated rather than in English linear measurements.

MEN'S EVENTS AND APPARATUS

Horizontal Bar.—This is a polished steel bar, 28 mm. in diameter, 2.35 to 2.50 m. long and 2.40 to 2.50 m. high from the floor: supported at the ends by steel poles which are held upright by guy wires. Only movements of swinging and vaulting, without pause. are permitted. Such exercises as upstarts, back and front (by which the gymnast swings himself from a hang to a support above the bar); giant circles forward and backward (rotating around the bar from a handstand position with the arms fully extended) and with inverted or dislocate grips and changes from one to another; vaulting over the bar. releasing the grip and regrasping the bar; movements requiring turns and changes of the position of the body and the releasing and regrasping of the bar; and finishes with straddles over the bar or forward and backward somersaults from the bar are performed on this apparatus.

Parallel Bars.—The two bars, made of wood, are oval in form, 42 to 48 cm. apart, 3.50 m. long and 1.60 to 1.70 m. high. The requirements for this apparatus are movements combining swings, vaults, strength and balances, although the elements of swings, and vaults must predominate. There may not be more than three balances (such as handstands) in an exercise (a sequence of at least ten different movements or tricks) and there must be at least one movement of strength (as a handstand which is pressed into by strength from a support, rather than swung up into). Movements below the bars and movements that require the release and regrasping of the bars are also required.

Side or Pommelled Horse.—This apparatus is a leather covered form, 1.60 m. long, 35 to 37 cm. wide and raised 1.08 m. from the floor (measured to its top) by a support in its centre. Curved wooden pommels, 12 cm. high are inserted in the top of the horse 40 to 45 cm. apart in the centre, or "saddle" of the horse. The gymnast supports himself on the pommels over the horse and performs movements of the trunk and legs, without stops, such as single or double leg circles, crosses of the legs (scissors); with turns and changes of the grasp to the forward (neck) part of the horse, the centre (saddle) and the rear (croup). It is necessary to vary the movements and also to perform them both to the left (clockwise) and to the right.

Long or Vaulting Horse.—The same apparatus is used as for the side horse, except that the pommels are withdrawn and the horse is placed lengthwise so that when the gyinnast faces it the part nearest to his stand is the croup, and the neck is farthest away from him, with the saddle in between. The height of the horse is raised to 1.35 m. The Reuther-type elastic board, placed in front of the croup end of the horse, is 1.20 m. long, 60 cm. wide and raised 12 cm. on the end nearest to the horse, tapering back to the floor. The gymnast takes a run, gathers momentum as he nears the horse, rebounds off the elastic board and, supporting his hands on the horse. vaults over it. A variety of vaults is performed such as vaulting over with straddled legs, with the legs together and bent into a squatting position or the legs straight with the hips bent into a "stooping" position; a handspring over the horse, a cartwheel, etc. The hands may be placed on either the croup or the neck end of the horse, but the space for the support of the hands is limited and encroaching beyond this space inflicts a penalty on the scoring of the vault. Each vault is evaluated by a table as to its difficulty.

Stationary Rings.—The rings are made of wood, 28 mm. in thickness and 18 cm. in diameter (inside). They are suspended by straps at a height of j.50 m. from the floor to the point of suspension, with the rings themselves hanging 2.40 to 2.50 m. above the floor. The exercise must be performed with the rings in a stationary position (without a swinging or pendulum movement of the rings) and must combine swinging movements of the body, strength and holding of positions. There must be at least two handstands in an exercise, one of which must be pressed into by strength from a support above the rings, and the other swung up into from a hanging position below the rings, and at least one other part of strength such as a cross (holding the body vertical with the arms fully stretched sideways); or a lever (hanging with straight arms, with the body stretched out horizontally, either in front of the arms or in a dislocated hang (changing in an inverted position: with the head nearest the floor, and then lowering the body backward, stretching it in a horizontal position with the body stretched backward in back of the arms). Combined with such required movements may be movements of upstarts, either forward or backward, forward or backward uprises, straight or inverted hangs, and dislocate circles of the body, either forward or backward.

Floor Exercises or Calisthenics.—KOapparatus is used in the floor exercises or calisthenic event. The exercise is done on the floor, which may be covered by canvas or felt, in an area 12 by 12 m., and must be at least one minute and not more than two minutes in duration. The type of exercise required is a series of combined movements of the elements of flexibility (tumbling movements

such as handsprings, cartwheels, somersaults in the air, etc.), jumps, strength, holding of poses, balances and other tricks. The exercise must be performed with rhythm and harmony and the gymnast must move in different directions and utilize a major portion of the allotted area. The exercise usually starts and finishes with a series of tumbling movements such as a cartwheel with half a turn ("round-off") continuing with handsprings and somersaults backward or forward in the air. In between the start and finish balances are held on one leg (scales), handstands are pressed into by strength, movements resembling ballet are employed and a variety of tumbling movements and jumps are interposed.

WOMEN'S EVENTS AND APPARATUS

Balance Beam. — This is a wooden beam 5 m. long, 10 cm. wide and raised 120 cm. from the floor. The performer begins the exercise by mounting the beam either by a vault or a jump and executes movements which must include steps, running, jumps, turns, sitting and lying positions and some held or posed positions. The duration of the exercise is from one and one-half to two minutes.

Uneven Parallel Bars. — These are of the same dimensions and construction as the men's parallel bars, except that the top bar is 2.30 m. above the floor while the lower bar is only 1.50 m. high. This apparatus is the latest to be developed, being first used in the 1936 Olympic games, and permits of a great variety of movements, although hanging and swinging exercises predominate (such as hanging from the higher bar and swinging forward to grasp the lower bar and transferring to a support on the lower bar), interspersed with support and balance movements. The performer uses either of the bars, or combines movements using both bars.

Vaulting Horse. — This is the same as men's long horse. except that it is only 1.10 m. high and is placed sideways instead of lengthwise. Women also use the Reuther-type elastic board and perform similar vaults to those done by men except that the vault is much shorter, inasmuch as it is performed over the width of the horse, rather than its length.

Floor Exercises or Calisthenics. — This event is similar to the men's except that it is performed to music and the duration is from 1 to 1½ min.

Other Apparatus

Mats. — Mats to protect the gymnasts against injury in the event of a fall off the apparatus or when dismounting are placed around the apparatus at all times for both men and women.

Elementary Apparatus. — In addition to the apparatus used in competitive gymnastics, an elementary form of apparatus is usually employed by children's classes or beginners in gymnastics to learn the rudiments and elementary movements of the sport and for body development. Examples of such elementary apparatus are the low parallel bars (3 ft. 4 in. high), the low horizontal bar (about chest height), the vaulting buck (a modified form of the long horse), climbing ropes and poles, wall bars and horizontal and oblique ladders.

Rebound Tumbling Apparatus. — To the traditional gymnastic apparatus may be added an apparatus developed in the late 1930s — for rebound tumbling — a table-height metal frame to which is attached a canvas or a webbing bed, the elasticity of which permits the performer to continue springing upward by rebound and perform acrobatics in his flight.

FESTIVALS AND DEMONSTRATIONS

Although gymnastics as a sport also has its recreational qualities, this form is popular mainly in the European countries where it is practised by groups ranging from a few gymnasts to mass demonstrations of many thousands. The *Sokols*, gymnastic societies, in Czechoslovakia have promoted gymnastic festivals in which as many as 10,000 gymnasts participated simultaneously in a mass calisthenic drill. The *Turnvereins* of Germany and the gymnastic societies of the Scandinavian countries also participate in mass demonstrations not only in calisthenic drills but also on apparatus.

OTHER TYPES OF GYMNASTICS

Generally speaking, in addition to being recognized as a sport, there are two other types of gymnastics — physical education and remedial exercises.

Physical Education. — The value of physical education had long been recognized in military circles as a means of promoting general health and self-discipline and had become an essential part of the training of the army recruit, particularly in England and the United States during World Wars I and II, when untrained civilians were inducted into the armed forces. In the elementary schools the term physical education appeared in England and the United States in 1880 and took the imagination of the educational authorities at the beginning of the 20th century. The principal object was the introduction of a balanced and graduated system of exercises to children in the early grades, progressing to more advanced exercise in the secondary schools and colleges. *See* also Physical Education.

Remedial Gymnastics. — Much study and research has been made of the value of remedial gymnastics in connection with the rehabilitation of men badly wounded in wartime and persons with injuries caused by industrial accidents and those handicapped by such diseases as cerebral palsy, poliomyelitis, etc. It was found that with specially graduated exercises constructed for individual needs it was possible to enable a crippled or handicapped individual to enjoy greater mobility by flexing and moving atrophied muscles. Incorporating many of the theories and movements used in gymnastics is a regular feature of practice in orthopedic hospitals. Great progress has been made in the development of remedial gymnastics and the application of its therapeutic qualities. *See* Physical Therapy.

Swedish System. — In Sweden a system of free exercises on the ground was developed in mid-19th century with the objective of developing perfect rhythm of movement. This system was introduced in England and the United States in about 1889 and for the next 20 years the relative merits of Swedish (rhythmic) gymnastics and the German gymnastic system (apparatus work of a formal nature. stressing muscular development) were debated intensively by both the educational authorities and adherents of the sport. A solution was found by the International Gymnastic Federation in the 1920s which blends the rhythmic, fluent movements of the Swedish system with the precision and developmental emphasis of the German system.

Although the Swedish system is still popular in the country of its origin, the combined version has been adopted by sport authorities.

SCHOOL AND COLLEGE GYMNASTICS

Although gymnastics had been practised as a competitive sport in the schools and colleges for many years in the United States it wasn't until shortly after World War II that it came into prominence and gained recognition as a major sport with dual meets and sectional and national championships being regularly scheduled. The school and college program does not comply with the F.I.G. rules inasmuch as it does not require the performance of prescribed exercises and lays more stress on the difficulty of the optional exercise rather than on its execution. The schools and colleges also have competition in events not recognized by the F.I.G. such as tumbling on the mats, rebound tumbling, a 20-ft. rope climb for speed and the flying or swinging rings (the same apparatus as the stationary rings except that the rings are suspended from a point 24 ft. from the floor and the gymnast performs on them while they are swinging). While women participate in physical training, competition in gymnastics in the schools and colleges is confined to men only.

AMATEUR ATHLETIC UNION

The Amateur Athletic union (A.A.U.) is responsible for the administration of amateur gymnastics in the United States. It conducts local, district and national championships under F.I.G. rules and sponsors visiting groups of foreign gymnasts and trips of U.S. gymnasts abroad for international competition. It publishes the rules and regulations governing competitions in its *Gymnastic Yearbook*, basing them on F.I.G. rules and amending them whenever the F.I.G. promulgates changes.

To provide for competition in events which, although not on the international program, still hold a wide interest in the United States, the A.A.U. also includes in its program events such as tumbling, rebound tumbling, rope climb and swinging rings for men and tumbling and rebound tumbling for women. No prescribed exercises are required in these events. Also, the A.A.U. does not require a gymnast to compete in every event (although it encourages all-around gymnasts) but permits competition in individual events.

The various gymnastic clubs holding membership in the A.A.U., such as the German and Swiss Turnvereins, *Sokols* and Y.M.C.A.'s, as well as the colleges, participate in the A.A.U. program and are the nucleus of developing gymnasts to represent the United States in the Olympic games and other international competitions.

For gymnastic records see OLYMPIC GAMES. (J. F. **HY.**)

GYMNOSOPHISTS, the English form of the name *gymnosophistai*, by which the ancient Greeks sometimes designated the ascetic philosophers of India (*gymnos* "naked" and sophistes "teacher of wisdom"). Diogenes Laertius quotes Aristotle as mentioning Indian gymnosophists in a catalogue of the names for wise men and wonder-workers current among non-Greek peoples.

Strabo, however, who writes at some length, though rather superficially, about Indian philosophers and wise men (*Geographica,* sections 703 and 711–715), does not speak of "gymnosophists" but cites Megasthenes as having drawn a distinction between Brachmanes (Brahmans) and the ascetic "dwellers in the forests," who fed on leaves and wild fruits and made what covering they wore from bark.

GYMNOSPERMS. Most of the trees commonly referred to as evergreens belong to the group of seed plants called gymnosperms. They are abundant in nature in many parts of the world and are to be seen everywhere in cultivation. In addition to these common representatives of the group, however, the interesting and often bizarre cycads and Gnetales also belong here. As a group the gymnosperms are particularly interesting to the biologist because of their antiquity. their excellent fossil record, and their great diversity of form and life cycle.

All living seed plants customarily are divided into two main groups, the gymnosperms and the angiosperms (*q.v*). By definition the gymnosperms have naked ovules, exposed to the pollen at the time of pollination, and naked seeds. The angiosperms have ovules enclosed within the ovary of a pistil (gynoecium), with the pollen falling on the stigma at its tip. so that the pollen tube must grow through considerable tissue before reaching the ovules. The seeds of the angiosperms throughout their development are enclosed within the ovary, which becomes a fruit that may be single seeded or many seeded.

The ovules of some gymnosperms are buried rather deeply between the scales of the cone in which they are produced. but the pollen is able to sift down through to them. In a few angiosperms the carpels are open so that the ovules are exposed, but the pollen always lands on the stigma. The basic difference between the two groups thus lies in the behaviour of the pollen, nhich produces a long tube growing down the style in the angiosperms, but which usually enters the ovule directly in the gymnosperms.

All the seed plants have an alternation of generations and the prominent plant ahich is seen is the sporophytic or asexual generation. Spores produced by these plants give rise to the alternating generation. the gametophytes. In the lower plants the gametophyte is the dominant generation. and even in the ferns it is relatively conspicuous. On the other hand, in the gymnosperms and angiosperms the gametophytes are usually quite small, the male gametophyte or pollen grain being transported through the air to the ovule from which the female gametophyte never escapes.

Another basic difference between the two groups lies in the gametophytic generations. The male gametophyte of the gymnosperms always produces more sterile cells than the male gametophyte of the angiosperms. The female gametophyte of most gymnosperms is comparatively large and, like that of the ferns, produces large eggs in cellular structures called archegonia. No archegonia are formed in the angiosperms where the gametophyte is small and produces but one egg.

As a consequence of there being several eggs, the gymnosperms are nearly always polyembryonic — that is, they have several embryos beginning their development, depending upon how many eggs are fertilized. Actually only one embryo usually survives the intense competition to maturity. Angiosperms, having usually a single egg and embryo in an ovule, are rarely polyembryonic. In exceptional cases it is common for several of the embryos to survive to the maturity of the seed.

There are anatomical differences between the gymnosperms and the angiosperms, as well. The phloem of gymnosperms lacks companion cells associated with the sieve cells (which are not sufficiently specialized to be called sieve tubes, as in the angiosperms). Vessels and vessel elements are characteristic of the angiosperms and they are lacking in all the gymnosperms except the Gnetales. In the latter group, as will be seen below, it can be shown that the vessels arose independently of those in the angiosperms.

In addition to the living gymnosperms there are several entire groups which have become completely extinct. The fossil seed ferns (Pteridospermae) are related to the cycads and the Cordaitales are related to Ginkgo and the conifers. The false cycads (Cycadeoidales) are of uncertain affinities.

The only other plants which might be considered to have seeds are fossil. These belong to the group of club mosses (Lycopsida; see PALAEOBOTANY: Plants *of the Palaeozoic* Ern) and there are differences of opinion as to whether the structures produced by them can properly be regarded as seeds. They are so similar to seeds, however, as to suggest that even this characteristic probably has arisen more than once in the evolution of the vascular plants and that perhaps the true gymnosperms are not the homogeneous group they are often thought to be.

Present day gymnosperms include only woody perennial plants which are usually evergreen trees. seldom shrubs. or lianas. There are several more or less distinct growth forms: the palm or tree fern type of the cycads; the profusely branched evergreen tree type of nearly all conifers, conical in their youth and often becoming irregular with age; and the shrubby types represented by dwarf conifers and most of the Gnetales. Nearly all of the latter are either shrubs or woody vines. These growth forms are associated with pronounced differences in size. While the cycads may remain small palmlike trees with a trunk about a foot in diameter and less than 10 to 20 ft. high, surmounted by a crown of compound palm- or fernlike leaves, the conifers include the largest trees known. The giant sequoia, *Sequoiadendron giganteum,* is the world's most massive organism, but it has not been proved to be, as was once thought, the oldest. The latter distinction belongs to another conifer. *Pinus* aristata (foxtail pine). The coast redwood. Sequoia *sempervirens,* is probably the tallest tree known. The cycads. though small in comparison. grow relatively slowly and may become very old. Even the small *Welwitschia* mirabilis of the coastal desert region of western South Africa may live for a century.

Gymnosperms are sometimes referred to as "living fossils." In many features they remain essentially unchanged from their fossil ancestors and their history extends back in an uninterrupted series to the Paleozoic era. There are apparently at least eight phyletic branches of gymnosperms, of which three are entirely extinct and one is represented by a single living representative. the maidenhair tree (Ginkgo). Two other divisions of the gymnosperms include relatively rare plants; only one group. the Coniferales (including pines, cedars, firs. spruces, redwoods. cypresses, etc.), constitutes a really large conspicuous and important part of our existing vegetation.

If we accept the view that all gymnosperms had a common origin, it seems likely that the group from which they evolved is the Filicales or true ferns. There are other possible interpretations, however, and there is not even general agreement that the group is a natural one with a single common ancestor. The earliest fossil types date from the Devonian and they are relatively advanced. An important part of the divergence which they show in their fundamental structures nas attained during the close of the Paleozoic era. They were dominant land plants during the greater part of

the Mesozoic era. Angiosperms did not become abundant until the latter part of the Mesozoic era. Gymnosperms were contemporaneous with the dinosaurs but, unlike these reptiles which have become extinct, a fairly representative group of the former, including some of the most massive organisms that ever existed, remain as a part of our living vegetation.

The eight divisions (taxonomic orders) of gymnosperms are as follows:

1. Pteridospermae or Cycadofilicales. The so-called seed ferns which combine a fernlike habit with seed production are wholly extinct (see PALAEOBOTANY: Plants of the Palaeozoic Era).

2. Cycadales. The cycads, comprising about nine living tropical or subtropical genera, were more abundant in the Mesozoic than today.

3. Cycadeoidales or Bennettitaies. A group of wholly extinct cycadlike plants whose relations are uncertain (see PALAEOBOTANY: Plants of the Mesozoic Era).

4. Cordaitales. The cordaites are now completely extinct, but apparently gave rise to the Ginkgoales, Coniferales, Taxales and possibly the Ephedraceae in the Gnetales (see PALAEOBOTANY: Plants *of* the Palaeozoic Era).

5. Ginkgoales. Mostly extinct but with a single surviving species.

6. Coniferales. The largest and most important order of living gymnosperms; 45 genera with many Mesozoic fossil representatives (see CONIFERS).

7. Taxales. A small group of gymnosperms (the yews) formerly included in the Coniferales.

8. Gnetales. An order including three peculiar genera of uncertain affinities. mostly tropical and subtropical, with few, if any fossil representatives.

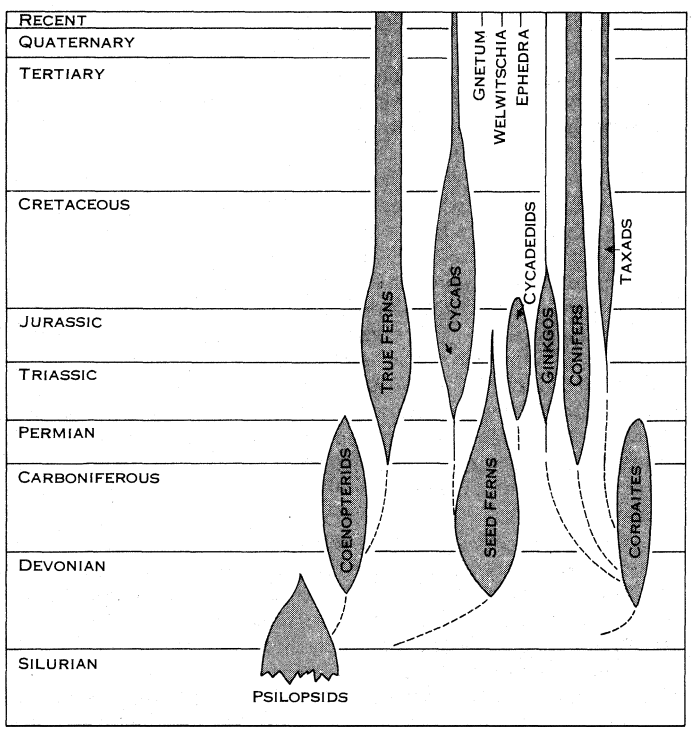

FIG. 1.—DIAGRAM SHOWING EVOLUTION OF GYMNOSPERMS AND RELATIONSHIPS OF THE LIVING GROUPS

The general relationships of the gymnosperms is diagramed in fig. 1 which also shows the major divisions of the geological time scale. Representations of this sort are very general and tentative but may be useful in visualizing one hypothesis of the evolutionary history. Each of the larger divisions represented by living forms has had a continuous history down to the present. Only the Gnetales have no history of which one can be certain. They must have been derived in relatively recent times in areas where fossils rarely if ever were formed.

Gymnosperms are classified primarily on the basis of their reproductive structures. Although these structures are often described as flowers, especially in the original descriptions, it is better to avoid that term and speak of cones or strobili. All of the living gymnosperms have cones of two kinds: the pollen or staminate cones and the seed or ovulate cones. The latter are greatly reduced in some species so that the cone structure is scarcely or not at all obvious and some orders, such as the Ginkgoales and Taxales, probably never had ovulate cones. In those conifers which are monoecious both kinds of cones are borne on the same plant. In other conifers and in all other living gymnosperms, the species are dioecious with pollen cones and seed cones formed on different plants.

The pollen producing plant is often referred to as the male plant and the seed bearing plant as the female. This terminology is not strictly accurate, for the gymnosperms, like the mosses, ferns, and angiosperms, have an alternation of an asexual sporophytic generation with the sexual or gametophytic generation. Although the gametophytic plants in gymnosperms and angiosperms are quite small (sometimes comprising only three cells), they are nonetheless individual plants of a separate generation and are properly called male or female. Since there is not general agreement as to whether the gymnosperms are truly heterosporous, rather than merely heterothallic. it appears preferable to avoid using the terms microspore and megaspore for the spores which will give rise to the male and female gametophytes respectively.

The classification in all groups involves many histological details including the succession of events that go on within the ovules of the cones that bear them. Much of the following discussion necessarily has to do with these internal microscopic details. It is possible to distinguish the gymnosperms on the basis of vegetative characteristics, such as the morphology of the leaves, stems, buds, and on the externally obvious characteristics of the cones. But their classification and phylogenetic position is determined by their reproductive mechanism.

CYCADALES

This division includes about 85 species situated in the tropics and subtropics and includes also a large group of Mesozoic fossil cycads not placed with the Cycadeoidales. The living species belong to nine genera; all are dioecious, bearing only one kind of a cone on a particular plant, either seed cone or pollen cone. Four genera are found in the new world, five in the old world. There are two slightly different growth forms, those with columnar stems and those with stems usually referred to as tuberous. The columnar types consist of erect cylindrical stems, seldom branched, that may become 10 to 30 ft. high, surmounted by a crown of large compound leaves at the top giving the appearance of a palm. The tuberous forms have stems that are subterranean or remain very short and are often branched, but are otherwise similar. The stems of the columnar forms may have an armour of persistent leaf bases covering the younger portion only or occurring throughout their entire length, while in the tuberous forms the leaf bases may scale off. In some of the tuberous forms only the tip of the stem, the cones and the crown of leaves appear above the ground level.

Though cycads are regarded as woody plants, they really have only a scanty zone of wood surrounding a very large pith and enclosed by a very large cortex. Thus the stem is relatively weak in comparison with other gymnosperms. The softer tissues are often permeated with mucilage canals. All cycads grow very slowly. Cycads of the columnar type attain their maximum height only after many centuries of growth. A new crown of leaves is produced annually in some species, biennially in others and the leaves of each successive crown usually persist for several years. Whenever cones are produced, a new crown of leaves is not formed until the following year or the plant may remain dormant for several years before growth is resumed.

The leaves of cycads are pinnately compound and remarkably like those of the palms in appearance. Usually the cuticle is relatively thick and hard and the leaves have a tough texture. In some species the tips of the leaflets are spiny and the entire plant with the spines pointing outward from all of the leaflets makes a formi-

dable barrier.

The following genera of cycads are known:

Cycas with about *16* species extending from southern Japan and Asia, through the Netherlands Indies to Australia, includes only columnar forms which diifer from the remaining genera in having the seed cones produced terminally. Upon resumption of vegetative growth. the crown of new leaves appears at the tip of the seed cone axis and individual cone scales are cast off rather than the entire cone. In all other genera the seed cone is crowded aside and may become detached as a unit if it has not already disintegrated. The meristem forming the new crown of leaves then appears laterally to the base of the old cone. This condition holds

FIG. 2.—SEED CONE SCALES OF CYCADS: (A) CYCAS REVOLUTA; (B) DIOON EDULE; (C) CERATOZAMIA MEXICANA

for the pollen cones of all species. *Cycas revoluta* is frequently found in cultivation. in conservatories or as decorative ornamental tub plants or growing in the open in subtropical or warm temperate regions. The leaflets of *Cycas* have a single median vein. The seed-bearing members of the cone have in several species a dissected terminal blade with several ovules or seeds attached laterally to the rachis *(see* fig. 2). The pollenbearing scales are narrower and have a broad pointed tip.

Macrozamia with about *14* species is confined to Australia. This genus includes columnar as well as tuberous species. The leaflets are parallel veined without a midrib and some species have a gland at the base of the leaflet. In many of them both kinds of cone scales are terminated by very long flat spines and in these, as well as in all remaining genera of cycads, only two ovules are produced on the ovulate scales. The seed cones of *Macrozamia denisonii* may become a yard long and weigh up to 85 lb.

Bowenia is the remaining genus found in Australia. It has two species. These are both low tuberous forms with the subterranean stem resembling a gigantic carrot. They differ from all other cycads in having leaves that are twice pinnate. The cones are relatively small and have peltate scales bearing two ovules each.

Encephalartos is a genus with 12 species, all South African cycads. Some are tuberous but most of them are of columnar habit. The margins of the leaves or the tips of the leaflets of many of these species are very jagged or spinous. The bread "palm." *Encephalartos caffer,* produces the largest known cone, sometimes fully a yard in length and weighing up to 100 lb. The other species have much smaller cones, but in several species these are borne in great numbers.

Stangeria, the other South African cycad. a genus with one (or possibly two) species. is a tuberous plant the leaflets of which have dichotomous veins branching off from a central midvein. Its leaves are so similar to those of some ferns that this plant was originally named and classified as a species of the fern *Lomaria* and not until many years later when seed cones were found. was its status as a cycad recognized. The cones are terminal, their scales having a distinct lamina terminating the stalk.

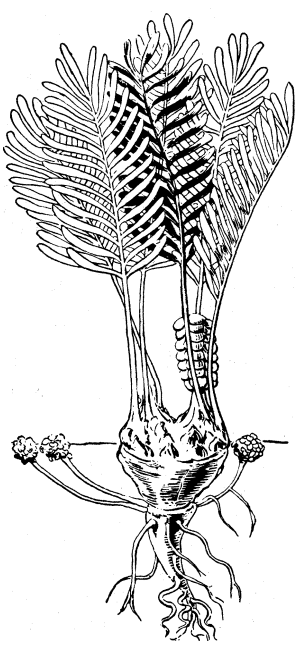
The four remaining genera are all new world plants. *Dioon,* with four species. occurs in central Mexico. The leaflets, without a midrib, are parallel veined and have a broad insertion on the rachis. The Dioons are all columnar in habit and have terminal cones. The ovulate cone scales are especially broad with the two ovules borne laterally on the stalks as shown in fig. 2. The pollen-bearing scales are also very broad at the apex which is broad triangular and turned upward.

Ceratozamia is another Mexican and Central American genus with three to four species. The leaflets are pointed and narrowed below at their insertion on the rachis. They are short. columnar in habit and bear terminal cones. The cone scales are tipped by two firm laterally divergent spines *(see* fig. 2).

Microcycas is a monotypic genus of western Cuba, columnar in habit. with stems that sometimes branch and may become 20 ft. in height. The leaflets are parallel veined and strongly reflexed on the rachis. The cones are large, the scales bearing two ovules each terminated by a rounded pyramidal extension. The single species, *Microcycas calocoma,* has not been successfully grown in cultivation.

Zamia is a genus of about 13 species, ranging from Florida through the Caribbean islands: Mexico. Central and South America to Brazil and Peru. Zamias are all tuberous in habit and frequently branched. The leaflets are parallel veined. *Zamia pygmaea* of western Cuba is probably the smallest cycad. with leaves only a few inches in length and a stem less than a half inch thick. It bears a correspondingly small seed cone with seeds less than 8 mm. long. Most species of *Zamia* are much larger and may produce more than a single cone. especially the pollen cones. The cone scales of *Zamia* are always shield shaped and though actually in a spiral arrangement, they are so regularly spaced that they appear to be attached in vertical rows. *(See* fig. 3.)

Uses of Cycads.—The cycads are valued as decorative, ornamental and conservatory plants. They are not hardy and only a few species may be used as tub plants in temperate regions. In subtropical regions. *Cycas revoluta,* a few species of *Dioon, Encephalartos,* and *Macrozamia* are sometimes grown in the open. Their firm leathery leaves find floricultural use. both while fresh as ceremonial "palm" leaves or as dried leaves which are sometimes dyed green and used in permanent decorations. The stems of *Cycas, Zamia, Encephalartos,* and other genera contain much starch and some yield a sort of sago used by the indigenous peoples. Most species contain an alkaloid which must be washed out and separated from the starch when used as food. The very young leaves of some East Indian species of *Cycas* are cooked as vegetables. The seeds of many species serve as food for animals and man. In South Africa the natives use the seeds of the bread palm. *Encephalartos caffer,* in making bread. On the other hand, in Australia the leaves of *Macrozamia moorei* are poisonous to cattle and this species is therefore being rapidly exterminated.



FROM SMITH ET AL., "A TEXTBOOK OF GENERAL BOTANY" (THE MACMILLAN CO.)

FIG. 3.—MATURE SPOROPHYTE OF ZAMIA BEARING A SEED CONE

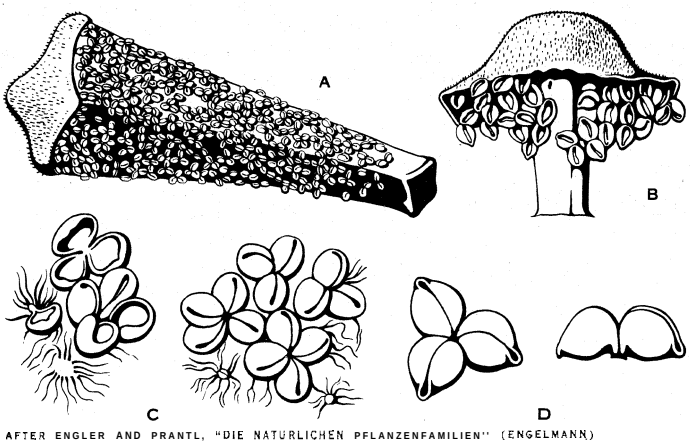
Relationships.— Of the genera enumerated above, when judged by morphology. *Cycas* is regarded as the most primitive. The cone scales of some of these show a closer resemblance to those of certain Mesozoic fossils than to the extremes found among other living species of *Cycas.*

In the old world the Australian *Macrozamia* includes several species that would stand close tb *Cycas,* and some of the species of *Encephalartos* would stand only slightly higher in the scale of evolution.

The Australian *Bowenia* is in some respects the most highly

specialized genus, but has twice compound leaves that may be among the most primitive, and likewise. *Stangeria* is primitive with respect to its fernlike leaves and cone scales, but more specialized in other directions. Among the American genera *Dioon* is the most primitive genus. In some respects it is not far removed from *Cycas. Zamia* is the most advanced, with *Cerutozamia* and *Microcycas* between these extremes and each of them is somewhat specialized.

Reproductive Morphology. — The development of the reproductive structures in the cycads is so little variable that a general description of the phases of the life cycle for any one of them will serve as a general outline for most of the other genera.



AFTER ENGLER AND PRANTL, "DIE NATURLICHEN PFLANZENFAMILIEN" (ENGELMANN)

FIG 4 — SCALESOF THE POLLEN CONES OF CYCADS
(A) Cycas circinalis: (B) Zamia *integrifolia;* (C) parts of A; (D) parts of B, showing sporangia grouped into sori

The spores which developed into the male gametophyte or pollen grain are produced on the scales of the pollen cone in sporangia that are arranged in groups (sori) on the lower surface of the scale and are similar in appearance to those of the Eusporangiate ferns. Fig. 4 shows the sporangia and sori of several species. The sporogenous tissue which will give rise to the spores arises below the epidermis and the sporangium has a jacket several cell layers thick. Within this is the tapetum, a layer of nutritive cells which produce materials needed by the developing spores.

The spore mother cells undergo a specialized type of cell division. called meiosis. which reduces the chromosome number by one-half and produces four cells, each of which is a spore. This reduction of chromosome number from the sporophytic (symbolized by *an)* to the gametophytic number (*n*) is necessary, of course, since fertilization subsequently will double the gametic number. The division of the spore nucleus results in the formation of a pollen grain which is a gametophytic plant — even though very small — equivalent to the prothallus of a fern or to a leafy moss plant. Further divisions will produce the gametes. In the development of pollen in cycads, a single vegetative cell is formed, the prothallial cell. and it persists. The remaining nucleus divides again giving rise to the tube nucleus and a generative cell. By this time the pollen grain has developed a specialized coat consisting of an outer layer, the exine, and an inner layer, the intine. Only the intine is capable of extension as the pollen tube in later stages of development. The pollen grains are in this three-celled condition at the time of shedding and all subsequent development must be observed in the nucellus of the ovules where some of the pollen eventually becomes lodged in the process of pollination. Fig. j shows in A and B the stages before the pollen grain is shed and in C and D stages after it germinates on the nucellus.

Pollination is accomplished by the wind in all of the genera: reports of possible insect pollination in one of the African species may indicate the evolution of another type of pollination. In the cycads that have been observed closely a pollination droplet appears at this time at the micropyle. a small opening through the integument of the ovule. This droplet originates from the tissues at the tip of the nucellus which is the tissue of the ovule in which the spore producing the female gametophyte arises. The formation of the pollination droplet produces the pollen chamber in the nucellus at its tip below the micropyle. The pollen grains falling upon the droplet are held within it by surface tension. As the liquid is resorbed into the nucellus, the entrapped pollen grains are brought into intimate contact with the cells lining the pollen chamber and here they germinate.

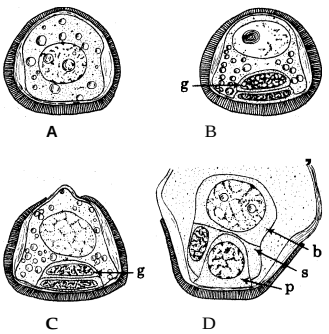
The pollen tubes are formed by an extension of the intine, which emerges at the side where the exine is thinnest. The tubes grow out into the nucellus and penetrate this tissue laterally. Usually there are several radiating outward and downward in all directions. The exine is spread open and adheres to the exposed end where it may be seen throughout the period of pollen tube growth. When the growing end has penetrated deeply into the nucellus, this opposite exposed end, tipped by the exine, elongates and bends downward toward the female gametophyte. Meanwhile the generative cell within the pollen tube has divided to form two cells called the stalk cell and the body cell. The stalk cell clasps or partially surrounds the prothallial cell and maintains contact with the body cell which enlarges greatly as the exposed end of the pollen tube expands and elongates. In fig. 5, C and D show stages in germination of the pollen grains and the formation of the pollen tube of which only the lower end is shown. The body cell divides later to form two cells within each of which a sperm is organized. Fig. 6 shows later stages of several pollen tubes in position above the eggs of the female gametophyte.

As the time of division of the body cell approaches, two conspicuous structures. the blepharoplasts, appear in the cytoplasm of the body cell on opposite sides of the nucleus. Similar blepharoplasts are found in sperm-producing cells of ferns. During division of the nucleus these play a role similar to that of the centrosome of animal cells in marking the poles of the spindle. After mitosis they organize the cilia of the sperm.

The sperms of cycads, nearly .3 mm. in diameter, are large enough to be observed with a hand lens. They are top-shaped cells, the greater part of which is occupied by nucleus. On the pointed end is a spiral row of thousands of cilia that emerge from the cytoplasm in a single spiral band that encircles the sperm many times between the point and the outer margin.

As the female gametophyte enlarges, the nucellar tissue between the exposed ends of the pollen tubes and the female gametophyte breaks down completely. Meanwhile the opening above the pollen chamber at the top of the nucellar tip extending into the lower end of the micropyle is closed. The nucellus becomes a very thin and membranous cap, tipped by a brown point, as shown in fig. 6.

The Ovule and Seed. — As previously stated, the ovulate cones of cycads vary considerably in appearance depending upon the size and shape of the scales of a particular species. Fig. 2 shows how the ovules are attached in three different genera. Ovules are borne at the lateral margins of species with peltate scales, as well as those having spatulate cone scales. They are only partially developed at the time of pollination, but become full grown before fertilization takes place.



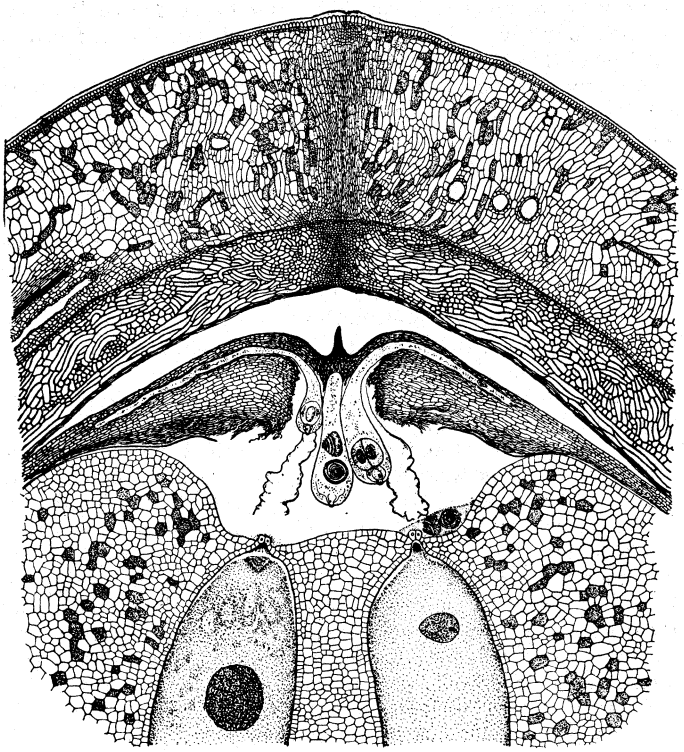
FROM CHAMBERLAIN, "GYMNOSPERMS, STRUCTURE AND EVOLUTION" (UNIVERSITY OF CHICAGO PRESS:

FIG. 5.—DIOON EDULE
(A) micraspore; (B) germinating micraspore showing tube nucleus above (g) the generative cell beside the prothallial cell: (C) exine ruptured by the young pollen tube; (D) later stage, the generative cell has divided, forming a stalk cell (s) and body cell (b). The prothallial cell (p) is protruding into the stalk cell

Young ovules consist of a central ovoidal mass of tissue, the nucellus, surrounded by a thick integument which leaves only a narrow passageway, the micropyle, leading to the tip of the nucellus. The ovules are always attached at the end opposite the micropyle and are thus regarded as atropous or erect.

Deep within the tissue of the nucellus an enlarged cell, the spore mother cell, appears. This cell undergoes meiosis during

which the chromosome number is reduced from *2n* to *n* in forming spores. Only one of the row of four spores persists; the three on the side toward the micropyle are usually aborted. This haploid *(n)* cell gives rise to the female gametophyte. The latter begins to develop by free-nuclear division. that is, no cell walls are formed between the nuclei at first. Soon it becomes an oval cellular structure situated in the centre of the nucellus. At the upper end of the gametophyte several cells enlarge greatly and form the archegonia or egg-containing structures. These may usually be recognized long before they are fully developed.



FROM CHAMBERLAIN, 'GYMNOSPERMS, STRUCTURE AND EVOLUTION' (UNIVERSITY OF CHICAGO PRESS)

FIG. 6.—DIOON EDULE

A reconstruction, from several sections, of an ovule at the time of fertilization. The pollen tube on the left shows the body cell still undivided; the one in the middle shows two sperms and the remains of the prothallial and stalk cells; the one on the right shows the two sperm mother cells and the spiral ciliated band beginning to develop. Two pollen tubes have discharged their sperms. A sperm has entered the egg on the left. Two sperms, in the liquid discharged from the pollen tube, are ready to enter the egg

The early formation of the archegonia checks the growth and enlargement of the gametophyte in this region so that these egg-bearing structures come to lie in a cylindrical depression, the archegonial chamber shown in fig. 6. The wall of the spore becomes thick and remains to envelop the entire gametophyte as a distinct tough spore coat. It is ruptured only in the region above the archegonial chamber a week or more before fertilization.

The archegonia are formed in a manner similar to that of ferns but are deeply embedded and have a distinct jacket of nutritive cells surrounding the eggs.

Fig. 6 shows the disposition of the female gametophyte with the archegonia and its relation to the pollen tubes above in the nucellus and to the surrounding tissues of the ovule. The eggs of cycads are so large that they are easily visible to the naked eye. In *Dioon* edule they are up to 4 mm. long and over 1 mm. in diameter, unquestionably the largest eggs produced anywhere in the plant kingdom.

FROM CHAMBERLAIN GYMNOSPERMS STRUCTURE AND EVOLUTION (UNIVERSITY OF CHICAGO PRESS)

FIG. 7.—CERATOZAMIA MEXICANA

Young embryos with suspensors; the rounded bodies at the top are the tough egg membranes; magnification x 1.5

At the time of fertilization a pair of motile sperms may be seen with a hand lens swimming about within the liquid of the pollen tube. These are discharged into the archegonial chamber upon the neck cells of the archegonia causing them to rupture and thus afford direct access to the egg. The motility of the sperms enables them to enter the neck of the archegonia, but soon afterward the cilia are left behind in the upper part of the cytoplasm of the egg. Only the naked nucleus penetrates deeper to unite with the nucleus of the egg cell. This is fertilization, and it restores the chromosome number from *n* to *2n* in forming a zygote.

Sometimes additional sperms enter the upper part of the egg. However, these remain lodged near the neck of the archegonium where they may still be found and recognized by their spiral bands of cilia in the embryos dissected out weeks or months later.

FIG. 8.— DIOON EDULE

Mature seed. The darkly shaded part at the top is the crushed suspensor and root tip (c); the two cotyledons and first leaf are shown; (s) indicates the stony layer of the seed, outside of which is the outer fleshy layer (a); (m) micropyle

Microcycas calocoma of Cuba differs from other cycads in having a large number of smaller archegonia situated over the surface of the gametophyte. Its pollen tubes differ also in giving rise to many sperms each, instead of the usual two.

The embryo of all cycads is formed from the repeated division of the zygotic nucleus. These early free-nuclear divisions and all stages before cell elongation has begun are usually included in what is called the proembryo stage. Nuclear divisions take place until there are from 500 to 1,000 free nuclei. Walls appear between the nuclei situated in the lower part of the archegonium and in some genera the entire egg may be blocked off into cell areas, but the growing meristem of the embryo is always confined to the lowest group of cells. The cells immediately above this meristem elongate to form a suspensor which. by elongating tremendously. thrusts the embryonic tip into the tissue of the gametophyte as the latter becomes the nutritive endosperm of the seed. This process is both mechanical and digestive. The embryonic structures secrete an enzyme which hollows out a cavity within the gametophyte while the suspensor, which becomes long and coiled, keeps the embryo pushed as far forward as possible.

FIG. 9.—DIOON EDULE

Seedling; (A) and (B) root tip is emerging and the root end is turning down; about two-thirds of the protruding part is cotyledon, with the root visible at the base. (C) later stage with three leaves between the cotyledons; (r), root; (s), cotyledons; half natural size

Since there are several eggs which may be fertilized. an embryo may begin to develop from more than one of them, a condition referred to as simple polyembryony. However the plural embryos are in intimate competition with each other. All save one are usually eliminated long before this embryo begins to form cotyledons and only a single embryo develops fully as the embryo of the seed.

Fig. 7 shows a tangle of suspensors originating from five fertilized eggs shown at the top. as they appear when dissected out about a month after fertilization. The largest embryo which has survived competition is shown at the tip and still is very small. Fig. 8 shows a similar seed at maturity. A single dicotyledonous embryo occupying a central position is surrounded by the endosperm (female gametophyte) and with the ovule wall, which now has a stony layer, forming the testa.

Fig. 9 shows a seed of ***Dioon*** *edule* in germination. Fig. 10 is a seedling with its first leaf expanded. The stem bearing this leaf and the scale leaves is still so small that it remains hidden while the primary root bearing secondary branches has become fleshy.

GINKGOALES

This order of gymnosperms has only a single living representative: ***Ginkgo*** bilobu, the maidenhair tree. It is native to China, although it has not been found forming native forests in any part of Asia. The tree is frequently cultivated in temperate regions, and in China it is usually found at temples and shrines, or under circumstances which could account for it as escaped from such cultivation.

According to Hui-Lin Li. ginkgo was unknown to the ancient Chinese and appears in the literature for the first time in the 11th century. Not only was it brought into cultivation. but it was introduced into poetry and painting, where it remains an important object of representation. This early interest in the plant stems from its edible seed and its ornamental qualities. The literary name of the seed, the fleshy outer layer of which has a waxy bloom. is Silver Apricot. From these beginnings the ginkgo spread rapidly to Japan and to the western world. Today it is one of the most highly valued street trees because of its resistance to smoke, disease, and insects. Only the staminate trees should be planted for the seeds produced by the ovulate trees have an oil in the fleshy coat with a most offensive smell. Horticultural varieties are now available which combine, in a staminate tree. predominantly upright, rather than spreading, habit and a rich golden color of the leaves before they fall in the autumn.

The habit and general appearance of ginkgo is that of a conifer. The wood is similar to that of conifers; its wedge-shaped leaves, which are not evergreen. have dichotomous veins that remind one of the leaflets of the maidenhair fern, though they are much larger. thicker and show considerable variability in size, shape and lobing. In winter the tree is not conspicuously different from the trees of many deciduous angiosperms. However, a closer examination of the twigs shows that these are long shoots bearing many dwarf branches. The long shoots continue the growth on the end of long shoots of the previous year, bearing leaves that alternate in a spiral arrangement. Along these twigs two or more years old are the dwarf branches, which originated from buds in the axils of the leaves of the first year's shoots. These spurs vary in length with their age. and bear groups of leaves terminally that arise from the bud at the tip in annual succession for many years. Occasionally, the dwarf branches give rise to long shoots growing out from their tips. Dwarf branches have a relatively thick cortex and large pith with the wood zone correspondingly narrowed. and taken as individual units they are comparable to a miniature cycad trunk with its terminal crown of leaves. It is on these dwarf branches that the reproductive structures are borne. and like all living cycads. the trees are strictly dioecious. Fig. 11 shows these branches with ovule-bearing stalks and pollen cones near the time of pollination when the new leaves appearing in the spring are half grown. The ovules are always paired though it is not usual that both ovules are developed; more frequently only one of the pair enlarges to develop fully (fig 11 C) The aborted ovule remains as a scar at the base of the enlarged seed.

The reproductive morphology differs only in minor details from that of cycads The pollen is borne in sporangial appendages of which there are many that make up the pollen cone Each appendage bedrs a pair of deflexed sporangia on the end of a short stalk as shonn in fig. 11 E The pollen grains. formed from spore mother cells as in cycads. also have double spore coats with several cells formed internally at the time of pollination. Likewise, the pollen is wind borne with the pollen falling into pollination droplets which appear at the micropyles of the ovules. The ovules enlarge and are soon full grown as represented by fig 12 which shows a longisection through a fully enlarged ovule near the time of fertilization, in A and a matured seed in B.

After fertilization. which is accomplished as in cycads by motile sperms the proembryo initiates its development in the same manner However. after about 250 free nuclei have been formed, cell walls appear between all of the nuclei so that the entire egg cavity is filled with cellular tissue. The cells of the lower part of the proembryo divide rapidly. while those near the upper part begin to elongate and push the embryo downward into the gametophyte (which becomes the endosperm of the seed), but usually not farther than one-third the length of this tissue before the seed is shed The seeds usually fall from the tree in autumn before they are fully matured and the soft. outer, fleshy seed coat soon develops a very putrid odour If planted, the seed will not germinate for many months but this delay is due only to the immaturity of the embryo. A small percentage of the seeds may contain two embryos matured to the stage with cotyledons, which may develop internally in ihe ginkgo seed with someuhat less close competition in their earliest stages than in cycads This is due to the fact that the smaller archegonia are slightly separated and long coiled suspensors are not formed. Nevertheless,

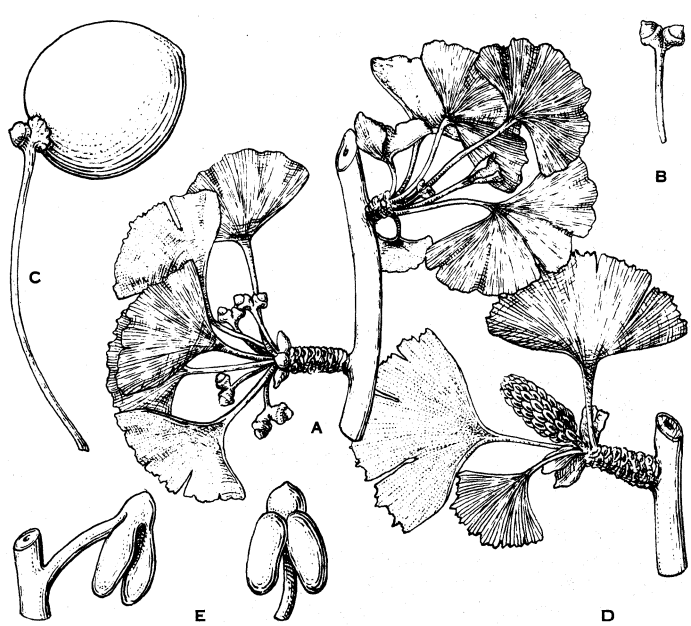

FIG. 11.—GINKGO BILOBA

the several embryos from simple polyembryony are usually eliminated; less than 2% of the ripe seeds contain more than a single embryo.

While the reproductive morphology of ginkgo has much in common with that of the cycads, they differ in other respects The stem anatomy aside from that of the spur shoots, is much

closer to that of the conifers; the long stems have relatively little pith, a narrow cortex and a very large volume of wood that grows rapidly from a cambium and forms distinct annual growth rings. In the spur branches the pith. wood zone and cortex are

proportioned more nearly as in a cycad trunk.

Ginkgo is regarded as a descendant of the Cordaitales (see PALAEOBOTANY; Plants of the Palaeozoic Era), to which it is linked by a series of many Mesozoic fossil forms—Baiera, *Ginkgoites*, etc.—found in widely scattered regions of North America, Europe and Asia.

TAXALES

The Taxales are a small order of gymnosperms usually included in the Coniferales. They are separated here since, according to the work of Rudolph Florin and others, the taxads proper have never had ovulate cones. That is, the ovules are borne terminally and singly on axes of the plant and are not aggregated into cone-like structures. Their evolutionary history can be traced back separately well into the Mesozoic. There are four or five genera recognized: *Taxus* (yew), Torreya (California nutmeg or stinking cedar), *Austrotaxus*, Amentotaxus, and Nothotaxus. All of them are shrubs or trees (rarely reaching a maximum height of go ft.).

The usually spirally arranged leaves are needlelike, but flat, fairly wide, and sharp pointed. The Upper Triassic genus *Paleotaxus* is similar to modern forms, and *Taxus* and Torreya extend hack to the Jurassic.

Taxus with about seven species is widely distributed in Europe, North Xmerica, eastern Asia and Asia Minor. It is the only member of economic significance, being extensively cultivated for ornament, having wood used for cabinetmaking. bows, etc., and having poisonous properties. Torreya has five or six species found in western Florida, California. China and Japan. while *Amentotaxus* has four species of subtropical regions of eastern Asia. *Austrotaxus* (Sew Caledonia) and Nothotaxus (eastern China! are monotypic.

Members of the Taxales are monoecious or often dioecious. The staminate cones are small and composed of a few peltate or radially symmetrical scales bearing several pollen sacs. The ovules are large and highly specialized and basically terminal. In *Taxus* there has been a relatively recent tendency toward aggregation of the ovules and thev are horne on reduced shoots and are sometimes crowded. The taxads have the ovules more or less enveloped in a so-called aril, a fleshy outgrowth from the axis. This may be bright red (as in the yews) or purple.

Development of both male and female gametophytes is specialized. The archegonia are often very small and may lack the ventral canal nucleus. Simple polyembryony prevails except in Torreya where cleavage polyembryony is retained.

GNETALES

These are perennial, normally dioecious plants with opposite simple leaves. The perianth of one or two whorls is distinctive, and sharply contrasts this division with other gymnosperms. The cones are more complex than in other forms, consisting of an axis bearing decussate pairs of bracts or a number of superposed whorls of bracts. each whorl connate in a cuplike form. In either case the ovulate or staminate structures, which for convenience we may call "flowers." are axillary to these bracts. The flower always consists of one or two pairs of free or connate scales, the perianth, enclosing either a single ovule with a long projecting micropylar tube, or from one to six stamens.

It is evident that it is the flowers of Gnetales, especially the ovulate flowers. which are equivalent to the cones of conifers (*e.g.*, compare the female cone of Torreya) and not the. whole "cone," which might well be called a compound cone, and which is also comparable to the catkinlike inflorescence of certain flowering plants.

The Gnetales are superficially similar to the angiosperms in their anatomy, for though the phloem remains typical of the gymnosperms in general, true vessels are associated with the typical gymnospermous tracheids and there are no resin canals. The tracheids have very large circular bordered pits and the vessels of Gnetales have evolved from them by the dissolution of the closing membrane of these pits. The cells. placed end to end. function as long tubes for the conduction of water. Vessels in the angiosperms have evolved from tracheids with an entirely different type of pitting and they are a completely independent acquisition.

The order Gnetales includes only three genera. which are so entirely different as to suggest that each should be regarded as the type of a different order. Perhaps such a taxonomic treatment would be preferable to that usually folloned; an intermediate course, recognizing each as the type of a family. will be followed here. The Gnetales, in the broad sense, have had only a very recent fossil history and the relationships of the plants are still imperfectly understood. It seems clear that none of the three can be regarded as ancestral to the flowering plants despite some interesting examples of convergent evolution. From the work of A. J. Eames there is considerable evidence that the Ephedraceae are related to the extinct Cordaitales; and there is some evidence that the other two families are not. Until the latter have been studied as thoroughly they are better lumped with the Ephedraceae in what is probably an unnatural order. The three families are characterized as follows:

The Ephedraceae includes only the genus Ephedra consisting of much branched. small-leaved xerophytic shrubs. The ovule has tn-o integuments containing a female gametophyte with archegonia. similar to that of the Coniferales.

Welwitschia is the only genus of the Welwitschiaceae and it contains a single species. The plants are large, tuberous and mostly underground. They develop only two enormously long and straggling parallel-veined leaves after the cotyledons. The ovule has one integument and no archegonia are formed.

The Gnetaceae are all put into the genus Gnetum and are either trees or large woody climbers with numerous net-veined leaves superficially indistinguishable from those of a dicotyledonous angiosperm. The ovule has two integuments and there are no archegonia in the female gametophyte.

Ephedra.—This largest genus of Gnetales has about 35 species, represented in America, Xsia and Europe. It is confined to more or less arid warm-temperature and tropical regions and one species is common on sand dunes along parts of the Mediterranean coast. The finer branches are green; the surface of the long internodes is marked by fine longitudinal ribs; and at the nodes are borne

pairs of small, partially connate scale leaves, the general appearance being similar to that of a stem of *Equisetum* or a twig of *Casuarina*. Some of the branches bear pairs of small cones in the axils of the scale leaves. The cone scales are broad and imbricate. Each staminate flower (fig. 13j consists of an inconspicuous perianth, composed of two more or less concrescent bracts. enclosing an axis projecting beyond the perianth and terminating in two (sometimes more. up to six or eight) sporangia. The resemblance of this structure to a stamen is obvious, but it is no less clearly homologous with the cone scale of conifers.

The ovulate flower is enveloped in a closely fitting perianth of two more or less connate bracts. as in the staminate flower. This perianth encloses a single ovule with two integuments, the inner, which is not more than two cells thick, prolonged upward as a beaklike micropyle, the outer. which is thicker and later becomes woody, only reaching about halfway up the micropylar beak. The micropyle secretes a pollination drop, as in conifers.

A prothallus is organized exactly as in conifers. the two to five archegonia being developed from separate superficial cells at the apex, and having long. multicellular necks. About the time when they first appear, the tip of the nucellus begins to break down, this disorganization proceeding downward until there is (when the archegonia are mature) a broad circular pollen chamber open to the top of the prothallus, thus permitting the pollen grains to rest on the necks of the archegonia. The development of the pollen grain is closely similar to that of *Larir* and it is shed in the five-nucleate condition.

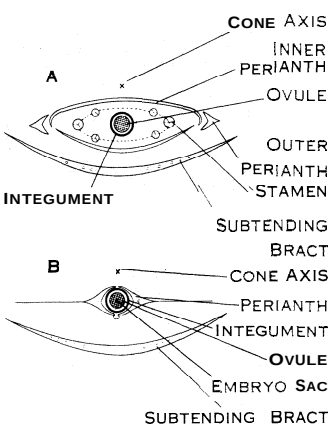
FROM ENGLER & PRANTL, "DIE NATURLICHEN PFLANZENFAMILIEN (ENGELMANN)

FIG. 13.—A STAMINATE FLOWER OF EPHEDRA FRAGILIS

Division of the body cell occurs immediately after pollination and the pollen tube forces its way between the neck cells and discharges its contents into the egg within a few hours. The fusion nucleus divides three times to form eight nuclei. some of which then become organized into walled cells, very loosely connected into a proembryo. Each of these cells. after division of its nucleus. elongates and cuts off a small embryonal cell containing one of the two nuclei, the larger cell remaining, the suspensor. elongating rapidly to thrust the embryo cell deep into the prothallus tissue. The embryo cell divides to form an ovoid mass of cells of which those next to the suspensor elongate in succession giving rise to embryonal tubes which add to the length of the suspensor. The whole process is strongly reminiscent of what takes place in *Actinostrobus* among the conifers where cleavage polyembryony prevails.

Welwitschia.—*W. mirabilis* is the only species of this remarkable genus and is found in two isolated and restricted areas of the coastal desert region of Damaraland in South-West Africa. It is by far the most remarkable member of the Gnetales not only in its habit but also both in the form of its flowers and the details of its development. Knowledge of these details is largely due to investigations carried out by H. H. W. Pearson.

An adult plant has somewhat the form of a gigantic radish 2 to 4 ft. in diameter, projecting less than 1 ft. above the ground, and terminating in a long taproot below. The two strap-shaped leaves trail along the ground to a length of 10 ft. or more, and become split into a number of narrow thonglike strips. They retain the power of growth at the base throughout the life of the plant which probably exceeds 100 years. The characteristics of the plant accord well with the interesting suggestion that it may represent an "adult seedling." Numerous circular pits occur on the concentric ridges of the depressed and wrinkled crown, marking the positions of former inflorescences, new ridges subsequently appearing outside the old ones. The inflorescences have the form of dichasially branched stalks bearing the cones, from 1 to 20 in the ovulate plant and up to 50 in the staminate. The ovulate cone is about ▮ in. long and scarlet in colour, the staminate smaller and more slender. Each consists of an axis bearing a large number of alternating pairs of overlapping bracts. in the axils of nhich are the flowers. The staminate flower (fig. 14 A) is enclosed by a perianth of two opposite pairs of bracts, surrounding a ring of six stamens united below but free above and each terminating in a trilocular anther. In the centre of the flower is an abortive ovule the integument of which projects upward as a spirally twisted tube with a stigmalike expansion at its apex. In the development of the pollen grain, a single prothallial nucleus is cut off. which disappears again about the time of pollination. There are only two further divisions resulting in a tube nucleus and two male nuclei, the formation of a stalk cell which occurs without exception in all conifers, as well as in *Ephedra*, being omitted. There is evidence that pollination is effected by insect agency. The ovulate flower consists of an erect ovule with two investments of which the outer is winged and represents the perianth, formed of a pair of completely connate bracts, the inner being the integument which has the usual long tubular micropyle (fig. 14 B). No pollen chamber is formed, but numerous pollen tubes grow downward in the nucellar cap. The spore begins to develop as usual, becoming filled with protoplasm containing over 1,000 nuclei before walls appear. The latter divide the whole sac into multinucleate compartments, those in the micropylar end containing fewer and larger nuclei! any of which may function as eggs. The remainder contain about a dozen nuclei each, all of which fuse together in the compartment, thus forming a tissue of uninucleate cells which then grows considerably and may be termed the endosperm.



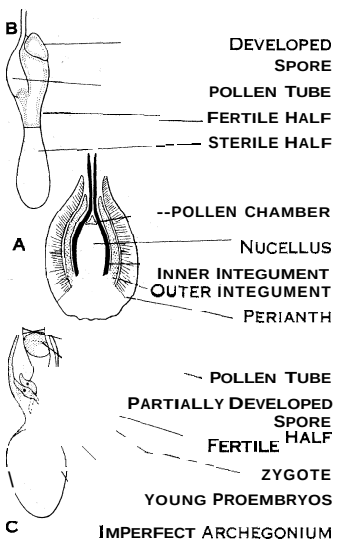
FROM H. H. W. PEARSON, IN THE "PROCEEDINGS OF THE ROYAL SOCIETY"

FIG. 14.— WELWITSCHIA
Cross section of floral structures. (A) staminate flower; (B) ovulate flower

The rnicropylar multinucleate cells put out long tubes which grow upward into the nucellar cap, and into which the egg nuclei pass. These ascending prothallial tubes meet, and fuse with the descending pollen tubes and at the point of fusion, fertilization occurs.

The fertilized egg forms a wall and elongates into a tube from which an embryo tip cell is cut off, the remainder of the tube being the suspensor which carries the embryo deep into the endosperm. Thus it appears that only a single embryo is produced from each zygote. in contrast with cleavage polyembryony in *Ephedra*. The further development is similar to that in *Ephedra*, including the formation of embryonal tubes from the young embryo

Gnetum.—This is represented by about 30 species, mostly climbers. found both in tropical America and in tropical regions of the old world. The oval leaves are 2 or 3 in long and are borne in pairs at the swollen nodes. The cones are long and cylindrical and bear uhorls of flowers at each node, accompanied by numerous sterile hairs. in the axil of cuplike concrescent bracts. In a staminate inflorescence very numerous flowers may be found, up to about 3,000 in one species, while in an- ovulate spike the number of flowers probably does not reach 100. The staminate flower consists of a perianth of



AFTER LOTSY IN THE "ANNALS DU JARDIN BOTANIQUE DE BINTENZORG" (E J BRILL)

FIG 15.—GNETUM GNEMON
(A) longitudinal section of ovulate flower; (B) prothallus at time of fertilization; (C) prothallus after fertilization

two concrescent bracts enclosing a slender axis projecting above the perianth and terminating in two sporangia. The pollen appears to be formed in precisely the same manner as that of *Welwitschia.* Incomplete ovulate flowers are often found in the staminate inflorescence containing ovules with one integument instead of two, but these rarely set seed.

A perfect ovulate flower (fig. 1j) consists of an ovule with three investments of which the outer is generally regarded as a perianth of two concrescent bracts. Of the other two the inner arises first and develops the long slender micropylar tube characteristic of all Gnetales and is followed by a much shorter outer covering. the outer integument.

Several spores may begin to develop in a young ovule. but only one attains full size. In all species the embryo sac, as in *Welwitschia,* becomes filled with numerous free nuclei, and in some species. probably in the large majority. fertilization occurs at this stage, the contents of pollen tubes being discharged into the embryo sac. any of the nuclei near the micropylar end apparently functioning as eggs. The lower half of the sac then becomes partitioned (as in *Welwitschia*) into multinucleate "cells," the nuclei of each cell subsequently fusing so that an endosperm of uninucleate cells results, into which the developing embryos penetrate.

Each zygote of *Gnetum gnemon* is stated to elongate and form a long tortuous multinucleate suspensor, from the lower end of which a small, also multinucleate, embryo cell is cut off. Walls are said to appear in this "cell" and so reduce it to a tissue of uninucleate cells.

While this account may not apply to all species of *Gnetum,* it is surprising to find certain resemblances to the embryogeny of some Cupressaceae, notably *Juniperus,* in which suspensor-embryo initial cells give rise to embryos in a specialized type of cleavage polyembryony.

The later development of the embryo is similar to that of *Welwitschia,* and in both genera a rodlike outgrowth is formed from the hypocotyl at its junction with the radicle. which serves as a feeder and draws nourishment from the endosperm during the germination of the seed.

The climbing species of *Gnetum* are characterized by the production of several concentric cylinders of wood and bast from as many successively formed cambium cylinders produced in the pericycle, as in *Cycas.* (J. T. Bz.; W. T. Sa.; R. W. H.; X.)

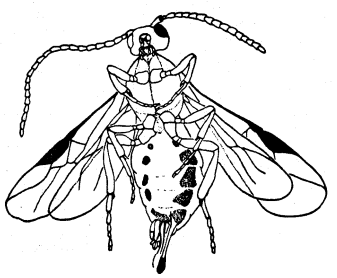
GYMPIE, a town of March shire. Queensland. Australia. 107 mi N. of Brisbane and 61 mi. S. of Maryborough by rail. Pop. (1954) 9.964. Gold was discovered by James Nash in 186; and mining continued up to 1930. The total gold yield was 4 500 000 oz.

Gympie became a municipality in 1880 and a city in 1905. The district is now one of the state's best dairying, agricultural and fruit-grot! ing areas.

GYNANDROMORPH (Gynander), a zoological term denoting an organism in which the body is of fundamentally different cunstitution in different regions. male in some, female in others, the areas being quite clearly demarked.

A hermaphrodite (*q.v.*) or an intersex may likewise show male characteristics in some parts of its body, female characteristics in others, but its mosaicism is only apparent. Fundamentally all parts are of the same sex.

Gynanders are reported in many invertebrates, especially in insects. In certain butterflies in which there is extreme sex difference in colour and wing form, they are very striking in appearance. In the fruit fly *Drosophila,* the genetic conditions of the formation of gynanders have been analyzed by use of mutant traits. In this fly most gynanders begin development as females with two sex chromosomes. One of these chromosomes is lost from a cell giving rise to part of the body, thus resulting in a patch of male tissue which may be large or small according to whether the loss occurred early or late in development. In other cases certain mutant genes cause elimination of a sex chromosome in many minute regions of the body surface. resulting in a gynander that is mostly female with many small male spots. Recessive mutant traits carried by the sex chromosomes supplement secondary sex characters in making the gynanders very conspicuous by their asymmetry in colour or form.



GYNANDER OF PARASITIC WASP HABROBRACON

Ventral view (X9); note the shorter antenna, the heavier structure of the abdomen and the elongate sting or ovipositor on the female side (right). The mother of this specimen had the mutant trait white eyes, shown on the fatherless male side. The dominant paternal black eye colour is visible on the female side

Many gynanders are reported in ants, bees and wasps, but some of these are undoubtedly intersexes. The genetic method of use of mutant traits has been employed in investigations with the parasitic wasp *Habrobracon.* Here the female parts are biparental, derived from a fertilized nucleus, while the male parts develop parthenogenetically (without fertilization) from a second egg nucleus or, much more rarely, from a second sperm nucleus.

Male regions of gynanders may be completely separated from female, as left *v.* right or anterior *v.* posterior. There may be one or more male islands in the female region or the reverse, or there may be considerable intermixture. These differences depend primarily upon chance distribution of the two types of nuclei in the insect egg preceding the formation of cells in the early embryo.

Reproductive reactions, mating, egg laying, etc., in the wasp *Habrobracon* have been shown to depend upon the sex type of certain regions of the head.

Tendency toward formation of gynanders is hereditary. Extensive breeding work with certain species of moths (*e.g.,* gypsy moth) has failed to reveal more than one or two gynandric individuals, while in other species (beeswax moth, silkworm moth) gynanders are frequent, especially in certain stocks. In moths both nuclei of the binucleate eggs must be fertilized in order that a gynander may develop.

In vertebrates there have been many reports of gynanders, but the cases are doubtful. In certain species of birds (pheasants and finches) in which the males differ strikingly from the females in form and colour of ieathers, a few apparent sex mosaics have been found, with male plumage on one side, female on the other. It has been suggested that a critical difference in rate of growth between the tno sides of the body resulting in a threshold effect may account for this condition.

Such birds would then be intersexes or hermaphrodites rather than gynanders. It is, nevertheless, possible that gynandrism may occur in vertebrates with its influence masked by sex hormones circulating in the blood. This would produce apparent symmetry of development despite a fundamental asymmetry of sex mosaicism.

See Sex.

GYNECOLOGY is that branch of medicine which deals primarily with disorders of the female reproductive tract. The practice of gynecology requires skill in surgery, especially pelvic surgery; in obstetrics; in female urologic conditions, because the symptoms of diseases of the urinary tract and the genital tract are often similar; in endocrinology as it applies to gynecology; in gynecological pathology; and in dealing with minor psychiatric problems which commonly arise among gynecologic patients.

The anatomy and physiology of the female genital tract are discussed in the article REPRODUCTIVE SYSTEM. PREGNANCY and CHILDBIRTH are dealt with in those articles.

HISTORY

Gynecology is an ancient branch of medicine. The Papyrus Ebers, one of the oldest known works on medicine (1550 B.C.), contains reference to diseases of women, and it is recorded that specialism in this branch was known among Egyptian medical practitioners. The Vedas contain a list of therapeutic agents used in the treatment of gynecological diseases. The treatises on gynecology formerly attributed to Hippocrates (460 B.C.) are now said to be spurious, but the wording of the famous oath shows that he was at least familiar with the use of gynecological instruments. Writers of the Greco-Roman period of medicine who treated of this branch are Celsus, Soranus of Ephesus and Galen. It is evident that during this period much gynecological work was in the hands of female healers. Martial (Marcus Valerius Martialis) refers to these *feminae medicae* in his epigram on Leda. These women must not be confused with the midwives, who are always described as obstetrices. Throughout the Byzantine and medieval periods of medicine, which comprise a period of more than 1,000 years, gynecology shared in the general sterility and even decadence which accompanied medical and all other branches of scientific learning; such writers on gynecology as Oribasius (A.D. *c.* 325–*c.* 400) were mere compilers of the work of their predecessors. and practice was bound by ancient authority and tradition. The growth of interest in diseases of women during the Renaissance is shown in the huge "Gynecia" or encyclopaedia of gynecology issued by Caspar Wolf of Zurich in 1566. In the 17th century what has been described as the first work on operative gynecology in the modern sense was written by Hendrik van Roonhuze; it contains case reports on extrauterine pregnancy and rupture of the uterus and the description of a scientific operation for vesicovaginal fistula.

Among contributions to gynecology in the 18th century are William Hunter's proposal for excision of ovarian cyst and his description of retroversion of the uterus; Robert Houston's treatment of ovarian cysts by tapping; Matthew Baillie's description of dermoid cysts of the ovary; and John Bard's removal of an extrauterine pregnancy.

Operative gynecology, as an independent specialty, had no real existence until the first half of the 19th century. Its founders may be said to be Ephraim McDowell (1771–1830) of Kentucky and James Marion Sims (1813–83) of South Carolina. McDowell performed the first ovariotomy (removal of an ovarian cyst by abdominal section) in 1809 in Kentucky. Sims was a great surgical genius whose fame quickly spread over the whole civilized world because of his success in curing vesicovaginal fistula. Gradually in the medical centres of the world surgeons and obstetricians undertook a limited variety of gynecological operations. Outstanding among these pioneers were Thomas A. Emmet (1828–1919), plastic gynecologic surgery; Robert Battey (1828–95), removal of both ovaries; the brothers, John L. Atlee (1799–1885) and Washington L. Atlee (1808–78), removal of fibroids; Charles Clay (1801–93) and Sir Thomas Spencer Wells (1818–97), oophorectomy; Sir James Y. Simpson (1811–70), the uterine sound; Robert Lawson Tait (1845–99), salpingectomy ; Joseph Récamier (1774–1852), revival of speculum examination. It must be remembered that all these pioneers had to combat the violent prejudice of the public against any exposure or examination of the female organs. This prejudice, fostered at first by midwives, was supported by the clergy and by many members of the medical profession.

The two great advances which finally and in spite of vigorous opposition made all surgery generally available were anesthesia and antisepsis.

DISORDERS OF THE FEMALE REPRODUCTIVE TRACT

CONGENITAL ABNORMALITIES

Congenital abnormalities of the female reproductive tract are relatively rare. Among these abnormalities is absence of the vagina which may be complete or partial. In either case, the uterus may or may not also be absent. In most instances the uterus is absent, but the ovaries are present and the patient is completely feminine, with all the secondary sexual characteristics. When the uterus is present and the vagina partially or completely absent, there is no egress for the menstrual blood. which is retained within the uterus or an upper compartment of the vagina and often regresses through the tubes and into the peritoneal cavity. Complete absence of the vagina may be corrected by forming surgically, lining it with a skin graft from the thigh; such vaginas usually function well.

Septate vagina, with a tissue partition, is commoner than absent vagina. Such a double vagina may give no trouble, and the patient may be unaware of its presence. If it bothers the patient at intercourse, the septum may be excised easily.

Underdevelopment of the uterus may exist in all degrees, to the point of complete absence. Small uteri, two-thirds to one-half normal size, are not uncommon. Underdevelopment of the uterus is sometimes associated with infantile external genitalia and breasts, but in many cases the other genital organs are normal.

Double uterus is the result of failure of complete fusion of the bilateral Mullerian ducts which are present in the embryo. These are cordlike masses of tissue from which the tubes, uterus and vagina are formed. In the normal fetus the lower portions of these ducts unite to form the vagina and uterus; the upper ends, which do not fuse, form the two Fallopian tubes. When union fails completely, there results a double vagina and double uterus. All degrees of failure are encountered; thus the uterus may be completely double (didelphic) or partially united (bicornuate). Women with these abnormalities usually have great difficulty in carrying a fetus to term. Unification of the double uterus may be carried out by surgery, after which successful pregnancy may occur.

See also HERMAPHRODITE; GONADS, DISORDER OF.

COMMON DISORDERS OF MENSTRUATION

Amenorrhea.—Amenorrhea, or absent menstruation, occurs physiologically prior to puberty, with pregnancy, during lactation and at the menopause. Amenorrhea also occurs with absent uterus. When the uterus is present and the vagina completely or partially absent, there is no visible evidence of menstruation but hidden menstruation actually, occurs (cryptomenstruation). Hidden menstruation also occurs when the hymen is imperforate. At the start of menstrual life there may be long periods of amenorrhea before the regular monthly tempo is established. Likewise, in the late 40s, before menstruation ceases, there are often lapses of menstruation for variable periods of time (see MENOPAUSE). Constitutional causes of amenorrhea are undernutrition and severe illnesses such as tuberculosis and typhoid fever. Mental depressions are also frequently associated with a cessation of menstruation. Periods sometimes cease for months and even years when there is no demonstrable cause, in such cases, the cause must be ascribed to an endocrine disorder. In some such cases the endocrine disorder can be recognized (thyroid or adrenal disease), but in others the primary cause is thought to be malfunction of the pituitary.

Hypermenorrhea. — Hypermenorrhea or menorrhagia, is excessive bleeding at the time of the menstrual period. The flow of blood may be extremely profuse, prolonged or both. Menorrhagia may be a symptom of organic disease or may be simply functional, without any demonstrable cause. The commonest organic condition causing excessive bleeding is uterine fibromyoma (see Tu*mours,* below). When fibromyomas grow into the uterine cavity, they also may cause intermenstrual bleeding. Cancer of the cervix or the body of the uterus rarely manifests itself by excessive bleed-

ing at the periods. Functional uterine bleeding, in which there is no demonstrable organic disease, often manifests itself by menorrhagia, although it can also cause intermenstrual bleeding.

Metrorrhagia.—Bleeding between the periods may be an indication of organic or functional disease. Cancer of the cervix or body of the uterus in a premenopausal woman usually manifests itself by intermenstrual bleeding, which is thus more diagnostic of malignancy than is excessive bleeding at the time of the period. Intermenstrual bleeding. though not prima facie evidence of malignancy—often benign disease (as cervical polyp) manifests itself thus—always demands thorough investigation of the cause.

Dysmenorrhea. — Painful menstruation is present to some degree in a high percentage of menstruating women. The exact percentage is impossible to state, for it is difficult to determine just how much discomfort is required to be considered dysmenorrhea. Some women are truly incapacitated with real physical pain; others may complain bitterly when there probably is only slight discomfort. A small percentage of women have no discomfort whatever at menstruation, and an even smaller number state that they feel better at the time of menstruation than at any other time of the month. Causes of real menstrual pain are varied; among them are endometriosis (*see* below), salpingitis, myomata, cervical canal obstruction and, in some instances, retrodisplacement of the uterus, In the majority of cases of dysmenorrhea, however, the pelvic organs are anatomically normal, and the real cause of the pain is not known. There is undoubtedly often a great psychic factor. Cervical dilatation relieves the pain in cases of congenital or acquired obstruction in the cervical canal. Childbearing, which dilates the cervical canal better than is possible surgically, cures more cases of dysmenorrhea than all other procedures combined. In severe cases, the sensory nerves of the uterus may be cut surgically. Very rarely, hysterectomy is performed for severe dysmenorrhea in women past the age when childbearing is desired or feasible. When organic disease is present, surgery is indicated if the symptoms are sufficiently severe. In most cases, nonhabit-forming pain-relieving drugs are sufficient to give relief.

See also MENSTRUATION.

TUBAL (ECTOPIC, EXTRAUTERINE) PREGNANCY

Union of sperm and ovum normally takes place in the tube. If, for some reason, the migration of the fertilized ovum down the tube to the uterus is interfered with, the embryo develops within the tube. Previous inflammation within the tube (salpingitis), causing adhesions and partial blockage of the passage way, is the commonest cause, but many cases of tubal pregnancy occur in tubes in which there has been no previous infection; congenital abnormality of development may be responsible. The conditions under which the embryo develops within the tube are not so favourable to normal growth as those within the uterus, and for that reason the embryo is often cast from its site into the tube; or, as the embryo grows, the thin-walled tube is stretched and ruptures. Either of these eventualities results in hemorrhage from the tube into the abdominal cavity, with sudden severe pain and often with fainting from pain or loss of blood. The treatment is immediate surgery, the operation usually consisting of simple removal of the tube. Very rarely tubal pregnancies go to term, but the chances of this are so slight that the gnyecologist is not justified in gambling on the possibility.

ENDOMETRIOSIS

Endometriosis is a condition in which the uterine mucosa (endometrium) grows in places other than its normal habitat within the uterine cavity; no other benign tissue possesses this ability to invade other tissues. Understanding of the mechanism whereby endometrium is transported to these abnormal sites is not completely understood.

Endometriosis is of two types, internal and external. In internal endometriosis the endometrial tissue grows within the musculature of the uterus itself. Minor degrees of internal endometriosis occur frequently without symptoms, but when the condition is more extensive it may be responsible for excessive and painful menstruation. If the symptoms are sufficiently severe it can be cured by hysterectomy.

Of much greater clinical importance is external endometriosis, in which the endometrium grows outside the uterus, on and in various pelvic structures. Endometrium growing between the rectum and vagina was first described in 1897, and it was first discovered in an ovary in 1899. Since then it has been found on all the organs in the lower abdomen, and more rarely, at the umbilicus and in the vagina and vulva. As the uterine endometrium goes through a monthly cycle under the influence of the ovary, so do these bits of endometrium growing outside the uterus, and at menstrual periods they bleed, causing severe pain in some women. The sudden occurrence of menstrual pain or aggravation of menstrual pain in a woman in her 20s or 30s should always arouse a suspicion of endometriosis (although, of course. there are several other possible causes). The sterility rate is high in women with this condition.

J. A. Sampson in 1921 began a series of publications which made physicians aware of this disease. He also brought forth his theory of retrograde menstruation as its cause, suggesting that the particles of endometrium cast off at the time of menstruation. instead of going down through the cervical canal and into the vagina, might go out through the Fallopian tubes in a retrograde manner, then grow within the abdomen and be further disseminated. Sampson's ideas were objected to by some who believed that endometriosis was the result of morphological changes in the pelvic peritoneum; they contended that the particles of endometrium cast off with the menstrual blood were dead and incapable of growth. In 1950 R. W. TeLinde and R. B. Scott produced endometriosis in monkeys by surgical rearrangement of the uterus so that the monkeys menstruated directly into the peritoneal cavity. By this method they established the fact that the particles of endometrium as cast off at menstruation are capable of growth, thus greatly strengthening Sampson's theory.

Endometriosis that produces no symptoms requires no treatment, since the growth is benign. When treatment is required for the relief of pain or sterility, surgery may be conservative or radical, depending upon the age of the patient, her desire for further children, and the extent of the disease process. Many women have been relieved of their symptoms by conservative surgery and thereafter have borne children. In some instances, however, hysterectomy and removal of both ovaries is necessary. Endometrium in these abnormal positions, as in the uterus, requires the ovarian hormone estrogen for its growth, and removal of ovarian function by menopause, surgery or irradiation stops the progress of the growth.

INFECTION

Infections of the reproductive organs may be divided into two groups: those affecting the upper tract (the body of the uterus. the tubes and ovaries) and those affecting the lower tract (cervix, vagina and vulva). Upper tract infections are principally of three types: gonorrheal, puerperal and tuberculous. The incidence is in the order named.

Gonorrhea. — Gonorrhea1 infections result from sexual intercourse with an infected male. The lower tract is infected first, and the infection may remain there. In a certain percentage of cases, the infection spreads upward, involving first the uterine cavity and then the tubes. Gonococcal inflammation of the tubes (salpingitis) may be of varying degree: sometimes it is slight, leaving the tubes with very little damage; in other instances. the entire tube may become distended with pus (pyosalpinx). Such tubes usually become sealed off, and the patient is permanently sterilized. Gonococcal salpingitis is not the serious condition it once was. If recognized and treated early, the progress of the inflammation may be stopped and healing take place. The sulfonamide drugs were the first to prove effective against the gonococcus, and penicillin is even more so, penicillin therapy greatly reducing the percentage of cases in which surgical removal of the tubes is necessary. The ovaries, lying in close proximity to the tubes, are often involved in the inflammatory process. (*See* also VENEREAL DISEASES.)

Puerperal Infections. — These occur at childbirth or as a result of abortion. Use of antibiotics has greatly redured their in-

cidence. The usual infecting agent is the streptococcus, although other organisms may be involved. Puerperal infections are less likely than gonococcal infections to close the tubes and thus sterilize the patient; also surgery is less often necessary.

Tuberculosis. — Tuberculous infection of the pelvic organs almost always takes place through the blood stream rather than by way of the vagina, as in gonococcal and streptococcal infections. The blood stream is infected from a distant part of the body, usually the chest. The Fallopian tubes are generally the first organs involved in the pelvis, but in many cases the uterus and ovaries are also affected. Formerly, surgical removal of the involved organs was the only treatment, but in modern times the antituberculosis drugs are used in conjunction with surgery and in some instances are able to conquer the disease alone. (See also TUBERCULOSIS.)

Lower Tract Infections. — In the lower generative tract, the cervix, Bartholin glands and urethra may be infected by the gonococcus. Vigorous penicillin therapy helps prevent the spread of the disease into the uterus and tubes, where such infection is of more serious consequence. Gonococcal infection of the vaginal wall does not occur in adults, but it may be found in prepubertal girls. Nongonorrheal infection of the cervix is one of the commonest gynecological conditions. Many of these infections gain entrance to the cervix at the time of delivery, when the cervix is torn and the open wound is exposed to the bacteria which are ever present in the vagina. The cervix also may be infected in women who have never had children and even in virginal women. The infection has a tendency to irritate the mucus glands of the cervix and cause them to secrete an excess of mucus mixed with pus. This vaginal secretion, leukorrhea, is one of the commonest complaints of women. Often douching is sufficient to keep the woman comfortable; in severe cases eradication of the infected glands by cautery usually results in cure.

The vagina and vulva of adult women are frequently infected by Trichomonas vaginalis and by yeast, which may give rise to an irritating discharge that is often quite resistant to treatment. These infections are not venereal in origin, and they are of little consequence except for the annoying discharge.

TUMOURS

Vulva. — Benign growths of the vulva are rare. Fatty tumours and fibrous tumours occasionally attain such size as to inconvenience the patient and require removal. The only growth of importance in this region is cancer, which may arise in the skin or mucosa of the vulva; this is rare, however, representing only about 3% of the malignancies of the pelvic organs. It makes its appearance as a small lump or ulcer. usually in elderly women. The treatment is radical excision of the entire vulva, together with the lymph nodes in the groin.

Vagina. — Primary tumours of the vagina, either benign or malignant, are exceedingly rare. Benign fibromyomas and polyps are so unusual as to be almost curiosities. Primary cancer of the vagina, much less common than that of the vulva, usually becomes manifest by the appearance of a bloody discharge. Because of the proximity to the bladder and rectum, treatment by surgery or irradiation is difficult. For the most part irradiation treatment is used; there is a small rate of cure.

Cervix. — The cervix is commonly the site of small benign polyps. These small tumours appear as reddish, tonguelike growths projecting from the cervical canal. They commonly cause bleeding between the periods or, in older women, after the menopause. These small growths can usually be safely removed in the physician's office. They should be examined pathologically, but malignant change in them is exceedingly rare.

Cancer of the cervix is the second commonest malignancy in women, being exceeded in frequency only by breast cancer. It is most often a disease of middle life, the age of maximum occurrence being 48 years, but it is not uncommon in the 30s and not at all rare after the menopause. For unknown reasons it is extremely rare in Jewish women; it has been suggested that this is due to ritual circumcision of the males, but other peoples who practise circumcision regularly do not share this immunity. It is also rare in nuns, suggesting that infections in the cervix due to sexual contact may be a factor in the subsequent development of cancer.

The symptom of cervical cancer which should cause the woman to consult a gynecologist is bleeding, which in the premenopausal woman usually takes the form of spotting between periods. During the menopausal years any abnormal bleeding should arouse suspicion. It is true that bleeding at this time of life is more likely to be of benign origin but it is also true that the menopausal years are the years of the greatest incidence of cervical cancer. In a woman who has not menstruated for a year or more, the sight of even a small amount of blood from the vagina should arouse a suspicion of cervical cancer. Though the initial symptom of cervical cancer is usually slight bleeding, as the disease advances the bleeding may become profuse and the patient very anemic. Most, but not all, cases of cervical cancer are curable when the bleeding first appears. Late in the course of the disease, the signs and symptoms of advanced malignancy — anemia, loss of weight, weakness and pain — appear.

Cervical cancer has been classified into four stages, according to the extent of the growth. This was first done by the League of Nations, and Iater the classification was modified by an international committee of gynecologists, which to the original four stages added a stage zero, indicating preinvasive cancer. In this stage the individual cells which are involved have the typical appearance of the cells of invasive cancer, but they are found on the surface of the cervix and have not invaded the underlying tissue. It now appears quite certain that many invasive cervical cancers begin as the preinvasive condition, remaining on the surface for many years before invading the tissues. In the preinvasive stage, cervical cancer is almost 100% curable. If it could be detected in this stage in all women, invasive cancer could practically be eliminated, and there would be few if any deaths from cervical cancer.

Early detection of cervical cancer depends in great measure on the detection of cancer cells in the vaginal secretions. After the work of G. N. Papanicolaou and H. F. Traut, published in 1943, on the diagnosis of uterine cancer by the study of individual cells, there was an ever-increasing interest in this subject. Cytological examination of the vaginal secretions is a remarkably accurate diagnostic measure for early cervical cancer, the percentage of error in good laboratories being less than 1%. It is less accurate in diagnosing cancer of the body of the uterus, but many cases of cancer of this type are first suspected by this procedure. Diagnosis of cervical cancer is confirmed by curettage or cervical biopsy, or both. Not until the exact origin, location and extent of the malignant tissue are ascertained should definitive treatment be carried out.

Treatment of cervical cancer is not standardized. In early days the lesions were cauterized, with little success. E. Wertheim made popular a radical type of hysterectomy, but even after this over three-fourths of the women with cervical cancer died of the disease; also the Wertheim operation had a mortality rate, even in good hands, of about 10%. Soon after the discovery of radium cervical cancer was treated by it. Many early cases and a few advanced cases mere cured; in most cases, there was at least temporary alleviation. With the addition of deep X-ray therapy the number of five-year cures has increased until about 50% of properly treated cervical cancer patients remain well for at least five years. There is general agreement that advanced cervical cancer is best treated with irradiation, but there is no such uniformity of opinion regarding the treatment of the disease in stage I (limited to the cervix). Notable among the surgeons who have revived and modified the radical surgical approach is J. Meigs of Boston, Mass., whose five-year cure rate in selected cases equals that of the better clinics where irradiation is used as the primary treatment. In cancer limited entirely to the cervix. the five-year salvage by surgery or irradiation in the better clinics ranges from 70% to 80%. Most gynecologists are agreed that in stage O (preinvasive) the treatment of choice is hysterectomy; cures in this stage approach 100%.

Corpus Uteri. — There are only two tumours of the body of the uterus sufficiently common to warrant mention.

Fibromyoma.—Fibromyomas, commonly called myomas or fibroids, of the uterus are the commonest tumours in the female genital tract; in fact, they are the commonest tumours in women. Fibromyomas vary in size from pinhead to enormous tumours of 50 lb. or more. They are usually multiple but may occur singly. They are benign, but very rarely malignant change takes place in them. The incidence of malignant change in a large series removed at the Mayo clinic, Rochester, Minn., was 0.7%, and the incidence based on all existing tumours is much smaller than that. Fibroids grow under the influence of the ovarian secretion, estrogen. After the menopause, when the ovaries no longer secrete estrogen, fibroids fail to grow and usually shrink, sometimes to the point of disappearing completely. When they do grow after the menopause, it is almost a sure sign of malignant change.

Since fibroids are benign growths, they do not require removal unless they give rise to symptoms. A large proportion of them never do this. and the woman would be unconscious of their existence if she were not told of their presence by a physician. The symptoms for which removal is indicated are: (1) excessive bleeding, usually at the time of menstruation; (2) pain from pressure of large tumours; (3) symptoms of pressure on other organs (such as the bladder, causing frequency of urination); (4) distortion of the abdomen due to the large size of the tumour; (5) history of miscarriages for which, after proper endocrinological studies, it seems likely that the fibroids are responsible; (6) rapid growth or any growth after the menopause, which may indicate malignant change.

Treatment consists of removal of the tumour (or tumours) or hysterectomy. In young women who wish to have more children it is desirable and sometimes possible to remove the tumours and save the uterus (myomectomy). Since childbearing is usually past or has been found impossible in the late 30s or 40s when these tumours commonly occur. the usual treatment is hysterectomy. Total hysterectomy is preferable, for removal of the cervix is prophylaxis against cervical cancer. In selected cases in women approaching the menopause, successful treatment of small tumours can be carried out by radium implanted within the uterine cavity for a short time, or by X-ray therapy.

Carcinoma.—The malignant tumour occurring in the body of the uterus is carcinoma, which arises in the endometrium. It is less common than cervical cancer, the average ratio of uterine carcinoma to cervical cancer being 1 to 5 or 6. Carcinoma of the corpus uteri is essentially a disease of the postmenopausal years. The average age of occurrence is 58 years, approximately a decade later than that of cervical cancer; it may occur before the menopause, but its appearance in the 30s is rare. The commonest symptom is vaginal bleeding after the menopause. Often this is not profuse and is described by the patient as "spotting." Sometimes there occurs a watery discharge which contains too little blood to be recognized by the patient. When the disease occurs before the menopause. bleeding takes place between periods. The appearance of vaginal blood a year or more after the menopause is an indication for curettage without delay.

Treatment in most clinics is the administration of radium within the uterine cavity, followed by total hysterectomy and removal of both tubes and ovaries five to six weeks later. In a few clinics, the value of preoperative irradiation is questioned, and hysterectomy is done without the application of radium. Reports of five-year "cures" vary widely, salvage rates ranging from 50% to 90% being reported; the rate of cure exceeds that of cervical cancer by a fairly wide margin. In a few patients of very advanced age the risk of operation is greater than seems justifiable, and irradiation alone is used; salvage in these cases is about half that obtained by irradiation combined with surgery.

Ovaries.—Ovarian tumours, benign and malignant, are common in occurrence. They vary greatly in size; in former days tumours up to 100 lb. were reported, and though they seldom attain that size today, because surgical help is called for earlier, tumours of 15 to 20 lb. still are occasionally seen. Benign ovarian tumours are fortunately commoner than malignant ones. Ovarian tumours may be benign for years and secondarily become malignant, but it is probable that most ovarian cancers start as malignant growths. Unfortunately, ovarian tumours are generally silent growers until they get so large that they cause distortion of the abdomen or pressure symptoms. If the tumour is malignant this usually means that the condition is incurable. Both benign and malignant ovarian tumours may occur at any age, but in general the chances of malignancy are greater in advanced age. Of special interest are ovarian tumours which secrete hormones. Certain tumours secrete an excess of the feminizing hormone, estrogen, and when these occur in young children they cause precocious sexual development; in postmenopausal women they may cause uterine bleeding resembling a recurrence of menstruation. Ovarian tumours which secrete the male hormone, androgen, cause masculinizing changes, such as deepening of the voice and excessive growth of hair.

Treatment of ovarian tumours varies with the type of tumour and the age of the patient. Malignant tumours require removal of both ovaries, the tubes and the uterus, regardless of age. In some instances, such surgery is followed by deep X-ray therapy. When dealing with benign unilateral tumours in young women, it is usually sufficient to remove only the ovary involved, usually with the tube. In women past the menopause, the opposite ovary and uterus are also removed, whether the ovarian growth is unilateral or bilateral. In women in midmenstrual life, the question of conservative or radical surgery depends upon the judgment of the operator as to the probability of later tumour formation in the opposite ovary. Some tumours have a great tendency to bilaterality, while others have much less tendency to involve both ovaries.

See also CANCER; TUMOUR.

SURGERY OF THE FEMALE REPRODUCTIVE TRACT

Surgery is performed in the female pelvis chiefly for determining or ruling out the presence of malignancy; for removal of tumours, benign and malignant; for correcting malpositions of the uterus; and for reconstructing the vagina after damage resulting from childbirth or other trauma.

DILATATION AND CURETTAGE

Dilatation and curettage is the operative procedure most frequently performed in gynecology. Dilatation of the cervical canal may be done alone to permit easier egress of menstrual blood when the patient suffers from menstrual pain, but much more often dilatation and curettage are done concurrently. The cervical canal is dilated to permit the introduction of the curette, an instrument that might be described as a miniature hoe, with which the endometrium is scraped off. Curettage of the uterine cavity may be done for either diagnostic or therapeutic purposes; in some instances both are accomplished by the same operation. The uterus is most often curetted to establish the cause of abnormal uterine bleeding. The tissue obtained by curettage is prepared for examination in the pathological laboratory and examined microscopically. It is only by this study that the condition of the tissue can be determined and the cause of the bleeding established. When the bleeding is not due to malignancy, curettage frequently temporarily, and sometimes permanently, relieves the bleeding. Curettage is never a cure for malignancy. It simply permits the gynecologist to make an accurate diagnosis and plan definitive treatment. On some occasions, dilatation and curettage are done with therapeutic intent, as after incomplete abortion, when some of the products of conception remain in the uterus and cause bleeding; removal of these remnants stops the bleeding.

In most clinics biopsy of the cervix, to detect early cervical cancer, is done routinely at the time of curettage.

HYSTERECTOMY

Hysterectomy, removal of the uterus, is the most commonly performed major gynecological operation. The uterus is most commonly removed through an abdominal incision (abdominal hysterectomy), and must be so removed when tumours have caused the organ to be greatly enlarged. When the uterus is normal in size or only slightly enlarged, it can be removed through the vagina (vaginal hysterectomy). Although vaginal hysterectomy is often more difficult to perform than abdominal hysterectomy, there is

great advantage to the patient in having the operation done by this route, since recuperation is usually faster and there is no visible scar.

The uterus may be removed *in toto*, the body and the cervix. and this is known as total or complete hysterectomy. When only the body of the uterus is removed, leaving the cervix attached to the vagina. the operation is called subtotal hysterectomy. The obvious advantage of total hysterectomy is that the patient cannot subsequently develop cervical cancer. Most gynecologists do it almost routinely, but occasionally, for reasons of technical difficulty, subtotal hysterectomy. which is simpler and more quickly done. is performed. It is commonly believed that "complete hysterectomy" means removal of the entire uterus together with the tubes and ovaries; this is incorrect. Such an operation is properly called total hysterectomy and double salpingo-oophorectomy. Removal of the uterus naturally stops menstruation. but it does not precipitate early menopause, since the ovaries continue to function.

Oophorectomy

Oophorectomy, the surgical removal of the ovaries. is done most often for ovarian tumours or pelvic inflammatory disease. Bilateral oophorectomy in young women is a regrettable procedure, but in case of ovarian malignancy it is unavoidable and with bilateral benign ovarian tumours is usually necessary. When hysterectomy is done after the menopause for any reason it is customary to remove the tubes and ovaries also. It is almost certain that the ovaries are functionless after the menopause. and their removal is prophylaxis against ovarian malignancy. The younger the woman, the more conservative the surgeon should be in dealing with the ovaries.

Restoration of Uterine Position

Operations for the restoration of the uterus from retrodisplacement to its normal position were formerly done very frequently. Today the operation is performed occasionally when the symptoms are sufficiently severe and further childbearing is desired. When the uterus has fallen to a much lower level than normal (prolapse) it commonly causes bearing-down discomfort in the pelvis and may even annoy the patient by protruding from the vagina. Such a prolapse of the uterus is commonly associated with faulty support of the vagina. When the anterior vaginal wall lacks support. herniation of the bladder may occur (cystocele). When the posterior wall is defective, the rectum may bulge into the vagina (rectocele). There are many different operations for correction of uterine prolapse and restoration of the vaginal supports. Removal of the entire uterus or part of the uterus through the vagina is commonly done. When there are defects in the vaginal walls, simple removal of the uterus in whole or in part does not correct the condition. Under those circumstances, the supporting structures (fascias) of the vagina should also be repaired. Often the muscles forming the floor of the pelvis (levator ani) are separated or torn as a result of childbirth. Under these conditions they are restored to their normal position as part of the vaginal plastic operation.

GYÖR (German, *Raab*), Hungary, the capital of Gyor-Sopron county (megye), at the confluence of the Raab with an arm of the Danube, with the main stream of which it has communication by river steamers. The town occupies the site of the Roman *Arabona* and has always been an important regional centre and in earlier days a powerful fortress which the Turks captured by treachery in 1594 but retained for four years only. Throughout history it has been regarded as the key to passage east and west as is exemplified by the French storming in 1809 and that by the Austrians in 1849. In the 11th century the town was made a Roman Catholic bishopric, and its fine cathedral, dating from the 12th century in origin though rebuilt in 1639–54, gathered around it many important expressions of spiritual leadership; *e.g.*, the seminary for priests.

The modern functions are based upon its position at the contact of the old alluvial plain and the drained marshes, and mixed farming originated an active trade in cereals and horses, which was supplemented by milling, textile manufactures, linen and wool, and the distillation of spirits. Pop. (1960) 70,812 (mun.). About 11 mi. S.E. of Gyor on a spur of the Bakony forest lies the famous Benedictine abbey of Pannonhalma (Ger., St. Martinsberg; Lat. Mons Sancti Martini). one of the oldest and wealthiest abbeys of Hungary. It was founded by King St. Stephen, and the original deed from 1001 is preserved in the archives of the abbey. The present building is a block of palaces, containing a beautiful church, some of its parts dating from the 12th century, and is situated on a hill 1,200 ft. high. In the convent there are a seminary for priests, a normal school, a gymnasium and a library of 120,000 volumes. The chief abbot has the rank of a bishop.

GYPSUM, a common mineral consisting of calcium sulfate dihydrate, $CaSO_4.2H_2O$, named from the Greek *gypsos*, "chalk." a word used by Theophrastus to denote both the naturally occurring mineral and also the product of its calcination. plaster of paris (the hemihydrate. $2CaSO_4.H_2O$), which was used in ancient times, as it still is, as a plaster. In well developed crystals the mineral commonly has been called selenite, from *selene*, "the moon," probably in reference to the pale moonlike lustre of its faces, or, after legend, because it was found nocturnally when the moon was on the increase.' The mineral also occurs as anhedral granular aggregates (alabaster), as cross-fibre veinlets (commonly referred to as satin spar because of the silky lustre). and as impure earthy pulverulent masses (gypsite). The mineral may be scratched by means of the fingernail. having a hardness of only 2. Most gypsum is colourless to white, but because of impurities may be gray, yellowish, pink or brownish. The specific gravity is 2.317. The streak is white, the lustre suhvitreous; cleavage pieces show a pearly lustre. Gypsum is used in the crude form as a fluxing agent, fertilizer, filler in paper and textiles, and retarder in portland cement. About three-fourths produced is calcined for use as plaster of paris in molding. casting and pottery plasters and dental plasters; and as building materials in plaster, Keene's cement, board products and tiles and blocks. The granular form called alabaster (the alabaster of the ancients was a marble) is used for statuary and carved ornamental objects.

Most gypsum occurs in sedimentary strata associated with other evaporite minerals. such as rock anhydrite and rock salt. and also limestone and shale. Other minerals commonly present include anhydrite, calcite, dolomite. halite, sulfur, barite, quartz and clay, and many strata are relatively impure; fine- to coarse-grained. equigranular to heterogranular. The gypsum appears as fine grains, as large prismatic crystals, as large plates, as parallel fibrous aggregates and as spherulites. Very commonly it may replace anhytlrite. but the converse relation also has been noted. Individual strata of rock gypsum range from a few feet to hundreds of feet in thickness. In addition, gypsum also is an important constituent of cap rock. an anhydrite-gypsum rock forming a covering on salt domes (*q.v.*), especially in the Texas and Louisiana Gulf coast area, where it may be an important source of native sulfur. Gypsum also may be deposited directly from sea water by evaporation, at 30° C. and at a salinity of 3.35 times that of normal sea water. In sedimentary strata where gypsum has been formed by the replacement of anhydrite, the process gives rise to a 30% to 50% volume increase, resulting in intense, tight folding of the remaining anhydrite layers. This replacement is the result of hydration by surface and ground waters; thus in many cases gypsiferous strata grade downward into anhydrite rocks.

In addition. gypsum also occurs as a disseminated mineral in limestones and dolomitic limestones, especially with anhydrite, barite, celestite and fluorite, as well as in similar fashion in some shales. Unusual crystals of gypsum are known from solution

caves in limestone regions; some of these are highly twisted, others are of extraordinary size. It is a gangue mineral of some relatively low-temperature hydrothermal mineral deposits, and is found in deposits of native sulfur: as in Sicily, and results from the reaction of sulfureous gases and waters on calcium-bearing minerals around fumaroles and solfataras in volcanic regions. In the United States commercial sedimentary gypsum deposits occur in rocks of Silurian age in New York, in rocks of Mississippian age in Michigan. Other significant economic deposits occur in Virginia, Ohio. Iowa, Kansas, Texas, Nevada and southern California. In Canada gypsum is produced for export in Nova Scotia and New Brunswick. Deposits occur in many countries but the United States. Canada. France, Germany. the U.S.S.R. and the United Kingdom are leading producers. In France gypsum is common in Tertiary marls and clays of the Paris basin (hence the name plaster of paris), especially in Montmartre: in England near Chellaston in Derbyshire, Newark in Nottinghamshire and Fauld in Staffordshire. Crystals up to 5 ft. long have been found in caves in Naica. Chihuahua. Mex. Northern Italy is the leading source of alabaster, also found in England, Colorado and other localities.

Cpon calcination gypsum loses three-fourths of its water between 120° C. and about 165° C.. yielding the hemihydrate (plaster of parisj. When this is mixed with water it rehydrates and sets to a white solid mass of interlocking fibrous crystals of gypsum. Heating of gypsum for three hours at about 240° C. ("dead-burnt") expells all water to produce anhydrite (*q.v.*).

Crystallography. — Gypsum crystallizes in the monoclinic system. forming thin to thickly tabular crystals which commonly show coarse striations parallel with the c-axis. Crystals may also be lenticular. resulting from rounding of terminal faces. Other crystals are warped. with extreme examples bent into irregular or helical forms twisted about the c-axis. Twinning on (100) is very common as swallow-tailed or cruciform penetration twins or as multiple lamellar twins. The side pinacoid cleavage (010) is well developed and the front pinacoid cleavage (100) is distinct. Many crystals contain inclusions of sand or clay particles which may show crystallographically oriented concentrations, parallel with edges or certain faces.

GYPSY (native name *Roma*, fem. *Romña;* popularized by George Borrow as Romaniesj. Gypsies were originally a low-caste people of India and are related by name to the Doms, a tribe of musicians and ropemakers.

Forced to leave northwestern India for unknown reasons about the first millennium A.D.. they migrated to Persia where they stayed probably until the time of the first Mongol inroads. These seem to have been their chief motive for wandering westward. first into Armenia. then into Ossetia. A number turned southward to Syria: Palestine and Egypt. The westward branch reached Greece via Anatolia by about 1300, for in 1322 they are found in Crete and by 1326 they had settled in Corfu. From the Balkans they spread rapidly beyond the Danube. for the Czech *Chronicle of Dalimil*, written in the early 14th century. quotes a Romany begging formula *kartas* boh (presumed to mean "we are hungry").

The Turkish invasions caused further migrations and many thousands must have found temporary asylum in Rumania. since most European Romany dialects are penetrated n-ith Rumanian words. Spreading westward through Hungary. Austria and Bohemia they reached Hesse about the year 1414. and were general throughout Germany by 1417. By 1418 a number had reached Hamburg and Augsburg. and in 1427–28 they were found in France and Switzerland. A band reached Bologna in 1422. By 1500 the first gypsies had reached England. First reactions to the newcomers seem to have been favourable. True. they had been regarded as serfs in the Balkan lands during the 14th century. But in 1496 Wladislaus II (Uászló II) of Hungary gave them the right of free circulation as a reward for "making rounds for shooting-tubes." and in 1505 James IV of Scotland gave to one described as an "earl of Little Egypt" certain letters of recommendation. A black period of gypsy history seems to be that from 1555 to 1780, when bestial acts were committed against gypsies in Britain and elsewhere. In 1768 Maria Theresa tried to settle them as peasants. Her son Joseph II abolished serfdom in 1781 and thereby released the gypsies from certain restraints. Archduke Francis Joseph entertained gypsies at his court and compiled a gypsy grammar.

Foundation of a Dynasty. — The only attempt by gypsies to found a dynasty is associated with the family of Kwiek. Gregory Kwiek. a kettlesmith of Polish origin, was born about 1856 and spent his early life in Italy or Spain. About 1883 he declared himself "king of the gypsies" and ruled them mainly from Poland. Having spent much of his lifetime between making kettles and touring the gypsy camps of Europe to gain favour and raise revenue, he abdicated in favour of his son, born at Bielcza in 1878 or 1886. In 1928 he became Michael II and was crowned near Warsaw in 1930. He tried to set up a Romany tribunal at Poznan. A brother Basil disputed the throne and a third brother, "kingmaker" Matthew returned from Spain to arbitrate, settling for Basil, with Rudolf as chancellor. The brothers Basil and Rudolf plotted to force Michael out of Poland. In 1934 Michael attended a gypsy congress in Rumania. returned, was confirmed king by a gathering at Lodz. but fearing vengeance fled to Czechoslovakia and was not heard of again. Matthew was murdered in 193j, and Basil reigned unchallenged until Rudolf transferred his favour to another brother Janusz, who in July 1937 was crowned Janusz I, "king of the gypsies" with great ceremony at the Warsaw stadium, in full view of 15,000 gypsies. The officiating priest was Orthodox Bishop Theodorowicz. The robes and regalia had been borrowed from the Warsaw opera house. Rudolf had meanwhile renounced all claim to the throne in return for an influential post in the cabinet; Sergej Kwiek became chief adviser, Alexander Kwiek was made president of the Federation of Gypsies and Zdunek became financial adviser. Once the ceremony was over Janusz demanded the takings from the stadium gathering. but this was refused by the authorities until expenses had been paid. King Janusz thus began his reign with an unbalanced budget. since he had promised to pay the expenses of his electors and musicians. Finally, impoverished, he returned to the village of Milanowky, his new home, to carry on his trade.

Janusz proclaimed himself ruler of the gypsies of Hungary, Spain, Germany, Bulgaria. Yugoslavia and Poland. and planned to go to Geneva to plead for a country for his people. But his rule was challenged about ten months later on the ground that the senate of only 17 members did not constitute a quorum. Other allegations were more nebulous, but the complaint that his election had not been unanimous was justified. At one point his subjects demanded free elections. At this Kmiek dismissed both cabinet and senate and regaled several hundred of his friends, who thereupon confirmed his "royal" status. His reign of about a year was followed by a shorter, that of another Matthew Kwiek.

Attempt at **Organization.**—Any political organization of gypsies was bound to cut across national frontiers and to operate in hostile territory. Mechanization and unemployment had caused unprecedented poverty among a people who could but make things n-ith their hands. The few existing gypsy lawyers were faced with the enormous task of presenting their case to the League of Nations and to the law courts of several countries. An attempt was made to organize the tribes locally under matriarchs known as "old mothers." whose duty it was to preserve morality, but who stubbornly refused to pay taxes when asked to do so.

In 1933 the president of the Burgenland assizes had complained of the unprecedented increase of gypsies in the province and had urged that all gypsies in Austria. Hungary. Yugoslavia and Czechoslovakia should be settled on an island in Polynesia. the League of Nations to supply the money. Neither Janusz's dream nor the demands of the Burgenland judge came true. With the outbreak of World War II frontier movements were halted and it was not long before the nazis decided upon a policy of extermination. Complete records are not available, but some of the worst atrocities were committed in Yugoslavia and Poland; thousands were done to death at Oswiecim (Auschwitz), among them gypsies from

Czechoslovakia, and 2,000 were killed in Belgium. Death camps existed at Treblinka, Belzec and Chelm in Poland, and many died at Buchenmald, Ravensbriick and Mauthausen, about 20,000 in all. Survivors joined the guerrillas. After World War II what remained of the gypsies in Poland rallied loosely round Rudolf Kwiek, who had spent some of the war years in Rumania. The fate of King Janusz is unknown. In 1946 Rudolf, content to be their president, made a rough census of Polish gypsies, finding 4,500 survivors out of a prewar total of more than 18,000. As president of the World Council of Gypsies he held congresses from time to time at Katowice, while continuing his trade of kettlesmith near Warsaw. He later called to his side an old gypsy called Zoga to be the gypsies' legal and spiritual leader.

A plan first voiced in 1875 for a Romany state was echoed in 1879 at the first gypsy congress, held at Kisztyal in Hungary, when the sole demand was for minority rights. From then on gypsy congresses became more frequent. One was held in Sofia, Bulg., in Jan. 1906, and another in 1919. Michael II summoned one to Cernaut, at which he demanded gypsy schools. The most elaborate was at Bucharest in 1933, when Lazarescu was elected president, but was later declared a tyrant and replaced by G. Niculescu, a flower seller. This energetic man set about making his people literate. and published at his own expense a weekly newspaper in Rumanian under the title *Glasul Romilor* (Voice of *the* Gypsies).

Distribution **and** Customs. — In general the gypsy population of Europe decreases from southeast, where it is greatest, to northwest, where it is least. The pressure of competition and mechanization in countries with a high standard of living is believed to have reduced their numbers. The small earnings of the skilled are in general sufficient to satisfy their simple needs in normal times, but they are beset by disease, especially tuberculosis, and their hunger is proverbial. A common gypsy conception of paradise is a place where there is plenty to eat.

The living conditions of gypsies are dictated by climate, geoggraphy and, above all, by the economic status of the host country, to which their own is often inferior. They are wealthiest in Sweden, poorest in the Balkans and southern Spain. Whatever their habitation, it is always in a sheltered spot, a sand pit, a quarry, a valley or a wood, away from wind. British, French and German gypsies live in painted caravans used mainly as sleeping quarters. Central European gypsies build one-room brick cottages in sand pits or on wasteland. Farther east and in the Balkans their dwellings are of wattle and daub or other crude materials. It is mainly the wanderers, despised by the settled gypsies, that live in tents. These roam in summer and pitch near towns in winter. Spanish gypsies build their houses partly in the hillside; some keep their children outside in covered pens flanked by wooden troughs to hold the bedding. Coastal wanderers of Spain sleep in the sandstone caves.

The one good daily meal of gypsies is a supper of' stew which is cooked on an outdoor fire. Autumn hedgehog is considered a delicacy.

Their crafts are most numerous in Yugoslavia, where they are smiths, farriers, tinkers, riveters, basketmakers, musicians, bear trainers and dealers in wool and cattle. In central Europe they are smiths, jugglers, musicians, bear trainers, horse dealers and circus players and there are a few lawyers. In England they make baskets, clothespins, paper flowers and other decorations and spend the summer months at casual outdoor labour. During World War II many were engaged in tree felling and simple agriculture — a sharp break with tradition. Some have become owners of traveling shows. Bargees form a separate clan.

Apart from their crafts gypsies have little special knowledge beyond that of horses and herbs. Illiteracy is high because they are always on the move, forcibly or otherwise, and their children cannot attend school.

European gypsies except those of the southeastern Balkans speak Wallachian Romany, to which Hungarian, Slavonic and German words have been added in its progress westward. The purest Romany in Britain is spoken in north Wales. Romany has given English the words *pal* and *cosh*. (See ROMANY LANGUAGE.)

All gypsies profess the dominant local religion. They chant their poetry, some of which is original, but their dances, music, folk tales and proverbs are of local origin. Their tribal customs sometimes have the force of law. Population figures are unreliable: Czechoslovakia's figure before World War II was given as 28,500; Austria's 24,000; Poland's 18,000 to 20,000. There may be 1,500 to 2,000 in Great Britain.

Gypsies tend to be swarthy with wavy black hair, being brachycephalous in central Europe and dolichocephalous in the maritime countries. The incidence of white gypsies in ascribable to associations with Europeans. (S. E. M.)

UNITED STATES

Although most of the descendants of the gypsies who went to America in colonial times from Great Britain, the Netherlands, Germany and France were absorbed, there were by the end of the first quarter of the 20th century probably between 50,000 and 100,000 persons of Romany origin; and the number increased thereafter. The majority arrived during the last quarter of the 19th century. British gypsies, fairly numerous in the United States and Canada, differed little from those of the old world. After the decline of horse trading, their chief occupation was fortunetelling; some settled on farms and others peddled various products such as oilcloth, hand-made baskets and rustic furniture. Many used Romany (*q.v.*) as their native tongue. A large group settled at Braddock, Pa. Families of Turkish, Syrian, Bulgarian and Spanish gypsies were widely scattered.

The majority of gypsies in America might be classified vaguely as Vlachs (*q.v.*). There are two distinct varieties. The smaller is known as the Karavlase (Black Vlachs) or Baias (Gold Washers). What little Romany they acquired was picked up from Anglo-American gypsies. Rumanian is their "secret" tongue, though they lived in Serbia for a time before starting on their wide migrations. Of these a number became fortunetellers. The other variety forms the bulk of American gypsies. For lack of a better term, they are called the nomads. Among themselves they speak a relatively pure dialect of Romany, but the percentage of Rumanian loan words would indicate that at one time they wandered in Vlach countries. They may be met anywhere, from China to Africa, but many of them made the United States their home. Large numbers also went to South America. They subdivide themselves into tribes: the Macvaya, so named from a region in northern Serbia; the Kalderas, from their former profession as coppersmiths; Rusore, Ungeresore, etc., from the countries where they lived longest before coming to America. In spite of slight differences of dialect and customs, these tribes are homogeneous and mix with no other group, not even the Baias. They established their own courts (romano-kris), conducted in the manner of the gypsylike peoples of India. Taboos are strictly enforced and punished by fines or by expulsion from the tribe (*mahrimé*).

The large silk kerchief worn over the head by the married women, the necklaces of gold coins and the gay dresses are distinctive. They travel by train and motorcar and live by the fortunetelling of the women. Formerly most of them were coppersmiths. A few became professional musicians. They preserve many stories and songs in their own language. In summer they live in tents; in winter they move into cities, many living in stores. With prosperity they tended to become assimilated into the U.S. culture, though the Romany inclination to revert to age-old traits remained.

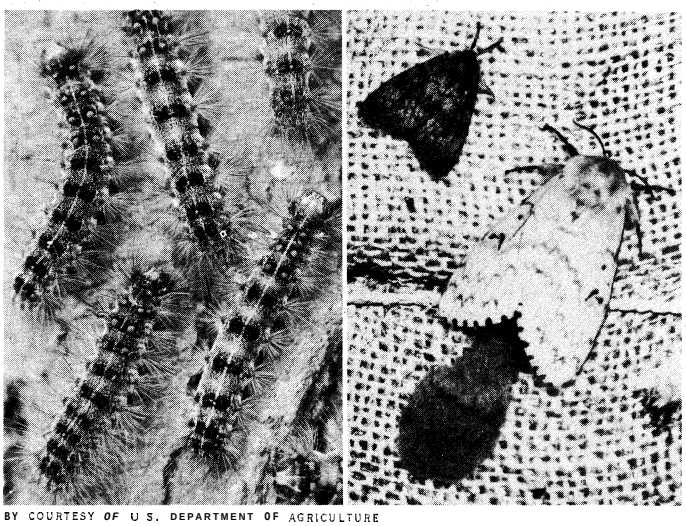
GYPSY MOTH, a European moth (Porthetria *dispar*) brought to the United States for experiment in 1869 but escaped from confinement, multiplied slowly and eventually became a serious pest of shade, fruit and woodland trees in New England.

The adult female moth is a heavy-bodied, light-coloured insect, with zigzag blackish marks on the wings. The body is so heavy that the female cannot fly. It has a wingspread of $2\frac{1}{2}$ in. The male is much smaller, dark in colour and flies readily. The winter is passed in the egg stage. The eggs are laid during July in clusters of 400 or more, on the bark of trees, fence rails, fallen logs. under loose bark, in cavities in tree trunks or branches and are sometimes placed on stones were they may be concealed from view. Each cluster is covered with buff-coloured hair.

With the appearance of the leaves in the following spring the eggs hatch and the young larvae feed rapidly, becoming full-grown early in July. When these ravenous eaters are numerous they may completely strip the trees before the end of June. At this time they are 2-in.-long, flattened, pale-brown caterpillars with long tufts of stiff brown and yellow hairs standing out from the sides of the body; a further distinguishing feature are the tubercles found in two rows down the back: five pairs of blue nodules followed by six pairs of red ones. The pupae or chrysalids, into which the larvae are changed, give out the adult moths after about ten days. There is one generation each year.

The gypsy moth spreads commercially on nursery stock, young trees, lumber, stone or other products likely to be sent away. They also spread as newly hatched caterpillars. in which condition they are blown to considerable distances by the wind on warm sunny days. In New England thousands of trees have been killed. Apple and oak have suffered more than other species, but pine and other coniferous trees have been killed when mixed with deciduous growth.

With the expansion of the infested area in the early 1900s the federal government took active part in the work and since then has co-operated with states in an effort to control and prevent its spread. These activities include the enforcement of a quarantine regulating the movement of articles which might carry the insect into new areas. The insect spread by natural means into new areas in the New England states, however, and in 1923 it was felt that natural spread to the west could best be prevented by eliminating all infestations which developed in an area along the eastern border of New York and adjoining states to the east. This barrier zone was maintained by the federal government and the state of New York.



BY COURTESY OF U S. DEPARTMENT OF AGRICULTURE

GYPSY MOTH (PORTHETRIA DISPAR)

Left: Leaf-eating caterpillars. Right: Male (upper), and female laying eggs

The insect by the 1950s was found throughout most of New England, in several counties in eastern New York and in an isolated area in Pennsylvania. Infestation varied greatly from year to year. Developments in the application of DDT sprays with aircraft greatly reduced the cost of artificial control operations. The remedial measures adopted after long investigation consisted of spraying with a suspension of lead arsenate, banding the trees to prevent the climbing of the caterpillars and treatment of the egg masses with creosote. Many species of parasites have been introduced from Europe and certain of these, especially the Braconids and the Tachina flies, have proved reasonably effective. A predatory beetle known as *Calosoma sycophanta* has also been introduced to good effect. These imported natural enemies have been the means of aiding very considerably in the control of the insect.

GYROCOMPASS or GYROSCOPIC COMPASS is a navigational instrument which makes use of a continuously driven gyroscope (*q.v.*) to accurately seek the direction of true (geographic) north. It operates by seeking an equilibrium direction under the combined effects of the force of gravity and the daily rotation of the earth. As such, it is immune to magnetic interferences such as those caused by ore deposits, steel structures or electric circuits. These properties make the gyrocompass a prime navigational device in ships and submarines It has found extensive use on ore ships on the Great Lakes. as the azimuth reference for gun and torpedo control on narships and as a reliable compass for navigation of any ship. It is not suitable as an aircraft compass because the speed of several hundred knots associated with such vehicles seriously affects the north-seeking properties of the instrument. (See also COMPASS)

Although the apparent effect of the earth's rotation on gyroscopes was first shown by Léon Foucault in 1852, the ability to construct sufficiently accurate units did not exist until the first decade of the 20th century. The first seaworthy gyrocompass was produced in 1908 by the firm of Hermann Anschutz in Germany, largely through the efforts of Max Schuler who developed the principles on which a practical ship borne gyrocompass depends. This compass was a marvel of mechanical ingenuity. In 1911 Elmer A. Sperry in the United States produced a gyrocompass that was easier to manufacture. In England, S. G. Brown, working with John Perry along somewhat the same lines as Sperry, produced a gyrocompass in 1916. Later the Arma corporation in the U.S. produced a unit that was a modification of the Anschiitz.

All gyrocoinpasses operate on the same basic principle. They differ in their methods of supporting the gyroscopic element (the spinning wheel)! of applying the pendulosity which is required for the north-seeking property and in the means used to damp out oscillations and thus cause the unit to settle on north.

Operating Principles.—One form of gyroscope is a spinning wheel mounted so that the direction of its spin axis has universal rotational freedom. The spin allows the mass, or inertial, properties of the material in the wheel to be used continuously and thereby gives rise to a relatively large gyroscopic momentum or inertia in a moderate sized wheel. The important property of a practical gyroscope is its angular momentum—the product of its spin and its inertia about the spin axis. This quantity is a vector, since it has both direction and magnitude. The angular momentum vector may be conveniently represented by curling the fingers of the right hand in the rotational sense of the spin! the extended thumb of the hand then pointing in the direction of the angular momentum vector. The angular momentum is nearly parallel to the spin axis in a practical gyrocompass.

In the same manner the moment of a force (torque, or turning

effect) is directed along the extended thumb of the right hand when the fingers of the hand curl in the sense of the rotation that the force is trying to produce. The following is the basic law of gyroscopics: when a torque is applied to a gyroscope, it will rotate (or precess) so as to attempt to align its angular momentum with the torque. The precession is with respect to inertial space, *i.e.*, a reference space that is nonrotating relative to the "fixed stars." Note that the earth is not part of inertial space because of its daily rotation. The magnitude of the precession is directly proportional to the magnitude of the torque and inversely proportional to the magnitude of the angular momentum. When no torque is applied, the spin axis remains motionless relative to inertial space; if aimed at a star it remains aimed at the star, and consequently one end of the axis appears to an earth observer, in the course of a day, to rise in the east and set in the west. This is shown in fig. 1 as the path encircling the pole. When an applied torque attempts to rotate a gyroscope about the vertical axis, the spin axis will rise or dip, *i.e.*, precess about a horizontal axis, as it attempts to align its angular momentum with the torque. Similarly, an applied torque about a horizontal axis will cause the spin axis to precess about the vertical axis.

A gyrocompass is a gyroscope having a frame with a mass unbalance giving it a pendulosity at right angles to the spin axis. In normal operation the spin axis will be nearly horizontal and pointed north, while the pendulosity is downward. Consider a gyrocompass started with its spin axis horizontal and pointing a few degrees east of north. The earth's rotation then causes the spin axis to rise above the horizon as seen by an earth observer (more accurately, the horizon dips below the spin axis, which initially

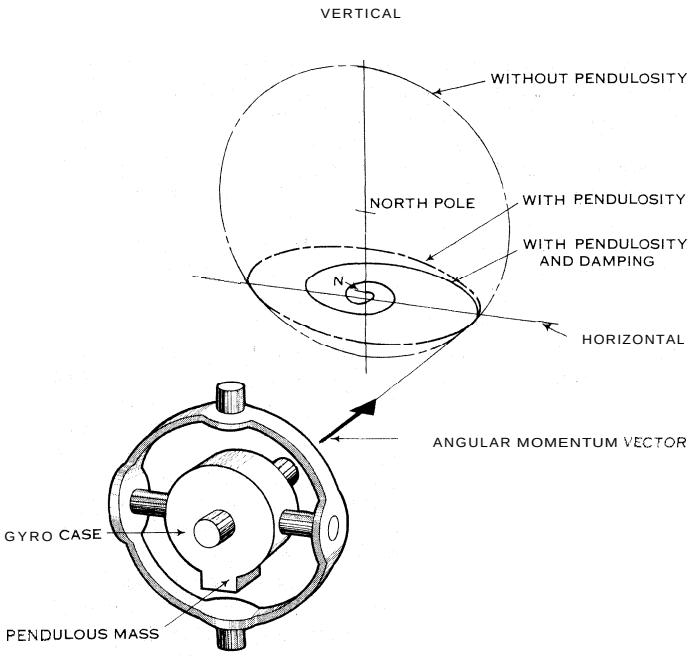

FIG. 1.— GEOMETRY OF GYROCOMPASS OPERATION

remains motionless in inertial space). This action produces a horizontal torque directed westward due to the effect of gravity on the pendulosity. The spin axis, obeying the basic law of gyroscopic precesses about the vertical toward the meridian, continuing to rise because of the earth's rotation until the meridian is reached. At this point the pendulous torque is maximum and the spin axis continues to precess through the meridian. When the spin axis is west of the meridian the earth's rotation causes the spin axis to set, thus reducing the pendulous torque. At the same distance west of north as the starting direction was east of north, the spin axis is horizontal again, but because of earth rotation continues to set. This causes the spin axis to dip below the horizon and produces an eastward pendulous torque. which causes the spin axis to precess toward the meridian again and eventually precess past the meridian and back to its starting direction, where this whole process is repeated. The spin axis thus traces out an ellipse about the meridian and horizontal, as shown in fig. 1. The flatness of the ellipse and the period of the oscillation depend on the strength of the pendulosity.

For a gyrocompass to point north, it is necessary that the oscillation be damped out so that the unit can settle on the meridian and not keep passing through it. Damping an oscillator involves changing its energy state by opposing the velocity of the body. Two methods for damping have been used. The first, used in all gyrocompasses except the Sperry, is due to Schuler. It consists in applying an antipendulous torque caused by the restricted flow of a viscous fluid responding to the tilt of the gyroscopic element. Viscosity and direction of flow through the constriction are combined so that the torque is applied in the proper phase for damping. The torque is horizontal and ideally is directed so as to precess the gyro toward the meridian at all times: *i.e.*, it points west when the spin axis is east of the meridian and east when the spin axis is west of the meridian. The combined action of pendulous and damping torques changes the previously mentioned elliptical motion of the undamped regime to a spiraling-in motion toward the meridian, as is shown in fig. 1. Viscous friction absorbs the energy withdrawn to effect the damping. The second method of damping is used in the Sperry gyrocompass. The Sperry compass is supported by a wire suspension with a pow-er-driven follow-up, known as a phantom ring: which is a type of servomechanism. Damping involves applying the pendulous torque in such a manner that its interaction with the phantom ring and follow-up motor produces a torque along the vertical axis. This attempts to reduce the tilt of the gyroscopic element. Since tilt and motion in the horizontal plane are coupled together in a gyrocompass, this method also serves to damp the spin axis toward the meridian. The energy for damping is furnished by the motor that operates the phantom ring. This system has antipendulous action and damping is obtained by adding energy to the system.

In its steady state a gyrocompass has a slight upward tilt on the north side of its spin axis in the northern hemisphere and a downward tilt in the southern hemisphere. This produces the torque required to precess the gyrocompass relative to inertial space about the vertical axis at the same rate that the meridian is rotating about that axis due to the earth rotation. This rate is zero at the equator and increases to full earth rate at the poles. Because of this equilibrium tilt the damping method used in the Sperry gyrocompass causes the spin axis to settle slightly east of the meridian in the northern hemisphere and west in the southern. This is a small known angle that is readily compensated for in the heading indication.

The Anschütz and Arma compasses are supported by flotation. The pendulous torque is obtained by simply mounting the unit with the centre of gravity below the pivot. Damping is obtained by restricted flow of a viscous fluid in a tube. The Brown compass is supported by a pulsing oil column. The pendulous torque is obtained by the flow of oil between two tanks. Air pressure generated by the spin of the gyro wheel forces the oil uphill to give it pendulosity, since it is naturally antipendulous or top-heavy. It is damped by restricted flow of a viscous fluid in a tube. The Sperry compass is supported by a wire suspension with a power-driven phantom ring to remove torsion from the wires. Surrounding the phantom ring is a frame called the ballistic. The pendulous torque is obtained by the flow of mercury between two tanks (the mercury ballistic). As this action is antipendulous, the equilibrium direction of the gyroscopic angular momentum is south. This combination of two potentially unstable components produces a stable system. It is damped by the follow-up motor, which receives a signal proportional to the displacement of the phantom ring from the wheel-supporting gimbal.

Dynamic Requirements (Schuler Tuning).—The period of oscillation of a gyrocompass is determined by the requirement that the compass operate usefully in an accelerated vehicle. The pendulosity that produces the north-seeking property responds to vehicle accelerations as well as to gravity. The torques associated with north-south accelerations (east-west accelerations are not important because of the system configuration) would cause a corre-

sponding wander of the gyrocompass about north and would render the instrument useless for navigation. Furthermore, when a vehicle travels north or south it acquires in its motion over the spherical earth an angular velocity relative to inertial, space that is perpendicular to the earth's daily rotation. This means that the apparent meridian. relative to which stars would appear from a moving vehicle to rise and set, is rotated about a vertical axis from the true meridian. westward for northerly velocity and eastward for southerly motion. The tangent of this angle of rotation is the vehicle's north-south speed divided by the product of earth rate (speed of a point on the equator: nine-hundred knots) and the cosine of the latitude. At ship speeds this angle is generally less than 4°. A major contribution by Schuler was the discovery that. when the period of oscillation is $2\pi\sqrt{\text{earth radius/gravity}}$, the heading precession of the gyroscope spin-axis due to acceleration is exactly the rate of change of the angle between the apparent and true meridians seen on a moving vehicle. The gyrocompass will then read true north at all times if its indicating reference is offset by the angle between these two meridians. The angle, at ship speeds. is a direct function of the north-south speed and is easily set into the system. The need for accurate speed measurement for this offset is the main reason why a gyrocompass is not usable in aircraft.

Description of Parts.—Only one type of gyrocompass is described because of space limitations; the Sperry unit is chosen as one that is representative and in extensive use at sea. The gyro wheel is electrically driven and mounted on spin-axis ball bearings within the rotor case. This case in turn is mounted to tilt on ball bearings about a horizontal, and nearly east-west, axis in the vertical ring. The vertical ring is pivoted about a vertical axis within the phantom ring, but its weight is borne by strands of steel wire from the phantom head. A follow-up system keeps the phantom ring aligned with the vertical ring, thus preventing torsion in the wires and reducing support friction about the vertical axis to a minimum. The compass card is mounted on the phantom head. The phantom is supported by thrust bearings in the spider which also carries the follow-up motor. This whole device is mounted with a small pendulosity in the binnacle within a covering case. The compass elements are thus protected and also free from the rolling of the ship. The mercury ballistic frame is pivoted to the phantom on horizontal and nearly east-west, bearings. The frame connects to the rotor case by a link that makes contact slightly east of the bottom of the case. The frame carries the tanks of mercury and the connecting tubes.

The master gyrocompass is usually installed in a compartment that will not be affected by the outside environment. Repeaters of its indication are mounted on the bridge and elsewhere as needed. The course recorder keeps a permanent record of the ship's heading. Fig. 2 shows a complete gyrocompass system.

Inertial Navigation.— Some of the principles of the gyrocompass were extended. starting in 1950, to a new method of navigation, known as inertial navigation, of submarines. In this method. the longitude, latitude and ground speed of the craft are indicated, as well as the direction of north.

GYROPLANE: set: AERONAUTICS.

GYROSCOPE, a rotating wheel universally mounted: *i.e.,* mounted in such a manner that it is free to turn about any axis. In 1852 the French physicist Léon Foucault used such a device to demonstrate the rotation of earth and coined the word "gyroscope." This comes from two Greek words, *gyros* meaning "turn or revolution," and *skopein* meaning "to view." Thus a literal meaning of the word gyroscope is "to view the turning."

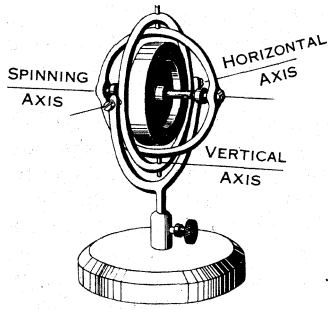
One of the first of these rotating devices was constructed about 1810 by G. C. Bohnenberger and is described in Gilbert's *Annalen* for 1818. It consisted of a heavy spheroid which could rotate on an axis passing through its diameter. which axis was mounted along the diameter of an outer circular ring. This ring with its contained spheroid was similarly made movable. inside a second ring. about an axis at right angles to the axis of the spheroid. In the same way the second ring with its contents could rotate. inside a third ring, about an axis at right angles to each of the others. From this it will be seen that the spheroid had all degrees of Tree rotation. one point only within it being fixed: namely, the intersection of the three axes.

In 1836. in a paper read before the Royal Scottish Society of Arts. Edward Lang suggested an experiment. with a universally mounted rotating wheel, by which the rotation of the earth on its axis could be directly proved. He said: "While using Trouphton's top an idea occurred to me that a similar principle might be applied to the exhibition of the rotation of the earth. Conceive a large flat wheel, poised on several axes all passing directly through its center of gravity. and whose axis of motion is coincident with its principal axis of permanent rotation, to be put in very rapid motion. The direction of its axis would then remain unchanged. But the directions of all surrounding objects varying, on account of the motion of the earth. it would result that the axis of the rotating wheel would appear to move slowly." This suggested experiment was actually carried out in 1852 by Foucault. probably without any knon-ledge of Lang's suggestion. Foucault's experiment for demonstrating the rotation of the earth by means of a gyroscope became widely known and stimulated much thought and research on the uses of the gyroscope.

In order to conduct these early experiments successfully it was necessary to construct the instruments with the utmost exactness. Further difficulty hindered the development of the gyroscope. in that rotation could not be kept up for any length of time without functional interference causing the rotor to be inaccurate. Consequently, the gyroscope remained largely an instrument used only for demonstration purposes. It was not until the latter part of the 19th century. when G. M. Hopkins introduced the first electrically driven rotor, that the utility of the gyroscope could be fully realized. It was about the turn of the century that Elmer A. Sperry visited France and became interested in the historic Foucault gyroscope. From this interest was built up the Sperry Gyro-

scope company which supplies ships and planes with gyroscopic devices for indicating direction, for steering and for stabilization.

Fundamental Principles of the Gyroscope.—The explanation of the phenomena displayed by a gyroscope can be given in terms of Newton's laws of motion. These laws are adapted to spinning objects without the introduction of any new physical laws, though new concepts are introduced. Newton's first law has to do with the fundamental property of all bodies that they have inertia. or mass. Inertia of a body causes it to stay at rest if initially at rest or to move with constant speed in a straight line unless some external force acts on the body. In a similar manner a gyroscope possesses inertia in that a freely rotating body will maintain its direction in space fixed.



BY COURTESY OF THE SPERRY GYROSCOPE COMPANY

FIG. 1.—AN ELEMENTARY FORM OF GYROSCOPE THAT CAN SPIN WITH ITS AXES IN ANY DIRECTION

In order to change either the amount or the direction, or both, of the speed of a body. Newton's second law states that an external force is necessary. This force depends both on the inertia or mass of the body and the amount of the change of speed; *i.e.*, its acceleration. For a rotating body a torque is necessary to change the direction of the axis of spin of a gyroscope. A torque exists about an axis whenever a force exerts a turning action about the axis measured by the force times the perpendicular distance from the force to the axis or the lever arm. A torque on a rotating wheel causes a precessional motion about the torque axis. We may then say that the two fundamental properties of a gyroscope are inertia and precession.

In order to investigate these properties consider the gyroscope shown in fig. 1. The three degrees of freedom of this elementary gyroscope are: (1) The wheel is free to rotate (spin) about its "spinning" axis. the wheel's axle. (2) The wheel (with its axle and axle bearings) is free to rotate about the "vertical" axis, which axis is the plane of the wheel and intersects the spinning axis at right angles. (3) The wheel (with its axle, axle bearings, vertical axis and vertical axis bearings) is free to rotate about the "horizontal" axis. which axis intersects the vertical axis at right angles at the intersection with the spinning axis. The spinning and vertical axes are always at right angles to each other, as are also the horizontal and vertical axes. but the spinning axis may make any angle with the horizontal axis. The spinning axis may also be in any direction horizontally, and therefore in any direction relative to space.

The spinning wheel is made so that most of its mass, or weight, is near its periphery, or rim. This gives the wheel a large rotational inertia or moment of inertia. Rotational inertia is measured by the sum of the products of the masses of the body and the square of their distance from the axis of rotation. Thus as the rim of the wheel is made larger and heavier its moment of inertia is increased. Suppose the wheel of this gyroscope is set into rapid rotation and the system is tilted about the horizontal axis. If the wheel is perfectly balanced then, instead of its tilting with the base. it would maintain its original plane of rotation. As shown in fig. 2, no matter how the base is moved the original plane of rotation of the wheel is maintained in space so long as friction at the bearings does not become sufficiently great so as to reduce the spin velocity. This experiment demonstrates the phenomenon of gyroscopic inertia that so long as no torques act on the wheel of the gyroscope it will maintain its orientation in space.

FIG. 2.—TILTED GYROSCOPE SHOWING THAT THE ORIGINAL PLANE OF ROTATION IS MAINTAINED WHEN THE BASE IS MOVED

The second important property of a gyroscope is that of precession which occurs when a torque is applied to it. In order to demonstrate this, let us imagine a uheel, such as a bicycle wheel, hung up by a cord attached to the end of the axle, or preferably to an extension attached to the axle, as shown in fig. 3. If the wheel is held in a vertical plane and is not rotating, then immediately after release it will fall. The weight of the wheel, acting at its centre of gravity; *i.e.*, at its geometrical centre, exerts a torque, or moment of force, about the point where the cord is attached. The moment of this torque is the weight of the wheel multiplied by its lever arm, Wl (the distance between the centre of gravity and point of support when the axle is horizontal). This torque Wl, if the wheel were not spinning, would cause a clockwise rotation about O, or about an axis perpendicular to the plane of the page, if W and 1 are in the plane of the page. The direction of this torque is given by the direction in which a right-handed screw would progress if turned in the direction of the torque. This clockwise rotation of W about O, whose torque or moment is Wl, would be represented by a line perpendicular to and into the page.

Suppose that the wheel now is set into rotation with a large spin velocity s, in the direction shown in fig. 3. If a right-handed screu is turned in the direction of s, the screw would progress to the right so that the spin velocity s is represented by a line through the centre of the wheel to the right. The rotating wheel then has an angular momentum to the right which depends on the moment of inertia of the wheel and the spin velocity s. Placing a heavy lead strip on the outer rim of the wheel increases the moment of inertia and angular momentum of the wheel. Suppose the suspended spinning uheel is now released, then the wheel does not fall but starts to turn around the cord, or to precess. with a precessional spin velocity s'. This precessional motion may be considered in the following manner. Bv Newton's laws of motion the torque Wl about O tends to cause motion or produce angular momentum in the direction indicated by the arrow Wl. Thus the wheel tends to turn its spin velocity; *i.e.*, to precess into this direction. Specifically the arrow representing the spin velocity s of the wheel turns into the direction of the torque arrow. Now the precessional spin velocity s depends on the moment of inertia I, the spin velocity s of the wheel and the value of the torque Wl. If the moment of inertia of the wheel is increased then the precessional spin velocity s is correspondingly increased. In this case the precessional spin velocity s' is given by Wl/Is nhere Is is the angular momentum of the spinning wheel.

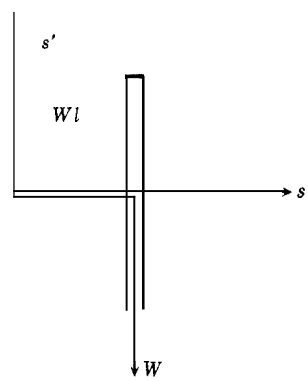

FIG. 3.—DIAGRAM SHOWING THE PRECESSIONAL PROPERTY OF A GYROSCOPE AS ADAPTED IN A SPINNING WHEEL SUSPENDED BY A CORD. THE PRECESSIONAL MOTION IS INDICATED BY S' (SEE TEXT FOR FURTHER INFORMATION)

Actually, the above analysis is only approximate for the case in nhich the angular momentum Is of the spinning wheel is considerably larger than that of the precessional spin angular momentum. If this is not the case, the axis of the wheel does not precess in a horizontal circle but wobbles about this circle with a motion called nutation, or nodding. This nutational motion is seen when the wheel slows down; *i.e.*, its angular momentum decreases. It may also be seen with a spinning top or a toy gyroscope having one point on the table.

The oldest known example of precession is that of the precession of the equinoxes, a term describing the gradual change in the direction of the earth's axis; that is, the axis of the earth describes a cone among the stars, moving in a circular path within a period

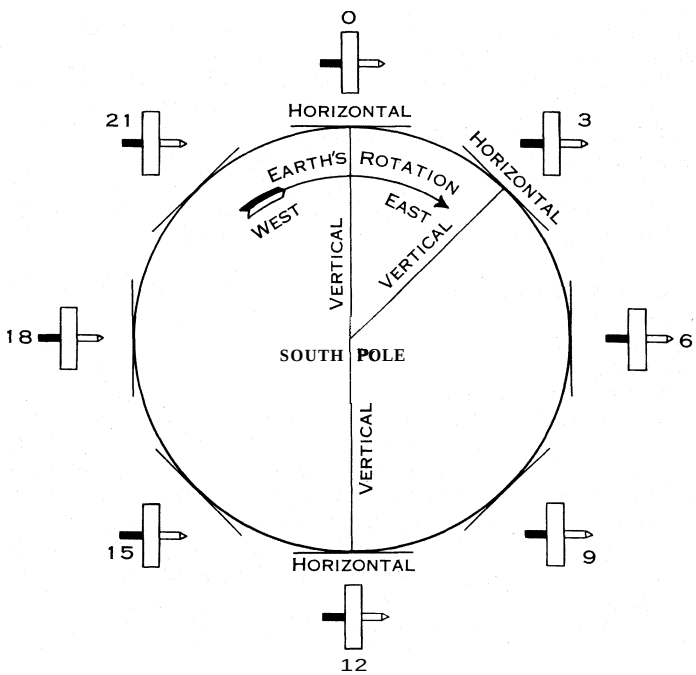
of 25.800 years. Despite the smallness of this effectit was known to the ancient astronomers who had available some careful measurements. The earth goes around the sun in a plane called the plane of the ecliptic. and the axis of spin of the earth makes an angle of 23° 27' with this plane. Our present polestar lies almost on the projection of the earth's axis into space and the stars in the sky appear to rotate about the polestar. With precession of the equinoxes the polestar changes but the axis of the earth remains at 23° 27′ to the plane of the ecliptic. The explanation of this precession is given in terms of gyroscopic action. A torque is exerted on the spinning earth by the gravitational attraction of the sun and moon on the earth. This torque arises on account of the equatorial bulge of the earth so that the forces of attraction of the sun and moon do not pass through the centre of mass of the earth. Just as a torque on the spinning wheel caused precession so a torque on the spinning earth produces precession. The calculation of this precession of the equinoxes requires much more analysis than is possible in this article and will be found in many advanced treatises on mechanics. Other gyroscopic phenomena are associated with the earth but these are too complicated to be described here.

Apparent Rotation of a Gyroscope on the **Earth.**—Suppose a gyroscope is placed at the earth's equator with its spinning axis horizontal in the east and west direction. The behaviour of this gyroscope is observed from a point in space looking at the earth's south pole, as shown in fig. **4.** In this figure only the wheel of the gyroscope is shown, the supporting rings being omitted for the sake of clarity. During the course of a day the gyroscope appears to rotate about a horizontal axis at right angles to the spinning axis. As seen from the earth at zero time the axis is along the horizontal while after three hours it is at 45° to the horizontal and after six hours it is along the vertical. making one rotation about the horizontal axis in a day. Actually. however, the gyro-spinning axis has remained parallel to its original direction in space. though the gyroscope has been carried along with the earth, including the revolution of the latter about its polar axis. Thus the rotation of the gyro axis is an apparent rotation just as in the case of the daily motion of the sun and stars. The horizontal rotation of the gyro axis at the equator is commonly referred to as the horizontal earth rate.

Suppose the gyro is placed, with its axis horizontal, at either the north or south poles of the earth. Again the gyro axis appears to rotate during the day but this time about a vertical axis. The vertical earth rate at the poles is again one revolution in **24** hours. An explanation of this is readily given in terms of gyroscopic inertia; *i.e.*, the fixed direction of the gyro axis relative to space. The earth turns while the gyro axis remains fixed in space so that the axis appears to turn under the earth at an equal and opposite rate to that of the earth. At the poles the vertical earth rate is a maximum. while at the equator the vertical earth rate is zero.

At places between the poles and the equator the gyro axis appears to turn partly about the horizontal axis and partly about the vertical axis. At intermediate places between latitudes oo and go" there is a component of rotation about both the horizontal and vertical axes. The component of vertical rotation is a maximum at the poles and zero at the equator and varies as the sine of the angle of latitude. Similarly the horizontal component varies as the cosine of the latitude, zero at go° (the polesj and maximum at o° (the equator). The horizontal earth rate causes the gyro axis to tilt while the vertical earth rate causes the gyro axis to move in azimuth. Since the gyro's axis is fixed in space it will continue to point at the same star and will describe a circle about the North Star. It is this rotation of the gyro's axis relative to the earth which enables us to apply the earth's gravitational force so as to convert the gyroscope into a north-seeking gyrocompass (*q.v.*).

It might be thought that since the gyro axis remains fixed in space this might be used to indicate direction. Unfortunately in practice the gyro axis does not remain fixed in space. Even while using the highest quality ball bearings and balancing the gyroscope carefully in gimbals so that there is no torque due to gravity. it has not been possible to reduce the rate of precession to zero. In fact in practice a precession of less than 2° per hour is very difficult to attain. For a short laboratory experiment this may seem negligible. but for practical use. for instance in steering a ship, it is not by any means good enough. If the gyro wandered only 2° per hour and in the same direction for a whole day it would change by 48°, which, of course, would render it useless for navigation.



BY COURTESY OF THE SPERRY GYROSCOPE COMPANY

FIG. 4.— GYROSCOPEWITH AXLE IN EAST-WEST DIRECTION AT THE EQUATOR OF THE EARTH APPEARS TO TURN ABOUT A HORIZONTAL AXIS ONCE EACH 24 HOURS

It is for this reason that a gyrocompass (*q.v.*) must make use of both the earth's rotation and its gravitational force.

In other applications, it must always be remembered that in practice the axis of the spinning gyro is not fixed in space but will deviate with time. It has been proposed at various times to use a gyroscope as a clock by setting it to point at some fixed star and then using its inclination with a fixed pointer to indicate time. If such a gyroscope really remained fixed with respect to space it could be used to indicate sidereal or star time. An error of 1% in a timekeeper amounts to about a quarter of an hour per day, and to keep time even as well as this the gyroscope would have to maintain its direction in space with a deviation of less than 4° per day, whereas we have seen that 2° per hour is better than we can guarantee.

PRACTICAL APPLICATIONS

Gyroscopic Gun Sights.—In an earlier section it was shown that the rate of precession of a gyroscope is equal to the applied torque divided by the angular momentum of the spinning wheel, or what is equivalent. the applied torque is equal to the rate of precession multiplied by the angular momentum. This principle is applied in the design of a naval gun sight which has been successfully used to defend ships against dive bombers. Suppose a gyroscope is mounted on the barrel of a gun with the spin axle constrained to be horizontal and at right angles to the barrel. Then when the gun is slued from one direction to another the gyroscope is slued with it, and if the wheel is spinning this sluing motion is. in fact, precession. The axle will only slue with the gun because a torque is being applied to the gyro about an axis parallel to the gun barrel. If the mounting is all solid and unyielding there is no means of knowing how great the torque is, but if the gyro is put in gimbals and the axle constrained to keep horizontal by a spring, then the pull of the spring will be shown by the tilt of the gyroscope. The pull on the spring will be a measure of the rate of precession of the gyro and therefore of the rate of sluing

of the gun. This pull on the spring will be proportional to the tilt of the gyroscope round the gun axis. From a measurement of the tilt the rate of slue can be obtained. In this case the precession initiates the torque, and the torque makes the precession go on. The information obtained from the gyro can be used either by reading the tilt and making calculations based on it, or better by making the tilt offset the gun sight by just the right amount required to make the shell hit the moving target instead of lagging behind it.

The first major tryout of gyroscopic gun sights produced during World War II occurred when the U.S.S. "South Dakota" virtually annihilated a force of attacking planes on Oct. 26, 1942. Since that time gyros have been used to compute the correct lead for guns, bombs or rockets fired from jet fighter planes. These were used in Korea. Gyros are also used to stabilize all types of fire control systems and as a controlling mechanism for guided missiles. (R. J. SN.)

Gyrocompass. — In the case of the marine gyrocompass (*q.v.*), both the gyroscopic inertia and the precession characteristics of the gyroscope are utilized, but the sensitive or rotating element is harnessed by the force of gravity so that the spinning axis of the gyro is brought into line with the north-south axis of the earth and is caused to remain there. The gyrocompass is a necessity in naval work where the great masses of iron and steel seriously impair the accuracy of the magnetic compass and where a high degree of accuracy is required for gun fire control. The gyrocompass is also in use in practically every large merchant fleet in the world because of the safety and added economy of navigation it affords. Vessels ranging from small power yachts to ocean liners use the gyrocompass.

Gyropilot for Ships. — The gyropilot was originally developed (1921) to serve the single purpose of automatic steering. Its introduction was the logical step which followed as soon as the gyrocompass had established a fixed reference by which a ship could be steered. With such a reference available it was obvious that the purely mechanical function of steering could be more accurately performed by a machine than by a human being. The performance of the early models, however, was limited by the character and condition of the connecting medium between the wheelhouse and the steering engine room, and it soon became evident that this mechanism would have to be improved if the full value of automatic steering was to be realized.

A gyropilot was therefore produced (1925) having a control unit or steering stand, containing the gyrocompass repeater, on the bridge, and a power unit in the steering engine room attached directly to the steering gear control. With this arrangement the output of the steering stand in the wheelhouse is transmitted to the power unit aft by an independent electrical system which parallels the existing ship's telemotor. Through this system course changes may be effected while steering automatically, and the ship may also be steered manually through the electrical system by means of a wheel on the steering stand.

Facilities are provided in the equipment to take care of variable factors which influence the steering of the vessel. Under certain conditions, for instance, it is desirable to let the vessel have a small amount of "weather yaw." An adjustment is provided on the bridge unit for this purpose. Another adjustment varies the amount of rudder applied for a given amount of departure from the set course. It will be seen, therefore, that the gyropilot can steer a loaded ship as well as it can a light one and that it is effective in heavy weather as well as in a smooth sea.

Course Recorder. — The course recorder, operated electrically from the gyrocompass, automatically provides on a moving chart a chronological, graphic record of all movements of the ship's head in azimuth. From this record the quality of the steering, the mean course steered and the times and amounts of alterations of course may be ascertained, either at the time of recording or at any subsequent time. These course records have frequently proved invaluable in cases of litigation following accidents and collisions.

Gyrostabilizer for Ships. — In order to add materially to the pleasure and comfort of ocean travel, as well as to reduce the stresses and strains imposed on a ship's framework when rolling in a heaw sea. many different forms of apparatus have been devised, one of which is shown in fig. 5. The only kind which met with any great degree of success was the gyroscopic stabilizer developed by Sperry. This stabilizer is a compact unit generally located below decks on the centreline of the ship. It consists of a rotor of special steel and a supporting casing resting in horizontal "thwartships" gudgeon bearings. so that the rotor axle, when central, is vertical, with the ship on an even keel. The only apparent movement of the stabilizer other than the spinning of its rotor is a tilting or precessing, fore and aft in the thwartships bearings. In so doing, honever, the gyro exerts a righting force against the action of the wave as it tends to roll the vessel over. By dealing with each nave increment individually and by exerting a small counteracting force against it at just the right moment. the gyrostabilizer quenches the force of each wave and never allows the vessel to build up a roll averaging more than 3" or 4°. With the increase in ship size in the 20th century, the use of the gyroscopic stabilizer began to give way to retractable fins near the bottom of the hull on each side amidships. Gyroscopes were still used with the fins to control the angle of tilt needed to offset the roll of the ship.

FIG. 5.—SHIP GYROSTABILIZER. THE STABILIZER OPERATES UNDER THE DIRECTION OF A SMALL, SENSITIVE CONTROL GYROSCOPE MOUNTED ON ITS BASE BOTH INSTRUMENTS HAVE ROTORS OR SPINNING FLY WHEELS. THE CONTROL GYROSCOPE RESPONDS INSTANTLY TO THE SLIGHTEST ROLL OF THE SHIP. TRANSMITTING PRECESSION OR COUNTERACTING MOTION TO THE GYROSTABILIZER WHICH SERVES TO BALANCE THE SHIP'S HULL

Roll and Pitch Recorder. — This is an instrument employing a gyroscopic pendulum to determine the amplitude of a vessel's roll and pitch and the period of these motions. It consists of a small gyroscope with controlling mechanism for two pens, one of which makes a record of the roll, the other of the pitch of the vessel. A sheet of recording paper is automatically drawn under the two pens, and a third operated by clockwork makes marks on the paper at fixed intervals of time.

Gyroscopic Track Recorder. — A Sperry gyroscopic pendulum has also been used with success in a mechanism employed to record the condition of a railroad rail bed. It has been used to record differences of elevation of the two rails on both curves and straightaway track, magnitude and location of rail spreads, depressions, depth of low rail joints and other inequalities in the roadbed at the time the track is subjected to the actual impact of the car passing over the rails at normal speed.

Aircraft Instruments. — The most widespread applications of the gyroscope are to be found in aircraft, since the airplane travels in a medium which makes possible not only changes in direction but changes in altitude as well. The gyroscope has become indispensable in the control of aircraft. Two instruments in particular have long been standard for flying blind or without reference to the

earth. These instruments are the directional gyro and the artificial horizon.

The directional gyro is an excellent example of practical use being made of the property of a free gyroscope to maintain a fixed plane in space without reference to the earth. It is a small instrument which goes on the instrument panel in front of the human pilot. It consists of a small gyro spun by an air jet. This gyro is so mounted in gimbals as to have three degrees of freedom. The normal positions of this gyro are with its axes horizontal or parallel to the earth's surface. Around the vertical gimbal ring of this gyroscope is mounted an azimuth card. By means of a manual setting knob, this gyroscope, together with its azimuth card, may be moved so that the indication of the card at the plane's head will correspond with that of the magnetic compass. The gyro then maintains this specific directional line in space with a possible error caused by drift of possibly two or three degrees in each half hour that the gyro is left free. The utility of this instrument may appear to be very limited but it happens to complement the magnetic compass in a remarkable degree. By itself, neither is satisfactory as a directional reference, but a combination of the directional gyro with a magnetic compass gives the pilot complete and stable directional information. The magnetic compass is useful in an airplane only so long as the airplane continues on a straight course and in smooth air. While the airplane is making banked turns, the magnetic compass may have errors of go° or more. Therefore, if the pilot desires to change his course by a definite number of degrees, the magnetic compass will be of little use to him. On the other hand, the directional gyro is not affected by banked turns or rough air. It therefore gives a positive and gyrostabilized indication of the exact number of degrees of turn that the airplane may make at any time. Since its indication is not affected by rough air, it is possible for the human pilot to steer a straighter and more accurate course to his destination. The relatively slow drift of the directional gyro from its heading may be corrected manually from time to time by comparing its heading with that of the magnetic compass when the airplane is in straight and steady flight.

Another important aircraft instrument is the artificial horizon, which is used to give accurate indications to the human pilot of the bank and pitch attitude of his airplane. This instrument is also a small gyroscope mounted in such a manner as to have three degrees of freedom but with its axle maintained in a vertical position with reference to the earth by means of a gravity-actuated pendulum-type erecting system. Therefore, throughout any maneuvers of the airplane, the axle of the vertical gyro in the artificial horizon is always vertical and the indicating mechanisms attached to this gyroscope give the human pilot the exact bank, dive or climb angle at which his airplane is flying. This information to the human pilot is essential uhen flying blind, since human senses are not able to determine accurately the true direction of gravity without reference to the earth's surface by visual means.

The artificial horizon is a good example of the averaging ability of the gyro. The vertical position of the gyro axle in the artificial horizon is the average of all the positions assumed by the small pendulum-actuated erecting system which controls this gyroscope. Because of small changes of course or altitude caused, for instance, by rough air or turns, the pendulum is constantly swinging about the mean position which, in itself, is a true vertical. The artificial horizon gyroscope endeavours to follow these swings of the pendulum mechanism but does it so slowly that, for all practical purposes, the gyroscope remains with its axle fixed about the mean of all positions assumed by the erecting pendulum.

These two fundamental gyroscopes used in all aircraft are a basis of many control, calculating and indicating devices used on airplanes. The gyroscopes may be driven by air jets or by electric motors. By means of relays and pick-up mechanisms of various types angular indications may be secured from the basic gyro reference and used to actuate servo mechanisms by which complete automatic control of the airplane may be secured as in the automatic gyropilot. The information from these basic gyroscopes may be fed into calculating devices which will compute true ground speed, as in the ground speed meter, or may be used as a basis for taking celestial fixes, as in the gyro sextant, or they may be used to provide the basic directional information for the air position indicator which indicates constantly the latitude and longitude at which the airplane is located. Other gyroscopes of the same basic type are used for the control of many types of computing sights, stabilized gun turrets and other fire control mechanisms used on military aircraft.

In the final analysis. the vertical and the horizontal gyroscope form the basis by which the modern airplane is controlled and navigated from its starting point to its destination.

GYTHIUM, the harbour and arsenal of Sparta, Greece (30 mi. distant), lies at the northwest extremity of the Laconian gulf, in a small fertile plain at the mouth of the Gythius. Its reputed founders were Heracles and Apollo, who frequently appear on its coins. In classical times it was a community of *perioeci,* politically dependent on Sparta. Subsequently it formed the most important of the Eleutherolaconian towns, a group of 24, later 18, communities leagued to maintain their autonomy against Sparta and declared free by Augustus. The highest officer of the confederacy was the general.

Pausanias (iii, 21 f.) has a description of the town in the reign of Marcus Aurelius, the agora, the Acropolis, the island of Cranae (Marathonisi) where Paris celebrated his nuptials with Helen, the Migonium or precinct of Aphrodite Migonitis (occupied by the modern town of Marathonisi or Gythium) and the hill Larysium (Koumaro) rising above it. Extant remains are all of Roman date; the theatre and the buildings partially submerged by the sea are noteworthy.

The modern town is a busy port with a good harbour protected by Cranae, now connected by a mole with the mainland; it is the capital of the prefecture (*νομός*) of Laconia with a population of 7,900 (1951 census).

H THIS letter corresponds to Semitic 𐤇 (chefh, consonantal) and Greek Η (eta). It may derive from an early symbol for fence. In the early Greek alphabets both the form 𐌇 with three horizontal bars and the simpler form Η were widely distributed. In Etruscan the prevailing form was 𐌇, and the same or a similar form occurs in very early Latin inscriptions, but the form Η came into general use in Latin, either from the Chalcidic Greek alphabet of Cumae or from some other source. The modern majuscule H is derived directly from the Latin. The cursive Latin form  resembled the modern minuscule, and the uncial form was  . Both these forms result from writing the letter without taking the pen from the paper, the right-hand vertical bar being thus foreshortened and the horizontal stroke rounded. From these came the Carolingian  and the modern minuscule *h*.

THE DEVELOPMENT OF THE LETTER "H" FROM THE PHOENICIAN THROUGH THE LATIN TO ITS PRESENT FORM

In the alphabets used to write the East Ionic dialect of Greek the letter became superfluous as a result of the disappearance of the aspirate which it represented in that dialect. It was accordingly put to a new use to indicate the open long e which had arisen through alteration of the primitive Greek long a. In a few inscriptions from Thera, Naxos, and several other localities the letter was used with syllabic value; that is, it included he, thus showing its old consonantal and its new vocalic value at the same time. But eventually, as a result of the spread of the Ionic alphabet, its use for the long vowel e or η became general throughout Greece, while its consonantal value as the aspirate h passed from the western Greek alphabets into the Etruscan alphabets and then into the Latin and other alphabets of ancient Italy. In the Romance languages the sound has largely disappeared, but the letter is still extensively used, partly with only etymological value, (*e.g.*, French homme), partly with fancied etymological value (*e.g.*, French haut from Latin *altus*, with h through the influence of hoh, the Old High German word of the same meaning), partly with special orthographical functions; for example, in Italian in combination with *c*, g to indicate the hard sound before a front vowel (*e.g.*, chi, ghetto).

In English, the initial h is pronounced in words of Germanic origin (*e.g.*, "hunt," "hook"); in some words of Romance origin, the h remains unpronounced (*e.g.*, "heir," "honour"), but in others it has been restored (*e.g.*, "humble," "humour"). The initial h often disappears in unaccented syllables (*e.g.*, "What did he say?").

In chemistry, H is the symbol for the element hydrogen.

(B.F.C.A.; J.W.P.)

In music in the German nomenclature, H stands for B natural, while the letter B is used for B flat. This confusing arrangement dates back to earlier centuries when, to get the semitone in the right place (between the 3rd and 4th notes) in the hexachord beginning on F, a new B, a half tone lower than the normal B, was introduced. This lowered B was called B molle (soft) and indicated by a rounded B (B *rotundum*) to distinguish it from the square sign of the natural B (B quadratum). B rotundum was later adopted as a general sign in the form of a flat (♭) to indicate the lowering of a note by a semitone, while B quadratum became the sign: in the form of a natural (♮), for a note not so lowered; and in this way, from the resemblance of the latter sign to an H, this letter came to be adopted in Germany for the natural or unlowered, B. In other words, H is here really an erroneous and misleading form of what was originally a square-shaped B.

HAAKON (Old Norse *Hákon*), the name of several kings of Norway, of whom the most important are the following:

HAAKON I, surnamed "the Good" (d. 961), was the youngest son of Harald Haarfager. He was fostered by King Aethelstan of England, who brought him up in the Christian religion, and on the news of his father's death in 933 provided him with ships and men for an expedition against his half-brother Erik, who had been proclaimed king. On his arrival in Norway Haakon gained the support of the landowners by promising to give up the rights of taxation claimed by his father over inherited real property. Erik fled, and was killed a few years later in England. His sons allied themselves with the Danes, but were invariably defeated by Haakon, who was successful in everything he undertook except in his attempt to introduce Christianity, which aroused an opposition he did not feel strong enough to face. He was killed at the battle of Fitje in 961, after a final victory over Erik's sons.

HAAKON IV, surnamed "the Old" (1204–1263), was declared to be the son of Haakon III, who died shortly before the former's birth in 1204. A year later the child was placed under the protection of King Inge, after whose death in 1217 he was chosen king; though until 1223 the church refused to recognize him, on the ground of illegitimacy, and the pope's dispensation for his coronation was not gained until much later. In the earlier part of

his reign much of the royal power was in the hands of Earl Skule, who intrigued against the king until 1239, when he proceeded to open hostility and was put to death. From this time onward Haakon's reign was marked by peace and prosperity, until in 1263 a dispute with the Scottish king concerning the Hebrides, a Norwegian possession, induced Haakon to undertake an expedition to the west of Scotland. A division of his army seems to have repulsed a large Scottish force at Largs (though the later Scottish accounts claim this battle as a victory), and, having won back the Norwegian possessions in Scotland. Haakon was wintering in the Orkneys. when he died on Dec. 15, 1263. A greater part of his fleet had been scattered and destroyed by storms. The most important event in his reign was the voluntary submission of the Icelandic commonwealth. Worn out by internal strife fostered by Haakon's emissaries, the Icelandic chiefs acknowledged the Norwegian king as overlord in 1262. Their example was followed by Greenland.

Haakon YII (1872–1957), the second son of Frederick VIII, king of Denmark. was born on Aug. 3. 1872, and was known as Prince Charles of Denmark. He married Maud. youngest daughter of Edward VII of England in 1896. In 1905 he accepted the throne of Norway and was crowned as Haakon VII in June 1906. In 1940. after the German invasion of Norway. he escaped to England, where he was able to act as a rallying-point for the Norwegian resistance. His return to Oslo in 1945 was warmly acclaimed. He died Sept. 21. 1957, at Oslo.

HAARLEM, a town of the Netherlands in the province of North Holland, on the Spaarne. Pop. (1957 est.) 167,264 (mun.).

Haarlem, a prosperous place in the middle of the 12th century, received its first town charter from William II, count of Holland and king of the Romans, in 1245. It played a considerable part in the wars of Holland with the Frisians. In 1492 it was captured by the insurgent peasants of North Holland and was retaken by the imperial stadholder, and deprived of its privileges. In 1572 Haarlem joined the revolt of the Netherlands against Spain, but in July 1573, after a seven months' siege, was forced to surrender to Alva's son Frederick. who exacted terrible vengeance. In 1577 it was recaptured by William of Orange and permanently incorporated in the united Netherlands. Haarlem was occupied by German troops in World War II.

Haarlem is the seat of the governor of the province of North Holland, and is a typical Dutch town, with numerous narrow canals and gabled houses. Of the ancient city gates the Spaarnewouder or Amsterdam gate alone remains. In the Frederiks park is a pump room supplied with a powerful chalybeate water from a spring, in the Haarlemmer polder. In the central market place are the old Fleshers' hall, built by Lieven de Key in 1603 and containing the archives: the town hall. the old Stadsdoelen, where the burgesses met in arms and the Groote Kerk ("Great Church"). This last, dedicated to St. Bavo, dates from the late 11th and early 16th centuries. Its great length (460 ft.) and the height and steepness of its vaulted cedarwood roof (1538) are very impressive. In the belfry are the damiaatjes, ("small bells") presented to the town, according to tradition, by William I, count of Holland (d. 1222), the crusader. The town hall was originally a palace of the counts of Holland. begun in the 12th century, and some old 13th-century beams still remain; but the building was remodeled in the beginning of the 17th century. Haarlem possesses a picture gallery celebrated for its fine collection of paintings by Frans Hals; there an exhibition was held in 1936, with contributions from all over the world. The town library contains several incunabula and a collection of early Dutch literature. At the head of the scientific institutions of Haarlem may be placed the Dutch Society of Sciences (Hollandsche *Maatschappij* van *Wetenschappen*), founded in 1752, and the Teyler society. Besides these there are the old weighhouse (1598) and the orphanage for girls (1608), originally an almshouse for old men, both built by the architect Lieven de Key of Ghent.

Cloth weaving and brewing declined in the beginning of the 16th century. A century later, silk, lace and damask weaving were introduced by French refugees, and became very important industries; but about the close of the 18th century this remarkable prosperity had also come to an end. and it was not till after 1830 that Haarlem began to develop the manufactures in which it is now chiefly engaged. Industries include cotton manufacture, dyeing, printing, bleaching, brewing, making of paint and type founding. One of the printing establishments has the reputation of being the oldest in the Netherlands, and publishes the oldest Dutch paper, De Opregte Haarlemmer Courant. Market gardening, especially horticulture, is extensively practised in the vicinity, so that Haarlem is the seat of a large trade in Dutch bulbs, especially hyacinths, tulips, fritillaries, spiraeas and japonicas.

HAARLEM LAKE (Dutch HAARLEMMER MEER), a commune of the province of North Holland, constituted by the law of July 16, 1855. It has an area of 70 sq.mi., and its population was 42,277 (mun.) in 1957 (est.). The commune was formerly a lake, which is said to have been a relic of a northern arm of the Rhine which passed through the district in the time of the Romans. In 1531 the Haarlemmer Meer and three smaller sheets of water in its vicinity had a united area of about 14,000 ac. The four lakes were formed into one by successive inundations and by 1647 the new Haarlem lake had an area of about 37,000 ac., which a century later had increased to more than 42,000 ac. As early as 1643 Jan Adriaanszoon Leeghwater proposed to endike and drain the lake; and similar schemes were brought forward from time to time. A furious hurricane in Nov. 1836 drove the waters as far as the gates of Amsterdam, and another on Christmas day sent them in the opposite direction to submerge the streets of Leiden. In Aug. 1837 the king appointed a royal commission of inquiry; the scheme proposed by the commission received the sanction of the second chamber in March 1839, and in the following May the work was begun. A canal was first dug round the lake for the reception of the water and the accommodation of the traffic which had previously been carried on. As the water from the lake had no natural outfall pumping by steam engines began in 1848, and the lake was dry by July 1852. The whole area of 42,096 ac. recovered from the waters brought in about £780,000, exactly covering the cost of the enterprise; so that the actual cost to the nation was only the amount of the interest on the capital. The soil is of various kinds, loam, clay, sand and peat; most of it is fertile, though in the lower portions there are barren patches where the scanty vegetation is covered with an ochreous deposit. Mineral springs occur containing a very high percentage of common salt; and a company was formed for working them. Corn, seeds, cattle? butter and cheese are the principal produce. Hoofddorp, Yenneperdorp or Nieuw Vennep, Abbenes and the vicinities of the pumping stations are the spots where the population has clustered most thickly.

HAAST, SIR JOHANN FRANZ JULIUS VON (1824–1887), German and British geologist, was born at Bonn on May 1, 1824. In 1858 he started for New Zealand to report on immigration possibilities. He assisted Hochstetter in his preliminary geological survey. The governments of Nelson and Canterbury then employed Haast to investigate the geology of those districts. He discovered gold and coal in Nelson, and carried on important researches with reference to the occurrence of *Dinornis* and other extinct wingless birds (Moas). His Geology of *the* Provinces of *Canterbury* and Westland, N.Z., was published in 1879. He was the founder and director of the Canterbury museum at Christchurch. He was surveyor-general of Canterbury from 1861 to 1871, and professor of geology at Canterbury college. He was elected F.R.S. in 1867; and he was knighted in 1887. He died at Wellington, N.Z., on Aug. 15, 1887.

HABAKKUK, the name borne by the eighth book of the Old Testament "Minor Prophets." Nothing is known of its writer, save what may be inferred from the book; legend connects him with Daniel ("Bel and the Dragon"). The book falls into three obvious parts, viz. (1) a dialogue between the prophet and God (i. 2–ii. 4); (2) a series of five woes pronounced on wickedness (ii. 5–ii. 20); (3) a poem describing the triumphant manifestation of God (iii.). There is considerable difficulty in regard to the interpretation of (1), on which that of (2) will turn; while (3) forms an independent section, to be considered separately.

In the dialogue the prophet cries to God against continued vio-

lence and injustice, though it is not clear whether this is done *within* or *to* Israel (i. 2–4). The Divine answer declares that God raises up the Chaldaeans, whose formidable resources are invincible (5–11). The prophet thereupon calls God's attention to the tyranny which He apparently allows to triumph and declares his purpose to wait till an answer is given to his complaint (i. 12–ii. 1). God answers by demanding patience, and by declaring that the righteous shall live by his faithfulness (ii. 2–4).

The interpretation of this dialogue which first suggests itself is that the prophet is referring to wickedness *within* the nation, which is to be punished by the Chaldaeans (*i.e.*, the Babylonians) as a Divine instrument; in the process the tyranny of the instrument itself calls for punishment, which the prophet is bidden to await in patient fidelity. On this view of the dialogue the subsequent woes will be pronounced against the Babylonians, and the date assigned to the prophecy will be about 600 B.C., *i.e.*, soon after the battle of Carchemish (605 B.C.) when the Babylonian victory over Egypt inaugurated a period of Babylonian supremacy which lasted till Babylon was overthrown by Cyrus in 538 B.C. It is strange, however, that the prophet should pass so abruptly in a single dialogue from the wickedness of Israel to that of Babylon, thus destroying his primary emphasis; moreover, the wickedness of i. 2 *seq.* and of i. 12 *seq.* seems identical. Possibly i. 5–11 is a misplaced earlier prophecy, whilst i. 2–4, 12 *seq.* refers to the Babylonian oppression of Israel (Giesebrecht, Nowack, Wellhausen), or it is a part of the Divine answer, following ii. 4, which would make the Babylonians the Divine instrument for punishing *Assyrian* tyranny (Budde). Duhm's theory (followed by Sellin) refers the whole book to the time of Alexander the Great, by the violent emendation of "Chaldaeans" to "Chittim" (= Greeks).

The most striking characteristic of the poem (iii.) lies in the superscription ("A prayer of Habakkuk the prophet. set to Shigionoth"), the subscription ("For the chief musician, on my stringed instruments"), and the insertion of the musical term "Selah" in three places (v. 3, g, 13). These liturgical notes make extremely probable the supposition that the poem has been taken from some collection like that of our present book of Psalms. The poem begins with a prayer that God will renew the historic manifestation of the exodus, which inaugurated the national history and faith; a thunderstorm moving up from the south is then described, in which God is revealed (3–7); it is asked whether this manifestation, whose course is further described, is against nature only (8–11); the answer is given that it is for the salvation of Israel against its wicked foes (12–15); the poet describes the effect in terror upon himself (16) and declares his confidence in God, even in utter agricultural adversity (17–19). There is nothing in this fine poem to connect it with the conception of the Chaldaeans as a Divine instrument. It is the nation that speaks through the poet (*cf.* v. 14), but at what period of its post-exilic history we have no means of inferring.

In regard to the theological teaching of the book: (1) the poem (iii.), though possibly latest in date, claims first consideration, because it avowedly moves in the circle of primitive ideas, and supplicates a Divine intervention, a direct and immediate manifestation of the transcendent God. He is conceived as controlling or overcoming the forces of nature; and though an earlier mythology has supplied some of the ideas, yet, as with the opening chapters of Genesis, they are transfigured by the moral purpose which animates them, the purpose to subdue all things that could frustrate the destiny of God's anointed (v. 13). The closing verses strike that deep note of absolute dependence on God, which is the glory of the religion of the Old Testament and its chief contribution to the spirit of the Gospels. (2) The prophecy of the Chaldaeans as the instruments of the Divine purpose involves a different, yet related, conception of the Divine providence. The philosophy of history, by which Hebrew prophets could read a deep moral significance into national disaster, and turn the flank of resistless attack, became one of the most important elements in the nation's faith. If the world powers were hard as flint in their dealings with Israel, the people of God were steeled to such moral endurance that each clash of their successive onsets kindled some new flame of devotion. Through the Chaldaeans. God worked a work which required centuries of life and literature to disclose its fulness (i. 5). (3) When we turn from this view of the Chaldaeans to the denunciation of their tyranny in "taunt songs" (ii. 5–20), we have simply a practical application of the doctrine of Divine government. God, being what He is, at once moral and all powerful, the immoral life is doomed to overthrow, whether the immorality consist in grasping rapacity, proud self-aggrandizement, cruel exaction, exulting triumph or senseless idolatry. (4) Yet, because the doom so often tarries, there arises the problem of the suffering of the innocent and the upright. How can God look down with tolerance that seems favour on so much that conflicts with His declared will and character? This is the great problem of Israel, finding its supreme expression for all time in the book of Job (*q.v.*). In that book the solution of the problem of innocent suffering lies hidden from the sufferer, even to the end, for he is not admitted with the reader to the secret of the prologue; it is the practical solution of faithfulness resting on faith which is offered to us. So here, with the principle of ii. 4, "the righteous shall live by his faithfulness." The different application of these words in the New Testament to "faith" is well known (Rom. i. 17; Gal. iii. 11; Heb. x. 38) though the difference is apt to be exaggerated by those who forget how much of the element of "faithfulness" lies in Paul's conception of "faith." In G. A. Smith's words, "as Paul's adaptation, 'the just shall live by faith,' has become the motto of evangelical Christianity, so we may say that Habakkuk's original of it has been the motto and the fame of Judaism: 'the righteous shall live by his faithfulness.' "

HABDALAH, in Judaism, the concluding ceremony of sabbaths and festivals. *See* KIDDUSH AND HABDALAH.

HABEAS CORPUS, in law, a writ issued by a judge or court of justice, commanding the person to whom it is directed to bring the body of a person in his custody before that or some other court for a specified purpose.

There are various forms of the writ, of which the most famous is that known as *habeas corpus ad subiiciendum,* the well-established remedy for violation of personal liberty. This is now the only important form of writ though there were originally many others. From the earliest records of the English law no free man could be detained in custody except on a criminal charge or conviction or for a civil debt. While the writ is a remedial mandatory writ—"of right." it is not "of course," and is granted only on application to the High Court or a judge thereof, supported by a sworn statement of facts setting up at least a probable case of illegal confinement. It is addressed to the person in whose custody another is detained, and commands him to bring his prisoner before the court immediately after the receipt of the writ, together with the day and cause of his being taken and detained, to undergo and receive (ad *subiiciendum et recipiendum*) whatsoever the court awarding the writ "may consider of concerning him in that behalf."

Writs of *habeas corpus* were issued before the Great Charter. The writ de *odio et atiâ* was used as early as the 12th century to prevent imprisonment on vexatious appeals of felony, and this writ is specifically mentioned in Article 36 of Magna Carta which provides that it shall issue gratuitously, and "not be refused." It played an important part in enabling a person to avoid trial by battle and obtain trial by jury. In the case of imprisonment on accusation of crime the writ issued from the court of king's bench (or from the chancery), and on its return the court judged of the legality of the imprisonment, and discharged the prisoner or admitted him to bail or remanded him to his former custody according to the result of the examination.

By the time of Charles I. the writ was fully established as the appropriate process for checking illegal imprisonment by inferior courts or by public officials.

In Darnel's case (1627) the judges held that the command of

the king was a sufficient answer to a writ of habeas corpus. The House of Commons thereupon passed resolutions to the contrary, and after a conference with the House of Lords the measure known as the Petition of Right was passed (1627, 3 Car. I c i.) which. inter alia, recited (s. j) that, contrary to the Great Charter and the good laws and statutes of the realm, divers of the king's subjects had of late been imprisoned without any cause shown, and nhen they were brought up on habeas *corpus* ad *subiiciendum*, and no cause was shown other than the special command of the king signified by the privy council, were nevertheless remanded to prison, and enacted "that no freeman in any such manner as is before mentioned be imprisoned or detained." By the Act of 1641 abolishing the Star Chamber, the right to a habeas corpus was given to test the legality of commitments by command or warrant of the king or the privy council.

The Act of 1679.—The reign of Charles II. was marked by further progress towards securing the freedom of the subject from wrongful imprisonment. Lord Clarendon was impeached, inter alia, for causing many persons to be imprisoned against law and to be conveyed in custody to places outside England.

Though the authority of the courts had been strengthened it was still rendered insufficient by reason of the insecurity of judicial tenure, the fact that only the chancellor (a political as well as a legal officer) and the court of king's bench had undoubted right to issue the writ, and the inability or hesitation of the competent judges to issue the writ except during the legal term, which did not cover more than half the year. A series of bills was passed through the Commons between 1668 and 1675, only to be rejected by the other House. In Jenkes's case (1676), Lord Chancellor Nottingham refused to issue the writ in vacation in a case in which a man had been committed by the king in council for a speech at Guildhall, and could get neither bail nor trial. In 1679, but rather in consequence of Lord Clarendon's arbitrary proceedings than of Jenkes's case, a fresh bill was introduced which passed both Houses and became the famous Habeas Corpus Act of 1679.

In the manner characteristic of English legislation the act is limited to the particular grievances immediately in view and is limited to imprisonment for criminal or supposed criminal matters, leaving untouched imprisonment on civil process or by private persons. It enacts in substance as follows: (1) When a writ of habeas *corpus* is directed to a sheriff or other person in charge of a prisoner, he must within 3. 10 or 20 days, according to the distance of the place of commitment, bring the body of his prisoner to the court, with the true cause of his detainer or imprisonment — unless the commitment was for treason or felony plainly expressed in the warrant of commitment. (2) If any person be committed for any crime — unless for treason or felony plainly expressed in the warrant — it shall be lawful for such person or persons (other than persons convicted or in execution by legal process) in time of vacation, to appeal to the lord chancellor as a judge, who shall issue a habeas corpus returnable immediately, and on the return thereof shall discharge the prisoner on giving security for his appearance before the proper court. unless the party so committed is detained upon a legal process or under a justice's warrant for a non-bailable offence. Persons neglecting for two terms to pray for a habeas corpus shall have none in vacation. (3) Persons set at large on habeas corpus shall not be recommitted for the same offence unless by the legal order and process of the court having cognizance of the case. (4) A person committed to prison for treason or felony shall, if he requires it. in the first week of the next term or the first day of the next session of oyer and terminer, be indicted in that term or session or else admitted to bail, unless it appears on affidavit that the witnesses for the Crown are not ready; and if he is not indicted and tried in the second term or session after commitment, or if after trial he is acquitted, he shall be discharged from imprisonment. (5) No inhabitant of England (except persons contracting. or, after conviction for felony, electing to be transported) shall be sent prisoner to Scotland, Ireland. Jersey etc , or any place beyond the seas. Stringent penalties are provided for ofienses against the act.

A judge delaying habeas corpus forfeits £500 to the party aggrieved. Illegal imprisonment beyond seas renders the offender liable in an action by the injured party to treble costs and damages to the extent of not less than £500, besides subjecting him to the penalties of praemunire and to other disabilities. "The great rank of those who were likely to offend against this part of the statute was," says Hallam, "the cause of this unusual severity." Indeed as early as 1591 the judges had complained of the difficulty of enforcing the writ in the case of imprisonment at the instance of magnates of the realm. The effect of the act was to impose upon the judges under severe sanction the duty of protecting personal liberty in the case of criminal charges and of securing speedy trial upon such charges when legally framed; and the improvement of their tenure of office at the revolution, coupled with the veto put by the Bill of Rights on excessive bail, gave the judicature the independence and authority necessary to enable them to keep the executive within the law and to restrain administrative development of the scope or penalties of the criminal law; and this power of the judiciary to control the executive, coupled with the limitations on the right to set up "Act of State" as an excuse for infringing individual liberty is the special characteristic of English constitutional law.

The habeas corpus ad *subiiciendum* was sometimes used in cases of illegal detention in private custody. In 1758 questions arose as to its application to persons in naval or military custody, including pressed men, which led to the introduction of a bill in parliament and to the consultation by the House of Lords of the judges. (See Wilmot's Opinions, p. 77.) In the same year the writ was used to release the wife of Earl Ferrers from his custody and maltreatment. But perhaps the most interesting instance of that period is the case of the Negro Somerset (1771) who was released from a claim to hold him as a slave in England.

The Act of 1816 (56 Geo. III. c. 100), does not touch cases covered by the Act of 1679. The object of it was to deal with cases of persons unlawfully detained in private custody. It enacts (1) that a writ of habeas corpus shall be issued in vacation time in favour of a person restrained of his liberty otherwise than for some criminal or supposed criminal matter (except persons imprisoned for debt or by civil process); (2) that though the return to the writ be good and sufficient in law, the judge shall examine into the truth of the facts set forth in such return, and if they appear doubtful the prisoner shall be bailed; (3) that the writ shall run to any port, harbour, road, creek or bay on the coast of England, although not within the body of any county. The last clause was intended to meet doubts on the applicability of habeas corpus in cases of illegal detention on board ship.

It will appear from the foregoing statement that the issue and enforcement of the writ rests on the common law as strengthened by the acts of 1627, 1640, 1679 and 1816, and subject also to the regulations as to procedure contained in the Crown *Office* Rules, 1906. The effect of tbe statutes is to keep the courts always open for the issue of the writ. It is available to put an end to all forms of illegal detention in public or private custody.

Suspension of the Act.—In times of public danger it has occasionally been thought necessary to "suspend" the Habeas Corpus act, 1679, by special and temporary legislation. This was done in 1794 (by an act annually renewed until 1801) and again in 1817, as to persons arrested and detained by his majesty for conspiring against his person and government. The same course was adopted in Ireland in 1866 during a Fenian rising. It has been the practice to make such acts annual and to follow their expiration by an act of indemnity. In cases where martial law exists the use of the writ is *ex* hypothesi suspended during conditions amounting to a state of war within the realm or the British possession affected (*e.g.*, the Cape Colony and Natal during the South African War), and it would seem that the acts of courts martial during the period are not the subject of review by the ordinary courts. The so-called "suspension of the Habeas Corpus act" bears a certain similarity to what is called in Europe "suspending the constitutional guarantees" or "proclaiming a state of siege," but "is not in reality more than suspension of one particular remedy for the protection of personal freedom."

A principle of the highest importance to the liberty of the subject was laid down by the house of lords in the case of Cox v. Hakes (1890), 15 A.C. 506, and further extended in the leading case of Ex *parte* Art *O'Brien* (1923), A.C. 603 This principle is that an appeal against the refusal of the writ may be taken by the applicant right up to the house of lords, but that an appeal by the crown against the grant of the writ by the divisional court cannot be taken any further. In other words, once the writ is granted, the crown cannot delay its operation or keep the applicant in custody by attempting to prosecute an appeal.

Furthermore it has been decided that it is no answer to the writ to plead that the person detained is no longer in the actual physical custody of the defendant; for example, mere power or control over a child is sufficient to justify the issue of the writ.

Scotland.—The writ of habeas corpus is unknown to Scots law, nor will it issue from English courts into Scotland. Under a Scots act of 1701 (c 6) provision is made for preventing wrongful imprisonment and against undue delay in trials. It was applied to treason ielony in 1848. The right to speedy trial is now regulated by

s. 43 of the Criminal Procedure Scotland act 1887. These enactments are as to Scotland equivalent to the English act of 1679. Under the Court of Exchequer Scotland act 1856 (19 and 20 V. c. 56) provision is made for bringing before the court of session persons and proceedings before inferior courts and public officers—which is analogous to the powers to issue *habeas corpus* in such cases out of the English court of exchequer (now the revenue side of the king's bench division). (W. F. C.; X.)

United States.—The common law of *habeas corpus* was inherited as part of the common law of the American states. The federal government as well as the states have founded their procedure upon the principles set forth in the act of 1679, most states specifically adopting its features by statutory enactment. The writ, as under the English system, is available to contest detention by public or private authority. The power of the court issuing it extends only to inquire into the jurisdiction of the court, administrative tribunal, or person detaining the prisoner, the legal sufficiency of the proceedings taken against him, or the validity of the judgment or order of commitment. No state or federal court can issue the writ beyond the territorial limits of its jurisdiction. The esteem with which the writ is regarded is illustrated by the embodiment of the provision in the federal constitution as well as in the constitutions of most states that the privilege of the writ "shall not be suspended unless when in cases of rebellion or invasion the public safety may require it." It is generally thought that the power to suspend the writ is vested in the legislative rather than the executive department of government Acting under such a theory during the Civil War, congress in 1863 granted the president the power of suspension whenever in his judgment the public safety demanded it. The proper exercise of such judgment by the president was held by the supreme court in Milligan's case (4 Wall. 2) to be subject to judicial review. In instances state supreme courts have regarded the privilege suspended by the state executives' proclamation that an insurrection existed in specified territory.

State courts have no power to issue the writ for the discharge of persons held under claim or colour of authority of any officer or court of the United States inasmuch as the federal government when acting within its sphere is supreme. Originally U.S. courts could not issue the writ to inquire into the cause of commitment by state courts. In 1833, however, due to the nullification movement in South Carolina resulting in resistance to the enforcement of federal revenue laws, congress extended the authority of the federal courts to inquire into any commitment for an act done in pursuance of a law of or authority under the United States. During the controversy over the Canadian boundary in 1842 this power was extended to authorize inquiry into the commitment of any foreign citizen for an act done under authority of a foreign state whose validity depended upon international law. In 1847 the power was again extended to all cases where a person was restrained of liberty in violation of the constitution, laws or treaties of the United States. This, however, does not permit the federal courts to obstruct the administration of justice in state courts whenever the accused claims that he is restrained in violation of a federal right. The state courts being themselves bound by the U.S. constitution, laws and treaties as the "supreme law of the land" can ordinarily be entrusted to determine the federal right, and in case the determination be contrary to the accused's contention he may resort by writ of error or *certiorari* to the U.S. supreme court. It is thus only in cases of peculiar urgency that the federal court will interfere in the first instance by *habeas corpus*. Such interference being an extremely delicate matter the supreme court has limited the issuance of *habeas corpus* to cases that concerned the authority or operations of the federal government, its obligations under international law to other nations or the vindication of a fundamental right in danger of violation before resort may be had to usual methods of appeal.

The various states have divergent views as to the accused's right of appeal from an order denying the issuance of habeas corpus The right where denied by judicial decision has commonly been granted by statute. It is also customary to provide by statute for a similar right of appeal on the part of the state. The original jurisdiction of the U.S. supreme court being limited by the constitution, it cannot issue the writ as an original matter except in cases within that jurisdiction. But in exercise of its appellate jurisdiction it may issue the writ to inquire into the validity of a detention under the authority of an inferior court to determine whether such court has acted without jurisdiction or exceeded its authority. (J. M. La.)

HABENARIA, a genus of plants of the orchid family (Orchidaceae), comprising in its most inclusive sense some 500 temperate and tropical species. In North America some 40 species occur, among which are the small purple-fringed orchis (*H. psycodes*), the white-fringed orchis (*H. blephariglottis*), the ragged orchis (*H. lacera*), the prairie fringed orchis (*H. leucophaea*), the yellow-fringed orchis (*H. ciliaris*), the white bog orchis (*H. dilatata*), the round-leaved orchis (*H. orbiculata*), the slender white orchis (*H. elegans*) and the western green orchis (*H. unalaschensis*). The frog orchis (*H. viridis*), scented orchis (*H. conopsea*) and butterfly orchis (*H. bifolia*) are native to the British Isles. *See* ORCHIDS.

HABER, FRITZ (1868–1934), German physical chemist, winner of the Nobel prize for chemistry in 1918 for his direct synthesis of ammonia from nitrogen and hydrogen, was born at Breslau. Dec. 9, 1868, and took his doctorate in organic chemistry at the Technische Hochschule, Berlin. He was essentially self-taught in his chosen field—physical chemistry with emphasis on technical application. His remarkable output of research began at Karlsruhe in 1894, beginning with a study of the thermal decomposition of hydrocarbons and combustion of gases in contact with cooled surfaces. This was a real contribution to the understanding of the cracking processes that have since become tremendously important.

Haber's work in electrochemistry was outstanding. He unraveled the complicated course of the electrolytic reduction of nitrobenzene. He was the first to demonstrate the significance of the electrode potential in oxidations and reductions, and developed the first general theory of electrochemical reduction. He destroyed the hopes that had been placed in fuel cells as a means for the direct electrochemical transformation of the energy of coal into electrical power. He showed that Faraday's law is valid for solid electrolytes. He worked out the theory of the glass electrode and developed its practical application. He provided standard methods for investigating and remedying the corrosion of underground gas and water mains due to stray currents from tramway systems. He studied beryllium compounds, the production of aluminum, the passivity of iron. the water gas equilibrium in the Bunsen flame, the speed of reaction in heterogeneous systems. the separation of gases by centrifugal force and the escape of electrons from metals. His studies of the optical analysis of gases led to the gas interferometer that bears his name. He devised a vibrating quartz manometer to measure low gas pressures, and constructed a fire damp whistle for use in mines. Among his later studies were: the chemical applications of Planck's quantum theory; the conditions determining the structure of precipitates; adsorption, chemiluminescence; chain reactions in gases; free radicals; the mechanism of combustion.

Haber's greatest achievement, which brought him the Nobel prize in 1918, was his successful synthesis of ammonia (*q.v.*). This was an outcome of his studies of the thermodynamics of gas reactions. He developed a small apparatus, but at first was quite skeptical about the feasibility of carrying out, on a technical scale, a reaction at red heat and under several hundred atmospheres of pressure. Eventually, he perfected his equipment so that the translation to the industrial scale, though still presenting gigantic problems, was far from hopeless. The credit for the large-scale development of the Haber process belongs mostly to Karl Bosch.

In 1911, Haber was called to direct the Kaiser Wilhelm Institut für Physikalische Chemie und Elektrochemie at Dahlem, Berlin. This research institute, which he headed until 1933, became the finest laboratory of its kind in the world, and mature chemists from all nations came there to work. In 1914, he placed his services at the disposal of the German imperial government, though he hated war and its horrors. He sensed at once that the issue could be decided by a lack of nitric acid, the essential raw material for high explosives. Haber's first efforts were to increase the supply of ammonia, which could then be oxidized to nitric acid. He also headed the organization of the gas warfare, and directed the chlorine gas attack at Ypres on April 22, 1915. He was made chief of the chemical warfare service in 1916.

Svante A. Arrhenius (*q.v.*) estimated that the oceans contain 8,000,000,000 tons of gold. When Germany was asked to pay in reparations the equivalent of 50,000 tons, Haber conceived the dramatic idea of securing the fabulous amount from the sea. He devised processes for the extraction of the metal from the water, whose gold content was believed to be at least five milligrams per ton. However, actual trials gave disappointing results, as it was discovered that the analyses had been erroneously high because of the gold content of the reagents and vessels. The actual content is about one-thousandth of a milligram per ton. The project was abandoned in 1928.

On a journey around the world, Haber spent two months in Japan, a nation with which he had great sympathy. In 1930 he

established the Japan institute, with headquarters in Berlin and Tokyo, to promote mutual understanding and cultural interests. The anti-Jewish policy of the nazi regime brought his resignation in 1933, and he accepted an invitation to work at the University of Cambridge. En route to Italy, to escape the dangers of the English winter, he suffered a heart attack at Basel and died on Jan. 29, 1934.

Besides his numerous scientific papers and published academic lectures, he was the author of: *Grundriss der technischen Elektrochemie auf theoretisclzer Grundlage* (1898); *Thermodynamik technische Gasreaktionen* (1905; English translation by Lamb, 1908); *Die elektrolytischen Prozesse der organischer Chemie,* with Moser (1910); *Beitrag zur Kenntnis der Metalle* (1919); *Aus Luft durch Kohle zum Stickstoffdünger, zu Brot und reichlicher Nahrung,* with Ramm and Caro (1920); *Über die Synthese des Ammoniaks* (1922); *Die Chemie im Kriege* (1922); *Fünf Vortrage aus den Jahren 1920–1923* (1924); *Über Die Herstellung des Ammoniaks aus Stickstoff und Wasserstoff* (1924); *Aus Leben und Beruf, Aufsatze, Reden, Vortrage* (1927).

(R. E. O.)

HABERL, FRANZ XAVER (1840–1910), German musical scholar and editor of ecclesiastical music. Born at Oberellenbach, Bavaria, April 12. 1840, he was ordained at Passau and in 1862 was appointed choirmaster of the cathedral. In 1867 he became organist at Sta. Maria dell'Anima in Rome, and in 1874 founded a school of ecclesiastical music at Regensburg which became an international centre of learning. He was appointed canon of the cathedral of Palestrina in 1879 and in the same year founded the Palestrina society. The publication of Palestrina's works had been begun in 1862, but Haberl discovered much new music and by 1894 had brought out 33 volumes of his works, followed by a supplement in 1907. He then began a similar publication of the works of Orlando di Lasso, in which he was assisted by Adolf Sandberger, who completed it (21 vol.; 1894–1927). Haberl wrote many works on the theory and practice of early ecclesiastical music, notably *Magister Choralis* (1864), and compiled a thematic catalogue of the archives of the Sistine choir. Toward the end of his life he was disappointed at seeing his studies of plain chant, on which he had spent 30 years, replaced by the official Vatican edition. His original research, particularly his editions of Palestrina and Di Lasso, remained the foundation of the work of later scholars. He died at Regensburg, Sept. 5, 1910.

See *Musica Sacra* ed. *by F.* Commer no. 10 and 12 (1910).

HABERLANDT, GOTTLIEB (1854–194j), Austrian plant physiologist best known for his studies in functional plant anatomy, was born at Ungarisch-Altenburg on Nov. 28, 1854. He received a doctorate from Vienna in 1876 and then studied under Simon Schwendener at Tiibingen. He became a *Privatdozent* of botany at Vienna in 1878, and in 1880 became professor of botany at Graz, where he remained until 1909. He visited the botanical gardens at Buitenzorg, Java, in 1891–92. His account of the journey appeared as *Eine botanische Tropenreise* (1893; 3rd ed., 1926). He accepted the chair of plant physiology at Berlin in 1909 and was founder-director of the plant physiology institute there until his retirement in 1923. He continued research as professor emeritus. He died at Berlin-Wilmersdorf on Jan. 30, 1945.

One of the foremost plant physiologists of his time, Haberlandt was the first to formulate the idea of plant-tissue culture (1902). However, his attempts at such culture were unsuccessful. He was also the first to present experimental evidence (1913, 1921) for the existence of "wound hormones" in plant tissues. He proposed several theories, *e.g.,* the "statolith theory," to explain geo- and phototropic movements of plants. *Pkysiologische Pflanzenanatomie* (1884; 6th ed., 1926), his best-known work, presents a classification of tissues based upon function, *i.e.,* dermal, photosynthetic, mechanical, absorptive, etc. Haberlandt's relating of physiology to anatomy had a profound influence on subsequent research and teaching.

See *Phyton* (article and bibliography), 6:1–14 (1955). Haberlandt's memoirs were published as *Erinnerungen: Bekenntnisse und Betrachtungen* (1933).

(J. W. Tr.)

HABIMA THEATRE, a Jewish theatrical group which was originally founded in Bialystok, Pol., in 1909 by Nahum L. Zemach, who wished to prepare a Hebrew acting group for eventual establishment in Palestine. This earlier venture was suppressed by tsarist police, but revived by Zemach in 1916 in Moscow, where the group's first efforts gained the support of Maksim Gorki, and Konstantin Stanislavski of the Moscow Art theatre. Evgheny Vakhtangov, assistant to Stanislavski, but critical of his extreme naturalism, became Habima's director. He found Jewish lore, especially Chassidic mysticism, congenial to his purpose and developed a new method, which he called fantastic realism, a dynamic theatricalism, applying music, dance and intense stylization to an essentially realistic intent. Characteristic Habima plays are Salomon Rappoport Ansky's *The Dybbuk,* Halper Leivick's *Der Golem,* David Pinski's *Wandering Jew* and Richard Beer-Hofmann's *Jacob's Dream.* Habima has applied its method to non-Jewish plays as well, especially since leaving Russia.

In Russia, Habima laboured under constant tension, even after the revolution. Hebrew was archaic; Zionism was even worse. Therefore, old themes, though criticized, were safer. In 1926, two years after the death of Vakhtangov, the group obtained permission to leave the country and tour Europe and America. It never returned. In 1928 it made a triumphant tour of Palestine. Habima. realizing completely the promise of its origin, settled permanently in Tel Aviv in 1931. Further tours abroad were made in 1937 and 1948. In 1945 a theatre building, including a dramatic school and library, was opened in Tel Aviv. (M. Rs.)

HABINGTON, WILLIAM (1605–1654), English poet whose best-known poems praise chastity and pure love, was born at Hindlip hall, Worcestershire, on Nov. 4, 1605. His best-known work is *Castara* (1634), a volume of rather frigid love poems. It was reprinted in 1635 with many additions: the third edition (1640) was further enlarged by the inclusion of some devotional poems, which show Habington at his strongest. He also wrote a tragicomedy, *The Queene of Arragon* (1640), and two prose works, *The Historie of Edward the Fourth* (1640) and *Observations Upon Historie* (1641). He died on Dec. 30, 1654.

HABIT, in psychology, a customary or automatic way of acting, usually as a result of frequent usage rather than of inborn origin. In a different sense "habit" is used to indicate the natural appearance, place and manner of growth of plants and animals. It is also a term for a coat or a form of clothing, especially one that is common to a species or is worn for a particular purpose. In botany and zoology "habit" may refer to innate tendencies and actions of plants or animals. Psychologists use "habit" to designate either a specific learned unit of behaviour or generically to refer to the several classes of acquired modes of acting or perceiving. Thus, a conditioned response is a habit, acquired and again modifiable. It shows variations in strength among individuals and in the same individual from one occasion to the next. Persons and animals exhibit changing tendencies to select and reorganize incoming stimulation from the environment. They acquire habitual rhythms of action that are independent of the immediate environment.

The acquisition and alteration of habits constitute topics of central concern in the study of behaviour. Psychologists and physiologists have concerned themselves with both the environmental and the organismic conditions and consequences of habit formation. They have shown that organisms differ in their susceptibility to the stimulus patterns which contribute to a change in behaviour. The social consequences of the use of habit-forming drugs have produced a highly specialized research area in applied psychophysiology.

The nature and optimum scheduling of reinforcement have been studied extensively in relation to the control of habitual activities of animals and people. Some investigators have stated that a full understanding of mechanisms of reinforcement promises to give a full understanding of how habits are changed. They assert that complexities of human behaviour arise out of the compounding of many habits based on many sources of reinforcement, some obvious and some extremely subtle. Other students of the subject have adopted an associationistic principle without recourse to a

"law of effect," the action of rewards or punishment being subsumed under a concept of motivation and acting only secondarily in habit formation.

William James discussed in his *Principles of Psychology* both the biological utility of habits as the means for conserving higher mental processes for more demanding tasks, and their more unfortunate consequences in behavioural inflexibility. He also theorized concerning their physiological basis in the nervous system. During the first half of the 20th century improved neurosurgical techniques and electrophysiological methods brought forth a sizable body of evidence on the structures necessary for habit formation, but answers to the fundamental biochemical questions remained elusive.

R. W. Sperry, R. E. Myers and their co-workers isolated visual and tactual discrimination habits to either half of the brain by cutting only certain essential nerve bundles that interconnect the right and left halves through the *corpus callosum*. Animals so prepared learned antagonistic habits depending upon which eye was uncovered or which paw was used in feeling the object. Careful experiments during 1955 to 1957 showed that cats so prepared developed independent sets of habits in the right and left hemispheres of the brain, where such habits were learned *following* the operation. Otherwise they behaved normally, as have human patients following similar brain surgery.

H. F. Harlow, D. O. Hebb and others showed that animals or children learn new habits with greater ease or difficulty depending upon previous experience in habit formation. The insightful solving of problems, once regarded by experts in the field of perception as being independent of previous learning, was shown to occur only after appropriate tool-using habits had been established. or, in the case of spatial detour problems, only after skills for discriminating relative positions in space had been developed. Spatial intelligence in man and animal depends in part upon early learning. Work in language and other symbol-using habits increased in response to the evidence that conceptual thinking requires prior acquisition of basic perceptual skills. One series of experiments in the 1950s showed that both early experience and frontal lobes of the brain are essential to the performance by dogs of spatial delayed-response problems.

The durability of emotional conditioning and the permanence of certain imprinted social discrimination habits in birds impressed scientists at mid-century with the need for continuing research on the effects of habits learned in infancy. *See* also ANIMAL BEHAVIOUR; BEHAVIOUR; CONDITIONING; LEARNING.

HABITUAL OFFENDERS. A habitual criminal is one who has frequently been punished, who has manifested a settled practice in crime and who presents a danger to the society in which he lives. American, English, commonwealth and most European penal systems provide for the more protracted imprisonment of such criminals than would normally be imposed in respect of their last crimes. The primary purpose of such provisions is the greater protection of the community. (N. R. M.)

United States.—The lams of the federal government of the U.S. and of the several states differ markedly on the definition of a habitual offender and on the punishment to be afforded criminals who have previously been convicted of crime. Legislation providing for specialized treatment of habitual offenders in the U.S. dates back only to the late 19th century in the more populous states and is of even more recent origin in most of the others. Only Maryland, Mississippi, North Carolina and South Carolina by the latter 1950s did not have such legislation. In those states which had taken action, the differences extended even to the term of description, so that a person convicted of crime more than once might be termed a "multiple," "habitual" or "persistent offender," or a "previous ofiender" (New York), a "repeater" (Wisconsin), a "persistent violator of law" (Idaho) or a "habitual criminal" (Illinois). In general, the statutes provided that a habitual offender may or shall be sentenced to an additional number of years of imprisonment on proof of his earlier conviction or convictions. In some jurisdictions, the prior offense must have been a felony to warrant the increased punishment. Some states, for example New York, provided for an increase in the number of years of imprisonment to be imposed up to a life sentence, according to the number of prior convictions. Differences in law were also based on whether the additional sanction should be mandatory or at the discretion of the court; whether the judge or the jury was to make the finding of prior conviction; and whether the jury ought to be informed of the prior conviction before it concluded its deliberations on the question of guilt on the immediate offense charged. It was not possible to say that the statutes had accomplished their intended purpose, whether the intent was to remove the more dangerous criminal from society or to give the penologists additional time within which to rehabilitate such a prisoner. It is contended that the powers generally given to a criminal court to impose indeterminate sentences have obviated the necessity for or desirability of habitual offender legislation.

Waite, *The Prevention of Repeated Crime* (1943); P. W. Tappan, "Habitual Offender Laws and Sentencing Practices in Relation to Organized Crime and Law Enforcement" in American Bar Association, Commission on Organized Crime, *Organized Crime and Law Enforcement* (1952). (P. B. K.)

English and European Law.—By the Prevention of Crime act, 1908, power was given to English courts to sentence habitual criminals to a period of preventive detention in addition to one of penal servitude in respect of their last conviction. Owing to procedural complexities and the reluctance of the courts to impose what seemed to be a double punishment, these provisions oi the 1908 act had fallen into desuetude when they were supplanted by section 21 of the Criminal Justice act, 1948. Under this section a court may sentence a habitual criminal to a prescribed period of preventive detention of irom 5 to 14 years, if it thinks such protracted segregation expedient for the protection of the public. To qualify ior such a sentence the criminal must be of or over the age of 30, convicted on indictment of an offense punishable with imprisonment for a term oi two years or more, and must have, since the age of 17, been convicted on at least three previous occasions of offenses so punishable and at least twice previously sentenced to prison or Borstal (*see* BORSTAL SYSTEM). Preventive detention is served in lieu of other punishment for the last crime.

From 1854, France had transported certain criminals to its penal colonies. In 1885 this punishment was made applicable to habitual criminals and, under the name of *relégation*, between that date and 1938 was extensively applied. No other European countries emulated the French practice and France too abandoned it.

The Swiss Draft Penal code of 1893, prepared by Carl Stoos, provided for the indeterminate detention of habitual criminals in institutions specially adapted to that purpose, such detention to take the place of punishment for their last offenses. He coined the phrase *mesure de sûreté* to describe this type of sentence. In 1937 this plan was accepted in Switzerland. though it had by then, with various modifications been applied widely throughout western Europe—Norway, in 1902, having been the first country to test it. The main differences between continental and English penal practice are the wider discretion which tends to be given to courts on the continent in determining which offenders may be punished as habitual criminals, and the wider discretion there held by the penal administrators or special administrative tribunals to determine the date of conditional or final release of the habitual criminal.

The purpose of sentences of this type being primarily to segregate and only secondarily to deter and reform, those administering European and English penal systems have endeavoured to ameliorate the penal conditions of such prisoners, particularly toward the end of their terms. Thus under the 1948 English act, preventive detainees pass through three stages of penal treatment; the first stage is served in a local prison under ordinary prison condition., the stcond in a central prison but to a degree separated from and with more privileges than the other prisoners. and the third in special prerelease conditions designed to fit the preventive detainee for release and to test his fitness therefor. The habitual criminal will normally be released on licence under the supervision of the Central After-Care association. (*See* also CRIMINOLOGY; RECIDIVISM.) (N. R. M.)

HABSBURG or HAPSBURG, the name of the family from which sprang the dukes and archdukes of Austria after 1282, kings of Hungary and Bohemia after 1526 and emperors of Austria after 1804. They were Roman emperors. 1438–1806, kings of Spain, 1516–1700, and held innumerable other dignities.

The name Habsburg was derived from the castle of Habsburg, or Habichtsburg (hawk's castle) on the Aar. near its junction with the Rhine. which was built in 1028 by Werner, bishop of Strasbourg, and his brother-in-law. Count Radboto. The founder of the house was probably Guntram the Rich, who has been identified with much probability with a Count Guntram who was involved in a rebellion under Otto I. Radboto's son Werner (d. 1096) and grandson Otto were called counts of Habsburg. Otto's son Werner (d. 1167) was father of Albert (d. 1199), who was count of Zürich and landgrave of Upper Alsace. His son Rudolph acquired Laufenburg and the protectorate over the "Waldstätte"

(Schwyz, Uri, Unterwalden and Lucerne). On his death in 1232, his two sons Albert and Rudolph partitioned his lands. The line of Habsburg-Laufenburg, Rudolph's descendants, became extinct in 1415, having previously sold back Laufenburg and other districts to the senior branch (Habsburg-Habsburg). Albert, founder of this branch, who died in 1239, had married Hedwig of Kyburg (d. 1260). Their son was Rudolph I. (*q.v.*), elected German king 1273.

Henceforward the history of the family of Habsburg is synonymous with that of their dominions. The present article will confine itself to stating the chief events in the history of the family as such. The attached genealogical tables show the ramifications of the family; its chief members are noticed in separate articles.

The earlier Habsburgs vested the government and enjoyment of their domains, not in individuals but in all male members of the family in common. Thus Rudolph I., as emperor, bestowed Austria and Styria on his two sons Albert and Rudolph, in common. By a family ruling of 1283, Rudolph renounced his share; but the question arose again after Albert's death. Owing partly to the representations of the Estates, a system of condominium was adopted, and the partition again avoided. In 1364 Rudolph made a fresh family compact with his younger brothers, which, while admitting the principle of equal rights, vested the rule and chief position de *facto* in the head of the house; but after his death, the partition was actually effected (agreement of Neuberg, 1379). Albert III. took the duchy of Austria, his brother Leopold III. Styria, Carinthia and the Tyrol, for himself and his descendants. Titles, arms and banner remained common to both lines, fiefs of the empire (Alsace) were held in condominium, and on the extinction of either male line, its dominions were to pass to the other.

This policy of partition was one of the main causes of the decline of Austria in the later Middle Ages. While the Austrian line was perpetuated only by one son in each generation until it became extinct on the death of Ladislaus Postumus in 1457, the domains then passing to the Styrian line, the latter had been again subdivided into an Inner Austrian and a Tyrolean line. The Emperor Frederick III. (*q.v.*) first acted, in his capacity as senior member of full age of his house, as regent both for Ladislaus Postumus in Austria and for Sigismund in the Tyrol; and as all the collateral lines now died out, his son Maximilian reunited all the Habsburg possessions in his own person.

During the period 1282–1493 the Habsburgs increased their dominions and dignities in many directions. The title of German king, held by Rudolph I., was held again by Albert I. (*q.v.*) from 1298–1308. Frederick the Fair, who assumed the title 1314–22, was the nominee of a minority of electors, and it then passed from the family until reassumed by Albert II. (*q.v.*) in 1438. From this date onward the titles of German king and Roman emperor remained in the Habsburg family uninterruptedly, with the single exception of the reign of Charles Albert, elector of Bavaria (1742–45), until their extinction. To the duchies of Austria and Styria, which the sons of Rudolph I. received in 1282, they and their successors were able to add the Tyrol, Vorarlberg. Carinthia, Carniola, and Gorizia. By the *privilegium maius* of 1453, they received a special status in the empire and the title of archduke (*q.v.*). On the other hand, a long series of reverses deprived them of practically all their possessions in Switzerland (Morgarten 1315, Sempach 1386, "perpetual peace" of 1474), and they were unable to retain the coveted crowns of Bohemia and Hungary. The crown of Bohemia, bestowed by Albert I. on his son Rudolph in 1306, was lost on Rudolph's death in the following year. It was again bequeathed, together with that of Hungary, to Albert II. by his father-in-law Sigismund of Luxemburg in 1437; but Albert died in 1439 and both crowns were lost when his son, Ladislaus Postumus, died unmarried in 1437.

Hitherto the Habsburgs had been identified only with the conduct of their Austrian dorninions, which, if increasing in extent, had certainly not added to their prosperity since the days of the Babenbergers; and with the somewhat equivocal title of German king and Roman emperor. Maximilian I. (q v j opened up a new era for his house. He restored and consolidated his Austrian dominions; and by his marriage with the heiress of Charles the Bold of Eurgundy, increased them by a second family domain on the other flank of the empire, consisting, as finally delimited, of the Netherlands, Artois, and the Franche Comté. His efforts to secure a foothold in Italy, after his second marriage with Bianca Sforza, daughter of the Duke of Milan, proved unsuccessful; but he more than compensated for many disastrous wars by the brilliance of his marriage policy. His only son, Philip I. (*q.v.*), married Joanna, daughter of Ferdinand and Isabella of Spain, and died in 1506, leaving two sons, Charles and Ferdinand. Charles succeeded his father in the Netherlands in 1506 and his grandfather in Spain in 1j16, becoming the emperor Charles V. (*q.v.*) on Maximilian's death in 1519. At the same time he succeeded to all the Habsburg dominions; but by the Treaty of Brussels (1522) he assigned to his brother Ferdinand (see FERDINAND I., Roman Emperor) the Austrian dominions. In the same year Ferdinand married Anne, daughter of Wladislaus, king of Hungary and Bohemia; and when his childless brother-in-law, King Louis, was killed at Mohacs (1526), he laid claim to Bohemia and Hungary both by right of his wife and by treaty. In each case the Estates denied the validity of the hereditary title; but those of Bohemia elected Ferdinand king in 1526. In Hungary he was also elected, but a counter-party elected John Zapolya (*q.v.*), with whom Ferdinand made a treaty in 1538, receiving north-western Hungary and the succession (afterwards repudiated) to Zapolya's dominions.

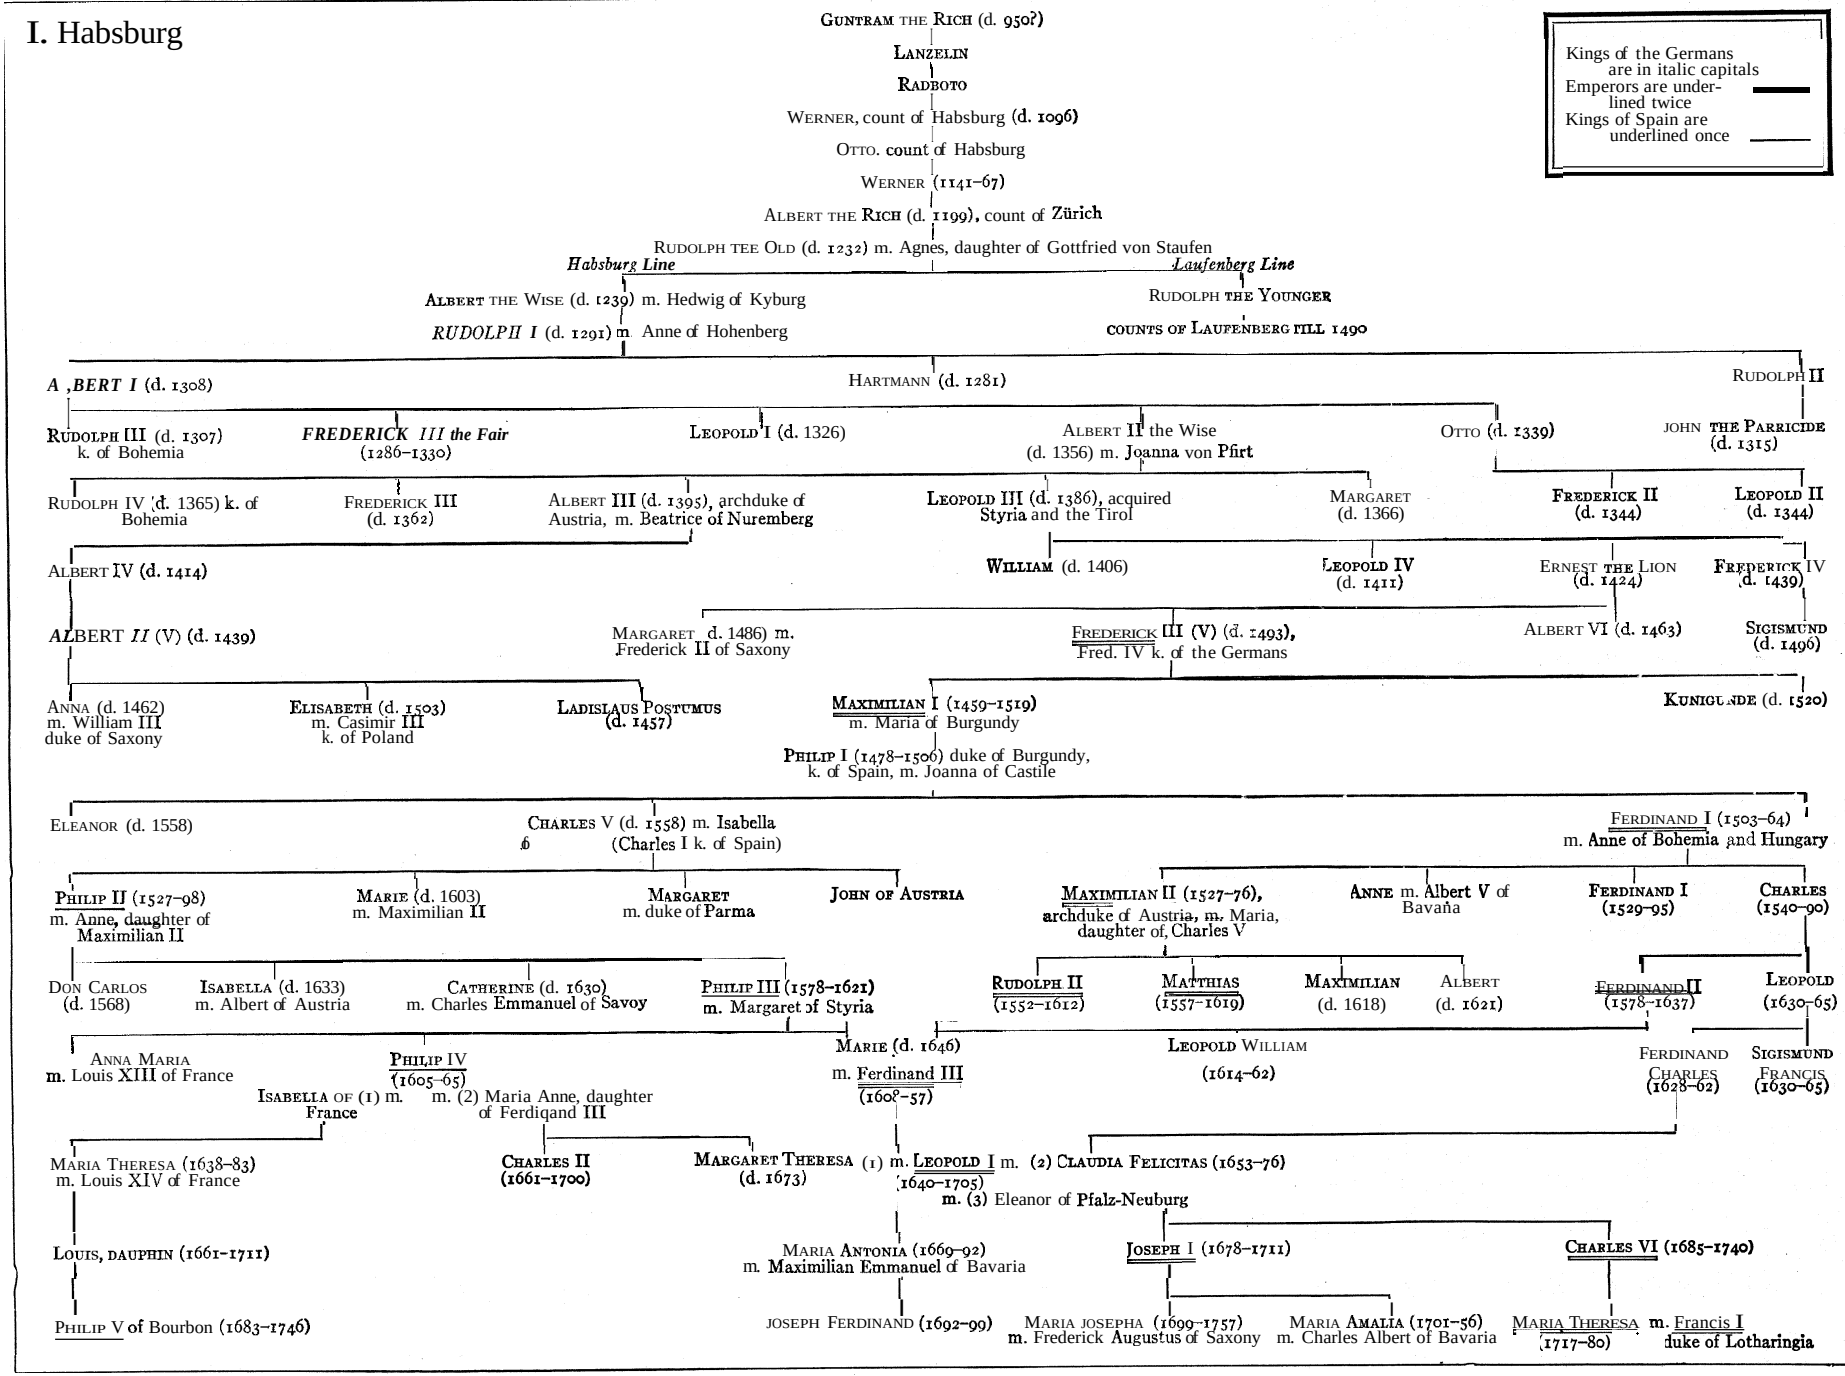
The Habsburgs had now reached the summit of their power. The prestige which belonged to Charles as head of the Holy Roman empire was backed by the wealth and commerce of the Netherlands and of Spain, and by the riches of the Spanish colonies in America. In Italy he ruled over Sardinia, Naples and Sicily, which had passed to him with Spain, and the duchy of Milan, which he had annexed in 1535; to the Netherlands he had added Friesland, the bishopric of Utrecht, Groningen and Gelderland, and he still possessed Franche-Comté and the fragments of the Habsburg lands in Alsace and the neighbourhood. Add to this Ferdinand's inheritance, the Austrian archduchies and Tirol, Bohemia with her dependent provinces, and a strip of Hungary, and the two brothers had under their sway a part of Europe the extent of which was great, but the wealth and importance of which were immeasurably greater.

When Charles V. abdicated he was succeeded as emperor, not by his son Philip, but by his brother Ferdinand. Philip became king of Spain, ruling also the Netherlands, Franche-Comte, Naples, Sicily, Milan and Sardinia, and the family was definitely divided into the Spanish and Austrian branches. For Spain and the Spanish Habsburgs the 17th century was a period of loss and decay, the seeds of which were sown during the reign of Philip II. (*q.v.*). The northern provinces of the Netherlands were lost practically in 1609 and definitely by the treaty of Westphalia in 1648; Roussillon and Artois were annexed to France by the treaty of the Pyrenees in 1659, Franche-Comté and a number of towns in the Spanish Netherlands by the treaty of Nijmwegen in 1678 Finally Charles II. (*q.v.*), the last Habsburg king of Spain, died childless in Nov. 1700, and by the peace of Rastatt (1714) which terminated the War of the Spanish Succession, Spain passed from the Habsburgs to the Bourbons. However, the Austrian branch of the family received the Italian possessions of Charles II., except Sicily, which was given to the duke of Savoy, and also the southern Netherlands, which are thus often referred to as the Austrian Netherlands; and retained the duchy of Mantua, which it had seized in 1708. In 1717 it received Sicily in exchange for Sardinia; but in 1735 had to cede Novara, Tortona and the two Sicilies, receiving in return the duchies of Parma and Piacenza.

In the Austrian line fresh partitions were effected during the 16th and 17th centuries; but after 1665 this disastrous policy was finally abandoned in favour of that of primogeniture throughout the Austrian dominions.

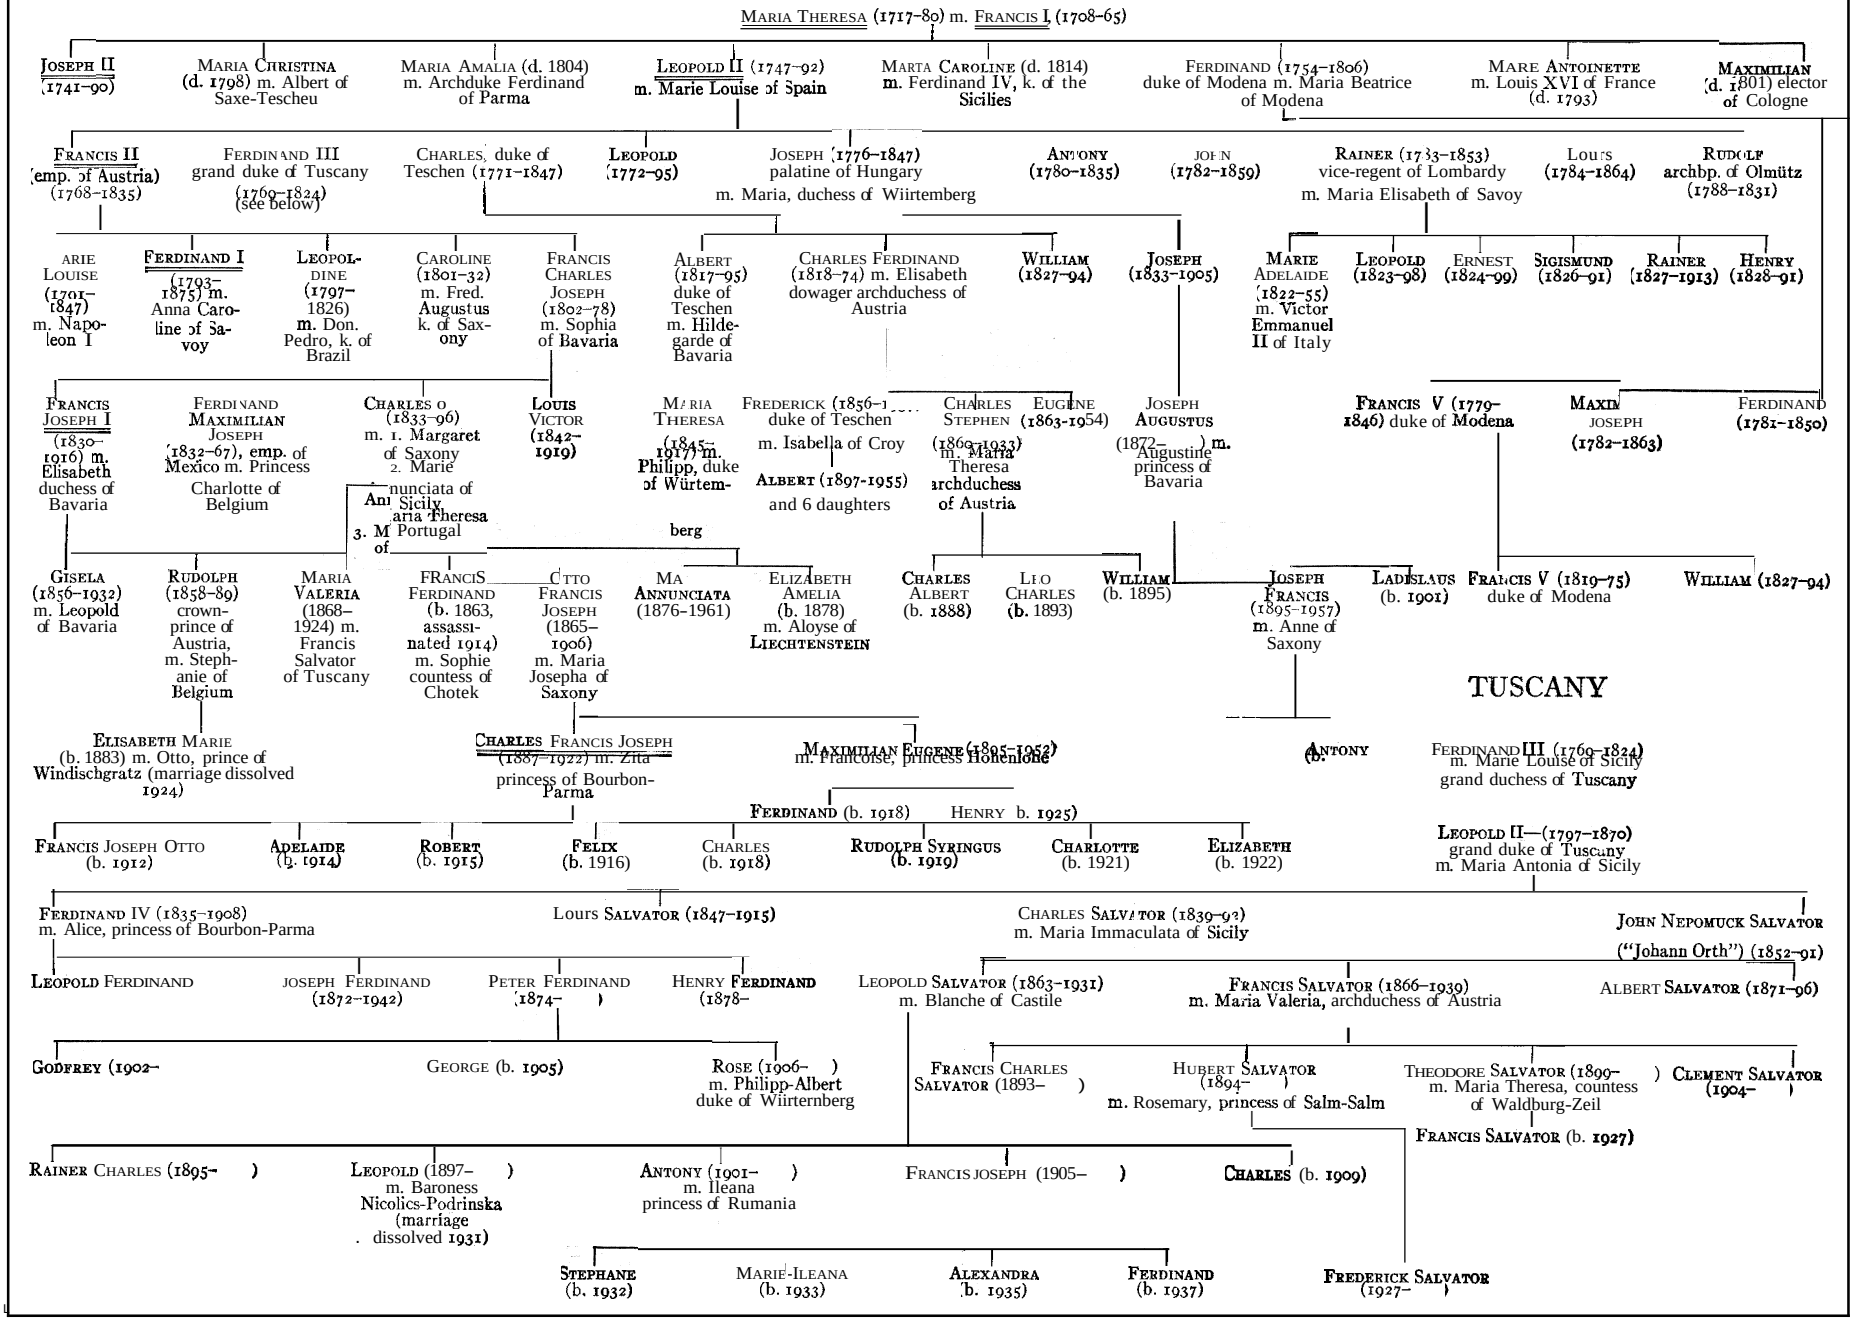
The Thirty Years' War deprived the Habsburgs of Alsace, came near to ruining the empire, and forced the Habsburgs to devote themselves more and more exclusively to their family dominions. After breaking the resistance of the nobles, Ferdinand II. (*q.v.*)

I. Habsburg



Kings of the Germans are in italic capitals
Emperors are underlined twice
Kings of Spain are underlined once
GUNTRAM THE RICH (d. 950?)
LANZELIN
RADBOTO
WERNER, count of Habsburg (d. 1096)
OTTO, count of Habsburg
WERNER (1141–67)
ALBERT THE RICH (d. 1199), count of Zürich
RUDOLPH TEE OLD (d. 1232) m. Agnes, daughter of Gottfried von Staufen
Habsburg Line
Laufenberg Line
ALBERT THE WISE (d. 1239) m. Hedwig of Kyburg
RUDOLPH THE YOUNGER
RUDOLPH I (d. 1291) m. Anne of Hohenberg
COUNTS OF LAUFENBERG till 1490
ALBERT I (d. 1308)
HARTMANN (d. 1281)
RUDOLPH II
RUDOLPH III (d. 1307) k. of Bohemia
FREDERICK III the Fair (1286–1330)
LEOPOLD I (d. 1326)
ALBERT II the Wise (d. 1356) m. Joanna von Pfirt
OTTO (d. 1339)
JOHN THE PARRICIDE (d. 1315)
RUDOLPH IV (d. 1365) k. of Bohemia
FREDERICK III (d. 1362)
ALBERT III (d. 1395), archduke of Austria, m. Beatrice of Nuremberg
LEOPOLD III (d. 1386), acquired Styria and the Tirol
MARGARET (d. 1366)
FREDERICK II (d. 1344)
LEOPOLD II (d. 1344)
ALBERT IV (d. 1414)
WILLIAM (d. 1406)
LEOPOLD IV (d. 1411)
ERNEST THE LION (d. 1424)
FREDERICK IV (d. 1439)
ALBERT II (V) (d. 1439)
MARGARET d. 1486) m. Frederick II of Saxony
FREDERICK III (V) (d. 1493), Fred. IV k. of the Germans
ALBERT VI (d. 1463)
SIGISMUND (d. 1496)
ANNA (d. 1462) m. William III duke of Saxony
ELISABETH (d. 1503) m. Casimir III k. of Poland
LADISLAUS POSTUMUS (d. 1457)
MAXIMILIAN I (1459–1519) m. Maria of Burgundy
KUNIGUNDE (d. 1520)
PHILIP I (1478–1506) duke of Burgundy, k. of Spain, m. Joanna of Castile
ELEANOR (d. 1558)
CHARLES V (d. 1558) m. Isabella (Charles I k. of Spain)
FERDINAND I (1503–64) m. Anne of Bohemia and Hungary
PHILIP II (1527–98) m. Anne, daughter of Maximilian II
MARIE (d. 1603) m. Maximilian II
MARGARET m. duke of Parma
JOHN OF AUSTRIA
MAXIMILIAN II (1527–76), archduke of Austria, m. Maria, daughter of Charles V
ANNE m. Albert V of Bavaria
FERDINAND I (1529–95)
CHARLES (1540–90)
DON CARLOS (d. 1568)
ISABELLA (d. 1633) m. Albert of Austria
CATHERINE (d. 1630) m. Charles Emmanuel of Savoy
PHILIP III (1578–1621) m. Margaret of Styria
RUDOLPH II (1552–1612)
MATTHIAS (1557–1619)
MAXIMILIAN (d. 1618)
ALBERT (d. 1621)
FERDINAND II (1578–1637)
LEOPOLD (1630–65)
ANNA MARIA m. Louis XIII of France
PHILIP IV (1605–65)
ISABELLA OF FRANCE (1) m.
m. (2) Maria Anne, daughter of Ferdiqand III
MARIE (d. 1646) m. Ferdinand III (1608–57)
LEOPOLD WILLIAM (1614–62)
FERDINAND CHARLES (1628–62)
SIGISMUND FRANCIS (1630–65)
MARIA THERESA (1638–83) m. Louis XIV of France
CHARLES II (1661–1700)
MARGARET THERESA (d. 1673)
(1) m. LEOPOLD I (1640–1705) m. (2) CLAUDIA FELICITAS (1653–76) m. (3) Eleanor of Pfalz-Neuburg
LOUIS, DAUPHIN (1661–1711)
MARIA ANTONIA (1669–92) m. Maximilian Emmanuel of Bavaria
JOSEPH I (1678–1711)
CHARLES VI (1685–1740)
PHILIP V of Bourbon (1683–1746)
JOSEPH FERDINAND (1692–99)
MARIA JOSEPHA (1699–1757) m. Frederick Augustus of Saxony
MARIA AMALIA (1701–56) m. Charles Albert of Bavaria
MARIA THERESA (1717–80) m. Francis I duke of Lotharingia

II. HOUSE OF HABSBURG-LORRAINE



declared the thrones of Bohemia (1627) and Moravia (1628) hereditary in his dynasty. Half a century later the Turks were driven back out of Hungary. The Diet of Pressburg (1687) recognized the male line of the Habsburgs in primogeniture as hereditary kings of Hungary; the Peace of Karlovitz (1699) gave them *de facto* possession of most of Hungary, including Transylvania, which had already accepted their rule. The Banat was added in 1718.

Leopold I. (*q.v.*) had made arrangements with his two sons, Joseph and Charles, for a fresh partition of the Spanish and Austrian dominions. The former were, however, lost to the Habsburgs after the War of the Spanish Succession. Joseph I. (*q.v.*) died without male issue, and Charles VI. (*q.v.*), who succeeded him as emperor in 1711, was also without sons. In 1713 he issued (as an unilateral expression of his will, communicated to his Privy Council) his wish that all his dominions should form an indivisible whole, and should pass as such to his male descendants in primogeniture, after them to his female descendants, after them to Joseph's daughters, after them to the other branches of his family. This "Pragmatic Sanction," the most famous of the Habsburg dynastic instruments, was that by which their relation within the dynasty and with their subjects were regulated until the fall of the dynasty. The formal acceptance of it was received in various forms by the Estates of all Charles' dominions from 1720 onward; it was publicly promulgated in 1724, and guaranteed by the imperial diet in 1731 and by the main European powers severally. With Charles' death in 1740, the true line of the Habsburgs became extinct; but his daughter, Maria Theresa (*q.v.*), who in 1736 had married Francis Stephen, duke of Lorraine (*see* FRANCIS I.) succeeded him, becoming founder of the house of Habsburg-Lorraine. The Pragmatic Sanction was respected within her dominions, but not outside them. Maria Theresa lost most of Silesia to Prussia, but later acquired part of Poland, while in Italy she surrendered Parma and Piacenza to Spain and part of Milan to Sardinia but acquired Tuscany through her husband. Under Joseph II. (*q.v.*) the Innviertel and the Bukovina were gained, and the Polish frontier revised, but the Netheriands rebelled successfully.

The Habsburgs emerged from the many changes brought about during the Napoleonic era shorn of the Netherlands, but in possession of Galicia and Lodomeria, Salzburg, Dalmatia and the kingdom of Lombardy-Venetia. The title of Holy Roman emperor had been abandoned by Francis II (*q.v.*) in 1806, but in 1804 he had assumed the title of emperor of Austria as Francis I. In addition, the family of Habsburg possessed certain lands in Italy which formed no part of the Austrian empire. These were the grand duchy of Tuscany, which passed on the death of the emperor Francis I., by special arrangement, to his younger son Leopold, and after his succession to the empire as Leopold II. (*q.v.*) to a third brother, Ferdinand, under whose rule and that of his son Leopold it remained until incorporated in the kingdom of Sardinia in 1859; and the duchy of Modena, acquired by the emperor Leopold II.'s younger son Ferdinand by his marriage with Mary Beatrice d'Este, which was also lost in 1859. The Modena-d'Este line of the Habsburgs became extinct with the death of Francis V. (*q.v.*) in 1875.

Francis I. was succeeded as emperor by his son Ferdinand I. (*q.v.*), who abdicated after the revolution of 1848 in favour of his young nephew Francis Joseph (*q.v.*). In the course of his long reign, Francis Joseph lost the Lombard-Venetian kingdom to Italy (1859, 1866), but acquired Bosnia and the Hercegovina (mandate of occupation 1877, annexation 1908). In 1867 his relations with Hungary were reorganised under the Compromise of that year; while in 1915 the title of "Austrian empire" was granted to his remaining dominions. A remarkable but short-lived extension of the Habsburg dominions was formed by the assumption in 1863 of the title of Emperor of Mexico by Francis Joseph's brother Maximilian (*q.v.*).

Fall of the Habsburgs.—Francis Joseph was succeeded in 1916 by his great-nephew Charles I. (*q.v.*). At that time his subjects still protested loyalty to the dynasty; but during the collapse of Oct. 1918, consequent on the World War, the Poles, Ruthenians, Czechoslovaks and Yugoslavs repudiated his authority. On Oct. 27 Count Andrássy, the Austro-Hungarian foreign minister, accepted President Wilson's demands "regarding the rights of the peoples of Austria-Hungary, particularly those of the Czechoslovaks and Yugoslavs." The states of Poland, Yugoslavia and Czechoslovakia soon after came formally into being, and although Charles never renounced his sovereign rights in these territories, the Habsburg family afterwards made no serious claim to reassert them. The treaties of Saint Germain and Trianon perpetuated the boundaries of these States, and confirmed Italy and Rumania in the possession of their parts of the former Habsburg monarchy.

There remained only German-Austria and Hungary. On Nov. 11, 1918, Charles issued a proclamation in which he stated:

> Still, as ever, filled with unchanging love towards all my peoples, I will not oppose my person as an obstacle to their free development. I recognise in advance the decision which German-Austria will take on its future form of State. The people has assumed the government through its representatives. I renounce any share in the affairs of State. At the same time I remove my Austrian Government from its office.

The provisional Government of German-Austria proclaimed a republic on the following day. On March 12, 1919, following the elections, the first national assembly repeated this declaration. Charles, however, refused to abdicate in his own name and that of his dynasty. Thereupon the national assembly, by decree of April 2, 1919, banished all Habsburgs from Austria acd confiscated the family property for the benefit of the war invalids. Habsburgs who renounced all rights other than ,those of private citizens were, however, allowed to live unmolested in Austria, and several of them did so. The legitimist movement in Austria has been very weak since these events. Austrian republicans claim that Charles's acceptance in advance of the republic was equivalent to a renunciation of the throne.

Charles issued a similar proclamation to Hungary on Nov. 13 which Karolyi answered by proclaiming the Hungarian republic on Nov. 16. When, however, the Right regained power in Hungary after Karolyi's and Kun's régimes, it proceeded by Act I. of 1920 to abolish all legislation passed by these two Governments. Hungary, therefore, reverted to the status of a kingdom, and controversy arose whether or not Charles's action had annulled the pragmatic sanction.

On Feb. 2, 1920, during the discussions on the draft treaty of Trianon, the Allied and Associated Powers declared that a Habsburg restoration in Hungary would be a matter of international concern and that they would neither recognise nor tolerate such a restoration. They attempted to insist on Hungary's styling herself a republic, but finally, in view of the objections raised by the Hungarian delegation, compromised on the word "Hungary."

Charles returned to Hungary and attempted to assert his claim on March 27 and Oct. 26, 1921 (see HUNGARY). After the second coup, under pressure from the Powers and the Little Entente. the Hungarian Parliament passed a decree (Nov. 3, 1921) whereby the sovereign rights of Charles and the pragmatic sanction were declared forever abrogated and the right of the Hungarian nation to elect its king by free choice restored. On Nov. 10 Hungary addressed a note to the Powers consenting only to elect its king in agreement with the Powers and accepting the notes of Feb. 2 and April 3, 1921. The Legitimist party, however, continued to look on Otto, Charles's eldest son, as the legitimate king after Charles's death on April 1, 1922.

Despite their unique career, the Habsburgs produced no statesman of great ability, with the exception of Charles V., and perhaps of Joseph II. Several members of the family displayed marked traces of insanity, and during the last century of their rule they were proverbial for their scandals and eccentricities. With hardly an exception, they were strongly conservative and intensely convinced upholders of the monarchical tradition. From the 16th century onward, they were nearly all extreme supporters of the Catholic idea; the title of Apostolic Majesty, which they wore as kings of Hungary, represented a very real attitude. The few exceptions—Joseph II., the Crown Prince Rudolph, and "Johann Orth"—all came to mysterious and unhappy ends. The

family tradition was exceedingly strict among them to the last, as was well exemplified when the Archduke Francis Ferdinand (*q.v.*) contracted his morganatic marriage. They owed their position chiefly to outward circumstance and to a series of marriages so adroit and successful as to give rise to the proverb *"Bella gerant alii, tu, felix* Austria, *nube"* (Let others wage war, do you, happy Austria, marry). As a family they succeeded in amassing great wealth, the fortunes accumulated by the Modena and d'Este branch and their heirs being particularly brilliant. After the fall of their dynasty they lost all valuables and estates owned in virtue of their rank.

For the origin and early history of the Habsburgs *see* G. de Roo, *Annales rerum ab Austriacis Habsburgicae gentis principibus a Rudolpho I. usque ad Carolum V. gestarum* (Innsbruck, 1592, fol.); M. Herrgott, *Genealogia diplomatica augustae gentis Habsburgicae* (Vienna, 1737–1738); E. M. Fürst von Lichnowsky, *Geschichte des Hauses Habsburg* (Vienna, 1836–1844); A. Gisi, *Der Ursprung der Häuser Zähringen und Habsburg* (1888); and F. Weihrich, *Stammtafel zur Geschichte des Hauses Habsburg* (Vienna, 1893). For the history of the Habsburg monarchy *see* Langl, *Die Habsburg und die denkwürdigen Stätten ihrer Umgebung* (Vienna, 1895); and E. A. Freeman, *Historical Geography of Europe* (1881). (C. A. M.)

HACHETTE, JEANNE, French heroine. Jeanne Laisné, or Fourquet, called Jeanne Hachette, was born about 1454, and is known solely for an act of heroism which on June 27, 1472, saved Beauvais when it was on the point of being taken by the troops of Charles the Bold, duke of Burgundy. The town was defended by only 300 men-at-arms, commanded by Louis de Balagny.

A Burgundian man-at-arms had actually planted a flag upon the battlements when Jeanne, a small axe (*hachette*) in hand, flung herself upon him, hurled him into the moat, tore down the flag and revived the drooping courage of the garrison. Louis XI of France instituted a procession in Beauvais (called the Procession of the Assault) and married Jeanne to her chosen lover Colin Pilon, loading them with favours.

See Georges Vallat, *Jeanne Hachette* (Abbeville, 1898).

HACHETTE, LOUIS CHRISTOPHE FRANÇOIS (1800–1864), French publisher, was born at Rethel in the Ardennes on May 5, 1800. In 1826 he established in Paris a publishing business for the issue of works adapted to improve the system of school instruction, or to promote the general culture of the community. He published manuals in various departments of knowledge, dictionaries of modern and ancient languages, educational journals, and French, Latin and Greek classics annotated with great care by the most eminent authorities. After 1850, in conjunction with other partners, he published a cheap railway library, scientific and miscellaneous libraries, an illustrated library for the young, libraries of ancient literature, of modern foreign literature, and of modern foreign romance, a series of guide-books and a series of dictionaries of universal reference. In 1855 he founded the weekly *Le Journal pour tous.* He died July 31, 1864.

HACHINOHE, Japanese city in southeastern Aomori prefecture (extreme northeastern Honshu), has been transformed from a castle town into Aomori's leading industrial centre, with large chemical (fertilizer), iron and cement works and small-scale shipbuilding. Its modernized port enables it to import coal and raw materials and to rank with Shiogama (Miyagi prefecture) as the most important fishing port of northeastern Honshu. Commercially, Hachinohe is the main centre for eastern Aomori and northeastern Iwate prefectures. Pop. (1955) 141,771. (J. D. Ee.)

HACHIOJI, Japanese city in the southwestern Kanto plain west of Tokyo. was in feudal times a fortified post and market town on a main highway leading from Edo (modern Tokyo) to the Honshu interior. It has emerged as a silk thread and cloth centre with a large labour force and many small and medium-sized factories. Pop. (1955) 133,447. (J. D. Ee.)

HACHURE, the term (French for "hatching") for the conventional lines used in hill or mountain shading upon a map (*q.v.*) to indicate the slope of the surface, the depth of shading being greatest where the slope is steepest. The method is less accurate than that of contour lines, but gives an indication of the trend and extent of a range or mountain system, especially upon small-scale maps.

HACKBERRY, a popular shade tree. *Celtis occidentalis,* of the family Ulmaceae (*q.v.*), to which also belong the elms (*Ulmus*). The wood is occasionally sold under the name of beaverwood and sugarberry. although the latter name is usually reserved for another closely related species, *C. laevigata.* Hackberry is a medium-sized tree, usually 40 to 60 ft. tall but occasionally attaining 130 ft. The ovate leaves, with long tapering apices, asymmetrical bases and sharply serrate marginal teeth (sometimes entire below the middle), are from three to five inches long, and soft-pubescent below. The tree bears both unisexual and bisexual flowers. which appear with leaf emergence. The fruit is a dark red or purple, thick-skinned edible drupe one-quarter inch in diameter. with a thin, slightly astringent flesh and large roughened pit containing a single seed.

The bark is tough, fibrous and features conspicuous corky excrescences and ridges. The wood is grayish white to yellow, coarse-grained and sometimes fragile. It is used for boxes. baskets, planing mill products, furniture and wooden novelties. The root contains a dye principle suitable for dyeing linen. Hackberry ranges over eastern U.S. and occurs sparingly in southern Canada in the vicinity of the Great Lakes. It is also grown in Europe. It attains its best development on rich, moist, alluvial soils. (E. S. Hr.)

HACKENSACK, a city of northeastern New Jersey, U.S., on the Hackensack river, 13 mi. N. of Jersey City; the seat of Bergen county.

The site was settled first by the Dutch, who called it New Barbadoes, and later by the British. Its name is supposedly of Indian origin, variously spelled Achkinchesacky, Hockumdachque and in other ways. A popular theory is that the town was named aiter the Hock and Sack, an old tavern. Many streets still bear pioneer Dutch family names. The Green, opposite the county courthouse, was the camping ground of both British and American troops during the American Revolution. The community was chartered as a city in 1921 with the official name of Hackensack although it had been called Hackensack by people for many years.

Located in the geographical centre of the county. Hackensack serves a densely populated area of 1,186,873 within the Paterson-Clifton-Passaic standard metropolitan statistical area. Its business establishments consist of a wide variety of small industries, insurance companies and banks. The river is not of primary importance but rather the great network of highways that link adjacent communities to the city. For comparative population figures *see* table in New Jersey: *Popztlation.* (S. He.)

HACKETT, JAMES HENRY (1800–1871), U.S. actor, whose importance lies chiefly in his encouragement of the native American drama. was born in New York city. March 15, 1800. Upon leaving Columbia university because of ill health, he tried various businesses. In 182 j, after Hackett lost his money in speculation. his wife, a former actress, returned to the stage, and the following year Hackett. who had achieved a social reputation for impersonations. began playing character parts. In 1828 his Falstaff, in *Henry* IV, part 1. mas successful, remaining one of his most popular roles. His *Rip* Van *Winkle* (1830) was the best prior to Joseph Jefferson's.

In answer to a prize competition established by Hackett, James Kirke Paulding submitted in 1831 his *Lion of the West,* a comic satirization of Davy Crockett, and as Nimrod Wildfire in this play, Hackett was successful in the U.S. and in England. He was manager of the Astor Place opera house at the time of the Macready riot (*see* Forrest, Edwin).

In 1863 he published his *Notes and Comments on Shakespeare,* which included a correspondence between himself and John Quincy Adams. He died Dec. 28, 1871. (S. W. H.)

HACKNEY, a metropolitan borough (1900) on the northeastern boundary of the county of London, Eng., with Stoke Newington and Islington on its west; Shoreditch, Bethnal Green and Poplar on its south. Pop. (1951) 171,342. Area 5.1 sq.mi. The

borough includes the districts of Clapton, Homerton. Dalston. Stamford Hill and part of Kingsland. On the east is the much-branching river Lea, in whose valley lie Hackney marshes where Dick Turpin and other 18th-century highwaymen had a hideout. Bones of prehistoric animals, flint tools and Roman remains have been found in the district, which has been inhabited since early times when it was densely forested. The name is said to derive from *Haca's eyot* or island. The manor, probably part of that of Stepney, was held by the bishop of London from about 1290 to 1550, and in 1652 it was detached. Brooke house. the manor house, dates from 1409 but was much damaged in World War II. The Knights Hospitallers and the Knights Templars held extensive property; the Templars owned the manor of Wyke (Wick), now remembered in Hackney Wick, and probably built the church of St. Augustine, where several of Daniel Defoe's children were christened and of which only the tower survives, near the 18th-century parish church of St. John. Hackney was popular in Elizabethan times; the 16th-century Sutton place at Homerton now belongs to the National trust. Joseph Priestley, the discoverer of oxygen, was Unitarian minister at South Hackney. 1791–94. and John Howard, the prison reformer, was born in Clapton about 1726.

Hackney's chief products are paints, essences, chemicals, briar pipes, furniture and clothes. Of its three parliamentary divisions, two are partly outside the borough.

HACKNEY, originally a riding horse (from Fr. *haquenée*, an ambling horse or mare, especially for ladies to ride; the English "hack" is simply an abbreviation). Now, however, the hackney is bred for driving as well as riding *(see* HORSE: *Breeds of Horses).* From the hiring out of hackneys, the word came to be associated with employment for hire (so a "hack" or "drudge"); *e.g.*, hackney chair, hackney boat. The hackney coach, a coach with four wheels and two horses, was a hired public conveyance *(see* CARRIAGE).

HADAD, the name of a Syrian deity, is met with in the Old Testament as the name of several human persons; it also occurs in compound forms such as Benhadad and Hadadezer. The divinity primarily denoted by it is the storm god who was known as Addu Ramman. The word Hadadrimmon (Zechariah xii. 11) has been a subject of much discussion. According to the older interpreters, the mourning for something that occurred at a place called Hadadrimmon (Maximianopolis) in the valley of Megiddo is meant, the event alluded to being held to be the death of Josiah. More recently it has been thought that Hadadrimmon is another name for Adonis (*q.v.*) or Tammuz. the allusion being to the mournings by which the Adonis festivals were usually accompanied.

HADAMARD, JACQUES SALOMON (1865–), French mathematician, distinguished for his work in various branches of pure mathematics, was born at Versailles on Dec. 8, 1865. He studied at the Ecole Kormale and the École Polytechnique, and became a professor at the Collège de France, the Ecole Polytechnique and the École Centrales des Arts et Manufactures. In 1911, he became a member of l'Institut de France (Académie des Sciences).

Hadamard's early work contained many important contributions to the theory of functions of a complex variable, in particular to the general theory of integral functions and to the theory of the singularities of functions represented by Taylor's series. In 1896, Hadamard proved the prime number theorem at the same time as de la Vallée Poussin but independently of him. He also obtained important results in connection with the partial differential equations of mathematical physics.

Hadamard's work on the calculus of variations helped to lay the foundations of the modern theory of functional analysis, and in particular he introduced the name functional. Moreover, a result of Hadamard's on determinants is important in the theory of integral equations.

Hadamard's books include *La Série de Taylor* (1902); *Leçons sur la propagation des ondes et les équations de l'hydrodynamique* (1903); *Leçons sur le calcul des variations* (1910); *An Essay on the Psychology of Invention in the Mathematical Field* (1945). (M. L. C.)

HADDINGTON, EARLS OF. In 1627 Thomas Hamilton, earl of Melrose (1563–1637), was created earl of Haddington, in the Scots peerage. He was a lawyer who had become a lord of session as Lord Drumcairn in 1592. He was on very friendly terms with James VI and was one of the "Octavians" appointed to manage the finances of Scotland in 1596. Hamilton became secretary in 1612 and was raised to the peerage as Lord Binning in 1613. In 1616 he became lord president of the court of session and in 1619 was created earl of Melrose. a title exchanged in Aug. 1627 for that of earl of Haddington. He had by then ceased to be lord president, but in Oct. 1627 he was appointed lord privy seal, and resigned his secretaryship. James referred familiarly to his friend as "Tam o' the Cowgate," his Edinburgh residence being in this street.

The earl's eldest son. THOMAS, the and earl (1600–40), was a covenanter and a soldier. His sons. THOMAS (*c.* 1625–45) and JOHN (1626–69), became respectively the 3rd and 4th earls of Haddington, and John's grandson THOMAS (1680–1735) succeeded his father. CHARLES (1650–85), as 6th earl in 1685, although he was his second son. Charles had married Margaret (d. 1700), the heiress of the earldom of Rothes. It was agreed that the two earldoms should be left separate; thus the elder son. John. became earl of Rothes while Thomas became earl of Haddington. He is chiefly remembered as a tree planter and agrarian improver.

THOMAS (1780–1858j, 9th earl. was lord lieutenant of Ireland (1834–3j) under Sir Robert Peel. and in Peel's second administration (1841–46) he was first lord of the admiralty and then lord privy seal. At his death (Dec. 1. 1858) the earldom passed to his kinsman GEORGE BAILLIE (1802–70), a descendant of the 6th earl. He took the name of Baillie-Hamilton, and his son GEORGE (1827–1917) became 11th earl of Haddington in 1870. In 1917 he was succeeded by his grandson GEORGE. 12th earl.

See Abbotsford Club, *State Papers of Thomas, Earl of Melrose* (Edinburgh, 1837); Sir W. Fraser, *Memorials of the Earls of Haddington,* 2 vol. (Edinburgh, 1889); Sir J. B. Paul, *The Scots Peerage,* 9 vol. (Edinburgh. 1904–14). (G. S. P.)

HADDINGTON, a royal and small burgh and the county town of East Lothian (Haddingtonshire). Scot. Pop. (1951) 4.498 It is on the left bank of the Tyne, 16½ mi. E. of Edinburgh by road. The town, originally built round a triangular space. consists mainly of Georgian gray stone buildings; the town house (1748–1831), with its 170-ft. steeple. stands where Court street branches into Market and High streets. In the early 15th century Haddington was Scotland's largest town. On the right bank of the river lies the old industrial suburb of the Nungate, which contains the Giffordgate. where John Knox is believed to have been born, and the 12th-century church of St. Martin. St. Mary's church is a 14th-century building in red and gray sandstone; the nave. restored in 1892, is used as the parish church, but the choir and transepts are roofless, though otherwise kept in repair. In the ancient vestry is a fine monument in alabaster of John. Lord Maitland of Thirlestane (1545–95), chancellor of Scotland. and his wife, with a laudatory sonnet by James VI. John, duke of Lauderdale (1616–82), is also buried there. In the choir is the tombstone which Thomas Carlyle erected over the grave of his wife, Jane Welsh. a native of the town. Samuel Smiles (*q.v.*) was born in the burgh. The corn exchange (1854) next to that of Edinburgh is the largest in Scotland. The Knox memorial institute was erected in 1879 to replace the old and famous grammar school, where John Knox. William Dunbar, John Major and possibly George Buchanan and Sir David Lyndsay were educated. The town is a shopping centre for the surrounding countryside. The chief industries are fellmongery. flour milling. malting and the manufacture of agricultural machinery, textiles and woollens: its grain markets (Fridays). once the largest in Scotland, are still of considerable importance.

Haddington was created a royal burgh by David I. It also received charters from Robert the Bruce, Robert II and James VI. In 1139 it was given as a dowry to Ada. daughter of William de Warenne, earl of Surrey, on her marriage to Prince Henry. only son of David I. .Alexander II was born there in 1198. Lying in the direct road of the English invaders. the town was burned by King John in 1216 and by Henry III in 1244. Fortified in 1348 by Lord

Grey of Wilton, it was besieged the next year by the Scots and French, nho forced the garrison to withdraw.

HADDOCK (*Melanogrammus aeglefinus*), a fish distinguished from its relative, the cod, by the smaller mouth and the blackish lateral line From Iceland it ranges southaard on both sides of the Atlantic; in the North sea it constitutes nearly half the total weight of fish taken in the trawl It feeds mainly on molluscs and crustaceans. It grows to a length of three feet, but specimens of this size are exceptional.

HADEN, SIR FRANCIS SEYMOUR (1818–1910), English etcher whose unaffected use of the lessons learned from the great masters place some of his works among the undeniable masterpieces of printmaking. He was born on Sept 16, 1818, in London. the son of Charles Haden, a surgeon. After pursuing a medical education in England and France, Haden became in 1842 a member of the Royal College of Surgeons

In 1843–44 he traveled in Italy and made his first sketches from nature. He studied the works of the great original engravers, Durer, Lucas van Leyden and Rembrandt, and these studies influenced his own efforts, leading to his important monograph (1897) on the etchings of Rembrandt. In 184; he married the sister of James McNeill Whistler. He received the Grand prix in Paris in 1889 and 1900 and was made a member of the Institut de France, Académie des Beaux-Arts and Société des Artistes Français. He was knighted in 1894. He retired in 1887 from his London medical practice and went to live in the neighbourhood of Alresford. Hampshire, where he died, on June 1, 1910.

Of Haden's original etched plates, more than 250 in number, one of the most notable is the large "Breaking Up of the Agamemnon." Some of his early and most beautiful etchings are "Thames Fishermen," "Sub Tegmine" and "Early Morning—Richmond." Other notable works, long popular with collectors, are "A By-Road in Tipperary," "Combe Bottom," "Shere Mill Pond" (both the small study and the larger plate), "Sunset in Ireland" and "Evening Fishing, Longparish." Toward the end of his life Haden began to practise mezzotint, and he also produced some charcoal drawings of landscape subjects. In recent years his plates have lost much of their popularity with collectors perhaps because of a fashion for other styles and manners. He wrote several well-known monographs. including *About Etching* (1878–79) and *The Art of the Painter-Etchers* (1890).

See H. Nazeby Harrington, The *Engraved Work of Sir* **Francis** *Seymour Haden* (1910). (H. Es.)

HADENDOA: *see* BEJA.

HADERSLEV, a town of Denmark in the *amt* (county) of the same name. Pop.. (1955) 18,867. It lies in a valley on the Hadersleben fiord, which is about 9 mi. in length, and communicates with the Little Belt, and is also an important railway junction. The beautiful church of St. Mary dates from the 13th century. The industries are iron founding, tanning and the manufacture of tobacco and gloves. The harbour is accessible only to small vessels.

Haderslev is first mentioned in 1228, and received municipal rights from Duke Waldemar II in 1292. It suffered considerably during the wars between Slesvig and Holstein in the 15th century. In Nov. 1864 it passed with Slesvig to Prussia, returning to Denmark with North-Slesvig by the plebiscite held in 1920 under the terms of the treaty of Versailles.

HADFIELD, SIR ROBERT ABBOTT (1858–1940), British metallurgist, was born in Sheffield, Eng., Nov. 29, 1858. Educated at Sheffield Collegiate school, he interested himself at an early age in metallurgy, subsequently becoming chairman of Hadfields, Ltd., Hecla and East Hecla works, Sheffield, and director of other important companies. In 1883 he patented his process for the production of manganese steel *(see* IRON AND STEEL) and became famous as the inventor and improver of various metallurgical processes, including low hysteresis steel and many other special ferrous alloys. He became a member of many scientific committees and was president of the Iron and Steel institute (1905–07), of the Faraday society (1914–20) and of the Society of British Gas Industries (1917–18), besides being master cutler of Sheffield, 1899–1900.

In 1908 he was knighted, the following year became F.R.S., and was created a baronet in 1917. Hadfield received many honours from learned societies. He published more than 220 scientific and technical papers. His book *Metallurgy and Its Influence on Modern Progress: With a Survey of Education and Research* (1925) became a standard work of reference. In 1932–33 he was manager of the Royal institution.

In 1894 Hadfield married Frances Belt, daughter of Col. Samuel Morris Wickersham, of Philadelphia, Pa. In 1914, soon after the beginning of World War I, they founded a hospital at Wimereux, Fr. Hadfield died in London on Sept. 30, 1940.

HADHRAMAUT, a region on the south coast of Arabia, bounded west by Yemen, east by Oman and north by the Rub al Khali. Its actual limits are generally understood to include also the Mahra and Qara country between 51° and 56° E., where the desert and the coastal range come close down to the sea.

The province, consisting of the Qu'aiti state of Shihr and Mukalla and the Kathiri state of Saiun, is comprised in the eastern Aden protectorate. Mukalla on the coast is the seat of the Qu'aiti state; Saiun is the capital of the Kathiri state. The province is bounded on the west by the Wahidi sultanates and on the east by the Mahri sultanate, all of which are in protective treaty relations with Great Britain.

The main body of Hadhramaut is a wadi which rises in the highlands of southwest Arabia about 45° E. and extends eastward for 400 mi. in a gentle curve, receiving numerous affluent from the northern slopes of a mountain range which extends eastward from Yemen and attains, in parts, a height of 8,000 ft. Between this range and the sea is a coastal plain of varying width, scored by the channels of wadis rising on its southern slopes. The principal ports are Mukalla and Ash Shihr, which are the centres of a considerable trade carried on with India and Java. There are also a number of fishing villages along this coast, while the valleys of the coastal plain support some fertile oases irrigated by springs and seasonal torrents.

The southern escarpment of the main range is steeper than the northern slope, which forms a plateau descending to the main wadi beyond it. The most westerly settlement in the latter is Shabwa, a former capital, now almost buried by the advancing sand. Farther east lies a group of important oasis settlements, of which the chief are Shibam, Saiun and Tarim in the main wadi; and Hauta near its junction with Wadi Du'an. Besides these there are numerous settlements, both in the main wadi and its affluents, with prosperous palm groves and other cultivation, which practically ceases below Qasm, the most easterly settlement of any importance. At some distance east of Qasm stands the shrine of Nabi Hud, a pre-Islamic saint, whose grave is an important centre of pilgrimage. A similar shrine is that of Nabi Salih in Wadi Sirr, near Shibam.

Except after rain, there is no running water in the Hadhramaut valleys, but springs and wells are numerous, and the principal crops are dates, wheat, millet, indigo and tobacco of excellent quality known as *hummi*, which is widely exported. Other exports are salt, coffee, gums and hides. The chief imports are fuel oil, cottons, coal and provisions.

The Mahra country, mainly desert, is ruled by a sultan residing at the coastal village of Qishn and, until 1886, owning the island of Socotra, under British protection. The mountains of this tract and of the adjacent Qara district come close down to the coast, and rise in parts to 4,000 ft. They are, in places, covered with gum-bearing forests producing myrrh and frankincense. This tract was visited and surveyed in 1894 by the Bents, who found Sabaean ruins near Dhufar (Dhafar), and a remarkable harbour at Khaur Raury, possibly the Moscha of antiquity.

The name of Hadhramaut is of great antiquity, and occurs in Genesis as Hazarmaveth, son of Joktan. Greek accounts of the incense country contain mention of Adramytta and Chadramotites.

The region certainly enjoyed great prosperity and a highly advanced civilization in ancient times, as evidenced by numerous ruins found in Wadi Du'an and 'Adim. Its peopie are, in the main, of Qahtan or south Arabian stock, though the population

contains a large element of Saiyids (descendants of the Prophet through his grandson Husain) and other immigrants of northern stock, as well as a considerable mixture of African (originally and to some extent still slave) blood.

The total population of the tract may be about 150,000, or rather more if all the Bedouins are included. The Saiyids, organized in families, each under a Mansab, are regarded as the religious leaders, and constitute a sort of aristocracy, owning much land but cultivating it through slaves or hired labourers. The tribesmen, partly nomad and partly settled, are divided into two main sections: the Qu'aiti, being by far the larger, and the Kathiri. The latter, formerly the more powerful, occupy Saiun, Tarim and their dependent settlements. The Qu'aiti, a branch of the Yafi' tribe in southwest Arabia, originally came in at the invitation of the Saiyids to protect them from marauding tribes, but became the virtual rulers of the whole country, with their capital at Mukalla.

The chiefs of this tribe long enjoyed a special hereditary status as jemadar or commander in chief of an Arab levy maintained by the Indian state of Hyderabad. Many of these tribesmen sought service in this levy, while the Kathiris, after the beginning of the 19th century, emigrated on a large scale to Java and Sumatra. A large share of the trade of Mukalla and Ash Shihr passed into the hands of Parsees and other Indians.

The Qu'aiti sultan Ghalib ibn-'Iwadh ibn-'Umar, who died in 1924, was a staunch supporter of Great Britain and a man of progressive tendencies. An endemic feud between him and the Kathiri sultan had been patched up by a treaty in 1918, but Capt. W. H. Lee-Warner was impressed by the conviction that progress in the Hadhramaut could be assured only by the elimination of the Kathiri sultans, whose tyranny and rapacity were the subject of much local complaint, while their intrigues made for unrest in the Qu'aiti territory. In both sections of the region the executive administration is in the hands of hereditary wazirs, who are thus the virtual, though not the nominal rulers. By treaties of 1938 and 1939, respectively, a British resident adviser was appointed to the Qu'aiti state of Shihr and Mukalla and the Kathiri state of Saiun.

Until World War I, knowledge of the region was mainly derived from the Bents and Leo Hirsch (who reached Tarim in 1893), but in 1919 much fresh inforniation was collected by Lee-Warner, who entered the country on a mission to the Kathiri sultans on behalf of the British government. At Ghail Ba-Wazir he found the chief centre of the *hummi* tobacco cultivation and followed up Wadi Himam. In 1919–20 further light was thrown on the Hadhramaut by O. H. Little *(The Geography and Geology* of *Makalla,* Cairo, 1925), who made a geological reconnaissance of great value of the coastal plain and southern slopes of the mountain range between Ghail Ba-Wazir and Wadi Hajr, south of 14° 45' N. Several journeys were made through a large portion of the country and yielded interesting and instructive literature.

The xenophobia of the Hadhramaut people long jealously guarded the country from the intrusion of European explorers, but the few who penetrated into its recesses made it possible to form a fairly complete idea of the whole.

HADING, JANE (1864–1941), French actress, whose real name was Jeanne Alfrédine Tréfouret, was born on Nov. 25, 1864, at Marseilles, where her father was an actor at the Gymnase. She was trained at the local conservatory and was engaged in 1873 for the theatre at Algiers, and afterward for the Khedivial theatre at Cairo, where she played, in turn, coquette, soubrette and *ingénue* parts. When she returned to Marseilles she sang in operetta, besides acting in *Ruy Blas.* Her Paris début was in La *Chaste Suzanne* at the Palais Royal, and she was again heard in operetta at the Renaissance. In 1883 she had a great success at the Gymnase in Le *Maître de forges.* In 1884 she married Victor Koning (1842–94), the manager of that theatre, but divorced him in 1887. In 1888 she toured the U.S. with Coquelin. Her later repertoire included *Le Demi-monde,* Capus's *La Châtelaine,* Maurice Donnay's *Retour de Jérusalem, La Princesse Georges* by Dumas *fils,* and Émile Bergerat's *Plus que reine.*

HADITH. The name given to a compilation of the teachings and life of the prophet Mohammed, which with the Koran forms the supreme authority on matters connected with the Mohammedan religion and legislation. This enormous literature of traditions, which was primarily meant for personal guidance and edification, has coloured the whole method and fabric of Moslem thought.

(See ISLAMIC LAW.)

HADLEIGH, a market town and urban district in the Sudbury and Woodbridge parliamentary division of Suffolk, Eng., 10 mi. W. of Ipswich by road, on the Brett. a tributary of the Stour. Pop. (1951) 3,089. Area 6.7 sq.mi. Hadleigh, the capital city of the East Angles, was called by the Saxons Heapde-leag and appears in Domesday Book as Hetlega. About 886 Aethelflaed. with the consent of Aethelred. her husband. gave Hadleigh to Christ Church, Canterbury. The dean and chapter of Canterbury have held it since the Dissolution. Flemings arrived in mediaeval times to make cloth and in the 17th century Hadleigh was famous for woollen manufacture. The town was incorporated in 1618, and in 1635. in a list of the corporate towns of Suffolk to be assessed for ship money, Hadleigh is named as third in importance. It declined after the plague in 1636 and in 1687 mas deprived of its charter; an unsuccessful attempt to recover it was made in 1701.

James I granted fairs on Monday and Tuesday in Whitsun week and confirmed an ancient fair at Michaelmas and a market on Monday. The church of St. Mary the Virgin is Perpendicular. with an Early English tower and Decorated spire. The Deanery tower. a turreted gatehouse of brick, dates from 1495 and has associations with the Oxford movement. The Guild hall nearby is a Tudor building and the High street contains many half-timbered houses. Coir matting. sacks. malting, milling, egg packing and agriculture are the main trades.

There is a Hadleigh in Essex near Southend-on-Sea.

HADLEY, ARTHUR TWINING (1856–1930), **U.S.** political economist and educator, president of Yale university, was born in Kew Haven, Conn., on April 23, 1856, the son of James Hadley, the philologist. He graduated from Yale in 1876 as valedictorian. having taken prizes in English, classics and astronomy; he studied history and political science at Yale and in Berlin; was a tutor at Yale in 1879–83, instructor in political science in 1883–86, professor of political science in 1886–91, professor of political economy in 1891–99 and dean of the graduate school in 1892–95; in 1899 he became president of Yale university, the first layman to hold that office.

He retired as president emeritus in 1921 but continued to act as director of various railroads. He was commissioner of the Connecticut bureau of labour statistics in 1885–87. As an economist he first became widely known through his investigation of the railway question and his study of railway rates, which antedated the popular excitement as to rebates. His *Railroad Transportation, Its History and Laws* (1885) became a standard work, and appeared in Russian (1886) and French (1887); he testified as an expert on transportation before the senate committee which drew up the interstate commerce law; and wrote on railways and transportation for the ninth and tenth editions (of which he was one of the editors) of the *Encyclopædia Britannica,* for Lalor's *Cyclopaedia of Political Science, Political Economy, and Political History of the United States,* 3 vol. (1881–84), for the *American Railway* (1888) and for the *Railroad Gazette,* of which he was associate editor in 1887–89, and other periodicals. His idea of the broad scope of economic science, especially of the place of ethics in relation to political economy and business, is expressed in his writings and public addresses. In 1907–08 he was Theodore Koosevelt professor of American history in the University of Berlin. He also lectured in England. He died at Kobe, Japan, on March 6, 1930. Among his publications

are: *Economics: an Account of the Relations between Private Property and Public Welfare* (1896); *The Education of the American Citizen* (1901); *The Relations between Freedom and Responsibility in the Evolution of Democratic Government* (1903); *Undercurrents in American Politics* (1915); *Economic Problems of Democracy* (1923); and *The Conflict between Liberty and Equality* (1925).

HADLEY, HENRY KIMBALL (1871–1937), American composer, was born in Somerville (Mass.), on Dec. 20, 1871. He studied in Boston and Vienna. In 1904 he went to Germany, where he was Kapellmeister at the Mainz Opera House for two seasons, and in 1909 produced his opera *Safie*. Hadley toured Europe in 1908 as a guest conductor, presenting his tone poem *Salome*, after Oscar Wilde's tragedy. He was conductor of the Seattle Symphony Orchestra (1909–11) and of the San Francisco Symphony Orchestra (1911–15) and became associate conductor of the N Y. Philharmonic Orchestra in 1921. He has composed four other grand operas: *A Night in Old Paris, Azora* (Chicago Opera Company), *Bianca* (Society of American Singers), and *Cleopatra's Night* (Metropolitan Opera House); ode music for the Worcester (Mass.) Festival (60th anniversary) and *Resurgam* for the Cincinnati Festival, 1923, in addition to four symphonies, overtures and cantatas, five tone poems, ballet suites and more than 150 songs. In 1923 he conducted in London, Stockholm and Amsterdam. He conducted a season, 1927, in Buenos Aires and in 1930 was guest conductor of the Tokyo Symphony Orchestra. In 1934, he organized the Berkshire Symphonic Festivals.

HADLEY, JAMES (1821–1872), American scholar, was born March 30, 1821, in Fairfield (N.Y.). He graduated from Yale in 1842, studied in the theological department of Yale, and in 1844–45 was a tutor in Middlebury college. Then at Yale he was tutor, assistant professor, and professor of Greek, from 1851 until his death in New Haven, Nov. 14, 1872. Although he knew many ancient and modern languages, he published little. He was also an able mathematician.

His most original written work was an essay on Greek accent, published in a German version in Curtius's *Studien zur griechischen und lateinischen Grammatik*. Hadley's *Greek Grammar* (1860; revised by Frederic de Forest Allen, 1884) long held its place in American schools. In 1873 were published his *Introduction to Roman law* (ed. by T. D. Woolsey) and his *Essays, Philological and Critical* (ed. by W. D. Whitney).

See the memorial by Noah Porter in *The New Englander*, vol. xxxii., p. 35–55 (Jan. 1873); and the sketch by his son, A. T. Hadley, in *Biographical Memoirs* of the National Academy of Sciences, vol. v. (1905), p. 247–254.

HADOW, SIR WILLIAM HENRY (1859–1937), British scholar and musician, was born at Ebrington, Glos., Dec. 27, 1859. He was educated at Malvern and Worcester College, Oxford, and after taking his degree remained at Oxford as a tutor and fellow of his college. In 1909 he became principal of Armstrong College, Newcastle, retaining this post until 1919, when he became vice-chancellor of Sheffield University. He was in 1918 appointed assistant director of education for the troops by the War Office and also worked for the Y.M.C.A. He was knighted in 1918 and was made a C.B.E. in 1920. In 1922 he became Stevenson Lecturer to the University of Glasgow and in 1927 he presided over a committee which investigated the possibilities of adult education by means of broadcasting.

Sir Henry Hadow first took up the study of music at Darmstadt in 1882. When his *Studies in Modern Music* appeared (vol. i. Berlioz, Schumann, Wagner, 1894; vol. ii. Chopin, Dvořák, Brahms, 1895), they were received with enthusiasm as representing a layman's wider outlook on, and keen insight into, subjects usually left to professional writers on music. In *A Croatian Composer* (1897) he contributed a valuable theory on the Slavonic origin of Haydn's melodic material. He also wrote *Sonata Form* (1896); the volume "The Viennese Period" (1904) in *The Oxford History of Music*, of which he was the editor; *Citizenship* (1923); and *Music* (1924) in the Home University Library. His compositions include songs, piano pieces and incidental music to Robert Bridge's *Demeter* (1905).

HADRIA [mod. *Atri* (*q.v.*)], an ancient town of Picenum, belonging to the Praetuttii. It became a colony of Rome in 286 B.C. and remained faithful to Rome. The family of Hadrian came from here. The crypt of the cathedral of the modern town was originally a large Roman cistern; another forms the foundation of the ducal palace; and in the eastern portion of the town there is a complicated system of underground passages for collecting and storing water.

HADRIAN (PUBLIUS AELIUS HADRIANUS), Roman emperor A.D. 117–138, was born on Jan. 24, A.D. 76, at Italica in Hispania Baetica, where his ancestors, originally from Hadria in Picenurn, had been settled since the time of the Scipios. On his father's death in 85 or 86 he was placed under the guardianship of two fellow-countrymen, his kinsman Ulpius Trajanus (afterwards the emperor Trajan), and Caelius Attianus (afterwards prefect of the praetorian guard). He spent the next five years at Rome, but at the age of fifteen he returned to his native place and entered upon a military career. Trajan sent for him to Rome in 93, and after filling the usual minor civil posts he started serious military service as tribune to the IInd legion, stationed at Buda-Pesth (95). He spent four years on that frontier, being sent to Trajan with the army's congratulations in 97, and returned to Rome with Trajan in 99. In 100 the Empress Plotina arranged a marriage between him and Vibia Sabina, Trajan's great-niece. In 101 Hadrian was quaestor, in 105 tribune of the people, in 106 praetor. He served with distinction in both Dacian campaigns; in the second Trajan presented him with a valuable ring which he himself had received from Nerva, a token of regard which seemed to designate Hadrian as his successor. In 107 Hadrian was *legatus praetorius* of lower Pannonia, in 108 *consul suffectus, legatus* in the Parthian campaign (113–117), in 117 *consul designatus* for the following year, in 119 consul for the third and last time only for four months. When Trajan, owing to a severe illness, decided to return home from the East, he left Hadrian in command of the army and governor of Syria. On Aug. 9, 117, Hadrian, at Antioch, was informed of his adoption by Trajan, and, on the 11th, of the death of the latter at Selinus in Cilicia. Whether he ever was formally adopted cannot be established. The army and the senate confirmed his succession, and he took office with danger threatening the empire on nearly every side.

Emperor.—Hadrian's first important act was to abandon as untenable the conquests of Trajan beyond the Euphrates (Assyria, Mesopotamia and Armenia), a recurrence to the traditional policy of Augustus. Mesopotamia and Assyria were given back to the Parthians, and the Armenians were allowed a king of their own. Some time after this there arose trouble in Dacia from the Roxolani. Whether Hadrian set out from Antioch to suppress it, or whether he had by then already reached Rome, is disputed. In any case, while he was in Dacia occurred the conspiracy of the four consulars, generals of Trajan's, discontented at the abandonment of the conquests of the last reign. The four were killed by order of the senate, and Hadrian left Turbo with a joint command of Dacia and Pannonia and hurried to Rome, where the affair had created an atmosphere of suspicion. He threw the responsibility for the executions upon the prefect of the praetorian guard, and swore that he would never punish a senator without the assent of the entire body, to which he expressed the utmost deference and consideration. Trajan's scheme for the "alimentation" of poor children was carried out upon a larger scale under a special official called *praefectus alimentorum*.

Travels Round the Empire.—The record of Hadrian's journeys[1] through all parts of the empire forms the chief authority for the events of his life down to his final settlement in the capital during his last years. They can only be briefly touched upon here. His first great journey probably lasted from 121 to 126. After traversing Gaul he visited the Germanic provinces on the Rhine, and crossed over to Britain (spring, 122), where he built the great rampart from the Tyne to the Solway, which bears his name.

[1]The chronology of Hadrian's journeys—indeed, of the whole reign—is confused and obscure. In the above the article by von Rohden in Pauly-Wissowa's *Realencyclopädie* has been followed. Weber's (see Bibliog.) is the most important discussion.

(See BRITAIN: *Roman.)* This part of the journey was mainly occupied with military inspections.. He returned through Gaul into Spain, and then proceeded to Mauretania, where he suppressed an insurrection. A war with the Parthians was averted by a personal interview with their king (123). From the Parthian frontier he travelled through Asia Minor and the islands of the Aegean to Athens (autumn, 125), where he introduced various political and commercial changes, was initiated at the Eleusinia, and presided at the celebration of the greater Dionysia. After visiting Central Greece and Peloponnesus, he returned by way of Sicily to Rome (end of 126). The next year was spent at Rome, and, after a visit to Africa, which produced measures for the encouragement of African agriculture, he set out on his second great journey (September 128). He travelled by way of Athens, where he completed and dedicated the buildings (see ATHENS) begun during his first visit, chief of which was the Olympieum. In the spring of 129 he visited Asia Minor and Syria, where he invited the kings and princes of the East to a meeting at Samosata; Chosroes of Parthia declined. Having passed the winter at Antioch, he set out for the south (spring, 130). He ordered Jerusalem to be rebuilt (see JERUSALEM) under the name of Aelia Capitolina, and made his way through Arabia to Egypt, where he restored the tomb of Pompey at Pelusium with great magnificence. After a short stay at Alexandria he took an excursion up the Nile, during which he lost his favourite Antinous. From Egypt Hadrian returned through Syria to Europe (his movements are obscure), but was obliged to hurry back to Palestine (spring, 133) to deal with the Jewish revolt that broke out in 132. (See art. JEWS; also E. Schiirer, *Hist.* of the *Jewish* People, Eng. tr., div. 1, vol. ii. p. 288; and S. Krauss in *Jewish* Encyc. *s.v.* ('Hadrian.") For a while he probably commanded in the field himself, then in 134, leaving the conduct of affairs in the hands of Julius Severus, he returned to Rome. The remaining years of his life were spent partly in the capital, partly in his villa at Tibur. His health now began to fail, and it became necessary for him to choose a successor. There were rumours that Servianus would be appointed, but he and his grandson Fuscus were put to death in 136. Why, is not known. Against the advice of his relatives and friends he adopted L. Ceionius Commodus under the name of L. Aelius Caesar, who was in a feeble state of health and died on Jan. 1, 138, before he had an opportunity of proving his capabilities. Hadrian then adopted Arrius Antoninus (see ANTONINUS PIUS) on condition that he should adopt M. Annius Verus (afterwards the emperor Marcus Aurelius) and the son of L. Aelius Caesar, L. Verus (afterwards co-emperor). Hadrian died at Baiae on July 10, 138.

Work of the Reign. — He was without doubt one of the most capable emperors who ever occupied the throne, and devoted his great and varied talents to the interests of the state. One of his chief objects was the abolition of distinctions between the provinces and the mother country, finally carried out by Caracalla, while at the same time he did not neglect reforms that were urgently called for in Italy. Provincial governors were kept under strict supervision; extortion was practically unheard of; the ius Latii was bestowed upon several communities; special officials were instituted for the control of the finances; and the emperor's interest in provincial affairs was shown by his personal assumption of various municipal offices. New towns were founded and old ones restored; new streets were laid out, and aqueducts, temples and magnificent buildings constructed. In Italy itself the administration of justice and the finances required special attention. Four iuridici of consular rank were appointed for Italy, who took over judicial functions formerly exercised by local magistrates. The judicial council (*consiliarii* Augusti, later called consistorium), composed of persons of the highest rank (especially jurists), became a permanent body of advisers, although merely consultative. Roman law owes much to Hadrian, who instructed Salvius Julianus to draw up an *edictum perpetuum,* to a great extent the basis of Justinian's Corpus *iuris.* (See M. Schanz, Geschichte der *römischen* Literatur, iii. p. 167.) In the administration of finance, in addition to the remission of arrears already mentioned, a revision of claims was ordered to be made every fifteen years, thereby anticipating the "indictions." (See CALENDAR; CHRONOLOGY.) Direct collection of taxes by imperial procurators was substituted for the system of farming, and a special official (advocatus *fisci*) was instituted to look after the interests of the imperial treasury. The gift of "coronary gold" (*aurum coronarium*), presented to the emperor on certain occasions, was entirely remitted in the case of Italy, and partly in the case of the provinces. The administration of the postal service throughout the empire was taken over by the state, and municipal officials were relieved from the burden of maintaining the imperial posts. Humane regulations as to the treatment of slaves were strictly enforced; the master was forbidden to put his slave to death, but was obliged to bring him before a court of justice; if he ill-treated him it was a penal offence. The custom of putting all the household to death when their master was murdered was modified. In military matters Hadrian was a strict disciplinarian, but his generosity and readiness to share their hardships endeared him to the soldiers. During his reign an advance was made in the direction of creating an organized body of servants at the disposal of the emperor by the appointment of equites to important administrative posts, without their having performed the *militiae* equestres. (See EQUITES.) Among the magnificent buildings erected by Hadrian mention may be made of the following: In the capital, the temple of Venus and Roma; his splendid mausoleum, which formed the groundwork of the castle of St. Angelo; the pantheon of Agrippa; the Basilica Neptuni; at Tibur the great villa 8 m. in extent, a kind of epitome of the world, with miniatures of the most celebrated places in the provinces. Athens, however, was the favourite site of his architectural labours; here he built the temple of Olympian Zeus, the Panhellenion, the Pantheon, the library, a gymnasium and a temple of Hera.

Hadrian was fond of the society of learned men — poets, scholars, rhetoricians and philosophers — whom he alternately humoured and ridiculed. His taste, however, was curious; he preferred Cato the elder, Ennius and Caelius Antipater to Cicero, Virgil and Sallust, the obscure poet Antimachus to Homer and Plato. As a writer he displayed great versatility. He composed an autobiography, published under the name of his freedman Phlegon; wrote speeches, fragments of two of which are preserved in inscriptions (a panegyric on his mother-in-law Matidia, and an address to the soldiers at Lambaesis in Africa). In imitation of Antimachus he wrote a work called *Catachannae,* probably a kind of miscellanea. The Latin and Greek anthologies contain about a dozen epigrams under his name. The letter of Hadrian to the consul Servianus (in Vopiscus, Vita *Saturnini,* 8) is no longer considered genuine. Hadrian's celebrated dying address to his soul may here be quoted (David Magie, Scriptures *Historiae* Augusti, Loeb Classical Library. Harvard University Press):

O blithe little soul, thou, flitting away,
Guest and comrade of this my clay,
Whither now goest thou, to what place
Bare and ghostly and without grace?
Nor, as they wont was, joke and play

Character. — The character of Hadrian exhibits a mass of contradictions. well summed up by Spartianus (14, 11). But it is doubtful nhether a good deal of this mas not rather due to the defeated imaginations of his contemporaries, whom his reserved nature entirely baffled Whatever his real character was like. the Empire under him enjoyed its golden age. The permanent marks he left. in addition to his legal and administrative reforms, were the towns he built and his contribution to the frontier system.

The chief ancient authorities for the reign of Hadrian are: the life by Aelius Spartianis in the *Scriptores historiae Augustae* (see AUGUSTAN HISTORY and bibliography); the epitome of Dio Cassius (Ixix.) by Xiphilinus; Aurelius Victor, *Epit.* 14, probably based on Marius Maximus; Eutropius viii. 6; Zonaras xi. 23; Suidas, *s.v.* 'Αδριανός; and numerous inscriptions and coins, The autobiography was used by both Dio Cassius and Marius Maximus. Modern authorities: C. Merivale, *Hist.* of the Romans under the Empire, ch. Ixvi; H. Schiller, Geschichte der romiscken *Kaiserzeit,* i. 2, p. 602 (1883); J. B. Bury, The Student's Roman Empire (1893), where a concise table of the journeys is given; P. von Rohden, *s.v.* "Aelius" (No. 64) in Pauly-Wissowa's *Realencyklopädie,* i. 1 (1894); J. HADRIAN'S WALL, the name usually given to the remains of the Roman fortifications which defended the northern frontier of the Roman province of Britain. It extends from Wallsend on the estuary of the Tyne to Bowness on the Solway, about 73½ English miles, and was erected by order of the emperor Hadrian under Platorius Nepos, governor of Britain about A.D. 122–126. The complete work was not built to a single plan, but reached its final form (probably within the years stated) by three stages: (1) a series of detached forts, each holding 500 men, four miles apart, on an average, lying in front (to the north) of an earthwork (the Vallum) which served as a visible delimitation of the civil

REECE WINSTONE

HADRIAN'S WALL, WHICH MARKED THE FRONTIER OF THE ROMAN EMPIRE IN BRITAIN. THE WALL STANDS 4 FT. HIGH AND IS 5 FT. WIDE

frontier of Rome; (2) the enlargement of certain of these forts to hold 1,000 men; (3) the connection of the forts by a stone wall, and the provision of smaller fortified posts at every mile (Milecastles) with intervening turrets. This wall was designed rather as a fortified sentry beat than as a defensive fortification. At certain points traces have been found of a wall of turf, which preceded the stone wall; this has yet to be elucidated fully, but may be a temporary step in the development between stages 2 and 3.

No definite evidence has yet been found that the wall was held by the Romans after A.D. 383.

See further BRITAIN: *Roman.*

HADRUMETUM, a town of ancient Africa on the southern extremity of the *sinus Neapolitanus* (mod. Gulf of Hammamet) on the east coast of Tunisia. The site is partly occupied by the modern town of Sousse (*q.v.*). The form of the name Hadrumetum varied much in antiquity; the Greeks called it Ἀδεύμης, Ἀδεύμητος, Ἀδεαμύτης, Ἀδεάμητος: the Romans *Adrumetum, Adrimetum, Hadrumetum, Hadrymetum,* etc.; inscriptions and coins gave *Hadrumetum.* The town was a Phoenician colony founded by Tyrians long before Carthage (Sallust, *Jug.* 19). It became subject to Carthage, but lost none of its prosperity. Often mentioned during the Punic Wars, it was captured by Agathocles in 310, and was the refuge of Hannibal and the remnants of his army after the battle of Zama in 202. During the last Punic War it gave assistance to the Romans; after the fall of Carthage in 146 it received an accession of territory and the title of *civitas libera* (Appian, *Punica,* xciv.; *C.I.L.* i. p. 84). Caesar landed there in 46 B.C. on his way to the victory of Thapsus (*De bello Afric.* iii.; Suetonius, *Div. Jul.* lix.).

In the organization of the African provinces Hadrumetum became a capital of the province of Byzacena. It was a busy port and the centre of a fertile country. Trajan made it a Latin colony under the title of *Colonia Concordia Ulpia Trajana Augusta Frugifera Hadrumetina;* a dedication to the emperor Gordian the Good, found at Sousse gives these titles to the town, and at the same time identifies it with Sousse. Quarrels arose between Hadrumetum and its neighbour Thysdrus in connection with the temple of Minerva situated on the borders of their respective territories (Frontinus, *Gromatici,* ed. Lachmannus, p. 57); Vespasian when pro-consul of Africa had to repress a sedition among its inhabitants (Suetonius, *Vesp.* iv.; Tissot, *Fastes de la prov. d'Afrique,* p. 66); it was the birthplace of the emperor Albinus. At this period Hadrumetum was after Carthage, the most important town in Roman Africa. Its bishops are mentioned at the councils of 258, 348, 393 and even later. Destroyed by the Vandals in 434 it was rebuilt by Justinian and renamed Justinianopolis (Procop. *De aedif.* vi. 6). After the Arabic invasion of the 7th century the place became the haunt of pirates. The Arabic geographer Bakri gave a description of the chief Roman buildings which were standing in his time (Bakri, *Descr. de l'Afrique,* tr. by de Slane, p. 83 *et seq.*). The modern town of Sousse, despite its commercial prosperity, occupies only a third of the old site.

There remains a fragment of the fortifications of the Punic town and of the substructions of the Byzantine acropolis, the circus, the theatre, the water cisterns and of other buildings, notably an interesting Byzantine basilica. In the ruins have been found numerous columns of Punic inscriptions, Roman inscriptions and mosaic, among which is one representing Virgil. In the large Christian catacombs are numerous sarcophagi and inscriptions painted or engraved of the Roman and Byzantine periods. There are also Punic and Pagan-Roman cemeteries. The town had no Punic coins, but under the Roman domination there were coins from the time of the Republic. These are of bronze and bear the name of the city in abbreviations, HADR or HADRVM accompanying the head of Neptune or the Sun. We find also the names of local duumvirs. Under Augustus the coins have on the obverse the imperial effigy, and on the reverse the names and often the effigies of the pro-consuls. After Augustus the mint was closed.

HAECKEL, ERNST HEINRICH (1834–1919), German zoologist, well known for his early adoption of the doctrine of evolution and for his confident construction of genealogical trees of living organisms, was born at Potsdam on Feb. 16, 1834. He studied medicine and science at Würzburg, Berlin and Vienna under such men as Johannes Müller, R. Virchow and R. A. Kölliker. In 1862 he became professor of comparative anatomy and director of the zoological institute at Jena, where a chair of zoology was created for him in 1865. He spent his life at Jena, with the exception of the time devoted to various tours. As a field naturalist (he coined the term ecology in 1866), Haeckel had extraordinary power and industry, displayed in his publications on *Radiolaria* (1862), *Siphonophora* (1869), *Monera* (1870) and *Calcareous Sponges* (1872), as well as several *Challenger* reports, viz., *Deep-Sea Medusae* (1881), *Siphonophora* (1888), *Deep-Sea Keratosa* (1889) and *Radiolaria* (1887).

Darwin believed that Haeckel's enthusiastic propagation of the doctrine of organic evolution was the chief factor in the success of the doctrine in Germany. His *General Morphology* (1866) was a suggestive attempt to work out the practical application of evolution to its final results. *Natürliche Schöpfungsgeschichte* (1867; 10th ed., 1902; Eng. trans., *History of Creation,* 1892) laid particular stress on the "fundamental biogenetic law" that ontogeny recapitulates phylogeny, that the organism in its development is to a great extent an epitome of the form modifications

undergone by the successive ancestors of the species in the course of their historic evolution. Haeckel's well-known "gastraea" theory is an outcome of this generalization. He divided animal creation into the Protozoa or unicellular animals, and the Metazoa or multicellular animals. In the Metazoa the single primitive egg cell is transformed by cleavage into a globular mass of cells (morula), which first becomes a hollow vesicle and then changes into the gastrula. The simplest multicellular animal resembles this gastrula with its two primary layers, ectoderm and endoderm, and the earliest hypothetical form of this kind, from which the higher animals are probably descended, may be called the gastraea.

Haeckel's genealogical constructions culminated in the paper he read before the fourth international zoological congress, held at Cambridge in 1898. when he traced the descent of the human race in 26 stages from organisms like the still existing Monera, simple structureless masses of protoplasm, and the unicellular Protista through the chimpanzees and the *Pithecanthropus erectus,* which he regarded as the link between primitive man and the anthropoid apes.

Haeckel's attempt to apply the doctrine of evolution to the problems of philosophy and religion appeared in *Die Welträtsel* (1899; Eng. trans., *The Riddle of the Universe,* 1900). Adopting an uncompromising monistic attitude, he asserted the essential unity of organic and inorganic nature. For him the chemico-physical properties of carbon in its complex albuminoid compounds are the sole and the mechanical cause of the specific phenomena of movement which distinguish organic from inorganic substances, and the first development of living protoplasm, as seen in the Monera, arises from such nitrogenous carbon compounds by spontaneous generation. Psychology he regarded as merely a branch of physiology. Every living cell has psychic properties, and the psychic life of multicellular organisms is the sum total of the psychic functions of the cells of which they are composed. Moreover, just as the highest animals have evolved from the simplest forms of life, so the highest human faculties have evolved from the soul of animals. Consequently Haeckel denied the immortality of the soul, the freedom of the will and the existence of a personal God.

Haeckel occupies no serious position in the history of philosophy, and it can be held that in the formulation of his ideas he was somewhat unscrupulous in his treatment of scientific facts. He is thus exposed to criticism, but he was very widely read in his own day and was very typical of the school of extreme evolutionist thought. He died at Jena on Aug. 8, 1919.

Haeckel's other works include: *Die systematische Phylogenie* (1894), which has been pronounced his best book; *Anthropogenie* (1874; 5th ed.. 1903; Eng. trans., 1879), dealing with the evolution of man; *Über unsere gegenwärtige Kenntnis vom Ursprung des Menschen* (1898; Eng. trans., *On Our Present Knowledge Regarding the Origin of Men,* 1898); *Der Kampf um den Entwickelungsgedanken* (1905; Eng. trans., *The Struggle Over Ideas Concerning Evolution,* 1906); books of travel such as *Indische Reisebriefe* (1882; 6th ed., 1922) and *Aus Insulinde* (1901). *Kunstformen der Natur* (1904), in 11 parts; consists of exceptionally fine paintings of protozoan organisms. Haeckel was an excellent artist but tended to be led by his imagination.

See W. Bolsche, *E. Haeckel. Ein Lebensbild* (1900; Eng. trans., 1906); H. Schmidt (ed.), *Was wir Ernst Haeckel verdanken,* 2 vol. (1914).

HAEMATOCELE, a medical term used to designate a collection of blood in a pre-existing sac or cavity. It usually results from injury but may occur from such a condition as ectopic pregnancy.

The blood may or may not become encapsulated. It is closely related to haematoma and the two may be associated.

(F. L. A.)

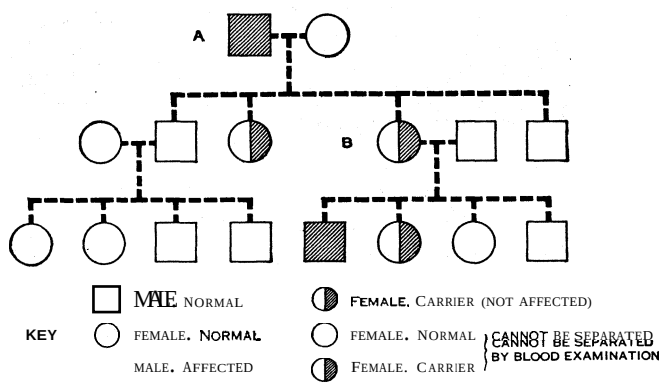
HAEMATOPODIDAE: *see* OYSTER-CATCHER.

HAEMOPHILIA. The word haemophilia means literally an affinity or liking for blood. Actually the term is used to designate a specific form of bleeding disease occurring in males and usually in certain male members of affected families; transmission taking place through female members of the same families. The disease has been known since biblical times and was noted in the Talmud by Hebraic writers, particularly in the unusual degree of bleeding which occasionally complicated ritual circumcision. Credit for the first clear delineation of the disease must be given to a U.S. physician, John C. Otto of Philadelphia, Pa., who described in 1803 . . . "an hemorrhagic disposition existing in certain families." He wrote as follows: "It is a surprising circumstance that the males only are subject to this strange affection . . . Although the females are exempt, they are still capable of transmitting it to their male children. . . ." It became popularly known as the "bleeder's" disease, or the "disease of kings," because of its common occurrence in the inbred royal families of Europe.

Only about half the cases give a well-defined history of "bleeders" in the family; there can be no doubt that there occur typical cases in which a history of familial disease is completely lacking. In the hereditary cases, the bleeders are always present in the mother's family; *i.e.,* in her brothers, her father or her uncles. Women transmit the disease through a recessive X-chromosome but are themselves free from it; careful studies have failed to demonstrate a specific abnormality. Sons of haemophiliacs are free from the disease and cannot transmit it. The actual hereditary defect which is transmitted is not completely clear. It is probable that the plasma either lacks a normal material in its globulin fraction (antihaemophilic plasma globulin) or that there is an excess of a circulating anticlotting material. The weight of the evidence now at hand is in favour of the former concept.

The fundamental abnormality of haemophilia is recognized by a great increase in the coagulation (clotting) time of the blood. Normally, if blood taken from a vein is placed in glass test tubes, it clots in from 5 to 15 min. In a haemophiliac, the clotting time is greatly increased, usually from 30 min. to several hours or even longer.

This diminished tendency of the blood to clot places the affected individual at a great disadvantage, since slight injuries such as occur during normal exertion (shovelling snow, striking at a golf ball) may result in uncontrollable bleeding. A relatively insignificant cut may lead to bleeding for days. Operations, even such simple ones as dental extractions, may be followed by uncontrollable bleeding, which in some cases is fatal. A child romping about and falling on its knees or elbows develops bleeding into the joints; this may eventublly lead to chronic swelling and finally to crippling deformities. Gross bleeding in the urine is common. The haemophiliac may be said to be constantly vulnerable, since at any moment his life may be endangered by what is to most persons a relatively insignificant situation.



TRANSMISSION OF HAEMOPHILIA: A. MATING OF AFFECTED (HAEMOPHILIC) MAN AND NORMAL WOMAN — ALL SONS NORMAL AND ALL DAUGHTERS CARRIERS. B. MATING OF CARRIER WOMAN AND NORMAL MAN — HALF OF SONS NORMAL AND HALF AFFECTED; HALF OF DAUGHTERS CARRIERS, HALF NORMAL

The increased tendency to bleed becomes noticeable very early in life. Large bruises of the skin and soft tissue are almost always present. The teeth become carious because dentists are naturally loath to carry out even ordinary procedures. Few haemophiliacs escape crippling joint disease. The diagnosis of the disease is usually readily made, especially if a history of bleeding disease

in the family is obtained. The only abnormality which is found in the blood is a well-defined increase in the coagulation time with simultaneously normal tests for platelets and other blood constituents.

The treatment of haemophilia depends upon reduction of the coagulation time, which is best performed by transfusing the patient with fresh, normal blood. A case with active bleeding may require several transfusions within a period of a week or more. Fresh normal liquid plasma or dried plasma derived from fresh blood have the same effects as whole blood. Also of some value is the material known as "antihaemophilic plasma globulin." derived from fractionation of the normal plasma. This substance is effective in very small amounts (100 to 300 mg.). When given by intravenous injection, however, it has no particular merit over the use of whole blood or fresh plasma, and indeed in some cases appears to have been responsible for the development of infectious jaundice. Attempts are continually being made to obtain a material which can be injected by the affected individual himself to reduce the clotting time, much as insulin is now injected by the diabetic patient to reduce the blood sugar. (W. DK.)

HAEMORRHAGE, a general term for the escapk of blood from a blood vessel. It may result from obvious damage to blood vessels by cutting or tearing or there may be spontaneous loss where no trauma is apparent but some disturbance of blood coagulation or blood vessel walls is at fault. Haemorrhage may be from an artery (where bright red blood is rapidly lost in a pulsating stream), from a vein (where darker blood is lost less rapidly as a steady stream) or from capillaries (where generalized oozing of blood from a raw surface takes place). Internal haemorrhage is loss of blood from vessels into a body cavity or organ and external haemorrhage is direct loss outside the body. Internal haemorrhage may be spontaneous (*e.g.*, ectopic pregnancy, bleeding peptic ulcer) or secondary to abdominal injuries (*e.g.*, ruptured spleen). Haemorrhage may occur into one of the body passageways and then later the blood may escape from a natural orifice. Thus, blood may be passed in vomitus (haematemesis), with the faeces (melaena), in the urine (haematuria), with sputum from the lungs (haemoptysis) or from the nose (epistaxis). In haematemesis and melaena the colour may be dark brown or black as a result of the action of gastric and intestinal secretions. Haemorrhage may also take place into or under the skin producing a bruise, or ecchymosis, or a petechial haemorrhage, where red pinhead-size spots are seen. A haematoma is a pocket of blood lying in the tissues. In severe fractures (*e.g.*, that of the femur) extensive blood loss may occur in the tissues without external bleeding.

The consequences of haemorrhage are varied and depend on the amount and rapidity of the blood loss. A very slow and prolonged loss may lead to a deficiency of red blood cells (anaemia) but a larger and more sudden loss may lead to profound circulatory disturbances (see SHOCK AND COLLAPSE) resulting in death unless the bleeding can be stopped and proper treatment administered. In healthy adults the loss of a pint of blood, the amount usually taken from blood donors, causes no harmful effects, but the sudden loss of a quart usually causes symptoms of mild shock. If a sizable temporary haemorrhage occurs, the body compensates for the loss by constricting vessels in some parts of the body, thus making the remaining blood available for circulation to vital organs such as the brain and heart wall. The body then makes up the deficient blood volume, first, by the addition of fluid from the tissues and later by addition of newly produced blood proteins and. finally, newly produced blood cells.

Haemorrhage may cease without treatment as a result of coagulation of blood over the open vessels, retraction and constriction of the severed blood vessels, or lowered blood pressure caused by the blood loss. Haemorrhage can usually be controlled temporarily by direct pressure on the bleeding point and elevation of the bleeding part. Haemorrhage from a large artery may necessitate use of a tourniquet which should be released momentarily every 1 j min. In surgical operations bleeding is controlled by clamping and ligating blood vessels or by the application of agents to enhance blood coagulation; *e.g.*, oxidized cellulose gauze, gelatin sponges and purified thrombin. Heat will also produce coagulation. Cold is sometimes applied to an intact part to minimize ecchymosis by constricting vessels.

There are a number of diseases in which a defect in blood coagulation may convert a trivial injury into a serious situation. The bleeding tendency in jaundice and in prothrombin deficiency resulting from other causes may be overcome by the administration of vitamin K. In haemophilia, the intravenous injection of fresh whole blood or of a specially prepared globulin fraction of human plasma will temporarily correct the defect. In thrombocytopenic purpura, removal of the spleen is of great benefit.

The essential features in the treatment of haemorrhage are control of bleeding and prompt replacement of blood loss by blood transfusions. If blood is not available immediately, the intravenous administration of plasma, albumin, gelatin or saline is helpful temporarily in restoring the circulating blood volume. In addition, a supine posture is always preferable to a sitting or erect one since the compensatory mechanisms which maintain blood volume and blood pressure are more effective in the supine position. Indeed, a partially head-down posture may be indicated to improve blood flow to the brain. (I. S. R.)

HAEMORRHOIDS, or HEMORRHOIDS, commonly called piles, swellings formed by the dilatation of veins of the lowest part of the bowel, or of those just outside the margin of its aperture. The former, internal piles, are covered by mucous membrane; the latter, external piles, are just beneath the skin. As the veins of the lining of the bowel become dilated they form definite bulgings within the bowel, and, at last increasing in size, escape through the anus when a motion is being passed. Growing still larger, they may come down spontaneously when the individual is standing or walking, and they are apt to be a grave source of pain or annoyance. Eventually they may remain constantly protruded; nevertheless, they are still internal piles because they arise from the interior of the bowel. Though a pile is sometimes solitary, there are usually several of them. They are apt to become inflamed, and the inflammation is associated with heat, pain, discharge and general uneasiness; ulceration and bleeding are also common symptoms, hence the term bleeding piles. The external pile is covered by the thin, dark-coloured skin of the anal margin. Severe pressure upon the large abdominal veins may retard the upward flow of blood to the heart and so give rise to piles; this is apt to happen in the case of disease of the liver, malignant and other tumours within the pelvis or abdomen, and pregnancy. Probably the anatomical arrangement of veins at the lower end of the rectum and habitual constipation are predisposing causes of piles. It is often said the exciting cause may be vigorous straining at stool or exposure to damp, as from sitting on the wet ground, but there is little solid evidence for the statements. Piles are often only a symptom, and in their treatment this fact should be kept in view: if the cause is removed the piles may disappear. Moreover, if they indicate the existence of cancer of the rectum the whole aspect of the case is altered. The appearance of piles or of haemorrhage assumed to be from piles for the first time in a person of middle age or over is highly suggestive of the major disease. Sometimes when a pile has been protruded, as during defaecation, it is tightly grasped by spasmodic contraction of the circular muscular fibres which guard the outlet of the bowel, and it then becomes swollen, engorged and extremely painful; the strangulation may be so severe that the blood of the vessels coagulates and the pile mortifies. This, indeed, is nature's attempt at curing a pile; but it is distressing, and, as a rule, it is not entirely successful.

The palliative treatment of piles consists in obtaining a daily and easy action of the bowels, in rest, cold bathing, astringent injections, lotions and ointments. The radical treatment consists in their removal by operation, but this should not be contemplated until palliative treatment has failed. If, for one reason or another, no operation is to be undertaken, and the piles are troublesome, relief may be afforded by warm sponging and by sitz baths, the pile being gently dried afterward by a piece of soft linen, smeared with vaseline and then carefully returned into the bowel.

Under surgical advice, cocaine or morphia may be brought in

contact with the tender parts, either in the form of lotion, suppository or ointment. If, as often happens, blood coagulates in the vein of an external pile, the small, hard, tender swelling may be treated with anodyne fomentations, or it may be rendered insensitive by the ether spray and opened by a small incision, the clot being turned out.

HAEMOSPORIDIA, an order of parasitic single-celled animals (Protozoa, *q.v.*) which live in the red blood corpuscles of vertebrates, and gradually destroy them. Prominent among the Haemosporidia are certain species of *Plasmodium,* organisms which cause the various kinds of malaria (*q.v.*).

HAFIZ (SHAMSUDDIN MOHAMMED) **(c.** 1325–1389 or 1390), the most famous lyric poet of Persia, was born at Shiraz, where he lived all his life. Never a man of substance, he lectured on Koranic and other theological subjects (his surname of Hafiz designates one who has learned the Koran by heart) and wrote commentaries on a number of religious classics. As a court poet, he enjoyed the patronage of several rulers of Shiraz and of other distinguished men, all of whom are mentioned in his poems.

Hafiz lived in troubled times; sovereigns were overthrown, Shiraz was taken by force more than once, and over the last years of his life loomed the menacing shadow of the world-conqueror Timur (Tamerlane). There are many echoes of these events in his poems; but they tell more of the "café" life of Shiraz, of the vagaries of his princely patrons and of his disputes with his orthodox and sectarian contemporaries. For the guiding influence in Hafiz's own life was Sufism, the mystical movement that demanded of its adherents complete self-abandonment to the pursuit of union with the Ultimate Reality, and the rejection of the restraints of conventional religion and morality.

Hafiz' principal medium of expression, and one that he brought to a perfection never achieved before or since, was the *ghazal,* a lyric poem of 6 to 15 couplets linked by unity of thought and symbolism rather than by a logical sequence of ideas. Traditionally the *ghazal* dealt with love and wine, motifs that, in their association with ecstasy and freedom from restraint, lent themselves naturally to the expression of Sufi ideas. Hafiz' achievement was to give these conventions a freshness and subtlety that completely relieves his poetry of tedious formalism. The western reader can appreciate this, even if he misses the hidden associations that make the imagery so potent to the sophisticated Persian audience.

It has been well pointed out that almost any poem of Hafiz can be read on at least three levels of significance — at its face value as an expression of the gay and civilized life of medieval Shiraz, as a tribute to his princely patron and, lastly and above all, in terms of Sufi mystical theology.

The extraordinary popularity of his poetry in all Persian-speaking lands, however, is to be sought rather in his simple and often colloquial language. free from artificial virtuosity, and his unaffected use of homely images and proverbial expressions. Above all, his poetry is characterized by love of humanity, sympathy for the problems of ordinary men, contempt for hypocrisy and mediocrity and an ability to universalize everyday experience and to relate it to the mystic's unending search for the reality of God. It is for these qualities that Hafiz' poems are sung even by the Persian villager. His wide appeal in the west is indicated by the fact that apart from several complete translations of his works, German and English, numerous translators (including 30 in England alone) published translations of selections of his poems.

The best edition of the Persian text of the poems is by Mohammed Qnzvini and Qasem Ghani (1941); there are English translations by H. Wilberforce Clarke, *Hafiz Shirazi. The Divan . . .* (1891), and by John Payne, *The Poems of Shemseddin Mohammed Hafiz of Shiraz* (1901). English translations of selected poems include those by Sir William Jones, with introductory notes, in *Grammar of the Persian Language* (1771); by Gertrude L. Bell, *Poems from the Divan of Hafiz,* 2nd ed. (1928); by A. J. Arberry, *Fifty Poems of Hafiz* (1947), which includes many Samples of earlier translations; and by Peter Avery and John Heath-Stubbs, *Hafiz of Shiraz. Thirty Poems* (1952).

HAFNIUM, a metallic element (atomic number 72), which was a laboratory curiosity for many years, became an important material of construction for certain nuclear power reactors in the early 1950s. Here its particular virtues of moderate strength, excellent corrosion resistance and high neutron absorption capacity make it an excellent regulator to control the rate of burn-up of atomic fuel (see *Use and Production,* below).

Hafnium is a metal having the symbol Hf. It is a higher homologue of zirconium, its atomic number being 72 and its atomic weight 178.58. Hafnium has six stable isotopes with the mass numbers 174, 176, 177, 178, 179 and 180, the last-named isotope being the most abundant (abundance 35%). The arrangement of electrons in the outer levels (*O* and *P*) and sublevels is: $5s^2$, $5p^6$, $5d^2$, $6s^2$.

DISCOVERY AND OCCURRENCE

The element was discovered by D. Coster and G. C. de Hevesy in 1923 and was named hafnium, the Latin name of Copenhagen (earlier G. Urbain and A. Dauvillier had given the name celtium to the element of atomic number 72, for which Urbain obtained some evidence from X-ray spectra in 1911). The missing element 72 had been considered to be a member of the rare-earth group, but Niels Bohr, in putting forward his views on the electronic arrangement in the atom (*q.v.*), reached the conclusion that the number of rare-earth elements, including cerium, could not exceed 14. Cerium having the atomic number 58, the last rare-earth element must have the atomic number 71 and, correspondingly, element 72 must belong to the titanium group, IVa in the periodic system, which includes zirconium, and should have properties, resembling the latter rather than the rare earths.

This conclusion induced Coster and De Hevesy to search for the missing element in zirconium minerals. The investigation of the X-ray spectra emitted by samples of Norwegian and Greenland zircons revealed the presence of element 72.

Later investigations showed the presence of hafnium in each zirconium mineral and in every commercial zirconium preparation; in no other case is the "camouflage" phenomenon more pronounced. The lowest hafnium content is shown by the zircons in nepheline syenites with low silica content, such as the zircons of Brazil. Zirconium/hafnium ratios up to 700:1 are found there. In the products of siliceous residual crystallization, on the other hand, there is sometimes a very appreciable decrease in the above ratio.

Altered zircons like some alvites and cyrtolites, products of residual crystallization, show an atomic ratio even as low as 6:1 (the $ZrO_2 + HfO_2$ content of such minerals amounting to about 50%). The highest hafnium content (17% HfO_2) was found in cyrtolite from Rockport, Mass. Hafnium-bearing zirconium minerals are found in beach sands and river gravels along with monazite, rutile, etc. Commercial sources exist in the United States (principally Florida), Australia, Brazil, French West Africa and India. The share of hafnium in building up the earth's crust is about $\frac{1}{180,000}$. The presence of hafnium vapour in the solar atmosphere has been ascertained.

USE AND PRODUCTION

Nuclear Energy Regulator. — An atomic bomb is simply an uncontrolled reactor while a power producing reactor, in its simplest sense, is a slow burning atomic bomb. In the construction of nuclear reactors it is important that a material of low neutron absorption capacity be used as a protective material for the atomic fuels because neutrons are the "bullets" that make possible splitting of the atom. Zirconium, with a specific absorption of 0.18 barns, is almost an ideal cladding material for reactors using thermal neutrons (it must be emphasized in this application that the absorption figures are for thermal neutrons, *i.e.* the lowest speed neutrons used in nuclear energy work). Conversely, a material of high neutron absorption capacity is needed to regulate the rate of burn-up of atomic fuel.

Hafnium with a specific absorption of 105 barns makes an excellent throttle or regulator; by raising or lowering the control

rods of hafnium metal properly inserted in a nuclear pile, the neutron density which controls the atomic reaction can be exactly controlled. For such special purposes, the cost of $7j a pound for sponge hafnium can be tolerated.

Separation from Zirconium. — As noted at the Geneva conference on peaceful uses of atomic energy in 1955, the separation of hafnium from zirconium can be accomplished in five different ways: (1) fractional crystallization; (2) selective extraction; (3) ion exchange; (4) fractional precipitation; and (5) disproportionation or fractional distillation.

The first hafnium salts in the late 1920s and early 1930s were prepared by fractional crystallization. In this method the difference in solubility of, say, the phosphate or fluoride salts is used to precipitate a less soluble from a more soluble salt. The method is laborious and in general does not lend itself to modern continuous production procedures. Selective extraction, which involves the preferential solubility of hafnium or zirconium in an organic liquid, has been the preferred commercial separation method. The two best known processes are the thiocyanate-isobutyl ketone and the tributyl phosphate-nitric acid separation systems. In either case a hafnium hydroxide is obtained which is calcined to produce pure hafnium oxide.

Production. — The commercial production of hafnium metal is accomplished by the use of both the Kroll and De Boer-Van Arkel processes. The Kroll process, developed by William J. Kroll for the production of ductile titanium, consists essentially of the reduction of titanium tetrachloride by molten magnesium under an inert atmosphere of helium or argon to produce titanium metal and magnesium chloride; the resultant magnesium chloride can be melted and distilled to leave behind the pure metal. The process can be used with hafnium tetrachloride: the conversion of hafnium oxide obtained by separation, as explained above, to hafnium tetrachloride can be accomplished in two ways: (1) by heating with carbon at a temperature above 800° C. the hafnium oxide can be made into hafnium carbide which is then chlorinated in a simple vertical shaft furnace to produce hafnium tetrachloride and carbon monoxide; or (2) the hafnium oxide can be briquetted with a sugar solution and lamp black and chlorinated directly at temperatures above 700° C. to produce hafnium tetrachloride. The latter method is preferred commercially. Hafnium chloride is a white solid that sublimes at 320°–330°. Before reduction, hafnyl chloride ($HfOCl_2$) must be removed from the chloride since it contains oxygen. This is performed by heating under helium and partial vacuum at temperatures up to zoo° C. After the chloride purification, the material is transferred to another furnace in the bottom of which is a container holding the calculated amount of magnesium required to accomplish the reduction $HfCl_4 + 2M_g \rightarrow Hf + 2M_gCl_2$ plus 40% excess. After evacuating the reduction furnace and backfilling with helium, the magnesium is melted and the chloride of hafnium is heated to a temperature above 3jo° C. to force it to sublime. As it passes over the molten magnesium surface it is reduced to hafnium metal which settles to the bottom of the pot and the resultant magnesium chloride remains as an intermediate layer in the pot. At the end of the reduction stage, the material is allowed to cool and is then removed to a second furnace where the pot is placed upside down in the top of a vertical furnace and heated under vacuum to a temperature of about goo° C. The magnesium chloride melts and is collected in a suitable container in the lower portion of the furnace. Residual magnesium and magnesium chloride in the final stages are removed by so-called vacuum distillation. The resulting sponge metal is cleaned of surface contamination or residues and then further purified by the iodide purification process.

Due to its higher atomic weight hafnium does not have the same tolerance for a given amount of oxygen as does titanium and zirconium. Consequently, the Kroll process sponge hafnium, which contains 1,000 to 1,500 p.p.m. (0.01% = 100 p.p.m.) oxygen must be purified by the iodide (De Boer—Van Arkel) process to reduce this level to 200 to 500 p.p.m. to obtain ductile hafnium metal.

The purified bars of hafnium must be melted under special conditions to avoid contamination. The molten metal reacts with virtually every refractory container known to man as well as with oxygen and nitrogen of the atmosphere. The only satisfactory method is that of consumable electrode arc melting in a water-cooled copper crucible under an inert gas cover. If necessary, alloying elements can be added during the course of melting. The resulting ingot freezes at the copper wall without sticking or contamination.

Once melted. the dense metal offers less surface for oxidation and can be heated for forming purposes to temperatures of the order of 1.000° C. It is then shaped by standard metallurgical methods of forging, rolling and welding to produce control rod material for nuclear reactors. Several tons of hafnium are used each year for this purpose. (E. T. H.)

PHYSICAL AND CHEMICAL PROPERTIES

In the laboratory the reduction of K_2HfF_6 with potassium, that of hafnium tetrachloride with sodium or of zirconium oxide with calcium and sodium leads to the formation of hafnium powder. Hafnium metal, even ductile single crystals, may be prepared by reducing hafnium tetraiodide, prepared from hafnium powder and iodine, on glowing tungsten mire. Physical constants of hafnium and zirconium metals are seen in Table I.

TABLE I.—*Some Physical Constants of Hafnium and Zirconium Metals*

Properties	Hafnium	Zirconium
Density (g./ml.)	13.31	6.52
Atomic volume (ml.)	13.42	13.97

below the transition point (in ev)	3.20	....

*Kelvin, or absolute temperature (*q.v.*), scale.

The structure of hafnium, like that of zirconium, is hexagonal, the value of a being 3.223, and $c = 5.123$, the log of vapour pressure is determined by

$$\log p = \frac{-30\,200}{T} + 9.46.$$

Hafnium is not superconductive at 1.35° K. on the absolute temperature scale; between 4.12° K. and 1.35° K. the resistance does not change and is 0.0947 of the resistance at o° C. Hafnium attains its maximum resistance (1.75 X 10^{-4} ohm) at 1,775° K., and its minimum (1.62 $\times$ 10^{-4} ohm) at 1,goo° K. The resistance (maximum and minimum) of hafnium indicates the existence of allotropic modifications which unfits this metal for use in lamps and valves.

Hafnium was first isolated by fractional crystallization of the hexafluoride, the hafnium concentrating in the mother liquor. Commercial hafnium compounds, available previous to World War II, were prepared by this method. Another method is based on the fractional precipitation of complex phosphates or fractional precipitation of the phosphates from concentrated sulfuric acid. A further method of isolation is the crystallization of the oxychloride from about 10 N hydrochloric acid. Separation of zirconium and hafnium as negative fluo-ions has been obtained by using anion exchange resins, or as perchlorate applying a cation exchanger. Hafnium in zirconium may be reduced to less than 0.1% by passing a solution of the chlorides in methanol through a silica gel column.

The ions of hafnium are tetravalent; in many compounds the hafnyl (HfO^{++}) ion is present. Prolonged ignition of sulfate and oxychloride leads to the formation of a monoclinic modification of the oxide, while by heating the hydroxide to about 400° C. a tetragonal modification (mol. vol. = 20.10, density = 6.13,

melting point = 2,812° C.) is obtained the production of which is accompanied by the emission of light. When ignited above 1,000° C., a third modification of the oxide can be obtained, this time in the cubic system. The molecular volumes of zirconium oxide and hafnium oxide of tetragonal type are identical within 0.5% and the molecular volumes of the monoclinic modifications of the two oxides differ by less than 0.8%. These data illustrate the very close resemblance between the hafnium and the zirconium.

Atoms of different nuclear charges show practically the same behaviour provided the quantum numbers of the valency electrons differ sufficiently to compensate exactly the effect of the difference in the nuclear charge. Hafnium and zirconium are examples of such atoms, the compensation of the effect of the difference in the nuclear charge being due to the appearance of the 14 rare-earth elements. Without the existence of these elements, the hafnium ion would show the properties of the ceric ion, which is the pseudo homologue of the zirconium ion.

The diamagnetic susceptibility of the oxide is 0.110×10^{-6}. Hafnium peroxide, which has the formula $Hf(OOH)(OH)_3$, is scarcely soluble in ice-cold alkaline hydrogen peroxide. The ratio of oxide: active oxygen: water is 1:1:2. The melting point of hafnium carbide (HfC) is 4,160° K.; the specific resistance of HfC ($w_{18°} \times 10^{-4}$) is 1.09. The mixture of four molecules of tantalum carbide and one molecule of hafnium carbide was found to melt at 4,215° K. No higher melting point is known for any substance. The melting point of hafnium boride was found to be 3,335° K.

Hafnium nitride has been prepared from a mixture of hafnium tetrachloride, nitrogen and hydrogen. When a glowing filament was introduced into this mixture hafnium nitride formed in the vicinity of the filament and was deposited thereon. The bromide was prepared in a similar manner, substituting boron tribromide for the mixture of nitrogen and hydrogen. The crystal structure of

TABLE II.—*Solubility of Hafnium and Zirconium Fluorides at 20° C.*

Compound	Solvent	Solubility (mol. per litre)
$(NH_4)_2ZrF_6$	Water	1.050

$(NH_4)_3ZrF_7$	Water	0.551
$(NH_4)_3HfF_7$	Water	0.558

hexafluoride is similar to that of K_2PtCl_6; that of the heptasalts, such as $(NH_4)_3HfF_7$, is regular; its molecular volume is 125.7. The solubility of the hafnium and zirconium fluorides is seen in Table II.

The refractive indexes of the corresponding zirconium and hafnium salts show only slight differences, as may be seen from Table III.

Hafnium tetrachloride is prepared through the action of chlorine on a mixture of hafnium oxide and charcoal. Above 200° C. tetrachloride sublimes. The tetrachloride hydrolyses immedi-

ately when coming in contact with water, leading to the formation of the fairly stable $HfO(4H_2O)^{++}$. Hafnium oxychloride crystallizes in tetragonal needlelike crystals. The refractive index of the needlelike crystals of $HfOCl_2.8H_2O$ is $n(\omega) = 1.557$; $n(\epsilon) = 1.543$. With increasing hydrochloric acid concentration the solubility of the oxychloride first decreases and then increases after a concentration of eight mols per litre is reached. Hafnium tetrachloride prepared through the action of bromine vapour on a mixture of hafnium oxide and sugar charcoal was used in the determination of the atomic weight of hafnium. The solubility of hafnium oxybromide decreases with increasing hydrobromic acid concentration. The heat of decomposition of hafnium sulfate is 110 cal. per mol. Hafnium phosphate $HfO(H_2PO_4)_2$ is the phosphate of lowest solubility known. Solubility figures are given in Table IV.

TABLE IV.—*Solubilities of Zirconium and Hafnium Phosphates*

10.21	.0043	.00012
5.94	.0031	.00009

Hafnium acetylacetonate $[Hf(C_6H_7O_2)_4.10H_2O]$ crystallizes in strongly birefringent monoclinic crystals. The density of the compound is 1.670; its melting point, 194° C. In a vacuum of 0.001 mm. a slight sublimation is observed at 82° C. One litre of ethylene bromide dissolves at 25° C., 0.620 mol of the salt. Hafnium can best be estimated and determined by X-ray spectroscopy. Optical spectroscopy is also applied in the estimation of hafnium in the arc spectrum; the strongest persistent Hf I line has the wave length of 4093.17 Å (Å = angstrom = 10^{-8} cm.); and the strongest Hf II line, 3399.80 Å (4093.17 Å is the *raye ultime* of neutral hafnium; and 2773.37 Å, for ionized atoms). The determination of the density of the zirconium oxide-hafnium oxide mixture is a suitable method to determine the hafnium content of zirconium. Denoting the density of the mixed crystal by d, the atomic ratio is

$$\frac{HfO_2}{ZrO_2} = \frac{d - 5.73}{9.74 - d}$$

A pure or very concentrated hafnium preparation shows a slightly different behaviour toward rufigallic acid, the colouring being more quickly obtained in the presence of hafnium. The absence of the formation of $Hf_2O_6SO_4.8H_2O$ when hydrogen peroxide is added to an acid hafnium solution, in contrast with the formation of a corresponding zirconium compound, can also be used to distinguish between a pure or concentrated hafnium and a zirconium preparation.

(G. C. DE H.)

HAFSTEIN, HANNES THORDUR (1861–1922), Icelandic statesman and poet, was born on Dec. 4, 1861. As a young man he became known as a lyrical poet. In 1901 he was elected a member of the althing, and soon became a leader of the Home Rule party. It was chiefly because of his influence that Denmark consented, in 1903, to the transfer of the residency of the minister for Iceland from Copenhagen to Reykjavik. On Jan. 31, 1904, Hafstein was appointed to this office and inaugurated a new era of practical reform. His first work was to arrange a telegraphic cable to Great Britain and a net of telegraphs and telephones all over the island. His efforts, however, were hampered by the extremists, who demanded greater political independence from Denmark. Their obduracy led to his resignation in 1908. On the victory of the Home Rulers in 1911, Hafstein again became minister in 1912, but had to resign in 1914 after new and fruitless effortsto effect reconciliation. He lived, however, to see the full reconciliation between the two countries in 1918, and the recognition of Iceland as an independent state in union with Denmark. He died on Dec. 13, 1922.

HAFTARAH (pl. haftaroth), in synagogue services, selected readings from the Prophets, following the readings from the Pentateuch. The word means literally "conclusion," signifying the end

of the scriptural lesson. The custom of adding a chapter from the Prophets to the pentateuchal reading long antedated the destruction of the Temple. It derived additional significance from the fact that it implied the sanctity of the prophetic books of the Old Testament, in opposition to the Samaritans who accepted only the five books of Moses. In the New Testament, the custom of preaching on the Haftarah is mentioned. (Acts xiii, 15. Luke iv. 17.)

In the modern synagogue, boys are usually trained to chant the haftarah on the Sabbath of their *Bar Mizvah.* (J. B. A.)

HAGEDORN, FRIEDRICH VON (1708–1754). German poet whose fables, love songs and anacreontics introduced a new lightness and grace into his country's poetry. was born on April 23, 1708, at Hamburg, where his father was Danish ambassador. In 1729 he became unpaid private secretary to the Danish ambassador in London. He returned to Hamburg in 1731, and in 1733 was appointed secretary to the *Englischer Hof,* an English trading company established there in the 13th century. He died at Hamburg, Oct. 28, 1754.

His first collection of verse appeared in 1729: most of the best of it—fables and tales in verse which stand comparison with those of his master La Fontaine both in neatness of form and lightness of touch, and love lyrics echoing Horace—appeared in *Versuch in poetischen Fabeln und Erzählungen* (1738) and *Oden und Lieder,* 3 vol. (1742–52). Hagedorn's works were edited by J. J. Eschenburg, 5 vol. (1800).

See H. Stierlung, *Leben und Bildnis Friedrichs von Hagedorn* (1911); *K.* Epting, *Der Stil in den lyrischen und didaktiscken Gedichten Hagedorns* (1929).

HAGEN, JOHANNES GEORG (1847–1930), Austrian Jesuit priest and astronomer known especially for his work on variahle stars. was born at Bregenz, on March 6, 1847. Educated at Feldkirch in Austria and at Münster and Bonn in Germany, he did some of his theological studies in England. He became director of Georgetown observatory, Washington, D.C.. in 1888. In 1906 Pope Pius X appointed him director of the Vatican observatory. Hagen died in Rome on Sept. 6, 1930, while still engaged in research.

His many publications include: *Atlas Stellarum Variabilium* Ser. i–vii (1890–1908); *Astrographic Catalogue* of *the Vatican Zone,* 10 vol. (1914–28). (D. J. K. O.)

HAGEN, a town of Germany, in the *Land* of North Rhine-Westphalia. Pop. (1959 est.) 191,635. It lies at the confluence of the Ennepe with the Volme, 15 mi. N.E. of Elberfeld. Hagen has extensive iron and steel works, large cotton print works, manufactures of leather, paper, tobacco. and iron and steel wares, sugar, breweries and distilleries. There are large limestone quarries in the vicinity and also an alabaster quarry.

HAGERSTOWN, a city of Maryland, U.S., and seat of Washington county, 70 mi. W.N.W. of Baltimore, is a commercial centre for the rich Cumberland valley between the Blue Ridge and Allegheny mountains.

Wide diversification of manufacturing includes pipe organs, aircraft, blast-cleaning and dust-collecting equipment, refrigerator doors, furniture, shoes and textiles.

Scotch-Irish and Germans moved into the valley from Pennsylvania in the 1730s. In 1762 Jonathan Hager, a German. laid out the town around his stone farmhouse which is still standing near the centre of the city. He named it Elizabeth Town after his wife, but neighbours soon called the place Hagerstown, under which name it was incorporated in 1814. Ft. Frederick (1756) in the state park of the same name is nearby, and is said to be the only fort of the French and Indian War remaining with its original walls. In the 1820s the town became a major stopping point on the Cumberland road to the west, and subsequently it became a railroad centre. It changed hands several times during the American Civil War, and within 30 mi. are a number of battlefields including Harpers Ferry and Gettysburg. About 5,000 Confederate soldiers are buried in the city.

Artisan labour, neat farmland and distinctive architecture give the area a typically German mellowness. Symbol for the city is "Little Heiskell," a tin soldier weathervane which has stood on successive town halls since 1769. The city has a fine library and an outstanding art museum. For comparative population figures *set* table in MARYLAND: *Population.* (G. H. CT.)

HAGFISH, a blind, eel-shaped. parasitic marine fish less than two feet long, that feeds on other living fish by boring its way into the flesh and devouring almost everything but skin and bones Along with its close relative the slime eel *(see* MYXINE) the hagfish constitutes one subclass of the primitive class Cyclostomata *(see* CYCLOSTOME). Several species infest the coastal waters of western North America, Japan, Chile, New Zealand and South Africa. They cause considerable damage by feeding on fish caught in nets and on set lines. When held in a container they excrete an unbelievably large quantity of mucus. (C. L. Hs.)

HAGGADAH ("narrative"), with Halakhah ("conduct"), two varieties of Midrash or scriptural exegesis. The former constitutes the poetical element and the latter the legal, though the two often are closely connected.

See MIDRASH.

HAGGAI, the tenth in order of the "minor prophets," whose writings are preserved in the Old Testament. The book contains four short prophecies delivered between September and December of the second year of Darius; that is, Darius Hystaspis (521–485 B.C.). The language of the prophet in ii. 3 has suggested that he was so old as to have seen the Temple of Solomon which had been destroyed in 586 B.C. This would agree with the shortness of the period covered by his book, and with the fact that his contemporary Zechariah, who began to prophesy in the same autumn, afterwards appears as the leading prophet in Jerusalem (Zech. vii. 1–4).

In his first prophecy (i. 1–11) Haggai addresses Zerubbabel and Joshua, rebuking the people for leaving the temple unbuilt. The prevalent famine and distress are due to Yahweh's indignation: let them build the house and Yahweh will take pleasure in it and acknowledge the honour paid to Him. The people thereupon began to work at the temple, strengthened by the prophet's assurance that the Lord was with them (i. 12–15). In a second prophecy (ii. 1–9) delivered in the following month, Haggai forbids the people to be disheartened by the apparent meanness of the new temple. The silver and gold are the Lord's. He will soon shake all nations and their choicest gifts will be brought to adorn His house. Its glory shall be greater than that of the former temple, and in this place He will give peace. A third prophecy (ii. 10–19) contains a promise, enforced by a figure drawn from the priestly ritual, that God will remove famine and bless the land from the day of the foundation of the temple onwards. Finally. in ii. 20–23, Zerubbabel is assured of God's special love and protection in the impending catastrophe of kingdoms and nations to which the prophet had formerly pointed as preceding the glorification of God's house on Zion.

The characteristic features of the book are three. (1) The importance assigned to the personality of Zerubbabel, who, though a living contemporary, is marked out as the Messiah. The hopes fixed on Zerubbabel, the chosen of the Lord, dear to Him as His signet ring (*cf.* Jer. xxii. 24), indicate the importance of the house of David. But in the book of Zechariah Zerubbabel is falling into the background, and the kingship is yielding to the priesthood. After the foundation of the temple Zerubbabel disappears from history and lives only in legend, which continued to busy itself with his story, as we see from the apocryphal book of Esdras. (2) An almost sacramental significance is attached to the temple. Haggai argues that material prosperity was conditioned by zeal in worship: the prevalent suffering was an indication of divine anger. While the temple lay waste, the people and all their works and offerings were unclean (ii. 14). In this Haggai stands in contrast to those prophet5 who warn their hearers against attaching intrinsic importance to the temple (*e.g.,* Isa. lxvi 1). and he betrays his affinity with Ezekiel, who taught that it was by the possession of the sanctuary and priesthood that Israel was sanctified (Ezek. xxxvii. 28). Finally (3) what is the cause of the indifference of the Jews to the desolate condition of their sanctuary? Neither Haggai nor his contemporary Zechariah mentions or implies any return of exiles from Babylon. and the view is accordingly held that the return under Cyrus described

in Ezra i.–iv. is unhistorical, and that the community addressed by Haggai consisted, in the main, of the Judaeans that had been left in Jerusalem and its neighbourhood after the majority had gone into exile or fled to Egypt (Jer. xliii.).

From the prophecies of Haggai and Zechariah it would never be supposed that about 50,000 Jews had returned when Cyrus became king of Babylon and showed high favour to the exiles (Ezra i.). Even if their enthusiasm had melted away under the stress of bad seasons. the enmity of jealous neighbours, and other troubles, the contrast which Zechariah draws between Yahweh's past wrath and his imminent intervention on behalf of his people, points to the approach of new conditions. And in fact the Jews everywhere were not likely to have been unmoved by the revolts which broke out in the Persian empire at the accession of Darius. Haggai accordingly sees a shaking of the nations which seemed destined to spread; and with the characteristic tendency of Hebrew prophecy to estimate history only in its bearing upon the destiny of Yahweh's people, he looks for an age when Yahweh's enemies would be overthrown, there would be peace, Yahweh's temple would be enriched by willing nations, and Zerubbabel would occupy the highest place of honour. *See* JEWS: *Exile and Restoration: Restoration of Judah.*

BIBLIOGRAPHY.—Haggai is usually treated along with Zechariah or with the rest of the minor prophets: *see* the bibliographies to these.

(W. R. S.; S. A. C.)

HAGGARD, SIR HENRY RIDER (1856–1925), English novelist, was born at Bradenham Hall, Norfolk. At the time of the first annexation of the Transvaal (1877), he was on the staff of the special commissioner, Sir Theophilus Shepstone, and then became a master of the High Court there. After the cession of the Transvaal to the Dutch he returned to England and read for the bar. He gained a great popular success with the novels *Dawn* (1884); *The Witch's Head* (1885), which contains an account of the British defeat at Isandhlwana; *King Solomon's Mines* (1886), suggested by the Zimbabwe ruins; and *She* (1887), another fantastic African story. The scene of *Jess* (1887) and of *Allan Quatermain* (1888) was also laid in Africa. A long list of other stories followed. Haggard showed great interest in rural and agricultural questions, being a practical gardener and farmer on his estate in Norfolk. He dealt with land questions in *Rural England* (2 vols., 1902); the report of an inquiry into colonial land settlement, in *The Poor and the Land* (1905), with suggestions for a scheme of national land settlement in Great Britain itself; and in *Rural Denmark and its Lessons* (1911). Haggard was knighted in 1912. He died in London on May 14, 1925.

HAGGIS. A dish consisting of a calf's, sheep's or other animal's heart, liver and lungs, and also sometimes of the smaller intestines, boiled in the stomach of the animal with seasoning of pepper, salt, onions, etc., chopped fine with suet and oatmeal. It is considered peculiarly a Scottish dish, but was common in England till the 18th century. The derivation of the word is obscure.

HAGIOLOGY, that branch of the historical sciences which is concerned with the lives of the saints (Gr. aytos, saint, Xbyos, discourse). If hagiology be considered merely in the sense in which the term has come to be understood in the later stages of its development, *i.e.*, the critical study of hagiographic remains, there would be no such science before the 17th century. But the bases of hagiology may fairly be said to have been laid at the time when hagiographic documents, hitherto dispersed, were first brought together into collections. The oldest collection of this kind, the *συναγωγὴ τῶν ἀρχαίων μαρτυρίων* of Eusebius, to which the author refers in several passages in his writings (*Hist. Eccl.*, v. proem 2; v. 20. 5), and which has left more than one trace in Christian literature. is unfortunately lost in its entirety. The *Martyrs of Palestine*, as also the writings of Theodoret, Palladius and others, on the origins of the monastic life, and, similarly, the *Dialogues* of St. Gregory (Pope Gregory I.), belong to the category of sources rather than to that of hagiologic collections. The In *gloria martyrum* and *In gloria confessorum* of Gregory of Tours are valuable for the sources used in their compilation. The most important collections are those which comprise the Acts of the Martyrs and the lives of saints, arranged in the order of the calendar. In the Greek Church these are called menologies (from Gr. *μήν*, month, Xbyos, discourse), and their existence can be traced back with certainty to the 9th century (Theodore of Studium, *Epist.* i. 2). One of them, the menology of Metaphrastes, compiled in the second half of the 10th century, enjoyed a universal vogue (*see* SYMEON METAPHRASTES). The corresponding works in the Western Church are the *passionaries* or *legendaries*, varieties of which are dispersed in libraries and have not been studied collectively. They generally draw from a common source, the Roman legendary, and the lives of the local saints, *i.e.*, those specially honoured in a church, a province or a country.

Development in 16th Century.—Hagiology entered on a new development with the publication of the *Sanctorum priscorum patrum vitae* (Venice and Rome, 1551–1560) of Aloysius Lipomanus (Lippomano), bishop of Verona. As a result of the cooperation of humanist scholars a great number of Greek hagiographic texts became for the first time accessible to the West in a Latin translation. The Carthusian, Laurentius Surius, carried on the work of Lippomano, completed it, and arranged the materials strictly in the order of the calendar (*De probatis sanctorum historiis*, Cologne, 1570–1575). What prevents the work of Surius from being regarded as an improvement upon Lippomano's is that Surius thought it necessary to retouch the style of those documents which appeared to him badly written, without troubling himself about the consequent loss of their documentary value.

The actual founder of hagiologic criticism was the Flemish Jesuit, Heribert Rosweyde (d. 1629), who, besides his important works on the martyrologies (*see* MARTYROLOGY), published the celebrated collection of the *Vitae patrum* (Antwerp, 1615), *a* veritable masterpiece for the time at which it appeared. It was he, too, who conceived the plan of a great collection of lives of saints, compiled from the manuscripts and augmented with notes, from which resulted the collection of the *Acta sanctorum* (*see* BOLLANDISTS). This last enterprise gave rise to others of a similar character but less extensive in scope.

Present Status.—To realize the present state of hagiology, the *Bibliotheca hagiographica*, both Latin and Greek, published by the Bollandists, and the *Bulletin hagiographique*, which appears in each number of the *Analecta Bollandiana* (*see* BOLLANDISTS), must be consulted. Thanks to the combined efforts of a great number of scholars, the classification of the hagiographic texts has in recent years made notable progress. The criticism of the sources, the study of literary styles, and the knowledge of local history now render it easier to discriminate in this literature between what is really historical and what is merely the invention of the genius of the people or of the imagination of pious writers (*see* H. Delehaye, *Les Légendes hagiographiques*, 2nd ed, pp. 121–141, Brussels, 1906 and art. "Hagiography" in the *Catholic Encyclopaedia*). "Though the lives of saints," says a recent historian. "are filled with miracles and incredible stories, they form a rich mine of information concerning the life and customs of the people. Some of them are 'memorials of the best men of the time written by the best scholars of the time.'" (C. Gross, *The Sources of Literature of English History*, p. 34, 1900.)

HAGIOSCOPE, in architecture, any opening, usually oblique, through the side or front malls of a church chancel to enable the congregation in transepts, chapels or other portions of the church, from which the altar would not otherwise be visible, to witness the elevation of the host during mass. Similar openings are sometimes furnished to allow an attendant to ring the sanctus bell at the proper time. or to permit someone in a vestry vision of the service so that he can notify the bell ringer. Hagioscopes or squints are more common in England than on the continent of Europe.

HAGUE, THE (Dutch, 's-GRAVENHAGE or DEN HAAG; Fr., LA HAYE), the seat of the government of the Netherlands and capital of the province of South Holland, lies on a plain about 2 mi. from the North sea. Pop. (1957 est.) 605,751 including Scheveningen, Loosduinen and Kijkduin. Area 25.1 sq.mi.

The city grew up around the castle. built by Count William II in 1248, which was the first of a group of buildings called the

Binnenhof ("inner court"). Of the great halls around this courtyard, the Knight's hall (c. 1280) is now the throne room. and the northwestern and southeastern sides of the square are occupied by the states-general and contain the Armistice or Truce hall. designed by Daniel Marot in 169;. The states-general sat in The Hague from the establishment of the republic until the revolution in 1795. and again from 1815 until 1830, during which time they sat alternately in Brussels and The Hague. The Binnenhof is surrounded by 15th to 18th-century buildings, and remnants of post 14th-century architecture are still to be found in the spacious layout of the Buitenhof ("outer court"). Plaats. Lange Vijverberg, Kneuterdijk and Lange Voorhout. In the 13th and 14th centuries a commercial district grew up around the central buildings, still to be seen in the shopping streets. such as Veenestraat, Spuistraat. Gravenstraat and Hoogstraat. At the beginning of the 17th century wide avenues and canals. lined by imposing aristocratic mansions. were constructed on the eastern side of this district (Tournooiveld. Korte Vijverberg, Korte Voorhout, Herengracht and Plein); to the southeast there grew up the Spui (craftsmen's district) and small inner harbours; and to the west the Prinsegracht (wealthy middle class) which was connected to the Westland by the Loosduinse canal. Under Prince Maurits, a belt of canals was constructed from 1613 to 1619 as a fortification for the town. Within this belt there was ample space for town development until long after the period of French domination.

In the first half of the 20th century a town grew up, characterized by broad avenues, parks and public gardens, in the surroundings of Nieuwe Parklaan, Laan van Meerdervoort, Weimarstraat, Bezuidenhoutseweg and Laan van N.O. Indië. In the north the Benoordenhout quarter was built, and near Wassenaar the fine residential park district of Marlot. In the southwest the Zuiderpark districts were laid out, containing many blocks of flats. Along the dunes in the west and near the Laan van Meerdervoort and Loosduinseweg small villas were built. and the Bomen and Bloemen district and the Fruit quarter (for middle-class people) were laid out. Between 1930 and 1940 radical improvements took place in Scheveningen. Old slums disappeared and were replaced by the new fishermen's district of Duindorp.

Surrounded as The Hague is by the North sea, the water works in the dunes, the adjoining municipalities and the nurseries of the horticultural area, called the Westland, the city had extended almost to its limits after World War II. The only possibility of expansion was toward the southeast, in the polders. Three feet under sea level, there arose a new town quarter for more than 100,000 inhabitants.

The Buitenhof is one of the centres of the town's activities, and contains several hotels and restaurants. The original entrance to it was the Gevangenpoort ("prisoners' gate"). which was built about 1400 and consists of a tower and a gate; it is a museum. Just north of the Binnenhof lies the Hofvijver, a big rectangular sheet of water, with a small island in the centre. Close by is the Church of the Old Catholics (1722) with a beautiful Baroque interior. The former royal palace in the Noordeinde was first built in the 16th century. The present building dates from 1640 and was designed by Pieter Post and Jacob van Campen. Northeast of the Binnenhof is the Mauritshuis (1633–44) originally built for Prince Johan Maurits van Nassau, governor of Brazil, and now the great Royal Museum of Painting of The Hague. Other artistic collections are contained in the municipal museum, housing modern paintings, musical instruments. etc.; the Mesdag museum, with European paintings of the 19th century; the Bredius museum (1645), with old pictures of the Dutch school; and many others. The royal library, designed by Marot in 1798, contains a collection of 800,000 volumes. The Renaissance town hall of 1564 stands southwest of the Buitenhof. It was enlarged in 1733 and again during the 19th century, but-as it eventually proved too small, a new one was completed in 1953. Near the old town hall stands the Great Church of St. James (11th and 16th centuries). which has a hexagonal tower and a richly decorated late Gothic choir: the new spire, designed as a copy of an old one and completed in 1957, has the largest carillon in the Setherlands (51 bells). The Royal theatre, in the Korte Voorhout, with its elegant façade by Peter de Swart, was originally the Nassau-Weilburg palace. The Nieuwe Kerk ("new church"), built between 1649 and 1656, contains the tombs of the De Witt brothers, who were murdered in the city in 1672, and of the philosopher Spinoza. The Peace palace (1907–13) is the seat of the International Court of Justice and of the Permanent Court of Arbitration. The more striking modern buildings include the Shell building (1941) and the K.L.M. building (1949). Beyond an extensive wooded area. the Haagse Bos, to the east of the Binnenhof. is the restored royal palace Huis ten Bosch built in 1645 by P. Post and containing a beautiful hall with a domed roof designed by Van Campen.

A considerable part of The Hague is composed of woods, public gardens, parks and recreation grounds, chief among which are Westduin park (617 ac.), Zuiderpark (210 ac.), Scheveningen woods (210 ac.) and Westbroek park (25 ac.) with an exhibition garden. There is a variety of educational institutions including the International school. the American school. the Royal Conservatory of Music, the Academy of International Law and the Institute of Social Studies in the former royal palace in the Noordeinde.

The city has rail connections with Amsterdam. Utrecht. Rotterdam and Paris, and there are also waterway communications with various parts of the Netherlands. The airfield is at Schiphol near Amsterdam., The main industries are metallurgy (electrical appliances, hardware, stoves, coachwork). building. and the manufacture of foodstuffs. clothing, luxury articles, chemicals, pottery and glass, and printing. The Hague is the headquarters of a large number of international firms. including more than 30 oil companies, and is a centre for international conferences.

Scheveningen, which is the Netherlands' principal herring harbour, is also an important seaside resort. At Loosduinen there are extensive horticultural grounds from which early fruit and vegetables are exported by air.

See Municipal Publications, *Enige grondslagen van de Stedebouwkundige ontwikkling van 's-Gravenhage* (1948), *The Hague, City in Expansion* (1957). (*D. P. M.*)

HAGUE CONFERENCES, the two international conferences held at The Hague in the Netherlands in 1899 and 1907, known also as the Hague Peace conferences. The first was called at the instance of Tsar Nicholas II of Russia, by a note of the Russian minister of foreign affairs; Count Mikhail N. Muraviev, under date of Jan. 11. 1899. addressed to the diplomatic representatives at St. Petersburg, in which the purpose of the conference was stated to be that of "a real and lasting peace and, above all, of limiting the progressive development of existing armaments." followed by details with respect to the regulation of specific instruments of warfare. Twenty-six states were represented at the conference. which sat from May 18 to July 29, 1899. Only two American states, the United States and Mexico, took part.

The conference failed to attain its chief objective of the limitation of armaments: the larger powers, particularly Germany. opposing any specific measures. Instead, two conventions dealing with the regulation of war were adopted, one concerning the laws and customs of war on land and a second adapting the principles of the Geneva convention of 1864 to maritime war (see GENEVA CONVENTIONS). Three declarations were adopted, one prohibiting the discharge of projectiles from balloons. a second prohibiting the use of asphyxiating gases and a third prohibiting the use of expanding bullets. More important, however, was the Convention for the Pacific Settlement of International Disputes creating the Hague Permanent Court of Arbitration, a list of judges from which the parties in controversy might select the members of an arbitral tribunal for their particular case. (See ARBITRATION, INTERNATIONAL.)

The conference of 1907, likewise called by the tsar after Pres. Theodore Roosevelt had first taken the initiative. was attended by representatives of 44 states and sat from June 15 to Oct. 18. Again the proposal of a limitation of armaments failed of acceptance. But two constructive steps were taken—the revision of the Convention for the Pacific Settlement of International Dis-

putes and a new Convention Respecting the Limitation of the Employment of Force for the Recovery of Contract Debts. Eleven additional conventions were signed, two of them revising and renewing the conventions on the laws of war on land and the adaptation of the principles of the Geneva convention to maritime war; and nine others dealing respectively with the commencement of hostilities (calling for a declaration of war). the rights and duties of neutral powers and persons in war on land, the status of enemy merchant ships at the outbreak of hostilities, the conversion of merchant ships into warships, the laying of automatic submarine contact mines, bombardment by naval forces in time of war, restrictions on the exercise of the right of capture in maritime war, the establishment of an international prize court and the rights and duties of neutral powers in maritime war. *(See* also CONTRABAND.) The conference renewed the declaration of 1899 prohibiting the discharge of projectiles and explosives from balloons; but the declarations of 1899 with respect to asphyxiating gases and expanding bullets were not renewed. the United States having opposed both declarations and Great Britain having signed them only on the eve of the conference.

The final act of the conference proclaimed the unanimity of the delegates in admitting the principle of compulsory arbitration and expressed a number of *voeux* (resolutions), the first of which declared the advisability of adopting the draft Convention for the Creation of a Judicial Arbitration Court and the last recommending the assembly of a third peace conference within another period corresponding to that between the first and second conferences. The other *voeux* dealt with topics that had not been included in the conventions. namely, relations between the inhabitants of the belligerent states and neutral countries. the position of foreigners in respect to military service and the future codification of the laws and customs of naval war.

The conference planned for 1915 failed to meet because of the outbreak of war in 1914, no provision having been made to meet emergencies. At the close of the war the more highly organized League of Nations replaced the Hague conference system. In the light of history the Hague conferences failed because they accepted war as inevitable and merely sought to reguiate it as a legal procedure. *See* also WAR; AGGRESSION; INTERNATIONAL LAW, PUBLIC. (C. G. FK.)

HAHN, AUGUST (1792–1863), German minister, was born on March 27. 1792, near Eisleben, and studied at Leipzig. In 1819 he was nominated professor extraordinarius of theology and pastor of Xltstadt in Konigsberg, and in 1820 received a superintendency in that city. In 1822 he became professor ordinarius and in 1826 moved as professor of theology to Leipzig. There he published two treatises, *De rationalismi qui dicitur vera indole et qua cum naturalismo contineatzir ratione* (1827) and also *Offene Erklärung an die Evangelische Kirche zunächst in Sachsen und Preussen* (1827). in which he sought to convince the rationalists that it was their duty voluntariiy and at once to withdraw from the national church. In 1833 Friedrich Wilhelm III summoned him to Breslau as theological professor and consistorial councilor, and in 1843 he became general superintendent of the province of Silesia. where he reintroduced the Augsburg Confession. He died at Breslau on May 13, 1863. His *Lehrbuch des christlichen Glaubens* (1828, 2nd [amended] ed. 1857) explains his position. Among his other works the most important is *Bibliothek der Symbole und Glaubensregeln* (1842; 3rd ed. 1897).

HAHN, OTTO (1879–), German chemist, who received the Nobel prize in 1944 for splitting the uranium atom, was born March 8, 1879, in Frankfurt am Main, and studied at the universities of Marburg and Munich, receiving his doctorate at the former in 1901. For many years Hahn was the outstanding radiochemist in Germany. His early interest in this field brought him to Sir William Ramsay's laboratory in London in 1904–05, and in the following year to Lord Ernest Rutherford's institute in Montreal, Que. Upon his return to Germany he worked first at the chemistry laboratory of the University of Berlin, headed at that time by Emil Fischer, and from 1912 on as member and later (1928–44) as director of the Kaiser Wilhelm Institute for Chemistry in Berlin-Dahlem. Hahn's co-operation with Lise Meitner, the physics partner of this group, started in 1907 in Fischer's institute and lasted until 1938 when the Hitler regime forced her to leave the country. The high lights of Hahn's scientific career were the detection of radiothorium. mesothorium, protactinium with Lise Meitner (1917) and finally uranium and thorium fission with Fritz Strassmann (1938). The latter discovery *(see* ATOMIC ENERGY) is the basis for all methods to tap atomic energy, including the development of the atomic bomb. Hahn had a foreboding that his discovery could be used for military purposes but, as his publications indicate, fervently hoped this would prove impossible. After World War II he became president of the Max Planck Gesellschaft in Gottingen, which took over the functions of the Kaiser Wilhelm institute in west Germany.

In April 1957 he joined with 17 other west German nuclear physicists in stating that they would refuse to co-operate in any way in the development of atomic weapons, and in the same month supported Albert Schweitzer in urging that world opinion demand the ending of atomic bomb tests.

Hahn's writings include: *Applied Radiochemistry* (1936); *Kiinstliche Atomumwandlungen und die Spaltung schwerer Kerne* (1944); *Die Kettenreaktion des Urans und ihre Bedeutung* (1948); *Die Nutzbarmachung der Energie der Atomkerne* (1950); *New Atoms* (1950); *Cobalt 60* (1955). (Js. F.; X.)

HAHN, REYNALDO (1875–1947), French composer of light operas and songs in the tradition of Offenbach and Messager. Born at Caracas, Venez., Aug. 9, 1875, he went to Paris when a child and studied at the Conservatoire under Massenet. In 1898 his *L'Île du rêve* was given at the Opéra Comique, and from then until 1939 he produced many light operas, the best of which is *Ciboulette* (1923), ballets (notably *La Fête chez Thérèse*, 1910) and *Le Dieu bleu* (1912), and incidental music for plays by Edmond Rostand. Sacha Guitry and others. His songs include the *Chansons grises* and the *Chansons latines* and the well-known "Si mes vers avaient des ailes." He was also known as a conductor of the operas of Mozart and gave *Don Giovanni* at Salzburg. His piano suite, *Portraits de peintres,* was inspired by early poems of Marcel Proust who portrayed Hahn in his novel *Jean Santeuil.* He was music critic of *Le Figaro* from 1934 and was appointed director of the Paris Opéra in 1945. His work is melodious, usually slender, but gracefully written. With André Messager he was responsible during his day for the main developments in the French operetta which had been established by Offenbach. His memoirs, *Journal d'un musicien* and *Thèmes variés,* are valuable sources for the musical and literary life of his time. He died in Paris, Jan. 28. 1947.

See Marcel Proust, *Lettres à Reynaldo Hahn,* ed. by Philippe Kolb (1956). (E. LR.)

HAHNEMANN, (CHRISTIAN FRIEDRICH) SAMUEL (1755–1843), German physician. founder of homeopathy was born at Meissen. Saxony. on April 10, 1755. He studied medicine at Leipzig and Vienna and settled in Leipzig in 1789. In the following year. while translating W. Cullen's *Materia medica* into German, he was struck by the fact that the symptoms produced by quinine on the healthy body were similar to those of the disordered states it was used to cure. This observation led him to assert the truth of the "law of similars." *similia similibus curantur; i.e.,* diseases are cured (or should be treated) by those drugs which produce symptoms similar to them in the healthy. He promulgated his principle in a paper published in 1796, and four years later. convinced that drugs in much smaller doses than were generally employed effectually exerted their curative powers, he advanced his doctrine of their potentization or dynamization. His chief work. *Organon der rationellen Heilkunst* (1810), contains an exposition of his system, which he called homeopathy. His *Reine Arzneimittelehre* (6 vol., 1811) detailed the symptoms produced by "proving" a large number of drugs; *i.e.,* by systematically administering them to healthy subjects. In 1821 the hostility of established interests, and especially of the apothecaries, forced him to leave Leipzig. and at the invitation of the grand duke of Anhalt-Cöthen he went to live at Cöthen. Fourteen years later he moved to Paris. where he practised until his death on July 2, 1843. Statues were erected to his memory at Leipzig and at Cöthen. *See* also HOMEOPATHY.

See T. Bradford, ***Life*** *and Letters of* ***Dr.*** *Samuel Hahnemann* (1912).

HAHN-HAHN, IDA, COUNTESS VON (1805–1880), German author, was born at Tressow, Mecklenburg-Schweriri, June 22, 1805, daughter of Count Karl Friedrich von Hahn (1782–1857). She married in 1826 her cousin Count Adolf von Hahn-Hahn. The marriage was unhappy, and in 1829 she procured a divorce. She traveled, produced some poetry indicating true lyrical feeling and in 1838 published *Aus der Gesellschaft,* a title given to a whole series of her novels, the book being renamed *Ida Schönholm.* The countess's patrician affectations at length drew upon her the merciless ridicule of Fanny Lewald in a parody of her style entitled *Diogena, Ronzan von Iduna H . . . H . . .* (2nd ed., 1847), and after the 1848 revolution she retired to a convent. *Ulrich* and *Gräfin Faustine* (1831) are her best works. Her *Gesammelte Werke* were published in 45 volumes (1903–04) with an introduction by O. von Schaching. She died at Mainz, Jan. 12, 1880.

See A. Jacoby, *Ida Gräfin Hahn-Hahn* (1894).

HAIBAK, a town of Afghanistan. province of Mazar-i-Sharif, famed in Persian legend. The valley of Haibak, 3.100 ft. above sea level, is fertile and richly cultivated. The inhabitants called themselves Jagatais, a Tutki race, now generally mixed with Tajiks and speaking Persian. Near Haibak are some typical Buddhist ruins. Haibak derives its importance from its position on the main line of communication between Kabul and Afghan Turkistan.

HAI BEN SHERIRA (939–1038), last of the outstanding Babylonian geonim *(see* GAON), under whose presidency the Pumbeditha academy reached its greatest heights. Though the office of gaon was not necessarily hereditary, Hai was the fourth in a direct line, in a family which traced its origin to the Davidic dynasty, to occupy the Gaonate of Pumbeditha, situated in Baghdad since the late 9th century. Hai first assisted his father, Sherira ben Hanina, in teaching and later as chief of court of the academy. A false accusation caused the imprisonment of father and son (997), but when they were proved innocent and freed, Hai was appointed Gaon (998) during the lifetime of his father.

Close to 1,000 *responsa* (advice or decisions on points in the Talmud) written by Hai. equaling the number of extant *responsa* written by all other geonim, have come down to modern times. He steered a middle course between the rationalistic and fundamentalist philosophical schools, explaining all anthropomorphisms as metaphors and upholding free will against predetermination. He couched his *responsa* in the same languages (Hebrew, Aramaic or Arabic) in which the questions were written. Hai died at the age of 99 on the eve of the last day of Passover 1038, and was eulogized by the famous Judaeo-Spanish poets Solomon Ibn Gabirol and Samuel haNagid as one who left no children but countless disciples in all countries of the world. (S. K. M.)

HAIDA, the natives of Queen Charlotte Islands. B.C. The Kaigani are an 18th-century offshoot on Prince of Wales Island. With the Tlingit and Tsimshian. the Haida constitute the Indians that have carried the peculiar native culture of the North Pacific coast Indians to its highest pitch. (See INDIANS, NORTHWEST COAST.) Their speech, usually considered distinct, has been linked with Tlingit (*q.v.*) and Athapaskan (*q.v.*) into a proposed larger Na-Dene family. In 1841, after decline had begun, the population was estimated at 8,300; in 1880, 2,000–2,800; in 1905, 900, and in 1951, 767.

HAIDER, KARL (1846–1912), German landscape painter, born in 1846. He studied at Munich under Anschütz and was a contemporary and friend of Wilhelm Leibl. who painted his portrait in a picture called "The Art Critics" in 1868. Although he lived and worked in the midst of genre painters, Haider turned to landscape and became a great linear stylist. His remarkable smoothness of line lent austerity to his pictures, which usually convey an impression of intense stillness.

HAIDUK, a term probably derived from the Turkish *haidud* ("marauder"). The Haiduks of Serbia and Bulgaria were political outlaws and guerrilla champions of liberty; and the national movement in these countries was first led by bands of Haiduks. In Hungary the name was applied to a class of mercenary foot soldiers of Magyar stock. In 1605 these Haiduks were rewarded for their fidelity to the Protestant party *(see* HUNGARY: *History)* with titles of nobility and territorial rights over a district situated on the left bank of the river Tisa known thenceforward as the Haiduk region. This was enlarged in 1876 and converted into the county of Hajdú. In Austria-Hungary, Germany, Poland, Sweden and some other countries, Haiduk came to mean an attendant in court of law, or a male servant, dressed in Hungarian semimilitary costume. It is also occasionally used as a synonym for footman or lackey.

HAIFA, a city in Israel at the foot of Mt. Carmel at the southern end of the Bay of Acre. Though Haifa never played a great role in history, it has lately grown into the most important port of Israel, with a thriving industrial and trading population. Its good roadstead has been transformed into a large modern port with depth for the greatest vessels. It is a terminal point of three railroads, one standard gauge double-track railroad to the Suez canal and Egypt, built immediately after World War I, an older narrow gauge one-track link with the Hejaz railroad, connecting with Damascus and Jordan and a new standard gauge rail to Beirut and Turkey, built during World War II. Haifa has also become the terminal of one of the two pipelines bringing the Iraq oil to the Mediterranean. The population of Haifa has grown from 35,000, mainly Arabic, in 1928 to 182.007 in 1961. The new immigrants have been mostly Jewish who have built and settled modern suburbs on the slopes and on the top of Mt. Carmel and in the plain northeast of the town, where they have founded large textile, cement and soap factories and flour mills.

(H. Ko.)

HAIG, DOUGLAS HAIG, 1ST EARL (1861–1928), British soldier, was born in Edinburgh, June 19, 1861, son of John Haig, of Cameronbridge, Fife. He was educated at Clifton and Brasenose college, Oxford, and in 1885 joined the 7th Hussars. He was promoted captain in 1891, afterward passed through the staff college and was employed with the Egyptian army in 1898 during the Nile campaign, for which he was given a brevet majority. On the outbreak of hostilities in South Africa in 1899, he went out to Natal on the staff, and was present during the opening engagements near Ladysmith. He was afterward chief staff officer of the cavalry division during Lord Roberts' victorious advance from Cape Colony through tlie Orange Free State into the Transvaal, and was promoted brevet lieutenant colonel for his services.

In the later phases of the struggle he was in command of a column and later was controlling groups of columns; at the close of the war he was appointed A.D.C. to the king, promoted brevet colonel, and given the C.B. Col. Haig subsequently commanded the 17th Lancers for a year, after which he went to India as inspector-general of cavalry; this appointment he held until 1906, having been promoted major general in 1905, in which year he married the Hon. Dorothy Vivian, daughter of the 3rd Lord Vivian. From 1906–09 he was a director in the war office, and during this time he was intimately concerned in the development of the general staff and the improvements effected in the organization of the army, which were set on foot while Lord Haldane was secretary of state. In 1907 he published a volume of *Cavalry Studies.* His next appointment was that of chief of the general staff in India, which he held for three years, being promoted lieutenant general in 1910. In 1912 he was brought home to take the command in Aldershot, and in 1913 he was made a K.C.B.

On the mobilization of the expeditionary force in 1914, Sir Douglas Haig took the field as commander of the 1st army corps, which he led during the Mons, Marne and Aisne operations, and the first battle of Ypres; he was promoted full general in November for his services. On the division of the British expeditionary force into two armies at the beginning of 1915, he was placed at the head of the first. On the front of his army during 1915 there took place the battles of Neuve Chapelle, Festubert and Loos, and at the end of the year he succeeded Sir John French in the chief command. He had been made a G.C.B. in the autumn.

At this time the armies were passing through a period of transition. The regular army, with the exception of its cavalry, had almost ceased to exist and the first need was to weld its remnants, the new armies created by Lord Kitchener and the territorial army, into a whole capable of combined action both in attack and in defense. This involved the organization of an elaborate system of training for which it was necessary that a certain

number of divisions should be placed sufficiently far behind the line to allow them the ground and the opportunities for gaining experience.

This policy often brought Sir Douglas Haig into discussion both with the French generals and with the French statesmen, who were continually pressing him to take over a large extent of front. Sir Douglas Haig pointed out that it was not possible to compare a national army created during the course of the war with one which had been long established in time of peace, and that the Germans throughout the war maintained a greater density of men opposite the British lines than they did elsewhere. In the event, his policy was justified by the fact that in the latter half of 1918 the British army was, as a whole, at least as efficient as any which was then fighting in the war.

The campaigns and battles of the British army in France and Belgium are dealt with elsewhere and it is here only necessary to refer to the principles which guided Sir Douglas Haig in certain of the crises of the war. The first of these during his command arose out of the German attack on Verdun during the first half of 1916. On that occasion he assisted the French by relieving their troops in the front and by preparing for the battle of the Somme. While that battle disclosed defects both of preparation and of execution, its results convinced Sir Douglas Haig that it had caused such exhaustion of the German armies as should be exploited at the earliest possible moment. He therefore agreed with Joffre to renew the battle early in 1917.

But the battle of the Somme had caused grievous losses and the gains of ground as shown on the maps appeared trifling, Therefore, neither French nor British statesmen were prepared to agree to a policy which to their minds seemed likely to exhaust their resources before it caused the enemy to yield. The consequence of this was the replacement of Joffre by Nivelle and the assembly of an Allied Conference at Calais at the end of Feb. 1917, at which it was decided to give Nivelle the general direction of the British army, while he was at the same time to be in active command of the French army. This arrangement, militarily unsound, early produced friction. For Nivelle, who was ill-informed of events on the British front, issued to Haig instructions which were inappropriate both as to form and substance. These differences were adjusted at a further conference in London, but they created the impression that Haig was opposed to any form of unity of command, which was not true.

The direct result of the failure of Nivelle's campaign was a wave of depression which spread through the French armies and resulted in serious mutinies. Pétain, who had succeeded Nivelle, appealed to Haig to keep the Germans occupied while he was restoring the morale of the French troops. To this appeal Haig responded by opening in the summer of 1917 a campaign in Flanders, which began with Plumer's victory at Messine and was followed by the battle of Passchendaele. It was only with difficulty that Haig won the consent of the British Government to this campaign. By the middle of October of that year Pétain was able to tell Haig that the French army was sufficiently restored to be able to look after itself; and it might have been wiser to have stopped the battle of Passchendaele then, as no adequate return was gained for the exhaustion caused by the prolongation of the attack in execrable weather.

The crisis brought about by the success of the German-Austrian attack on the Italians at Caporetto following on the collapse of Russia, resulted in the creation in Nov. 1917 of the Supreme War Council, the first meeting of which was held at the end of the following January. This meeting had been preceded by a renewal of French demands for an extension of the British front, which Haig eventually met by agreeing to take over a portion of the line at and south of Peronne with his V. Army. At this meeting a difference of policy between Haig and his Government was disclosed. The commander-in-chief anticipated an early attack by the Germans and asked for reinforcements; the Prime Minister wished for an offensive campaign in Palestine, and won his way; and at this same conference, it was decided to create an Allied general reserve on the Western front under the control of the military representatives of the Supreme War Council with Foch as chairman. During Feb. 1918 Haig became more than ever convinced that a great German attack on his front was imminent, in which he differed from the military representatives, who did not expect it before May. When the military representatives applied to him for divisions for the general reserve, he answered that in view of the lack of reinforcements, the extension of his front and the massing of German troops, he would be unable to furnish these divisions, and the formation of the general reserve broke down.

With what calm determination Haig met the great German offensive of the spring of 1918 is described elsewhere. In the most critical days of that offensive it was Haig's direct intervention with the British Government which brought Lord Milner to France, a visit which resulted eventually in giving Foch direct control of the Allied armies. With Foch Haig's relations were as harmonious as they had been with Joffre, and in the late summer of 1918 the British commander-in-chief reaped at last the reward of his patient policy. When in Aug. 1918 Rawlinson's IV. Army won the victory of Amiens, Foch desired that Rawlinson should follow up his success. Haig, convinced that this would result in another deadlock, and confident now in the superior morale and efficiency of his army, persuaded Foch to agree to an extension of the battle northwards, and so came about the breaking of the Hindenburg line which made it clear that victory could be won in 1918. For his great services Sir Douglas Haig was raised to the peerage as Earl Haig and Baron Haig of Bemersyde and was given a grant of £100,000. The Order of Merit was also conferred upon him, and the ancestral home of the Haigs at Bemersyde was purchased by national subscription and presented to him. On returning home he was for a short time commander-in-chief in Great Britain, but when that position was abolished he refused other offers of employment and devoted himself wholly to the welfare of ex-service men. Before leaving France he had learned that many disabled and discharged soldiers were in distress, and he refused to accept any reward for himself until the Government had made better provision for the men who had served under him. Being satisfied that official provision must be supplemented by private benevolence he succeeded in uniting the various organizations of ex-service men into the British Legion (*q.v.*), of which he became president. By organizing the sale of poppies on November 11th, which became known as "Poppy Day," he created a large fund for the benefit of ex-service men. He also created and became president of the British Empire Services League, a union of the ex-service men's organizations of Great Britain and the dominions; he was also appointed chairman of the United Services fund, which, together with the British Legion fund, forms one of the largest benevolent organizations in Great Britain. He died on Jan. 29, 1928, and was buried at Dryburgh Abbey, Scotland, after national tributes to his memory had been paid at Westminster Abbey and St. Giles's cathedral, Edinburgh.

HAIK, a piece of cloth, usually of coarse hand-woven wool, worn by Arabs, Moors and other Mohammedan peoples (Arabic *hak*, to weave). It is generally 6 to 6½ yd. long, and about 2 yd. broad. It is either striped or plain, and is worn equally by both sexes, usually as an outer covering, but it is often the only garment of the poorer classes. Women arrange the "haik" to cover the head and, in the Presence of men, hold it so as to conceal the face. A thin "haik" of silk, like a veil, is used by brides at their marriage.

HAIL consists of ice balls or lumps ranging from one-fifth to two or more inches in diameter, composed of clear ice or alternating layers of clear ice and opaque, snowlike layers. Hail occurs almost exclusively in violent or prolonged thunderstorms and

never with the ground temperature below freezing. Hail is most frequent in middle latitudes. in the interior of continents and during the summer season. On the New York-Denver airway, one thunderstorm in 800 produces hail as large as walnuts and one in 5,000 as large as baseballs. Hail is often found in the clear air surrounding the storm. Large hail may seriously damage aircraft. Hailstones are formed on a snow pellet nucleus (graupel or soft hail) and grow by collisions with supercooled cloud and raindrops in much the same manner that ice forms on aircraft. Large hailstones require large vertical air velocities, a large amount of water in suspension and a cloud which extends for a considerable distance above the freezing level. Although the hailstone may have an irregular path, it is not necessary that it be repeatedly carried below and above the freezing level, as was once thought. See THUNDERSTORMS. (H. G. HN.)

HAILE SELASSIE I: *see* MAKONNEN, RAS TAFARI.

HAILSHAM, a market town and rural district of East Sussex, Eng.. 8 mi. N.N.W. of Eastbourne by road. It is a centre for agriculture and market gardening with rope and twine factories and a large egg-packing station. From the 15th-century Perpendicular church of St. Mary the curfew is still rung. At Michelham. 2 mi. W., was an Augustinian priory. now a private residence. with gatehouse and crypt remaining. There was a Premonstratensian house at Otham, 3 mi. S.

HAINAN ISLAND, China's second largest offshore possession, is that country's most extensive tropical area. Long known but little explored. it is rich in iron ore. tin and hardwoods, and has a great potential for commercial crops. That it has been so sparsely settled by Chinese despite ample agricultural opportunities and convenience to the coast and southeast Asia trade routes is a puzzle of geographic and historic interest.

The island lies south of the Leichou (Luichow) peninsula, between 19° g' and 20° 15′ N. latitude. extending 160 mi. east-west and go mi. north-south. Hai-k'ou (Hoihow), the main port on the north coast. is 2jo mi. E. of Haiphong in Vietnam and 300 mi. W. of Hong Kong. In total area. Hainan is slightly smaller than Formosa (Taiwan), having 13,500 sq.mi. in contrast with Formosa's 13,886, with 647,100 ac. of cultivated land in 1946. Total population in 1941 was estimated as 2,500,000.

Structurally, Hainan is the southern side of a graben, in the lowest part of which is Hainan strait. 50 mi. long and from 10 to 14 mi. wide. Both the sandy coastal plain and the lateritic red clay lowlands behind the plain show scoriaceous lava that may have poured out when the graben was formed. In the southern half are the Five Finger mountains and associated northeast-southwest ranges of granites and porphyries, of which the crest peak is 6.800 ft. above sea level. They form the watershed of the streams that run into the South China sea in all directions, as well as the refuge of flora, fauna and aboriginal tribes not widely distributed in other parts of the island. Only 2j mi, from the southwest corner, a familiar landmark to mariners is Mt. Etna (Chien Feng Ling), a steep crater 4,967 ft. high.

The tropical climate provides a 12-month growing season. with temperature averages for lowland areas of 65° F. for January and 85° F. for June. Rainfall at Ch'iung-shan, the capital. on the north coast totals 62 in. a year, two-thirds falling from June to October from the monsoon and strong autumn typhoons, augmented in summer by intense afternoon thunderstorms.

Important natural vegetation includes six types of palm trees, rattan, bamboo: banyan. mahogany, rosewood and fragrant woods used in Chinese medicines. Tropical fruits, both wild and cultivated, are also abundant: date, fig, jack fruit, orange, lime. pomelo, pineapple, banana, mango. papaya and litchi. The native iauna is likewise varied, being notably different from that on the mainland: bear, leopard, deer, monkeys, squirrels, lizards, python. cobra and many species of birds and insects. Both streams and offshore waters abound in edible fish.

Under Japanese occupation, 1939–45, the rich mineral deposits were worked steadily. Approximately 2,700,000 tons of 60% iron ore were extracted from T'ien-tu. 10 mi. N.W. of Yü-lin harbour, and Shih-lu. 35 mi. N.E. of the improved harbour of Pei-li on the west coast! the latter a haematite deposit estimated at 35.000.000 tons. At Na-ta in the northwest from 200 to 300 tons of 70% alluvial tin were obtained yearly. while rich bauxite deposits near Yai-hsien on the south coast and salt pans farther east were also worked. Yü-lin was transformed into a naval base.

Agricultural improvement is promising. Two and three rice crops yearly are common. but rice has usually been imported because of drought. flood, typhoon winds and costly inland transport. Hong Kong has been the major market since 1876 for pigs, raw sugar. eggs, sesame seed. hemp. hides, glue, firewood, seafood products and salt. with shipments to Canton and southeast Asia of betel nut, coconut, copra and fruit.

In 1910 two Chinese companies from Singapore started rubber plantations. but ceased operations after 1920 because of low prices and insufficient capital. In 1943 the Japanese revived the industry, planning for 75.000 tons annually by 1948; in 1950 some of the output was shipped to Shanghai. Commercial prospects exist for coffee. pepper, sisal, ramie, peanuts. beef and processed fish.

With such favourable conditions. Hainan's lack of development is striking. Following Chinese subjugation of Kuangtung in the Early Han dynasty (206 B.C.–A.D. 8), Li tribes moved south to the island. Later Chinese settlements on the coastal plain compressed them toward the forested mountain interior. repeating the mainland pattern of economic control and suppressing their frequent uprisings. Thereafter they were interspersed with smaller and later Miao tribes from southwest China. living by hunting. gathering, shifting hillside farming and settled wet rice cultivation.

During the past 19 centuries various Chinese groups have migrated to Hainan in small numbers: the Hoklo from south Fukien, clustered around Wen-ch'ang in the northeast. providing the main source of Hainese emigrants to Thailand and Singapore and the standard "Hainan dialect"; Hakka from Kuangtung. mostly at Na-ta in the northwest; a Mandarin-speaking enclave at Tan-hsien, probably descendants of Hunanese troops landed in 1885: about 2.000 Chinese-Li Mohammedans at San-ya in the south believed to be descended from shipwrecked Arabs; and merchant families from Canton. Swatow and Hong Kong. From the T'ang dynasty (A.D. 618–906) to the Republic (1911), Hainan was a place of political exile from court, the most famous exile (A.D. 1098–1100) being the Sung poet. Su Tung-p'o. Distance from the mainland culture (yet not enough to prevent official control of venture capital), coastal pirates' interruption of contact with Canton, malignant malaria and frequent tribal outbreaks all discouraged sizable Chinese immigration and development.

Western contact began under Portuguese Jesuits: 1630. being resumed after their expulsion from China by French Jesuits in 1849 American Presbyterians started at Hai-k'ou in 1881. Foreign commercial residence began in 1876, but never expanded into a large settlement. Hainan was held by a foreign power only once —by the Japanese, 1939–45, when 180 mi. of narrow-gauge railway were built.

In April 1950 Hainan came under the Chinese People's Republic, and on July 1. 1952, the tribal areas in the mountainous south were designated the Li-Miao Autonomous district for the 270,000 non-Chinese tribesmen there. In Sept. 1951 a rubber-goods factor>-was opened at Hai-k'ou, and in Dec. 1951 a government plan was announced to increase existing rubber plantings of 3.000 ac. to 74.000 by 1961. In May 1953 two mountain reservoirs were finished that would raise rice output by 200 tons through irrigation. Mining was reported continuing, and naval and air bases expanded at Yü-lin.

(TE. H.)

HAINAUT, a province of Belgium. based on the ancient county of Hainaut. There are about 110,000 men and women employed in the coal and iron mines. and about 10,000 in iron and steel works. The chief towns are Nons, the capital, Charleroi, Tournai. Soignies and Thuin. The rivers are the Scheldt

and Sambre. There are 6 administrative arrondissements, 33 cantons and 443 communes. Pop. (1955) 1,261,125.

Under the successors of Clovis, Hainaut formed part, first of the kingdom of Metz, and then of that of Lotharingia. It afterward became part of the duchy of Lorraine. The first to bear the title of count of Hainaut was Reginar "Long-Neck" (c. 875), who made himself master of the duchy of Lorraine and died in 916. His eldest son inherited Lower Lorraine, the younger, Reginar II, the countship of Hainaut, which remained in the male line of his descendants, all named Reginar, until the death of Reginar V in 1036. His heiress, Richildis, later married Baldwin VI of Flanders, and, by him, became the ancestress of the Baldwin (VI of Hainaut) who in 1204 was raised by the Crusaders to the empire of Constantinople. The emperor Baldwin's elder daughter Jeanne brought the countship of Hainaut to her husbands Ferdinand of Portugal (d. 1233) and Thomas of Savoy (d. 1259). On her death in 1244, however, it passed to her sister Margaret, on whose death in 1279 it was inherited by Jeanne's grandson, John of Avesnes, count of Holland (d. 1304). The countship of Hainaut remained united with that of Holland during the 14th and 15th centuries. It was under the counts William I "the Good" (1304–37), whose daughter Philippa married Edward III of England, and William II (1337–45) that the communes of Hainaut attained great political importance. Margaret, who succeeded her brother William II in 1345, by her marriage with the emperor Louis IV brought Hainaut with the rest of her dominions to the house of Wittelsbach. Finally, early in the 15th century, the countess Jacqueline was dispossessed by Philip the Good of Burgundy, and Hainaut henceforward shared the fate of the rest of the Netherlands.

HAIPHONG, a chief seaport of Vietnam, lies 16 mi. from the Gulf of Tonkin on the Cua Cam, 63 mi. S.E. of the capital, Hanoi. Pop. (1954 est.) 217,000. Haiphong, which became a seaport in 1874, has few historic remains. A canal separates the northern part of the city from the southern part. Docks, harbour facilities and ship repair yards were restored and modernized following the end of Franco-Vietnamese hostilities in 1954, but in the early 1960s dredging was still required to keep open a channel for large vessels. Haiphong is connected by road, rail and river with Hanoi and other towns. Near Haiphong are the important Hongay coal mines; the town itself is an industrial centre, with a cement plant, a rice mill, textile, glass, chemical and fish-canning factories. (VN. T.)

HAIR, in mammals, the characteristic threadlike outgrowths of the outer layer of skin (epidermis) forming the coat or pelage. By analogy the filamentous bristles on nonmammalian forms and on plants are often called hairs.

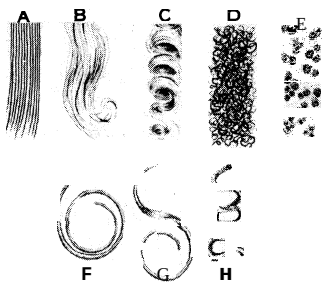
See also SKIN; FIBRES and allied articles; BALDNESS; FUR; LEATHER.

Anthropology.— One of the traditional bases for racial classifications of man has been the characteristics of hair—its growth, form and microscopic appearance. Although the general structure of all human hairs is similar, some variation occurs among ethnic groups. In fact, differences occur even among hairs of the same region of any person.

The hair of the scalp (capillus) has been studied more exhaustively than hair of other regions of the body, perhaps because of its greater abundance and accessibility. Its length, colour and type are gross characteristics seen with the naked eye, which are useful to the anthropologist in distinguishing ethnological groups. Microscopic studies have disclosed differences which are correlated with the gross characteristics. Certain of the microscopic differences, if found in the large majority of hairs of an adequate sample, are sufficiently specific to determine racial origin. Further, a single hair can be shown to have come from only one of a number of individuals of the same ethnological group. Thus, hair provides evidence for individual as well as racial identification.

Peter A. Browne of Philadelphia in 1853 was the first to demonstrate a relationship between the form and behaviour of hair and to correlate different forms with specific races. Ten years later M. Pruner-Bey published similar observations in Paris and to him the credit was almost invariably given until C. H. Danforth in 1926 pointed out the discrepancy. The form of the hair was said to be crisped or frizzled and the shape of a cross section of the hair was said to be circular or oval. In the latter part of the 19th century anthropologists classified hair as leiotrichous (including straight and wavy) and as ulotrichous (crisp, woolly or tufted). Early in the 20th century a third term was introduced, cymotrichous to stand between the other two and to include the wavy and curly hair.

As the 20th century has progressed there has been a slow and gradual change in the point of view of students of hair and with it the nomenclature of hair types has been expanded. The tendency has been away from the two or three large groupings and toward smaller and more clearly defined categories. Thus, in Hrdlicka's Practical *Anthropometry* the following classification was recommended: (1) straight, (2) wavy (slightly or markedly), (3) curly (slightly or markedly), (4) frizzly, (5) woolly, (6) peppercorn, *i.e.*, in more or less widely separated close spirals, en rouleux ("in little rolls").



(A B C D E) MODIFIED FROM RUDOLPH MARTIN, "LEHRBUCH DER ANTHROPOLOG E" (VOL. I) (F, G, H) BY COURTESY OF C. H. DANFORTH

FIG. 1.— TYPESOF HAIR

Diagrammatic sketches: (A) straight, (B) wavy, (C) curly, (D) woolly and (E) pepper-corn hair; single hairs: (F) wavy, (G) curly and (H) woolly

Likewise, the study of race differentiation has produced evidence of many overlapping characteristics which have resulted in a less rigid classification. In 1944 W. Howells wrote that no two persons would classify races in the same way. He pointed out that the three familiar great racial stocks (yellow, black and white) obviously represent an ancient separation and that the fourth, the Australian aborigines, is the most primitive of all races. The hair of the yellow race is straight, lank. long and coarse, round or nearly so in section, with a medulla usually present, and dark brown or black in colour (Chinese, American Indians) Frizzly, woolly and peppercorn hair of dark brown or black is found in the black race (African Negroes). It is short, coarse and crisp, elliptical or kidney-shaped in section, with a medulla which is masked by dense pigment granules.

Wavy and curly hair is smooth and silky, oval in section, with a medulla present more often than not. This is the hair of the white race (Europeans) and varies in colour from ash blond (Scandinavians) through the different tones of brown to black (Greeks, southern Italians) and is occasionally red. In length, wavy and curly hair holds an intermediate position. The hair of the Australian aborigines, although wavy or curly and oval in section like that of the white race, is consistently dark brown or black in colour and coarse like that of the black and yellow races. (*See* fig. 2.)

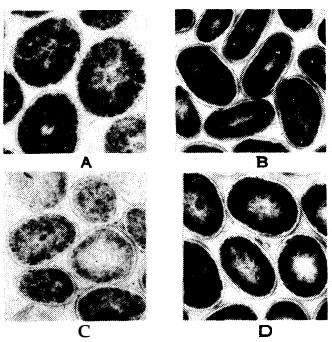


FIG. 2.— CROSS SECTIONS OF HAIRS

Exemplifying four races: (A) Mongoloid, from a Thai. Bangkok; (B) Negroid, from a Comorian, Madagascar; (C) Caucasoid. from a French Canadian, Quebec; and (D) Australoid, from an Australian aborigine, Cairns, Qsld. (enlarged approx. 50X)

The index of the hair (the figure determined by multiplying the smallest transverse diameter of the hair's shaft by roo and dividing by the largest diameter) is used to indicate the form of the hair or the degree of flattening. The index of straight and wavy hair varies generally between 80 and 100; of curly and frizzly hair between 75 and 80; and of the woolly and peppercorn form between 50 and 75. Hairs that grow side by side on the same head may vary in their index by 30 points or more. Although there is much variation in form among hairs of the same head there does exist an undeniable connection between cross section and

form. Also, the degree of curliness of the shaft is believed to be determined by the degree of obliquity of the hair follicle. The follicles are straight in races with straight and wavy hair and their direction is more or less parallel: the hairs leave them at the surface of the skin at an acute angle. In the curly haired the direction is not uniform and there is convergency toward many little centres at the surface. The follicle of Negro hair is strongly curved or sabre shaped.

Since this suggested relationship between the direction of the follicle and the form of its hair is borne out only in a general way, Danforth called attention to other factors which, if not the fundamental cause of the iorm of the hair, undoubtedly contribute to it, viz., a slight inequality between the two sides of the more or less flattened shaft and a twisting of the shaft on its long axis. To the former is due the primary curl seen in wavy hair and to the latter the change in direction of the primary curl from one side to the other seen in curly, frizzly, woolly and peppercorn hair. The degree of kinkiness increases as the number of twists along the shaft increases.

Other morphologic and genetic features that are used in classifying races may be found in ANTHROPOLOGY and RACES OF MANKIND.

HAIR IN MAMMALS

The most important function of hair in most mammals is that of insulation against cold. A second function is that of a sensory organ—snout hairs or whiskers sensitive to touch (vibrissae) are very helpful to many night-prowling animals. Man's eyelashes consist of sensory vibrissae which cause the reflex shutting of the eyelid when a speck of dust hits them. Important from the standpoint of survival is the coloration and pattern of coats which serve both as a camouflage to enemies and as an allurement to mates.

Mammalian hairs are developed in relatively deep pits in the skin, the hair follicles, which extend downward into the thickness of the dermis, or even into the subcutaneous tissue. In man the hair rudiments begin to appear about the third or fourth month of fetal life as small solid down growths from the Malpighian layer of the epidermis, their growth being completed about the fifth or sixth month, when they constitute the very delicate hairy covering, the lanugo, which is entirely shed either before birth or soon after. The hairs constituting the downy lanugo are fine, slender, faintly or not pigmented, with large cortical scales and no medulla, and possess some of the characteristics of wool.

At birth the hairs of the eyelashes, eyebrows and scalp, though still soft and more or less retaining the characteristics of lanugo, already show a much more vigorous growth and may be pigmented. During the first iew months of infancy this growth is shed, being replaced by the typical coarser hair of the eyebrows and head, while over the rest of the body grows the fine, short, generally unpigmented down hair or vellus. Finaliy, at and following puberty, coarse, longer and more heavily pigmented hair (terminal hair) is developed in armpits (axilla), pubes, certain areas of the trunk and limbs, and in males on the upper lip and chin.

The amount of terminal hair varies according to race, sex and even individual, though generally more abundant in males, the greater part of the body in adult females still being covered by vellus. While there are little or no sexual differences distinguishing the auxiliary hairs, slight differences are observed in the pubic hairs, which appear rather longer and more abundant in men, and relatively coarser in women. One characteristic human trait is that most of the body hairs never develop beyond more or less rudimentary vellus, whereas in other mammals the coarser forms predominate, and, in addition, tactile hairs (sensory vibrissae) are present. The total area of really hairless skin in man is relatively small, being confined to the palms of the hands, soles of the feet, undersurface of the fingers and toes, the margin of the lips, areolae of the nipples, umbilicus and immediate vicinity of the urogenital and anal openings.

The Hair Follicle.—This structure, which is essentially a recess of the skin, is composed of two tissue elements—one, of epithelial origin, closely invests the hair root, while the second is connective tissue. A cross section of a hair follicle shows that the epithelial layer consists of an outer layer of polyhedral cells forming the outer root sheath, and an inner, horny stratum, the inner root sheath, composed of three layers, known respectively as Henle's layer (the outermost) of horny, fibrous, oblong cells; Huxley's layer, consisting of polyhedral, nucleated cells containing pigment granules; and the cuticle of the root sheath, composed of a layer of downwardly imbricated scales (overlapping as roof tiles) that fit over the upwardly imbricate scales of the hair proper.

The connective tissue element consists internally of a vascular layer separated from the root sheath by a basement membrane, the hyaline layer of the follicle, and externally has a more open texture corresponding to the deeper part of the cutis containing the larger branches of the arteries and veins.

A small muscle, the arrector pili, is attached to each hair follicle. It passes from the superficial part of the corium, on the side to which the hair slopes, obliquely downward, to be attached near the bottom of the follicle to a projection formed by localized hypertrophy of the outer root sheath. If this muscle is contracted, the hair becomes more erect and the follicle is dragged upward to cause a prominence on the general surface of the skin, producing that temporarily roughened condition popularly called "goose skin."

Process of Growth.—The hair grows upward from the bottom of the follicle by multiplication of the soft cells which cover the papilla and these become elongated and pigmented to form the fibrous substance of the hair shaft, and are otherwise modified to produce the central medulla and cuticle of the hair.

The hair shaft is chiefly composed of a pigmented, horny, fibrous material, which consists of long, tapering, fibrillated cells that have coalesced. Externally this fibrous substance is covered by a delicate layer of imbricated scales forming the cuticle. In many hairs, the centre of the shaft is occupied by an axial substance, the medulla, formed of angular cells containing granules of eleidin (a substance allied to keratin) and frequently in addition, minute air bubbles which give the cells a dark appearance.

The medullary cells tend to be grouped along the central axis of the hair as a core; continuous or interrupted in single, double or multiple columns. The variations in the medulla may be summarized as: (a) the continuous type, which may be homogeneous, as in the chimpanzee, or nodose (having a knotty appearance) as in the gelada baboon; (b) discontinuous medullas, which in simple forms may be ovate, elongated, or flattened (in the gibbon it is discontinuous and elongated); (c) a fragmental type, as in the langur, *Semnopithecus.*

Cuticular Scales.—The delicate cuticular scales are most varied in shape and size and constitute the most important microscopical structure of the mammalian hair, for they possess definite and constant specific characters. The dominant form is an imbricate scale, like a tile of irregular shape, having its edges rounded, minutely notched or flattened. There are many varieties of the imbricate scale, each typical of its species; thus in man, chimpanzee, gorilla and orang-utan, the hairs have imbricate scales which are, however, quite distinctive in size, shape and structure of the edge—slightly oval in chimpanzee, slightly ovate and shallowly notched in man and gorilla, with more deeply notched edges in orang. The second type of cuticular scale is the coronal in which each individual cuticular cell completely encircles the

hair shaft and may have a smooth or saw-toothed edge. While the imbricate scale is typical of the higher Primates. the coronal scale in its simpler form is present in the Lemuridae and *Tarsius;* becoming in the Insectivora more specialized, with saw-tooth edges.

In some Indian bats the cuticular scales are developed as leaflet-like processes arranged in whorls at regular intervals along the hair shaft. In many deer *(Cervus),* the cortical substance is nearly indistinguishable, almost the entire hair appearing to be composed of thin-walled polygonal cells. In the peccary the cortical envelope sends inward radial prolongations. the interspaces being occupied by medullary substance; and this, on a larger scale, is the structure of the porcupine's "quills." One of the most remarkable mammalian hairs is that of the Australian platypus, *Ornithorhynchus,* in which the lower portion of the shaft is slender and woollike, while the free-end terminates as a flattened, spear-shaped, pigmented hair with broad imbricated scales. In the three-toed sloth *(Bradypus tridactylus),* a microscopic alga grows between the cuticular scales of the hairs and would appear to be symbiotic, inasmuch that its presence, giving a curious greenish-gray hue to the coat of the sloth, helps to disguise the animal among the trees, giving it when viewed from the ground almost the appearance of a mass of moss.

Tactile Hairs.—These occur in all mammals except man, and are large, stiff hairs of pre-eminently sensory character, having highly specialized follicles, the root being embedded in a mass of true erectile tissue *(corpus cavernosum, corpus spongiosum pili),* and having a rich sensory nerve supply, presumably controlled by the sympathetic nervous system. These specialized hairs are few in number, their distribution being chiefly confined to the lips, cheeks and supraorbital regions, occasionally occurring elsewhere.

HAIRPIECE: *see* WIG.

HAITI (RÉPUBLIQUE D'HAÏTI), a republic occupying the western third, (10,656 sq.mi.) of the Caribbean island Hispaniola. which it shares with the Dominican Republic. This article deals with Haitian history, people, administration, social conditions and economy. The geography of Haiti is treated unitarily with that of the Dominican Republic in the article HISPANIOLA.

History.— The aboriginal Indians, probably fewer than 1,000,000 Arawaks. called the entire island Quisqueya or Haiti. On Dec. 6, 1492, Columbus landed at Môle Saint-Nicolas on the northwestern tip and named the island Española, later anglicized to Hispaniola. By the end of the 16th century most of the Indians had been exterminated either through the hardships of slavery or in battle. Since few Spaniards had settled in the western part of Española, French buccaneers from Tortuga Island gained permanent footholds, which subsequently led to the founding of Port-de-Paix (1664). The treaty of Ryswick (1697) recognized French possession of the western third, which France named Saint-Domingue. In the 18th century the export of sugar, coffee, indigo, cotton, cacao and dyewoods made Saint-Domingue one of the most prosperous colonies in the new world. This prosperity was largely the result of Negro slave labour which the Spanish and later the French continually brought in from Africa. On the eve of the French revolution (1789) Saint-Domingue had a population of about 32,000 Frenchmen, 24,000 freedmen of mixed ancestry and almost 500,000 Negro slaves. A relatively small percentage of Frenchmen and freedmen owned most of the plantations and slaves.

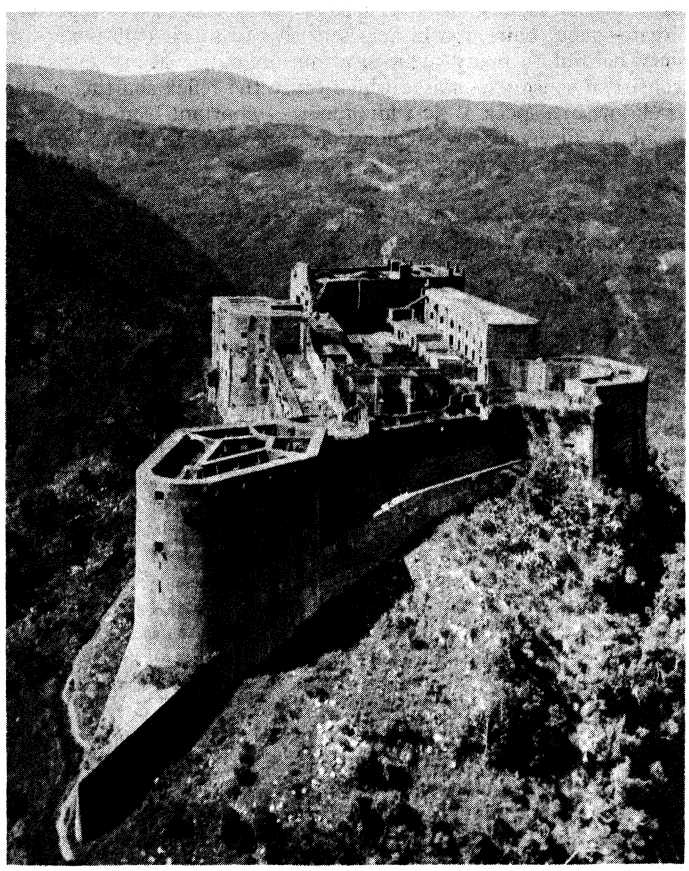
The slogan of the French Revolution, "Liberty, Equality and Fraternity," precipitated the revolution which ended colonial rule in Saint-Domingue. On Aug. 14, 1791, the slaves launched an insurrection. After 1793, France fought Great Britain and Spain for control of Saint-Domingue. Partly inspired by the need for additional troops, France decreed emancipation, Feb. 4, 1794. In May 1801, Pierre-Dominique Toussaint l'Ouverture (*q.v.*), a former slave, proclaimed a constitution, which named him governor general for life, without submitting it for ratification to Napoleon Bonaparte. Late in 1801 Bonaparte sent Gen. Charles Leclerc with a veteran force, including Alexandre Sabbs Pétion and other mulatto officers, to crush the "First of the Blacks."

The French captured Toussaint by a ruse and sent him to France where he died a prisoner in Fort de Joux. April 7. 1803. Negro generals in the French army, notably Jean Jacques Dessalines, Henry Christophe (*q.v.*) and mulatto generals, fearful that Bonaparte in 1802 planned to restore slavery in Saint-Domingue, renewed the bitter war against the French. Arms and supplies furnished by American merchants helped the hard-fighting former slaves and freedmen to turn the tide. The critical situation in Saint-Domingue and the likelihood of the renewal of war in Europe led Bonaparte to sell Louisiana to the United States, April 30, 1803. *(See* LOUISIANA PURCHASE.)

Decimated by yellow fever, the last of the French troops under Gen. Jean Baptiste Rochambeau, who took command after Leclerc died of the fever, surrendered on Nov. 9, 1803. An armistice was signed Nov. 18, 1803, providing for complete evacuation of French troops. Dessalines on Jan. 1, 1804, declared the independence of the entire island with the aboriginal name of Haiti, sometimes spelled Hayti. In Oct. 1804, Dessalines was proclaimed Emperor Jacques I.

Independence.—The 12-year war had destroyed most of the irrigation system and plantation machinery, the principal basis of the colony's economy, and added to the colonial legacy of hatred and fear of whites. The death or expulsion of practically all whites by Dessalines' military oligarchy deprived Haiti of much-needed intellectual and technical aid and capital. Hostility between black and light-coloured Haitians, rooted in the colonial period and strengthened by the service of mulattoes in Leclerc's army, increased after Dessalines' tyrannical acts led to his assassination, Oct. 17, 1806.

Civil mar ensued, especially between the mulatto Pétion. who was elected president in Port-au-Prince and was trying to organize a republic in the south, and the black Christophe, proclaimed King Henry I in the north. Pétion granted farm lands to the officers



BYRON CORCNEOS—PIX FROM PUBLIX

CITADEL OF HENRI CHRISTOPHE, SOUTH OF CAP HAITIEN

and soldiers of the army of independence but the small size of the farms aggravated the agrarian problems. Like Christophe, Pétion engaged a few foreign teachers. In the meantime, Christophe used forced labour to restore economic productivity and to build the palace of Sans Souci and a citadel (Citadelle Laferrière) erected on the summit of Bonnet à l'Evêque. After a general revolt against his despotism he committed suicide in 1820.

Jean Pierre Boyer, a mulatto, succeeded Pétion on his death in 1818 and after Christophe's suicide became president of a reunited Haiti. In 1822 a Dominican revolt against Spanish authority and internal strife facilitated Boyer's seizure of the eastern part of the island, which had proclaimed its independence Nov. 30, 1821. Boyer abolished slavery, but he also "africanized" the short-lived Dominican Republic, closed the University of Santo Domingo and despoiled monasteries and churches. Many Dominican nriters emphasized the destructive aspects of his policy in order to foment animosity against Haiti. Boyer lost control over the whole island when the Dominicans revolted and declared independence in 1844.

The hostility of many nations aggravated Haiti's inherent problems. Although Pétion had twice given aid to Simón Bolivar, Haiti was not invited to the congress of Panama, 1826. France, the first country to recognize Haiti's independence (1825), exacted in return an indemnity reduced in 1838 from 150,000,000 fr. to 90,-000 000 fr. The payment of this debt, liquidated in 1887, reduced funds available for schools, roads and general welfare. Great Britain recognized Haiti in 1833. The United States permitted trade with Haiti, but slave owners prevented recognition until 1862, after the secession of the southern states.

Boyer's overthrow in 1843 inaugurated a cycle of ephemeral and strong leaders. There mere 16 rulers who held office between Dec. 1843 and Aug. 1911, and 11 were overthrown by revolution. In 1847, the former Negro slave Faustin Élie Soulouque (Emperor Faustin I), illiterate but wily and despotic, seized power. He resumed the policy of seeking control over the Dominican Republic. Temporarily halted in 1851 by the tripartite intervention of Great Britain, France and the United States, he renewed his invasions. His defeat in 1855 by a much smaller Dominican army eventually resulted in his overthrow as emperor of Haiti in 1859 by Fabre Geffrard, a more enlightened ruler who signed a concordat with the Vatican in 1860 for the organization of the Catholic clergy.

Haiti permitted Union warships to refuel and undergo repairs during the American Civil War. Haitian presidents suspected American designs on the republic but nevertheless continued to offer coaling stations and other concessions to the United States in order to maintain themselves in power. A treaty between Haiti and the Dominican Republic (1874) engaged each of the republics not to alienate any of its territory to a foreign nation.

Prolonged civil strife in Haiti, the attempt of American shipping interests to gain special concessions and the desire of the United States to obtain Môle Saint-Nicolas as a coaling station, led to an abortive U.S. naval intervention in 1891. Shortly before World War I, U.S. bankers obtained shares in the Haitian bank, which extensively controlled the government's fiscal policies, and participated in a loan to the Haitian government. U.S. capitalists were granted concessions to build a railroad and to develop banana plantations. The total amount of the loan was a small fraction of U.S. foreign investments but it loomed large in the Haitian economy. The United States government renewed its strategic interest in Haiti as the Panama Canal neared completion.

U.S. Occupation.—Between Aug. 1911 and Feb. 1915 one Haitian president was blown up in his palace, one died by poison and three were overthrown by revolutions. On July 27, 1915, a mob seized Pres. Vilbrun Guillaume Sam in the French legation and butchered him. The next day, U.S. marines began an occupation which lasted until Aug. 1934. The U.S. government justified the intervention in the name of the Monroe Doctrine and of humanitarianism. Haitian and other critics accused the United States of protecting business interests and seeking a base to guard one of the main approaches to the Panama canal. Under pressure, Haiti signed a ten-year treaty with the U.S., which became effective in May 1916. The treaty. which was later extended to 1936, established a United States political and financial protectorate. In 1918, U.S. marines supervised a farcical plebiscite for a new constitution, which for the first time permitted aliens to hold land.

The balance sheet of the U.S. occupation is difficult to establish. Haitians resented the racial attitudes of many Americans, the racial implications of the emphasis placed upon vocational training at the expense of the French tradition, the funding of the national debt by U.S. loans (1922), the use of force to impose law and order and the virtual exclusion of Haitians from their own government. But the U.S. occupation provided efficient and honest fiscal control: it reduced the national debt from about $36,000,000 in 1915 to around $19,000,000 in 1928; and it organized and trained a militarized police force. Roads and schools were built and the telephone and telegraph service improved. Perhaps the most notable achievement was the public health service rendered by the U.S. navy medical corps (attached to the marines) with the assistance of the Rockefeller foundation. The corps improved sanitation, introduced modern methods in the few hospitals, set up rural clinics and dispensaries and also reduced the incidence of malaria and yaws (frambesia). The occupation did little, however. to improve the nation's economy. Pres. Louis Eustache Borno announced in 1929 that there would be no elections in 1930 of senators and deputies, who sitting together as the national assembly, would choose a new president.

Americans joined Haitians in demanding a new policy. Pres. Herbert Hoover in 1930 sent a mission to liquidate the U.S. occupation and another to recommend improvements in the educational system. In Oct. 1930, the people elected the first national assembly to sit since 1918. This assembly, controlled by opponents of the occupation, elected Sténio Joseph Vincent to the presidency. Haitians took over control of public works, public health, agricultural and technical services. In Aug. 1934, Pres. Franklin D. Roosevelt under an agreement signed with Haiti on Aug. 7. 1933 and in accordance with the good-neighbour policy, terminated the occupation and ordered the withdrawal of the marines. U.S. direct fiscal control continued until 1941 and indirect fiscal control until 1947 when, by an internal loan, the Haitian government liquidated the 1922 loans.

Later Developments.—Vincent, in 1939, toward the end of his second term. planned to have the constitution amended to allow him a third term. Yielding to opposition in Haiti and probably influenced by the United States, he withdrew in favour of Élie Lescot, who mas elected by the national assembly, April 1 j, 1941. After Lescot had the constitution amended to permit his re-election, he was overthrown by student strikes and mob violence. A military triumvirate ensured election of a national assembly, which chose Dumarsais Estimé as president on Aug. 16, 1946. When the senate refused to amend the constitution to permit his re-election in April 1950, the triumvirate which had overthrown Lescot seized power and allowed Estimé to leave the country. Col. Paul E. Magloire, a member of the triumvirate, was elected president by the people, Oct. 23. 1950. Magloire also sought to remain in office after the end of his constitutional term. but the army compelled him to resign on Dec. 13, 1956 and to leave the country. After a prolonged period of strikes, mob violence, recurrent closing of business houses and the overthrow of several provisional presidents, the people elected François Duvalier as president on Sept. 22, 1957. But considerable unrest continued and a poorly organized revolt was crushed on July 29, 1958.

The long-standing controversies between Haiti and the Dominican Republic erupted in Oct. 1937, in the massacre by Dominicans of several thousand Haitians who had sought employment east of the border. nhich was all-defined despite a treaty of March 9, 1936. Dominican workers denounced the lower salaries accepted by Haitians, their lower standard of living, and their "inferior, African" culture. The Dominican government agreed on Jan. 31, 1938, to pay $750,000 to the families of the victims; however, it paid only a part. An agreement, ratified in April 1952, regulated the seasonal employment of Haitians. Intellectuals and politicians in both countries kept alive the controversy until a common fear of invasion from Cuba after the advent to power of Fidel Castro, led to at least a temporary friendship. See DOMINICAN REPUBLIC for further aspects of Haitian history.

The People. — Haiti is one of the most densely populated of the American republics. Its first official census (1950, with the aid of the U.S. census bureau), revealed a population of 3,097,220 or 291 per square mile. A 1958 estimate showed a total of 3,407,438 or 313 per square mile. Since at least two-thirds of Haiti is mountainous, its population density in terms of arable land is closer to 1,000 per square mile. About 90% of the population is black or dark brown; the others are light and almost white. Resident foreigners number only a few thousand — principally Syrians, Lebanese and after the 1930s European refugees. Haiti's literacy rate, 11%, is the lowest of the Latin-American nations. The official language of the country is French but the vast majority of Haitians are illiterate peasants who speak and understand a sonorous patois known as Creole. The vocabulary of this dialect was derived largely from the Norman French spoken by the 17th-century buccaneers, and includes some Spanish, African tribal and a few Arawak Indian words. The pronunciation is slurred and the syntax informal.

Roman Catholicism is the predominant Christian religion and there is complete freedom of religious worship. Many peasants practise Vodun or Voodoo (*q.v.*), a folk religion of African beliefs, fascinating dances, rituals and superstitions, with its own priests and priestesses and a tendency to resist Catholic influence. Formal marriages are almost as rare as they were during the colonial period. Family life, however, is the dominant characteristic of peasant life.

Haiti lacks a middle class as the term is usually understood in more developed countries. In the 1950s it consisted of about 40,000 business, agricultural and industrial workers; 12,000 lox-er-scale government employees; and 60,000 domestic servants. In the 1940s struggling trade unions, first recognized in Feb. 1946, strengthened this middle class.

The aristocracy or elite, perhaps 5% of the population, consists of business and professional men, owners (usually absentee) of landed estates, members of the legislature and the upper bureaucracy — civil and military. The aristocracy are not only a class, but almost a caste. Most of them live in Port-au-Prince and Cap Haitien (*qq.v.*) and in the smaller urban agglomerations. Many frequently speak Creole in private and to servants, but they take great pride in their precise knowledge of the French language, their distinguished French names. their sophisticated appreciation of French fine arts, dress, customs and food. As writers they have produced some outstanding works of literature, history and jurisprudence. And in the 1950s, a Haitian art movement was started under the auspices of the Centre d'Art.

Most of the elite are Roman Catholics, at least nominally, and a few are Protestants. A small number have faith in Vodun, but since it is folk religion, they do not publicly manifest it. Those who can afford to do so send their children to Catholic schools. They marry formally, but some also have common-law wives.

The black and dark-brown elite are increasingly resenting the efforts of the light-coloured and almost-white elite to manipulate power, enjoy the social prerogatives and siphon off for their personal advantage a disproportionate amount of revenues of the nation's slim resources. Many of the civil wars and revolutions were essentially struggles for power between the two elite groups. But the colour line has become increasingly blurred, especially since the black and dark-brown men tend to marry lighter women. While President Vincent was almost white and President Lescot a copper brown, Estimé, Magloire and Duvalier were black. Two members of the triumvirate which overthrew Lescot and Estimé were almost white. The U.S. government furthered this blurring of the colour line by taking black and dark-brown as well as light-coloured Haitians to the United States for university education, for training in industry and in government departments. Abroad, Haitian black diplomats were received as cordially as the light coloured. The latter, therefore, reassessed their own values. Moreover, the black masses increasingly realized that the black elite had little more capacity or desire than did the light-coloured elite to solve the nation's basic problems. Despite the blurring of the colour line, it remained, in the early 1960s, a continuing problem.

Living Conditions. — Most of the peasants live in primitive wooden frame huts with mud-daubed wattle malls and thatched roofs; they sleep on the floor or on mats made of banana branches. The huts lack running water and sanitary facilities and are usually lighted by candles. The majority of farms are too small to provide more than a family subsistence. The typical Haitian peasant has only a hoe and a machete for farming tools. Diet is often close to the starvation level; malaria, tuberculosis and the diseases of malnutrition are rife. Peasant women perform the usual domestic duties, work in the fields and carry marketable goods, except coffee, to the markets. Heavy loads on their heads frequently flatten their cranial bones, bend their spines and damage their internal organs. Both peasant owners and workers on the banana, sugar and sisal plantations live at about the same level. The cost of living (Port-au-Prince) rose steadily in the 1950s (1953 = 100, 1958 = 112).

Administration. — '4 constitution, adopted by a constitutional assembly on Nov. 25, 1950, granted woman suffrage for the first time. Previously restricted to municipal elections, women over 21 years of age voted in the 1957 presidential election. The president is elected for six years by a majority of adult voters in a secret ballot. Legislative authority resides in the national assembly comprising a chamber of deputies and the senate, which has the sole power to amend the constitution; 37 deputies and 21 senators are indirectly elected for four and six years respectively. In case of serious controversy between the two houses and the president and his cabinet, the president has the power to dissolve the legislature and hold new elections within three months. The chamber of deputies initiates la s concerning the budget, taxes and other government revenues, but the president has control over public expenditures. The cabinet consists of a minimum of five members; a council of government of nine members, also appointed by the president, advises him on proposed laws and administrative matters. An independent agency (Grand Conseil Technique des Ressources Nationales et du Développement Economique) appointed by the president and a bureau of the budget, work in liaison under him. The budget bureau prepares receipts and expenditures, supervises their administration, and seeks to promote the national economy. The president is authorized to make treaties, international conventions, and executive agreements, subject to ratification by the national assembly. Judicial power is vested in a court of cassation. courts of appeal and lower courts of justice. The president appoints all justices and justices of the peace. Haiti's legal system is based on the Napoleonic code. As from April 1963, the constitution of 1957 provides for a single-chamber legislature of 67 deputies elected for six years.

For administrative purposes Haiti is divided into nine departments: L'Artibonite, Centre, Nord-est, Nord-ouest, Ouest, Sud, Sud-est, Grand Anse and Nord. These are subdivided into *arrondissements* which are made up of *communes.* The national capital is Port-au-Prince (*q.v.*) which is also the chief port and commercial centre. The second city of the republic is historic Cap Haitien (*q.v.*).

Education. – –Primary education is free and compulsory although the law is not strictly enforced and only about one-fifth of the children attend school. There are a number of schools maintained by religious orders. Secondary and higher education is free to all. According to the 1950 census 89.3% of those 10 years of age and over were illiterate.

Economy. — Haiti's economy is basically agricultural with coffee, sisal, cotton, castor beans, cacao, plantains, sugar and essential oils as the main products. As a French colony it was one of the most productive regions in the Caribbean. However, during the bloody wars for independence and the revolutions that followed, the large colonial estates and irrigation systems were destroyed. (See History above.) Thousands of peasants owning small parcels of land struggle against erosion. Constant planting of the same crops has depleted the soil. The stripping of mountain tops and steep slopes of their protective forest cover brought new land into cultivation, but rains quickly carried off the thin layer of fertile soil. Agricultural reconstruction has therefore become a vital necessity, and advances in irrigation and land reclamation projects have been made.

The irrigation of the Artibonite river valley, projected during the colonial period, and the construction and projection of hydroelectric power facilities during the 1940s and 1950s aroused great hopes for overpopulated, poverty-stricken Haiti. At the end of 1956 the Peligre dam was completed, but considerable work remained to be done in building secondary and tertiary canals and in preventing soil erosion. Choosing the most efficient utilization of 80,000 ac. of land, representing about 22,000 farms, was a major problem. Cotton, rice and yellow corn were the most promising crops. Other possibilities were bananas, sugar cane, dairy farms and beef cattle. By the late 1950s the cost of the project had reached approximately $40,000,000, most of it in the form of loans by the U.S. Export-Import bank and grants from the C.S. International Cooperation administration. The Artibonite Valley Development authority. established by law on June 9, 1958, is governed by the ministers of agriculture, finance and public works, and is headed by a Haitian administrator, with a U.S. technical director. A contract was signed on Aug. 3, 1959, with the International Engineering company of San Francisco to complete the irrigation project. The construction of a hydroelectric project was postponed. Since Oct. 1949 when a law was passed giving industries certain tax exemptions and duty-free entry of raw materials, a number of small manufacturing plants have made articles for local consumption such as compound-lard, cotton textiles, soap, ice, shoes and handbags. A flour mill began production in 1958.

Trade and Finance.— *In* the 1950s, Haiti's per capita income of about $70 was one of the lowest of the American republics. The total value of exports fluctuated considerably ($38.479.928 in 1950, $55,532,626 in 1954, $32,932,480 in 1957). The chief exports were coffee (about 62%), sisal (18%), raw sugar (8%), cacao (2%) and essential oils (2%). **A** small quantity of bauxite, the only mineral resource actively exploited, was exported in the late 1950s. Imports, also subject to fluctuation, were $36,200,294 in 1950, $47,556,494 in 1954 and $38,297,991 in 1957.

Foods, including wheat flour. and textiles usually constitute about one-half of the total value of imports; chemicals and pharmaceuticals, oil products, iron and steel, agricultural machinery and motor vehicles, less than one-fifth. It was hoped that the opening of the first flour mill in 1958 would reduce flour imports. In the 1950s, actual government revenues for the fiscal years averaged about $30,000,000, expenditures mere slightly higher. About 71% of the revenue was derived from customs duties and 29% from internal revenue. About 70% of the appropriations went for government ordinary expenditure, 5% toward the national debt and a5% for investments. The monetary unit is the gourde, valued in 1958 at 20 cents U.S. currency, official rate.

Transport and Communications.— *The* one passenger railway, Compagnie Nationale des Chemins de Fer, is government owned and runs from Port-au-Prince to Verrettes. Other railways are privately owned and serve mainly to carry freight. Roads, some of which are asphalted, link the various towns and are important to the farmers of the interior as the means for transporting their produce. Air services link Port-au-Prince with other Caribbean islands and New York and a domestic airline, Corps d'Aviation de la Garde d'Haiti. serves the interior. Haiti's 12 seaports are served by U.S.. British. Dutch, German and Panama shipping lines. World-wide cable and telegraph communications are maintained.

(R. W. LN.)

HAKE, EDWARD (*fl.* 1579), English Puritan satirist, who resided in Gray's Inn and Barnard's Inn, London. and held civic office at New Windsor. is known for *Newes out of Powles Churchyard* (1567?; 2nd ed. 1579), a dialogue between Bertulph and Paul, who meet in the aisles of the cathedral. It is in rhymed 14-syllable metre and divided into eight "satyrs," dealing with the 'corruption of the higher clergy, and of judges, the greed of attorneys, the tricks of physicians and apothecaries, the sumptuary laws, extravagant living, Sunday sports and the abuse of St. Paul's cathedral as a meeting place for business and conversation, usury, etc. Hake's other works include a translation of Thomas à Kempis, *The Imitation, or Following of Christ* (1567, 1568); another satire, *A Touchestone for This Time Present* (1574); and Of *Colds Kingdome* (1604), a collection of pieces in prose and verse, inveighing against the power of gold.

HAKE (*Merluccius merluccius*), an important food fish of the Mediterranean and the Atlantic coast of Europe, most abundant south of the British Isles. It differs from other fishes of the cod family (Gadidae) in skeletal characters, and is, perhaps, best placed in a separate family. It is a slender fish, with long, acute snout, large terminal mouth and sharp teeth, and reaches a length of 4 ft.; it is a voracious fish. living in rather deep water; the flesh is soft. Other species of *Merluccius* are known from both coasts of North America, and from Chile and Patagonia, South Africa and New Zealand.

HAKKAS ("guests" or "sojourners"), a people of South China, found in Fu-kien, Formosa, Kwangsi and Hainan—however, their main centre of influence is Kai-Yen district, Kwangtung province, of which Kit-Yang is the seat. According to tradition they were found in Shantung and other provinces north of the Yangtze river as early as the 3rd century B.C. They fled south of the Yangtze to escape the Tatar, Mongol and other invasions of China. They would not submit to foreign rule, so were considered rebels and there was constant warfare with the prevailing powers. The Hakkas are the Highlanders of China, and their speech is a form of ancient Mandarin. (P. C. ME.; X.)

HAKLUYT, RICHARD (*c.* 1552–1616), British geographer and publicist, was born in or near London about 1552. The Hakluyts were of some standing in the Welsh Marches and held property at Eaton, near Leominster in Herefordshire. A Richard Hakluyt of a cadet branch was apprenticed to a member of the Skinners' company in 1510, and was himself later admitted to the company. He died in 1557, leaving his family, Richard Hakluyt the geographer being his third son, to the care of a cousin, another Richard Hakluyt. This Richard, a lawyer of the Middle Temple, had numerous friends among prominent city merchants, geographers and explorers of the day and was expert in overseas trade and economics. He was well placed to assist the future geographer in his life work.

Young Richard, with the help of various exhibitions, was educated at Westminster school. and Christ Church, Oxford, entering in 1570 and taking his M.A. degree in 1577. His interest in geography and travel had been aroused some years earlier on a visit to the Middle Temple when his cousin, supported by "certain books of cosmographie, an universall mappe, and the Bible," had discoursed on the recent discoveries and the new opportunities for trade. The schoolboy had thereupon resolved to "prosecute that knowledge and kind of literature" at the university. Some time before 1580 he took holy orders. "My exercises of duty first performed. I fell to my intended course and by degrees read over whatsoever printed or written discoveries and voyages I found extant" in several languages.

Hakluyt also gave public lectures—he is regarded as the first professor of modern geography at Oxford—and was the first to display "both the old imperfectly composed and the new, lately reformed maps, globes. spheres and other instruments of this Art for demonstration in the common schools." He made a point also of getting to know "the chiefest Captains at sea, the greatest merchants. and the best Mariners of our nation." This was the time when English attention was fixed on the northeast and northwest passages, and on Francis Drake's circumnavigation. Hakluyt was concerned with the activities of Sir Humphrey Gilbert and Martin Frobisher, was consulting Abraham Ortelius and Gerardus Mercator on cosmographical problems and was gaining the approval of Lord Burghley, Sir Francis Walsingham and Sir Robert Cecil (later earl of Salisbury). He thus embarked upon his career as a "publicist and a counselor for present and future national

enterprises across the ocean." His policy, constantly expounded, was the exploration of temperate North America in conjunction with the northwest passage, the establishment oi England's claim to possession based on the discoveries of the Cabots and the foundation of a "plantation" to foster national trade and national well-being. These views are first set out in the preface to a translation of Jacques Cartier's voyage to Canada, which he induced John Florio to make from G. B. Ramusio's *Viaggi* in 1580, and are further developed in his first work of importance, *Divers Voyages touching the Discouerie of America* (1582). In this he pleaded also for the establishment of a lectureship in navigation: In 1583 Walsingham sent him to Paris as chaplain to Sir Edward Stafford. There he served also as a kind of intelligence officer, collecting information on the fur trade of Canada and on overseas enterprises from French and exiled Portuguese pilots. In support of Walter Raleigh's colonizing project in Virginia, he prepared a report, known briefly as *The Discourse on the Western Planting* (1584), which set out very forcefully the political and economic benefits from such a colony, and the necessity for state backing. This was presented to Queen Elizabeth I, who rewarded Hakluyt with a prebend at Bristol but took no steps to help Raleigh. *The Discourse*, a secret report, was not printed until 1877. In Paris, Hakluyt also edited an edition of the *Decades* of Peter Martyr, so that his countrymen might have knowledge of the early successes and failures of the Spaniards.

Hakluyt returned to London in 1588. The outbreak of war having put an end to the need for overseas propaganda. he began work on a project which he had had in mind for some time. This was *The Principall Navigations, Voiages and Discoveries of the English nation* . . . , and the first edition. in one volume, appeared in 1589. In 1590 he married Douglas Cavendish, a relation of Thomas Cavendish, the circumnavigator, and was presented to the living of Wetheringsett in Suffolk. Until after the death of his wife in 1597, little is heard of any geographical work, but he then completed the greatly enlarged second edition of *The Principall Navigations*, which appeared in three volumes between 1598 and 1600. Shortly before its completion, he was granted by the queen the next vacant prebend at Westminster, that he might be at hand to advise on colonial affairs. He gave information to the newly formed East India company, and continued his interest in the North American colonizing project. being a patentee of the Virginia company in 1606 and contemplating a voyage to the colony. Nor did his belief in the possibility of arctic passages to the east fade, for he was also a charter member of the North-west Passage company of 1612. In 1613 appeared the *Pilgrimage* of Samuel Purchas (*q.v.*), in spirit a continuation of his own work, and the two editors probably became acquainted. I'urchas procured some of Hakluyt's manuscripts after his death and was able to use them in *Purchas His Pilgrimes* of 1625. Hakluyt died on Nov. 23, 1616, and was buried in Westminster abbey.

Works by Hakluyt in addition to those mentioned above include translations of Antonio Galvão's *The Discoveries of the World* . . . (1601), and of Fernando de Soto's account of Florida, under the title *Virginia richly valued by the description of . . . . Florida* (1609). But it is the *Voyages* which remain his memorial. This, "the prose epic of the English nation," is more than a documentary history of exploration and adventure; with tales of daring it mingles historical, diplomatic and economic papers to establish British right to sovereignty at sea and to a place in overseas settlement. Its overriding purpose was to stimulate, guide and encourage an undertaking of incalculable national import. At the same time he was not blind to the profits arising from foreign trade. Sir Thomas Smith asserted that the income of the East India company was increased by twenty thousand pounds through a careful study of Hakluyt's *Voyages*.

BIBLIOGRAPHY. — The *Principall Navigations* were reprinted with additional matter as *Hakluyt's Collection of the Early Voyages, Travels, and Discoveries of the English Nation*, 4 vol. (1809–12), and for the Hakluyt Society with a preface by Walter Raleigh, 12 vol. (1903–05). The *Divers Voyages* was edited by the Hakluyt Society (1850). The best text of *The Discourse on the Western Planting* is in E. G. R. Taylor (*see* below). Many narratives from Hakluyt's collection have been republished by the Hakluyt Society (founded 1846). For his life, the dedications to the two early editions of *The Principall Navigations* should be consulted (*see* above). *See* also G. B. Parks, *Richard Hakluyt and the English Voyages* (1928); E. Williamson, "Richard Hakluyt," in *Richard Hakluyt and His Successors*, Hakluyt Society, 2nd ser., vol. 93 (1946). (G. R. CE.)

HAKODATE, a town on the south of the island of Hokkaido (Yezo), Japan, for many years regarded as the capital of the island until Sapporo was officially raised to that rank. Pop. (1960) 243,012. The town is built along the northwestern base of a rocky promontory (1,157 ft.), which forms the eastern boundary of a bay and is united to the mainland by a narrow isthmus.

Hakodate is one of the ports originally opened to foreign trade. The bay of Hakodate, an inlet of Tsugaru strait, is completely landlocked, easy of access and spacious, with deep water almost up to the shore. The Russians formerly used Hakodate as a winter port. The staple exports are beans, pulse and peas, marine products, sulfur, furs and timber; the staple imports. comestibles (especially salted fish), kerosene and oil cake. Hakodate was opened to foreign commerce in 1854, but it has lost its former importance in foreign trade and shipping, though it remains an important point of transit between Hokkaido and the main island.

HALAKHA: *see* MIDRASH.

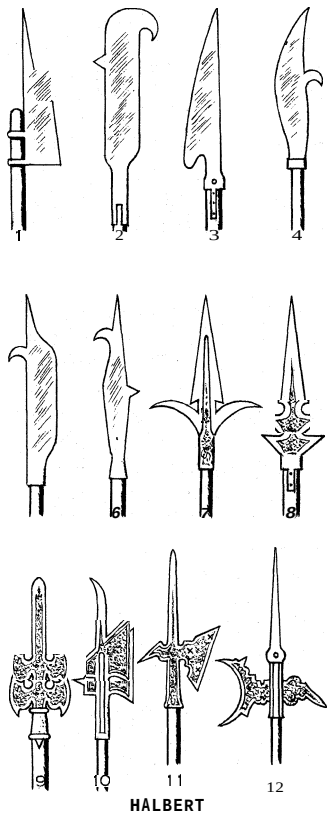
HALBERSTADT, a town in the district of Magdeburg, Ger., 56 mi. N.W. of Halle. It lies north of the Harz mountains, on the Holzemme. Pop. (1959 est.) 44.699. The history of Halberstadt begins with the transfer to it, in 820, of the see founded by Charlemagne at Seligenstadt. At the end of the 10th century it received a charter and the bishops were granted by the emperors the right to exercise temporal jurisdiction over their see, which became one of the chief ecclesiastical principalities of the empire. In 1648 it was converted by the treaty of Westphalia into a secular principality for the elector of Brandenburg. By the treaty of Tilsit in 1807 it was annexed to the kingdom of Westphalia, but came again to Prussia on the downfall of Napoleon. The town has many old houses decorated with woodcarving still surviving. The Gothic cathedral (now Protestant), dating from the 13th and 14th centuries, is remarkable for the great height of the interior, with its slender columns and lofty, narrow aisles. The treasure. preserved in the former chapter house. is rich in reliquaries, vestments and other objects of medieval church art. The Liebfrauenkirche (Church of Our Lady), a basilica. with four towers, in the later romanesque style, dating from the 12th and 13th centuries and restored in 1848, contains old mural frescoes and carved figures. The other old buildings are the town hall, of the 14th century and restored in the 17th century, with a crypt, and the Petershof, formerly the episcopal palace. The principal manufactures of the town are sugar, cigars, paper, gloves, boots, leather and machinery. About $1\frac{1}{2}$ mi. distant is the Klusberge, with prehistoric cave dwellings in the sandstone rocks.

HALBERT, HALBERD or HALBARD, a weapon consisting of an axe blade balanced by a pick and having an elongated pike head at the end of the staff, which was usually about 5 or 6 ft. in length. The utility of such a weapon in the wars of the later middle ages was that it gave the foot soldier the means of dealing with an armoured man on horseback. The pike could do no more than keep the horseman at a distance. This ensured security for the foot soldier but did not enable him to strike a mortal blow, for which a long-handled, powerful weapon capable of striking a heavy cleaving blow, was required. Several different forms of weapon responding to these requirements are described and illustrated below; it will be noticed that the thrusting pike is almost always combined with the cutting-bill hook or axehead, so that the individual billman or halberdier should not be at a disadvantage if caught alone by a mounted opponent, or if his first descending blow missed its object. It will be noticed further that, concurrently with the disuse of complete armour and the development of firearms, the pike or thrusting element gradually displaced the axe or cleaving element in these weapons, until there evolved the court halberts and partisans of the late 16th and early 17th centuries and the so-called "halbert" of the infantry officer and

sergeant in the 18th, which can scarcely be classed even as partisans.

Figs. 1–6 represent types of these long cutting, cut and thrust weapons of the middle ages, details being omitted for the sake of clearness. The most primitive is the vouge (fig. 1), which is simply a heavy cleaver on a pole, with a point added. The next form, the gisarme (fig. 2), appears in infinite variety but is always distinguished from vouges, etc., by the hook, which was used to pull down mounted men, and generally resembles the modern agricultural bill hook. The glaive (fig. 3) is a broad, heavy, slightly curved sword blade on a stave; it is often combined with the hooked gisarme as a glaive-gisarme (fig. 4). A gisarme-vouge is shown in fig. 5.

The weapon best known to Englishmen is the bill, which was originally a sort of scythe blade, sharpened on the convex side (whereas the glaive has the cutting edge on the convex side), but in its best-known form it should be called a bill-gisarme (fig. 6). The partisans, *ranseurs* and halberts proper developed naturally from the earlier types. The feature common to all is the combination of spear and axe. In the halberts the axe predominates *(see* figs. 10, 11, 12). In the partisan the pike is the more important, the axeheads being reduced to little more than an ornamental feature. A south German specimen (fig. 9) shows how this was compensated by the broadening of the spearhead, the edges of which in such weapons were sharpened. Fig. 8, a service weapon of simple form, merely has projections on either side, and from this developed the *ranseur* (fig. 7), a partisan with a very long and narrow point, like the blade of a rapier, and with forklike projections intended to act as "sword breakers," instead of the atrophied axeheads of the partisan proper.



HALBERT

(1) Vouge; (2) gisarme; (3) Late German glaive; (4) Burgundian glaive-gisarme. *c.* 1480; (5) Swiss gisarme-vouge, 14th century; (6) bill-gisarme; (7) ranseur; (8) service halbert; (9) German partisan, 1615; (10) Swiss halbert, early 15th century; (11) Swiss halbert, mid-16th century; (12) German court halbert, mid-16th century

The halbert played almost as conspicuous a part in the military history of middle Europe during the 15th and early 16th centuries as the pike. (*See* TACTICS: *Longbow and Halberd.)* But, even in a form distinguishable from the vouge and the glaive, it dates from the early part of the 13th century, and for many generations thereafter it was the special weapon of the Swiss. It was also in the 15th and 16th centuries that the halberts became larger; the blades were formed in many varieties of shape, often engraved, inlaid or pierced in open work and exquisitely finished as works of art. This weapon was in use in England from the reign of Henry VII to the reign of George III, when it was still carried (though in shape it had certainly lost its original characteristics and had become half partisan, half pike) by sergeants in the guards and other infantry regiments. It is still retained as the symbol of authority borne before the magistrates on public occasions in some of the burghs of Scotland. The Lochaber axe may be called a species of halbert furnished with a hook on the end of the staff at the back of the blade. The godendag (Fr. *godendart)* is the Flemish name of the halbert in its original form.

HALCYONE: *see* ALCYONE.

HALDANE, JOHN SCOTT (1860–1936), English scientist, was noted for his contributions to health and safety in mining and for his fundamental work on respiration. Born in Edinburgh, Scot., May 3, 1860, he was the son of Robert Haldane of Cloanden, a writer to the signet, who was also the father of Viscount Haldane (*q.v.*) and Elizabeth Sanderson Haldane. John Haldane studied at Edinburgh university, where he was graduated in medicine in 1884. and the University of Jena. From 1885 he was engaged in scientific investigation and teaching. He was a demonstrator in physiology at University college, Dundee, and in 1887 became a demonstrator at Oxford university where he was a reader in physiology from 1907 until he resigned in 1913. He also lectured at Yale university (1916), Glasgow university (1927–28) and Dublin university (1930).

Haldane investigated the action of gases that caused suffocation in coal mines and the physiological effects of the carbon monoxide present after a mine explosion. His report to the home secretary on the causes of deaths in mine explosions and fires (1896) was an important contribution to mine safety, and from that time he was a member of several government advisory committees and commissions. In 1912 he became director of a mining research laboratory founded near Doncaster by the mine owners; when it was transferred to Birmingham university in 1921, he became an honorary professor of mining there. He was also president of the Institution of Mining Engineers, 1924–28. Haldane did work on such mining problems as rescue equipment and pulmonary disease, and in 1907 he developed a method of stage decompression which made it possible for a deep-sea diver to ascend to the surface safely. He developed apparatus for the investigation of respiration and for blood-gas analysis. In 1905 he reported his fundamental discovery that the regulalion of breathing is usually determined by the effect of the tension of carbon dioxide in the blood on the respiratory centre in the brain. In 1911 he led an expedition to Pikes Peak, Colo., where he studied the effect of low barometric pressure.

His publications include *Organism and Environment* (1917); *Respiration* (1922); *The Sciences and Philosophy* (1929); and *The Philosophy of a Biologist,* 2nd ed. (Oxford, 1936). He died at Oxford at midnight, March 14–15, 1936.

HALDANE, RICHARD BURDON HALDANE, 1ST VISCOUNT (1856–1928), British statesman and philosopher, born July 30, 1856, was educated at the universities of Edinburgh and Gottingen. He was called to the bar in 1879. and took silk in 1890. In 1885 he entered parliament as liberal member for Haddingtonshire; he was re-elected continuously up to and including 1910. He was included in 1905 in Sir H. Campbell-Bannerman's cabinet as secretary for war, and carried out the reorganization of the British army. To Lord Haldane was due the decision of the dominion conference in 1907, accepting the principle of an imperial general staff, by which co-operation between armies drawn from all parts of the empire was made possible. In 1910 he was appointed chairman of the royal commission on university education in London. In March 1911 he was raised to the peerage and appointed a member of the judicial committee of the privy council. He aided in raising the committee to a commanding position.

Haldane was responsible, under the cabinet, for the conversation with France which laid down the lines of British and French co-operation in case of need. Simultaneously he acted as the agent of the cabinet in seeking an understanding with Germany which would prevent the outbreak of war. In 1906 he attended the German military manoeuvres, and at that time he visited the German war office, and studied German staff methods. On Feb. 8–12, 1912, he went on a definitely diplomatic mission to Berlin. with instructions to discuss all outstanding questions, including Morocco, the Baghdad railway and naval armaments. On his return he reported to the cabinet information he gathered there as to the attitudes and conditions of those then guiding the policy of Germany. Something resulted from the mission, but the war party in Germany prevailed. Haldane accepted the thwarting of the full result he had looked for with characteristic courage and dignified silence. In 1912 he succeeded Loreburn as lord chancellor.

Practical reasons and popular prejudice (his visits to Germany and his known preoccupation with German philosophy were used by the ignorant as a basis for a charge of pro-Germanism) account for his absence from the first Coalition Ministry in 1915, when he

received the Order of Merit. He was not given the opportunity of developing in wartime the army of which he had laid the firm foundation in peacetime. He was free—as free as any patriot of his nature and temperament could be in such stressful days—to return to the philosophical studies which had been interrupted by his long term of office. In 1903 he had published his *Pathway to Reality*, the Gifford lectures delivered by him at St. Andrews. They were a restatement of the Hegelian doctrine in the light of modern scientific work. He published in 1921 *The Reign of Relativity*, a masterly presentment of profound, scientific and metaphysical thought, and in 1922, *The Philosophy of Humanism*, an abiding memorial of the dictum *Das Geistige allein ist das Wirkliche*. Always eager to promote national education. Haldane now devoted much time and energy to the Workers' Educational association, which owed much to his support and counsel.

Haldane was lord chancellor in the Labour ministry of Ramsay Macdonald (1924), and working chairman of the committee of imperial defense. where his experience, tact and indefatigable industry were invaluable, and, on the fall of the Labour ministry, Baldwin invited him to continue his long association with it. The report of the machinery of government committee (Cd. 9230, 1918), of which Haldane was chairman, pointed out that "Further provision is needed in the sphere of civil government for the continuous organization of knowledge and the prosecution of research in order to furnish a proper basis of policy." Accepting this declaration of principle. Baldwin established in 1925 the committee of civil research, on which Haldane served as a member. Thus, through every department of state, in education. in university life, in the army. in the law and in industry are found the effects of his master mind, of his clear vision, of his resolute adherence to first principles and of his practical philosophy. Elected first chancellor of Bristol university, he was also lord rector of Edinburgh, and received many honorary degrees. His book, *Before the War*, gives an account of his political activities at that time. Haldane never married. He died at Cloan on Aug. 19, 1928.

HALDEN (formerly FREDRIKSHALD), **a** town in the county of Östfold in the south of Norway. It is situated at the mouth of the Tista river near the border of Sweden. Pop. (1950) 9,939. In early times there existed a settlement called Halden on the same site. The town was founded in 1661, and from 1665 was called Fredrikshald; in 1928 the name was changed back to Halden. The fort, Fredriksten, was begun in 1659, and repeatedly had to take the brunt of the conflicts between Sweden and Denmark-Norway. There in the siege of 1718, Charles XII was killed. In 1906, after the separation of Norway and Sweden, the fort was dismantled and hence was not able to offer effective resistance to the Germans in 1940. The most important industries of Halden are the mills for sawing and for making pulp and paper from the great timber production of the area. Boots, shoes and textiles are also manufactured, and quarries produce granite for export. The town has good facilities for shipping by boat or rail. (F. D. S.)

HALDER, FRANZ (1884–), German army officer, outstanding German staff officer in World War II, was born in Würzburg. Bavaria. on June 30, 1884. He was chief of operations in 1936 and was appointed chief of the general staff by Hitler on Sept. 1, 1938. Fearing that a disastrous war would arise from the Sudeten crisis, he joined General von Witzleben in a plot to overthrow Hitler, but the plan was dropped after Hitler's triumph at Munich. Halder supervised the planning of the Polish, French and Russian campaigns but had increasingly bitter disagreements with Hitler over the latter's amateurish interference; these led to his dismissal in Sept. 1942. He was arrested after the assassination plot of 1944, and although he was not involved was held prisoner until May 1945. After the war he devoted himself to research in military history and served as occasional military consultant to the west German government. He wrote *Hitler als Feldherr* (1949), published in English as *Hitler as War Lord* (1950). (P. N. T.)

HALDIMAND, SIR FREDERICK (1718–1791), British general and administrator, was born at Yverdun, Neuchâtel, Saitz., on Aug. 11, 1718, of Huguenot descent. He entered the British service in 1754 and later was naturalized as a British citizen. In 1778 he succeeded Sir Guy Carleton (afterward Lord Dorchester) as governor general of Canada. His measures against French sympathizers with the Americans have incurred extravagant strictures from French-Canadian historians, but he really showed moderation as well as energy. In 1785 he returned to London. He died at his birthplace on June 5, 1791.

HALE, EDWARD EVERETT (1822–1909), U.S. clergyman and author, is best remembered for his short story *The Man Without a Country* (1863), "a document of the Civil War." Hale was born in Boston, April 3, 1822, a grandnephew of the Revolutionary martyr, Nathan Hale, and a nephew of Edward Everett, the orator. Trained on his father's newspaper, the *Boston Daily Advertiser*, Hale turned early to letters. For 70 years newspaper articles, historical essays, short stories, pamphlets. sermons, and novels poured from his pen. He was intimately associated with the *North American Review*, *Atlantic Monthly* and *Christian Examiner*. From 1870 to 1875 he published and edited the Unitarian journal *Old and New*. "My Double and How He Undid Me" (1859) established the vein of realistic fantasy which was Hale's forte and introduced a group of loosely related characters figuring in *If, Yes, and Perhaps* (1868), *The Ingham Papers* (1869), *Sybaris and Other Homes* (1869), *His Level Best* (1872), and other collections. *East and West* (1892) and *In His Name* (1873) were his most popular novels.

Hale became pastor of the Church of the Unity at Worcester, Mass., in 1846. He married into the crusading Beecher family and took an active interest in western emigration and the Kansas-Nebraska controversy. In 1856 he became pastor of the South Congregational (Unitarian) Church of Boston. His forceful personality, organizing genius and liberal theology placed him in the vanguard of the "social gospel" movement. Many of his 150 books and pamphlets were tracts for such causes as emigrant aid, Negro education. workmen's housing and world peace. A moralistic novel, *Ten Times One Is Ten* (1871), inspired the organization of several young people's groups. The reminiscent writings of his later years are rich and colourful: *A New England Boyhood* (1893), *James Russell Lowell and His Friends* (1899), and *Memories of a Hundred Years* (1902). His *Works*, in ten volumes, appeared in 1898–1900. In 1903 he was named chaplain of the United States senate. He died at Roxbury, Mass.. June 10, 1909.

See E. E. Hale, Jr., *The Life and Letters of Edward Everett Hale* (1917); Jean Holloway, "Checklist," *Bulletin of Bibliography* (1954), and *Edward Everett Hale: a Biography* (1956). (JN. M. H.)

HALE, GEORGE ELLERY (1868–1938), U.S. astronomer, was known for his development of great astronomical instruments, including the zoo-in. Palomar telescope, and for his pioneering researches in solar physics, particularly his discovery of magnetic fields in sun spots. He was born at Chicago, Ill., on June 29, 1868. He graduated from Massachusetts Institute of Technology in 1890 and carried out research work at the Harvard College observatory (1889–90) and the University of Berlin (winter 1893–94). In 1888–91 he organized the Kenwood observatory in Chicago, where he invented and developed the spectroheliograph (*q.v.*), an instrument for photographing the sun in monochromatic light. In 1892, when he became associate professor of astrophysics (later professor) at The University of Chicago, he began the organization of the Yerkes observatory, of which he was director until 1904. Here he built the 40-in. refracting telescope which remains the largest of its type in the world. He established the *Astrophysical Journal*, an international review of spectroscopy and astronomical physics, in 1895. In 1904 he organized the Mt. Wilson observatory of the Carnegie Institution of Washington and was its director until 1923. Here he built solar apparatus of great power as well as the huge 60-in. and 100-in. stellar telescopes, both of the reflecting type. He organized the National Research council (1916). As foreign secretary of the National Academy of Sciences for many years he took an active part in international affairs. His plans and efforts led to the construction by the California Institute of Technology (with funds supplied by the Rockefeller foundation) of the zoo-in. reflecting telescope on Palomar mountain. His work was recognized by the awarding of many honors and by his election as a foreign member of most of the

world's leading academies of science.

He assisted in the organization of the Henry E. Huntington Library and Art gallery (San Marino, Calif.), of which he was a trustee, and in the improvement of the city of Pasadena as a member of the city planning commission. He took a leading part in the expansion and strengthening of the California Institute of Technology in Pasadena. He died at Pasadena on Feb. 21, 1938, after years of illness. He wrote *The Study of Stellar Evolution* (1908), *Ten Years' Work of a Mountain Observatory* (1911), *The New Heavens* (1922), *The Depths of the Universe* (1924), *Beyond the Milky Way* (1926), and *Signals From the Stars* (1931).

(P. W. M.)

HALE, JOHN PARKER (1806–1873), **U.S.** statesman, remembered chiefly for his long service in the U S, senate, of which he was a member from 1847 to 1853 and again from 1855 to 1865. Born at Rochester, N.H., on March 31, 1806, he graduated at Bowdoin college in 1827 and was admitted to the New Hampshire bar in 1830. In 1843–45 he was a Democratic member of the national house of representatives. In Jan. 1845, he refused in a public statement to obey a resolution of the state legislature directing him and his New Hampshire associates in congress to support the cause of the annexation of Texas, a Democratic measure which Hale regarded as being distinctively in the interest of slavery. The Democratic state convention was at once reassembled. Hale was denounced. and his renomination was withdrawn. Hale then set out to win over his state to the antislavery cause. The election resulted in the choice of a legislature controlled by the Whigs and the independent Democrats. He was one of the organizers of the Republican party, and during the Civil War was an eloquent supporter of the Union. He died at Dover, S.H., on Nov. 19. 1873.

HALE, SIR MATTHEW (1609–1676), lord chief justice of England under Charles II and one of the most learned and capable lawyers in English legal history, was born on Nov. 1, 1609. at Alderley, Gloucestershire. Left an orphan at the age of five, he was placed by his guardian under the care of the Puritan vicar of Wotton-under-Edge, with whom he remained until his 16th year, when he entered Magdalen Hall, Oxford. There, Hale studied with a view to taking holy orders, but, attracted by a company of strolling players, he threw aside his studies and plunged carelessly into gay society. For a time he considered entering the army of the prince of Orange in the Low Countries. He was drawn to the law, however, when in the course of settling his private legal affairs he met the celebrated Serjeant John Glanville (1586–1661), who recognized Hale's native ability and persuaded him to prepare for a career at the bar. He entered Lincoln's Inn, probably in 1628, and immediately devoted himself to legal studies with great intensity. His regimen included not only study of the conventional legal materials but broad reading in mathematics and the sciences.

He was called to the bar in 1637 and within a very few years mas at the head of his profession. He entered public life shortly before the onset of the Puritan revolution and in the confused and critical period that followed he conscientiously sought to steer a middle course. Hale was persuaded that a lawyer and a judge could best serve his country by holding aloof from partisanship and violent prejudices. He played a prominent role in the trials of political offenders that characterized the times. Some believe he was engaged as counsel for the earl of Strafford; it is certain that he acted for Archbishop Laud. Lord Maguire, Christopher Love, the duke of Hamilton and others. The assertion that Hale signed the Solemn League and Convenant. regarding the constitution of the Anglican church *(see* COVENANTERS), is not supported by satisfactory evidence. He did, however, take the engagement of loyalty to the Commonwealth required of all lawyers, and in 1653, already serjeant, he became a judge in the court of common pleas. Two years later he sat in Cromwell's parliament as one of the members for Gloucestershire. After the death of the protector he declined to act as a judge under Richard Cromwell, although he represented Oxford in Richard's parliament. At the Restoration in 1660 he was graciously received by Charles II, and in the same year he was appointed chief baron of the exchequer, and accepted. apparently with reluctance, the honor of knighthood. After holding the office of chief baron for 11 years he became chief justice of the king's bench in 1671. He resigned his office in 1676 and retired to his native Alderley, where he died on Dec. 25 of the same year.

As a judge Hale made a remarkable impression on his contemporaries for his probity. fairness, piety and moderation, traits that too often did not characterize those who then exercised judicial functions. It was these qualities that secured his position in the violent and shifting political life of the 17th century. The principal blot on his record involves the conviction of two women for witchcraft in 1661 or 1662. Hale presided at the trial and expressed "no doubt at all" of the existence of witches, a view already rejected by many educated men of the day.

Hale was a prolific writer, his works including discussions of theological and scientific matters as well as legal studies; most of them were left in manuscript and published posthumously. Perhaps his most important work is the *Historia placitorium coronae*, or *History of the Pleas of the Crown* (1685; 2 vol. 1736), one of the most influential treatises on the criminal law of England ever produced. Hale's other legal work of continuing importance is the *History of the Common Law of England* (1713). Among his numerous religious writings the *Contemplations, Moral and Divine* (1676–77) occupies the first place. One of his most popular works is the collection of *Letters of Advice to His Children and Grandchildren,* the first of which were published in 1762. He left a valuable collection of manuscripts and records to the library of Lincoln's Inn.

BIBLIOGRAPHY.—Hale's life has been written by G. Burnet (1682); by J. B. Williams (1835); by H. Roscoe, in *Lives of Eminent Lawyers* (1838); by Lord Campbell, in *Lives of the Chief Justices* (1849); and by E. Foss in *Lives of the Judges* (1848–70). (F. A. A.)

HALE, NATHAN (1755–1776), American Revolutionary officer and hero, was born at Coventry, Conn., on June 6, 1755. After he graduated from Yale in 1773, he became a school teacher. He joined a Connecticut regiment after war broke out, served in the siege of Boston and was commissioned a captain at the opening of 1776. When William Heath's brigade departed for New York he went with them. and the tradition is that he was one of a small and daring band who captured a provision sloop from under the very guns of a man-of-war. On Sept. 21, having volunteered to enter the British lines to obtain information concerning the enemy, he was captured in his disguise of a Dutch school teacher and was hanged the next day. The penalty was in accordance with military law, but young Hale's act was a brave one, and he has always been glorified as a martyr. Tradition attributes to him the saying (similar to a remark in Joseph Addison's play *Cato)* that he only regretted that he had but one life to lose for his country; and it is said that his request for a Bible and the services of a minister was refused by his captors.

HALEBID, a village in Hassan district, Mysore, India, 15 mi. N.W. of Hassan. It is the site of the Hoysala dynastic capital, Dwarasamudra or Dorasamudra, plundered by Moslem invaders in 1310 and 1326. The Hoysalesvara (built 1141–82), one of its two surviving temples, is the most luxuriantly sculptured of all Hoysala shrines. The podium is covered nith order upon order of figures carved in the easily worked chloritic schist.

HALES, JOHN (1584–1656), English scholar, frequently referred to as "the ever memorable," was born at Bath on April 19, 1584. In 1618 he nent to Holland as chaplain to the English ambassador. Sir Dudley Carleton. In 1619 he returned to Eton, where he held a fellowship. His eirenical tract entitled *Schism and Schismaticks* (1636) fell into the hands of Archbishop Laud, and in 1639 Hales was made one of Laud's chaplains and also a canon of Windsor. In 1642 he was deprived of his canonry by the parliamentary committee, and two years later was obliged to hide in Eton with the college documents and keys. In 1649 he refused to take the "Engagement" and was ejected from his fellowship. He lived in poverty till his death on May 19, 16j6.

HALES, STEPHEN (1677–1761), English clergyman, physiologist, chemist and inventor, famous for his pioneering studies

in animal and plant physiology, was born at Bekesbourne, Kent, on Sept. 7, 1677. Educated at Corpus Christi college. Cambridge, he took holy orders at Cambridge and in 1709 was presented to the perpetual curacy of Teddington, Middlesex, where Alexander Pope was his neighbour and friend; there he spent his life. In 1718 he was elected fellow of the Royal society, which awarded him the Copley medal in 1739, and in 1753 he became foreign associate of the French Académie des Sciences. He died at Teddington on Jan. 4, 1761.

Hales is best known for his *Statical Essays.* The first volume, *Vegetable Staticks* (1727), describes experiments in plant physiology: transpiration, the rate of growth of shoots and leaves, variations in root force at different times of the day and the nourishment taken in by plants from the air. In his experiments he was able to collect gases over water in vessels separate from those in which they were generated, and thus used what was to all intents the pneumatic trough, later perfected by Joseph Priestley (*q.v.*). The second volume, *Haemastaticks* (1733), is the most important contribution to the physiology of the circulation after William Harvey *(see* MEDICINE. HISTORY OF: *Albrecht von Haller).* Hales made the first quantitative estimate of blood pressure, and his work led to the development of the instruments now in general use for that purpose. Like Robert Whytt, Hales showed the necessity of the spinal cord for reflex movements. He also devised a ventilator (a modified organ bellows) by which fresh air could be conveyed into jails, hospitals and ships' holds, and invented a sea gauge for sounding and processes for distilling fresh from sea water, for protecting corn from weevils by fumigation aith brimstone, for salting animals whole by passing brine into their arteries and for bottling chalybeate waters. His *A Friendly Admonition to the Drinkers of Brandy and Other Distilled Spirit* was published anonymously in 1734 and passed through six editions, and *A Description of Ventilators,* a pioneer work of great practical importance, appeared in 1743.

HALESOWEN, a municipal borough (1936) in the Oldbury and Halesowen parliamentary division of Worcestershire, Eng., 7 mi. W.S.W. of Birmingham. Pop. (1951) 39,903. Mentioned as Halas in Domesday, Halesowen had a Premonstratensian monastery, ruins of which exist, 1214–1539. William Caslon (1692–1766), inventor of the Caslon type face. was born at Cradley and William Shenstone, the poet, at Halesowen. There are a grammar school (1652) and a county technical school (1939).

HALEVI, JUDAH BEN SAMUEL (*c.* 1085–*c.* 1140), the greatest Hebrew poet of the middle ages, was born in Toledo, Spain, about 1085, and died in Palestine after 1140. He wrote a philosophical dialogue in five books, called the *Cuzari,* translated into English by H. Hirschfeld. This book, based on the historical fact that the Crimean Kingdom of the Khazars adopted Judaism, describes what Halevi conceived to be the steps by which the Khazar king satisfied himself as to the claims of Judaism. His real fame depends on his liturgical hymns. which are the finest written in Hebrew since the Psalter, and are extensively used in the Sephardic rite. He wrote some memorable odes to Zion, which have been commemorated by Heine.

HALÉVY, ÉLIE (1870–193j), French historian, the author of an important history of 19th-century England, mas born at Etretat (Seine-Inférieure), Sept. 6, 1870, a son of the playwright Ludovic Halévy. He was educated at the Lycée Condorcet and the École Normale Supérieure and became professor at the École Libre des Sciences Politiques in 1898. His *History of the English People in the Nineteenth Century,* which, though written in French, is better known in English translation. nas begun shortly before World War I. After three volumes dealing with the years 1815–41 (Paris, 1913–23), Halévy turned to the end of the century in his two-volume *Épilogue* covering 1895–1914 (Paris, 1926–32). He projected a further three volumes for the period 1841–95, but died, at Sucy-en-Brie (Seine-et-Oise), Aug. 21, 1937, before the work could be completed. A volume dealing mith the years 1841–52 mas later prepared from his notes (Paris, 1946). A translation was published as follows: *England in 1815* (1949); *The Liberal Awakening, 1815–1830* (1949); *The Triumph of Reform, 1830–1841* (1950); *Victorian Years, 1841–1895* (1951); *Imperialism and the Rise of Labour, 1895–1905* (1951); *The Rule of Democracy, 1905–1914* (1952).

Halévy's work remains the best detailed general account of English history in the 19th century and his introductory survey of England in 181j is particularly brilliant. As an informed foreign observer he was at an advantage when passing judgment on English history, especially where non-conformity, in which he was very interested, was concerned. He was the first to suggest that the absence of any revolt in England during the French revolutionary period might be due to the influence of Wesleyanism. Another service rendered by Halévy to English history was the revival of interest in Bentham, both in England and France, through his *La Formation du radicalisme philosophique,* 3 vol. (1901–04).

, HALÉVY, JACQUES FRANÇOIS FROMENTAL ÉLIE (1799–1862), French composer knoan for his romantic opera *La Juive.* Born, May 27, 1799, in Paris of a Jenish family originally named Lévy, he studied under Henri Berton and Cherubini. In 1819 he won the Prix de Rome with his cantata *Herminie.* He wrote more than 30 operas, from *L'Artisan* (1827) to *La Magicienne* (1858). Among the earlier operas *La Dilettante d'Avignon* (1829) was a satire on the poverty of contemporary Italian librettos. In 183j he wrote the five-act grand opera *La Juive* on a libretto by Eugène Scribe, based on episodes from *The Merchant of Venice* and *Ivanhoe.* Remarkable for its choral writing, psychological characterization and imaginative orchestration, *La Juive* was, mith Meyerbeer's *Les Huguenots,* the prototype of early French romantic opera. Equally successful was *L'Éclair* (1835) in which Halévy revived the 18th-century traditions of *opéra comique. La Tempesta,* based on *The Tempest,* was written in Italian for production in London (1850) and introduced the air by Thomas Arne, "Where the bee sucks." His last opera, *Noé,* was completed by his pupil Bizet who married Halévy's daughter, Geneviève, later portrayed as the Duchesse de Guermantes in Proust's *À la recherche du temps perdu.* Halévy was greatly influenced by Meyerbeer, and was in his day overshadowed by him, though some of Meyerbeer's more delicate orchestral effects were borrowed from *La Juive.* He published *Souvenirs et portraits* (1861) and *Derniers Souvenirs* (1863). He died at Nice, March 17, 1862.

HALÉVY, LUDOVIC (1834–1908), French playwright and novelist, who in collaboration with Henri Meilhac wrote the librettos for the operettas of Oifenbach and satirical comedies about contemporary Parisian life. He was born in Paris, Jan. 1, 1834, the son of Léon Halévy, a versatile writer, and the nephew of the composer Fromental Halévy. While still a member of the civil service he began writing for the stage and collaborated anonymously in *Orphée aux enfers* (1858, music by Offenbach). In 1861 he entered into a partnership with Meilhac which was to last more than 20 years. While Halévy concentrated on the subject and its development and also directed the productions, the script was left to his partner. *La belle Hélène* (1864), a burlesque on the Homeric theme, opened a brilliant series of operettas with music by Offenbach. Among the best known of their plays are *Fanny* (1868) and the sentimental *Froufrou* (1869). They also wrote the libretto for *Carmen* (187j, music by Bizet).

Halévy's own nondramatic works, which are of a high quality, include *L'Invasion* (1872)—impressions of the Franco-German War and the Commune; *Monsieur et Madame Cardinal* (1873)—amusing studies of the theatrical world; and short stories and novels, in particular *L'Abbé Constantin* (1882). After his election to the Académie Française in 1884, he almost ceased to write. He died in Paris, May 8. 1908. (D. Ks.)

HALFBEAK, fishes belonging to the family Hemiramphidae, distinguished from the garfish or needlefish, which they closely resemble by the shortness of the upper jaw, whence they take their name. Many are small attractively coloured fish native to the coasts of tropical countries. The largest grow to about 18 in.;

the smaller to a foot or less. The North American halfbeak, *Hyporhamphus unifasciatus,* is found along the Atlantic coast.

HALFPENNY, WILLIAM (fl. 1752), English 18th-century architectural designer, was also known as Michael Hoare. He published about 20 books dealing almost entirely with domestic architecture and especially with country houses in the Gothic and Chinese fashions of his period. His most influential works were *New Designs for Chinese Temples* (1750–52); *Rural Architecture in the Gothic Taste* (1752); *Chinese and Gothic Architecture Properly Ornamented* (1752); and *Rural Architecture in the Chinese Taste* (1750–52). The first of these books disproves the statement that Thomas Chippendale and Sir Thomas Chambers introduced the Chinese taste into England. John Halfpenny, said to have been his son, was associated with William in the production of the above-mentioned works.

HALF-TIMBER WORK, in building, a method which exposes to view the heavy wood framing of the walls. Spaces between the structural members are filled with contrasting materials such as brick, plaster or wattle and daub. The strong cagelike skeleton is often stiffened with corner braces. Traditionally it is made of squared oak timbers joined by mortices, tenons and wooden pegs. The nature of the structure is expressed in rectangular buildings, the rhythmic spacing of posts and beams facilitating division into boxlike rooms. In the country, units of various sizes can be combined domino fashion to produce rambling plans and picturesque silhouettes, while in crowded towns narrow buildings with steep gables may rise six or seven stories. Although occasional structures are still built to take advantage of the strength and slow-burning properties of heavy timbers, the universal method today is to use light sills, studs, and joists only 2 in. thick nailed together to make "balloon frames" in place of the old pegged girts, beams and braces. Where the decorative effect of half-timber work is desired, boards are applied to the wall surface in a sham version of the old structural pattern. A more genuine, if unintentional, reflection is seen when the framing of concrete and steel buildings is made visible as part of the exterior effect.

Half-timber work is used where the climate is moderate, suitable wood is available, and there are craftsmen skilled in working with hand tools. It was common in China, and, in a refined form, in Japan, and was used for domestic architecture throughout northern Europe until the 17th century. At Pompeii there are remains of many houses whose upper floors were constructed in half-timber technique, and it is likely that Roman villas in wooded country were largely constructed in this way.

Extant medieval examples, from the 12th century, have projecting upper stories. The overhang, which probably originated in military construction, gains a small amount of space on the upper levels and gives some weather protection for walls and openings below. However, the main advantage is structural, since the cantilevers at the ends of the beams partially counterbalance the load carried by their spanning portions. The system permitted a series of open panels to serve as windows. Originally provided with shutters, louvres, or bars, in the 13th century these began to be fitted with leaded glass. The use of many studs set close together gives a pronounced vertical rhythm to the exteriors of this era. Along both coasts of the English channel this effect was retained even after the squarer panel forms of the Renaissance had been adopted elsewhere. The wooden frames of 13th- and 14th-century structures were elaborately ornamented, the moldings and carvings displaying the same forms used in Gothic artifacts and buildings of stone. Exposed ground floor posts, hewn from tree trunks and placed upside down, were often carved with the images of craftsman inhabitants or patron saints, while other framing elements were enriched with delicate running patterns. In France the latter emphasized the vertical elements, while in England the tendency was to stress the horizontals and the raking bargeboards which follow the edge of the roof. In the 15th and 16th centuries the decorative contrast between timber and filling was fully exploited. Panels were made of brick in herringbone patterns, of plaster molded or incised with floral forms or with inlays of slate, tile or marl. Carved ornament was lavish and fanciful, and showed classical motives. Many wooden members were added without structural necessity. These were often crisscrossed under windows, and, in England where more timber work was exposed, they were assembled in cusped shapes or chevrons to create the striking patterns of the "black and white" manor houses of Cheshire and Lancashire. In Germany a bolder and cruder effect was obtained by using fewer elements and emphasizing angle bracing. In the American colonies the English found it expedient to use an insulating layer of wood siding (clapboards or weatherboarding), and half-timbering was not visible from outside. In the French and German settlements, however, the buildings were faithful copies of the European models, an occasional one appearing as late as mid-19th century. *See* also **CARPENTRY.**

HALFTONE: *see* PHOTO-ENGRAVING.

HALIBURTON, THOMAS CHANDLER (1796–1865), Canadian humourist and satirist, is best known as the creator of Sam Slick, the Yankee clock peddler and cracker-barrel philosopher. Born in Windsor, Nova Scotia on Dec. 17, 1796, he was educated at King's college, Windsor. In 1820 he was admitted to the bar and became in turn a justice of the court of common pleas (1829) and a judge of the supreme court (1841). But the formative development of his career was his election in 1826 to the provincial house of assembly and his subsequent involvement in the assembly's struggle against the misuse of powers by the ruling clique. For a time Haliburton led the popular movement for reform; but when, as it seemed to him, agitation for responsible government began to threaten the colony's ties with Great Britain and the crown, his Tory convictions reasserted themselves. Alienated from most of his contemporaries, he resigned his seat in the assembly and turned to writing as an outlet for his opinions. Of the 16 books he wrote, nearly all were rooted in his strongly conservative views on political and social questions.

Sam Slick made his first appearance in the *Novascotian* newspaper in 1835; and in the three series of *The Clockmaker* (1836, 1838, 1840), in *The Attache'; or, Sam Slick in England* (1843–44) and in *Sam Slick's Wise Saws and Modern Instances* (1853) Haliburton pressed home his attack against the political shiftlessness of the Nova Scotians, against the shortcomings of American "mobocracy" and indeed against the whole broad front (Britain not excepted) of the levelling tendencies of the age. In sum it is a remarkable body of writing — sometimes too blunt in its preachment or merely bad-tempered, but constantly quickened by the tremendous vitality of Sam Slick's colloquial speech and by his fund of anecdotes and tall tales. Artemus Ward is said to have called Haliburton "the father of the American school of humor," and Justin M'Carthy remembered the time when Sam Slick was as well known to English readers as Dickens' Sam Weller. Important volumes in similar vein, though without the central character of Mr. Slick, are *The Old Judge* (1849) and *The Season Ticket* (1860).

In 1856 Haliburton moved to England, where he represented Launceston in the house of commons for six years prior to his death in Middlesex, on Aug. 27, 1865. A son, Robert Grant Haliburton (1831–1901), was a prominent figure in literary circles at the time of Canadian confederation.

See V. L. O. Chittick, *Thomas Chandler Haliburton* (1924).

(R. L. McD.)

HALIBUT (*Hippoglossus hippoglossus*), the largest of the flat fishes, reaching a length of 10 feet. It is found in the north Atlantic and north Pacific, and extends into the Arctic ocean, but is not certainly circumpolar. The eyes are on the right side, and the mouth is large; the body is longer and less compressed than in other flat fishes. The halibut feeds on other fishes. It is a valued food fish, with very firm white flesh.

HALICARNASSUS (mod. *Budrum*), an ancient Greek city on the southwest coast of Caria, Asia Minor, on the Ceramic gulf or Gulf of Cos. It originally occupied only the small island of Zephyria close to the shore (which now has the great castle of St. Peter, built by the Knights of Rhodes in 1404), but in course of time this island was united to the mainland and the city extended so as to incorporate Salmacis, an older town of

the Leleges and Carians.

About the foundation of Halicarnassus various traditions were current; but they agree as to its being a Dorian colony, and the figures on its coins, such as the head of Medusa, Athena and Poseidon, or the trident, support the statement that the mother cities were Troezen and Argos. The inhabitants appear to have accepted Anthes as their legendary founder, and were proud of the title of Antheadae. At an early period Halicarnassus was a member of the Doric Hexapolis, which included Cos, Cnidus, Lindus, Camirus and Ialysus; but owing to the lapses of Agasicles, one of its citizens, the city was cut off from the league. In the early 5th century Halicarnassus was under the sway of Artemisia, who made herself famous at the battle of Salamis. Halicarnassus and other Dorian cities of Asia were afterwards to some extent absorbed by the Delian League, but the peace of Antalcidas in **387** made them subservient to Persia; and it was under Mausolus, a Persian satrap who assumed independent authority, that Halicarnassus attained its highest prosperity. Mausolus increased the population of Halicarnassus by the inhabitants of six towns of the Leleges. He was succeeded by Artemisia, whose magnificence has been perpetuated by the "Mausoleum," the monument she erected to her husband's memory. *(See* MAUSOLUS.) One of her successors, Pixodarus, tried to ally himself with the rising power of Macedon.

Alexander, as soon as he had reduced Ionia, summoned Halicarnassus, where Memnon, the paramount satrap of Asia Minor, had taken refuge with the Persian fleet, to surrender; and on its refusal took the city and devastated it, but not being able to reduce the citadel, was forced to leave it blockaded. He handed the government back to the family of Mausolus. Later the citizens received the present of a gymnasium from Ptolemy, and built in his honour a stoa or portico; but the city never recovered entirely from the siege, and Cicero describes it as almost deserted. The site is now occupied in part by the town of Budrum; but the ancient walls can still be traced round nearly all their circuit, and the position of several of the temples, the theatre, and other public buildings can be fixed with certainty.

Excavations of the Mausoleum show that the building consisted of five parts—a basement or podium, a pteron or enclosure of columns, a pyramid, a pedestal and a chariot group. The basement was built of greenstone and cased with marble. The pteron consisted (according to Pliny) of thirty-six columns of the Ionic order, enclosing a square *cella.* Between the columns probably stood single statues. From the portions that have been recovered, it appears that the principal frieze of the pteron represented combats of Greeks and Amazons. Above the pteron rose the pyramid. mounting by 24 steps to an apex or pedestal. On this apex stood the chariot with the figure of Mausolus himself and an attendant. The height of the statue of Mausolus in the British Museum is g ft. 9½ in. without the plinth.

See C. T. Newton and R. P. Pullan, *History of Discoveries at Halicarnassus* (1862–63); J. Fergusson, *The Mausoleum at Halicarnassus restored* (1862); E. Oldfield "The Mausoleum," in *Archaeologia* (1895); F. Adler, *Mausoleum zu Halikarnass* (1900); J. P. Six in *Journ. Hell. Studies* (1905); W. B. Dinsmoor, in *Amer. Journ. of Arch.* (1908); J. J. Stevenson, *A Restoration of the Mausoleum of Halicarnassus* (1909); J. B. K. Preedy, "The Chariot Group of the Mausoleum," in *Journ. Hell. Stud.,* 1910.

HALICZ (GALICH), a small town of the Ukrainian S.S.R., 70 mi. by rail S.S.E. of Lwow (Lemberg), on the Dniester. In the neighbourhood are the ruins of the old castle, the seat of the ruler of the former kingdom from which Galicia derived its name. Halicz, which is mentioned as early as 1113, was from 1141 to 1255 the residence of the Russian princes of that name. It probably suffered during the Mongol invasion of 1240. It has changed hands among Poland, Austria, Russia and Germany during its history; in World War II it was occupied in Sept. 1939 by the U.S.S.R., which surrendered it to German armies in the summer of 1941; it was ceded to the U.S.S.R. in 1945.

HALIDE EDIB ADIVAR (1883–), Turkish author, was a pioneer of the emancipation of women in Turkey. Born in Istanbul and educated by private tutors and at an American college there, she was soon actively engaged in literary, political and social movements. Her novel *Yeni Turan* (1912; German trans., *Das neue Turan,* 1916) portrays the nationalistic trends of the period. After educational work in Syria during World War I she and her husband, Adnan Adivar, joined the Nationalists and she served as a corporal in Anatolia. During 1925–38 she traveled extensively, lecturing in Paris, London, the United States and India. She became professor of English literature at Istanbul university (1939) and a member of parliament (1950–54). Her early novels. such as *Handan* (1912). written with passionate intensity, are studies in the problems of the educated women of her day. Later books, such as *Ateshten Gömlek* (1922) and *Zeyno nun Oglu* (1926), are concerned with war in Anatolia and renascent Turkey. Novels of her third phase, such as *Sinekli Bakkal* (1936; originally written in English as *The Clown and His Daughter)* and *Doner Ayna* (1953), are character studies and well-drawn portraits of Turkish society. Other books written in English include her *Memoirs* (1926) and *Conflict of East and West in Turkey* (1936). (F. I.)

HALIDON HILL, BATTLE OF. When the Scottish War was renewed after a four years' uneasy truce, this battle of July 19, 1333, proved the sequel to the unauthorized expedition and battle of Dupplin (*q.v.*) and confirmed the changed balance of fortune. Bruce was dead and the Scots neglected to fulfil his "testament" of guerrilla warfare. Compared with Bannockburn (*q.v.*) the strategical situation was also reversed, for in 1333 Edward III. was besieging Berwick and a great Scottish host marching to relieve it. With him were Baliol and Beaumont, the victors of Dupplin, and there is little doubt that his tactics were inspired by their advice and experience. His force was drawn up in three "battles,'.' composed of dismounted knights and men-at-arms, with archers on the wings. When the Scottish impetus failed and disorganization spread, Edward ordered his knights to mount and charge, until the Scottish host was a dissolved-rabble.

HALID ZIYA USHAKLIGIL (1865–1945), Turkish author, was the first true exponent in Turkey of the novel in its contemporary European form. Born in Istanbul of a western Anatolian family and educated at a French school in Izmir, he founded the newspaper *Hizmet* in which was serialized his early work: essays, translations from the French and several sentimental novels. Two of these, *Bir Ölünün dejteri* (1889) and *Ferdi ve Shürekasi* (1894), revealed his potentialities. The hero of his novel *Mai ve Siyah* (1897), published in the periodical *Servetifünun,* was the spokesman for the "new literature" movement. His masterpiece, *Ashk-i Memnu,* appeared in 1900 and was followed by many more novels and a series of short stories. His characters and situations, though mainly limited to westernized upper-class circles, are drawn from experience. In his short stories he depicts the everyday scenes of Turkish life. (F. I.)

HALIFAX, CHARLES MONTAGUE, EARL OF (1661–1715), English statesman and poet, fourth son of the Hon. George Montague, was born at Horton, Northamptonshire, on April 16, 1661. He was educated at Westminster school, where he was king's scholar in 1677 and at Trinity college, Cambridge, where he was one of the students who assisted Newton in forming the Philosophical Society of Cambridge. His clever panegyric on the death of Charles II. attracted the notice of the earl of Dorset, through whose patronage, he entered parliament in 1689 as member for Maldon. About this time he married the countess-dowager of Manchester, and after the coronation of William and Mary he purchased a clerkship to the council. His poetical *Epistle occasioned by his Majesty's Victory in Ireland* brought him a pension of £500 per annum. In 1692 he was made one of the commissioners of the treasury. His success as a politician was mainly due to his skill in finance. In 1692 he proposed to raise a million of money on annuities for 99 years. The Scotsman William Paterson (*q.v.*) had already submitted to the Government his plan of a national bank, and when in the spring of 1694 the prolonged contest with France had rendered another large loan absolutely necessary, Montague introduced the bill for the incorporation of the Bank of England. Immediately after the prorogation of parliament Montague was rewarded by the Chancellorship of the Exchequer.

In 1695 he was returned for Westminster to the new parliament, and pushed through the House his famous Recoinage Bill. Rapid restoration of public credit secured him a commanding influence; but although Godolphin resigned office in Oct. 1696, the king hesitated for some time between Montague and Sir Stephen Fox as his successor, and it was not till 1697 that Montague was appointed first lord. In 1698 and 1699 Montague acted as one of the council of regency during the king's absence from England. After the return of the king in 1699 he was compelled to resign his offices. He succeeded his brother in the auditorship of the Exchequer.

On the accession of the Tories to power he was raised to the peerage (1700) as Lord Halifax. In 1701 he was impeached for malpractices along with Lord Somers and the earls of Portland and Oxford, but all the charges were dismissed by the Lords; and in 1703 a second attempt to impeach him also failed. He was a member of the council of regency in 1714 pending the arrival of George I., and was first lord of the treasury in the new ministry. He was also created earl of Halifax and Viscount Sunbury. He died on May 19, 1715 and left no issue. He was buried in the vault of the Albemarle family in Westminster Abbey. Montague was a friend to many men of letters. He procured from Godolphin a commissionership for Addison, and enjoyed a life-long intimacy with Newton, for whom he obtained the mastership of the Mint. In administrative talent he surpassed all his contemporaries. and his only rival in parliamentary eloquence was Somers.

His *Miscellaneous Works* was published at London in 1704; his *Life and Miscellaneous Works* in 1715; and his *Poetical Works,* to which also his "Life" is attached, in 1716. His poems were reprinted in Johnson's *English Poets,* vol. ix.

HALIFAX, EDWARD FREDERICK LINDLEY WOOD, 1ST EARL OF (1881–1959), British statesman who was viceroy of India from 1925 to 1931 and foreign secretary in the period culminating in the outbreak of World War II, was born at Powderham castle, Devon, on April 16. 1881. He was the fourth son of the 2nd Viscount Halifax, a well-known churchman and a leader of the Anglo-Catholic movement! whose family had been established in Yorkshire for generations. He was educated at Eton and Christ Church, Oxford, being elected a fellow of All Souls college. Oxford, in 1903.

Wood entered parliament as Conservative member for Ripon, Yorkshire. in Jan. 1910, and for the next 30 years had a most successful career in politics. His grave manner and his air of aristocratic detachment counted in his favour, but some who knew him well regarded him as a very astute politician. During World War I he served for a time with the Yorkshire dragoons in France, but was assistant secretary to the ministry of national service from 1917 to 1918. Before 1925, when he was appointed viceroy of India and raised to the peerage as Baron Irwin. he was successively undersecretary of state for the colonies (1921–22), president of the board of education (1922–24) and minister of agriculture (1924–25). He was viceroy until 1931. On his return from India he again became president of the board of education (1932–35). He succeeded to his father's viscountcy in 1934. Thereafter he was lord privy seal (1935–37), leader of the house of lords (1935–38) and lord president of the council (1937–38), before being appointed foreign secretary on Feb. 25, 1938, on Anthony Eden's resignation from Neville Chamberlain's government.

Halifax had been close to Chamberlain long before he became foreign secretary, and when Chamberlain resigned in May 1940 he hoped Halifax would succeed him as prime minister. In fact. the issue was decided otherwise at a meeting between Chamberlain. Halifax and Churchill. Halifax remained foreign secretary for the first seven months of Churchill's ministry, but in Dec. 1940 he was named British ambassador to the U.S.

Halifax's career thus had three notable phases: as viceroy, as foreign secretary and as ambassador. His term of office in India coincided with a period of intense nationalist ferment among Hindus and Moslems alike, but his own deep concern with religious faith (like his father, he was a devout high churchman) enabled him to work on terms of understanding with Gandhi, the most powerful figure among Indian nationalists at that time. Halifax accelerated the processes of constitutional advance by using his great influence to that end both during his viceroyalty and after. His tenure of the foreign office was the most controversial period of his career! for by accepting this appointment he identified himself completely with Chamberlain's policy of "appeasement" toward Hitler. As lord privy seal he had visited Hitler and Goering in Nov. 1937, and he accompanied Chamberlain on a visit to Mussolini in Rome in Jan. 1939. As ambassador to the U.S. he gave great service to the Allied cause during World War II, in recognition of which he was created earl of Halifax in 1944. Named British delegate to the San Francisco conference in March 1945, he attended the first sessions of the United Nations. His resignation as ambassador became effective on May 1, 1946. In 1957 he published a volume of recollections *Fullness of Days.* He died at Garrowby hall, near Tork, on Dec. 23, 1959.

(J. F. B.)

HALIFAX, GEORGE MONTAGU DUNK, 2ND EARL OF (1716–1771), son of George Montagu, 1st earl of Halifax (of the second creationj, was born on Oct. j or 6, becoming earl of Halifax on his father's death in 1739. Educated at Eton and at Trinity college, Cambridge, he became in 1748 president of the board of trade. He helped to found Halifax, the capital of Nova Scotia, which was named after him, and in several ways he rendered good service to trade, especially with North America. In March 1761 Halifax was appointed lord lieutenant of Ireland, and was also for a time first lord of the admiralty. He was from 1762 to 1765 secretary of state for the northern department under Bute and under George Grenville. He signed the general warrant under which Wilkes was arrested in 1763, for which action he was mulcted in damages by the courts of law in 1769, and he was mainly responsible for the exclusion of the name of Augusta, princess of Wales, from the Regency bill of 1765. He returned to office in 1770 under his nephew, Lord North, but died on June 8, 1771.

HALIFAX, GEORGE SAVILE, 1ST MARQUESS OF (1633–1695). English statesman and political writer. was born at Thornhill. Yorkshire, on Nov. 11, 1633, and succeeded his father, Sir William, as 4th baronet on Jan. 24, 1644. Too young to take any part in the Great Rebellion, in which Sir William was prominent on the royalist side, he spent his early years partly in travel, with a private tutor, in France and Italy. and partly in retirement at Rufford abbey, Nottinghamshire, which he was to make the principal seat of his family. In the spring of 1660 he was returned as member for Pontefract to the convention which recalled the king, but there is nothing to suggest that he made any strong impression on contemporaries during this, his sole appearance in the house of commons. On Jan. 13, 1668. he was elevated to the peerage as Baron Savile of Eland and Viscount Halifax, and in the ensuing session of parliament took his seat in the house of lords.

For this promotion he was indebted partly to his extensive estates and connections with the great families of Talbot, Wentworth and Coventry, but partly also. it may be presumed. to the influence of the 2nd duke of Buckingham, then at the height of his power, with whose fortunes he and other young Yorkshiremen had chosen to associate themselves. To Buckingham he certainly owed his local offices of justice of the peace. deputy lieutenant and colonel in the militia. When, however. the duke embarked on the policy which ultimately led to the secret treaty of Dover, Halifax began to draw away from him. and although admitted to the privy council on April 17, 1672, and sent on a mission to Louis XIV in connection with the Anglo-French attack on the Dutch. he remained faithful to the principles of the triple alliance and therefore opposed t~ the existing government. On the other hand, when Charles II reversed his policy and gave the chief place in his counsels to the earl of Danby, Halifax proved equally unready to accept what seemed to him the extravagances of the new regime. He strenuously opposed Danby's non-resisting test bill, by which members of both houses of parliament. and all holding office under the crown. were to be required to subscribe a declaration that it was unlawful, upon any pretence whatsoever, to take up arms against the king. and to swear that they would not. at any time. endeavour the alteration of the government either in church or state; he denounced the court's attempt to control public opinion by sup-

pressing the coffeehouses; and he condemned the policy of continuing the Cavalier Parliament in existence long after it had ceased to be representative of national feeling. Thus early did he adopt that policy of "trimming." or balancing between opposing factions, with which his name came to be inseparably connected.

On Jan. 7, 1676. Halifax had been dismissed from the privy council for criticizing the government's measures against the coffee sellers. but on April 21. 1679, on the complete remodelling of the council associated with the name of Sir William Temple, he was again admitted. and for some time thereafter enjoyed a position of considerable power and dignity. On July 16, 1679, he was created earl of Halifax; on Aug. 22. 1682. marquess of Halifax; and on Oct. 27 of the same year lord privy seal. During these years his ambition was to secure the establishment of a truly national government on a moderate basis, and the chief dangers he had to provide against were the Catholic-despotic developments threatened by the probable succession of James. duke of York, on the one hand. and on the other the semirepublican designs of those who wished to exclude the dyke altogether from the throne. His greatest personal triumph was the defeat of the exclusion bill in the house of lords on Nov. 15. 1680; but he proved unable to devise any generally acceptable substitute for the policy of exclusion. and as the duke's influence increased after 1682 his own inevitably declined. Ton-ard the close of Charles's reign a reaction seemed to be developing which might have led to his restoration to power, but all prospect of this disappeared with the death of the king on Feb. 6. 168 j. Appointed lord president of the council by James. he was retained in office only to give an appearance of moderation to a government which was rapidly tending toward extremes. On Oct. 21, as a result of his refusal to support the repeal of the Test and Habeas Corpus acts, he was summarily dismissed.

For the next three years Halifax remained in retirement. criticizing James's designs, as they revealed themselves, in the political pamphlets on which his fame so largely rests. In his *Letter to* a *Dissenter,* published in 1687. he warned nonconformists of the danger of placing their trust in the king's promises of toleration; and in his *Anatomy of an Equivalent*, which appeared a year later, he demonstrated the absurdity of relying on any substitute for the safeguards of the established religion which already existed. Meanwhile he kept in touch with the more moderate among those who were contemplating resistance; but actual revolution he deprecated. The king's designs, he confidently maintained. were bound to fail of themselves, and all that was necessary was to wait.

When William of Orange landed in England and civil war seemed inevitable Halifax was thus in a strong position to mediate between the king and the prince, and exerted himself to the utmost. first to induce them to accept a reasonable accommodation. and then, after the flight of James, to set up a provisional government which might negotiate with either or both. Only when all such expedients had failed did he boldly take the side of William, and it was largely as a result of his efforts in the Convention Parliament of 1689 that William and Mary were accepted as king and queen. On him. as speaker of the lords. fell the duty of formally requesting the prince and princess to accept the crown.

To contemporaries it appeared that the reappointment of Halifax to his old office of lord privy seal and his acceptance as chief minister of the crown were natural consequences; but in actual fact the favour which Halifax enjoyed with William was due not so much to his services at this time as to the similarity of their political outlook. William was as anxious as Halifax for a reconciliation of parties based on a policy of "trimming," and hoped through Halifax to achieve that end. Only when it became apparent that in the heated atmosphere of the time such a policy was impracticable did his confidence in Halifax begin to waver, and even then it was Halifax who on Feb. 11, 1690, tendered his resignation. not William who required it. Thereafter Halifax was to be found mainly in opposition to the government of the moment. Toward the close of 1694 his health began to fail. and on April 5, 169 j. he died suddenly in his 62nd year. He was succeeded by his second and only surviving son William, with whose death on Aug. 31, 1700, the peerage became extinct.

The high reputation of Halifax among moderns is due to the fact that the political principles which guided his conduct and inspired his writings are such as mould now be generally approved; but in his own day these principles were regarded with little favour. The moderation which he consistently advocated mas denounced as treachery by every group of partisans who hoped to enlist his support, and not infrequently he had to withstand attacks from opposite sides at once. He lacked the practical capacity. and indeed the inclination, to organize a band of followers in support of his principles. and suffered from serious personal weaknesses which exposed him to the criticism of his numerous enemies. His passion for titles. leading to his rise from the dignity of baronet to that of marquess. seemed scarcely in accordance with his high professions of disinterestedness. His inordinate love of applause cast doubt on the sincerity of his most brilliant speeches. His tendency to see both sides of a question made him unready. even at a time of crisis. to take any resolute action. Few statesmen of comparable capacity have had less direct influence on the actual events of their time.

(1898), *A Character of the Trinzmer, Being a Short Life of the First Marquis of Halifax* (1946); *W. Raleigh* (ed.), *The Complete Works of George Savile, First Marquis of Halifax* (1912). **(A. BG.)**

HALIFAX, capital of Nova Scotia, Canada, and leading commercial, industrial and cultural city of the province. is on a rocky, boot-shaped peninsula. 4½ mi. long and 2 mi. wide. The harbour proper. on the east side of the peninsula. has extensive berthing facilities, while the inner harbour, Bedford basin. 6 mi. long and 4 mi. wide, is deep enough for the world's largest ships. Pop. (1961) city 92.511; metropolitan area 183.946. Included in the metropolitan area is the city of Dartmouth (*q.v.*), linked to Halifax by the mile-long Angus L. Macdonald suspension bridge completed in 1955.

The harbour of Halifax was noted by Champlain in 1605 but was not exploited until 1695 when the French established the fishing station, Chebucto. on McNab's Island. Plans were drawn up for a large fortress at Chebucto. but mainland Nova Scotia was lost to the English in 1713 and the French subsequently constructed a fortress (Louisbourg) on Cape Breton Island. Seeking a counterpoise to Louisbourg. Edward Cornwallis founded Halifax in 1749, naming it after the president of the Board of Trade and Plantations. For many years Halifax was little more than a military garrison. with forts and Martello towers (*q.v.*) strategically located throughout the area. Prince Edward. Queen Victoria's father. and others fortified Halifax until it had the strongest defenses outside of Europe. Halifax was an imperial army and naval base until 1906 when the defenses and dockyard were taken over by the Canadian government. Because of its strategic position it was Canada's largest and most important naval base during World Wars I and II.

Although the city has never been besieged, it has had more than its share of disaster during wartime. In 1917 the French steamship. "Mont Bianc," laden with TNT, explosive acid and benzine, collided in the Narrows with the Norwegian steamer, "Imo." The explosion that followed killed nearly 2,000 people and seriously injured an equal number. Windows were rattled 60 mi. away and an anchor shaft, weighing 1,000 lb., was hurled over 2 mi. from the scene. Much of the north side of the city was devastated, with property damage amounting to $35,000,000. A similar holocaust almost occurred in 1945, but the periodic explosions were not so great and they took place in Bedford basin well away from the populated areas.

Halifax is a leading Canadian port, particularly during the winter months, with fish: fish products, lumber and agricultural products being its major exports. It is the Atlantic terminus of the Canadian National railway and the Dominion Atlantic railway, the latter a part of the Canadian Pacific system. The area is served by two airports, one across the harbour at Eastern Passage, and an international airport at Kelly Lake, 20 mi. N.E. of Halifax.

Industries of Greater Halifax include foundries! oil refining. shipbuilding. fish processing. and the manufacture of candy and food products. rope and twine, paint and varnish, clothing,

electronic equipment and furniture. There are ship and aircraft overhauling facilities.

Among many prominent historic buildings are St. Paul's (Anglican) church, built in 1750, with many interesting memorial tablets and graves of celebrated Nova Scotians; Government house, erected in 1900, the residence of the lieutenant-governor; Province house, completed in 1819, the provincial legislative building; and the Old Clock, regarded as a Haligonian symbol, built on the side of Citadel Hill in 1803. Educational institutions include Dalhousie university (founded 1818), to which is affiliated the University of King's college (Anglican, founded 1789); St. Mary's university (Roman Catholic. founded 1811); Mount St. Vincent college, for women (Roman Catholic, chartered 1925); and Nova Scotia Technical college (founded 1909). Other interesting features are Citadel Hill, the Public Gardens, Point Pleasant park and Ft. Needham.

See T. Raddall, *Halifax, Warden of the North* (1948). (C. W. RD.)

HALIFAX, a municipal, county and parliamentary borough in the West Riding of Yorkshire, Eng., 191 mi. N.N.W. from London and 8 mi. S.W. from Bradford by road. Pop. (1961) 96,073. Area 22.0 sq.mi.

It lies in a hilly district on the Hebble, a tributary of the Calder which forms the southern boundary. The steep left bank of the Hebble restricts urban development: and Beacon.hill, rising sharply to 850 ft., overlooks the town. Road and railway bridges span the valley. the principal one being North bridge: opened in 1871. The main part of the town is situated on the slope of a long declivity facing east on the right bank of the stream. After World War II extensive suburban development took place on the northern side of the town, in the elevated district of Illingworth and at Mixenden in the Wheatley valley.

In Saxon times Halifax formed part of the extensive manor of Wakefield held by Edward the Confessor. After the Norman Conquest the manor of Halifax (Feslei in Domesday Book) was granted to William, earl of Warenne and Surrey. who made a gift of Yorkshire churches, including Halifax, to the Cluniac priory at Lenes in Sussex. The church was dedicated to St. John the Baptist. patron saint of wool weavers. The cloth trade has been plied in Halifax from an early date — the first record of a weaver being in 1275. In the alnagers' accounts for 1473–75 Halifax parish had the largest cloth production in the West Riding, a position it retained for three centuries. The late survival of the Halifax Gibbet law has been ascribed traditionally to the need for safeguarding the kerseys left on tenter frames in the open fields. The inhabitants retained the power to behead anyone found guilty of stealing goods "of the value of thirteen pence halfpenny." The gibbet, similar to the Scottish maiden and French guillotine. operated without human handling, a rope drawn by horse or sheep pulling out the pin to release the blade. The last of the executions. which took place on market days. was in 1650. The stone platform may still be seen at Gibbet hill. The blade is in the possession of the lord of the manor of Wakefield. During the Civil War Halifax was garrisoned by parliament although in 1643 royalist troops occupied it for six months.

Built largely in the 19th century. Halifax is a development of the industrial era. though some older buildings remain. The parish church is Perpendicular and two earlier churches are traceable — the first of Norman origin and the second of the Early English period. Features of the church are the western tower completed in 1482, unique Commonwealth windows of plain glass with beautifully designed leading and some fine woodwork. Among the public buildings are the town hall in the Palladian style. designed by Sir Charles Barry, opened in 1863; the central library and Bankfield museum housed in Victorian mansions: and Shibden hall. a 15th-century timbered house with the Halifax and West Riding Folk museum on its grounds. Heath grammar school was founded in 1585 with a royal charter. The Piece hall. u-here woollen piece goods were lodged and sold, was opened in 1779; is now scheduled as an ancient monument. Wainhouse tower. an octagonal tower with staircase and balconies, is a familiar landmark in the borough.

Halifax. an industrial town. is prosperous because of its manifold trades. It is a centre of the uoollen and worsted industries, other textile products being cotton, silk. rayon and moquette. The manufacture of carpets is important and further industries are iron and steel. wire drawing, breuing and confectionery; machine tools are a noted product and others include boilers, card clothing and cash registers Freestone and fire clay are abundant in the neighbourhood. The town is well equipped with gardens and parks, the most notable being Savile park, an expanse of 72 ac. of grassland. There are numerous charitable endowments, the earliest, the Waterhouse charity. dating from 1635 The town is the regimental depot of the duke of Wellington's regiment. which has been accorded the freedom of the borough. There are literary and artistic associations nith Sir Thomas Browne, Daniel Defoe, Laurence Sterne and the Brontes.

Halifax was first represented in parliament in 1654 but lost the seat aiter the Restoration. The Reform act of 1832 gave Halifax two members. It was a borough by prescription but was not incorporated until 1848; the county borough was created in 1888 and one member is returned to parliament. (F. C. P.)

HALITE, the mineralogic name for naturally occurring sodium chloride, common or rock salt. It occurs in well-formed cubic crystals. which occasionally exhibit hopper-shaped depressions. Halite also occurs commonly in granular masses. Although it is characteristically colourless. it may exhibit brownish. bluish, and other tints. The mineral is characterized by high solubility in water, distinctive salty taste, low specific gravity (2.16), and cubic cleavage.

Most halite occurs in bedded deposits formed by evaporation of bodies of salt water. Deposits range from a few feet to hundreds of feet in thickness and from a few tens of square feet to thousands of square miles in area. The deposits are characteristically associated with beds of limestone. dolomite. shale, and not uncommonly are interbedded with gypsum, anhydrite, and other soluble sodium. potassium, magnesium and calcium salts.

Such deposits are widely and abundantly distributed throughout the world, notably in the U.S.S.R., Germany, Poland, France, Spain and the U.S. In the U.S. very extensive deposits occur in New York, Ohio, Michigan and Pennsylvania and in Kansas, Colorado. Oklahoma. Texas and New Mexico. Halite also occurs along the Gulf of Mexico and the Mediterranean sea, in Rumania and in the U.S.S.R. in large pluglike bodies termed salt domes. Petroleum and sulfur are frequently associated with such domes.

Halite is an essential raw material for the preparation of soda ash, the production of sodium and chlorine compounds in the chemical industry. preservatives in the food-processing industry and for a host of other purposes. *See* also SALT: *Rock Salt;* SALT DOME. (D. M. H.)

HALL, ASAPH (1829–1907), U.S. astronomer and discoverer of the two satellites of Mars, was born on Oct. 15, 1829 at Goshen, Conn. In 1863 he was appointed professor in mathematics at the U.S. Naval observatory. Washington. D.C. This position he held until his retirement in 1891. From 1893 to 1901 he mas professor of astronomy at Harvard. At the naval observatory Hall had the 26-in. equatorial telescope under his charge from 1875 to 1891. His work with it was chiefly in three fields: planetary observations and the orbits of their satellites; observations of double-star orbits; determinations of the stellar parallax. In each of these fields Hall's extensive observations were of great value. His most spectacular achievement was the discovery in 1877 of the two satellites of Mars, whose orbits he calculated. He died at Annapolis, Md., on Nov. 22, 1907.

See G. W. Hill, *Biographical Memoir of Asaph Hall* (1908), which contains a full bibliography of Hall's scientific writings.

HALL, BASIL (1788–1844). British naval officer and traveler who increased geographical knowledge of the far east and of the west coast of South America, was born on Dec. 31, 1788, the son of the geologist Sir James Hall of Dunglass. Basil Hall entered the navy in 1802. He accompanied Lord Amherst's embassy to China in the sloop "Lyra" in 1816, and in that year was made a fellow of the Royal society. His *Account of a Voyage of Discovery to the West Coast of Corea and the Great Loo-Choo Island* appeared in 1818. After an interval for European travel. Hall

made his South American coastal expedition. described in *Extracts From a Journal Written on the Coasts of Chili, Peru, and Mexico, in the Years 1820–21–22* (2nd ed., 2 vol., 1824). Having left the navy. he traveled privately in North America, publishing in 1829 *Travels in North America in the Years 1827 and 1828* (3 vol.). His *Fragments of Voyages and Travels* (9 vol., 1831–33) give an interesting picture of the British navy of the early 19th century. Hall died in Haslar naval hospital near Portsmouth on Sept. 11, 1844.

HALL, CARL CHRISTIAN (1812–1888), Danish statesman, was born at Christianshavn on Feb. 2J, 1812, and was educated for the law. Returned to the *Rigsforsamling* of 1848 as member for the first district of Copenhagen, which he continued to represent in the *Folketing* till 1881, he displayed rare ability as a debater, while his extraordinary tact and temper disarmed opposition. Hall was not altogether satisfied with the fundamental law of June; but he accepted the existing constitution and sought to unite the best conservative elements of the nation in its defence. Failing to rally the landed aristocracy to the good cause, he determined to organize the middle class into a political party. Hence the "June Union," whose programme was progress and reform in the spirit of the constitution, and at the same time opposition to the *Bondevenner* or peasant party. The "Union" exercised an essential influence on the elections of 1852, and was, in fact, the beginning of the national Liberal party, which found its natural leader in Hall. During the years 1852–54 the burning question of the day was the connection between the various parts of the monarchy. Hall was "eiderdansk" by conviction. He saw in the closest possible union between the kingdom and a Slesvig freed from all risk of German interference the essential condition for Denmark's independence; but he did not think that Denmark was strong enough to carry such a policy through unsupported, and he was therefore inclined to promote it by diplomatic means and international combinations.

Hall first took office in the Bang administration (Dec. 12, 1854) as minister of public worship. In May 1857 he became president of the council after Andrae, Bang's successor, had retired, and in July 1858 he exchanged the ministry of public worship for the ministry of foreign affairs, while still retaining the premiership. Hall's programme, "den Konstitutionelle Helstat," *i.e.*, a single State with a common constitution, was difficult enough in a monarchy which included two nationalities, one of which, to a great extent, belonged to a foreign and hostile jurisdiction. But as this situation had been guaranteed by the Conventions of 1851–52, Hall sought to establish this "Helstat" by the Constitution of Nov. 13, 1863. For the failure of the attempt *see* DENMARK: *History*. Hall himself soon became aware of the impossibility of the "Helstat," and his whole policy aimed at making its absurdity patent to Europe, and substituting for it a constitutional Denmark to the Eider which would be in a position to come to terms with an independent Holstein. That this was the best thing possible for Denmark is indisputable, and "the diplomatic Seven Years' War," which Hall in the meantime conducted with all the powers interested in the question, is the most striking proof of his superior statesmanship.

After 1864 Hall's unconquerable faith in the future of his country made him, during those difficultyears, a power in the public life of Denmark. In 1870 he joined the Holstein-Holsteinborg ministry as minister of public worship; he passed many useful educational reforms, but on the fall of the administration, in 1873, he retired from public life. He died on Aug. 14, 1885.

See V. C. S. Topsoe, *Polit. Portraetstudier* (Copenhagen, 1878); S. P. V. Birkedal, *Personlige Oplevelser* (Copenhagen, 1890–91).

HALL, CHARLES FRANCIS (1821–1871), American arctic explorer, was born at Rochester, N.H. His enthusiasm for arctic exploration led him in 1859 to volunteer to the American Geographical Society to "go in search for the bones of Franklin." With the proceeds of a public subscription he was equipped for his expedition and sailed in May 1860 on board a whaling vessel. The whaler being ice-bound, Hall took up his abode in the regions to the north of Hudson bay, where he found relics of Frobisher's 16th century voyages. He published an account of his experiences under the title of *Arctic Researches and Life among the Esquimaux* (1864). Determined to learn more about the fate of the Franklin expedition he returned to the same regions in 1864, and passing five years among the Eskimo was successful in obtaining a number of Franklin relics, as well as information pointing to the exact fate of 76 of the crew, whilst also performing some geographical work of interest. In 1871 he was given command of the North Polar expedition fitted out by the U.S. Government in the "Polaris." Making a remarkably rapid passage up Smith sound at the head of Baffin bay, which was found to be ice-free, the "Polaris" reached on Aug. 30, the lat. of 82° 11′, at that time and until the English expedition of 1876 the highest north attained by vessel. He died suddenly on Nov. 8, 1871.

HALL, CHARLES MARTIN (1863–1914), American inventor, was born at Thompson, O., on Dec. 6, 1863, and graduated at Oberlin college in 1885. While still at college he became interested in the problem of devising a cheap process for the reduction of aluminium. Working with such apparatus as the Oberlin laboratory afforded, he invented, eight months after his graduation, the electrolytic process, which forms the basis for the present commercial production of the metal. The next three years were spent perfecting his process and interesting capitalists. In 1889 the Pittsburgh Reduction Company (later the Aluminum Company of America) began to manufacture aluminium and in 1890 Hall was made its vice-president. The invention made aluminium a common article of commerce, for which constantly increasing uses are being found. Hall's death occurred in Dayton& Fla., on Dec. 27, 1914. The fortune resulting from his invention was bequeathed chiefly to educational institutions, Oberlin receiving gifts totalling more than $3,000,000.

HALL, EDWARD (*c.* 1498–1547), English chronicler and lawyer, was a son of John Hall of Northall, Shropshire. Educated at Eton and King's college, Cambridge, he became common serjeant of the city of London and judge of the sheriff's court. He was also M.P. for Bridgnorth. Hall's great work, *The Union of the Noble and Illustre Famelies of Lancastre and York,* commonly called *Hall's Chronicle,* was first published in 1542, and continued by Richard Grafton (*q.v.*). The value of the *Chronicle* in its early stages is not great, but is very considerable for the reign of Henry VIII. To the student of literature it has the exceptional interest of being one of the prime sources of Shakespeare's historical plays.

HALL, GRANVILLE STANLEY (1844–1924), U.S. psychologist. one of the most influential of the pioneers in American psychology, was born at Ashfield, Mass., on Feb. 1, 1844. He did much to give the science of psychology a broad base, directing into the psychological currents of his time the ideas of Charles Darwin, Wilhelm Wundt. Sigmund Freud and others. Hall was the first president of Clark university (1888–1920) and at the same time professor of psychology there. At Clark he established the first institute of child psychology in the United States. Many of the studies issuing from this institute employed the questionnaire method: staunchly advocated by Hall as a psychological tool. One of the first psychological laboratories in the United States was founded by Hall in 1883 at Johns Hopkins university, where he served as lecturer and professor of psychology from 1881 to 1888. He was a leading spirit in the founding of the American Psychological association and its first president (1892). He launched four psychological journals—the *American Journal of Psychology* (1883), the *Pedagogical Seminary* (1891), the *Journal of Applied Psychology* (1915) and the *Journal of Religious Psychology and Education* (1902)—and published 489 works in nearly all the major areas of psychology. Among his most important published works are *Adolescence; senescence, the Last Half of Life; Youth; The Contents of Children's Minds on Entering School;* and *Founders of Modern Psychology.* A great teacher, Hall had many illustrious students. among them John Dewey, Joseph Jastrow, James McKeen Cattell, Henry Goddard, E. C. Sanford and Lewis Terman. He died at Worcester, Mass., on April 24, 1924.

of Granville Stanley Hall," *Amer.* J. Psychol. (1925); Lorine Pruett, G. *Stanley Hall* (1926). (H. L. K.)

HALL, SIR JAMES (1761–1832), Scottish geologist and physicist, was born at Dunglass on Jan. 17, 1761. He made a series of experiments to demonstrate the views of James Hutton with regard to intrusive rocks, and was thus the founder of experimental geology. The results of his experiments were brought before the Royal Society of Edinburgh. He was M.P. for Michael, Cornwall, from 1807–12. He died on June 23, 1832, at Edinburgh. He left three sons, of whom the second, Basil (*q.v.*), was a well known writer of travel books.

HALL, JAMES (1793–1868), U.S. author, particularly successful in sketching life in the French settlements of the Illinois country and in interpreting such authentic figures as the backwoodsman, voyageur and Indian hater, was born in Philadelphia, Pa., Aug. 19, 1793. A versatile figure, he was a soldier in the War of 1812, a lawyer and circuit judge, a newspaper and magazine editor, state treasurer of Illinois (1827–1831), a banker in Cincinnati, O., and a writer of history and fiction. During his twelve years in Illinois (1820–1832) he lived at Shawneetown and Vandalia and played an important role in literary and cultural activities. In 1828 he compiled the first western literary annual, the *Western Souvenir,* and he edited the *Illinois Monthly Magazine* (1830–1832) which he continued at Cincinnati until 1836 as the *Western Monthly Magazine.* Much of the material in these periodicals he supplied himself although he consistently encouraged western contributors. He compiled statistical volumes on the steamboating and economic history of the Ohio valley. He died in Cincinnati on July 5, 1868.

Hall wrote an interesting travel book, *Letters from the West* (1828); one novel, *Harpe's Head* (1833); a readable survey of western exploration, *The Romance* of *Western History* (1857); and several volumes of short stories. Tales like "Pete Featherton" and "A Legend of Carondelet," which find a place in many anthologies, early established Hall as a short-story writer of distinction. His best stories appear in *Legends of the West* (1832) and *Tales* of *the Border* (1835).

See John *T.* Flanagan, *James Hall, Literary Pioneer of the Ohio Valley* (1941). (J. *T.* FN.)

HALL, **JAMES** (1811–1898), U.S. geologist and paleontologist, was born at Hingham, Mass., on Sept. 12, 1811. Extreme poverty was the lot of his family, and he acquired through his own efforts his early education, which was, however, sufficiently complete to prepare him for admission to the Rensselaer Polytechnic institute of Troy, N.Y. Even as a boy he was passionately interested in natural history, and at the time of Silliman's Lowell lectures he walked to Boston and back from Hingham in order to attend them. As a student he collected and determined more than 900 species of plants. He spent his summers and all of his limited finances doing field work. After his graduation from the Rensselaer institute in 1832 he became librarian at the institute, and later in the same year an assistant professor; subsequently he became professor of chemistry, natural science and geology. Stephen Van Rensselaer became interested in Hall and sent him to make geological explorations in the St. Lawrence valley.

In 1836 he was appointed one of four geologists on the geological survey of the state of New York which had been established just before that time. Although the youngest of the group, his is the only one of the four final reports which deals broadly with the problems of the science and has endured with authority as a classic of geological literature.

Eventually Hall became state geologist and director of the Museum of Natural History of Albany. Through various periods when state support was withdrawn from geological work, he carried it on at his own expense. At one time he sold 2,000 ac. of Ohio land in order to gain funds to pay obligations incurred through his work, receiving $15,000 for the land, which was valued at $200,000 ten years later. It was only through this sacrifice that the continued publication of the volume of the *Palaeontology of New York* (1847–94) was made possible. These volumes, the results of his chief work, contained descriptions of the invertebrate fossils of New York, in which he dealt with the graptolites, brachiopods, mollusca, trilobites, echini and crinoids of the palaeozoic formations. He was also at one time state geologist of Iowa and afterward of Wisconsin.

His publications, dating from 1836, include more than 260 scientific papers and 35 books, dealing with numerous phases of geology and paleontology of the different regions of the United States and Canada, including reports on the geology of Oregon and California (1845), of Utah (1852), Iowa (1859) and Wisconsin (1862). He received the Wollaston medal from the Geological society of London in 1858.

Hall was regarded as a great teacher as well as collector. In his 86th year he journeyed to St. Petersburg (Leningrad) to take part in the International Geological congress, and then joined the excursion to the Ural mountains. He died at Echo Hill, Bethlehem, N.H., on Aug. 7, 1898, and was buried at Albany, N.Y.

His most important publications were: *Palaeontology of New York,* vol. 1–8 (1847–88; vol. 8, in collaboration with J. M. Clarke, of especial importance); *Geology of New York,* part iv (comprising the survey of the fourth geological district, 1843); with J. M. Clarke, *An Introduction to the Study of the Brachiopoda,* part *I* (11th annual report of New York state geologist, 1892); and part II. (13th annual report, 1894). A complete bibliography of his work is given in the *Bulletin of the Geological Society of America,* vol. *X* pp. 436–451 (1898). *See* also "Life and Works of James Hall," by H. C. Hovey, *American Geol.,* XXIII, p. 137 (1899) (portraits); "Memoir of James Hall," by John J. Stevenson, *Bull. of Geol. Soc. of America,* vol. *X* pp. 425–435 (1898).

HALL, JOSEPH (1574–1656), English bishop, moralist, controversialist and satirist, a notable figure in literature in his own right and as the opponent of Milton and of some importance in the history of ideas both as a churchman and as a moral philosopher. He was born at a farm near Ashby-de-la-Zouch, Leicestershire, on July 1, 1574. Destined for the ministry, he was educated, under Puritan influences. at the Ashby school and in 1589 entered Emmanuel college, Cambridge, then a strongly Puritan college. He had a successful academic career; he was elected for two years running to the university lectureship in rhetoric; and he won a name by his two volumes of satires. But he felt called to the active ministry and accepted Sir Robert Drury's offer of the rectory of Hawstead, Suffolk, and took up his duties there on Dec. 2, 1601. Apart from a visit to Belgium (1605) his leisure at Hawstead was spent, he tells us, in "writing books to buy books." His writings brought him to the notice of Prince Henry and he was appointed a domestic chaplain to the prince and resigned Hawstead (1608) to take up the cure of Waltham Holy Cross, Essex. While absent as chaplain to an embassy to France (1616) he was made dean of Worcester, and on his return he accompanied King James on the visit to Scotland in 1617. He was one of the representatives of the king at the synod of Dort (1618). Consecrated bishop of Exeter on Dec. 23, 1627, he was repeatedly suspected of Puritan leanings by Archbishop Laud, but accepted Laud's suggestion to write *Episcopacy by Divine Right* (publ. 1640) against Puritan attacks on episcopacy. In 1641 he engaged in pamphlet controversy with Puritan opponents. On Nov. 15, 1641, he was translated to the bishopric of Norwich but was for four months imprisoned with the other bishops in the Tower of London before he went to his new see. Deprived of most of his episcopal revenues in 1643 he was finally ejected from his palace and retired to a small house at Higham, near Norwich, where he lived until his death on Sept. 8, 1656.

As a man of letters Hall is remarkable for his versatility and his innovations. The *Contemplations* (151 meditations on the moral and spiritual implications of biblical stories; 1612–26) are not perhaps especially original except for their "Senecan" prose—a clear, curt, pointed style of which Hall was one of the foremost English practitioners, though he could use a full, sonorous style on occasion. In other literary forms, however, he was a pioneer. Although he was not the first to write formal satire in English, his *Virgidemiarum. Six Books* ("six books of harvests of rods") are the first English volumes of satire successfully modeled on Latin satire. The first three books, of "toothless satires" (1597), deal with the defects of contemporary literature, abuses in the professions and ostentation in social life. The last three books, of "biting satires" (1598), deal with graver social, moral and economic evils. Although much of his material is derived from books,

Hall's work is lively and original. The satire is sharply and often wittily pointed; the couplets, often balanced and enclosed, anticipate the satiric heroic couplets of Dryden; and the pictures of Elizabethan life are vivid and striking. The satires were immediately popular and inaugurated a series of satirical books of which the most notable were John Marston's.

Hall was certainly the first to emulate Theophrastus in English when he published (1608) a volume of *Characters of Vertues and Vices* (pithy and witty delineations of such types as "The Flatterer" or "The Good Magistrate"), and he claimed to be an innovator with his volumes of *Epistles* imitating Seneca's *Moral Epistles*. Original and entertaining also, in spite of Milton's scorn for it, is Hall's Latin satire, *Mundus Alter et Idem (c.* 1605). An early example of the imaginary voyage, it is influenced by Rabelais, and itself influenced Swift's *Gulliver's Travels*. Finally, beginning with *Meditations and Vows Divine and Moral* (1605), Hall continued to write meditations for the rest of his life, and here too he showed the way to later writers, enriching the manner and extending the scope of the meditation.

His clash with Milton began in 1641, when, in reply to Hall's *Defence* against "Smectymnuus" (a name made up of the initials of the Puritan divines who had attacked his *Humble Remonstrance to the High Court of Parliament),* Milton wrote *Animadversions.* This provoked a writer on Hall's side (perhaps his son) to turn (in *A Modest Defence)* Milton's technique of unpleasant imputation upon Milton himself, thus stinging Milton into *An Apology* (1642), containing even worse invective, but also precious passages of autobiography. In this Anglican-Puritan conflict, Hall was a moderate, pleading for unity among fellow Christians and for a brotherly tolerance in place of embittered strife about nonessentials. He did not appreciate how strong in such Puritans as Milton was the passion for individual liberty of speech and religious thought, he was bewildered by their readiness to reject established authority and he did not share their confidence in the ability of the common man to govern a church or to extemporize prayer worthy of public worship; but he was prepared, in the interests of peace, to make compromises on church government and on liturgy.

As a moral philosopher Hall achieved a European reputation for his Christianization of Stoicism and became widely known as "the English Seneca" and "the Christian Seneca." In a series of works beginning with *Heaven upon Earth* (1606) he expounded a neo-Stoicism by which men might achieve "true Peace, and Tranquillity of mind." This, discarding the pagan elements of Stoicism, adds to the philosophy of Seneca the Christian doctrines of Grace and Redemption and the efficacy of Faith.

Hall's satires and *Contemplations* were read and appreciated throughout the 18th and 19th centuries; in the 20th century scholars took an increasing interest in his moral and meditative work and in his place in the development of English prose.

BIBLIOGRAPHY.--The standard modern edition of Hall's works is *The Collected Works,* ed. by *P.* Wynter, 10 vol. (1863); *see* also *Collected Poems,* ed. by *A.* Davenport (1949); *Heaven upon Earth and Characters,* ed. by *R.* Kirk (1948); J. Healey's translation of the *Mundus, The Discovery of a New World,* ed. *by* H. Brown (1937). HALL, MARSHALL (1790–1857), English physiologist, was born on Feb. 18, 1790, at Basford, near Nottingham, the son of a cotton manufacturer. He studied medicine at Edinburgh, and became resident house physician to the Royal infirmary. This appointment he resigned after two years to visit the medical schools of Paris, Berlin and Gottingen. He then settled at Nottingham, where he became physician to the General Hospital, and in 1826 removed to London. Hall's principal works are: *Diagnosis* (1817); *Mimoses* (1818), on the affections designated as bilious, nervous, etc.; *Observations on Blood-letting* (1830), and *Experimental Essay on the Circulation of the Blood in the Capillary Vessels* (1831) in which he showed that the blood channels intermediate between arteries and veins serve the office of bringing the fluid blood into contact with the material tissues of the system, previously discovered by M. Malpighi and A. van Leeuwenhoek. In 1832 he read before the Royal society a paper "On the inverse ratio which subsists between respiration and irritability in the animal kingdom." His most important work in physiology was concerned with the theory of reflex action, embodied in a paper "On the reflex function of the Medulla Oblongata and the Medulla Spinalis" (1832), supplemented in 1837 by another "On the true Spinal Marrow, and the Excito-motor System of Nerves." Hall thus became the authority on the multiform deranged states of health referable to an abnormal condition of the nervous system. His "ready method" for resuscitation in drowning and other forms of suspended respiration has saved innumerable lives. He died on Aug. 11, 1857.

A list of his works are given in his *Memoirs* by his widow (1861).

HALL, ROBERT (1764–1831), English Baptist divine, was born on May 2, 1764, at Arnesby near Leicester, where his father, Robert Hall (1728–91), was pastor of a Baptist congregation. Ending his studies at Aberdeen university he became classical tutor at the Bristol academy. In 1790 he became pastor of a church at Cambridge, where he remained for 15 years and made a great reputation as a preacher. He died on Feb. 21, 1831.

See *Works of Robert Hall, A.M., With a Brief Memoir of His Life, by Olinthus Gregory, LL.D., and Observations on his Character as Preacher by John Foster,* 6 vol. (1832).

HALL, a meeting place, entry, or passageway, ranging in size from a large reception room in a public building to a corridor or vestibule of a house. For the feudal society of medieval Europe, the hall was the centre of all secular activities. Originally it was used for cooking and sleeping by large groups of people, as well as for the activities it still shelters when it is used as courtroom, banquet room, or place of entertainment. Beginning as a rectangular, barnlike structure, the hall probably evolved from the prehistoric wood framed tribal dwellings of northern Europe. Early examples had much in common with contemporary churches, employing a rhythmic structural system of three or more bays. The larger halls were divided by two rows of posts or stone columns into a nave and aisles. The rough stones of the fireplace were set near the centre of an earth floor strewn with an unsanitary layer of rushes to provide insulation. Smoke found its way out through the open roof framing at the gable ends or by means of a louver, near the centre of the ridgepole, protected by a wooden turret. The doors were opposite the end of the building reserved for the lord and his family. Eventually this area was distinguished by a low platform or dais, and a partial ceiling was brought forward the full width of the end wall behind it to form a canopy overhead. Dating from the 12th century, the remains of the bishop's palace at Hereford and the timber roof at Leicester castle are probably the oldest surviving fragments of gabled feudal halls.

As a defense against marauders halls were placed to take advantage of terrain and were often protected by moats or palisades. In Norman castles and English border fortresses the hall was part of the principal stone tower, built over a vaulted storage room with wooden beams supporting rooms above. Until the 14th century the medieval town house consisted of an undivided all-purpose living room, or hall, over a street-level shop area. In the country the hall began to evolve into the manor house in the 13th century as smaller rooms were added at the ends of the great central space. A low structure was built against the end wall for cooking and storage of supplies. A centre door leading to the kitchen was flanked by the hatches or doors to the pantry and buttery. As the outside doors were placed opposite each other in the long walls at this end, a passageway was formed which was provided with porches and wooden screens to protect the rest of the hall from drafts. Behind the dais a two-story structure was annexed with a solar or private room over a storage basement accessible from it. The solar was entered from an outside ladder or stair and communicated with the hall by means of a window or

Bottom right: Great hall of Ockwell Manor, Berkshire; 15th century

peepholes. Later, more secure conditions and the desire for privacy and for more easily heated rooms led to the development of living quarters on the lower floor, with entrances directly into the hall. As the end structures were extended they were linked with scattered service buildings and the gatehouse to form courts on one or both of the long sides of the hall.

From the 14th century halls were built with uninterrupted interiors spanned by great timber roofs. The aisled type was retained only in monastic hospitals where it was convenient to continue to place beds in the side bays. At Westminster hall the Norman interior supports were removed and a hammerbeam roof (*q.v.*) installed. A series of halls in northwestern England retained only the pair of columns nearest the doors to support a great wooden arch and light wooden screen walls blocking the aisles. A large freestanding screen like that at Rufford Old hall provided further protection from drafts. But the typical 15th- or 16th-century hall was entered through doors in a screen structure that terminated in the ornamented parapet of a musicians' gallery installed over the low passageway ceiling. The large fireplace and its chimney were built into a side wall. The dais was extended at one or both ends to provide a large bay which from the exterior appeared to balance the porch. It had full-length mullioned windows supplementing the traditional openings high in the side or end walls. With the development of the separate dining room and the decline of the old social order at the end of the middle ages began the descent of the hall in domestic architecture to its present status of entrance and passageway. However, towns. guilds. colleges, and other organizations built halls rivaling those of the barons. The names of many public buildings reflect the fact that a ceremonial reception room is their major feature.

HALLAM, the name of a family of Anglo-U.S. actors and theatrical managers associated with the beginnings of the professional theatre in America. LEWIS HALLAM (1714–1756) was sent to the American colonies by his brother. WILLIAM HALLAM, manager of a London theatre. With Lewis Hallam were his wife. MRS. SARAH HALLAM, and their son, LEWIS HALLAM (1740–1808). Their first appearance in the new world was at Williamsburg, Va., where, on Sept. 15, 1752, they presented *The Merchant of Venice.* This production marked the first appearance of a professional acting company in the American colonies. The following year they built the first theatre in New York city. After six years in New York. Philadelphia and Jamaica, the elder Lewis Hallam died; and the company re-formed under David Douglass, whom Mrs. Hallam married. It was in this company that Lewis Hallam the younger first became a leading man. In 1775 the war forced them into temporary retirement in Jamaica. Ten years later the company returned under the leadership of Lewis Hallam, Mrs. Hallam having died and David Douglass having retired. For the next 25 years the younger Hallam managed and acted with various companies throughout the United States. He was an accomplished actor but was known as a quarrelsome manager. He died in Philadelphia in 1808.

ISABELLA HALLAM (1746–1826), a daughter of the elder Lewis Hallam, was, as Mrs. Mattocks, a well-known actress in England. (S. W. H.)

HALLAM, HENRY (1777–1859), English historian. was the only son of John Hallam, canon of Windsor and dean of Bristol. and was born on July 9. 1777. He was educated at Eton and Christ Church. Oxford. nhere he graduated in 1799. Called to the bar, he practised for some years on the Oxford circuit; but his tastes were literary, and nhen. on the death of his father in 1812. he inherited a small estate in Lincolnshire. he gave himself up wholly to the studies of his life. His Whig connections won for him a well-paid and easy post of commissioner of stamps. He supported the abolition of the slave trade; and he was throughout his life a sincere upholder of Whig principles General sympathy was felt for him when he lost his tno brilliant sons, Arthur Henry Hallam (d. 1833), the A.H.H. of Tennyson's *In Memoriam,* and Henry Fitzmaurice Hallam (d. 1850). Hallam was a fellow of the Royal Society and a trustee of the British Museum. He died on Jan. 21, 1859. His great reputation rests on three standard works: *The View of the State of Europe during the Middle Ages* (1818; supplementary note, 1848); *Constitutional History of England* (1827); and *Introduction to the Literature of Europe in the 15th, 16th and 17th Centuries* (1838–39).

The *Middle Ages* is made up of nine long chapters, each of which is a complete treatise. The history of France, of Italy, of Spain, of Germany and of the Greek and Saracenic empires, sketched in rapid and general terms, is the subject of five separate chapters. Others deal with the great institutional features of mediaeval society—the development of the feudal system, of the ecclesiastical system and of the free political system of England. The last chapter sketches the general state of society, the growth of commerce, manners and literature in the middle ages.

The *Constitutional History of England* takes up the subject at the point at which it had been dropped in the *View of the Middle Ages,* viz., the accession of Henry VII., and carries it down to the accession of George III. An unwillingness to excite the prejudices of modern politics, which withheld him from touching perhaps the most interesting period in the history of the Constitution, did not save him from a violent attack by Southey in the *Quarterly Review,* 1828; he was accused "of heaping obloquy on all who supported the established institutions of the country." His chief unfairness was in tacitly assuming the 19th-century theory of the Constitution to be the right theory in previous centuries, and that those who departed from it on one side or the other were in the wrong. But though his work is thus coloured by his opinions, this was not the outcome of a conscious purpose, and he was scrupulously conscientious in collecting and weighing his materials. In this he was helped by his legal training, and the *Constitutional History* remains a standard authority.

Like the *Constitutional History,* the *Introduction to the Literature of Europe* continues one of the branches of inquiry opened in the *View of* the *Middle Ages.* The great qualities displayed in this work have been universally acknowledged—conscientiousness, accuracy. judgment and enormous reading. In science and theology, mathematics and poetry. metaphysics and law. Hallam is a competent and always a fair if not a profound critic. The bent of his own mind is manifest in his treatment of pure literature and of political speculation—which seems to be inspired with stronger personal interest and a higher sense of power than other parts of his work display.

Hallam is generally described as a "philosophical historian." The description is worthy in that he fixed his attention on results rather than on persons. His conception of history embraced the whole movement of society. But sweeping theories of the government of society. and broad characterizations of particular periods of history had no attraction for him.

HALLAM, ROBERT (d. 1417), bishop of Salisbury and English representative at the council of Constance. was educated at Oxford. and was chancellor of the university from 1403 to 1405. In the latter year the pope nominated him to be archbishop of York. but the king objected. However. in 1407 he was consecrated by Gregory XII. at Siena as bishop of Salisbury. At the council of Pisa in 1409 he was one of the English representatives. On June 6, 1411, Pope John XXIII. made Hallam a cardinal, but there was some irregularity. and his title was not recognized. At the council of Constance (*q.v.*), nhich met in Nov. 1414, Hallam was the chief English envoy. In the discussions which led up to the deposition of John XXIII. on May 29. 1415, he had a leading share. With the trials of John Hus and Jerome of Prague he had less concern. Under Henry V.'s direction, he gave the emperor Sigismund vigorous support in the endeavour to secure a reform of the Church, before the council proceeded to the election of a new pope.

Hallam died suddenly, on Sept. 4, 1417.

HALLÉ, SIR CHARLES (originally KARL HALLE) (1819–1895), English pianist and conductor. German by nationality. was born at Hagen, Westphalia, on April 11, 1819. He studied under Rink at Darmstadt in 1835. and in 1836 nent to Paris. where for

12 years he mixed nith Cherubini, Chopin, Liszt, Alfred de Musset, George Sand and other celebrities. He had started a set of chamber concerts with Alard and Franchomme, when the revolution of 1848 drove him from Paris, and he settled, with his wife and two children, in London. His pianoforte recitals, given at first from 1850 in his own house, and from 1861 in St. James's Hall, were for many years an important feature of London musical life. At the Musical Union founded by John Ella, and at the Popular Concerts from their beginning, Hallé was a frequent performer, and from 1853 he was director of the Gentlemen's Concerts in Manchester, nhere, in 1857, he started the famous Hallé Concerts. In 1888 he married Madame Norman Neruda (1839–1911), a noted violinist. In the same year he was knighted. He died at Manchester Oct. 25, 1895.

HALLE (known as HALLEANDER SAALE to distinguish it from the small town of Halle in North Rhine-Westphalia), a city in the German Democratic Republic (east Germany), chief town of a district (*bezirk*) of the same name, lies 361 ft, above sea level in a sandy plain on the right bank of the Saale river, which there divides into several arms, 21 mi. N.W. from Leipzig. Pop. (1950) 289,119.

Halle is first mentioned as a fortress erected on the Saale in 806. In 968 Halle, with its valuable saltworks, was given by the emperor Otto I to the newly founded archdiocese of Magdeburg, and in 981 Otto II gave it a charter as a town. From the first there were separate jurisdictions for the *Halloren* (or "salt-workers") and the German settlers in the town. The conflict of interests and jurisdictions led to the usual internecine strife during the middle ages, and both groups resisted the pretensions of the archbishops. In the 13th and 14th centuries Halle was a member of the Hanseatic league (*q.v.*). Its liberty perished, however, as a result of the internal feud between the democratic guilds and the patrician owners of the saltpans. In 1478 a demagogue member of the town council, with his confederates, opened the gates to the soldiers of the archbishop. The townsmen were subdued, and to hold them in check the archbishop built the castle of Moritzburg. Notwithstanding the efforts of the archbishops of Mainz and Magdeburg, the Reformation found an entrance into the city in 1522. After the peace of Westphalia in 1648 the city was passed to the house of Brandenburg.

Its situation at the junction of railway lines from Berlin, Breslau, Leipzig, Frankfurt-on-Main, the Harz country and Hanover has developed the commercial and industrial importance of Halle. It consists of the old, inner town and two small towns, Glaucha in the south and Neumarkt in the north. The centre of the town is occupied by the market square, on which stand the medieval town hall (restored in 1883) and the Gothic Marienkirche, dating mainly from the 16th century, with two towers connected by a bridge. In the square is a bronze statue of Handel, the composer, a native of Halle. Among'the churches the St. Moritzkirche, dating from the 14th century, with fine wood carvings and sculptures, and the cathedral (belonging since 1689 to the Reformed or Calvinist church), built in the 16th century, are worthy of note. The castle of Moritzburg, formerly the residence of the archbishops of Magdeburg, was destroyed by fire in the Thirty Years' War, with the exception of one wing. The university was founded by the elector Frederick III of Brandenburg (afterward king of Prussia) in 1694, was closed by Napoleon in 1806 and again in 1813, but in 1815 was re-established and united with the University of Wittenberg. It has long been recognized as one of the principal seats of Protestant theology.

Among the industries of Halle are sugar refining, machine building, the manufacture of spirits, malt, rubber, cement, paper, chicory, lubricating and illuminating oil, wagon grease, printing, dyeing and coal mining (soft brown coal).

During World War II Halle was taken by U.S. forces on April 19, 1945, after four days of street fighting, during which it suffered much damage. It was included in the Soviet occupation zone, prior to the establishment of the German Democratic Republic in 1949.

HALLECK, FITZ-GREENE (1790–1867), U.S. poet, was a leading member of the Knicirerbocker group, and known both for his satirical and romantic verse. He was born at Guilford, Conn., July 8, 1790, and died there Nov. 19, 1867. He was an employee in various New York city banks, including that of John Jacob Astor. In collaboration with Joseph Rodman Drake he contributed the satirical "Croaker Papers" to the New *York* Evening *Post* in 1819, and on the death of his friend he wrote the moving tribute beginning "Green be the turf above thee." Fanny (1819), his longest poem, was a satire on social climbers. Other popular favourites were the feudal romance "Alnwick Castle" (1822), "Burns" (1822, publ. 1827), the often recited "Marco Bozzaris" (1823, publ. 182j), "Red Jacket" (1828) and "Young America" (1865). Strongly influenced by Scott and Byron, he was a poet of slight but genuine gift.

His *Life and Letters* by *J. G.* Wilson appeared in 1869. His *Poetical Writings* were edited by Wilson in the same year. *See* also N. *F.* Adkins, *Fitz-Greene Halleck* (1930).

HALLECK, HENRY WAGER (1815–1872), U.S. general and jurist, was born at Westernville, Oneida county, N.Y., in 1815. Upon graduation from West Point military academy in 1839 he was appointed to the engineers, and in 1844 he was sent by the government to visit the principal military establishments of Europe. After his return, Halleck delivered a course of lectures on the science of war, published in 1846 under the title Elements of Military *Art* and Science, a later edition of which was widely used as a textbook by volunteer officers during the Civil War. On the outbreak of the hlexican War in 1846. he served with the expedition to California and the Pacific coast, acting for several years in California as a staff officer, and as secretary of state under the military government, and in 1849 he helped to frame the state constitution of California. In 1854 Captain Halleck resigned his commission and took up the practice of law with great success. On the outbreak of the Civil War he returned to the army as a major general, and in Nov. 1861 he was charged with the supreme command in the western theatre of war.

There can be no doubt that his administrative skill was mainly instrumental in bringing order out of chaos in the hurried formation of large volunteer armies in 1861, but the strategical and tactical successes of the following spring were due rather to the skill and activity of his subordinate generals, Grant, Buell and Pope, than to the plans of the supreme commander. In July, however, he was called to Washington as general in chief of the armies. At headquarters his administrative powers were conspicuous, but he proved to be utterly wanting in any large grasp of the military problem; the successive reverses of McClellan, Pope, Burnside and Hooker in Virginia were not infrequently traceable to the defects of the general in chief. In March 1864 Grant was appointed to replace him, Halleck becoming chief of staff at Washington. This post he occupied with credit until the end of the war. Halleck's position as a soldier is easily defined by his uniform success as an administrative official, his equally uniform want of success as an officer at the head of large armies in the field, and the popularity of his theoretical writings on war. While his interference with the dispositions of the commanders in the field was often disastrous, his services in organizing and instructing Union forces were of high value. He died at Louisville, Ky., Jan. 9, 1872.

Besides *Military Art and Science*, Halleck wrote *Bitumen, Its Varieties, Properties and Uses* (1841); *The Mining Laws of Spain and Mexico* (1859); *International Law* (1861; new ed., 1908); and *Treatise on International Law and the Laws of War, Prepared for the Use of Schools and Colleges*, abridged from the larger work. He translated Jomini, *Vie politique et militaire de Napoléon* (1864), and De Fooz, *On the Law of Mines* (1860). The works on international law mentioned above entitle General Halleck to high rank among the jurists of the 19th century.

HALLEFLINTA (a Swedish word meaning "rock flint"), a white, gray, yellow, greenish or pink fine-grained rock found in Scandinavia consisting of an intimate mixture of quartz and feldspar. hlany examples are banded or striated; others contain porphyritic crystals of quartz which resemble those of the felsites and porphyries. Mica, iron oxides, apatite, zircon, epidote and hornblende may also be present in small amounts. The more micaceous varieties form transitions to granulite and gneiss. Halleflinta under the microscope is very finely crystalline, or even cryptocrystalline, resembling the felsitic matrix of many acid rocks. It is essentially metamorphic and occurs with gneisses, schists and gran-

ulites, especially in the Scandinavian peninsula, where it is regarded as being very characteristic of certain horizons. Of its original nature there is some doubt, but its chemical composition and the occasional presence of porphyritic crystals indicate that it has affinities to the fine-grained acid intrusive rocks. In this group there may also have been placed metamorphosed acid tuffs and a certain number of adinoles (shales, contact-altered by intrusions of dolerite). The assemblage is not a perfectly homogeneous one and includes both igneous and sedimentary rocks, but the former preponderate. Rocks very similar to the typical Swedish hälleflintas occur in the Tirol, Galicia and eastern Bohemia.

HALLEL, a Jewish liturgical term designating Ps. cxiii–cxviii, as read in synagogue services on festive occasions. The theme is faith in and gratitude for Divine Providence. These hymns or psalms were recited by the Levites in the services of the Jerusalem Temple, probably with the refrain "Hallelujah" ("Praise ye the Lord"). Later the term meant Ps. cxxxvi, used in the daily morning service. In modern times the Hallel is often recited in English antiphonally.

See S. Singer and I. Abrahams, *The Authorised Daily Prayer Book* (1922).

HALLER, ALBRECHT VON (1708–1777), Swiss anatomist and physiologist, notable for, among many other contributions, his conceptions of the nature of living substance and of the action of the nervous system, was born at Berne on Oct. 16, 1708. Prevented by ill-health from joining in sports, he developed an amazing precocity. He studied medicine at Tübingen under Camerarius. and then at Leiden under Boerhaave and Albinus. graduating in 1727 with a thesis that proved the so-called salivary duct to be merely a blood vessel. After visiting London, Oxford and Paris, in 1728 he went to Basel, where the awakening of his interest in botany led him to begin a collection of plants which was afterward the basis of his great work on Swiss vegetation. About the same time he wrote his poem "Die Alpen," included in the first edition of his *Gedichte* (1732).

In 1730 Haller began to practise as a physician in Berne, but the fame of his botanical and anatomical researches led to his appointment, in 1736, to the chair of medicine, anatomy, surgery and botany in the newly founded University of Gottingen. He held this post for 17 years, conducting at the same time a monthly journal (the *Gottingische gelehrte Anzeiger*), to which he is said to have contributed about 12,000 articles on almost every branch of knowledge. In 1753 Haller resigned his chair and returned to Berne, where he prepared his *Bibliotheca medica,* the botanical, surgical and anatomical parts of which he lived to complete; wrote three philosophical romances, *Usong* (1771), *Alfred* (1773) and *Fabius and Cato* (1774), expounding his views on various types of government; produced among other medical works, the justly famed *Elementa physiologiae corporis humani* (1757–66); and fulfilled various municipal and state duties. Haller died on Dec. 12, 1777.

Among Haller's most important contributions to medicine may be named his recognition of the mechanism of respiration and the automatism of the heart; his admission of the use of bile in the digestion of fat; his descriptions of the development of the embryo; his work on the anatomy of the organs of generation, of the brain, of the heart and of many imperfectly known arteries; and above all his classification of the bodily parts as sensible and insensible, irritable and nonirritable, together with his noteworthy demonstration that sensibility and irritability are independent, the former being a property of tissues endowed with nerves, the latter a peculiarity of all muscular tissue, independent of the nerves proceeding to it and surviving in severed parts.

Apart from the works mentioned above. Haller's chief writings are *Enumeratio methodica stirpium Helveticarum* (1742); *Icones anatomicae* (1743–54); *Disp. anatomicae Selectiores* (1746–52); *De respiratione experimenta anatomica* (1747); *Opuscula botanica* (1749); *Opuscula pathologica* (1754); an edition of Boerhaave's *Artis medicae principia* (1769); and *Disp. chirurg. collectio* (1777).

See J. G. Zimmermann, *Das Leben des Herrn von Haller* (1755); and the detailed biography in L. Hirzel's edition of the *Gedichte* (1882).

HALLEY, EDMUND (1656–1742), English astronomer who observed the comet of 1682 now called by his name, was born in London on Oct. 29, 1656, and was educated at St. Paul's school, London, and at Queen's college, Oxford. His first paper, concerning planetary orbits, was published in the *Philosophical Transactions* of the Royal society in 1676. He formed a friendship with John Flamsteed, who had been appointed astronomer royal in the preceding year, and was often in his company, helping him and Robert Hooke to design and construct the Greenwich observatory. Halley also assisted Flamsteed in his observations. Influenced by Flamsteed's great project of forming an accurate catalogue of northern stars, Halley proposed to do the same in the south, and obtaining an introduction, through Charles II, to the East India company, he left Oxford without a degree in Nov. 1676, and sailed to St. Helena in a ship of that company. At St. Helena he catalogued more than 300 stars, observed a transit of Mercury (Nov. 7, 1677) and made numerous pendulum observations. He also named a new constellation, Robur Carolinum, in honour of Charles II, but this is no longer recognized by celestial cartographers.

Upon his return to England in 1678 he was granted the degree of M. A. by the University of Oxford and began a friendship with Sir Isaac Newton, which resulted in his publication, at his own expense, of Newton's *Principia.* This work's debt to Halley was well expressed by Augustus De Morgan: ". . . but for him, in all human probability, that work would not have been thought of, nor when thought of written, nor when written printed." Halley calculated the orbit of the comet of 1682, and his correct prediction of its return in 1758 was the first application of Newton's laws of motion. His work on comets involved the calculation of orbits for all those for which sufficient observations existed, and, as well as making the important discovery that some comets are periodic, he noticed that their orbital planes are distributed at random, in sharp distinction to those of the planets. Under instructions from the admiralty he commanded the war sloop "Paramour Pink" from 1698 to 1700 on the first sea voyage undertaken for purely scientific purposes and again in 1701 during a survey of tides in the English channel. In 1703 Halley was appointed Savilian professor of geometry at Oxford and in 1720 he succeeded John Flamsteed as astronomer royal. Although then in his 64th year, he undertook to observe the moon through an entire revolution of its nodes (18 years), and actually carried out his purpose. Halley also detected the proper motions of the stars (1718), the acceleration of the moon's mean motion (1693) and the long inequality of Jupiter and Saturn. He indicated first in 1679 and again in 1716 a method extensively used in the 18th and 19th centuries for determining the solar parallax by means of the transits of Venus. He died at Greenwich on Jan. 14, 1742.

As an observational astronomer Halley was much inferior to Flamsteed and his astronomical observations remained largely unreduced and unpublished. His genius lay in discussing large bodies of data and reducing them to some kind of order. His *Breslau Table of Mortality,* published in 1693, is one of the first attempts to found tables of annuities on a basis of fact. He was the originator of graphical methods of representing on maps the geographical distribution of the physical features of the earth; the first meteorological chart appeared in 1688 and the first magnetic chart in 1701. The magnetic charts, constructed from all available observations augmented with many of his own made in England and on sea voyages, were of great practical value and were used for many years after his death.

Halley's principal works are *Catalogus stellarum Australium* (1679), the substance of which was embodied in the third volume of Flamsteed's *Historia coelestis* (1725); *Synopsis astronomiae cometicae* (Eng. trans., *A Synopsis of the Astronomy of Comets,* 1705); *Astronomical Tables* (1752); and 81 papers scattered through the *Philosophical Transactions* of the Royal society. To these should be added an edition of the *De sectione rationis* (1706) and the *Libri conicorum* of Apollonius of Perga (1710). Two books of the *De sectione rationis* and three of the *Libri conicorum* were known only in Arabic and Halley, after learning this language for the purpose and with some help from an Arabic scholar, produced a translation including a restitution of some passages in

which the Arabic text was corrupt. One lost book was restored from a summary given by Pappus and from references to it elsewhere in Apollonius. Halley also edited an unauthorized version of Flamsteed's *Historia coelestis* in 1712.

HALLGRÍMSSON, JÓNAS (1807–1845), one of the greatest and most popular poets of Iceland, was born at Hraun in Öxnadalur in the north of the country. He began his education at the school of Bessastaðir, near Reykjavik, from which he graduated to the University of Copenhagen, Den., in 1829. He first of all studied law and afterward turned to science and literature. Hallgrimsson returned to Iceland in 1837 and engaged himself in scientific research in the island with the support of the Danish government until 1842. He then returned to Copenhagen, to remain in Denmark until his death in 1845.

Valuable as was Hallgrimsson's work as a scientist, he is remembered chiefly as a poet. His poetry is predominantly lyrical, and he excels in descriptions of Icelandic scenery. He greatly admired the romantic poets, especially Heinrich Heine, and adapted and translated much foreign poetry into Icelandic. Hallgrimsson's interest in romantic poetry led him to revolt against and criticize the *rimur*, narrative poems in traditional, artificial form, composed in stereotyped metres and phrases, which had long been popular in Iceland. He strove to puriiy and to simplify the language of poetry as Wordsworth did in England. Hallgrimsson's poetry is filled with patriotism and with a love of nature, and some of it was inspired by stories of ancient Icelandic heroes as well as by the Edda and other mediaeval poetry.

Much of Hallgrimsson's poetry was published in the periodical *Fjölnir*, which he, together with other Icelandic students, founded in Copenhagen in 1835. He was also the author of critical works and of short stories in prose, some of which were published in *Fjölnir* after his death.

See the complete works of Hallgrimsson, published under the title ***Rit***, 5 vol. (Reykjavik, 1929–36); also Richard Beck, History of Icelandic Poets, *1800–1940* (Ithaca, N.Y., Oxford, 1950). (G. T.-P.)

HALLMARK is a series of symbols stamped on an article of gold or silver to denote that it conforms to one of the legal standards. These standards define the maximum proportion of base metals which may be alloyed with pure gold or silver for hardening or other purposes. The presence of a hallmark on an article indicates that it has been sampled and tested at an authorized assay office. Most articles are required by law to be hallmarked before sale, although there are certain exemptions (*e.g.*, gold rings other than mourning or wedding rings).

Hallmarking in Great Britain dates from the reign of Edward I. A statute of 1300 provided that no gold or silver should be sold until tested by the "Gardiens of the Craft" and struck with the leopard's head. The London Guild of Goldsmiths (later the Worshipful Company of Goldsmiths) has since that date been responsible for the assay and marking of plate in London. The word hallmark means literally a mark applied at Goldsmiths' hall. There are now also assay offices at Birmingham, Chester, Sheffield, Edinburgh and Glasgow. (J. S. Fs.)

In the United States, there are no hallmarks on silver or gold objects, since there is no history of guild or government regulation comparable to that of Great Britain. Local regulatory practices were established in New York, Boston, Mass., Baltimore, Md., and elsewhere in the late 18th and early 19th centuries, but no consistent system of symbols was adopted. Maker's marks appear, usually consisting of the initials or name of the maker. Beginning in the early 19th century the words coin (900 parts fine silver to 100 parts alloy) and sterling (925 parts fine silver to 75 parts copper) were stamped on silver objects and in 1906 the use of the words became subject to federal regulation. The purity of gold is given in carats, pure gold being 24 carats; its marking is also subject to federal regulation. (X.)

MARKS ON SILVER

The history of the symbols making up a complete hallmark on modern silver (fig. 1) is as follows.

Town or Assay Office Mark.—The leopard's head, first known as the king's mark. indicated that a silver article was of sterling standard; *i.e.*, containing at least 92.5% fine silver. When the lion passant was introduced as the standard mark (see below), the leopard's head was retained as the London town mark. In 1478 a crown was added (see fig. 2); but since 1821 the head has remained uncrowned. Provincial offices, when subsequently recognized, had their own distinctive town marks (fig. 3).

Maker's Mark.—This was introduced by a statute of 1363. At first a device was used, examples being a fish, a key or a fleur-de-lis, often taken no doubt from the sign outside the goldsmith's shop. Gradually, it became the practice for the maker to use the initials of his Christian and surnames, either alone or in conjunction with a device.

In 1697, when the Britannia standard was introduced (see below), the adoption of the first two letters of the maker's surname was made compulsory. The previous form of mark was revived in 1720 when the sterling standard was restored. The new mark, however, was struck on articles made in the Britannia standard. In 1739 a statute ordered all silversmiths to substitute for their two existing forms of mark a single one with the initials of their Christian and surnames in new characters.

Manufacturers are obliged to register their marks at the assay officeto which they submit their wares. The original significance of the maker's mark has been lost to some extent by the occasional use of the registered mark of the subsequent retailer in place of that of the manufacturer.

Date Letter.—The assaying of plate was entrusted to one of the wardens of the London Goldsmiths' company, who held office for one year. It is probable that it was in order to identify the warden responsible for assaying a particular ware that an alphabetical date-letter system was introduced (fig. 4). Such a system is known to have existed as early as 1478. The letter was changed annually and, on completion of one alphabet, the character of the letters or the shape of the surrounding shield was altered. This practice has been adopted by all British assay offices. The London office uses the alphabet from A to U omitting the J and changes the date letter each May. At the Birmingham, Sheffield and Chester offices, the alphabets selected are of 25 letters; the change is made each July.

The date letter denotes the year of assay and marking, not necessarily that of manufacture, although in most cases these are the same. Occasionally an old ware which has not been previously submitted is sent to be marked so that it can be sold legally.

Standard Mark or Marks.—Sterling Standard.—The lion passant (fig. 5[A]) was introduced in 1544 and is used by all the English offices to denote that a silver article is of the sterling standard. At Edinburgh the sterling standard mark is a thistle and at Glasgow a thistle and a lion rampant (fig. 5[B]).

Britannia Standard.—In 1697 the standard of wrought plate was compulsorily raised to 95.84%. This step was taken to prevent silversmiths from melting coins for their raw material. The figure of Britannia and a lion's head erased replaced the lion passant and leopard's head respectively on silver of this standard which was known as Britannia or New Sterling. The higher silver content resulted in a softening of the alloy. Consequently, it proved to be not entirely suitable for domestic plate and in 1720 the old standard was restored together with the former marks. Articles which are made occasionally in the higher standard are struck with the Britannia marks (fig. 5[C]). For this standard the English provincial offices use their normal town marks in conjunction with the figure of Britannia. The Edinburgh and Glasgow offices include the lion's head erased with the figure of Britannia and their own town marks.

Additional Marks.—The following are sometimes found on silver.

Duty Mark.—From 1784 a duty imposed on plate was collected by the assay offices on behalf of the commissioners of customs and excise. To signify that the duty had been paid, a mark consisting of the sovereign's head in profile was struck in addition to the usual symbols. The duty was finally abolished in 1890 (in 1798 in respect of watchcases), the mark then becoming obsolete. Silver of this period therefore normally bears the head of one of the following: George III (fig. 6[A]), George IV, William IV, Victoria (fig. 6[B]).

Silver Jubilee Mark.—A special mark of the crowned heads of

EXAMPLES OF BRITISH HALLMARKS FOR GOLD AND SILVER WARES

King George V and Queen Mary was authorized in 1935 to commemorate their silver jubilee (fig. 6[C]). This was not a compulsory mark but was struck by the assay offices at the manufacturer's request on silverware made in 1933, 1934 and 1935.

Coronation Mark.—A special voluntary mark was authorized by Queen Elizabeth II to commemorate her coronation (fig. 6[D]). It represented the crowned head of the sovereign and was struck on wares bearing the date letter for 1952–53 or 1953–54.

MARKS ON GOLD

The fineness of gold alloys is usually expressed in carats, pure gold being 24 carats. The legal standards for gold plate prior to 1798 were as follows: 1300–1477, 19⅓ carats (80% gold); 1477–1575, 18 carats (75%); 1575–1798, 22 carats (91.66%). The hallmarks used were identical to those on silver. An act of 1798 authorized an additional standard of 18 carats which was marked with a crown and the figure 18. The lion passant continued to be struck on 22-carat gold until 1844 when a crown and the figure 22 were substituted. At Edinburgh a thistle and at Glasgow a thistle and a lion rampant take the place of the crown.

In 1854 lower standards of 15, 12 and 9 carats (62.5%, 50% and 37.5% gold) were permitted. The prescribed marks were the carat figure and its decimal equivalent. In 1932 the 15- and 12-carat standards were abolished in favour of one of 14 carats (58.5%). (*See* fig. 7.)

The maker's mark and town mark on gold wares are the same as for sterling silver except that a York rose replaces the crown at the Sheffield office. The date letter is frequently surrounded by a shield of a different design.

The duty and coronation marks are also to be found on gold.

PROVINCIAL, SCOTTISH AND IRISH MARKS

Provincial.— Under a statute of 1423, York, Newcastle, Lincoln, Norwich. Bristol. Salisbury and Coventry were allowed to assay and mark plate, although there is no evidence that this was ever carried out in the last two cities. Assay offices existed, however, at Chester, York, Exeter and Newcastle in the 18th and 19th centuries. Offices in Birmingham and Sheffield were opened in 1773, the responsible bodies being "The Guardians of the Standard of Wrought Plate in Birmingham" and "The Guardians of Wrought Plate within the Town of Sheffield."

Marks have been found on antique silver which have been ascribed to other provincial towns; *e.g.*, Barnstaple, Hill, Plymouth and Taunton. Although such pieces are sometimes of great interest, their marks were probably not applied by any recognized office.

Scottish.— An act of 1457 provided for the election in Edinburgh of a deacon to be responsible for controlling the standard. The marks of the maker and deacon were to be stamped on all gold and silver plate. The town mark for Edinburgh, a castle, was added in 1485. In 1681, after a date-letter system had been introduced, the deacon's mark was replaced by the initials of the assay master. This was discontinued in 1759 with the introduction of the thistle as the mark to denote the standard. Plate has been marked in Glasgow since the 17th century but it is improbable that an authorized assay office was established there before 1819. Marks occasionally found on Scottish silver have been attributed to Aberdeen, Arbroath, Dundee, Greenock. Wick, etc.

Irish.— At Dublin a charter of 1637 prescribed a crowned harp mark indicating the standard and a maker's mark. A date letter was also used. These marks became statutory in 1729. The date letter. however, is often missing on Dublin marked silver of the 18th century and an act of 1729 provided primarily for a duty on gold and silver. A further mark consisting of the figure of Hibernia was struck to denote that duty had been paid. In 1807, after the union with Great Britain, the mark of the sovereign's head was added. It was discontinued in 1890 when the plate duty was abolished. The figure of Hibernia has been retained.

The symbols used on gold are the figure of Hibernia. the date letter and the folloning standard marks: 22 carats, crowned harp; 20 carats, plume of feathers; 18 carats, unicorn's head; 14 carats, "14.585"; g carats, "9.375." Irish marks applied after 1922 are not recognized in the U.K.

MARKS ON IMPORTED WARES

Many countries outside the United Kingdom have a system of plate marks but these are not legally recognized in the U.K. Imported foreign wares were first required to be hallmarked by the Customs act, 1842. The importer's mark replaced the maker's mark. The same marks were in use until 1867 when a capital letter F was added. In 1904 distinctive marks were authorized for imported wares (fig. 8). The standard marks consist of the decimal equivalent in the case of silver and the carat figure followed by the decimal equivalent in the case of gold.

By the Hall-marking of Foreign Plate act, 1939, wares manufactured abroad more than 100 years before being imported or being sold in the U.K. are exempted from assay and marking.

HALLMARKING PRACTICE AND LAW

Assay Office Procedure.— Manufacturers normally send their wares to an assay office complete except for final polishing. Representative scrapings are taken from every article and accurately assayed by chemical methods. Articles which pass are stamped with the appropriate symbols of the hallmark, but any which are below the lowest standard are required by law to be broken before being returned to the manufacturer. An exception is made in the case of a substandard foreign ware. The importer or owner has the option of exporting such a ware within one month.

(See ASSAYING.)

Hallmarking Offenses.— Forgery of hallmarks is a felony. On conviction an offender is liable to a maximum penalty of 14 years' imprisonment. Transposition of hallmarks from one ware to another is likeuise a felony as is the sale, with guilty knowledge, of wares bearing forged or transposed marks.

Where an addition or alteration to a hallmarked article is intended the law requires that it shall be submitted again to an assay office. Additions of base metal are not allowed, nor is it permitted to add gold or silver of a lower standard than the original ware.

The sale or offering for sale or export of a ware that has not been hallmarked, unless it has been specifically exempted, is an offense, the penalty for which is a fine.

Foreign wares, if imported by a dealer, must be hallmarked at the time of entry into the country by arrangement with the customs authorities. The obligation is waived in the case of a private person who makes a statutory declaration that he does not intend to sell such wares.

HALL OF FAME. The Hall of Fame for Great Americans is a semicircular granite colonnade on the campus of New York university at New York city. It was established in 1900 from a gift of $100,000 (later $250,000) by Mrs. Finley J. Shepard, and was dedicated in 1901 when the first 29 inscriptions of outstanding Americans, including Washington, Lincoln, Webster, Franklin, Grant, Marshall and Jefferson, were unveiled. On the walls of the open colonnade are 150 panels destined to be filled with bronze inscriptions surmounted by busts of the persons elected. Selections are made each five years (1940, 1945, etc.) by a committee of 100 prominent electors representing each state in the union and appointed by the New York university senate. Nominations may be made by any citizen of the United States.

Eligible nominees must have been dead 25 years or more and must receive a vote of three-fifths of the electors. At first only native-born U.S. men were qualified for election, but the rules were later changed to permit the election of women and of distinguished foreign-born U.S. citizens.

HALLOWEEN (ALLHALLOWS EVEN) is the evening of Oct. 31. In its strictly religious aspect, this occasion is known as the vigil of Hallowmas or All Saints' day, Nov. 1, observed by the Roman Catholic and Anglican churches. Pope Gregory III (731–741) assigned this date for celebrating the feast when he consecrated a chapel in St. Peter's basilica to all the saints. Gregory IV extended the feast to the entire church in 834. The vigil of All Saints, which constitutes Halloween in the church calendar, is as old as the feast.

Students of folklore believe that the popular customs of Halloween exhibit traces of the Roman harvest festival of Pomona and of Druidism. These influences are inferred from the use of nuts and apples as traditional Halloween foods and from the figures of witches, black cats and skeletons commonly associated with the occasion.

In Latin countries the evening of Oct. 31 is observed only as a religious occasion, but in Great Britain, Ireland and the United States ancient Halloween folk customs persist alongside the ecclesiastical observance.

Evidence that Halloween reflects influences from the festival of

Pomona is scanty, but the occasion shows clear connections with the religion of the Druids in pre-Christian Ireland and Scotland. The Celtic year ended on Oct. 31, the eve of Samhain, and was celebrated with both religious and agrarian rites. For the Druids, Samhain was both the "end of summer" and a festival of the dead. The spirits of the departed were believed to visit their kinsmen in search of warmth and good cheer as winter approached. It was also the period for threshing and of food preparation for the winter season.

Divination and auguries for the new year mere practised at Samhain. These magical practices concerned such questions as who would die during the next year, the identity of future marriage partners and the chances of good fortune. It was also an occasion when fairies, witches and goblins terrified the populace. These agents of the supernatural were alleged to steal infants, destroy crops and kill farm animals. Ronfires were lighted on hilltops on the eve of Samhain. The fires may have been lighted to guide the spirits of the dead to the homes of their kinsmen or to kill and ward off witches. This Halloween fire ceremony persisted, particularly in Scotland, as late as the 19th century.

There is little doubt that the Christian church sought to eliminate or supplant the Druid festival of the dead by introducing the alternative observance of All Saints' day on Nov. 1. This feast was established to honour all saints, known or unknown, but it failed to displace the pagan celebration of Samhain. In 998 A.D. Odilo, abbot of Cluny, made another effort to Christianize the occasion by instituting in all Cluniac monasteries the feast of All Souls' day on Nov. 2. This celebration honoured all those who died in the faith and had some, though incomplete, success in neutralizing the ancient pagan rites.

As Christianity spread gradually over Europe and the British Isles, it attempted to displace or suppress pre-existing pagan cults devoted to the worship of such deities as Apollo, Diana or Ymir. Though the church mas able to destroy the temples and outward forms of worship of these heathen religions, it could not completely eradicate the faith and beliefs of their priests and worshippers. These found an outlet during the middle ages in witchcraft which was devoted to the worship of Satan. This cult included periodic meetings, known as witches' Sabbaths, which were given over to feasting and revelry. One of the most important Sabbaths was held on Halloween. Witches were alleged to fly to these meetings on broomsticks, accompanied by black cats who were their constant companions. Stories of these Sabbaths are the source of much folklore about Halloween.

By the end of the middle ages, the celebration of Allhallows Eve was an established part of the annual calendar of the Roman Catholic Church. However, after the Reformation, Protestants rejected this feast along with other important ones such as Christmas and Easter. Nevertheless, Halloween folk customs of pagan origin flourished in Ireland, Scotland, Wales, parts of England and in isolated localities such as the Orkney and Shetland Islands. In these places, the inhabitants lighted bonfires on hilltops on the evening of Oct. 31 and played Halloween games such as "bob apple." They also engaged in divination by such means as pulling kale, placing stones or nuts in the fire and throwing a shoe over the house. Some divination occurred even on the church porch, which was believed to be an especially reliable place to learn of future events.

Pranks and mischief were also common on Halloween in rural areas of Ireland and Great Britain. Wandering groups of celebrants blocked doors of houses with carts, carried away gates and plows, tapped on windows, threw vegetables at doors and covered chimneys with turf so that smoke could not escape. In some places, girls and boys dressed in clothing of the opposite sex and, wearing masks, visited neighbours to play tricks. These activities generally resembled the harmful and mischievous behaviour attributed to witches, fairies and goblins. The contemporary "trick or treat" custom resembles an ancient Irish practice associated with Allhallows Eve. Groups of peasants went from house to house demanding food and other gifts in preparation for the evening's festivities. Prosperity was assured for liberal donors and threats were made against stingy ones. These contributions were often demanded in the name of Muck Olla, an early Druid deity. or of St. Columb Cille, who worked in Ireland during the 6th century. In England some of the folk attributes of Halloween were assimilated by Guy Fawkes day, celebrated on Nov. 5. Consequently Halloween lost some of its importance there.

Immigrants from Great Britain and Ireland took secular Halloween customs to the U.S., but the festival did not become popular in that country until the latter part of the 19th century. This may have been because it had long been popular with the Irish, who migrated there in large numbers after 1840. In any event, a number of the traditional Halloween symbols and folk practices appeared in the U.S. during the late 1800s. Among these mere the figures of the witch, the black cat, the death's head cut from a pumpkin, candles, bobbing for apples, the "trick or treat" custom, masks, parties and pranks. Though some churches observed Halloween with religious services, most persons regarded it as a secular festival. This reflected the prevailing American Protestant attitude toward a great many church festivals and holy days.

During the latter decades oi the 19th century, Halloween pranks and mischief became common in the U.S. and often descended to vandalism. In rural areas, fences were built across roads, wagons placed on top of barns, gates removed, outbuildings overturned and farm animals hidden. In cities and towns, "spooks" placed porch furniture on top of telephone poles, overturned garbage cans, opened water faucets and soaped windows in houses and stores. In some cities overenthusiastic celebrants filled cloth sacks with flour and rubbed these against the clothing of passers-by.

In the course of the 20th century, the American public became less tolerant of Halloween pranks. This mas the result, in large part, of a different mode of life, brought about by increasing urbanization and the ubiquity of the automobile. These factors altered the material environment and lessened the vitality of folk beliefs and customs. In addition, Halloween mischief became very costly to property owners and was of serious concern to public officials.

Consequently, civic authorities and private citizens attempted to deal with this difficulty by both repressive and educational means. As early as 1908 some U.S. communities sponsored Halloween parties for the young in the hope of preventing injury to life or possessions. The police, local merchants or civic groups organized these festivities, and both parents and teachers cautioned children against vandalism. In some instances, merchants even invited the young to soap the windows of their stores on Halloween in the belief that this might lessen property damage. These efforts had only limited success.

The tendency to manipulate rather than to celebrate folk festivals such as Hallomeen is characteristic of the 20th century. It reflects the growing influence of a rational outlook on life and the loss of interest in imagination and fantasy. The secular character of contemporary culture is also reflected in public neglect of the religious significance of Halloween as well as in progressive loss of its folk vitality. Children are least affected by this disenchantment and consequently the more important folk occasions tend to be dominated by the young.

HALLSTATT. The first Iron Age of central and western Europe and the Balkans is known as the Hallstatt period after the place of that name in upper Austria. It is not the cradle of the earliest Iron Age culture, but the site where objects characteristic of it were first identified. There, between 1846 and 1899, more than 2,000 graves were found. The majority fall into two groups, an earlier (*c.* 900–700 B.C.) and a later (c. 700–400 B.C.). Hallstatt became an important settlement in the first Iron Age. Both cremation and inhumation were practised, the latter slightly preponderating. The cremation graves are on the whole the richer and, viewed in the mass, contain older objects than the inhumation burials, but this should not be pressed too strictly, for the two rites overlapped chronologically. Most of the types of grave furniture are found elsewhere in phase C and D burials (*see* below), but objects of a peculiar character occur as well. The pottery unearthed by the earlier excavators was practically all destroyed. Near by lies the prehistoric salt mine where salt was extensively obtained. A number of shafts were sunk, often to a considerable depth, sometimes at a steep angle. Thanks to the preservative nature of the salt, their implements, parts of their clothing and even (at Hallein as well as at Hallstatt) the bodies of the miners themselves have come to light.

Typology and Art.—Reinecke divides the Hallstatt period into four phases, A, B, C, D (*see* ARCHAEOLOGY: *Iron Age*). He equates the first of these with the period of the urn-field culture. Schumacher regards the latter as comprising the last phase of the Bronze and the first of the Iron Ages. Others hold that Hallstatt A and B are in reality the latest Bronze Age, and that the Iron Age did not begin until Hallstatt C. Others regard it as the last period of the Bronze Age. The fourfold division is adhered to in the following account.

Phase A.—Iron, though known, is rare, but Villanovan influences are already apparent. The rite is cremation in cemeteries of flat graves (or under very low mounds). The pottery in southwest Germany is thin walled of various forms, some betraying strong metallic influence. The large urns often contain a number of smaller vessels (fig. 1). Farther east (Stillfried, Mariarast, etc.) the Silesian influence (Lusatian B) is noticeable in much of the pottery. Among the metal objects are: Antennae, Ronzano (fig. 2) and other bronze swords; razors (fig. 3) and knives, compound fibulae and, in the east, harp and simple bow brooches, torques, pins,

TYPES OF GRAVE FURNITURE OF THE HALLSTATT PERIOD

PHASE A; (1) Urn containing smaller vessels, (2) Ronzano bronze sword, (3) Metal razor, (4) Brooch, (5) Vessel with "sun boat and swans": PHASE B; (6) Globular urn, (7) Bronze sword with scrolled ohape, (8) Vase-headed bronze pin: PHASE C; (9 & 10) Bronze pins, (11) Winged Hallstatt axe, (12) Urn with conical neck, (13) Bronze girdle mount, (14) Onion-shaped urn, (17) Pointed tutulus: PHASE D; (15) Girdle mount, (16) Earring, (18) Cup brooch, (19) Urn, (20) Early archalo Greek vessel

the so-called "Old Italian" bronze vessels: cups, vessels with "sun boat and swans" (fig. 5), etc.

Phase B, if it can be said to have a general chronological significance, is marked by the reassertion of the old Bronze Age population of southwest Germany over the comparatively newly come urn-field peoples. It is confined to the more western regions. The tumulus again becomes common; cremation is the usual rite. The pottery (sometimes polychrome) is extremely well made and of various forms. The urns are often globular in body and with funnel-shaped necks (fig. 6) and influenced by Hallstatt A and older Bronze Age forms. The chief metal objects which have been found are the slender bronze Hallstatt sword with winged or slightly scrolled chapes (fig. 7) and the vase-headed pin (fig. 8).

Phase C.—Iron is first in general use. The rite is mixed; the tumulus prevails. The pottery is both polychrome and unpainted (often with polished graphite slip). In the west the urns are more onion shaped than in phase B (fig. 14); the Bronze Age chip carving (Kerbschnitt) reappears. In the east—Moravia, eastern Austria, etc.—where the culture of D is not represented, this phase probably lasted longer. The urns (graphite or polychrome) often have high conical necks (fig. 12); the so-called "moon idols," their horns often ending in beasts' heads, are very characteristic (fig. 13). Among the many metal types are: long, heavy iron and bronze swords with beautifully scrolled chapes; the winged Hallstatt axe (fig. 11); long bronze girdle mounts with *repoussé* ornamentation (fig. 13); various types of pins (fig. 9 and 10); fibulae, rare in the west (spiral spectacle and half-moon brooches), in the east, these and other types; bronze vessels (broadly ribbed bucket and other types); chariot-and-horse-harness—among the latter, the pointed tutulus (fig. 17), a type which occurs in the warrior's tomb at Corneto and gives a synchronism with Italy.

Phase D.—Not represented in eastern Austria, etc., but lasts until the appearance of the La Tène period (*q.v.*) in other areas. The tumulus prevails; the rite is mostly inhumation. The pottery, which is not common, degenerates; the urns are derived from C forms but are less crisp in profile (fig. 19). Among the metal objects are: the dagger-sword (sometimes one edged) with "horseshoe" or antennae hilt; pins are rare, brooches common (the drum, cup [fig. 18] and the later variants of the bow and serpentine fibulae); a variety of ring ornaments: ear- (fig. 16), neck-, arm- and footrings; girdle mounts, shorter than in C, sometimes in pierced work (fig. 15); bronze vessels, among them the narrowly ribbed bucket, and in upper Italy and the Veneto-Illyrian zone, situlae with figured motifs in friezes, stylized scenes from everyday life. Early archaic Greek vessels appear in the west, Pertuis (fig. 20), Grachwyl, etc. Amber occurs in C and D, gold mostly in D; ivory, lignite, jet and coral are not unknown, the last is found in D.

Hallstatt art, with the exception of the Veneto-Illyrian "situla style," is severely geometric in feeling; the advances made were on technical rather than aesthetic lines. It reveals indirect connections with the Greek Dipylon art, but developments of older Bronze Age elements are more prominent. There is a general tendency toward the extravagant, the baroque. The Greek orientalizing influence is hardly felt. Even the figural motifs are geometric in feeling as is shown by urns from Oedenburg and many of the girdle mounts; these are mainly confined to the Austrian area. The typical bird motif, probably derived from Italy, may perhaps be traced back to late Helladic times in Greece. Plant patterns are very rare and strongly stylized (Urmitz). Among the other motifs are lozenges, triangles, concentric circles, arcs, chevrons, "garlands," herringbone groups of parallel lines (sometimes grooved) and occasionally the swastika, triskele and maeander, etc. Contrasts in colour and the breaking up of smooth surfaces were in favour. The arrangement of figures in pairs is very characteristic. In H_3 pottery we find designs grouped in a circular field around a star or cross, or arranged in bands. Generally speaking, the arrangement consists in mechanical repetitions and a rigid regard for symmetry, rather than in the treatment of the design as an organic whole. Compared with the art of the northern Bronze Age or of the La Tène period, the Hallstatt style is lifeless and sterile.

HALLUCINATION, a psychological term denoting a response the stimulus of which is within a person's phantasy but is mistakenly ascribed by the responding individual to sources outside it. Hallucination must be distinguished from illusion, which denotes the misinterpretation of verifiable receptor stimulation. The most common varieties of hallucination are the auditory, which include voices, mutterings, laughter, cries, bells, music and shots, and the visual, which may be of everyday persons, animals. objects and scenes, or of something strange, horrible or unearthly. Hallucinations of smell, taste and movement and of visceral and cutaneous sensitivity are not unusual. One, two or several varieties of hallucination may be present at the same time.

Hallucination occurs most commonly in ordinary dreaming; it may also develop during periods of deep preoccupation. In the person who is awake, hallucination is facilitated by profound emotional arousal or urgent need, and it is supported by delusional attitudes. Thus, under conditions of great excitement, fear, ecstasy or tense anticipation, many persons report seeing and hearing things which they would otherwise identify as their own phantasy. The hallucination of a person suffering from transient, chronic or progressive delusion is nearly always in keeping with his previously delusional convictions, and its character is in large part determined by his personality organization. *(See* ABNORMAL PSYCHOLOGY.)

See Norman Cameron, *The Psychology of Behavior Disorders* (Boston, London, 1947). (N. A. CN.)

HALLUIN, a frontier town of northern France, in the department of Nord, near the Lys, 14 mi. N. by E. of Lille by rail. Pop. (1946) 12,935. The family of Halluin, which became extinct in the 14th century, is mentioned in the 13th century. Halluin has a Gothic church. The manufactures comprise linen and cotton goods, chairs and rubber goods, and brewing and tanning are carried on; there is a board of trade arbitration.

HALM, CARL FELIX (1809–1882), German classical scholar and critic, was born at Munich on April 5, 1809, and died there on Oct. 5, 1882. He is known chiefly as the editor of Cicero. He also edited a number of other classical texts for the Teubner series, the most important of which are Tacitus (4th ed., 1883); *Rhetoves Latini minores* (1863); Quintilian (1865); Sulpicius Severus (1866); Minucius Felix together with Firmicus Maternus, De *errore* (1867); Salvianus (1877); and Victor Vitensis's *Historia persecutionis Africanae provinciae* (1878).

HALMAHERA ("great land"; also Djailolo), an island of Indonesia in the administrative district of Ternate, lying under the equator and about 128° E. It consists of four peninsulas enclosing three great bays: Kau (northeast). Buli (east) and Weda (southeast); and its total area is 6,500 sq.mi. The northern peninsula is connected, with the others by an isthmus, only 5 mi. wide, on the western side of which lies Dodinga bay. In the mouth of this bay are the two islands Ternate and Tidore, whose political importance exceeds that of the larger island *(see* these articles). Of the four peninsulas of Halmahera the northern and the southern are reckoned to the sultanate of Ternate, the northeastern and southeastern to that of Tidore; the former having 11, the latter 3 districts. The four peninsulas are traversed in the direction of their longitudinal axes by mountain chains 3,000 to 5,000 ft. high,

covered with forests rich in a great variety of trees. The mountain chains. from mhich spurs extend to the coast, are frequently interrupted by plains. The western and northern parts of the mountain chain of the northern peninsula are volcanic. the volcanoes continuing the line of those of Makian, Motir, Ternate and Tidore. Two volcanoes along this western coast are active and one. Gam Konora (5,364 ft.), is active on the north. Coral formations on heights in the interior would indicate oscillations of the land in several periods, but a detailed geology of the island is wanting. There are numerous small rivers and several lakes, and near Weda is a beautiful stalactite grotto. Halmahera is the largest island of the Ternate group of the Moluccas (*q.v.*).

The inhabitants are mostly of immigrant Malayan stock. In the northern peninsula, which is the most thickly populated, are found people akin to the Papuan-Malay type; and the members of a tribe around Galela resemble the Polynesians in physique and are possibly remnants. much mixed by subsequent crossings with the Papuan aborigines, of the Polynesian migration into the Pacific. Achille Raffray gave a description of them in *Tour du Monde* (1879): "They are as unlike the Malays as we are. excelling them in tallness of stature and elegance of shape. and being perfectly distinguished by their oval face, with a fairly high and open brow, their aquiline nose and their horizontally placed eyes. Their beards are sometimes thick; their limbs are muscular: the colour of their skins is cinnamon brown. Spears of ironwood, abundantly barbed, and small bows and bamboo arrows free from poison are their principal weapons." They are further described as having temples (*sabuas*) in which they suspend images of serpents and other monsters, as well as the trophies of war. They believe in a better life hereafter, but have no idea of a hell or a devil, their evil spirits only tormenting them in the present state. The people in the Tidore part of the island. as the result of keen propaganda of the sultans, are all Mohammedans, but in the Ternate division they are largely pagan. The people have crisp. wavy hair, a skin even lighter than that of the average Malay and are strongly built and well made. though the women are inclined to be thickset. They are true forest people, some nomads. living only in shelters. A loincloth, with headdress, is their only covering. They were headhunters in the past. and though generally orderly they are prone to violence from motives of revenge. Many indigenous dialects are spoken and on the coast Ternatan is largely used, but the official language is Indonesian (Bahasa Indonesia). The sago palm supplies their staple food, but they hunt. fish and cultivate the land in a simple style. growing chiefly rice and coconuts. They collect dammar gum (especially in Morotai), wild nutmegs and ironwood (*Mesua ferrea*) from the forests. In Ternate cacao and cloves are grown on the coconut plantations. The sea yields trepang and pearl shells.

The chief town is Gamsungi, with about 2,000 inhabitants in 1954, and other ports are Galela, Tobelo, Kau and Weda and Wayabula in Morotai. Galela is a considerable settlement, situated on a bay of the same name on the northeast coast, in a well-cultivated plain which extends southward and inland. In 1954 the population of Halmahera was about 55,000.

About 11 mi. N.E. of the northern peninsula is the considerable island of Morotai (635 sq.mi.), mhich is more than 50 mi. long and from 13 to 26 mi. wide, with mountains reaching 4,100 ft. (the Snbatai range) and several rivers. There are some Moslems and Christians among its population which numbered about 10.000 in 1954. During World War II Morotai was an important military base for the Japanese.

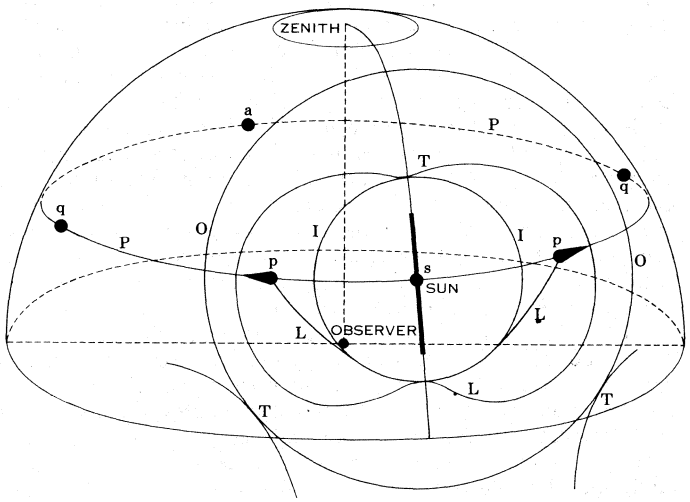
To the west of the southern peninsula lie the more important island of Batjan (*q.v.*) and other islands.

The Portuguese and Spaniards were better acquainted with Halmahera than with many other parts of the archipelago; they sometimes called it Batu Tjina, and sometimes Moro. It was circumnavigated by one of their vessels in 1525. The name (Djailolo) was really that of a native state, the sultan of which had the chief rank among the princes of the Moluccas before he was supplanted by the sultan of Ternate about 1380. His capital, Djailolo, lay on the west coast on the first bay to the north of that of Dodinga. The Dutch obtained a footing in Halmahera with the aid of their ally, the sultan of Ternate, and when they severed relations with this chief in 1683. the lands in Halmahera under the suzerainty of Ternate came under Dutch influence. By their treaty of 1660 with the sultan of Tidore, they had become overlords of all Tidorese fiefs and this had opened up to them that part of Halmahera under Tidorese influence. In 1876 Danu Hassan, a descendant of the sultans of Djailolo, raised an insurrection in the island against the authority of the sultans of Tidore and Ternate and would probably have been successful but for the intervention of the Dutch. The Moluccas were captured by the British in 1810, given back to the Dutch in 1814 who transferred sovereignty to the Indonesian republic in 1949. The Japanese occupied Halmahera in World War II.

HALMSTAD, a seaport of Sweden, chief town of the district (*län*) of Halland, on the east shore of the Cattegat, 76 mi. S.S.E. of Goteborg by the railway to Hälsingborg. Pop. (1960) 39,064. Mention of the church of Halmstad occurs as early as 1462, and the fortifications are mentioned first in 1225. The latter were demolished in 1734. There were formerly Dominican and Franciscan monasteries in the town. The oldest town privileges date from 1307 and Halmstad appears to have been frequently chosen as the meeting place of the rulers and delegates of the three northern kingdoms. Under the union of Kalmar it was appointed to be the place for the election of a new Scandinavian monarch whenever necessary. Until 1658, when it was ceded to Sweden, the *län* of Halland formed part of the territory of Denmark in Sweden. The town lies at the mouth of the Nissa river, having a harbour (20 ft. depth) and roads giving safe anchorage. In the neighbourhood there are quarries of granite, which is exported chiefly to Germany. Other industries are engineering, shipbuilding and brewing, and there are cloth, jute, hat, woodpulp and paper factories. The principal exports are granite, timber and matches, and butter through Halsingborg and Goteborg. The imports are coal, machinery, manures. jute and cloth. Potatoes are largely grown in the district, and the salmon fisheries are valuable. The castle is the residence of the governor of the province. There are both mineral and sea-water baths in the neighbourhood.

HALO, a luminous circle or a segment of a circle with the sun or moon in its centre caused by ice crystals in the atmosphere and is produced by the refraction or reflection of light rays striking or passing through the crystals. Halos of well-developed form are rare except in higher latitudes and in polar regions. where they attain great brilliance and considerable complexity, being accompanied by small coloured arcs or luminous columns or pillars. The similar phenomenon caused by difiraction by water or ice particles generally is referred to as a corona.

Parts of Halo.—The phenomenon of a halo as seen from the ground is represented schematically in the figure. The fundamental features of a halo are two circles surrounding the centre of illumination (S), the "inner" halo (I) and the "outer" halo (O),



FROM G. DIETZE EINFUHRUNG IN DIE OPTIK DER ATMOSPHARE

HALO AND RELATED PHENOMENA AS PROJECTED ON THE SKIES BY THE OBSERVER (IN THE CENTRE OF THE SPHERE). (AFTER G. DIETZE)

having radii of about 22° and 46°, respectively. Their inner contour is sharp and shows a distinct red tint. The spectral sequence of colours fades rapidly toward the outer. diffuse edge of the circle. Passing through the centre (S) and parallel to the horizon, a luminous white ring, the parhelic circle (P), can occasionally be seen with a number of bright coloured spots that are the images of the sun or moon (p). Of these images the most pronounced are situated at the intersections of the inner halo and the parhelic circle and are known as parhelia (mock suns or sun dogs) or as paraselenae (mock moons). They are quite brilliant when the sun is on the horizon. Their inner edges, directed toward the sun, are red, the outer edges are blue and they are extended into an arc For higher sun elevation they retain the same elevation as the sun, but their angular distances from the sun increase up to 45° for the sun elevation of 60°. Their angular width, as well as their brilliance, decreases with increasing sun elevation. The parhelia at the intersection of the outer halo and the parhelic circle are seen only on rare occasions. Other images on the parhelic circle are the paranthelia (q) and the anthelion (a). Paranthelia are situated 90°–140° from the sun on the parhelic circle while the anthelion is located at the antisolar point as a patch of white light often exceeding in size the apparent diameter of the sun.

Among other features occasionally observed are two different types of arcs. "Arcs of Lowitz" are two convex arcs (L in the figure) tangential to the inner halo, named after J. T. Lomitz. who first described these phenomena in 1794. Similar arcs can be seen as tangential to the visible upper and lower parts of inner and outer halos (T in the figure). On some occasions the arcs tangential to the inner halo seem to be prolonged and, for higher sun elevation, joined to give the appearance of a luminous closed curve.

Conditions of Formation. — The first step to a proper explanation of the halo and related phenomena was that of René Descartes who ascribed their formation to the effect of ice crystals. His explanation was pursued further by Henry Cavendish. Thomas Young, J. G. Galle and A. Bravais; Bravais demonstrated the general validity of the theory in his classical treatise about the halos published in the *Journal* de *l'École royale polytechnique* (1847).

The fundamental form of ice crystals in high level clouds (cirrostratus) or of those floating in lower levels in sub-zero weather is a hexagonal prism, either elongated as a needle or flattened like a thin plate. The rays of the sun or moon penetrate the crystals under three main refracting angles: 120° between two adjacent faces, 60° between tno alternate faces and go° between the prism face and the base. If a myriad of such crystals falls in any manner between the sun and observer, there will always be some prisms whose alternate faces are traversed by the sun's rays and these rays will be refracted. The deviation of the refracted rays from the incident direction depends on the angle of incidence. Among the large number of crystals occur crystal faces with all possible orientations and hence the refracted rays will fill up the range between the minimum and maximum deviation for 60° refracting angle. The rays will be crowded close to the minimum deviation and there mill be no refracted rays between the minimum deviation and the sun. Furthermore, the minimum deviation increases for shorter wave lengths, being smallest for the red light (22°). All the refracted rays will then form a circle, with sharp inner boundary of a red tint. In this way Edmé Mariotte, 17th-century physicist, explained the characteristic feature of the inner halo. Cavendish similarly explained the existence of the outer halo as the consequence of refraction under go° refracting angle; the minimum deviation in this case is 46°.

For the occurrence of these two halos no special arrangement of ice crystals is necessary. The circular shape of the halo indicates indeed all possible orientations of the symmetry axes of the prisms or plates. Nevertheless, certain arrangements of the ice crystals will predominate, for they will tend to fall with the axis so oriented as to offer the least resistance to their motion—a prolongated prism tending to keep its axis vertical, a plate-shaped crystal to keep its axis horizontal. If the axes of prolongated prisms are vertical and the sun is at the horizon, the refraction of the sun's rays by the alternate faces will produce the sun image at the same elevation as the sun, at an angular distance between the minimum and maximum deviation corresponding to the refracting angle of 60°. In this way the origin of parhelia and their characteristic features are explained. If the axes of the crystals deviate slightly from the vertical direction, the images of the sun will be moved from the parhelic circle, producing the arcs of Lowitz. When the sun's rays traverse the alternate faces of thin plates with their axes in a horizontal direction, a similar phenomenon will be produced, but above and below the sun. With all possible orientations of the horizontal axes of thin plates, a continuous series of parhelia will form the tangential arcs of the inner halo. The tangential arcs to the outer halo are due to the refraction through the faces inclined at go°; these arcs are more brilliant than those at the inner halo.

Some of the features described above and indicated in the figure can be explained as due to the reflection of the sun's rays either externally or internally from the faces or bases of the prism. Young explained the parhelic circle as caused by the reflection from the vertical faces of the long prisms and from the bases of the short ones. Reflections from the faces or bases slightly deviated from a horizontal position will produce a vertical pillar through the sun (see figure) observed on rare occasions. All features due to the reflection can be distinguished from those due to the refraction; they appear white, without the colouring always present with refraction. The paranthelia (q) and the anthelion (a) may be explained as being caused by two internal or two external reflections. The paranthelia will appear when the reflecting faces are inclined at 120°. Double internal reflection by an equilateral triangular prism would produce a single coloured image on the parhelic circle about 98° from the sun. The anthelion can be explained as being caused by two internal reflections of solar rays by a hexagonal prism of ice having its axis horizontal and one of the diagonals of its base vertical. The emerging rays are then parallel to their original direction and form a light spot on the parhelic circle opposite the sun. With the more complicated structure of the ice crystals other rare forms of halo may be produced.

Systematic observations of halos for 22 years (in the Netherlands) indicate the inner halo as the most frequent (in 209 days in a year at the average); the next are parhelia (71) and the tangential arcs to the inner halo (59). (Z. S.)

HALOGENS, a term applied to the chemical elements fluorine, chlorine, bromine and iodine because of the great similarity of their sodium salts to ordinary sea salt (Gr. *hals*, "salt," and *gen*, "to produce"). These four elements show a great resemblance to one another in their general chemical behaviour and in that of their compounds, while their physical properties show a gradual transition. Some of the properties of the halogens are tabulated below.

Some Properties of the Halogens

Name	Fluorine	Chlorine	Bromine	Iodine
Symbol	F	Cl	Br	I
Atomic number	9	17	35	53
Atomic weight	19.00	35.457	79.916	126.91
State at 70° F.	gas	gas	liquid	solid
Boiling point ° C.	—188	—34.7	58	183
Colour of gas	light yellow	green-yellow	red	violet
Electron affinity (Electron volts)	3.58	6.75	3.53	3.22

The halogens constitute main Group VII of the periodic system. Their atoms, having seven valence electrons, all readily combine with an additional electron to form a stable negative ion having a completed octet. The electron affinity given in the table is a measure, in electron volts, of the tendency for this reaction to occur with the atoms of the gaseous element. Fluorine is the most reactive (the best oxidizing agent) and iodine the least (see OXIDATION AND REDUCTION). Fluorides are formed with the greatest evolution of energy and are the most stable. Conversely. fluorine is prepared in the free state with the greatest difficulty and iodine with the least.

In the elementary state the halogens exist as diatomic molecules, the sharing of electrons by a pair of atoms satisfying in part their electron affinities. The binary compounds of the halogens,

except their oxides, are known as halides. The halides of the metals are solid saltlike substances and with a few exceptions, notably among the fluorides, soluble in water. The halide ions are colourless. The hydrogen halides are colourless gases, very soluble in water, forming strongly acid solutions. The halides of nonmetallic elements are volatile, reactive and generally decomposed by water.

In alkaline media the halogens, with the exception of fluorine, may be readily oxidized, the maximum state of oxidation being plus seven. While the oxygen-containing salts are fairly stable, the corresponding acids are not. The relative activity of the halogens in the oxidized state is reversed from that for the reduced state as halide ions. For example. chlorine will displace elementary iodine when added to potassium iodide solution, but iodine will displace chlorine from potassium chlorate, forming the more stable potassium iodate. That is, of the halide ions, iodide is the best reducing agent, and of the halogenates, chlorate is the best oxidizing agent.

A number of compounds have been made by direct combination of two halogens. Their formulas and melting points (° C.) are: IF_7 (5°), IF_5 (9.6°), ICl (two forms α 27.2°, β 13.9°), ICl_3 (101°), IBr (36°), BrF_5 (−61.3°), BrF_3 (9°), BrF (−33°), BrCl (−66°), ClF_3 (−83°) and ClF (−156°).

Element 85, or astatine (At), is a member of the halogen family but only short-lived radioactive isotopes are known. For additional information about astatine as well as other members of the halogen family see individual articles on each element.

(R. P. S.)

HALOPHYTES, a general name used in botany to denote plants growing in salt marshes and similar environments with a high salt content. Such plants often show adaptations for conservation of water. See PLANTS AND PLANT SCIENCE.

HALS, FRANS (c. 1580–1666), celebrated Dutch painter of portraits and groups, to whom, of all the Dutch school, only Rembrandt unquestionably and Vermeer more doubtfully may be considered superior by reason of their profounder spiritual or intellectual qualities. The originality of Hals rests largely in technique, and as a manipulator of oil paint he has few rivals in his own or any other age. Belonging to the first generation of the great era of Dutch art, he lived into the period when symptoms of decline were beginning to appear among the most literally "popular" painters in the form of glossy finish and laboured, imitative technique. Hals mas not a successful artist in the material sense, but he remained true to his instincts and, contrary to the nide current of Dutch painting, his style grew steadily looser, fresher and more spontaneous.

Hals's place of birth is credibly supposed to have been Antwerp, but the date is not certain. According to A. Houbraken, he was 85 or 86 when he died, which places his birth in 1580 or 1581; another early source states that he died aged "ninety, or not much less," while N. S. Trivas in the best modern monograph on the painter suggests that he was born "about 1585." The family moved to Haarlem while Frans was still a child, and it was in Haarlem that he lived and worked throughout his recorded life, but the question of where and under what masters he received his early training remains open. One tradition says that he studied in Haarlem under Karel van Mander, another that he was a pupil of Adam van Noort in Antwerp. Both may be true. His known work shows no trace of Van Mander, but it does show marks of Flemish style, in particular of the bravura of Rubens, whom he could conceivably have met in Van Noort's studio.

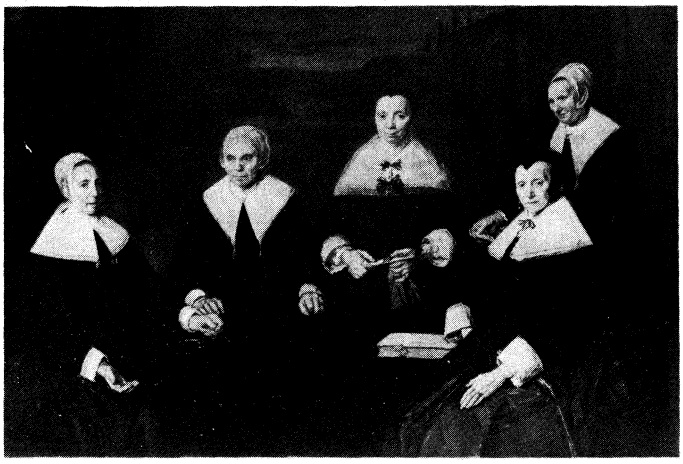
About 1608 Hals married Annetje Harmensdr, who died in 1615, and in 1617 he took as his second wife Lysbeth Reyniers, who outlived him. The number of his children varies in the accounts of different authorities, but it was certainly very large. Seven sons followed him in the career of painting, though not all of them are now knonn by identifiable works. The expense of supporting a huge family, aggravated by his own habits, uhich were irregular to say the least, can explain in part the poverty in which much of his long life was spent, but the fact remains that. in spite of occasional commissions for civic portraits, he was never a fashionable or highly paid artist, and his patronage was virtually confined to Haarlem. The records of his name in the city archives are mainly concerned with the succession of financial difficulties and disasters that beset him, and with measures taken to relieve or redeem his erring children. In 1662 he was granted a small pension, and in the winter of 1663/64 he was further provided by the city with three cartloads of fuel. He died on Aug. 29, 1666, and was buried in the Groote Kerk.

No work of Hals's youth has been identified. The earliest dated picture is the "Banquet of Officers of the St. Joris-Doelen" ("Civic Guard of St. George") of 1616, and on evidence of style a few portraits can be assigned to about the same date, such as "Nurse and Child" (Berlin) and "Man Holding a Skull" (Barber institute, Birmingham, Eng.). These are mature works, confident and crisp in handling, and in the "Banquet" Hals displays already his astonishing ability to give his heads the animation of fleeting yet characteristic expressions. His faces are never masks. By a swift collaboration of eye and hand he captures the momentary movements of expression about the eyes and mouth as his sitters smile or turn to speak to each other or to the spectator. Though his portraits seldom display the deep human understanding of Rembrandt, there are none that "live" more vividly on the canvas than his. There are no landscapes, still lifes, genre or historical subjects in Hals's work. His lifelong preoccupation was with living humanity. Burgher or beggar, his subject is set before us in the fullness of life, with no overtone of social or moral comment, no philosophy beyond the simple one that life is good. The painter's own zest for life is evident in the freedom and audacity of his brushwork, while the typical mood of his sitters ranges from confident good humour to downright merriment. Most of his pictures are single portraits of respectable Haarlem citizens, but there are also character studies of laughing children (his own) and of ragged but exuberant tavern society.

His most solid achievements are the eight large group portraits which hang in the Frans Halsmuseum, and no true idea of Hals's stature as a painter can be formed without seeing them. The first of these, the "Banquet" already referred to, shows understanding of contemporary baroque composition in its swinging diagonals through the rows of heads and the banner. Its colour is fresh and masterly, a harmony of black and white, enlivened by the red and orange of sashes and banner. Similar, but less interesting in design, is the "Banquet of Officers of the Cluveniers-Doelen" ("Civic Guard of St. Andrew") of 1623/24. In 1627 Hals painted a second "Banquet of Officers of the St. Joris-Doelen," in which one may admire an increasing freedom and vivacity of brushstroke while regretting an increasing carelessness in formal design. More thought is apparent in the composition of the "Meeting of Officers of the Cluveniers-Doelen" (1633), in which the open-air background was possibly painted by another hand.

The last and most formal of the civic guard groups is again of "Officers of the St. Joris-Doelen" (1639), and includes a self-portrait of Hals, who is to be seen second from the left in the rear rank. The fine seated group of "Governors of the St. Elisabeth Hospital" (1641) shows Hals at the height of his powers and is only excelled in its kind by Rembrandt's "Syndics," which it may have influenced. A gradual progression from bright colour to a more monochrome treatment can be traced in these pictures, culminating in the last two groups that Hals painted. These, both of 1664, are respectively of the "Men Governors" and the "Lady-Governors of the Old Men's Home at Haarlem." In both there is a moving quality in the presentation of character that the earlier pictures lacked, and the technique also attains a peak in which passion mingles with dexterity to move the spectator. The "Men Governors" suffers like many an earlier work from slipshod composition, but the "Lady-Governors" has no such fault. Firmly designed and marvelously handled, it is the crowning masterpiece of Hals's erratic career.

The single portraits show a parallel development toward more monochrome colouring and looser handling. Their quality becomes uneven in the later years, looseness sometimes degenerating into incoherence. Good examples are: the inaptly nicknamed "Laughing Cavalier" (1624, Wallace collection, London); "Portrait of a Man" (dated 1633, National gallery, London); "Man holding a



BY COURTESY OF FRANS HALSMUSEUM

"LADY-GOVERNORS OF THE OLD MEN'S HOME AT HAARLEM" BY FRANS HALS. IN THE FRANS HALSMUSEUM, HAARLEM. THE NETHERLANDS

Watch" (1643, Barnes foundation, Merion. Pa.); the portraits in Antwerp of "Stephanus Geraerdts" and his wife "Isabella Coymans" (about 1650/52); and the "Man in a Big Hat" (about 1661/64, Cassel). Of the character pieces, most of which belong to his earlier period, one may pick out "Malle Babbe, the Haarlem Witch" (Berlin) and the so-called "Gipsy Girl" (Louvre, Paris), both of about 1628.

Of Hals's pupils and followers in Haarlem the most talented was Judith Leyster, whose pictures are often confused with his.

DIRCK HALS (1591–1656), younger brother of Frans Hals the elder, was born in Haarlem. He was principally a painter of festive genre scenes, of which the earlier examples. such as "Cavaliers and Ladies at Table" (1626, National gallery), have the naive elegance seen also in W. Buytewech and W. C. Duyster. Some of the later ones aspire (less successfully) to the more polished grace of G. Terborch.

Of the sons of Frans Hals: HARMEN HALS (1611–1669) was a genre painter of the school of A. Brouwer and A. van Ostade; FRANS HALS, THE YOUNGER (c. 1620–1669), imitated his father and others with little subtlety (in "Malle Babbe and the Smoker," at Dresden, one figure is borrowed from Frans the elder, the other from Brouwer); REYNIER HALS (162 j?–1671) is represented by genre pictures of moderate quality in the Frans Halsmuseum; CLAES HALS (1628–1686) was a more varied artist, and his few known landscapes in the Ruisdael manner, such as "Village Street" (Ashmolean museum, Oxford), show considerable talent.

(R. E. W. J.)

HALSBURY, HARDINGE STANLEY GIFFARD, 1ST EARL OF (1823–1921). English lord chancellor remarkable for his grasp of legal principles and for his mastery in applying them, was born in London on Sept. 3, 1823. Educated at Merton college, Oxford, he was called to the bar at the Inner Temple in 1850, subsequently working at the central criminal court and at the Middlesex sessions. He became queen's counsel and a bencher of the Inner Temple in 1865. Giffard had twice unsuccessfully contested Cardiff as a Conservative candidate for parliament when he was appointed solicitor general by Disraeli in 1875 and knighted. From 1877, however, he represented Launceston, until he was created Baron Halsbury and appointed lord chancellor in 188 j. Halsbury held this post continuously from 1886 to 1892, and again from 1895 to 1905. In 1898 he was created earl of Halsbury and Viscount Tiverton and became the leader of the group of Conservative "die-hard" peers who resisted to the end the abridgement of the powers of the house of lords embodied in the Parliament act of 1911. The digest famous as *Halsbury's* Lams of *England* was produced under his direction between 1905 and 1916. Halsbury died in London on Dec. 11, 1921. (W. T. Ws.)

HALSEY, SIR LIONEL (1872–1949), British admiral, was born on Feb. 26, 1872, son of Sir Frederick Halsey of Gaddesden. He was educated at Stubbington house, Fareham. He entered the navy, joining H.M.S. "Britannia" in 1885, and was one of those who served in the defense of Ladysmith (1899–1900). For his services in the defense he was promoted commander in 1901. He nas promoted captain (1905), and after the outbreak of World War I was in command of H.M.S. "New Zealand" in the actions in the Heligoland bight (1914) and at the Dogger Bank (1915). At the battle of Jutland he served in H.M.S. "Iron Duke." In 1917 he was promoted rear admiral and appointed third sea lord, and from 1918 to 1919 commanded the Royal Australian navy. He acted as chief of staff to the prince of wales during his tours in Canada (1919), Australia and New Zealand (1920) and India and Japan (1921–22), being promoted vice-admiral in 1921. He retired in 1922, and was given the rank of admiral in 1926. He was created knight grand cross of the Royal Victorian order (1920), knight commander of the Indian empire (1922) and knight grand cross of St. Michael and St. George (1925). He died Oct. 26, 1949, at Biggleswade, Beds.. Eng.

HALSEY, WILLIAM FREDERICK (1882–1959), U.S. naval officer and commander of the 3rd fleet, operating in the Pacific area, during World War II, was born in Elizabeth, N.J., Oct. 30, 1882, the son of a naval officer, and graduated from the United States Naval academy in 1904. He became a naval aviator May 1 j, 193 j, was promoted to rear admiral in 1938, to vice-admiral in 1940 and to admiral in 1942. After commanding aircraft of the Pacific fleet, Halsey became commander of the South Pacific force and the South Pacific area on Oct. 19, 1942. Naval task groups under his command defeated the Japanese in the battle of Santa Cruz Islands, Oct. 26, 1942; the naval battle of Guadalcanal, Nov. 12–1 j, 1942; and in a series of lesser fights. He became commander of the 3rd fleet on June 15, 1944, and led his carrier task forces in brilliant air strikes. In the battle for Leyte gulf his fleet sank four Japanese carriers and a battleship. He led the U.S. forces in the final naval operations of the war around Okinawa, from May 28 to the Japanese surrender on Sept. 2, 1945. Halsey was promoted to the rank of fleet admiral on Dec. 12, 1945, and retired in 1947. He died on Aug. 16, 1959. (J. B. HN.)

HALSTED, WILLIAM STEWART (1852–1922), U.S. surgeon, who developed original operations for hernia, carcinoma of breast, goitre, intestinal and gall bladder diseases and aneurysms, was born in New York city on Sept. 23, 1852. He studied at Andover and Yale and took his medical degree from the College of Physicians and Surgeons, New York, in 1877, later studying in the European clinics of E. T. Kocher, Theodor Billroth, Richard von Volkmann and Ernst von Bergmann. Halsted was visiting surgeon at Bellevue, Presbyterian, New York and Roosevelt hospitals from 1880 to 1886. During this period he discovered the anesthetic properties of injected cocaine, to which in the course of his investigations he became addicted, recovering after two years of treatment. From 1886 to 1889 he worked in the laboratory of William H. Welch, and in 1890 was appointed professor of surgery at Johns Hopkins university, which position he held until his death on Sept. j, 1922.

A surgical philosopher, Halsted established at Johns Hopkins the first school of surgery in the United States. He emphasized the concepts of complete hemostasis, absolute asepsis, gentleness in the handling of tissues, and accurate reapproximation of divided tissues. concepts that are accepted as fundamental in all techniques of surgery. In 1890 he introduced the wearing of rubber gloves by all members of the surgical team during an operation. He was author of numerous surgical papers and of several monographs, published in two volumes in 1924 and reprinted in 1951.

(EE. F. H.)

HALTEMPRICE, an urban–district (1935) and parliamentary division of the East Riding of Yorkshire, Eng., on the Humber immediately west of Hull, for which it is a residential district. Pop. (1931) 16,757; (1951) 35,654. Area 14.1 sq.mi. It includes the old villages of Hessle, Anlaby, Cottingham, Kirk Ella, Willerby—all mentioned in Domesday—West Ella and Dunswell. A small Elizabethan manor house in Cottingham was built on the site of Baynard castle. Among the industries are horticulture

under glass. agricultural products, shipbuilding at Hessle, precision engineering, mink farming and the making of trailers, carpets and essences.

HAM (in the Douai version of the Bible, CHAM) is the name of Noah's second son. (Though he appears in Gen. ix, 24 as the youngest of Noah's three sons, close examination of this story makes it clear that the name Ham has replaced an original Canaan.) The table of nations in Gen. x represents Ham as the ancestor of Cush (= Ethiopia), Egypt, Put and Canaan; that is, of the original inhabitants of Palestine and the peoples to the southwest. Ham appears also as a place name in Gen. xiv, 5, and as the designation of a people or place in I Chron. iv, 40; both references are obscure.

HAM, a small town of northern France, in the *département* of Somme, 36 mi. E.S.E. of Amiens on the Northern railway between that city and Laon. Pop. (1954) 3,545. It stands on the Somme, dominated by a ruined 10th-century castle. The castle of Ham has frequently been used as a state prison both in ancient and modern times, and the list of prisoners includes Joan of Arc, Louis of Bourbon, the ministers of Charles X, Louis Napoleon and Gen. L. E. Cavaignac and Gen. C. L. L. J. de Lamoricière.

During 1870–71 Ham was several times captured and recaptured by the belligerents. From the 9th century onward it was the seat of a lordship which, after the extinction of its hereditary line, passed in succession to the houses of Coucy, Enghien, Luxembourg, Rohan. Vendôme and Navarre, and was finally united to the French crown on the accession of Henry IV. The church, damaged during World War I, includes 12th-century effigies of the lords of Ham in its ancient crypt. Ham is at an important position on the Somme and suffered greatly during the campaigns on the western front in 1914–18. It was in this vicinity that tanks were first used.

HAM. The term ham is commonly applied to the fresh or cured thigh of the hog, or, in some parts of the world to the thigh and hind leg, or gammon. The somewhat similar but rather less choice shoulder portions of the carcass are produced, processed, marketed and in part consumed in a fashion so similar to ham that considerable mingling may occur in the statistics and no little fuzziness results in the mind of the public and the consumer. This confusion is increased by the term picnic ham employed in trade and commerce for that portion of the shoulder from which the butt and plate portions have been trimmed. Henceforth in this article ham refers to the thigh ham.

Processing. — After the carcass has been butchered and chilled it is cut up. Each pork carcass yields two thighs, or hams. A long ham is cut off just behind the rise in the pelvic arch; the more popular short ham is obtained by cutting through the second vertebra behind the rise. They are carefully trimmed, not only to shape them but to remove blood spots and excess fat. Some fat is left as protection on the inside or face of the ham. Ham may of course be consumed promptly, or kept in frozen storage for three or four months, but most hams are cured.

Before refrigeration became common curing the hams was the only way of preserving them. In practice, curing has many variations but basically consists in a race between the multiplication of spoilage bacteria in the ham and the penetration of the preserving and drying salt. Salt may be used alone or with sugar to improve flavour and texture of the meat. Saltpetre may be included to fix the bright red colour of the lean meat. These chemicals may be rubbed on the hams periodically as a dry-sugar cure or made into a brine in which the hams are immersed, or cold brine may be forced into the joints and arteries of the ham under pressure, called pumping.

A standard brine for 100 lb. of ham includes 8 lb. of salt, 2 lb. of sugar, 2 oz. of saltpetre and 4½ to 6 gal. of water. Temperatures during curing of 36° to 38° F. are safest, but much farm curing is done at temperatures even up to 50° F. The curing time depends on the weight of the ham and the temperature and length of time the ham is to be kept after curing. Some mildly salty commercial products cured by pumping cold brine into them may require only 5 to 21 days, but are almost as perishable as fresh pork and are stored under refrigeration. Hams to be safely stored in the country smokehouse over summer without refrigeration require about 4 days in the cure per pound of ham (*i.e.*, a 15-lb. ham requires 60 days), with one or more turnings and repacking to assure uniform penetration.

After curing, the scrubbed hams are hung and smoked for 1 to 15 days at temperatures ranging from 70° to 175° F. depending on the type of ham produced and the amount of smoky flavour desired. Normal smoking temperatures are 100° to 120° F. and the time two or more days. Hardwoods, especially hickory and apple, provide a smoke which yields a desirable flavour. After cooling, the ham may be peppered, partly for flavour, wrapped in grease-resistant paper, bagged and hung in dark, dry, well-ventilated storage. Some special types may be aged and mellowed for 50 to 70 days in heated storage (105° to 110° F.). Some hams are canned. Prepared in a variety of ways, they may be partly skinned, completely skinned and glazed, fully cooked, "ready to eat." They may be sold by half, or by butt end, shank end and centre slices.

Marketing and Trade. — Fresh, cured or canned, name-branded and attractively wrapped or unnamed and unwrapped, standardized or specialty types, government-inspected or country-killed and cured. Irish ham, Polish ham, Canadian ham, Smithfield or Virginia ham. U.S. western ham—a wide variety of kinds and types and cures is available on the market.

Uses and Food Value. — Flavour, palatability, versatility and convenience, storability, comparative economy and nutritional characteristics give ham high rank as a meat food. Its use is widespread and popular except among peoples who are forbidden by their religious lams to eat it. Ham is not eaten raw because of its being a possible carrier of trichinae, but its cookery includes variations of broiling, frying and baking. It is a nonbulky source of high-grade animal protein, comparing favourably in this respect with good beef. (*See* Table I.) Available energy ranges from 1,200 to 2,600 cal. per pound, depending on the degree of fatness. It is an outstanding source of thiamine (B_1) and perhaps of some of the less well-explored vitamins.

TABLE I. — Ham and Beefsteak Compared as to Food Values

	Composition, 100 g, edible portion, cooked	
	Ham, cured and smoked (Medium fat)	Beefsteak, round (Medium fat)

Production. — The geography of ham production is closely associated with swine distribution. World hog numbers in the late 1950s were estimated at nearly 375,000,000. Concentrations occurred in some midlatitude areas of temperate climate and favourable food supply, such as the corn belt of the United States, some potato and grain areas of Europe and in China. Some of the warmer areas of the world also were rather well represented. China (with perhaps 75,000,000 head), the United States (60,000,000), the U.S.S.R. (50,000,000), Brazil (35,000,000), and western Germany (15,000,000) were the major producing countries.

Many hogs are slaughtered under one year of age, and it is estimated that the annual pork harvest approaches the number in the swine population, or 375,000,000. If so, and the hogs average 200 lb. each, of which the usual 13% is ham, the total annual world ham harvest

TABLE II. — Estimated Ham Production for Some Leading Producing Countries
(in 000,000 lb.)

Country	1934–38 (average)	1946–50 (average)	1955
United States	1,342	1,929	2,024
Western Germany	526	280	601
France	273	247	343
United Kingdom	154	92	289
Denmark	124	95	206
Canada	114	174	186
Brazil	89	94	104

is nearly 5,000,000 short tons. The estimated ham production, as computed from pork carcass production reported by the U.S. department of agriculture, is shown for some leading countries in Table II.

HAMA, a city in northern Syria, on the river Orontes (Asi), capital of Hama province, population (1960) 110.809. Formerly an important military station, the town is dominated by the citadel hill. partly artificial. about 130 ft. high, although the citadel itself disappeared early in the Ottoman period. Peculiar to Hama are the nine. vast water wheels (*na'ura*) which raise water from the river to irrigate fields and gardens at a higher level. In the 14th century there were more than 30 of these wheels. Hama is connected by rail through Aleppo with the Istanbul-Baghdad railway and through Homs with Beirut and Damascus.

History.— Hama was an early Hittite settlement and is the southernmost place in which Hittite inscriptions have been found. After the fall of the Hittite empire it became the seat of a local dynasty, which eventually succumbed to the Assyrians after successive occupations and campaigns by Assur-nasir-pal and Shalmaneser III in the 9th century B.C. and by Adad-nirari III, Tiglath-Pileser III and Sargon II in the 8th. According to II Kings xvii. 24, a portion of its inhabitants was transported to Samaria.

In the Seleucid period Hama received the name Epiphania in honour of Antiochus IT' Epiphanes. It was occupied by the Moslem Arabs, and in 637 its Christian basilica was transformed into the Great mosque. In 1180 Saladin gave it to his nephew Taki ud-Din Omar, whose descendants held it as an independent principality until 1299. In 1310 the Mameluke sultan al-Nasir restored it to a cousin of the last prince. the famous historian Abu'l-Fida (d. 1331), with the personal rank of sultan. After the death of his son (1341) Hama was reincorporated in the Mameluke structure of Syria. After the Ottoman conquest in 1516 it sank in importance and population. In the 18th century it became tributary to the Bedouin tribes on its borders. (E. Ro.; X.)

HAMADAN, a General Governorship and a city in west central Iran. A high mountain range on the west supplies the plains with water. making possible extensive grain production. The population of the General Governorship was 11956) 693.690; area 7,567 sq.mi. Hamadan, the chief city of the General Governorship, is about 180 mi. W.S.W. of Tehran, on the Kazvin-Kermanshah motor road. at an elevation of over 6,000 ft., near the foot of the Mount Alvand, whose granite peak has an altitude of 11.641 ft. It is one of the principal trade and distributing centres of Iran. The main east-west highway passes through Hamadan and lesser roads connect with the principal towns east and south. The population was (1956) 100,029, of whom about one-fourth were Turks or of Turkish origin, the remainder being Iranians, Jews (about 5,000), with a sprinkling of Armenians. The bazaars are extensive and well stocked, the narrow and somewhat tortuous streets are intersected by broad tree-lined avenues that meet in a parklike plaza.

Hamadan is the seat of the leather, shellac and gallnut trade of Iran and it is one of the principal as well as one of the oldest centres of rug production. The climate is delightful and has made Hamadan a much favoured summer resort, not only for Iran but for Iraq as well. The winters are long and severe with heavy falls of snow.

The city has had a long and eventful history. It is first mentioned by Tiglath-Pileser I (c. 1100 B.C.) when it bore the significant name, Amadana, which means "place of meeting of many ways." According to tradition, Semiramis built herself a palace there in 800 B.C. as a refuge from the intolerable summer heat of the Mesopotamian plain.

Hamadan became the capital of the Medes in the late 7th and early 6th century B.C. It is the Ecbatana (*q.v.*) of the classical authors and the Bible (Ezra vi 2). Herodotus, recounting an ancient Medean legend, describes the city as enclosed in "seven round walls of increasing height with battlements painted in white, black, purple, lapis blue, orange; the last two plated with gold." But the number of colours and the metals which signify the planets are really Babylonian conceptions. He is specific that each successive wall out-topped the preceding by the height of its battlement and at the centre was the royal treasury, which had been the repository of the plunder from Nineveh in 612 B.C., and housed the wealth of Croesus after his defeat by Cyrus in 550 B.C. It is reputed to have had 1,000 treasure chambers and eight double iron doors, each nearly 30 ft. high.

Under the Achaemenids (550 to 330 B.C.) it became one of the capitals, and great temples and palaces, which have not yet been located or excavated, were built. Polybius, the historian, was quite dumfounded by the power and splendour of the structures on which had been lavished incredible wealth. The beams of the ceilings and the columns of the arcade were covered with plates of silver and gold.

Antiochus was able to coin over 6,000,000 dollars out of the gold and silver tiles of the temple of Anahit.

According to tradition Darius rebuilt the city which had long lain in ruins in order to have a safe asylum for his family and treasures during the war with Alexander. Whether the later citadel of Hamadan actually dated back to such early times must remain uncertain.

A famous relic of ancient times is the colossal, badly battered figure of a lion which once guarded a gate that was destroyed in A.D. 931.

According to Curzon this lion, ancient symbol of the sun, is still regarded as a potent talisman against hunger and cold.

As a centre of a well populated district, at vital crossroads, Hamadan developed at a very early period, and in early Islamic times was said to have extended nearly 15 mi. Jews have been established in Hamadan since the 4th century, attracted by the favourable conditions of trade and more recently also by the alleged tombs of Mordecai and Esther, in a small domed building in the middle of the town, to which Jews from other countries make a pilgrimage.

There also is the tomb of the celebrated philosopher, physician and scientist, Avicenna (*q.v.*), who died there in 1037, and a beautiful 12th century tomb tower, the Alaviyan, decorated with magnificent carved stucco. Hamadan served as capital for both the Parthians and Sassanians.

HAMADHANI, AL- (ABU AL-FADL AHMAD IBN AL-HUSAIN AL-HAMADHANI) (967–1007), Arab poet and writer known as Badi'-al-Zaman ("the wonder of the age") whose reputation is based on his letters and *maqamat* (romances and anecdotes) in rhymed prose. He was born and educated at Hamadan in west Persia in 967. He traveled, after 990, in Khorasan and Sijistan. finally settling in Herat (northwest Afghanistan) under the protection of the vizier of Mahmud. the Ghaznevid sultan. He was renowned for a remarkable memory and for fluency of speech, as well as for the purity of his language, and was one of the first to use rhymed prose in letters, *maqamat* and dialogues (of which he claimed to have composed 400), as well as in theological discussions, sermons and poetical puzzles.

His letters were edited by Ibrahim al-Ahdab (1890). The *maqamat* were edited by Mohammed 'Abduh (and ed. 1908) and translated into English by W. J. Prendergast (1915).

See Zaki Mubarak, *La Prose Arabe* (1931); C. Brockelmann, *Geschichte der arabischen Litteratur,* vol. i (1898) and Suppl., vol. i (1937).

HAMAMATSU, Japanese city (1960 pop. 333,009), is located on the Pacific coast of Honshu in Shizuoka prefecture, midway between Tōkyō and Kyoto. A leading industrial centre with strong Nagoya ties, it is noted for cotton weaving and dyeing, high qual-

ity musical instruments (pianos, violins, harmonicas and organs), hats, cellophane and other consumer goods. Hamamatsu is the regional marketing centre for western Shizuoka, serving the Lake Hamana and lower Tenryū river areas. Long a transportation hub, it is served by the Tōkaidō railway line and the Shinano and Tōkaidō highways. (J. D. Ee.)

HAMANN, JOHANN GEORG (1730–1788), German philosopher known as the "Magus of the North" because of his cryptic and paradoxical style of utterance, was born at Königsberg in Prussia on Aug. 27, 1730. After miscellaneous studies he worked intermittently as a tutor at Riga and in Courland from 1752 to 1759 (apart from a journey to London with a merchant in 1757–58) and then returned to Konigsberg. Having secured a post in the excise office in 1767, he was appointed administrator of the customshouse in 1777 but fell into financial difficulties in 1784 and was pensioned off. Thereafter he lived mainly with friends, in particular with F. H. Jacobi at Pempelfort and with F. K. Buchholtz at Wellbergen near Miinster. He died in Miinster on June 21, 1788.

Hamann's principal works were Biblische *Betrachtungen* eines Christen (1758); Sokratische Denkwiirdigkeiten (1759); *Kreuzzüge eines* Philologen (1762), in which he makes the much-quoted remark that poetry is the mother-tongue of mankind; Golgatha und *Scheblimini* (1784), against Moses Mendelssohn; and *Metakritik über* den *Purismus* der *Vernunft* (written 1780; published 1800). Temperamentally rather unstable, Hamann was radically opposed both to the rationalism of the Enlightenment and to the systematic idealism of Kant (with whom he nevertheless maintained friendly relations). He contended that truth was a matter of subjective belief, which the individual must attain for himself through experience or intuition. Against the prevalent tendency toward abstraction and distinction he upheld Giordano Bruno's doctrine of the identity of opposites. Everything, moreover, is a revelation of God and serves to convince us of His benevolence.

Hailed as a seer by the writers of the *Sturm und* Dvang movement in German Literature, Hamann was despised for his irrationalism by the academic philosophers of the 19th century but came to command more respect with the development of Christian existentialism.

The best edition of Hamann's works is by J. Nadler (1949–). *See* J Nadler, *Johann* Georg *Hamann* (1949).

HAMASAH, the name of a famous Arabic anthology compiled by Habib ibn Aws, surnamed Abu Tammam (*q.v.*). The collection is so called from the title of its first book, containing poems descriptive of constancy and valour in battle, patient endurance of calamity, steadfastness in seeking vengeance, and under reproach and in temptation, all which qualities make up the attribute called by the Arabs *hamasah* and best rendered into English by the word "fortitude."

The Hanzasah consists of ten books or parts, containing in all 884 poems or fragments of poems, and named respectively—(I) *al-Hamasah*, 261 pieces; (2) *al-Marathi,* "Dirges," 169 pieces; (3) *al-Adab,* "Manners," 54 pieces; (4) al-Nasib, "The Beauty and Love of Women." 139 pieces; (5) *al-Hija,* "Satires," 80 pieces; (6) al-Adyaf *wa-l-Madih*, "Hospitality and Panegyric," 143 pieces; (7) al-Sifat, "Miscellaneous Descriptions," 3 pieces; (8) *al-Sair wa-l-Nu'as,* "Journeying and Drowsiness," 9 pieces; (9) *al-Mulah,* "Pleasantries," 38 pieces; and (10) *Madhammat al-nisa,* "Dispraise of Women," 18 pieces. The poems are for the most part fragments selected from longer compositions. They are taken from the works of Arab poets of all periods down to that of Abu Tammam himself (the latest ascertainable date being A.D 832), but chiefly of the pre-Islamic period (*Jahiliyyun*), of the early days of Islam (*Mukhadrimun*) and of the reigns of the Umayyad caliphs. A D 660–750 (*Islamiyyun*) Perhaps the oldest pieces in the collection are those relating to the mar of Basus, nhich ended nith the peace of Dhu-al-Majaz, about A.D. 534.

Most of the poeins belong to the class of extempore or occasional utterances, as distinguished from qasidahs, or elaborately finished odes. While the *qasidahs* abound nith comparisons and long descriptions, the poems of the Hanzasah are short. direct and for the most part free from comparisons. Abu Tammam in compiling his collection chose hardly anything from the works of the most famous poets of antiquity. Not a single piece from Imru'-al-Qays occurs in the *Hamasah*, nor are there any from 'Alqamah, Zuhayr or A'sha; Nabighah is represented only by two pieces of four and three verses respectively; 'Antarah by two pieces; Tarafah by one piece; Labid by one piece; and 'Amr ibn Kulthum by one piece.

The book entitled al-Nasib is, however, an important exception, and contains verses relating to women and love. In the classical age of Arabic poetry it was the established rule that all qasidahs must begin with the mention of women and their charms, in order that the hearts of the hearers might be softened. These fragments are therefore generally taken from the opening verses of *qasidahs;* where this is not the case, they are chiefly compositions of the early Islamic period.

About A.D. 935 Abu Tammam, the compiler, visited Khurasan, then ruled by 'Abdallah ibn Tahir, whom he praised and by whom he was rewarded; on his journey home to Iraq he passed through Hamadhan, and was there detained as a guest of Abu al-Wafa, son of Salama. During his stay at Hamadhan, Abu Tammam is said to have compiled or composed five poetical works, of which one was the *Hamasah.* This collection remained as a precious heirloom in the family of Abu al-Wafa until it fell into the hands of Abu l-'Awadhil, who carried it to Isfahan and made it known to the learned of that city.

The worth of the Hanzasah as a storehouse of ancient legend can hardly be exaggerated. The high level of excellence which is found in its selections caused it to be said that Abu Tammam displayed higher qualities in his choice of extracts than in his own compositions. The class of poetry of which the *Hamasah* is a specimen is remarkable for the evident firsthand experience which the poets possessed of all about which they wrote. For historical purposes the value of the collection is considerable; but most of all there shines forth from it a complete picture of the strenuous life of passion and battle, which marked the valiant stock who bore Islam abroad over the outworn civilizations of Persia, Egypt and Byzantium.

The importance of the *Hamasah* in the history of Arabic literature is indicated by the fact that no fewer than 20 commentaries on it by medieval Arab scholars are enumerated by Hajji Khalfah, the historian and bibliographer. Of these the most famous are those of Abu Riyash, Xbu al-Fath ibn al-Jinni, Shihab-al-Din Ahmad al-Marzuqi of Isfahan and Abu Zakariya Yahya al-Tibrizi (1030–1109). This last is a mine of information regarding the classical age of Arabic literature.

When the *Hamasah* is spoken of, that of Abu Tammam, as the first and most famous of the name, is meant; but several collections of a similar kind, also called Hanzasah, exist. The best-known and earliest of these is the *Hamasah* of Buhturi (*q.v.*). Four other works of the same name, formed on the model of Abu Tammam's compilation, are mentioned by Hajji Khalfah. Besides these, a work entitled *Hamasat* al-Rah ("the Hamasah of wine") was composed by Abu-al-'Ala al-Ma'arri.

Bibliography.—Editions of the *Hamasah* include those by G. W. Freytag, with Latin trans. and al-Tibrizi's commentary (1828–1851); and by Mohammed Sa'id al-Rafi'i, with notes from al-Tibrizi's commentary, 2nd ed. (1913). The text was published by A. Amin and A. S. Harun with al-Marzuqi's commentary (1951). There is a German verse trans, by F. Ruckert (1846) and an English trans. of some excerpts by Sir Charles Lyall (1885). See also the bibliography to Arabic Literature. (C. J. L.; X.)

HAMBURG, a city-state, is a Land of Germany; situated on the Elbe, 7 j mi. from its mouth of Cuxhaven. It is the largest seaport on the continent of Europe and has an area of 288 sq.mi. Pop. (1950) 1,605,606. The city proper lies on both sides of the little Alster river; which, dammed up a short distance from its mouth, forms a lake, of which the southern portion within the line of the former fortifications bears the name of the Inner Alster (Binnen Alster), and the other and larger portion, that of the Outer Alster (Aussen Alster). The oldest portion of the city lies to the east of the Alster.

To the west lies the new town (Neustadt), incorporated in 1678; beyond this is St. Pauli, incorporated in 1876, and toward the northeast St. Georg, which arose in the 13th century but was not

Bottom left: View from the harbour with St. Michael's church in the background

incorporated till 1868. During the following centuries numerous rural communities were incorporated. On April 1. 1938, the former Prussian towns of Altona. Harburg and Wandsbek as well as several rural communities were united with Hamburg (Gross-Hamburg). Among the communities which Hamburg had to relinquish in return was the town of Cuxhaven at the mouth of the Elbe.

The old town lies low, and it is traversed by a great number of narrow canals or "fleets" (*Fleeten*) which serve as convenient channels for transport of goods. As they are subject to the ebb and flow of the Elbe, at certain times they run almost dry. The Binnen and Aussen Alster are separated by the Lombardsbrücke (a second bridge over the Alster was completed in 1953) and surrounded by newer buildings. Shallow-draught screw steamers provide means of communication between the business centre of the city and the outlying suburbs. The largest of the public squares in Hamburg is the Hopfenmarkt, which contains the church of St. Nicholas (~Nikolaikirche). Others of importance are the Rathausmarkt, the Gänsemarkt, the Zeughnusmarkt and the Grossneumarkt. The St. Petrikirche, St. Nikolaikirche. St. Katharinenkirche, St. Jakobikirche and St. Michaeliskirche give their names to the five old city parishes. The old Nikolaikirche was destroyed in the great fire of 1842, which destroyed a great part of the Altstadt, and the new building. designed by Sir George Gilbert Scott in 13th-century Gothic, was opened in 1863. Except for the steeple, it was destroyed in World War II. The Michaeliskirche, on the highest point in the city, is remarkable for its bold construction, there being no pillars. The St. Petrikirche, originally consecrated in the 12th century and rebuilt in the.14th, was the oldest church in Hamburg; it was burned in 1842 and rebuilt in its old form in 1844–49. It has the granite columns from the old cathedral. The St. Katharinenkirche and the St. Jakobikirche are the only surviving medieval churches. Both were seriously damaged by bombs during World War II.

The nen- Rathaus, a German Renaissance building, constructed of sandstone in 1886–97, contains the city archives. Immediately adjoining it and connected with it is the exchange, erected in 1839–41 on the site of the convent of St. Mary Magdalen. Along the line of the former town wall are the criminal law courts (1879–82, enlarged 1893), the civil law courts (finished in 1901) and the Oberlandesgericht (finished in 1912). Facing the botanical gardens a new central post office in the Renaissance style was built in 1887. The picture gallery contains works by modern masters, and the museum for art and industry, founded in 1874–76, is one of the most important institutions of the kind in Germany. Nearby are Hagenbeck's zoological gardens. schools of music, arts and navigation and schools of engineering and commerce. In 1900 a high school for shipbuilding was founded, and in 1901 an institute for seamen's and tropical diseases, with a laboratory for their physiological study, was opened.

History. — Hamburg probably had its origin in a fortress erected by Charlemagne, on an elevation between the Elbe and Alster, as a defense against the Slavs. and called Hammaburg because of the surrounding forest (*Hamme*). In 811 Charlemagne founded a church there. perhaps on the site of a Saxon place of sacrifice, and this became a great centre for the evangelization of the north of Europe, missionaries from Hamburg introducing Christianity into Jutland and the Danish islands and even into Sweden and Norway. In 834 Hamburg became an archbishopric, St. Ansgar, a monk of Corbie and known as the apostle of the north, being the first metropolitan. In 84j church, monastery and town were burned down by the Norsemen, and two years later the see of Hamburg was united with that of Bremen (*q.v.*) and its seat transferred to the latter city. The town, rebuilt after this disaster, was again more than once devastated by invading Danes and Slavs. In 1110 Hamburg, with Holstein, passed into the hands of Adolph I. count of Schauenburg, and it is with the building of the Neustadt (the present parish of St. Kicholas) by his grandson, Adolph III of Holstein (1188), that the history of the commercial city actually begins. In return for a contribution to the costs of a crusade, he obtained from the emperor Frederick I in 1189 a charter granting Hamburg considerable franchises, including exemption from tolls, a separate court and jurisdiction and the rights of fishery on the Elbe from the city to the sea. The city council (Rat), first mentioned in 1190, had jurisdiction over both the episcopal and the new town. Craft guilds were already in existence, but these had no share in the government. The defensive alliance of the city with Lübeck in 1241, extended for other purposes by the treaty of 12j5, practically laid the foundations of the Hanseatic league (*q.v.*), of which Hamburg continued to be one of the principal members. The internal organization of the city, too. was rendered more stable by the new constitution of 1270 and the recognition in 1292 of the complete internal autonomy of the city by the count of Schauenburg. The exclusion of the craftsmen from the Rat led, early in the 1 jth century, to a rising of the craft guilds against the patrician merchants; and in 1410 they forced the latter to recognize the authority of a committee of 48 burghers, which concluded with the senate the so-called First Recess; there were. however, fresh outbursts in 1458 and 1483, which were settled by further compromises. During the 16th century Hamburg became a free imperial city.

In 1529 the Reformation was definitively established in Hamburg by the Great Recess of Feb. 19. which at the same time vested the government of the city in the *Rat*, together with the three colleges of the *Oberalten*, the Forty-eight (increased to 60 in 1685) and the Hundred and Forty-four (increased to 180). The ordinary burgesses consisted of the freeholders and the master workmen of the guilds.

The 17th and 18th *Centuries.*—The 17th century saw notable developments. Hamburg had established. as early as the 16th century. a regular postal service with certain cities in the interior of Germany, *e.g.*, Leipzig and Breslau; in 1615 it was included in the postal system of Turn and Taxis. In 1603 Hamburg received a code of laws regulating exchange, and in 1619 the bank was established. In 1515 the Neustadt was included within the city walls. During the Thirty Years' War the city received no direct harm. but the ruin of Germany reacted upon its prosperity, and the misery of the lower orders led to an agitation against the Rat, culminating in 1708 in the victory of the democratic factions. The imperial government, hon-ever, intervened. and in 1712 the Great Recess established durable good relations between the Kut and the commonalty.

The trade of Hamburg received its first great impulse in 1783, when the Cnited States. by the treaty of Paris. became an independent power. From this time dates its first direct maritime communication with America. Its commerce was further extended and developed by the French occupation of Holland in 1795, when the Dutch trade was largely directed to its port. The French Revolution and the later occupation of the city by Napoleon (1811–14), however, exercised a depressing and retarding effect. Under the long peace which followed the close of the Kapoleonic Wars, its trade gradually revived. fostered by the introduction of steam navigation and the declarations of independence of South and Central America, with both of which it opened close commercial relations. In 1866 Hamburg joined the North German confederation, and in 1871 became a constituent state of the German empire, retaining its own constitution which had become liberalized after 1848. In 1921 a democratic *bürgerschaft* (parliament) was set up; this was dissolved in 1933.

The jurisdiction of the free port was, on Jan. 1, 1882, restricted to the city and port by the extension of the *Zollverein* to the lower Elbe, and in 1888 the whole of the state of Hamburg, with the exception of the so-called free harbour (comprising the port proper and some large warehouses. set apart for goods in bond), was taken into the *Zollverein.*

Before 1937 *Land* Hamburg had an area of 16j sq.mi. and consisted of the city of' Hamburg, several islands in the Elbe, the ton-11s of Cuxhaven. Bergedorf and Geesthacht and several small districts (enclaves) wholly enclosed in the territory of the neighbouring Prussian provinces of Schleswig-Holstein and Hanover. In 1937, by a rearrangement of boundaries between the *Länder* of Hamburg and Prussia to do away with the inconvenience of having outlying enclaves. the new *Reichsland* of the "Hanseatic city of Hamburg" (*Hansestadt*) was extended to include an area of 288

sq.mi. with a population in 1939 of 1,712,011. What existed till 1937 as the *Land* of Hamburg. a separate and autonomous state, became a new incorporated German territory *(Reichsland)*. with something like the status of Alsace-Lorraine after 1871. Most of its administration was placed under the minister of the interior at Berlin. who exercised his authority through the local nazi district leader (gauleiter) and federal governor *(Reichsstatthalter)*. Karl Kaufmann. The new Hanseatic city of Hamburg retained, however. corporative autonomy for some local matters. with a burgomaster who was assisted by 45 assessors *(Ratsherren)*. But the burgomaster had to be the same person as the *Reichsstatthalter,* who thus served in a double capacity—as agent for the reich minister of the interior and as local governor. This was a step in Hitler's process of securing greater unity and centralization of administration in the third reich.

The *Land* of Hamburg was re-established by the constitution of 1952. Its parliament consists of 120 deputies elected for four years who in their turn elect a senate of 1j from which the first and second *Bürgermeister* are chosen.

Effects of World Wars I and II.—Hamburg's commercial prosperity was seriously affected by World Wars I and II. In Nov. 1918 the Council of Workmen and Soldiers assumed political power in the city. and endeavoured to form a state of Great Hamburg; but in the following February. after a conflict with the soldiers of the German reich. the movement was suppressed. *(See* H. Ströbel, *The German Revolution and After;* Eng. trans., 1923.) In Oct. 1923 serious Communist riots again broke out. The rising was not put down until a cruiser and three torpedo boats had entered the harbour and marines had been landed to assist the police.

During World War II. Hamburg was of vital importance because of its large trade. great railway yards and warehouses, numerous industries and especially its shipyards. where large naval vessels were built and repaired and submarines were fitted out. It was therefore subjected to severe bombing; seven big air raids during July and Aug. 1943 killed more than 50,000 persons and destroyed 53% of Hamburg's dwellings, 60% of the port installations and much of its business and industrial premises.

Education.— Hamburg university was founded in 1919 as a development of the Colonial institute (1908); it has faculties of law, medicine, philosophy, natural science and Protestant theology. Special facilities exist for the study of phonetics and of the history and culture of India. China. Japan, Africa and the South seas. In 19jj there were 8,000 students.

Between World Wars I and II Hamburg became known for its experimental attitude to education and in 1949 a law was passed combining the older types of school into a comprehensive system. All children were to attend the primary school for six years; they then went on to one of three types of secondary school. In 1954 some modifications were made.

Religion.— From the Reformation to the French occupation, in the beginning of the 19th century, Hamburg was a purely Lutheran state; according to the Recess of 1529, re-enacted in 1603, non-Lutherans were subject to punishment and expulsion from the country. Exceptions were gradually made in favour of foreign residents. but it was not till 1785 that regular inhabitants were allowed some religious freedom. In 1860 full religious liberty was guaranteed. and the identification of church and state abolished. After 188; a church rate was levied on the Evangelical-Lutheran communities, and after 1904 upon the Roman Catholics also. Civil marriages were permissible after 1866.

The religious divisions of the population in 195j were as follows: Evangelical Church of Germany 77.82%; Free churches 13.56%; Catholics 6.66% (Roman Catholics 6.51%); Free Evangelical communities 1.01%; non-Christian religions 0.08% (Jewish 0.06%); freethinkers 0.87%.

Trade, Shipping and Industry.— Hamburg, the "gateway to the world" and an important traffic centre, is one of the largest trade and shipping places of the European continent and the most important industrial town of the Federal Republic of Germany. A dense network of shipping lines with 500 monthly sailings connects the port with all parts of the world. A lively inland traffic by rail and road, waterways and canals! passes through Hamburg, which is about 75 mi. from the estuary of the Elbe. The division of Germany after World War II, however. caused heavy loss to Hamburg by separating it from its hinterland in central and eastern Germany and by thus reducing east-west traffic. These effects of German division were so serious that they could not even be compensated by increased industrialization.

The port is the centre of Hamburg's economy. To a large extent commerce and industry receive their impetus from shipping. Shipbuilding and its manifold auxiliary industries, factories manufacturing import and export goods and consumer-goods industries for the city's own population have settled there. About 180.000 of 650,000 employed persons living in Hamburg work in the town's industries. In 1954 the shipyards built 55 seagoing vessels with a total of 223,000 tons gross. about one quarter of the output of the whole of the Federal Republic. Nearly half of these ships were built for foreign customers.

Hamburg is the port of registry of j5% of the merchant marine of the Federal Republic. which comprises about 2,500,000 tons gross. In 19j5 it was expected that seagoing vessels would be able to occupy 50 km. of berths at the quays and in midstream, as against 74 km. in 1938. More than 300,000.000 marks (RM./DM.) were spent during the first ten years after World War II for the reconstruction of the port, As much as 80% of copper production, 40% of oil extraction, 35% each of shipbuilding and mineral-oil refining. 32% of fish.curing and processing and 25% each of the margarine and cigarette industries of the Federal Republic were by 19jj established in Hamburg. Many of the goods coming in by sea, such as mineral oil, coal. iron ore. copper. wheat, feeding stuffs, fruit and tropical fruits. coffee, tea, cocoa, fish, meat, oilseeds, animal and vegetable oils and fats, timber and wood manufactures. wool, cotton and skins and hides, are processed in Hamburg. Most of its exports consist of the finished products of west German industries. such as machinery and industrial equipment, metal goods, glass and glassware, vehicles. timber and wooden articles, and also cement, mineral-oil derivatives. fertilizers: sugar and coal. In 1954 the number of ships entering the port was 15,775, with a tonnage of 19,296,000 (1936: 16,268 ships, with a tonnage of 18,922,000). Considering the serious destruction of port facilities during World War II and the interruption of commercial connections. this was a visible sign that Hamburg had begun to play its former role in German and European trade. Hamburg had also become important for its airport. Fuhlsbüttel. In 1954 there were 23 air lines with about 30.000 take-offs and landings; 170,000 passengers were carried within Germany, and 126,000 to and from foreign countries. Air freight was transported to all parts of the world.

Hamburg's leading position in foreign trade was also shown by the fact that most of the consular representations in the Federal Republic and many foreign trade banks had established themselves there. The federal post office had installed the largest number of its telautograph lines in Hamburg and most of the telephone calls to foreign countries were put through from there.

HAMDANI (ABU MOHAMMED AL-HASAN IBN AHMAD IBN YA'KUB AL-HAMDANI (d. 945), Arabian geographer, belonged to a family of Yemen. He was held in repute as a grammarian and poet. He compiled astronomical tables, studied the history and geography of Arabia and died in prison at Sana in 945.

His *Geography of the Arabian Peninsula (Kitab Jazirat ul-'Arab),* by far the most important work on the subject, was edited by D. H. Müller (Leyden. 1884). His other important work is the *Iklil* ("Crown"), concerning the genealogies of the Himyarites and the wars of their kings, in ten volumes. Of the surviving parts of this work, vol. 1, 2, 8 and 10 were published, and vol. 8 was trans-

lated into English by N. A. Faris as The Antiquities of South Arabia.

See the introduction to *The Antiquities of South Arabia,* trans. *by N.* A. Faris (Princeton and Oxford, 1938); also C. Brockelmann, *Geschichte der arabischen Litteratur,* 1st supplementary volume, p. 409 (Leyden, 1937).

HAMDI BEY, OSMAN (1842-I~IO), Turkish statesman and art expert, son of Hilmi Pasha, one of the last of the grand viziers of the old regime, was born at Istanbul. Hamdi Bey's great service to his country was the assertion of the right of Istanbul to receive the finds made by various archaeological enterprises in the Turkish empire. He founded the museum of antiquities at Istanbul and became its director in 1881; it owes much to his enlightened taste and to his energy.

Hamdi Bey secured for Turkey the famous Greek sarcophagi found in Sidon in 1887, which are among the treasures of the museum of antiquities. These are not only magnificent examples of Greek art of the jth and 4th centuries B.C., but are in perfect preservation, and the magnificent "Alexander" sarcophagus even retains traces of its original colouring (see SIDON). In 1888 Hamdi Bey founded the School (later, Academy) of Fine Arts in Istanbul. He died on Feb. 23, 1910.

His brother, HALIL EDHEM BEY (b. 1860), was also a distinguished archaeologist. He held various ministerial posts, and eventually became director of the Turkish museums in Istanbul.

HAMEG (or HAMAG), a name shared by the Kanembu of the Lake Chad area and the Negroid subjects of the Fung to the south of Sennar (*q.v.*) in the Anglo-Egyptian Sudan. It implies a servile position.

In the Sudan the Hameg are the descendants of the aboriginal inhabitants of the southern Gezira before the coming of the Fung, who probably gave them the name of Hameg. At mid-20th century they were particularly centred on Jebel Guli (between Renk and Roseires) and Keili, farther south on the borders of Beni Shangul.

About the middle of the 18th century. Mohammed Abu el Kaylak or Abulikeilik, a famous Hameg (really the son of a Ja'ali by a Hameg mother), became commander of the Fung army and governor of Kordofan; from that date the real power belonged to him and his descendants rather than to the Fung kings. On the Egyptian occupation, his grandson Idris Adlan retired to Guli and was recognized as chief of all the area south, including Sillok, Kurmuk, Ulu, the Burun and Fadasi. His descendant was still nazir of Dar Fung in modern times, although he would resent being called a Hameg, because of the servile association of the name.

See J. W. Robertson, "Fung Origins," *Sudan Notes and Records,* xvii, 260–265 (Khartoum, 1934). (A. J. AL.)

HAMELIN, FERDINAND ALPHONSE (1796–1864), French naval officer. an early advocate of armour for naval vessels, was born at Pont l'Évêque on Sept. 2. 1796. He took part in the expedition to Spain in 1823 and distinguished himself in the action at Algiers in 1830. In the later years of Louis Philippe's monarchy he held a command in the Pacific. Having become vice-admiral in 1848, he led the Black sea squadron in the Crimean War, collaborating with the English admiral J. W. D. Dundas in the bombardment of Sevastopol. He became an admiral in 1854 and was minister of marine from 1855 to 1860.

When Napoleon III made his first concession to the Liberal opposition. Admiral Hamelin was among the first ministers to be dismissed. He held no further command, and died in Paris on Jan. 10. 1864.

Hamelin was an able administrator and took a notable part in developing the use of armour; the "Gloire," launched in 1859, set the model for seagoing ironclads.

HAMELN, GLÜCKEL VON (1646–1724), German author of memoirs of the early period of European capitalism. was born in Hamburg. Ger.. in 1646, the daughter of Lob Pinkerle. She married a businessman, Chajim Hameln. in 1659, and headed his extensive enterprises after his death in 1689. In 1690 she began her memoirs. The seven books describe the everyday life of a German Jewish matriarch, the mother of 14 children. and also vividly cover her relations with the ruling families and the business practices of early capitalism in western Europe. In 1700 Glückel was married to a banker, Cerf Lévy of Metz, who died a few years later. Gliickel died in Metz in 1724.

Her memoirs were published in 1896, and thereafter were widely used as a source for early capitalism, especially by the German economist Werner Sombart (1863–1941) (*q.v.*).

In 1932 an abridged English translation of her memoirs was published by Marvin Lowenthal.

The poet Heinrich Heine (1797–1856) was a descendant of Gliickel von Hameln.

BIBLIOGRAPHY.—D. Kaufmann, *Die Memoiren der Gluckel von Hameln* (1896); Bertha Pappenheim, *Gliickel von Hameln* (1910); Alfred Feilchenfeld, *Gluckel von Hameln* (1923); *E.* Toeplitz, *Gliickel von Hameln* (1929).

HAMELN, a town in Lower Saxony, Ger., at the confluence of the Weser and Hamel, 33 mi. S.W. of Hanover, on the line to Altenbeken. Pop. (1950) 48,122. The older name of Hameln was Hameloa or Hamelowe. and the town owes its origin to an abbey. It existed as a town in the 11th century. Hameln fell into French hands, and in 1806 it was incorporated in the kingdom of Westphalia. In 1814 it again became Hanoverian, but in 1866 fell with that kingdom to Prussia. The chief public buildings are the minster, dedicated to St. Boniface and restored in 1870–7j; the town hall; the so-called Rattenfangerhaus (rat-catcher's house) with mural frescoes illustrating the legend (see below); and the Hochzeitshaus (wedding house) with beautiful gables. The principal industries are the manufacture of paper, leather, chemicals and tobacco, sugar refining and shipbuilding. There is communication with Karlshafen and Minden by steamboats on the Weser. In order to avoid the dangerous part of the river near the town, a channel was cut in 1734 and deepened in 1873.

Hameln is famed for its legend. In 1284 it was infested by a plague of rats, when there appeared a piper who offered for money to charm the vermin into the Weser. His conditions were agreed to, but after he had fulfilled his promise the inhabitants, saying he was a sorcerer, broke their bargain, whereupon he reappeared and played a tune which drew all the children. He led them out to the Koppelberg hill, in which a door opened. He entered and the children after him, all but one who was lame. Some trace the origin of the legend to the children's crusade of 1212, others to an abduction of children, though not on quite so large a scale.

HAMERLING, ROBERT (1830–1889), Austrian poet, was born at Kirchenberg-am-Walde, Lower Austria, on March 24, 1830, of humble parentage. In the revolutionary year of 1848 he joined the student's legion and in 1849 shared in the defense of Vienna against the imperialist troops of Prince Windischgrätz. From 1855 to 1866 he was master of the gymnasium at Trieste. After his retirement he lived quietly at his villa in Stiftingstal near Graz, where he died on July 13. 1889. Hamerling's most popular poem is *Ahasver in Rom* (1866), of which the emperor Nero is the central figure. Among his other works are *Venus im Exil* (1858); Der Konig von Sion (1869). generally regarded as his masterpiece; Die sieben *Todsünden* (1872); *Blätter im Winde* (1887); *Homunculus* (1888): *Amor* und *Psyche* (1882). He also wrote a novel, *Aspasia* (1876), and a tragedy, *Danton und* Robespierre (1870).

A popular edition of Hamerling's works in four volumes was published by M. M. Rabenlechner (Hamburg, 1900). For the poet's life, *see* his autobiographical writings, *Stationen meiner Lebenspilgerschaft* (1889) and *Lehrjahre der Liebe* (1890); also *M.* M. Rabenlechner, *Hnmerling, sein Leben und seine Werke,* i (Hamburg, 1896); a short biography by M. M. Rabenlechner (Dresden, 1901); R. H. Kleinert, *R. Hanzerling, ein Dichter der Schönheit* (Hamburg, 1889); A. Polzer, *Hamerling, sein Wesen und Wirken* (Hamburg, 1890).

HAMHŬNG (Japanese KANKŌ), a city of Korea. about 115 mi. N.E. of Pyongyang, was the commercial and governmental centre of northeastern Korea during the Yi dynasty (1392–1910) and was further developed by the Japanese (1910–45). Even greater transformation took place in Hungnam, a nearby fishing village which became a major industrial centre and port. Chemical and other industries depended largely upon the large scale hydroelectric

power projects developed inland from Hamhŭng.

During the Korean war, UN troops captured Hamhŭng and the reservoir areas, but were forced to retreat by massive numbers of Chinese Communist troops. The hydroelectric power facilities and many industrial plants in the Hungnam area were destroyed. The population of the Hamhŭng-Hungnam area in 1958 was estimated at 400,000. (S. McC.)

HAMI (QOMUL) an oasis in Chinese Turkestan (Sinkiang) in lat. 42° 48′ N. and long. 93° 28′ E. Hami is situated in the northeast of the Tarim basin, on the southern slopes of the eastern spurs of the Thian Shan Mts., and on the western verge of the Gobi desert. It lies at an elevation of 3,150 ft. Its position as a fertile tract at the point of convergence of the two main routes north and south of the Thian Shan connecting China with the West has given it importance since the westward expansion of the Chinese Empire under the Han dynasty in the first century A.D. It is first mentioned in Chinese history under the name of I-Wu-lu. Whenever China was strong enough to assert her claims to the control of central Asia, it was Hami which served as the main rendezvous and supply base for Chinese forces sent to overcome the hostile nomadic tribes in the north. Its commercial importance was equally great since the Pei-shan desert would have been a far more formidable obstacle if Hami had not been available as a place where caravans could re-victual and where animals could be rested. One serious drawback, however, in early times was the constant liability to raids from the nomadic tribes of the good grazing lands on the northern slopes of the eastern Thian Shan. When the Chinese lost their hold on eastern Turkestan, Hami fell into the hands of the Uighurs, who made it their chief town and held it for several centuries. It continued to be an important Buddhist centre long after Islam was dominant in the west of the Tarim Basin. In the early part of the 17th century, however, Hami was ruled by the Mohammedan khan of Kashgar. It was recovered for the Chinese in 1720 during the period of vigorous expansion under the early Manchus, lost for a short time during the great Mohammedan rebellion of 1865 and again recovered in 1873 as part of the successful reconquest of Sinkiang. Hami is now a small town of about 6,000 inhabitants and is still a busy trading centre. Its population consists in part of descendants of the Uighurs and in part of Mohammedan immigrants from Kashgar, Bukhara and Samarkand.

HAMILCAR BARCA or BARCAS, Carthaginian general and statesman, father of Hannibal, was born c. 270 B.C. During the First Punic War in 247, he took over the chief command in Sicily, which at this time was almost entirely in the hands of the Romans, and seizing Mt. Ercte (Monte Pellegrino, near Palermo), carried his raids as far as the coast of south Italy. By the peace of 241 Hamilcar's unbeaten force was allowed to depart from Sicily without any token of submission. On returning to Africa his troops broke out into open mutiny when their rewards were withheld by Hamilcar's opponents among the governing aristocracy. The serious danger into which Carthage was brought was averted by Hamilcar, whom the government reinstated. After crushing the revolt (237), Hamilcar enjoyed a virtual dictatorship. On his own responsibility he led an expedition into Spain to gain a new empire to compensate Carthage for the loss of Sicily and Sardinia. In eight years by force of arms and diplomacy he secured an extensive territory, but his premature death in battle (228) prevented him from completing the conquest.

This Hamilcar has been confused with another general who succeeded to the command of the Carthaginians in the First Punic War, and after successes at Therma and Drepanum was defeated at Ecnomus (256 B.C.). Apart from subsequent unskillful operations against Regulus, nothing is certainly known of him. For others of the name see CARTHAGE, SICILY, Smith's Classical *Dictionary*.

See Polybius i.–iii.; Cornelius Nepos, *Vita Hamilcaris;* **Appian,** *Res Hispanicae,* chs. 4, 5; Diodorus, *Excerpta,* xxiv., xxv.; O. Meltzer, *Geschichte der Knrthager* (1877), ii., also PUNIC WARS.

HAMILTON, the name of a famous Scottish family. The first authentic ancestor of the Hamiltons is one Walter FitzGilbert, one of the witnesses (Jan. 10, 1295) to a charter by James, the high steward of Scotland, to the monks of Paisley; in 1296 his name appears in the Homage Roll as Walter FitzGilbert of "Hameldone." He joined the English party, but after Bannockburn went over to Bruce, was knighted and subsequently received the barony of Cadzow. His younger son John was father of Alexander Hamilton who acquired the lands of Innerwick by marriage, and from him descended a certain Thomas Hamilton, who acquired the lands of Priestfield early in the 16th century. Another Thomas, grandson of this last, who had with others of his house followed Queen Mary and with them had been restored to royal favour, became a lord of session as Lord Priestfield. His eldest son, Thomas, was made an ordinary lord of session as early as 1592 and was eventually created earl of Haddington (*q.v.*). The 5th earl of Haddington by his marriage with Lady Margaret Leslie brought for a time the earldom of Rothes to the Hamiltons to be added to their already numerous titles.

Sir "David FitzWalter FitzGilbert," who carried on the main line of the Hamiltons, was taken prisoner at Neville's Cross (1346); in 1371 and 1373 he was one of the barons in the parliament. His son David succeeded in the representation of the family, Sir John Hamilton of Fingaltoun was ancestor of the Hamiltons of Preston, and Walter is stated to have been progenitor of the Hamiltons of Cambuskeith and Sanquhar in Ayrshire. David Hamilton, the first apparently to describe himself as lord of Cadzow, died before 1392, leaving four or five sons, from whom descended the Hamiltons of Bathgate and of Bardowie, and perhaps also of Udstown, to which last belong the lords Belhaven. Sir John Hamilton of Cadzow, his eldest son, was twice a prisoner in England. John Hamilton's two younger sons are stated to have been founders of the houses of Dalserf and Raploch. His eldest son, James Hamilton of Cadzow, like his father and great-grandfather, visited England as a prisoner, being one of the hostages for the king's ransom. From him the Hamiltons of Silvertonhill and the lords Hamilton of Dalzell claim descent, among the more distinguished members of the former branch being General Sir Ian Hamilton, K.C.B.

James Hamilton was succeeded by his eldest son Sir James Hamilton of Cadzow, an hereditary lord (1445) of parliament. He married (1474) as his second wife, Mary, sister of James III. and widow of Thomas Boyd, earl of Arran. Their son, James, second lord Hamilton, was created (1503) earl of Arran. Of his many illegitimate children Sir James Hamilton of Finnart, beheaded in 1540, was ancestor of the Hamiltons of Gilkerscleugh; and John, archbishop of St. Andrews, hanged by his Protestant enemies, was ancestor of the Hamiltons of Blair, and is said also to have been ancestor of Hamilton of London, baronet. James, second earl of Arran (*q.v.*) son of the first earl by his second wife Janet Beaton, was chosen governor to the little Queen Mary, being nearest of kin to the throne through his grandmother, though the question of the validity of his mother's marriage was by no means settled. He received (1549) the duchy of Châtellerault in France. He was succeeded in the title in 1579 by his eldest son James, who became insane, his brother John, afterwards first marquess of Hamilton, administering the estates. From the third son, Claud, created a lord of parliament as Baron Paisley (1587), descends the duke of Abercorn, heir male of the house of Hamilton.

The first marquess of Hamilton had a natural son, Sir John Hamilton of Lettrick, who was legitimated in 1600 and was ancestor of the lords Bargany. His two legitimate sons were James, 3rd marquess and first duke of Hamilton, and William, who succeeded his brother as 2nd duke and was in turn succeeded under the special remainder contained in the patent of dukedom, by his niece Anne, duchess of Hamilton, who was married in 1656 to William Douglas, earl of Selkirk. The history of the descendants of this marriage belongs to the great house of Douglas, the 7th duke of Hamilton becoming the male representative and chief of the house of Douglas, earls of Angus. Claud Hamilton, Baron Paisley, had five sons, of whom three settled in Ireland, Sir Claud being ancestor of the Hamiltons of Beltrim and Sir Frederick, distinguished in early life in the Swedish wars, being ancestor of the viscounts Boyne.

James, eldest son of Lord Paisley, was created in 1603 lord of

Abercorn, and in 1606 earl of Abercorn and lord of Paisley, Hamilton, Mountcastell and Kilpatrick. His eldest son James, 2nd earl of Abercorn, eventually heir male of the house of Hamilton and successor to the dukedom of Châtellerault, was created in his father's lifetime lord of Strabane in Ireland, but resigned this title in 1633 in favour of his brother Claud, whose grandson, Claud, 5th Lord Strabane, succeeded eventually as 4th earl of Abercorn. The 8th earl of Abercorn, who was summoned to the Irish house of peers in his father's lifetime as Lord Mountcastle, was created a peer of Great Britain in 1786 as Viscount Hamilton of Hamilton in Leicestershire, and renewed the family's connection with Scotland by repurchasing the barony of Duddingston and later the lordship of Paisley. His nephew and successor was created marquess of Abercorn in 1790, and was father of James, 1st duke of Abercorn.

See the article HAMILTON, MARQUESSES AND DUKES OF, and other articles on the different branches of the family (*e.g.*, ABERCORN, HADDINGTON and BELHAVEN) in Sir J. B. Paul's edition of Sir R. Douglas's Peerage of Scotland; and also G. Marshall, Guide to Heraldry and Genealogy.

HAMILTON, MARQUESSES AND DUKES OF. The holders of these titles descended from Sir James Hamilton of Cadzow (see HAMILTON).

JOHN, 1st marquess of Hamilton (c. 1542–1604), third son of James Hamilton, 2nd earl of Arran (*q.v.*) and duke of Châtellerault, was given the abbey of Arbroath in 1551. In politics he was largely under the influence of his unscrupulous younger brother Claud, afterwards Baron Paisley (see HAMILTON). At first hostile to Mary, they later became her devoted partisans. Claud met Mary on her escape from Lochleven and escorted her to Hamilton palace. John appears to have been in France in 1568 when the battle of Langside was fought, and it was probably Claud who commanded Mary's vanguard in the battle. With others of the queen's party they were forfeited by the parliament and sought their revenge on the regent Murray. Although the Hamiltons disavowed all connection with Murray's murderer, James Hamilton of Bothwellhaugh, he had been provided with horse and weapons by the abbot of Arbroath, and it was at Hamilton that he sought refuge after the deed. Their uncle, Archbishop Hamilton, was hanged at Stirling in 1571 for alleged complicity in the murder of Darnley, and is said to have admitted that he was a party to the murder of Murray. At the pacification of Perth in 1573 the Hamiltons abandoned Mary's cause. On the uncertain evidence extracted from the assassin by torture, the Hamiltons had been credited with a share in the murder of the regent Lennox in 1571. In 1579 proceedings against them for these two crimes were resumed, and when they escaped to England their lands and titles were seized by their enemies. James Stewart becoming earl of Arran. John Hamilton presently dissociated himself from the policy of his brother Claud, who continued to plot for Spanish intervention on behalf of Mary. With other Scottish exiles he crossed the border in 1585 and marched on Stirling; he was admitted on Nov 4, and formally reconciled with James VI., with whom he was thenceforward on the friendliest terms. He was created marquess of Hamilton and Lord Evan in 1599, and died on April 6, 1604.

His eldest surviving son JAMES, and marquess of Hamilton (c. 1589–1625), was created baron of Innerdale and earl of Cambridge in the peerage of England in 1619, and these honours descended to his son James, who in 1643 was created duke of Hamilton (*q.v.*). William, 2nd duke of Hamilton (1616–1651), succeeded to the dukedom on his brother's execution in 1649. He was created earl of Lanark in 1639, and in the next year became secretary of state in Scotland. Arrested at Oxford by the king's orders in 1643 for "concurrence" with Hamilton. he escaped, and was temporarily reconciled with the Presbyterian party. Sent by the Scottish committee of estates to treat with Charles I. at Newcastle in 1646, he sought in vain to persuade the king to consent to the establishment of Presbyterianism in England On Sept 26, 1647 he signed on behalf of the Scots the treaty with Charles known as the "Engagement" at Carisbrooke Castle, and helped to organize the second Civil War. In 1648 he fled to Holland; he returned to Scotland with Prince Charles in 1650, and joined in the Scottish invasion of England. He died on Sept. 12, 1651 from wounds received at Worcester. He left no male heirs, and the title devolved on the 1st duke's eldest surviving daughter Anne, duchess of Hamilton in her own right.

Anne married in 1656 William Douglas, earl of Selkirk (1635–1694), who was created duke of Hamilton in 1660 on his wife's petition, receiving also several of the other Hamilton peerages, but for his life only. He resisted Lauderdale's measures in Scotland, and was dismissed from the privy council in 1676. He presided over the convention of Edinburgh which offered the Scottish crown to William and Mary in March 1689. He died at Holyrood on April 18, 1694. His wife survived until 1716.

JAMES DOUGLAS (1658–1712), 4th duke of Hamilton and duke of Brandon (cr. 1711), eldest son of the preceding and of Duchess Anne, succeeded his mother, who resigned the dukedom to him in 1698. On Nov. 15, 1712 he fought the duel with Charles, Lord Mohun, narrated in Thackeray's Esmond, in which both the principals were killed.

The title of Lord Hamilton and that of Viscount Hamilton, in the peerage of Great Britain, conferred on the 8th earl of Abercorn in 1786, are borne by the dukes of Abercorn, whose eldest son is usually styled by courtesy marquess of Hamilton, a title which was added to the other family honours when the 2nd marquess of Abercorn was raised to the dukedom in 1868.

Bain (2 vols., Edinburgh, 1890–92); Gilbert Burnet, Lives of lames and *William. dukes* of Hamilton (1677); The Hamilton Papers relative to *1638–1650*, ed. S. R. Gardiner for the Camden Society (1880); G. E. C[okayne], Complete Peerage (1887–98); an article by the Rev. J. Anderson in Sir J. B. Paul's edition of the Scots Peerage, vol. iv. (1907).

HAMILTON, ALEXANDER (1755–1804), American statesman, was born a British subject, on the island of Nevis in the West Indies, on Jan. 11, 175j. He came of good family on both sides. His father was James Hamilton, a Scottish merchant of St. Christopher. His mother, Rachael Fawcett (Faucette, of French Huguenot descent), married a Danish proprietor of St. Croix with whom she lived unhappily and whom she soon left, subsequently living with James Hamilton; her husband procured a divorce in 1759 and the court forbade her remarriage. Whatever the fault or the excuse of the parents, the anxiety bestowed upon these facts by the son's biographers seems exaggerated. Business misfortunes having caused his father's bankruptcy, and his mother dying in 1768, young Hamilton was thrown upon the care of maternal relatives in St. Croix, where, in his 12th year, he entered the counting-house of Nicholas Cruger. Shortly afterward Cruger, going abroad, left the boy in charge of the business. The extraordinary specimens we possess of his letters, mercantile and friendly, written at this time, attest an astonishing poise and maturity of mind. His opportunities for regular schooling must have been very scant; but he early formed the habits of wide reading and industrious study that were to persist through his life. An accomplishment later of great service to Hamilton, common enough in the Antilles but very rare in the English continental colonies, was a familiar command of French. In 1772 some friends, impressed by his talents, made it possible for him to complete his education in the colonies of the mainland. He prepared for college at Elizabethtown. NJ., and in 1774 entered King's college (now Columbia university) in New York city. His studies, however, were interrupted by the Revolutionary War. A visit to Boston confirmed him in an opinion that he should cast his fortunes with the colonists. Into their cause he threw himself with ardour. In 1774–75 he wrote two influential anonymous pamphlets (entitled "A Full Vindication of the Measures of the Congress from the Calumnies of their Enemies," and "The Farmer Refuted") which were attributed to John Jay; they show remarkable maturity and controversial ability, and rank high among the political arguments of the time Concerning them George Ticknor Curtis (Constitutional History of the *United* States, vol. i. p. 274) has said, "There are displayed in these papers a power of reasoning and sarcasm, a knowledge of the principles of government and of the English constitution, and a grasp of the merits of the whole controversy, that would have

done honour to any man at any age." He then organized an artillery company, was awarded its captaincy on examination, won the interest of Nathanael Greene and Washington by the proficiency and bravery he displayed in the campaign of 1776 around New York city, joined Washington's staff in March 1777 with the rank of lieutenant-colonel, and during four years served as his private secretary and confidential aide. The duties with which he was entrusted — including constant correspondence with Congress, and some very important military missions — attest a complete confidence in his abilities and character. But Hamilton was ambitious for military glory — it was an ambition he never lost; he became impatient of detention in what he regarded as a position of unpleasant dependence, and seized a slight reprimand administered by Washington as an excuse for abandoning his staff position (Feb. 1781; see his Works, vol. ix., p. 232); the incident, however, involved no break in their good relations. Later he secured, through Washington, a field command and won laurels at Yorktown, where he led the American column that captured the first redoubt of the British works.

Meanwhile, in 1780, he had married Elizabeth, daughter of Gen. Philip Schuyler, and thus became allied with one of the most distinguished families in New York. Also, he had begun the political efforts upon which his fame principally rests. In letters of 1779–80 he correctly diagnosed the ills of the Confederation, and suggested with admirable prescience the necessity of centralization in its governmental powers. After a year's service in Congress in 1782–83, in which he experienced the futility of endeavouring to attain through that decrepit body the ends he sought, he settled down to legal practice in New York. The call for the Annapolis Convention (1786), however, presented an opportunity which he immediately improved. A delegate from New York, he supported Madison in inducing the Convention to exceed its delegated powers and summon the Federal Convention of 1787 at Philadelphia (himself drafting the call); secured a place on the New York delegation thereto; and, after his anti-Federal colleagues withdrew from the Convention, signed the constitution for his State. So long as his colleagues were present his own vote was useless, and he absented himself for some time from the debates after making one remarkable speech (June 18, 1787). In this he held up the British Government as the best model in the world. It is worth while noting that it was the monarchy of George III. that Hamilton defended and admired. Both parties, as Sir Henry Maine pointed out (Popular Government, 1886, pp. 212–13), had in mind "monarchy" as practised by George III. It is with this in mind that the quarrel of Hamiltonians and Jeffersonians is to be judged. Hamilton favoured an elective executive of life tenure, holding an absolute veto on national legislation, and with power to appoint the State governors who should hold a similar veto on State legislation; an upper house chosen for life on a property basis; a lower house (this, doubtless, a sop to democrats!) chosen by manhood suffrage; and control by the Federal Government of all militia. Complete extinction of the States he deemed desirable but impracticable. (See Works, vol. i., p. 347; and cp. x., pp. 446, 431, 329.)

Hamilton certainly realized that such proposals could serve no purpose except to focus conservative aims. Though fully conscious that monarchy in America was impossible, he wished to obtain the next best solution in an aristocratic, strongly centralized, coercive, but representative union, with devices to give weight to the influence of class and property. Aside from his one elaborate argument, and membership (undoubtedly, with his aamirer Madison as chairman, no fruitless membership) of the committee on style that gave final form to the constitution, he played an inconspicuous part in the Convention. "No man's ideas," he wrote when the work was done, "are more remote from the plan than my own are known to be; but is it possible to deliberate between anarchy and convulsion on one side and the chance of good to be expected on the other?" Unable to secure all that he desired he used his talents and utmost endeavours to secure what was attainable.

To this struggle was due the greatest of his writings, and the greatest individual contribution to the adoption of the new Government, The *Federalist*, a series of essays that appeared in the New York journals between Oct. 1787 and April 1788. Its inception and much more than half its contents were Hamilton's; the rest, Madison's and Jay's (see Amer. *Hist.* Review, vol. ii., pp. 443–60, 675–80). It remains a classic commentary, not merely on American constitutional law but on the principles of Government generally. Guizot said of it that "in its application of elementary principles of government to practical administration" it was the greatest work he knew; and Chancellor Kent declared it--quite justly — to be "equally admirable in the depth of its wisdom, the comprehensiveness of its views, the sagacity of its reflections, and the fearlessness, patriotism, candour, simplicity and elegance with which its truths are uttered and recommended." Sheer will and reasoning could hardly be more brilliantly and effectively exhibited than they were by Hamilton in the New York convention of 1788, whose vote he won, against the greatest odds, for ratification.

When the new Government was inaugurated he became secretary of the treasury in Washington's cabinet. Congress immediately referred to him a press of queries and problems, and there came from his pen a succession of papers that have left the strongest imprint on the administrative organization of the national Government — two reports on public credit (1790), upholding an ideal of national honour higher than the prevalent popular principles; a report on manufactures (1791), advocating their encouragement (*e.g.*, by bounties paid from surplus revenues amassed by tariff duties) — a famous report, one of the first notable revolts against the doctrines of Adam Smith, which has served ever since as a storehouse of arguments for American protective policy, and served also as an inspiration for Friedrich List; a report favouring the establishment of a national bank (1790), the argument being based on the doctrine of "implied powers" in the Constitution, and on the application that Congress may do anything that can be made, through the medium of money, to subserve the "general welfare" of the United States — doctrines that, through judicial interpretation, have revolutionized the Constitution; and, finally, a vast mass of detailed work by which order and efficiency were given to the national finances. In 1793 he put to confusion his opponents who had brought about a congressional investigation of his official accounts. The success of his financial measures was immediate and remarkable. They did not, as is often but loosely said, create economic prosperity; but they propped it, in an all-important field, with order and confidence. His ultimate purpose was always the strengthening of the Union; but before particularizing his political theories, and the political import of his financial measures, the remaining events of his life may be traced.

His activity in the cabinet was by no means' confined to the finances. He apparently regarded himself as premier, and sometimes overstepped the limits of his office in interfering with other departments. The heterogeneous character of the duties placed upon his department by Congress seemed in fact to reflect the English idea of its primacy. It is often said that Hamilton's counsels were predominant with Washington. In domestic affairs this is, on the whole, true; partly because their views were naturally sympathetic, and partly because Hamilton's advice was naturally accepted in the field of his special competence where Washington really needed guidance — finance. With regard to foreign relations, common sense and better judgment usually supported Jefferson's counsels — but where those qualities were involved Washington needed no counsel. Neutrality and isolation were American policies (to be found in the letters of every public man) before any occasion arose for their official promulgation. There was here no real difference between Hamilton and Jefferson: one sympathized with England, the other with France, but both desired neutrality. On domestic policy their differences were vital and in their conflicts over Hamilton's financial measures they organized, on the basis of varying tenets and ideals which have never ceased to conflict in American politics, the parties of Federalists and Republicans. In Jan. 1795 Hamilton resigned and returned to the practice of law in New York, leaving it for public service only in 1798–1800, when he was the active head, under Washington (who insisted that Hamilton should be second only to him-

self), of the army organized for war against France. But though in private life he remained the continual and chief adviser of Washington, notably in the serious crisis of the Jay Treaty, of which Hamilton approved, Washington's "Farewell Address" can not fairly be said to have been "written" by Hamilton; for Washington had worked upon it for years, and Madison had contributed to it. But though Washington supplied what he called the "body" to Hamilton, the latter apparently largely redressed it; and in particular he added what he described as "such reflections and sentiments as will wear well, progress in approbation with time, and redound to future reputation"—which can hardly be other than the passages which, to-day, give to the address its life.

After Washington's death the Federalist leadership of John Adams, who had the prestige of a varied and great career and greater strength than any other Federalist with the people, was disputed by Hamilton, who controlled practically all the leaders of lesser rank. Hamilton's faults were glaringly displayed in this connection. He sacrificed his influence and his future in political intrigues. Twice, when Adams had been nominated for the presidency he sought to bar him from that office by manipulations of the electoral college; after Adams became president, and so the official head of the party, Hamilton directed the members of the cabinet, and colluded with Federalist senators, in an endeavour to control the president's policy; and finally, on the eve of the crucial election of 1800, he wrote a bitter personal attack on the president (containing much confidential cabinet information) which he only privately circulated, but which was secured and published by the Democrats.

Had he been prosecuted for this under the Sedition Act passed by his Party, as was threatened by a political opponent, it would have been only a just rebuke to him and to his Party. The result of his efforts against Adams was that his agents were dismissed from the Cabinet, that the president turned to southern Federalists, and that he made peace (in 1799) with France; thereby ending such influence as Hamilton enjoyed, and such ambitions as he may have cherished, as head of the army. Similarly, when in Washington's cabinet, he had carried on for five years behind the back of the secretary of State confidential communications with the British minister, which—aside from the ill effects (discernible in the Jay Treaty) of the false ideas that they conveyed of American sentiment—in substance amounted to intrigue. Again, after Aaron Burr outgeneralled Hamilton in the New York campaign of 1799, carrying the State for the Democrats, Hamilton proposed to Gov. John Jay to call together the out-going Federalist legislature in order to choose Federalist presidential electors, a suggestion which Jay simply endorsed. "Proposing a measure for party purposes which it would not become me to adopt" (Works, vol. x., p. 371). Indeed, his opposition to Burr for a decade was conducted very largely by indirection, innuendo and whisper, in letters and conversation.

In short, as a political manager Hamilton, though ready in intrigue, was unsuccessful in it. He was a fighter through and through, and his courage was superb; but he was indiscreet in utterance, impolitic in management, opinionated, self-confident and uncompromising in nature and methods. To considerations of what was politic or practical he could not yield, and yet he could not leave politics alone and devote himself to law. With the establishment of democratic power in 1801 he lost all influence upon national affairs. His courage, and his high ideal of public rectitude were displayed in publishing the details of his *amour* with Mrs. Reynolds, that the favours shown to her complacent husband might permit no suspicion of impropriety in his conduct of the Treasury.

To his antipathy against Adams he sacrificed much prestige; to that against Burr, his life. No matter what may be the final judgment on Burr's character and schemes, doubtless Hamilton judged it a patriotic duty to thwart him in his ambitions; defeating his hopes successively of a foreign mission, the presidency, and the governorship of New York. Unfortunately, personal rivalry was also clearly involved, and personal dislike, and his methods of attack certainly, under the customs of that day, gave abundant cause for the duel in which he died. If his unsparing denunciations were known to Burr they were ignored by him until his last defeat. After that he forced a quarrel on a trivial bit of hearsay (that Hamilton had said he had a "despicable" opinion of Burr); and Hamilton, believing as he explained in a letter he left before going to his death that a compliance with the duelling prejudices of the time was inseparable from the ability to be in the future useful in public affairs, accepted a challenge from him. The duel was fought at the same spot where his eldest son, a boy of 20, had fallen in a duel in 1801. He was mortally wounded, and died on the following day, July 12, 1804. The tragic close of his career appeased for the moment the fierce hatreds of politics, and his death was very generally deplored as a national calamity.

No emphasis, however strong, upon the mere events of Hamilton's life suffices to show his importance in American history. In his earliest pamphlets he started out with the ordinary pre-Revolutionary Whig doctrines of natural rights and liberty; but the first experience of semi-anarchic States'-rights and individualism released by the Revolution ended his fervour for ideas so essentially alien to his mind, and they have no place in his later writings. The loose and barren rule of the Confederation, its feeble inadequacy of conception, infirmity of power, disintegrating particularism, and vicious finance were realized by many; but none other saw so clearly the concrete nationalistic remedies for these concrete ills, or pursued remedial ends so constantly and so ably. An immigrant, Hamilton had no particularistic ties; he was by instinct a "continentalist" or Federalist. Liberty, he remarked in the New York convention in 1788, was too exclusively considered, but there was another thing equally important: "a principle of strength and stability in the organization . . . and of vigour in its operation." He wanted a strong union and energetic Government that should "rest as much as possible on the shoulders of the people and as little as possible on those of the State legislatures"; that should have the support of wealth and class; that should curb the States to such an "entire subordination" as nowise to be hindered by those bodies; that should overbear all local and sectional prejudices and influences, and control the people. At these ends he aimed with extraordinary skill in all his financial measures—though of course he also regarded them as merely justice to creditors. As early as 1776 he urged the direct collection of Federal taxes by Federal agents. From 1779 onward we trace the idea of supporting Government by the interest of the propertied classes; from 1781 onward the idea that a not-excessive public debt would be a blessing in giving cohesiveness to the union: hence his device by which the Federal Government, assuming the war debts of the States, secured greater resources, based itself on a high ideal of nationalism, strengthened its hold on the individual citizen, and gained the support of property. From 1784 onward he seems to have been clear in his desire for judicial review of all legislation. In his report on manufactures his chief avowed motive was to strengthen the union. To the same end he conceived the constitutional doctrines of liberal construction, "implied powers," and the "general welfare," which were later embodied in the decisions of John Marshall. The idea of nationalism pervaded and quickened all his life and works.

The adoption of the constitution was less the end than the beginning of the struggle between its supporters and its opponents. The issue was not merely one of political abstractions; the literature of the Confederation epoch is full of discussions of class rights and economic interests; The Federalist, as Beard says, is "the finest study in the economic interpretation of politics which exists in any language" The constitution's "champions as well as its opponents knew that its real character was to be determined by the measures of law and administration to be established under it. . . . It did not go into effect until the economic measures which its adoption implied were put upon the statute books and carried into execution" (Economic Interpretation of the Constitution, pp. 10, 153, 189; *Economic* Origins *of Jeffersonian* Democracy, pp. 3, 85–86). Here was Hamilton's contribution. He believed with Hume that men are moved only by force and by interest, and in The Federalist he remarked: "Every institution will grow and flourish in proportion to the quantity and extent of the means concentrated towards its formation and support." This explains all

his financial measures. Madison and Hamilton reasoned alike, but they parted, as the former stated years later, "upon its plainly becoming his (Hamilton's) purpose to administration the government into something totally different from that which he and I perfectly knew the convention when it framed that government intended, and from what the people intended in adopting that framework." With one great exception, the dictum of Guizot is hardly an exaggeration, that "there is not in the Constitution of the United States an element of order, of force, of duration, which he did not powerfully contribute to introduce into it and to cause to predominate."

The exception, as history has shown—though Hamilton, of course, would have held it an element merely of disorder and dissolution—was American democracy. It is a commonplace today that colonial experience shaped the Constitution. It was Hamilton's weakness—and misfortune—that he did not share that experience, and lacked feeling for its lessons. It is a weakness everywhere apparent in his calculations, but especially apparent in his total failure to understand the democracy created by two centuries of frontier life. It explains, also, his total lack of understanding of the West, When scores of thousands of settlers were yearly pouring over the Alleghanies, north and south of the Ohio, he was opposed to the wide distribution of public land; and was so fatuous as to encourage the British minister to believe that his country would share with Great Britain the navigation of the Mississippi. Only a few lesser contemporaries were so lacking in judgment of their own time and place. This misunderstanding of American society, and exaltation of administration over the ends of government, condemned him to increasing isolation and impotence; confidence in the integrity, the self-control, and the good judgment of the people, which was the content of Jefferson's political faith, had almost no place in his theories. "Men," said he, "are reasoning rather than reasonable animals"; "opinion is as much influenced by appearances as by realities"; "I have an indifferent opinion of the honesty of the country." It is easy to understand why he received but twice an office at the hands of the people, and none after 1788. The charge that he laboured to introduce monarchy by intrigue was a gross underestimate of his good sense. The idea, he wrote to Washington, was "one of those visionary things none but madmen could undertake, and that no wise man will believe" (1792). We may accept as just, and applicable to his entire career, the statement made by himself in 1803 of his principles in 1787: "(1) That the political powers of the people of this continent would endure nothing but a representative form of government. (2) That, in the actual situation of the country, it was itself right and proper that the representative system should have a full and fair trial. (3) That to such a trial it was essential that the government should be so constructed as to give it all the energy and the stability reconcilable with the principles of that theory."

Throughout life, however, he held to his preference for such a government as he proposed in the convention of 1787; and though its inconsistency with American tendencies was yearly more apparent, he never ceased to avow on all occasions his aristocratic-monarchical partialities. Since Jefferson's assertions, alike as regards Hamilton's talk and the intent and tendency of his political measures, were, to the extent of the underlying basic fact—but discounting Jefferson's somewhat intemperate interpretations—unquestionably true,[1] it cannot be accounted strange that Hamilton's Democratic opponents mistook his theoretic predilections for positive designs. Nor would it be a strained inference from much that he said, to believe that he hoped and expected that in the "crisis" he foresaw—and in which he evidently hoped to play a military rôle—when democracy should have caused the ruin of the country, a new government might be formed that should approximate to his own ideals. No Jeffersonian obsession regarding "monocrats" is more fantastic than this counter obsession of his great opponent.

After the Democratic victory of 1800, his letters are but rarely relieved in their sombre pessimism by flashes of hope and courage. "Every day," he wrote, "proves to me more and more that this American world was not made for me." His last letter on politics, written two days before his death, illustrates the two sides of his thinking already emphasized: in this letter he warns his New England friends against dismemberment of the Union as "a clear sacrifice of great positive advantages, without any counterbalancing good; administering no relief to our real disease, which is democracy, the poison of which, by a subdivision, will only be more concentrated in each part, and consequently the more virulent." To the end he never appreciated the value of his own labours, never lost his fear of the States, nor gained faith in the future of the country. He laboured still, in mingled hope and apprehension, "to prop the frail and worthless fabric," but for its spiritual content of democracy he had no understanding, and even in its nationalism he had little hope. (See his Works, vol. x., pp. 363, 425, 434, 440, 445.) Yet to no other men, except to Washington and Marshall, does American nationalism owe so much.

In the development of the United States the influence of Hamiltonian nationalism and Jeffersonian democracy has been a reactive union; but changed conditions since Hamilton's time, and particularly since the Civil War, have created misconceptions as to Hamilton's position in his own day. Great constructive statesman as he was, he was also in that day essentially a reactionary. He was in sympathy with the dominant forces of public life only while they took, during the war, the predominant impress of an imperfect nationalism. Jeffersonian democracy came into power in 1800 in direct line with colonial development; Hamiltonian Federalism had been a break in that development; and this alone can explain the ouster of the Federalists despite their brilliant success in constructing the Government. Hamilton stigmatized his great opponent as a political fanatic; but actualist as he claimed to be, himself, he could not see, or would not concede, the predominating forces in American life, and would uncompromisingly have minimized the two great political conquests of the colonial period—local self-government and democracy.

Few Americans have received higher tributes from foreign authorities. Talleyrand, personally impressed when in America with Hamilton's brilliant qualities, declared him greater than Fox and Napoleon. Of the judgments rendered by his countrymen, Washington's confidence in his ability and integrity is perhaps the most significant. Chancellor James Kent, and others only less competent, paid remarkable testimony to his legal abilities. Chief-justice Marshall ranked him second to Washington alone. No appraisal is more justly measured than Madison's (1831): "That he possessed intellectual powers of the first order, and the moral qualities of integrity and honour in a captivating degree, has been awarded him by a suffrage now universal If his theory of government deviated from the republican standard he had the candour to avow it, and the greater merit of co-operating faithfully in maturing and supporting a system which was not his choice."

In person Hamilton was rather short (5 ft. 7 in.) and slender; in carriage, erect, dignified and graceful. Deep-set dark eyes vivified his features, and set off his light hair and very fair and rosy complexion. His head in the famous Trumbull portrait is boldly poised and striking. The charm of his manners and conversation is attested by all who knew him, and in familiar life he was artlessly simple. Friends he won readily, and held in devoted attachment by a frank, ardent, generous, warm-hearted and high-minded character. As Lodge says, "the roll of his followers is enough of itself to establish his position in American history." It is therefore the more notable that reciprocal confidence and respect took the place, between Washington and Hamilton, of personal attachment—at least as regards Hamilton. This may be under-

[1] *Cf.* Gouverneur Morris, *Diary and Letters,* vol. ii., pp. 455, 526, 531 and even Lodge's judgments, *Life,* pp. 90–92, 115–116, 122, 130, 140. When he says (p. 140) that "In Hamilton's successful policy there were certainly germs of an aristocratic republic, there were certainly limitations and possibly dangers to pure democracy," this is practically Jefferson's assertion (1792) that "His system flowed from principles adverse to liberty"; but Jefferson went on to add: "and was calculated to undermine and demolish the reoublic." Jefferson merely had exaggerated fears of a moneyed political engine, and seeing that Hamilton's measures of funding and assumption did make the national debt politically useful to the Federalists in the beginning he concluded that they would seek to fasten the debt on the country forever.

stood, considering their extremely different temperaments. It is more difficult to understand why Hamilton—although on the score of personal and Federalist indebtedness he left explicit recognition—never really appreciated Washington's great qualities: Jefferson differed equally from him in temperament and vastly more in opinions, yet fully recognized his greatness. A firm will, tireless energy, courage and bold self-confidence were other leading qualities of Hamilton's nature. Amiability and enthusiastic aggressiveness seem to have been equally characteristic. In his mind, clarity and penetration were matched with logical solidity. Its remarkable quality lay in a combination of acute analysis and grasp of detail with great comprehensiveness of thought. So far as his writings show he was almost wholly lacking in humour. and in imagination little less so. In public speaking, however. he often combined a rhetorical effectiveness and emotional intensity that might take the place of imagination. and enabled him, on the coldest theme. to move the feelings of his auditors.

He died insolvent, leaving a widow and seven children, none of whom revealed the brilliance of their father.

BIBLIOGRAPHY.—Hamilton's Works have been edited by H. C. Lodge (New York, 9 vols., 1885–86, and 12 vols., 1904); all references above are to the latter edition. There are various editions of *The Federalist,* notably those of H. B. Dawson (1863), H. C. Lodge (1888), and—the most scholarly—P. L. Ford (1898); cf. *American Historical Review,* vol. ii., pp. 413, 675. Among modern biographies *see* A. M. Hamilton, *The Intimate Life of Alexander Hanzilton* (1910), very valuable for its materials but both biased and naïve in judgments; H. J. Ford, *Alexander Hamilton* (1920), carefully reasoned; James Schouler, *Alexander Hamilton* (1901), a slender but very judicious study; J. T. Morse, *Life of dlexander Hamilton* (1876), and *H.* C. Lodge, *Alexander Hutnilton* (1882), both partisan; and G. Shea's two books, his *Historical Study* (1877) and *Life and Epoch* (1879). W. *G.* Sumner's *Alexander Hamilton* (1890) is important for its criticism from the point of view of an American free-trader; *see* also, on Hamilton's finance and economic views, C. F. Dunbar, *Quarterly Journal of Economics,* vol. iii. (1889), p. 32; E. G. Bourne in *ibid.,* vol. x. (1894), p. 328; E. C. Lunt in *Journal of Political Economy,* vol. iii. (1895), p. 289; W. C. Culbertson, *Alexander Hanzilton: an Essay* (New Haven, 1911); and the two indispensable books by C. Beard cited in the text. F. S. Oliver's *Alexander Hamilton: An Essay on American Cnion* (1906), an English study, which uses its subject to illustrate the necessity of British imperial federation, has been criticized as being too partisan. *See* also James Bryce, "Predictions of Hamilton and de Tocqueville," in *Johns Hopkins University Studies,* vol. v. (Baltimore, 1887); and the capital essay of Anson D. Morse in the *Political Science Quarterly,* vol. v. (1890), pp. 1–23. The unfinished *Life of Alexander Hamilton,* by his son, J. C. Hamilton, going only to 1787 (New York, 1834–40), was superseded by the same author's valuable, but partisan and uncritical *History of the Republic . . . as traced in the Writings of Alexander Hamilton* (New York, 1857–64; Boston, 1879). New materials and viewpoints have rendered somewhat antiquated the earlier biographies mentioned. (F. S. P.)

HAMILTON, ALLAN McLANE (1848–1919), U.S. physician. was born in Brooklyn. N.Y., on Oct. 6. 1848. He graduated from the College of Physicians and Surgeons (Columbia universityj in 1870.

In 1879 for an essay on "Diseases of the Lateral Columns of the Spinal Cord" Hamilton won the first prize given by the American Medical association. Later he took up more specifically the work of an alienist and medico-legal practitioner. He was present in an advisory capacity at more than 100 murder trials where insanity was the issue, notably at the trials of the assassins of Presidents Garfield and McKinley and in the Thaw case and was influential in the reform of court methods in dealing with criminals of this type. He was professor of mental diseases at Cornell Medical college.

He died at Great Barrington. Mass., on Nov. 23, 1919.

See "Allan McLane Hamilton, 1870–1919," *J.A.M.A.,* 73:1714 (Nov. 29, 1919); Allan McLane Hamilton, *Recollections of an Alienist* (New York. 1916).

HAMILTON, ANTHONY (1646–1720), French author, was probably born in Tyrone or Tipperary. His grandfather, earl of Aberdare, settled in Ireland in the Plantation of Ulster. The family moved to France in 1651 and returned at the Restoration to a house near Whitehall.

Anthony's sister Elizabeth, *la belle Hamilton,* married the comte de Gramont (*q.v.*). Anthony probably went to France in 166; with his brother George, after the expulsion of the Roman Catholics from the army. In any case. he served in the *régiment d'Hamilton,* was wounded in the Palatinate in 1674 and at intervals went over to Ireland for recruits. The regiment was not a success after George's death, and Anthony seems to have left France for Ireland in 1678.

King James II gave him command of an Irish regiment in 1687. After the siege of Limerick. Anthony joined the court of James at Saint Germain, where he shared the general poverty and died on April 21, 1720.

The *Mémoires du conzte de Gramont* were written, theoretically at Gramont's dictation, at the château of the duchesse du Maine at Sceaux, and published, probably much against the author's will, under the rubric of Cologne, but really in Holland. in 1713. The memoirs are after the manner of Bussy-Rabutin. halfway between English memoirs and the French *roman prétendu historique.* The prose is typically early 18th-century, well-bred and conversational. They are generally accurate in substance, though weak in chronology. and are especially valuable for their pictures of the English court.

Of Hamilton's other works, *Le Bélier* is a parody on the followers of Charles Perrault, and the *Contes des fées, Fleur d'épine, Zénéyde* and *Les quatre facardins* satirize the romantic tales popularized by Galland's *Arabian Nights.* He also wrote some light verse and corresponded with Lady Mary Wortley Montague. His *Oeuvres diverses* were collected in 1731.

The *Mémoires* were first translated into English by Abel Boyer in 1714. *See* Kuth Clark, *Anthony Hamilton* (London and New York, 1921); E. Legouis and L. Cazamian, *Histoire de la littérature anglaise* (Paris, 1924).

HAMILTON, ELIZABETH (1758–1816), British author, born in Belfast: of Scottish extraction, spent the greater part of her life in Scotland and at Bath.

Her most famous works are *Letters on Education* (1801–02); *The Cottagers of Glenburnie* (1808), a picture of Scottish rural life which aimed to shake country-dwellers out of their complacency and general backwardness; and the popular song "My Ain Fireside." Her *Hints addressed to the Patrons and Directors of Schools* (1815) recommended the "natural" methods of teaching used by J. H. Pestalozzi. She died at Harrogate on July 23, 1816.

See E. O. Benger, *Memoirs of Mrs. Elizabeth Hamilton,* 2 vol., 2nd ed. (London, 1819).

HAMILTON, EMMA, LADY (*c.* 1765–1815), wife of Sir William Hamilton (*q.v.*), the British envoy at Naples, and famous as the mistress of, Nelson, was the daughter of Henry Lyon, a blacksmith of Great Neston, Cheshire: where she mas christened on May 12, 1765. When she went to live with Charles Greville in 1781 she called herself Emily Hart. Under the protection of Greville, whose means were narrowed by debt, she was taught to sing, dance and act with professional skill. In 1782 he introduced her to his friend Romney, whose portraits of her may have somewhat idealized her apparently robust and brilliantly coloured beauty, but her vivacity and powers of fascination cannot be doubted. She seems to have been sincerely attached to Greville. In 1784 his uncle, Sir William Hamilton, saw—and admired—her. Two years later she was sent on a visit to him at Naples, as the result of an understanding between Hamilton and Greville—the uncle paying his nephew's debts and the nephew ceding his mistress. Emma at first resented the exchange, but submitted. Her beauty, her artistic capacity, and her high spirits made her a great favourite in Neapolitan society, and Queen Maria Carolina became closely attached to her. She became famous for her "attitudes," a series of *poses plastiques* in which she represented classical and other figures. On Sept. 6, 1791, during a visit to England, Hamilton married her, in order to justify her public reception at the court of Naples, where she was the channel of communication between the queen and the British minister—sometimes in opposition to the policy of the king. It was claimed that she secured valuable information in 1796, and was of essential service to the British fleet in 1798 during the Nile campaign, by enabling it to obtain stores and water in Sicily. When Nelson returned from the Nile in Sept. 1798 Lady Hamilton subjugated him, and drew him into a most unhappy participation in the domestic troubles of Naples, and when Sir W. Hamilton was recalled in 1800 she travelled with him and Nelson across Europe. In England Lady

Hamilton paraded her hold over Nelson. Their child, Horatia Nelson Thompson, was born on Jan. 30, 1801. On her husband's death in 1803 she received by his will a liferent of £800, and the furniture of his house in Piccadilly. She then lived with Nelson at his house at Merton. On his death she received Merton, and an annuity of £500, as well as the control of the interest of the £4,000 he left to his daughter. But gambling and extravagance kept her poor, and in 1813 she was put in prison for debt and remained there for a year. She died at Calais in distress if not in want on Jan. 15, 1815.

See *The Memoirs* of *Lady Hamilton* (anon., 1815); and Walter Sichel, Emma, Lady *Hamilton* (1905); J. Turquan and J. d'Auriac, *Une aventurière de haut vol.: Lady Hamilton et la Révolution de Naples 1763–1815* (1913). *See* also the references *s.v.* NELSON.

HAMILTON, LORD GEORGE (1845–1927), English statesman, was born on Dec. 17, 1845, son of the first duke of Abercorn. He was educated at Harrow school and entered the house of commons in 1868 as member for Middlesex. After 1885 he sat for the Ealing division until his retirement in 1906. Lord George took a keen interest in education throughout his life. He was vice-president of the committee of council on education from 1878 to 1880, and chairman of the London School Board from 1894 to 1895. He was a well-known economist and statistician, and rendered signal service to social science as chairman of the Poor Law commission, 1904–09. But his most famous achievements were in two departments of state, the India office and the admiralty. Disraeli made him under-secretary at the India office in 1874, and he spent four years there. He returned to the office as secretary of state in 1895 and held office until 1903. This important period in Indian affairs covered the vice-royalties of Lord Elgin and Lord Curzon. At the outset he laid down a moderate frontier policy which secured the Indian government from much fruitless border warfare. His other and perhaps greatest work was done as first lord of the admiralty (1885–1886 and 1886–1892). He carried through the Naval Defence act of 1889, which formed the framework for the development of the navy up to the beginning of World War I. He secured the transfer of the control of naval ordnance from the war office to the admiralty, created the naval intelligence department and "discovered" Lord Fisher. His long service with unionist governments ended in 1903, when he and Ritchie resigned on the fiscal question. His last public service was as chairman of the Mesopotamia commission (1916–17). He died in London on Sept. 22, 1927.

Lord George married in 1871 Lady Maud Lascelles, daughter of the third Earl Harewood. He wrote *Parliamentary Reminiscences and Reflections* (1917).

HAMILTON, SIR IAN STANDISH MONTEITH (1853–1947), British soldier, was born at Corfu on Jan. 16, 1853. Educated at Wellington college and in Germany, he joined the army in 1872. He served with the 92nd Highlanders in the Afghan War and the Boer War of 1881, and was severely wounded on Majuba hill, one arm being permanently disabled. He was then for several years intermittently on the staff of Sir F. (Lord) Roberts. He served in the Nile Expedition of 1884–85, in Burma in 1886–87, and on the staff of the Chitral Relief Force in 1895. He commanded a brigade on the North-West Frontier in 1897, and afterwards the School of Musketry, Hythe. In the South African War he commanded a mounted infantry division during the advance from Bloemfontein to Pretoria and into the eastern Transvaal. He returned home early in 1901 to become military secretary at the War Office, but towards the end of the year went back to South Africa nominally as chief of the staff to Lord Kitchener, although in reality he was employed chiefly as the commander-in-chief's deputy to control particular groups of operations from time to time during the closing stages of the struggle.

He was afterwards again military secretary and then quartermaster-general at the War Office, and in 1904 he went out to the Far East to accompany the Japanese armies in the field. His impressions under the title *A Staff Officer's Scrap Book* (2 vol., 1906–07), by reason of the interest of its subject, the charm of the author's style, and the combination of war experience and of imagination which inspired his judgments and criticisms; at once took rank in Europe as a modern military classic. His literary ability, though a token of unusual imagination and clearness of thought, rather prejudiced him throughout his career in the eyes of old-fashioned soldiers. On his return he had charge of the Southern Command until 1909, and was afterwards adjutant-general at the War Office for a year. He took a prominent part on behalf of the voluntary service system during the campaign in favour of compulsory service led by Lord Roberts, and in the course of this controversy he published a book *Compulsory Service* (1910), which he wrote at the request of Lord Haldane. In 1910 he was appointed commander-in-chief in the Mediterranean and inspector-general of the Overseas Forces.

On the outbreak of World War I in 1914 Hamilton served for some months as commander in chief of the Home Defence army in England. Then in March 1915, he was selected to take charge of the Mediterranean expeditionary force *(see* DARDANELLES CAMPAIGN). The naval effort to force the Dardanelles having failed, he found himself obliged to undertake operations in the Gallipoli peninsula, and although his army was ill-equipped for the task, he succeeded in landing it in the face of the enemy, but was brought to a standstill. Having, after considerable delay, received substantial reinforcements, he made a great effort in August to improve his position, but partly through the inertia of some of the local commanders, sent out without consulting him, the operations miscarried, and a situation of stalemate arose. The government consulted him in October as to the expediency and feasibility of withdrawing from the peninsula, and on his pronouncing himself strongly opposed to such a policy he was replaced by Sir C. Monro and returned home. In 1920, after the issue of the *Report* of the Dardanelles commission, he published his own story of the campaign under the title of *Gallipoli Diary* (2 vols., 1920), and in 1921 *The Soul and Body of an Army*. Hamilton was the recipient of many honours, including the G.C.M.G. (1919) and the D.S.O. (1891). He died Oct. 12, 1947, at London. (B. H. L. H.)

HAMILTON, JAMES HAMILTON, 1ST DUKE OF (1606–1649), Scottish nobleman, son of James, 2nd marquess of Hamilton, and of the Lady Anne Cunningham, daughter of the earl of Glencairn, was born on June 19, 1606. As the descendant and representative of James Hamilton, 1st earl of Arran, whose mother was a daughter of James II. of Scotland, he was the heir to the throne of Scotland after the descendants of James VI. He married in his fourteenth year May Feilding, aged seven, daughter of Lord Feilding, afterwards 1st earl of Denbigh, and was educated at Exeter College, Oxford, where he matriculated on Dec. 14, 1621. He succeeded to his father's titles on the latter's death in 1625. In 1628 he was made master of the horse, gentleman of the bedchamber and a privy councillor. In 1631 Hamilton took over a force of 6,000 men to assist Gustavus Adolphus in Germany. He guarded the fortresses on the Oder while Gustavus fought Tilly at Breitenfeld, and afterwards occupied Magdeburg, but his army was destroyed by disease and starvation, and after the complete failure of the expedition Hamilton returned to England in September 1634. He now became Charles I.'s chief adviser in Scottish affairs. In 1638, after the outbreak of the revolt against the English Prayer Book, he was appointed commissioner for Scotland to appease the discontents. He was easily intimidated by the covenanting leaders and accomplished nothing. Charles offered an assembly and a parliament, and eventually revoked the prayer book. On Nov. 21, Hamilton presided over the first meeting of the assembly in Glasgow cathedral, but dissolved it on the 28th on its declaring the bishops responsible to its authority. The assembly, however, continued to sit notwithstanding, and Hamilton returned to England leaving the enemy triumphant and in possession. War was now decided upon, and Hamilton was chosen to command an expedition to the Forth to menace the rear of the Scots. He failed, and in July 1639 resigned his commissionership.

Hamilton supported Strafford's proposal to call the Short Parliament, but otherwise opposed him as the chief adversary of the Scots. In Feb. 1641 he persuaded Charles to admit some of the

parliamentary leaders to the council. Hamilton was now confronted by a new antagonist in Montrose, who detested both his character and policy and repudiated his supremacy in Scotland. On Aug. 10, 1641, he accompanied Charles on his last visit to Scotland.

As no reconciliation proved possible between Charles and Argyll, Hamilton sided with Argyll at Edinburgh. In consequence he received a challenge from Lord Ker, of which he gave the king information, and obtained from Ker an apology. Montrose wrote to Charles declaring he could prove Hamilton to be a traitor. Shortly afterwards the plot—known as the "Incident"—to seize Argyll, Hamilton and the latter's brother, the earl of Lanark, was discovered, and on Oct. 12 they fled from Edinburgh.

In July 1642 Hamilton, who, in spite of his intrigues, retained Charles's confidence, went to Scotland on a hopeless mission to prevent the intervention of the Scots in the war, and a breach then took place between him and Argyll. When in February 1643 proposals of mediation between Charles and the parliament came from Scotland, Hamilton instigated the "cross petition" which demanded from Charles the surrender of the annuities of tithes in order to embarrass Loudoun, the chief promoter of the project, to whom they had already been granted. This failing, he promoted a scheme for outvoting Argyll in the Scottish parliament by sending to Scotland all the Scottish peers then with the king, while Charles was to guarantee the establishment of Presbyterianism in Scotland only. Montrose was eager to strike and anticipate the plans of the Covenanters. Hamilton, however, gained over the queen for his project, and in September was made a duke, while Montrose was condemned to inaction. Hamilton's scheme completely failed. On refusing to take the Covenant, he and Lanark were obliged to leave Scotland. They arrived at Oxford on Dec. 16. Hamilton's conduct had at last incurred Charles's resentment and he was sent, in Jan. 1644, a prisoner to Pendennis Castle, in 1645 being removed to St. Michael's Mount, where he was liberated by Fairfax's troops on April 23, 1646.

Hamilton showed great activity in the futile negotiations between the Scots and Charles at Newcastle. In 1648 he obtained a temporary influence and authority in the Scottish parliament over Argyll, and led a large force into England in support of the king on July 8. He showed complete incapacity in military command; mas kept in check for some time by Lambert; and though outnumbering the enemy by 24,000 to about 9,000 men, allowed his troops to disperse over the country and to be defeated in detail by Cromwell, during the three days Aug. 17-19, at the so-called battle of Preston, being himself taken prisoner on the 25th. He was tried on Feb. 6, 1649, condemned to death on March 6 and executed on the 9th.

For his successors *see* HAMILTON, MARQUESSES AND DUKES OF.

Burnet; *Lauderdale Papers* (Camden Society, 1884–85); *The Hamilton Papers*, ed S *R.* Gardiner (Camden Society, 1880) and *addenda* (Camden Miscellany, vol. ix., 1895); *Thomason Tracts* in the British Museum, 550 (6), 1948 (30) (account of his supposed treachery), and 546 (21) (speech on the scaffold).

HAMILTON, JAMES (1769–1831), English educationist, and author of the Hamiltonian system of teaching languages, was born in 1769. He went in 1814 to America, intending to become a farmer and manufacturer of potash; but, changing his plan before he reached his "location," he started as a teacher in New York. There, and in other cities, he mas very successful, using a method of teaching languages which he had learned in Harnburg from a French émigré, General d'Angelis. He returned to England in 1823, and taught in various centres. The two master principles of his method were that the language should be presented to the scholar as a living organism, and that its laws should be learned from observation and not by rules. As textbooks for his pupils Hamilton printed interlinear translations of the Gospel of John, of an *Epitome historiae sacrae*, of Aesop's *Fables*, Eutropius, Aurelius Victor, Phaedrus, etc., and many books were issued as Hamiltonian with which he had nothing personally to do. He died on Oct. 31, 1831.

HAMILTON, JOHN (*c.* 1511–1571), Scottish prelate and politician, natural son oi James Hamilton, 1st earl of Arran, became a monk and abbot of Paisley. After studying in Paris he returned to Scotland. where. under his half-brother, the regent Arran. he was made keeper of the privy seal (1543), bishop of Dunkeld (1546). archbishop of St. Andrews (1546) and finally became treasurer of the kingdom. He was imprisoned, owing to Protestant hostility, in 1563. After his release he was an active partisan of Mary, queen of Scots; he baptized the infant James, afterward King James VI, and pronounced the divorce of the queen irom Bothwell. After the battle of Langside he took reiuge in Dumbarton castle. There he was seized, and on the charge oi complicity in the murders of Lord Darnley and the regent Murray he was tried, and hanged on April 6, 1571.

HAMILTON, PATRICK (1504–1528), Scottish protomartyr of the Reiormation, second son of Sir Patrick Hamilton and of Catherine Stewart. daughter of Alexander. duke of Albany, second son of James II of Scotland. In 1517 he was appointed titular abbot of Ferne. Ross-shire. He graduated in Paris in 1520, and then went to Louvain, attracted probably by the fame of Erasmus. On returning to Scotland he became a member of the University of St. Andrews where he conducted, as precentor, a musical mass of his own composition in the cathedral. Early in 1527 the attention of James Beaton. archbishop of St. Andrews, was directed to the heretical preaching of the young priest. Hamilton fled to Germany, first visiting Luther at Wittenberg and afterward enrolling as a student in the new University of Marburg. He returned to Scotland, bold in the conviction of the truth of his Protestant principles. He accepted Beaton's invitation to a conierence at St. Andrews, and for nearly a month was permitted to preach and dispute. At length he was summoned before a council of bishops and clergy presided over by the archbishop; there were 13 charges, seven of which were based on the doctrines affirmed in his Loci *communes*. The council convicted him, after a sham disputation with Friar Campbell, and handed him over to the secular power. The sentence of burning at the stake was carried out on the same day (Feb. 29, 1528) lest he should be rescued by his friends. His courageous bearing greatly helped to spread the Reformation in Scotland. The "reek of Patrick Hamilton infected all it blew on." He represented in Scotland the Lutheran stage oi the Reformation. The *Loci communes*, known as "Patrick's Places." set forth the doctrine of justification by faith and the contrast between the Gospel and the law in a series of clear-cut propositions. It was translated into English by John Frith (1528), and is to be found in Fox's *Acts and Monuments*.

See Lorimer, *Patrick Hanzilton, the First Preacher and Martyr of the Scottish Reforn:zation* (1857).

HAMILTON, SIR WILLIAM (1730–1803), British diplomat and archaeologist, son of Lord Archibald Hamilton, governor of Greennich hospital and of Jamaica, nas born in Scotland on Dec. 13. 1730 and served in the 3rd regiment of foot guards from 1747 to 1758. He left the army after his marriage with a Welsh heiress. and inherited an estate in Snansea upon her death in 1782. From 1764 until his recall in 1800 he was British envoy to the court of Naples. Hamilton made or caused to be made, at Vesuvius and Etna, a series of observations on the action of volcanoes, and published several treatises on earthquakes and volcanoes betneen 1776 and 1783. He was a notable collector and many of his treasures nent to enrich the British museum. In 1791 he married Emma Lyon. The outbreak of the French Revolution and the rapid extension of the revolutionary movement in western Europe soon overwhelmed Naples a situation with which he was incapable of dealing.

See, for the rest of his career, the articles HAMILTON, EMMA, and NELSON, HORATIO. He died on April 6, 1803.

HAMILTON, SIR WILLIAM, BART. (1788–1856), Scottish metaphysician, who as a teacher exerted a remarkable influence over the thought of the younger generation in Scotland, was born in Glasgow on March 8. 1788, the son of William Hamilton, professor of anatomy and botany there. Educated at Glasgow, Edinburgh and Balliol college. Oxford, he took his B.X. in 1811 and became a member of the Scottish bar two years later. Hamil-

ton was an unsuccessful candidate for the chair of moral philosophy at Edinburgh university in 1820 but was appointed professor of civil history there in 1821. His essay in the *Edinburgh Review*, on the "Philosophy of the Unconditioned" (1829), a critique of Victor Cousin's *Cours de philosophie*, led to a long and friendly correspondence between him and Cousin. His subsequent articles on German philosophy (he had taken up the study of the German language as a result of visits to Germany in 1817 and in 1820) established his reputation as a philosopher; and in 1836 he was elected to the chair of logic and metaphysics at Edinburgh. His knowledge embraced anatomy, physiology, literature and theological lore as well as his professed subjects.

Hamilton published a pamphlet on Presbyterian church affairs, *Be Not Schismatics, Be Not Martyrs by Mistake*, in 1843. In the following year he was stricken with paralysis. His edition of Thomas Reid's works appeared in incomplete form in 1846. Later publications were *A Letter to Augustus De Morgan* (1847). part of a controversy on the principles of logic; *Discussions on Philosophy, Literature and Education* (1852), a collection of articles reprinted from the *Edinburgh Review;* and 9 vol. (1854–56) of an edition of the works of Dugald Stewart. He died in Edinburgh on May 6, 1856.

Hamilton was not a great originator, and his attempt to combine the Scottish ,"philosophy of common sense" with elements of Kantianism was not successful. He was. however. influential both in stimulating a taste for metaphysics in his students and in introducing some of Kant's ideas to the British public. At the lowest estimate. he made British philosophy less narrow and one-sided than it was. In the history of logic he has a place for his doctrine of the "quantification of the predicate" (an attempt to elaborate the traditional classification of propositions by expanding "All *A* is *B*" into the two forms "All *A* is all *B*" and "All *A* is some B"; and so on) ; but its radical implications in leading to an extensional conception of logic were not perceived by him. In the field of education Hamilton's *Edinburgh Review* articles on "The State of the English Universities" (1831) and "The Right of Dissenters to Admission Into the English Universities" (1834) were among the factors which led to the royal commission of 1850 and the subsequent reforms.

BIBLIOGRAPHY.—Hamilton's *Lectures on Metaphysics and Logic* were *edited by H. L.* Mansel and J. Veitch, 4 vol. (1858–60). *See* further J. Veitch, *Memoir of Sir W. Hamilton* (1869) ; J. S. Mill. *Examination of Sir William Hamilton's Philosophy,* 6th *ed.* (1889) ; J. Hutchison Stirling, *Sir* W. *Hamilton* (1865) ; S. V. Rasmussen, *The Philosophy of Sir William Hamilton* (1925). (W. H. W.; X.)

HAMILTON, WILLIAM, OF GILBERTFIELD (*c.* 166*j*–17j1). Scottish poet whose vernacular poetry (*e.g.,* "The Last Dying Words of Bonnie Heck." printed in James Watson's *Choice Collection,* 1706) is among the earliest in the 18th-century revival. He was born at Ladyland, Ayrshire. He exchanged with Allan Ramsay "Familiar Epistles" in verse, which are usually included in editions of Ramsay; and his modernized version of Blind Harry's *Wallace* (1722) influenced Burns. He died at Latrick, Lanarkshire, May 24, 1751. (E. *G.* M.)

HAMILTON, WILLIAM GERARD (1729–1796), English statesman, popularly known as "Single Speech Hamilton," was born in London on Jan. 28, 1729, and educated at Winchester and at Oriel college. Oxford. His maiden speech in the house of commons. delivered on Nov. 13, 1755, during the debate on the address. which excited Walpole's admiration. was. in fact, not the only one which he made in the house. Hamilton was one of the commissioners for trade and plantations (1756), chief secretary to Lord Halifax, the lord lieutenant of Ireland (1761), chancellor of the exchequer in Ireland (1763) and filled other offices.

HAMILTON, SIR WILLIAM ROWAN (1805–1865), Irish mathematician, whose works were of great value in mathematical physics, was born in Dublin on Aug. 4, 1805. His great mathematical intelligence was awakened by the reading of Newton's *Arithmetica universalis* when he was 12 years old. He went on to the *Principia,* and when he was 1; attacked Laplace's *Mécanique céleste.* In this he detected an error which was communicated to John Brinkley, then royal astronomer in Ireland. who at once recognized one of the first mathematical minds of the age. Hamilton had a brilliant career at Trinity college. Dublin, but before it was completed he was appointed, at the age of 22, to the Andrews chair of astronomy in succession to Brinkley. The rest of his life was spent at the observatory at Dunsink, near Dublin. in the close study of mathematics. He was knighted in 183j. At the time of his death, Sept. 2, 1865, Hamilton was working on his *Elements of Quaternions,* on which the last six years of his life had been spent.

His earliest papers were the "Theory of Systems of Rays" (*Trans. Roy. Irish Acad.,* 1828–32); in the last of these, by the aid of mathematics. he predicted conical refraction. These were followed by papers on "The Principle of Varying Action" and in 1834 and 183j by two memoirs "On a General Method in Dynamics." The latter papers made a great addition to the methods of inquiry in dynamics, being of great value particularly in the quantum theory.

Hamilton's *Lectures on Quaternions* were published in 1853 and his great book. *The Elements of Quaternions,* posthumously in 1866. In the preface to the *Lectures* he describes the steps by which he reached his important conclusions which form the germ of the later basic theories of hypercomplex numbers.

The discoveries, papers and treatises mentioned might well have formed the whole work of a long and laborious life. But he left an enormous collection of manuscript books, full of original in-i-estigations, that were handed over to Trinity college. His paper on *Fluctuating Functions* and his extremely ingenious invention of the hodograph must be mentioned. Only a few items of his investigations into the solution (especially by numerical approximationj of certain classes of differential equations were published in the *Philosophical Magazine.* Hamilton was a neat, precise and fastidious writer; this may be the reason that he published so little compared with the extent of his investigations.

See R. *P.* Graves, *Life of Sir W. R. Hamilton* (1882–89) ; Royal Irish Academy, *Mathematical Papers of Sir W. R. Hamilton,* 2 vol. (1931–40). (O. OE.)

HAMILTON, a city in southwestern Victoria, Austr. Pop. 1 j 8,507. It lies 613 ft. above sea level on Grangeburn river! south of the Grampians, the most western of the plateaus forming the Great Divide and a sheep and agricultural district. Hamilton has saleyards and abattoirs. and its manufactures include butter, leather. knitted goods and tools. There is a mechanics' institute with a large library and also a botanic garden. Hamilton was proclaimed a borough in 1863, a town in 1928 and a city in 1949.

HAMILTON, the capital of the British colony of Bermuda, is situated on the main island along the sloping northern shore of a deepwater, landlocked harbour. Pop. (1960) 2.763. Rectangular in shape, its streets are parallel and cross at right angles. An imposing neo-Gothic cathedral is centrally situated on Church street at the highest point in the city, which it dominates. Near the cathedral is the handsome Sessions house, accommodating the house of assembly, the supreme court and judicial offices. It is surrounded by government departments, including the Public building, containing the colonial secretariat and the council chamber, in which the executive and legislative councils meet and the colonial parliament is convened and prorogued. The city possesses the Bermuda historical museum and a public library. which stands in the Par la Ville gardens. In the northwest is Victoria park. Hamilton was founded in 1790. incorporated in 1793, succeeded historic St. George as capital in 1815 and was raised to city status in 1897. In 1956 it was made a free port to encourage business and employment. Cars were not permitted in the city until 1946 when a 15 m.p.h. speed limit was imposed. External communications are maintained by sea, and by air from the terminal which is 11 mi. S.E. of the city. The principal industry is the thriving tourist trade.

HAMILTON, one of the chief cities of Canada, the capital of Wentworth county, Ont., occupies a site upon the shore of a large landlocked harbour, Hamilton bay, at the western extremity of Lake Ontario. It covers a plain stretching between the water front and an escarpment called "the mountain," over 250 ft. high.

La Salle landed on the shore of Hamilton bay in Aug. 1669. but European settlement did not begin until 1778 with the arrival of Robert Land and Richard Beasley, United Empire loyalists. The actual founder of the city was George Hamilton who bought a farm between James and Wellington streets and between the mountain and King street. In 1813 he laid out a town. naming the first streets after members of his family. Incorporated in 1816. the village became a town in 1833 and a city in 1846.

During the first decades. Hamilton was overshadowed by nearby Dundas which had important industries. was an early focal point for roads and in 1837 gained access to the bay with the opening of the Desjardins canal. Hamilton. however. was more important in trade and finance. It benefited from the opening in 1830 of the Burlington canal. which linked the bay with Lake Ontario. After 1850 Hamilton became a railway centre and the real growth of the city began.

Railway repair shops, bridge building and a variety of other metal-working industries were established. The basic iron and steel industry began in 1893. In its wake a large variety of metal-using industries followed: transportation equipment. structural steel shapes, building equipment. bolts, screws, wire. farm machinery. etc.

Called the "Pittsburgh of Canada." Hamilton is a leading industrial centre producing over 50% of the steel made in the country. The heavy industries are mainly concentrated on the water front. and the port handles over 8.000.000 tons of freight annually. including direct overseas trade. The harbour covers about 10 sq.mi. and is separated from Lake Ontario by a four-mile-long sand and gravel bar which carries a railway and highway. The approach to the harbour was greatly improved with the completion of a high-level bridge for the highway in 1958. The business district is centred around King and James streets as are the civic buildings such as the library. the city hall and the courthouse.

Hamilton is the centre of one of the finest fruit-growing districts on the continent. and behind the city hall is Canada's largest open air market. held three days a week with fresh displays of fruits. vegetables and flowers. The better residential districts are toward the foot of the mountain, and residential development has spread to the top of the escarpment.

McMaster university, founded in Toronto in 1887 and moved to Hamilton in 1930. and its affiliate Hamilton college are on the western edge of the city. The university is known for nuclear research, having Canada's first privately owned nuclear reactor. Nearby is Hamilton's art gallery. The city has four high schools (one Roman Catholic) and several other educational institutions. four hospitals. a tuberculosis sanatorium and a mental hospital.

On the western fringes are the Royal Botanical gardens of 1.900 ac.. established in 1941 by provincial legislation and including the famous rock gardens, an outstanding horticultural attraction. Well-known is the monument in the park at Stoney Creek. 5 mi. E. of the city. marking the site where in 1813 a British force of 700 men defeated an invading force of 2,000 Americans in a decisive battle of the War of 1812.

The population of Hamilton is largely of British. Polish. Italian and Hungarian descent. The leading religious denominations are Anglican. United Church of Canada, Roman Catholic. Presbyterian and Baptist. Pop. (1961) 273,991; greater Hamilton. 395.189.

(JB. S.)

HAMILTON, a large burgh of Lanarkshire, Scot., situated about 1 mi. from the junction of the Xvon water with the Clyde and 11 mi. S.E. of Glasgow by road over Bothwell bridge. Pop. (1961) 41.928. Hamilton. which is crossed by many winding burns, is flanked on the east side by the Hamilton Low parks and by alluvial haughs. The area has been settled since prehistoric days, the original capital of the parish being Cadzow castle, now about 2 mi. S.E. on a precipitous rock, 200 ft. in height. washed by the Avon. After a charter of 1145 it was renamed after the 1st Lord Hamilton, and became a burgh of barony in 1456 and a royal burgh in 1548, this last dignity being surrendered in 1670 when it was made the chief burgh of the regality and dukedom of Hamilton.

The disco\-ery of coal caused great expansion of the town, and later iron foundries and engineering works n-ere established, but by 1947 all the pits had closed down. Now mainly a residential and shopping town. its industries include the making of metal castings and goods, electrical equipment, radio sets. carpets. knitwear and ioodstufis. In the district are orchards, market gardens and dairy farms.

The Mote hill in the Hamilton Low parks is the site of the original village of Ketherton whose 10th-century cross now stands in front of the parish church. In the churchyard is a monument to a group of Covenanters executed at Edinburgh in 1600. The dukes of Hamilton had a palace on the part of their estate called the Low parks: the building was begun in 1591 and added to through the centuries: but because of subsidences caused by mining it was demolished in 1927. In the town is a domed mausoleum. 120 ft. high. erected by the 10th duke of Hamilton (d. 1852). and bought by the burgh in 1922. Near the mausoleum stood the tolbooth. built in 1642 and demolished in 1951. except for the clock steeple. The 16th-century grammar school. called the Academy, is housed in buildings dating from 1913. The municipal buildings were opened in 1914.

At Barncluith, 1 mi. S.E of the town, are the Dutch gardens laid down in 1583 on the Avon terraces. Two mi. S.E. of Hamilton, near the ruined Cadzow castle, is the chase with its ancient oaks — remains of the great Caledonian forest; there is a herd of wild, white cattle in this estate of the High parks.

HAMILTON, a city of southwestern Ohio, U.S., the seat of Butler county, is located on the Great Miami river. 23 mi. N. of Cincinnati. The population in 1960 was 72,354; the population of the Hamilton-Middletown standard metropolitan statistical area (defined by the federal census as comprising all of Butler county, was 199.076. Fort Hamilton, the first of a chain of forts on the Miami and Maumee rivers, was built there in 1791 by Gen. Arthur St. Clair. A town called Fairfield was laid out adjoining the fort in 1794. The fort was abandoned in 1796 and about that time Fairfield was renamed Hamilton. for Alexander Hamilton. When Butler county was organized in 1803, Hamilton became the county seat. It was incorporated as a village in 1810 and as a city in 1857. Across the river was Rossville, a lusty rival until it united with Hamilton (1854).

Hamilton had the advantages of being in a fertile agricultural district, at the centre of many turnpikes, on a useful river. on the Miami and Erie canal (from 1827 to 1913), and on the Baltimore and Ohio and the Pennsylvania railways. .Abundant water power encouraged early industrial development, including the manufacture of farm machinery, paper, textiles and tools. Manufactures include paper. paper-mill felts, safes, vaults, automobile bodies; machinery, diesel engines, woolen blankets. machine tools, prefabricated houses and hydraulic and mechanical presses. The city has several parks and public buildings, and owns its public utilities (water since 1884; electricity since 1895). (W. E. SH.)

HAMILTON RIVER (GRAND or ASHUANIPI), is the principal river of Labrador. in northeastern Canada. It rises on the central plateau of Labrador-Ungava in a chain of lakes 1.750 ft. above sea level; and wanders aimlessly for 208 mi. until it falls precipitously into the Bowdoin canyon at Grand falls, 250 mi. from its mouth. The falls are 302 ft. high, and the river drops more than 800 ft. in 10 mi. Grand falls have a hydroelectric power potential in excess of an estimated 4,000,000 h.p.; a program to harness them was begun in 1956. The upper stream, at the outfall from Menihek Lakes. was developed in 1953 to provide power for Schefferville. Below Grand falls the river flows in a deeply cut valley about 800 ft. below the plateau level, opening out only in the final six miles before discharging into Lake Melville and thence into the Atlantic ocean. Dense spruce forests vegetate the lower sections of the valley. Grand falls were discovered in 1839 by John McLean. Hudson's Bay company. (J. D. I.)

HAMIRPUR, a municipality, tehsil (subdivision) and district in the Jhansi division of Uttar Pradesh. India. The town stands near the confluence of the Betwa and the Jumna, 110 mi. N.W. of Allahabad. Pop. (1951) 8,469. It was founded, according to tradition, in the 11th century by Hamir Deo, a Karchuli Rajput expelled from Alwar by the Mohammedans.

HAMIRPUR TEHSIL (416 sq.mi.) had a population in 1951 of 109,316.

HAMIRPUR DISTRICT has an area of 2,776 sq.mi. and forms part of the great plain of Bundelkhand, which stretches from the Jumna to the central Vindhyan plateau and contains the famous artificial lakes of Mahoba. These magnificent reservoirs were constructed by the Chandel rajahs before the Mohammedan conquest, for irrigation and as sheets of ornamental water. Many of them enclose craggy islets or peninsulas, crowned by the ruins of granite temples, exquisitely carved and decorated. From the base of this hill and lake country the plain spreads northward, arid and treeless, toward the rivers. Of these the principal are the Betwa and its tributary the Dhasan.

The deep black soil of Bundelkhand, known as *mar,* retains the moisture under a dried and rifted surface, making the district fertile, but the rainfall is precarious and droughts are frequent. The staple products are grains of various sorts, the most important being gram. Cotton is also a valuable crop. Agriculture suffers much from the *kans* grass, a noxious weed which overruns the fields and is almost ineradicable wherever it has obtained a footing. In 1951 the population was 665,429. Exports are chiefly agricultural produce and cotton cloth. Rath (pop. 13,852) is the principal commercial centre! and other important towns are Mahoba (19,244) and Charkhari (11,631).

From the 9th to the 10th century this district was the centre of the Chandel kingdom, with its capital at Mahoba. The rajahs adorned the town with many splendid edifices, remains of which still exist. At the end of the 12th century Mahoba fell into the hands of the Mohammedans. In 1680 the district was conquered by Chhatar Sal, the hero of the Bundelas, who assigned at his death one-third of his dominions to his ally the Maratha peshwa. Until Bundelkhand became British territory in 1802 there was constant warfare between the Bundela princes and the Maratha chieftains.

HAMITIC LANGUAGES: *see* AFRICAN LANGUAGES: *The Hamito-Semitic (Afro-Asiatic) Languages.*

HAMITIC RACES. The term Hamitic as applied to race is not only extremely vague but has been much abused by anthropological writers. Sergi and Meinhof have both made classifications. Sergi includes the Hamites, racially, as a branch of his Mediterranean Race and distinguishes an eastern branch including the Nubians, Bejas, Abyssinians, Gallas, Somalis, Masais, etc., and a northern branch including the Berbers, Fulani, etc. Meinhof's classification is on broad lines essentially the same but he would include the Hottentots, on very unsatisfactory grounds, mainly linguistic. The southern Abyssinians have certainly absorbed Galla blood but the majority are Semitic or Semito-Negroid. There is still some support for the contention that only Sergi's eastern branch should be called definitely Hamitic and that the northern should take the name Libyan.

The definition of the term Hamitic as an anthropological description is still a type of brown people with frizzy hair, of lean and sinewy physique, with slender but muscular limbs, a thin, straight or even aquiline nose with delicate nostrils, thin lips and utter absence of prognathism. There is still much confusion in the use of the term from linguistic and ethnologic viewpoints. *See* G. Sergi, *Africa Anthropologia della stirpe camitica* (1897), and *The Mediterranean Race* (1901); C. Meinhof. *Die Hamitensprachen (Hamburg Kolonials-Institute).*

MASAI WARRIORS, OF BRITISH EAST AFRICA

Masai men live in military kraals for several years during their youth, and then settle down as cattle-breeders

HAMLET, the hero of Shakespeare's tragedy, a striking figure in Scandinavian romance. Saxo Grammaticus devotes parts of the third and fourth books of his *Historia Danica,* written at the beginning of the 13th century, to the story of Hamlet. Amleth or Amloði, which is supposed to have been contained in the lost Skjöldunga saga. The close parallels between the tale of Hamlet and the English romances of Havelok, Horn and Bevis of Hampton make it conceivable that Hamlet is of British rather than of Scandinavian origin. His name does in fact occur in the Irish *Annals of the Four Masters* (ed. O'Donovan 1851).

Late in the 10th century there is evidence of the existence of an Icelandic saga of Amloði or Amleth in a passage from the poet Snaebjorn in the second part of the prose *Edda:* "'Tis said that far out, off yonder ness, the Nine Maids of the Island Mill stir amain the host—cruel skerry-quern—they who in ages past ground Hamlet's meal." This passage may be compared with one of Hamlet's sayings quoted by Saxo: "As they passed the sand-hills, and bade him look at the meal, meaning the sand, he replied that it had been ground small by the hoary tempests of the ocean." According to Saxo (Books iii. and iv., chaps. 86–106), Hamlet's history is briefly as follows. In the days of Rorik, king of Denmark, Gervendill was governor of Jutland, and was succeeded by his sons Horvendill and Feng. Horvendill married Gerutha, Rorik's daughter, who bore him a son Amleth. But Feng, out of jealousy, murdered Horvendill, and persuaded Gerutha to become his wife, on the plea that he had avenged her of a husband by whom she had been hated. Amleth, afraid of sharing his father's fate, pretended to be imbecile, but the suspicion of Feng put him to various tests. Among other things they sought to entangle him with a young girl, his foster-sister, but his cunning saved him. When, however, Amleth slew the eaves-dropper hidden, like Polonius, in his mother's room, Feng despatched him to England in company with two attendants, who bore a letter enjoining the king of the country to put him to death. Amleth secretly altered the message on their wooden tables to the effect that the king should put the attendants to death and give Amleth his daughter in marriage. After marrying the princess, Amleth returned to Denmark, taking with him certain hollow sticks filled with gold. He arrived in time for a *funeral feast,* held to celebrate his supposed death. At the feast he plied the courtiers with wine, and during their drunken sleep fastened down over them the woollen hangings of the hall with pegs he had sharpened during his feigned madness, and then set fire to the palace. Having slain Feng with his own sword, he was proclaimed king. Returning to England for his wife he found that his father-in-law and Feng had been pledged each to avenge the other's death. The English king, unwilling personally to carry out his pledge, sent Amleth as proxy wooer for the hand of a terrible Scottish queen Hermuthruda, who had put all former wooers to death, but fell in love with Amleth. On his return to England his first wife, whose love proved stronger than her resentment, told him of her father's intended revenge. In the battle which followed Amleth won the day by setting up the dead men of the day before with stakes and thus terrifying the enemy. He then returned with his two wives to Jutland, where he was slain in a battle against Wiglek, Rorik's successor.

The other Scandinavian versions of the tale are: the *Hrolfs-saga Kraba;* the modem Icelandic *Ambales Saga,* a romantic tale the earliest manuscript of which dates from the 17th century; and the folk tale of Brjám which was put in writing in 1707. Saxo Grammaticus was certainly familiar with the Latin historians, and it is most probable that, recognizing the similarity between the northern Hamlet legend and the classical tale of Lucius Junius Brutus, he deliberately added circumstances from the classical story. 0. L. Jiriczek first pointed out the striking similarities existing between the story of Amleth and that of Kei Chosro in the *Shāhnāma* ("The Book of the Kings") of the Persian poet Firdousi, and *R.* Zenker *(Boeve Amlethus,* pp. 207–268, Berlin and Leipzig, 1904) even concluded that the northern saga rested on an earlier version of Firdousi's story. Further resemblances exist in the *Ambales Saga* to the tales of Bellerophon, of Hercules and of Servius Tullius. In *The Classical Tradition in Poetry* Gilbert Murray has drawn an interesting parallel between the story of Hamlet and the story of Orestes. The tale of Hamlet's adven-

tures in Britain forms an episode so distinct that it was at one time referred to a separate hero.

The story of Hamlet uas known to the Elizabethans in François de Belleforest's *Histoires tragiques* (1559), and as early as 1587 or 1589 Hamlet had appeared on the English stage, as is shown by Thomas Nashe's preface to Robert Greene's *Menaphon:* "He will afford you whole Hamlets, I should say, handfulls of tragical speeches." The Shakespearian Hamlet owes, however, little but the outline of his story to Saxo. *See* also SHAKESPEARE.

HAMLEY, SIR EDWARD BRUCE (1824–1893), British general and military writer, was born on Aprii 27, 1824, at Bodmin, Cornwall, and entered the Royal Artillery in 1843. He served in the Crimean War, and in 1859 became professor of military history at the staff college at Sandhurst. In 1866 he weni to the council of military education, returning in 1870 to the staff college as commandant. From 1879 to 1881 he was British commissioner successively for the delimitation of the frontiers of Turkey and Bulgaria, Turkey in Asia and Russia, and Turkey and Greece. He commanded the 2nd division of the expedition to Egypt under Lord Wolseley. From 1885 he represented Birkenhead in parliament as a Conservative He died in London on Aug. 12, 1893.

HAMLIN, HANNIBAL (1809–1891), vice-president of the United States (1861–65), was born at Paris, Me., on Aug 27, 1809. After studying in Hebron academy, he conducted his father's farm for a time, became schoolmaster and later managed a weekly newspaper at Paris. He then studied law, was admitted to the bar in 1833 and rapidly acquired a reputation as an able lawyer and a good public speaker. Entering politics as an anti-slavery Democrat, he was a member of the state house of representatives in 1836–40, serving as its presiding officer. He was a representative in congress from 1843–47, and was a member of the U.S senate, 1848–56. From the very beginning of his service in congress he was prominent as an opponent of the extension of slavery; he was a conspicuous supporter of the Wilmot proviso, spoke against the compromise measures of 1850 and in 1856, chiefly because of his party's endorsement of the passage in 1854 of the Kansas-Nebraska bill, which repealed the Missouri compromise, he withdrew from the Democrats and joined the newly organized Republican party. The Republicans of Maine nominated him for governor in the same year, and having carried the election by a large majority he was inaugurated in this office on Jan. 8. 1857. In February, however, he resigned the governorship, and was again a member of the senate, 1857–61. From 1861 to 1865, during the Civil War, he was vice-president of the United States. While in this office he was one of the chief advisers of Pres Abraham Lincoln, and urged both the Emancipation proclamation, and the arming of the Negroes. After the war he again served in the senate (1869–81), was minister to Spain (1881–83) and then retired from public life. He died at Bangor, Me., on July 4, 1891.

See *Life and Times of Hannibal Hamlin* by C. E Hamlin, his grandson (1899).

HAMM, a town in the province of North Rhine-Westphalia, Ger., on the Lippe, 19 mi. by rail N.E. from Dortmund on the main line Cologne-Hanover Pop. (1960) 68 775. The town possesses very extensive wire factories and machine works breweries and manufactories of brushes, baskets, leather, starch, varnish and oil Nearby are some thermal baths and coal mines Because of its factories and very extensive railway yards and connections Hamm was one of the German cities most heavily bombed by British and U S planes during World War II

HAMMAD AL-RAWIYAH (ABU AL-QASIM HAMMAD IBN ABI LAILA SABUR) (*c.* 694–*c.* 772) Arab scholar, famous for his knowledge of pre-Islamic and early Islamic poetry and credited nith the collecting of the early odes known as the *Mu'allaqat* (q *v.*). He was born in Kufa, probably in 694, of the tribe of Dailam Reputed to be the most learned man of his time in regard to the "days of the Arabs" (*i.e*, their chief battles). their stories, poems. genealogies and dialects, he is said to have boasted that he could recite 100 long *qasidas* (odes) for each letter of the alphabet (*i.e.,* rhyming in each letter) and these chiefly from pre-Islamic times. Hence his name *al-Rasiyak* ("the reciter of verses from memory"). A favourite of the caliphs Yazid II and Hisham, he came to live in Damascus, where he died c. 772.

See Ibn Khallikan's biographical dictionary in French trans. by M'G. de Slane, vol i (1842).

HAMMANN, OTTO (1852–1028) German journalist, who as director of the press section of the German foreign office from 1894 to 1916 exercised considerable influence, was born at Blankenhain, Jan. 23, 1852. He studied law and in the 1880s moved to Berlin where he became a journalist. He was appointed leader of the foreign office press section by the imperial chancellor, Count Leo von Caprivi, and played a leading part in Caprivi's defensive campaign against Bismarck's followers. Hammann maintained friendly relations with Caprivi's successor Prince Hohenlohe, and under the chancellorship of Prince von Bülow, who fully recognized the importance of the press, his influence increased, arousing, however, much hostility. Among his tasks was the preparation of the important declarations of policy which the chancellor made before the *Reichstag.* His works include *Der neue Kurs* (1918), *Zur Vorgeschichte des Weltkriegs* (1918) and *Um den Kaiser, Errinerungen . . .* 1906–09 (1919). He died in Berlin, June 18, 1928.

See *Deutsches Biographisches Jahrbuch,* vol. x, 1928 (1931).

HAMMARSKJÖLD, DAG (HJALMAR AGNE CARL) (1905-1961), Swedish statesman, economist and United Nations official who was posthumously awarded the 1961 Nobel peace prize, was born at Jönköping, Swed . on July 29, 1905 Son of a former Swedish prime minister, Hjalmar Hammarskjold, he studied law and economics at the universities of Uppsala and Stockholm At Stockholm he became an assistant professor of political economy in 1933. He joined the civil service in 1936 as permanent undersecretary in the ministry of finance He was also for several years president of the board of the Bank of Sweden.

In 1947 Hammarskjöld was appointed to the ministry of foreign affairs and was made responsible for all international financial and economic questions He served for two years as permanent secretary-general of that ministry and entered the cabinet in 1951 as minister of state with the functions of deputy foreign minister. In April 1953, he was elected secretary-general of the U S and was re-elected unanimously for another term of five years in Sept 1957. In 1956-57 Hammarskjöld was deeply involved in the Suez canal crisis Thereafter the middle east continued to occupy his attention, and he went there several times to confer with Israeli and Arab leaders. On March 27. 1959, he visited Soviet Premier N S Rhrushchev at Sochi, U.S S R

Civil strife broke out in the Belgian Congo after it gained independence in 1960 and Hammarskjdld dispatched UN troops to the area in an effort to reunite—by force if necessary—the warring factions This action was denounced by the U S S R , which demanded that Hammarskjold resign and that a three-man board replace the office of secretary-general. The members of this *troika* (a Russian word meaning a three-horse team). one each from the western, neutralist and Communist nations, would exercise veto power over the other two and thus over the actions of the secretariat. Hammarskjold refused to resign. but while on a peace mission to the Congo he was killed in a plane crash near Ndola, Northern Rhodesia. on Sept 18. 1961, just one day before the scheduled opening of the 16th session of the UN general assembly. A month after his death Hammarskjöld was awarded the 1961 Nobel peace prize.

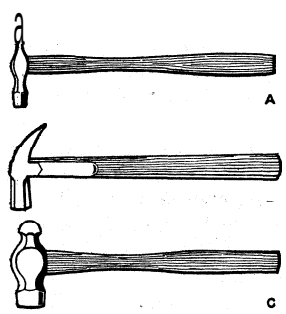
HAMMARSKJOLD, HJALMAR (1862–1953), Swedish statesman. was horn at Tuna on Feb. 4, 1862. He studied at Uppsala, where in 1891 he was appointed professor of civil law. He became minister of justice in the Van Otter cabinet, holding this post from 1901–02, when he was appointed president of the Göta high court. In 1905 he was minister of education in the

Lundeburg cabinet and also a delegate to the conference with Norway at Karlstad at the time of the dissolution of the union. He was Swedish minister in Copenhagen from 1905–07 when he became governor (*landshörding*) of the province (Ian) of Uppsala.

He had been Swedish delegate at The Hague conferences in regard to private international law in 1900 and 1904, and from 1904 was Swedish member of The Hague international board of arbitration. In 1907 he was Sweden's leading delegate to The Hague Peace conference and in 1909 acted as president of the Franco-German board of arbitration in regard to the Casablanca affair. He presided in 1913 over the Franco-Italian arbitration court regarding the seizure of vessels during the Tripoli war. In Feb 1914 he succeeded Karl Staaff as prime minister, retaining this post during World War I until 1917 (*see* SWEDEN). Hammarskjold became a curator of the Académie de Droit International at The Hague. He was president of the Institut de Droit International (1924–38) and chairman of the Nobel Prize foundation (1929–47).

Hammarskjold died in Stockholm on Oct. 12, 1953.

HAMMER, an implement consisting of a shaft or handle with head fixed transversely to it. The head, usually of metal, has one flat face. the other may be shaped to serve various purposes, *e.g.*, with a claw, a pick. etc. The implement is used for breaking, beating, driving nails, rivets, etc., and the aord is applied to heavy masses of metal moved by machinery, and used for similar purposes. (*See* TOOL.) The word is also applied to many objects resembling a hammer in shape or function. Thus the "striker" in a clock, or in a bell. when it is sounded by an independent lever and not by the swinging of the tongue is called a hammer; similarly. in the action of a pianoforte the word is used of a wooden shank with felt-covered head attached to a key, the striking of which throws the hammer against the strings.



SPECIMENS OF HAMMERS
A, cross-peen pin hammer. B, claw hammer. C, ball-peen engineer's hammer

In the-mechanism of a firearm the hammer is that part which by its impact on the cap or primer explodes the charge. (*See* SMALL ARMS, MILITARY.)

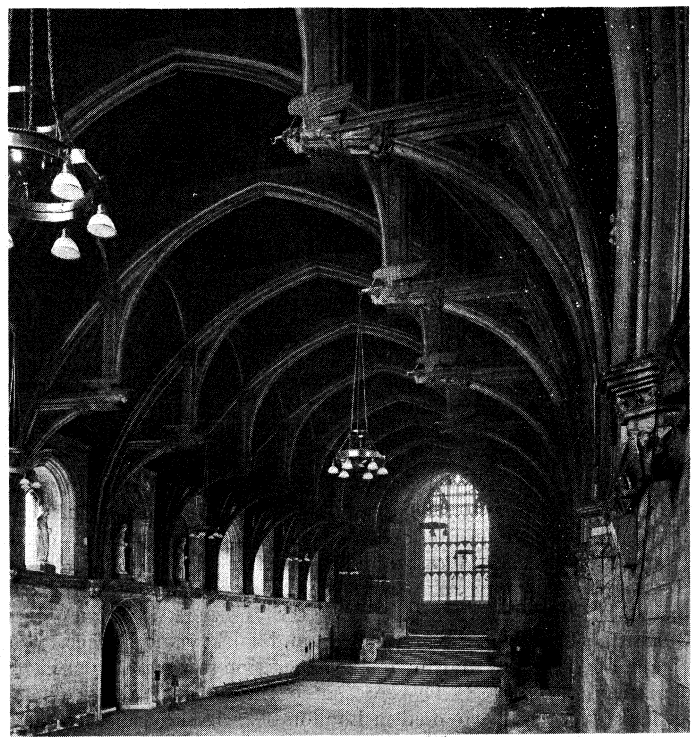
The hammer. more usually known by its French name of *martel de fer,* was a medieval hand weapon. With a long shaft it was used bv infantrv, especially when acting against mounted troops. With a short handle and usually made altogether of metal it was also used by horse-soldiers.

HAMMERBEAM ROOF, in architecture, a term for a type of truss used in an open timber roof In this construction, the ordinary tie beam, *i.e.,* the horizontal beam in a roof nhich ties together the feet of the rafters, is cut through, leaving a horizontal portion, the hammerbeam, which projects from the wall. The cutting of the tie beam allows a higher open space in the centre of the building.

The hammerbeam is supported by curved braces springing from wall posts which rest on corbels. A post usually rises vertically from the end of the hammerbeam to the intersection of the rafter and the cross tie. For greater strength a large arched piece of timber, rising from the wall post or from the hammerbeam, is often carried across the hall. The hammerbeam ends usually terminate in carved figures and all other parts are richly decorated with moldings. Two rows of hammerbeams are occasionally used, and the hammerbeam is also found in conjunction with other forms of trusses.

Although this principle of trussing was known in the 13th century. it received its most characteristic development in 14th-century England. The earliest extant example is the Great Hall, Palace of Westminster, London, begun 1394. Other important examples exist over the halls of the palaces of Hampton Court and Eltham, and many examples are to be found, especially in East Anglia, in parish churches of the 15th and 16th centuries.

(E. B. MACD.)



A f KERSTING

HAMMERBEAM ROOF IN **WESTMINSTER** HALL, LONDON

HAMMERFEST, the most northerly town in Europe. Pop. 11959 est) 5.131. It is situated on an island (Kvaloy) off the northwest cosst of Norway, in Finmark county. in 70° 40' 11″ N., the latitude being that of the extreme north of Alaska. In spite of this, its average January temperature is little below freezing point. owing to the influence of the warm westerly winds and North Atlantic drift. and the harbour is ice-free. The district around is barren and naturally treeless. but a "forest" of birches has been successfully planted. Hammerfest is 674 mi. by sea S.E. of Trondheim, and 78 mi. S.W. from the North cape. The narrow strait Strommen separates Kvaloy from the larger Seiland, whose snow-covered hills with several glaciers rise above 3,500 ft., while an insular rampart of mountains, Soro, protects the strait and harbour from the open sea. The town is timber-built and modern; much of it having been rebuilt after fire in 1890. The sun does not set at Hammerfest from May 13 to July 29. Vessels set out to the fisheries, as far as Spitsbergen and the Kara sea; and trade before World War II was brisk, not only Norwegian and Danish but British, German and Russian vessels engaged in it.

Cod-liver oil, train oil and salted fish are exported with some reindeerskins, foxskins and eiderdown; and coal and salt for curing are imported. In the spring the great herds of tame reindeer are driven out to swim Strommen and graze in the summer pastures of Seiland; toward winter they are called home again. From Nov. 18 to Jan. 23 the sun is not seen, and the enforced quiet of winter prevails. Electric light was introduced in the town in 1891.

HAMMERHEAD SHARK. Any of several species of ovoviviparous sharks of the genus *Sphyrna,* characterized by the unique configuration of the head, the anterior portion of which resembles a hammer. They are formidable and ferocious and occur in all tropical and subtropical seas. particularly in the Indian ocean. The common hammerhead shark (*S. zygaena*), which attains a length of 16 ft., occurs on the milder coasts of Europe and ranges northnard along American shores to Massachusetts and California *See* SHARK; CHONDRICHTHYES.

HAMMERKOP or HAMMERHEAD (*Scopus umbretta*), an African wading bird related to the storks and herons (*qq.v.*) and constituting the family Scopidae in the order Ciconiiformes. It is found over Africa south of the Sahara, as well as Madagascar and southwest Arabia. It is nearly uniform umber or

earthy-brown, whence the name umbrette, has a large head with a horizontal crest and a heavy. compressed. hook-tipped bill. black like the shortish legs. It sits beside a stream. head pulled down. or wades slowly stirring the mud with one foot and then the other, feeding on mollusks, frogs, small fishes and water beetles. Though only about 2 ft. long, it builds an enormous nest of sticks. 6 ft. across and 3 to 4 ft. high, on rocky ledges or trees in which it lays 3 to 6 chalky white eggs. The dome-shaped nest has an entrance on the side and a narrow tunnel leading to a central chamber lined with mud. (G. F. Ss.)

HAMMER-PURGSTALL, JOSEPH, FREIHERR VON (1774–1856), Austrian diplomat and author. the pioneer of Islamic studies in Germany, mas born at Graz. June 9. 1774. In 1799 he was appointed to a post in the Austrian embassy in Constantinople and subsequently took part in an English campaign against the French in the eastern Mediterranean. He returned to Austria in 1807, and on inheriting estates in Syria in 1835. he was ennobled and retired from the diplomatic service. He died in Vienna, Nov. 23, 1856.

Hammer-Purgstall's services to oriental studies in Germany resembled those of Sir William Jones in England and Silvestre de Sacy in France. For jo years he wrote incessantly on many subjects, but more important than his scholarly works were his texts and translations of Arabic. Persian and Turkish authors. which made their work known to a public outside narrow academic circles and opened the way for later studies. His principal historical work is his *Geschichte des Osmanischen Reiches,* 10 vol. (1827–35). He also wrote poems, plays and novels, now forgotten. He was largely responsible for the foundation of the Akademie der Wissenschaften at Vienna.

Despite faults. Hammer-Purgstall did more for oriental studies than those who criticized his inaccuracies.

For a full list of Hammer-Purgstall's works, see *Comptes rendus* of the Xcademie des Inscriptions et des Belles Lettres (1857). *See* also **C.** Schlottmann, *Joseph von Hammer-Purgstall* (1857).

HAMMERSMITH, a western metropolitan borough (1899) of London. Eng., bounded east by Kensington and south by Fulham and the Thames river, and extending north and west to the boundary of the county of London. Pop. (1951) 119.36;. Area 3.6 sq.mi. Hammersmith is mentioned with Fulham as a camp of Danish invaders in 879. when they occupied the island of Hame, identified with Chiswick Eyot. Hammersmith. though retaining little of its early rural charm, is a residential area with many large industrial concerns. chiefly in the north, in the part called Shepherd's Bush. Industry is mainly electrical and light engineering and food and drink manufacture. Old Hammersmith bridge, designed by W. Tierney Clark (1824), was the earliest suspension bridge erected near London. It was replaced in 1884–87 by another suspension bridge by Sir Joseph Bazalgette.

Until 1834 Hammersmith formed part of Fulham parish. Its church of St. Paul was built as a chapel of ease to Fulham and consecrated by William Laud in 1631. The modern building dates from 1890. St. Paul's school was founded in or about 1509 by John Colet, dean of St. Paul's, under the shadow of the cathedral church. But it appears that Colet actually refounded and reorganized a school which had been attached to the cathedral from at least the early 12th century. The school was moved to its site in Hammersmith road in 1883. The number of foundation scholars was set at 153, according to the number of fishes taken in the miraculous draught (John xxi. 11). The school governors are appointed by the Mercers' company (by n-hich body the new site was acquired) and the universities of Oxford. Cambridge and London. There are also the Latymer Upper school for boys (1624); the Godolphin school, founded in the 16th century and remodelled as a grammar school in 1861; St. Paul's school for girls, in Brook Green; Nazareth House of Little Sisters of the Poor; and other institutions. By the large Shepherd's Bush green is the White City stadium. first occupied by the Franco-British exhibition of 1908. By it is a television centre. The new town hall (1939) faces Furnivall gardens which are crossed by the Cromwell road extension to the west completed in 1956 to relieve congestion in King street. Other buildings include the Olympia, an exhibition centre, built in 1884 and refaced in 1930, and Wormwood Scrubs prison, built in 1874 by convicts. In the neighbourhood of the Mall, bordering the river, are the Dove inn, where James Thomson is said to have written part of "The Seasons." and Kelmscott house, residence successively of Sir Francis Ronalds, who there invented a telegraph in 1816, George Macdonald and William Morris. Hammersmith returns two members to parliament. for North Hammersmith and, with part of Fulham, for Baron's Court.

HAMMER THROWING is the name given the 16-lb. weight-throwing event of the Olympic games track-and-field program that was developed into a sport centuries ago in Ireland, Scotland and England.

The earliest authentic date for a hammer-throwing contest outside the British Isles was Sept. 4, 1838, at Hoboken, N.J. On Sept. 11, 1839, there was a similar competition near Toronto. Ont. In 1900 the event was placed on the Olympic games program. It was made popular in the United States by a group of Ireland-born U.S. citizens, who raised the world record to 189 ft. 63 in. in 1913—an increase in distance of 111 ft. 1½ in. over the winning performance at the first English amateur championships, March 23. 1866. (For hammer throwing in the Olympic Games, *see* OLYMPIC GAMES.)

The principal reason for the increase in record distances was the improvement in equipment and technique. In the early years of the sport, which goes back at least to 1154, a blacksmith's sledge hammer with a stiff wooden handle was used, and it was from the employment of that implement that the event originally derived its name.

The modern implement bears little resemblance to that used by the early Irish. Scottish and English hammer throwers. In its specifications of the implement to be used in its hammer-throwing event, the Amateur Athletic Union of the United States stated that the head should be of lead or a brass shell filled with lead or cast gray iron and spherical in shape. The handle must be a single unbroken and straight length of spring steel wire not less than ⅛ in. (3.175 mm.) in diameter. or no. 36 piano wire .102 in. (2.591 mm.) in diameter. The handle may be looped at one or both ends as a means of attachment. The grip may be either of single or double loop construction, but must be rigid and without hinging joints of any kind. The handle must be connected to the head by means of a swivel which may be either plain or ball bearing. The grip must be connected to the handle by means of a loop. A swivel may not be used. The weight must be not less than 16 lb. (7.257 kg.) complete as thrown. The length must not be more than 4 ft. (1.219 m.) complete as thrown.

There was also a diversity of rules governing the event prior to 1900. In Ireland: the thrower was permitted to make one or more turns before releasing the hammer. In Scotland, the thro was made from a stand. A go-ft. circle was used in Oxford and Cambridge university competition from 1866 to 1881. The English Amateur Athletic association used a seven-foot circle from 1866 to 1887, changed that year to a nine-foot circle and a few years later returned to the seven-foot circle, which became the standard in Olympic games competition. In the United States; from 1876 to 1886, rules of the national championship specified that the throw was to be made from a stand without follow. After 1887. turns were permitted in national A.A.U. competitions. The throw is made from a seven-foot circle, the thrower must not touch the circle or the area outside the circle. and the hammer must fall within a go° sector marked on the ground. These also became the rules governing the event in Olympic games competition.

Method **of** Throwing. — All successful hammer throwers use the same basic technique. The effort is begun at the rear of the circle with the thrower's back toward the intended direction of flight. The athlete swings the hammer several times about his head and then begins the first of three full turns of the body. Upon the completion of the third turn the hammer is released. It is important that each turn be faster than the preceding one. The first half of each turn is usually made on the heel of the left foot and completed on the ball of the left foot. During the course of the throw, the left foot should always maintain contact with the ground.

Hammer throwing performance depends upon the efficiency with which centrifugal force is developed. Thus, the orbit of the hammer must be circular until its release. An athlete best develops centrifugal force by twisting his body from right to left about a perpendicular axis. In this way the body is twisted from a position of nonalignment to and past a position of alignment. The fundamental principle employed in hammer throwing is similar to that used in swinging a bat or golf club. However, the use of body turns permits repetitions of the twisting motions with a consequent increase in centrifugal force. In the 1950s there was remarkable improvement in hammer throwing performance throughout the world. In 1952 at Oslo. Nor , Sverre Strandli first threw a 16-lb. hammer more than 200 ft. officially, the distance being 200 ft. 11⅜ in. Throws of better than 200 ft. became common, and in the 1960s throws of more than 230 ft. were recorded Advances in the style of throwing did not involve a new principle of centrifugal force development, instead, changes were designed to obtain a fuller and faster twisting movement of the body.

See Jacob Weber and Frank Rasky, *Training Olympic Champions in Track and Field* (1951). (H. AR. RX.; F. J. RN.)

HAMMERTOE, a painful condition in which a toe, commonly the second toe, is rigidly bent due to pressure from short shoes. The salient angle on its upper aspect is constantly irritated by the shoe and develops a corn (*q.v.*). It is treated surgically, by the simple excision of the small digital joint causing the toe to lie flat.

HAMMETT, (SAMUEL) DASHIELL (1894–1961), U.S writer whose works may be considered the first and best attempt to depict realistically the world of American crime, was born in St. Mary's county, Md., on May 27. 1894. His writings stem from his eight years' experience, as a young man. with Pinkerton's Detective agency. Hammett's countless short stories and novelettes in the magazine *Black Mask,* starting in 1923, and his first tno novels—Red *Harvest* (1929) and *The Dain Curse* (1929)—are about the Continental Op, an anonymous agency operative modeled on Jimmy Wright of Pinkerton's Baltimore office. *The Maltese Falcon* (1930) introduces the more complex Sam Spade, in a work which many critics rank not only as a great detective story but as an important American novel. *The Glass Key* (1931) is a subtle study in loyalties. *The Thzn Man* (1934) is his least typical book—a poor detective story but a bright comedy, ieaturing Nick and Nora Charles. After 1934 Hammett stopped writing for publication. In only a decade of creative activity, he exerted an influence on the American detective story greater than that of any other author since Poe, and no small influence upon the American novel. His gifts of characterization and dialogue have been compared, notably by André Gide, to those of Ernest Hemingway. Hammett died in New York city Jan. 10, 1961. (AY. B.)

HAMMOND, EDMUND HAMMOND, 1ST BARON (1802–1890), British civil servant, nho, as head of the foreign office for nearly 20 years, exercised considerable influence behind the scenes on late 19th-century diplomacy. He was a son of George Hammond (1763–1853), the first British minister to the Cnited States (1791–95) and permanent undersecretary for foreign affairs (1795–1806 and 1807–09). Edmund Hammond was born in London on June 25, 1802, and was educated at Eton, Harrow and Cniversity college, Oxford. He began his official career in the privy council office in Oct. 1823, but was transferred to the diplomatic service early in 1824. Apart from four special missions abroad, he passed the rest of his working life in the foreign office. Lord Palmerston made him head of the Turkish department. In 1854 Hammond was permanent head of the office as undersecretary for foreign affairs, a post he retained until 1873. He was distinguished by an exceptional capacity for work. coupled with an exceptional grasp of detail; though always subordinate. he often influenced foreign secretaries. He inexpediently assured Lord Granville. then foreign secretary, on July 5, 1870, ten days before the Franco-German War began, that he had never known "so great a lull in foreign affairs," an opinion also expressed by a French prime minister five days earlier. On retirement, Hammond was raised to a barony Feb 22, 1874. almost an unprecedented honour for a civil servant. He died at Menton, France, on April 29, 1890; as he had no male heir the peerage became extinct. (M. R. D. F.)

HAMMOND, JOHN HAYS (1855–1936), U.S. mining engineer, was born in San Francisco. Calif.. on March 31, 1855. He studied at the Sheffield scientific school. Yale university, until 1876, and later at the Royal School of Mines, Freiburg, Saxony. In 1880 he was engaged in the U.S. geological survey of the California gold fields; afterward as consulting engineer, he visited most of the countries of North and South America. In 1893 he became associated with Barnato Bros. and Cecil Rhodes in South Africa. acting as consulting engineer for the Consolidated Gold Fields Company of South Africa. the British South Africa company and the Randfontein Estates Gold Mining company. As a leader of the Rand faction, he was, in Jan. 1896, after the Jameson raid, arrested and condemned to death. but was released on payment of a $125,000 fine. In 1900 he became interested in mining properties and irrigation projects in the United States and Mexico. He was chairman of the World Court commission, 1914–15; and chairman of the U.S. coal commission, 1922–23. In 1903 he became general manager and consulting engineer of the Guggenheim Exploration company. In 1911 he was special U.S. ambassador at the coronation of King George V.

He died at Gloucester. Mass., on June 8, 1936.

His son. JOHN HAYS HAMMOND, JR. (1888–), was in 1959 anarded the Edward Cresson medal by the Franklin institute for inventions and developments in radio and electronics, particularly for remote radio control of marine and submarine vehicles. (S. C. HR.)

HAMMOND, JOHN LAWRENCE LE BRETON (1872–1949), British author and journalist, was educated at Bradford grammar school and St. John's college, Oxford. He was editor of the *Speaker* from 1899 to 1906, when he joined the staffof the *Tribune* as leader (editorial) writer. In 1907 he was appointed secretary to the civil service commission. He served in World War I with the Lowland division (Sept. 1915 to Aug. 1916), and on his discharge obtained a post in the ministry of reconstruction.

Hammond was the historian of the Industrial Revolution in England; in his works on this subject, which are indispensable to the student, he had the assistance of his wife, Barbara Hammond. His chief journalistic work was done on the *Manchester Guardian.* His publications include: *Charles James Fox* (1903); *The Village Labourer, 1760–1832* (1911, and later editions); *The Town Labourer, 1760–1832* (1917); *The* Skilled *Labourer, 1760–1832* (1919); *Lord Shaftesbury* (1923); *The Rise of Modern Industry* (1925); *The Age of the Chartists* (1930). He mas one of the authors of *Liberalism and tlze Empire* (1900). He died April 7, 1949, near Hemel Hempstead, Hertfordshire, Eng.

HAMMOND, an industrial city of Lake county, Ind., U.S., adjacent to Chicago and Calumet City, Ill., a part of the Gary-East Chicago-Hammond standard metropolitan statistical area. The city had its beginning in 1869 when George H. Hammond, a Detroit butcher and pioneer in shipping refrigerated beef hy rail, established with Marcus M. Towle the State Line Slaughter house, ultimately the G. H. Hammond company, on the Grand Calumet river. This site mas selected because the ice used for refrigeration could be readily obtained irom the river and inland lakes, and it was far more economical to ship dressed beef than live cattle fronn the Chicago stockyards to distant markets.

Until it was destroyed by fire in 1901. the packing house, which at that time employed 1,500 workers, was Hammond's largest industry.

It was originally called Hohman's Inn, then State Line because of,its location on the Illinois-Indiana boundary. The name was changed in 1873 to Harnmond, in honour of the meat packer. The city was incorporated in 1883. It was heavily populated by Germans in the earlier years, manifested by the many streets that bear German names. In 1910 the census showed that almost 30% of its people were born in Germany and Austria or their parents were natives of those countries.

While Hammond was served by numerous railroads and had a frontage on Lake Michigan, heavy industrial development was initially handicapped by the lack of a harbour. Consequently, it

failed to Secure the heavier basic industries such as steel mills and oil refineries as did its neighbours, East Chicago, Whiting and Gary. The city attracted smaller industries which included iron and brass foundries, steel fabricators, and those manufacturing railroad equipment, surgical instruments and metal toys; other products include soaps, corn products, chemicals, gasoline and motor oils, clothing and stock feeds. There is also a large printing works.

Hammond is the site of a Purdue University extension centre which includes a technical institute for the advanced training of industrial employees. The Calumet centre of Indiana university presents a regular schedule of classes.

The population increased from 5,428 in 1890 to 20,925 in 1910 and soared to 55,378 in 1920. It was 87,594 in 1950 and 111,698 in 1960.

For comparative population figures *see* table in INDIANA: *Population.* (P. *ME.*)

HAMMURABI, 6th king of the Amoritic or West Semitic dynasty of Babylonia, reigned 43 years, 2067–2025 B.C. and is one of the most illustrious figures of ancient history. The so-called 1st Babylonian dynasty was founded by Sumuabi in 2169 B.C. at Babylon, which thus was raised from an unimportant town on the eastern bank of the Euphrates to the dignity of a capital, and a rival of the far more ancient and greater city, Kish, 8 m. to the east. The invasion of Babylonia by the Canaanitic race of the west had already resulted in the founding of a West Semitic dynasty at Isin in 2301 B.C., a city in southern Sumer, which, until the rise of the Canaanitic kingdom of Babylon, shared with Ellasar the control of Sumer and Accad. At first, the kingdom founded at Babylon by this ancestor of the famous line of 11 kings at Babylon had control of only a small region north and south of the capital, and under the first two kings there was even a rival kingdom at Kish, only 8 m. away. During the reigns of Hammurabi's five predecessors the kingdoms of Isin and Ellasar successfully maintained control of the whole southern area of Babylonia; and Sinmuballit, predecessor of Hammurabi, conquered and put an end to the kingdom of Isin with the aid of Rim-Sin of Ellasar, in 2076, or only nine years before Hammurabi came to the throne, only to lose it again to Rim-Sin, the powerful king of Ellasar, seven years later, and Hammurabi himself did not gain control of the whole of Babylonia and put an end to the kingdom of Rim-Sin until his 30th year (2038).

Although his father, Sinmuballit, had largely succeeded in bequeathing to his illustrious son the united control of Sumer and Accad, the military and political achievement of Hammurabi in finally establishing a central and efficient Government at Babylon, which included not only Sumer and Accad, but extended northward to the central provinces of the Tigris and Euphrates, must be regarded as one of the most far-reaching events in ancient history. Henceforth Babylon was to be the political and intellectual centre of West Asiatic history right down to the Christian era. His name is particularly associated with the great law code promulgated for the use of the courts throughout the empire. The only fairly complete text of this Semitic code was found at Susa, inscribed on a diorite stela 8 ft. high, which had been taken to Elam as plunder by invaders during the later period of Babylon's decline, probably in the period of the Pashe dynasty (12th–11th centuries). The text is inscribed in 21 horizontal columns on the obverse beneath a bas relief of the king, who stands in attitude of prayer before the seated sun god (Shamash), who delivers to Hammurabi the laws of the kingdom, a *motif* undoubtedly connected with the legend of Moses and the revelation of the Decalogue from Yahweh on Mt. Sinai. The last five or six columns of the obverse have been defaced by the Elamitic invader, who probably intended to inscribe here a relation of his conquest of Babylon. The reverse is complete and carries 28 horizontal columns. The first four columns and top of column five of the obverse, contain the prologue, which is the principal source for Hammurabi's extensive restorations of the temples and cults of Babylonia and Assyria. The last five columns of the reverse contain the epilogue, a glorification of the mighty works of peace executed by Hammurabi. Sixty-five laws are contained on the obverse, and about 40 laws are defaced at the bottom; the reverse contains 183 laws. Fragments of the code as redacted on a series of tablets for use at Nippur in the same period have been excavated there, and fragments of an Assyrian copy of the 7th century were found at Nineveh. These partially restore the great gap in the Susa stela.

Hammurabi is generally identified with Amraphel, king of Shinar, who with Arioch of Ellasar, Cheodorla'omar of Elam and Tidal, king of Goiim, invaded Canaan in the days of Abraham. Since Hammurabi apparently enjoyed peaceful relations with the powerful Elamitic king, Rim-Sin of Ellasar, and his father, Kudurmabug, *ad-da* of Emutbal and of Amurru, the biblical records appear to harmonize with these facts and the identification has never been successfully disproved.

Although no great literary or historical documents from his reign have survived, a great number of administrative documents and letters from it are known and are constantly increasing. There is little doubt but that the theological reconstruction of the Sumerian pantheon, by which the priests of Babylon raised Marduk, the local deity, to the rank of a great god, began at this time. To his and the succeeding reigns of Samsuiluna, Abi-eshu', Ammiditana and Ammizaduga, may certainly be ascribed the gradual completion of the Accadian version of the Epic of Creation in six books or tablets, in which Marduk is made to displace the older Ninurta of the Surnerian legend of Creation. Hammurabi regularly employs *Sumerian* as the language of his records of temple and cult restorations and of other dedicatory inscriptions, as did all his successors.

The derivation of his name is disputed; the element *ḫammu, ʿammu, ammu, ammi* is clearly the West Semitic word *ʿam,* "family, relative," Arabic *"uncle,"* and it is characteristic of West Semitic religion to describe a deity as "father, brother, uncle." A grammatical gloss explains *ḫammu* by *kimtu,* "family." The element *rabi* is usually explained as meaning "great," "the uncle is great." There is another king by this name of the Canaanitish kingdom of Hana, whose capital Tirga is the modern Ashârah on the middle Euphrates, near the mouth of the Ḫabur. This name is spelled Ammurabi, and Ḫammurapiḫ; the Ḫana kingdom is contemporary with the Cassite dynasty of Babylonia. Since the name of the famous king of Babylon is once written *Ammurapi* it has been argued that the name should be pronounced *Hammurapi, Ammurapi,* with the meaning "the uncle is exalted, high," but this suggestion is not generally accepted.

HAMPDEN, HENRY BOUVERIE WILLIAM BRAND, 1ST VISCOUNT (1814–92), 23rd Baron Dacre, was speaker of the house of commons and, earlier, a prominent member of the English Liberal party. Born on Dec. 24, 1814, Brand was elected to parliament for Lewes in 1852 and retained the seat until 1868, sitting for Cambridgeshire from 1868 to 1884. He was parliamentary secretary to the treasury between 1859 and 1866 and was chief whip during the last ministries of Lord Palmerston and Lord (John) Russell. Brand was speaker of the house of commons from 1872 until 1884, when he retired and was raised to

the peerage. He died at Pau. France. on March 14, 1892.

Brand was a greatly respected political manager in a difficult period for the Liberal party and laid the foundations of the party's later organization. His success as whip led to criticism of his election as speaker. However. Brand proved an excellent choice. His tenure of the chair was memorable for the part he played in reforming parliamentary prvcedure in 1882, having taken the initiative in meeting Irish obstruction in 1881; and for his dignified conduct during the disputes caused by Charles Bradlaugh's election to the commons. (A. F. T.)

HAMPDEN, JOHN (*c.* 1595–1643), English statesman. the eldest son of William Hampden. of Great Hampden in Buckinghamshire. and of Elizabeth. second daughter of Sir Henry Cromwell and aunt of Oliver, the future protector. was educated at the grammar school at Thame and at Magdalen college. Oxford. In 1613 he was admitted a student of the Inner Temple. He first sat in parliament for the borough of Grampound in 1621. representing later Wendover in the first three parliaments of Charles I. Buckinghamshire in the Short Parliament of 1640 and again in the Long Parliament. In his early parliamentary career he was content to be overshadowed by Sir John Eliot. as later he n-as content to be overshadowed by Pym and to be commanded by Essex.

In 1626 Hampden helped prepare the charges against Buckingham. In Jan. 1627 he was bound over to answer at the council board for his refusal to pay the forced loan. Later in the year he was committed to the gatehouse. and then sent into confinement in Hampshire, from which he was liberated just before the meeting of the third parliament of the reign. in n-hich he once more rendered useful but unobtrusive assistance to his leaders. After Eliot's imprisonment he often consulted Hampden on national and family matters. It was not till 1637, however, that Hampden's resistance to the payment of ship money gained for his name the lustre which it has never since lost. (*See* SHIP MONEY.) Seven out of the 12 judges sided against him. but the connection betrreen the rights of property and the parliamentary system was firmly established in the popular mind. The tax had been justified, says Clarendon. who expresses his admiration at Hampden's "rare temper and modesty" at this crisis. "upon such grounds and reasons as every stander-by was able to swear was not law." In the Short Parliament of 1640 Hampden led the opposition (May 4) to the grant of 12 subsidies in return for the surrender of ship money. Parliament was dissolved the next day, and on the 6th an unsuccessful search was made among the papers of Hampden and of other chiefs of the party to discover incriminating correspondence with the Scots. In the Long Parliament, though Hampden was by no means a frequent speaker, it is possible to discern that his power consisted in his personal influence and as a debater rather than as an orator. Unwearied in attendance upon committees, he was always at hand to second Pym. whom he plainly regarded as his leader. Hampden was one of the eight managers of Strafford's prosecution. Like Pym, he was in favour of procedure by impeachment rather than by attainder. and his influence secured a compromise under which Strafiord's counsel were heard as in the case of an impeachment, and thus a serious breach between the two houses was averted.

Hampden was among the opponents of episcopacy. It is not that he was a theoretical presbyterian. but he distrusted the bishops as he distrusted the monarchy. He was not tempted by the offers of advancement made him and his friends by Charles who would gladly have given them office if they had been ready to desert their principles. Every day Hampden's conviction grew stronger that Charles would never abandon the position which he had taken up. In Xug. 1641 Hampden was one of the four commissioners who attended Charles in Scotland. He was a warm supporter of the Grand Remonstrance and. when opposing members were at sword's point on the motion to print it. his intervention prevented a free fight. He was one of the five impeached members whose attempted arrest on Jan. 4, 1642, brought at last the opposing parties into open collision (see HOLLES. DENZIL HOLLES: LENTHALL, WILLIAM; PYM, JOHN; STRODE. WILLIAM). After the attempted impeachment Hampden laid down the two conditions under which resistance to the king became the duty of a good subject. Those conditions were an attack upon religion and an attack upon the fundamental laws. There can he no doubt that Hampden fully believed that both those conditions n-ere fulfilled at the opening of 1642.

When the Civil War began Hampden was appointed a member of the committee for safety, levied a regiment of Buckingharnshire men for the parliamentary cause and in his capacity of deputy lieutenant carried out the parliamentary militia ordinance in the county. He took no actual part in the battle of Edge Hill. His troops in the rear. however. arrested Rupert's charge at Kineton, and he urged Essex to renew the attack there. and also after the disaster at Brentford. In 1643 he was present at the siege and capture of Reading, though he had argued that the greater importance of Oxford made it a fitter objective. But it is not on his skill as a regimental officer that Hampden's fame rests. In war as in peace his distinction lay in his power of disentangling the essential part from the nonessential. In the constitutional struggle he had seen that the one thing necessary was to establish the supremacy of the house of commons. In the military struggle which follon-ed he saw, as Cromwell saw afterward, that the one thing necessary was to beat the enemy. He protested at once against Essex' hesitations and compromises. In the formation of the confederacy of the five associated counties. which was to supply a basis for Cromwell's operations. he took an active part. His influence was felt alike in parliament and in the field. But he was not in supreme command, and he had none of that impatience which often leads able men to fail in the execution of orders of which they disapprove. On June 18, 1643. he joined the parliamentary horse that u-as trying to intercept Rupert's cavalry returning to Oxford after a successful raid on Essex' outposts. At Chalgrove field he was fatally wounded and died at Thame on the 24th. He was buried in the church of Great Hampden. His loss was felt by his party "as if their n-hole army had been defeated or cut off."

Hampden married (1) in 1619 Elizabeth. daughter of Edmund Synieon of Pyrton. Oxfordshire, and (2) Letitia. daughter of Sir Francis Knollys and widow of Sir Thomas Vachell. By his first wife he had nine children, one of whom, Richard (1631–95), was chancellor of the exchequer in William III's reign; from two of his daughters are descended the families of Trevor-Hampden and Hobart-Hampden. the descent in the male line becoming apparently extinct in 1; 54 in the person of his grandson John Hampden.

See S. R. Gardiner, *History of England* (London, 1883–84) and the *Gveat Civil War* (London, 1893); the article on Hampden in the *Dictionary of National Biography*, by C. H. Firth, with authorities there collected; Clarendon, *History of the Rebellion* (Oxford, 1888); Lord Nugent, *Memorials of John Hampden* (London, 1831); Macaulay's review is in *Essays*, ed. by F. C. Montague (London, 1903). The printed pamphlet announcing his capture of Reading in Dec. 1642 is shown by Firth to be spurious, and the account in *Mercurius Aulicus* (Jan. 27 and 25, 1643) of Hampden commanding an attack at Brill to be also false. n-hile the published speech supposed to have been spoken by Hampden on Jan. 4, 1642, and reproduced by Forster in the *Arrest of the Five Members* (London, 1860) has been proved by Gardiner to be a forgery (*History of England*, x, 135). Firth has also shown, in The *Academy* (Nov. 2 and 9, 1889), that "the belief that we possess the words of Hampden's last prayer must be abandoned." (G. Ds.)

HAMPDEN, JOHN (1653–1696), English politician. was the second son oi Richard Hampden (1631–95). An intimate of Lord William Russell and Algernon Sidney. he was arrested with them in 1683 for alleged complicity in the Rye House plot. As he could not pay the fine of £40.000 imposed upon him he remained in prison. In 1685, after the failure of the duke of Monmouth's rising. Hampden was again brought to trial and, pleading guilty, was condemned to death on a charge of high treason. But the sentence was not carried out and having paid £6.000 he was set at liberty. In the Convention Parliament of 1689 he was an extreme Whig and because of his violent opposition to the government he was not elected to the parliament of 1690. Disappointed again in 1696. he died by his own hand on Dec. 12, 1696.

HAMPDEN, WALTER (WALTER HAMPDEN DOUGHERTY) (1879–1955), U.S. actor, was born in Brooklyn. N.Y.. June 30, 1879. After a year at Harvard. he graduated from Brooklyn Polytechnic institute. Following a year's study of singing, dancing,

speech and the cello in France, he joined Sir Frank Benson's company in England, where he played over 70 classical roles in three years. In 1905 he married Mabel Moore. an actress in the troop, and the following year he played Hamlet in London to great applause. After his return to the U S in 1907 he appeared in several modern dramas with Nazimova. but his *Hamlet* was so successful that when he formed his own repertory company that play became its foundation. In 1923 Hampden revived Edmond Rostand's *Cyrano* dc *Bergerac,* a play that will forever be associated with his name. He opened his own theatre (1925), with Ethel Barrymore as his leading lady, and among his outstanding performances in the ensuing years were *Hamlet* and *The Merchant* of *Venice* (1925–26), *The Immortal Thief* and *Caponsacchi* (1926–27) and *An Enemy of the People* (1927–28). In 1939 Hampden appeared in his first motion picture, *The Hunchback of Notre Dame,* and later played the part of an aging actor in *All About Eve.* He made his television debut as Macbeth in 1949. Hampden was the fourth president of the Players' club, succeeding John Drew, Edwin Booth and Joseph Jefferson. He died in Los Angeles, Calif., June 11, 1955. (S. W. H.)

HAMPSHIRE (abbr. HANTS) is a county of southern England bounded W. by Dorsetshire and Wiltshire, N. by Berkshire. E. by Surrey and Sussex, S. by the English channel. Area (1951) 1.650. j sq.mi., including the Isle of Wight (147.1 sq.mi.), which formed part of ancient Hampshire but became a separate administrative county in 1890 *(see* WIGHT, ISLE OF). Hampshire was styled the County of Southampton for legal purposes until April 1, 1959, when its name was officially changed to Hampshire.

Geology.—The county falls physiographically into four areas. A broad belt of rolling chalk downland, at times more than 800 ft. high, runs across the middle from west to east. To the north and south lie mixed Tertiary clays, sands and gravels, often covered by heath and woodland. In the east the western extremity of the Weald. with its typical scarps and vales, crosses the county border. The oldest rocks occur in this Wealden area—the Lower Greensand (Hythe. Sandgate and Folkstone Beds) and the Gault and Upper Greensand. The Upper Cretaceous beds are. for the most part, flint-bearing Upper Chalk. although the Middle and Lower Chalk strata are exposed toward the Surrey-Sussex border. Scattered over the chalk are small Tertiary outliers. The Tertiary rocks of the north, about Aldershot. Farnborough and Kingsclere, comprise the Reading Beds and London Clay, often covered by the more sandy Bagshot Beds. The Tertiaries, south of the chalk boundary by Romsey and Bishops Waltham to Havant. include the Eocene Reading Beds, London Clay and Bagshot, Bracklesham and Barton Beds and, at Brockenhurst, Hordle and Lyndhurst, the Oligocene Headon Beds. The Barton and Headon strata are rich in fossils.

The narrow strait called the Solent and known at its eastern end as Spithead. which divides the Isle of Wight from the mainland, marks the lower course of the ancient Frome or Solent river. Submergence, further evidence of which can be seen in the drowned valleys and estuaries of the Hampshire coast line, converted it into an arm of the sea, and rivers which were formerly tributaries in that greater system are now independent streams. These streams, flowing southward, drain nearly the whole of the chalk and southern Tertiary areas. The Avon, in the southwest, rises in Wiltshire and is joined by the Dorset Stour near its mouth at Christchurch. The Test, with its tributary the Anton, and the Itchen rise in the chalk downs near Ashe and Hinton Ampner respectively and flow into the head of Southampton water. The Lymington or Boldre, the Beaulieu, Hamble, Meon and Wallington also drain southward. The Wey, Loddon and Blackwater, rising in the northeastern part of the county, flow northward into the Thames basin. The clear, swift chalk streams, especially the Test and Avon, are famous for their trout and salmon fishing.

History and Antiquities— There is considerable evidence of prehistoric settlement in Hampshire, particularly on the chalk downs and heathlands. Palaeolithic tools have been found in the river gravels and Mesolithic implements near Petersfield and elsewhere, and there are Neolithic long barrows, *e.g.,* near Bournemouth, Danebury, Meonstoke and Rockbourne. Bronze Age settlement is represented by round barrows of different types and by the remains of small farmsteads. as at Quarley. Most notahle among Iron Age remains are the hill forts, *e.g.,* Danebury. Hengistbury. Ladle. Old Winchester. Quarley and St. Catherine's.

Hampshire was conquered within a fen. years of the Roman invasion in A.D. 43. During the occupation. urban settlements developed at Silchester (Calleva Atrebaturn) and Winchester (Venta Belgarum), the focal points of the Roman road system in the area. There was a small settlement at Southampton (Clausentum). Villa sites are especially numerous in the northwest of the county. There were potteries in the New forest and an imperial weaving works at Winchester. The most substantial Roman remains are the town walls of Silchester (*q.v.*) and the outer wall at Portchester castle which formed part of the defenses of what was probably the most westerly of the forts of the Saxon shore. Reading museum houses a large collection of objects from Silchester.

The progress of the early English settlement of Hampshire is obscure and the contributions of the Jutes, along the coast and in the Hamble and Meon valleys, the followers of Cerdic and Cynric, the Genisse and the peoples moving in from the northeast. are uncertain. The county. first mentioned by name in the Anglo-Saxon Chronicle in 755, became the cradle of Wessex and the English kingdom. with Winchester the capital. It suffered severely from the attacks of the Norsemen. During the middle ages, apart from coastal raids during the Hundred Years' War. the county enjoyed a comparatively peaceful existence and the influence of the church and such men as William of Wykeham was of major importance. Few castles were built and only at Christchurch, Odiham, Portchester and Winchester are there substantial remains. At Winchester and, more especially. Southampton, town walls and gates still survive. Later 16th-century coastal defenses exist in Calshot and Hurst castles. During the Civil War, battles were fought at Alton (1643) and Cheriton (1644), Portsmouth and Basing house suffered notable sieges. and Charles I stayed at Hurst castle and Titchfield. Some postmediaeval fortifications can be seen in and near Portsmouth. During World War II Portsmouth and Southampton were heavily damaged by enemy air raids.

The conversion of Hampshire to Christianity was begun by Birinus (634) and Wilfrid (687). At first the county formed part of the West Saxon bishopric of Dorchester-on-Thames. but on the transference of the episcopal seat in 676 it was included in the diocese of Winchester. The whole of the county remained in this diocese until the creation of the see of Portsmouth in 1927. Mediaeval Hampshire had many religious houses. There were pre-Conquest Benedictine foundations at Romsey and Wherwell besides three in Winchester—St. Swithun's. New Minster and St. Mary's. After the Conquest, houses of Augustinian canons were established at Breamore. Christchurch. Mottisfont. Portchester (later moved to Southwick), Selborne and Southampton (St. Denys); of Cistercians at Beaulieu. Hartley Wintney and Netley; and of Premonstratensians at Titchfield. Alien priories existed at Andover. Andwell. Ellingham, Hamble. Hayling and Monk Sherborne. There were houses of Franciscan friars at Southampton and Winchester, and of Austins, Carmelites and Dominicans at the latter. Substantial monastic remains can still be seen at Beaulieu and Netley, in the great churches of Christchurch and Romsey and in the cathedral at Winchester. Although not renowned for its parish churches. Hampshire can show interesting Saxon work. *e.g.,* at Boarhunt, Breamore, Corhampton and Headbourne Worthy; Norman work, *e.g.,* at East Meon, Hambledon and Portchester; and early English, *e.g.,* at Cheriton, Grateley. Hound and Sopley. Decorated and Perpendicular work are represented in a number of places. but only by details. Eighteenth-century churches can be seen at Avington. Wolverton and St. George's, Portsmouth and good examples of 19th-century Gothic at St. Michael's and St. Peter's, Bournemouth and St. Mary's, Portsea.

Interesting domestic architecture includes Norman houses at Southampton, and Christchurch, the mediaeval palace at Bishops Waltham, 16th-century and later work in the Vyne at Sherborne St. John, the Jacobean Bramshill. the work of Henry Holland at Broadlands and Charles Barry's 19th-century restoration of High-

clere. The homes of Jane Austen at Chawton and of Gilbert White at Selborne are museums.

Hampshire has always been essentially agricultural, but its history shows some evidence of industrial activity. Woollen manufactures mere formerly widespread throughout the county, *e.g.,* in the Xlresford. Andover, Romsey and Winchester areas. and survived in some places until the early 19th century. Iron was smelted at Sowley in the New forest and near Bramshott until the 18th century. Salt manufacture was carried on at a number of places along the coast, particularly at Lymington, where the last saltworks disappeared as late as 1865. Among the many ships built in Hampshire yards, the men-of-war launched at Bucklers Hard in the late 18th and early 19th centuries are perhaps the most famous. Other industries practised at different times include malting, brewing and tanning, and silk weaving and papermaking which were introduced into the county by Huguenot refugees. Winchester (St. Giles) and Weyhill were nationally important fairs. Southampton, since the Conquest. has been preeminent in overseas and coastal trade. There the mediaeval wine and wool trade and the business with northern Italian merchants in rich Levantine commodities were followed by a period of decline until the railway and dock development of the mid-19th century. From early in the 18th century, Portsmouth grew rapidly as a naval dockyard town. The earliest turnpike road in Hampshire was a section of the London to Portsmouth road (1710), and the earliest railway, the London to Southampton (1840).

In 1832 the county was represented in parliament by no less than 26 members, the majority from pocket and corrupt boroughs.

Famous figures connected with Hampshire include Tane Austen. William Cobbett Charles Dickens, John Keble, Charles Kingsley, George Meredith Mary Mitford. Florence Nightingale, Isaac Watts, Gilbert White and Charlotte M Tonge

The National trust in the mid-1950s owned more than 3.000 ac and protected 30 ac

Agriculture, Industries and **Communications.**—In 1954 the following acreage was under crops and grass: tillage and fallow 296,000, temporary grass 112,000. permanent pasture 147,000, rough grazing 35,000, with an additional 9,000 ac. of agricultural holdings of which 3,000 ac. were devoted to horticulture. Great changes took place in Hampshire farming after 1939. The old system of folded sheep and barley on the chalkland. the extensive water meadows and much formerly semi-derelict farmland disappeared. In the main. Hampshire agriculture is almost equally concerned with corn production and dairying. This revolution has been facilitated by the large farms, found especially in the chalk country, rapid mechanization, the supply of piped water and the replacement of the old root rotations by grass leas and kale. thus making possible the combination of corn growing and dairying on individual farms. Relatively few sheep are now reared in the county and breeds of the Clun type have mostly replaced the old folded Hampshire Downs sheep. On the Tertiaries. particularly in the south, farms are generally smaller, and between Southampton and Portsmouth market gardening, with strawberries and potatoes, is an especially large industry. In the greensand area, in addition to corn and dairy produce, hops are grown near Xlton. There is still a high proportion of woodland in the county. In the New forest (*q.v.*), once a royal hunting ground. the rights of the Forestry commission. commoners and general public are carefully defined by the New Forest act (1949).

There has been a marked increase recently in cattle rearing and milk production in this area. Around Aldershot, Blackmoor and Bordon large tracts of wasteland are used by the army for military training.

Portsmouth and Gosport form one of the principal naval centres of Great Britain. The great port of Southampton is especially concerned with passenger traffic. Eastleigh has important railway works. Two modern industries which are of particular importance are petroleum refining at Fawley on the western side of Southampton water, and aircraft engineering at Christchurch, Farnborough and near Southampton. The holiday industry affords much employment. particularly at Bournemouth, which has grown since the beginning of the 19th century from a few scattered houses to a town of nearly 150,000 people. and at Southsea. Smaller resorts along the coast include Highcliffe. Barton. Milford, Lee-on-the-Solent and Hayling Island. Bursledon, Christchurch, Hamble and Lymington are well-known yachting centres. Shipyards of varying size and character are to be found at a number of places. Most market towns have light industries; engineering, *e.g.,* at Andover, Basingstoke. Lymingron and Ringwood, and brewing, *e.g.,* at Alton and Romsey, are two of the major ones.

The county is served by three main lines of the Southern region of British railways which also own the docks at Southampton. A main route from London to the southwest crosses the county from Farnborough to Xndover. From it the Southampton-Bournemouth line branches south at Basingstoke. Portsmouth is linked with London via Petersfield. Some of the secondary lines were closed after World War II. There are civil airports at Blackbushe. Hurn. Portsmouth and Southampton.

Population and Administration.— In 1951 the population of Hampshire, excluding the Isle of \\Tight (95,625), was 1,197,170, which represents a growth of 18% since 1931. The 1951 populations of the county boroughs of Bournemouth, Portsmouth and Southampton were 144,845, 233,545 and 178,343 respectively, leaving a total of 630,437 in the administrative county area. Bournemouth and Southampton each return two members to parliament and Portsmouth returns three. The county is divided into seven parliamentary divisions: Aldershot, Basingstoke, Eastleigh, Gosport and Fareham. New Forest, Petersfield and Winchester, each of which returns one member. There are 9 municipal boroughs, 6 urban and 11 rural districts.

HAMPSTEAD, a metropolitan (1900) and parliamentary borough of northwest London, Eng., about 4 mi. N.N.W. of Hyde Park corner by road. Pop. (1951) 95,131. Area 3.j sq.mi. It is built up the steep southern slopes of a hill from the top of which the Spaniards road leads across the heath to Highgate, the other prominent hill of north London. From between the rather sterile Bagshot Sands of Hampstead heath and the London Clay flowed chalyheate springs, one of which in the early 18th century caused a fashionable spa to grow up by Well walk near the heart of the old village—still a complexity of streets, alleys, tenements, flats, mansions and cottages. Down the hill are the late-19th-century residential accretions of Belsize Park, Chalk Farm. Swiss Cottage, the Finchley road area and Kilburn near the Edgware road. The borough, almost entirely residential, has long been the home of lawyers, artists. writers and politicians; the few industries include the making of Christmas cards. In the borough are two colleges of London university, several big schools, hospitals and medical research centres. Samuel Johnson, Sir Richard Steele, Sir Rowland Hill! Kate Greenatvay. John Galsworthy and four prime ministers are among the well-known people once resident there. Hampstead ("farm site") was settled in Anglo-Saxon times; a Roman burial and a barrow on Parliament hill are the only antiquities. The manor, which included Kilburn priory, belonged to Westminster abbey until the Reformation. In St. John's parish church (rebuilt 1744–47) and its churchyards lie buried many famous men including John Constable, George du Maurier and Sir Herbert Beerbohm Tree. Old houses include Fenton house (c. 1693), George Romney's house (1797) and the Keats Memorial house. The Spaniards, Jack Straw's Castle and the Bull and Bush near Pitt house, home of the first earl of Chatham, are well-known local inns. At Wyldes farm, near North End, William Blake was a frequent guest of John Linnell. Kenwood, reconstructed about 1767 by Robert Adam and with gardens by H. Repton, was presented. with its paintings and other works of art, to the nation in 1927 by Lord Iveagh.

The heath, consisting of 793 ac., rising to 443 ft., of woods, grassland and ponds includes Golders Hill park, Parliament hill

and Ken wood, all largely outside the borough; foxes and badgers, owls, woodpeckers and other country birds have been seen there. On bank holidays two fun fairs are held. The last 74 ac. were acquired for the public in 1927, thus completing negotiations begun nearly 100 years before. The heath is administered by the London County council.

HAMPTON, WADE *(1818–1902)*, U.S. statesman and Confederate general during the Xmerican Civil War, was born on >larch *28. 1818,* at Charleston, S.C. He was the son of Wade Hampton (1791–1858), planter and politician, and grandson of Wade Hampton (1754–1835), who served as a colonel in the American Revolution and as a brigadier general in the War of *1812.* He graduated from South Carolina college in *1836* and inherited vast estates. As a South Carolina legislator he opposed secession but nevertheless raised "Hampton's Legion" for Confederate service when war came. He was an infantry colonel at the first battle oi Bull Run and a brigadier general at the battle oi Seven Pines. Transferring to Gen. J. E. B. Stuart's cavalry oi the army of Northern Virginia in *1862,* he won praise and promotion and was wounded five times. After Stuart's death Hampton became a lieutenant general and served as chief of General Lee's cavalry during the defense of Petersburg. In *1865* he assisted Gen. Joseph E. Johnston's effort to oppose Gen. W. T. Sherman's march through the Carolinas and attempted to save Pres. Jefferson Davis from capture after Johnston's surrender.

During the reconstruction period Hampton worked for conciliation and the restoration of southern home rule. He was governor of South Carolina, 1877–79, U.S. Senator. *1879–91,* and U.S. commissioner of Pacific railways. *1893–97.* He died at Columbia. S.C., on April 11, *1902.* (M. W. We.)

HAMPTON COURT, a palace in Twickenham *(q.v.)*, Middlesex. Eng.. on the Thames *1 j* mi. S.W. of St. Paul's cathedral, London. It was built by Cardinal Wolsey who in 1526 presented it to Henry VIII whose favourite residence it became. George II was the last reigning sovereign to occupy it and Queen Victoria threw the state rooms open to the public. Later, nearly 1.000 rooms were assigned by the sovereign as "grace and favour" apartments for the widows or children of distinguished servants of the crown.

Henry VIII enlarged the palace. building wings on either side of the Great gatehouse behind which is the Base court and Anne Boleyn's gateway leading to the Clock court. This contains Henry VIII's Great hall and the colonnade and King's staircase built by Sir Christopher Wren. Over the gateway is the clock made by N. Oursian for the king in 1540; the George II gateway opposite leads to Fountain court rebuilt by Wren for William III n-ith the state apartments on the south side. Beyond are the Broad n-alk and the Great Fountain garden.

The Chapel, Royal, built by Wolsey, was embellished by Henry VIII. and by Grinling Gibbons according to designs by Wren for Queen Anne. Charles II filled in the moat which was dug out again in 1910 when Henry VIII's bridge was uncovered. The tennis court. built for Henry VIII. is the oldest in the world where the game is still played.

The gardens. laid out in the Dutch style for William III. contain a vine planted in 1768. two orangeries along the south side of the palace, a wilderness and a maze.

See G. H. Chettle, *Hampton* Court Palace, reprinted (H.M.S.O., 1954).

HAMPTON INSTITUTE, a coeducational college located in Hampton, Va. Founded in *1868.* Hampton attained distinction under the principalship of Samuel Chapman Armstrong as an agricultural. normal and industrial school for Negroes. Xrmstrong's most noted student was Booker T. Washington, who founded Tuskegee institute in Tuskegee Institute, Ala.; and gave international stature through Tuskegee to the principles of industrial education and advocacy of racial harmony learned from Armstrong at Hampton institute. (H. M. Bd.)

HAMPTON ROADS, a natural roadstead or harbour of Virginia, U.S.. formed by the confluence of the James. Nansemond and Elizabeth rivers. It lies to the west of Chesapeake bay. with which it is connected by Thimble Shoal channel *(1.000* ft. wide, *40* ft. deep and *11* mi. long); two deepwater channels branch out from the harbour. The southern channel is linked with the sounds of North Carolina through the Intracoastal waterway. The port of Hampton Roads, administered by a state port authority, includes the port cities of Norfolk. Newport News *(qq.v.)* and South Norfolk, which connect with nine trunk railroads and which have a combined water frontage of about *50* mi. The Hampton Roads tunnel bridge (4½ mi.) spans the James river between Norfolk and Newport News.

An important naval base since colonial days, Hampton Roads embraces the most significant concentration of naval establishments in the U.S., including the headquarters of the Atlantic fleet (at Norfolk) and the Norfolk naval shipyard (at Portsmouth). Army and air force installations are also located in the vicinity. The Civil War naval engagement between the "Monitor" and "Virginia" ("Merrimack") was fought in Hampton Roads (*see* "Monitor" and "Merrimack." Battle of). The abortive peace conference between President Lincoln and Confederate representatives was held there aboard the "River Queen!" Feb. *3. 1865.*

In the second half of the 20th century waterborne commerce exceeded *80.000.000* tons annually. Foreign commerce (mainly exports, comprising about 75% of total tonnage) increased considerably after World War II. Coal is the principal export, but tobacco, grain, scrap metal. fertilizer and cotton are also important. Crude-oil residues, oils, ores and crude gypsum are leading imports. (G. M. Be.)

HAMSTER, a mammal of the order Rodentia, belonging to the mouse group, Muroidea. in which it typifies the family Cricetidae. Hamsters are short-tailed nocturnal rodents with large cheek pouches and thick soft fur. There are many species representing several genera, of which three are well known. *Cricetus,* the European genus, ranges throughout Europe and into Asia: *Cricetulus,* commonly known as the Chinese hamster. is a larger genus and its distribution extends throughout Asia and into southern parts of Europe; *Mesocricetus,* the Syrian hamster. is limited to Asia Minor and the Balkans. The European hamsters are the largest in size. n-ith a body length of more than 200 mm. The most common species. *Cricetus cricetus,* is light brown above and mainly black underneath. The Chinese hamsters are small and gray, and one species (*Cricetulus barabensis*) has a middorsal black stripe. *Mesocricetus auratus,* the most common species of the Syrian genus, is medium in size with reddish brown above and gray underneath, and is commonly known as the golden hamster.

Species of these three genera have been introduced into the laboratory for research purposes. but the most successful in captivity by far is *Mesocricetus auratus.* It has been extensively used since 1930, when one litter was captured in Aleppo, Syr., and brought to the laboratory at the Hebrew university. Israel (then Palestine). All golden hamsters in laboratories in Europe and America derive from this original litter raised in captivity. The golden hamster is very easily tamed and has become a popular pet. It is a clean and attractive small creature which requires little care and can be fed very common foodstuffs.

Cricetus cricetus inhabits cultivated lands of central Europe. where it constitutes a pest to agriculture because of the enormous quantities of grain and vegetables which it ransacks from the field. It digs elaborate burrows consisting of galleries and chambers: in the summer these are short and shallow with one central chamber for grain. while in the winter they are one or two yards deep with several storage places. Provisions are stored in great quantities for the winter, and the animals. having fattened themselves during the previous season, retire to their burrows to spend the cold months in a state of inactivity. They are very prolific, the female producing several litters in one year. At birth the young are blind and naked. but they mature fast and by three weeks set forth to build their own burrows.

Hamsters are usually pugnacious and attack other rodents. lizards and small birds. which they consume as part of their diet. although their chief food consists of fruits. vegetables and grain. They are preyed upon by carnivores and killed by man hut nevertheless remain abundant. The skin of the hamster is of some value. and its flesh is used for food. (E. O.)

HAMSUN, KNUT (1859–1952), Norwegian author, was born on Aug. 4. 1859. at Lom in the Gudbrandsdal valley. of poor parents. He started to write at the age of 19 when he was a shoemaker's apprentice at Bodö in north Norway, and for the next ten years earned his livelihood in various ways; *e.g.*, as coal trimmer and country schoolmaster. He eventually went to the U.S., where he became a streetcar conductor in Chicago and a farm labourer on the prairies. In 1888 he published, in a Danish magazine, the fragment of a novel. *Sult*, later translated into English as *Hunger*. He is chiefly known to the English-speaking world by three novels. *Hunger, Growth of the Soil* and *The Woman at the Well*. The influence of Nietzsche and Strindberg (*qq.v.*) was apparent in Hamsun's impatience with contemporary emphasis on man's social problems; his talents were long centred more directly on the psychological analysis of the individual at grips with a simpler reality (hunger. physical labour, etc.). In 1920 he mas awarded the Nobel prize for literature. After World War II he was charged with treasonable hehaviour during the German occupation, but charges were dropped in view of his advanced age. He died near Grimstad. Nor., on Feb. 19, 1952.

HAMTRAMCK, a city of Wayne county, Mich., U.S., is completely surrounded by Detroit. Named for Col. John F. Hamtramck, the first American commander at Detroit (1796), the area was originally settled by French and later by German farmers. After 1910, stimulated by the growth of the automobile industry, a great migration of Poles to this area began. In this decade Hamtramck's population increased from about 3.500 to more than 45,500. After World War II the city was a haven for refugees from central Europe and the Balkans. The Hamtramck public school code. fostered by Maurice R. Keyworth in the 1920s, was a notable plan for educating children of foreign-born parents for American democracy, and its principles were widely adopted by educators in other cities. Hamtramck was incorporated as a village in 1901 and as a city in 1922. The automobile industry is the most important; other industrial products include paints, varnishes, automobile radiators. wire, electrical supplies, dishes and metal products. For comparative population figures *see* table in MICHIGAN: *Population.* (P. P. M.)

HANAU, a town in the *Land* of Hesse, Ger., on the right bank of the Main, 14 mi. E. of Frankfurt. Pop. (1950) 30.702. From the number of finds near Hanau, it would appear that it owes its origin to a Roman settlement. It received municipal rights in 1393, and in 1528 it mas fortified and the castle rebuilt. At the end of the 16th century its prosperity received considerable impulse from the accession of the Walloons and Netherlanders. Early in the 15th century Hanau became the capital of a principality of the empire, and in 1785 the province was united to Hesse-Cassel. In 1803 it again became an independent principality. In 1815 it reverted to Hesse-Cassel, and in 1866 it was joined to Prussia.

The streets of the old town are narrow and irregular. but the new, founded at the end of the 16th century by fugitive Walloons and Netherlanders, is built in the form of a pentagon with broad streets crossing at right angles. Among the principal buildings are the ancient castle, formerly the residence of the counts of Hanau, who are buried in the old church of St. Mary; the church of St. John, dating from the 17th century. with a handsome tower; and the church in the new town, built by the Walloons in the beginning of the 17th century in the form of two intersecting circles. Hanau is the birthplace of the brothers Grimm, to whom a monument was erected there in 1896. In the neighbourhood of the town are the palace of Philippsruhe and the spa of Wilhelmsbad. Hanau manufactures ornaments of various kinds; cigars; leather; paper; gold, silver and platina wares; chocolate; soap; hats; gloves; machinery; chemicals; and lamps. Diamond cutting is carried on and the town has also foundries and breweries. It carries on trade in wood, wine and corn.

HANCOCK, JOHN (1737–1793), American revolutionary statesman, was born in that part of Braintree. Mass., now known as Quincy. on Jan. 23, 1737. After graduating at Harvard in 1754, he entered the mercantile house of his uncle, Thomas Hancock of Boston, who had adopted him, and on whose death, in 1764, he fell heir to a large fortune and a prosperous business. In 1765 he became a selectman of Boston. and from 1766 to 1772 was a member of the Massachusetts general court. An event which is thought to have greatly influenced Hancock's subsequent career was the seizure of the sloop "Liberty" in 1768 by the customs officers for discharging, without paying the duties, a cargo of Madeira wine consigned to Hancock. Many suits were thereupon entered against Hancock. which, if successful. would have caused the confiscation of his estate, but which undoubtedly enhanced his popularity with the Whig element and increased his resentment against the British government. He was a member of the committee appointed in a Boston town meeting immediately after the "Boston massacre" in 1770 to demand the removal of British troops from the town. In 1774 and 1775 he was president of the first and second provincial congresses respectively, and he shared with Samuel Adams the leadership of the Massachusetts Whigs in all the irregular measures preceding the American Revolution. The famous expedition sent by Gen. Thomas Gage of Massachusetts to Lexington and Concord on April 18–19, 1775, had for its object, besides the destruction of materials of war at Concord. the capture of Hancock and Adams. who ivere temporarily staying at Lexington, and these two leaders were expressly excepted in the proclamation of pardon issued on June 12 by Gage. their offenses: it was said. being "of too flagitious a nature to admit of any other consideration than that of condign punishment." Hancock was a member of the Continental Congress from 1775 to 1780, was president of it from May 1775 to Oct. 1777, being the first to sign the Declaration of Independence, and was a member of the Confederation Congress in 1785–86. In 1778 he commanded, as major general of militia, the Massachusetts troops who participated in the Rhode Island expedition. He was a member of the Massachusetts constitutional convention of 1779–80, became the first governor of the state and served from 1780 to 1785 and again from 1787 until his death. Although at first unfriendly to the federal constitution as drafted by the convention at Philadelphia. he was finally won over to its support, and in 1788 he presided over the Jlassachusetts convention which ratified the instrument. Hancock was not by nature a leader, but he wielded great influence on account of his wealth and social position, and. was liberal. public-spirited and. as his repeated election—the elections were annual—to the governorship attests, exceedingly popular. He died at Quincy. Mass., on Oct. 8, 1793.

HANCOCK, WINFIELD SCOTT (1824–1886), U.S. general. was born on Feb. 14. 1824. in Jfontgomery county. Pa. He graduated in 1844 from the Military academy and was breveted first lieutenant for "gallant and meritorious conduct" in the Mexican War. After serving in the west, in Florida and elsewhere he married in 1850 Miss Almira Russell of St. Louis; became first lieutenant in 1853 and assistant quartermaster with the rank of captain in 1855. At the outbreak of the Civil War he was ordered east at his own request and on Sept. 23, 1861, was made brigadier general of volunteers and assigned to command a brigade in the army of the Potomac. He took part in the Peninsula campaign: and the handling of his troops in the engagement at Williamsburg on May 5, 1862, was such that McClellan reported "Hancock was superb." an epithet always afterward applied to him. At the battle of Antietam he was placed in command of the 1st division of the 2nd corps. and in November he mas made major general of volunteers, and about the same time was promoted major in the regular army. In the battle of Fredericksburg (*q.v.*) Hancock's division was among the troops that were ordered to storm Marye's heights. Out of the 5,006 men in his division 2,013 fell. At Chancellorsville his division received the brunt of the attack of Lee's main army. Soon after the battle he was appointed commander of the 2nd corps.

In the battle of Gettysburg (*q.v.*), after the defeat of the left wing of the army of the Potomac and the death of General Reynolds, Hancock arrived on the field with orders from Meade to assume command and to decide whether to continue the fight there or to fall back. He decided to stay, and held Cemetery hill and ridge until the arrival of the main body of the Federal army. During the second day's battle he commanded the left centre of the

Union army and, after General Sickles had been wounded, the whole of the left wing. In the third day's battle he commanded the left centre, upon which iell the full brunt of Pickett's charge, one of the most famous incidents of the war. As the guns of the Confederate army opened the attack Hancock rode along the front of his line to show his soldiers that he shared the dangers of the cannonade with them. His corps lost in the battle 4,350 out of less than 10,000 fighting men; but it captured 27 Confederate battle flags and as many prisoners as it had men when the fighting ceased. Hancock himself was struck in the groin by a bullet, but continued in command until the repulse of the attack. Six months passed before he resumed command. In the battles of the year 1864 Hancock commanded at the Wilderness. during the second day's fighting: half of the Union army; at Spottsylvania he had charge of the successful attack on the "salient"; at Cold Harbor his corps formed the left wing in the unsuccessful assault on the Confederate lines. In August he was promoted to brigadier general in the regular army. His old wound troubling him, he obtained a short leave of absence, expecting to return to his corps. He was, however, detailed to raise a new corps. and later was placed in charge of the "middle division." Before he could take the held Richmond had fallen and Lee had surrendered. After the assassination of Lincoln. Hancock was placed in charge of Washington, and it was under his command that Booth's accomplices were tried and executed. In July 1866 he was appointed major general in the regular army. A little later he was placed in command of the department of the Missouri, and the year following assumed command of the jth military division, comprising Louisiana and Texas. His policy, however, of discountenancing military trials and conciliating the conquered did not meet with approval at Washington, and he was at his own request transferred.

His war record and personal popularity caused Hancock's name to be considered as a candidate ior the presidency; and in 1880 he was nominated by the Democrats, but was defeated by his Republican opponent, General Garfield. He died at Governor's Island, near New York city, on Feb. 9. 1886. Grant said of him, "Hancock stands the most conspicuous figure of all the general officers who did not exercise a separate command. He commanded a corps longer than any other, and his name was never mentioned as having committed in battle a blunder for which he was responsible." (F. H. H.)

HAND, (BILLINGS) LEARNED (1872–1961), **U.S.** jurist, whose more than 2,000 opinions ranged virtually through all fields of law, was born in Albany, N.Y., on Jan. a7, 1872. Both his grandfather, Xugustus Hand (1803–78), and his father, Samuel Hand (1833–86), were judges; the former, justice of the New York supreme court and the latter, judge of the New York court of appeals. New Tork's highest state bench. With his cousin and boyhood companion, Augustus Noble Hand (1869–1954), also an outstanding U.S. judge in New York, Learned Hand attended Harvard. where he studied philosophy under William James: Josiah Royce and George Santayana, graduating in 1893. He received an M.A. degree (1894) and an LL.B. (1896) from Harvard. For 12 years he practised law in Albany and New York city.

In 1909 he was appointed United States district judge in New York. In 1913 he ran unsuccessfully on the Progressive ticket for chief judge of the New York state court of appeals. In 1924 he was elevated to the federal court of appeals ior the second circuit (New York. Connecticut and Vermont). where he became chief judge in 1939 through seniority. Augustus N. Hand reached the same bench in 1927.

His notable cases included the celebrated antitrust suit against the Aluminum Company of America (1945) in which his court acted for the supreme court where a quorum, because of disqualifications. was impossible. Summarizing his view of 40,000 pages of testimony, taken over four years. Hand said in characteristic epigram: "Congress did not condone 'good trusts' and condemn 'bad ones'; it forbade all." He upheld in 1gjo the conviction of the top 11 Communist party members on Smith-act charges of conspiracy to teach and advocate overthrow of the government. His opinion (183 Fed.. 2nd 201) was adopted by Chief Justice Frederick M. Vinson in 1951 when the supreme court also sustained the convictions (*Dennis* v. *U.S.*, 341 U.S. 494). But in 1957, under Chief Justice Earl Warren and with other changes in the justices, the supreme court substantially altered the application of the Smith act and with it the Hand and Vinson decisions. "Advocacy or teaching of abstract doctrine." the court said (Yntes v. *U.S.*, 354 U.S. 298), was not punishable "even though uttered with the hope that it may ultimately lead to violent revolution."

In delivering the Holmes lectures at Harvard in 1958, Hand cautioned strongly against judge-made law by "a third legislative chamber." with the result that his views were claimed as support for the Jenner-Butler bill (then before Congress) to limit severely the supreme court's jurisdiction. Asked to clarify this. Hand wrote to Sen. Thomas C. Hennings, Jr.. that he believed enactment of the bill "would be detrimental to the best interests of the United States" inasmuch as the supreme court "should have the last word on the questions of the character involved." Describing the highest tribunal as "the least contentious organ of government generally." he said that n-hile he did not think it always right, "some final authority is better than unsettled conflict."

Hand's Harvard lectures appeared as *The* ***Bill*** of *Rights* (1958). A collection of his papers and addresses, *The* ***Spirit*** of Liberty (1952; reissued with new material, 1959), appeared in his 81st year. The combination of faith and skepticism that distinguishes his thought was movingly presented in his "I Am an American" day address in New Work city, May 21, 1944. This brief definition of the spirit of a free people had an impact so immediate and profound that it was likened to Lincoln's Gettysburg address. Hand retired officially in 1951, hut continued to sit in many cases.

On April 10, 1959, Judge Hand. then 87 years old, set a record of 50 years of service in the United States judiciary, an occasion marked by a special session of his court at which Chief Justice Warren led the national bench and bar in paying him warm and admiring tribute. He died in New York city on Aug. 18, 1961.

See citations in *The Spirit of Liberty: Papers and Addresses of Learned Hand,* collected and with an introduction and notes by Irving Dilliard (1952–59). (I. Dd.)

HAND. That man has a hand, rather than a paw, hoof, fin or wing, has set him above all other animals and has enabled him to develop a culture based on toolmaking and tool using. It is quite possible that the emergence of a culture in turn accelerated the pace of hominid evolution to hasten the appearance of modern man, Homo *sapiens* (see MAN, EVOLUTION OF). It is thought that the hand has evolved from the five-rayed forepaw of early vertebrates. Occasionally, however, a child is born with an extra rudimentary thumb (prepollex) and an extra rudimentary little finger (postminimi) which has led some to speculate that the hand was originally seven-rayed.

In the human hand there are 8 small bones (carpals), 5 longer tubular bones (metacarpals) and 14 shorter tubular bones (phalanges). The phalanges compose what are called fingers; the thumb contains two phalanges, the other four fingers. three each.

Scientifically the thumb is numbered finger I; index finger, II; middle. III; ring. IV; and little finger, V.

The thumb is the outstanding part of the human hand. Although the anthropoid apes can flex and extend their thumb (bend it, straighten it) and can abduct it and adduct it (move it away from and return it to the midline), only man has true opposability (*i.e.,* he can rotate it inwardly so that very precise pincerlike movements are possible).

From anthropoid to man the thumb has increased in relative and absolute length. For example. the pollicial index (total phalangeal length of finger I × 100/total phalangeal length of finger III) may be noted: gibbon 35.2%, orangutan 30.2%, chimpanzee 35.4%, gorilla 37.3%, man 56.9%. In man the total absolute finger length is, in descending order, most often III, IV, II, V, I, though frequently IV equals II.

Anthropoids tend to be ambidextrous. But man is predominantly right-handed; only about 8% favour their left hand. (See HANDEDNESS.) A man-made flint implement possibly 1,000,000 years old appears to have been beveled to be held between the right thumb and forefinger. In prehistoric Europe a cave painting shows a man throwing a spear with his right hand.

The hand is very important in the study of the growth and development of the child. In carpals, metacarpals and phalanges centres of ossification appear in a time-sequence that (via the X-ray film) gives a biological growth-age of the child.

As an important cultural symbol the hand is used in gestures which impart meaning; the hand is important also medico-legally; *i.e.*, fingerprints (*q.v.*) serve to identify; and other marks, calluses, worn areas, etc., give clues to the possesser's occupation.

For a discussion of the anatomy of the hand see SKELETON, VERTEBRATE: *Appendicular* Skeleton; MUSCLE AND MUSCULAR SYSTEM; NERVOUS SYSTEM. See also HAND, DISEASES AND DISABILITIES OF.

Huxley, "From Fins to Fingers: the Evolution of Man's Hand," *Illustrated London News,* pp. 1138–1139 (Dec. 1938); M. F. A. Montagu, "On the Primate Thumb," *Amer. J. Phys. Anthrop.,* 15:291–314 (1931); A. S. Romer, *Man and the Vertebrates,* 3rd ed. (1941); Charlotte Wolff, *The Human Hand* (1942). (WN. M. K.)

HAND, DISEASES AND DISABILITIES OF. The hand is composed of skin, fatty tissue, tendons, nerves, muscles, bones and joints. Disease may affect each tissue separately or the whole hand.

Abnormality of the hand may occur as an anomaly of development. Two or more fingers may be conjoined (syndactyly). A finger or thumb may be duplicated, presenting a hand with six or more digits. Conversely, the hand may be formed with absence of part of a finger or an entire finger or fingers. One such deformity is seen in the hand that has only a thumb and little finger and resembles a lobster claw; although unsightly, such hands may be very agile. A less severe but commoner developmental abnormality is the thumb that cannot be completely straightened due to constriction of a tendon by adjacent tissues, a condition known as a trigger thumb.

The hand is subject to frequent and severe injuries. Lacerations of the skin of the hand are more serious than such lacerations in most other parts of the body, because in the hand there it little fatty tissue protecting the vital nerves and tendons. Should a nerve be severed the finger will lose sensation and therefore most of its function. A severed tendon leaves the finger as useless as a marionette without strings. Fingertips are prone to crushing injuries in doors and under ill-aimed tools. Should such an injury result in loss of the tip of the finger, the tip is frequently replaced by tender scar, greatly reducing the effectiveness of the digit. Tendons may be severed without an exterior wound, as when a baseball is caught on the end of an outstretched finger; the tendon near the base of the nail is pulled loose and the end of the finger cannot be straightened. Drummers may wear out the tendon that straightens the thumb on the left hand. Other tendons break spontaneously in arthritic hands. Fractures of the bones of the hand result from direct blows or when the hand is used as a striking instrument, as in boxing. Most fractures in these bones heal readily. Serious injuries may occur to the hands when they are caught in machines, as washing-machine wringers.

Diseases affecting other parts of the body may show evidence in the fingers. Swelling of finger joints may indicate arthritis (rheumatoid), and enlarging prominences near joints may indicate osteoarthritis or gout.

Infections may occur as a result of minor cuts and scratches, "hangnails" (causing infection in the base of the nail called run-around), pin pricks into finger tips (abscess in the pulp). The most serious infections of the hand are those occurring in the tendons and deep in the palm.

Function of the hand is of paramount importance, and this is most severely impaired when one of the three major nerves to the hand is damaged. Such damage may take place as a result of fractures of the arm, birth injury to the neck, lacerations of the wrist or poliomyelitis. Should the nerve to the small muscles of the thumb be destroyed, almost 80% of the function of the hand is lost. Damage to one of the major nerves results in loss of sensation to the skin, and this impairs the ability of the hand to feel objects.

Tumours (*q.v.*) may be found in all the composite tissues of the hand. Within the bones occur benign tumours of cartilage; along the tendons occur tumours of fatty tissue; tumours of a gelatinous substance occur in joints.

Disability of the hand arises from a loss of one or both of its functions, feeling and grasping. Feeling is lost when a nerve is severed. Grasp is lost when motor power in the muscles is lost or when stiffness of the fingers robs them of their flexibility. Such stiffness may be due to arthritis, too long immobilization for treatment of a fractured finger, swelling of the hand due to injury of the arm, infection in the tendons or scarring of the skin and fatty tissue after an extensive burn.

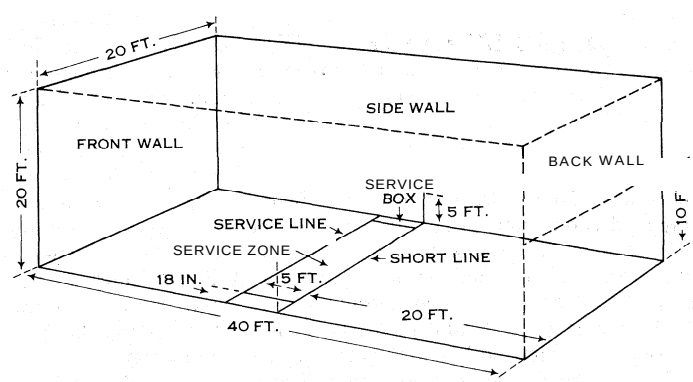
For the anatomy of the hand, *see* SKELETON, VERTEBRATE; MUSCLE AND MUSCULAR SYSTEM; NERVE. (T. D. B.)

HANDBALL, an active game that is popular in the United States, Canada and in various forms in other countries, is played mith a small rubber ball that is struck with a gloved hand against a wall or walls. (For English versions of the game, see FIVES.) Two or four persons play at a time. When two play, the game is called singles and when four play, doubles. The object is to strike the ball in such a manner that the opponent or opposing team has difficulty in returning it or is unable legally to keep the ball in play.

The game is played on a court, either indoors or outdoors. The court usually has one wall or four walls (see below for variations). Three organizations in the United States formerly issued playing rules; co-operation among the three—the Amateur Athletic union (A.A.U.), National Jewish Welfare board (N.J.W.B.), the United States Handball association (U.S.H.A.) and the Young Men's Christian association (Y.M.C.A.)—resulted in the publication in 1959 of one set of official unified handball rules.

The game involves strenuous physical activity, and persons of all ages and both sexes enjoy it. It helps develop speed, skill and endurance, and has been used by athletes as a conditioner for other sports.

History.—The Irish hard handball is often considered one of the national games of Ireland (see below). In the late 19th century, the game was introduced to the United States, and thereafter it grew rapidly in popularity There were more players in



FOUR-WALL HANDBALL COURT ACCORDING TO OFFICIAL UNIFIED RULES

the United States, it was believed, than in any other country of the world in the second half of the 20th century.

The first international match was the Lawlor-Casey series played in 1887 with a prize of $1,000 for the best of 21 games, 10 to be played in Cork, Ire., and 11 in the U.S. John Lawlor won six games to four in Cork; Phil Casey, the U.S. champion, won seven straight in New York city, winning the match. Casey, who retained his title against all challengers until he retired in 1900, was spoken of as "the father of handball in the U.S." Bernard McQuade, Drew Cashman and Michael Eagan were other outstanding stars of former days.

After 1900 handball developed into three separate games (covered separately below): a four-wall game called soft handball; the one-mall game; and the Irish four-wall, hard-ball game. National hard-ball championships were discontinued in the U.S. after 1938.

In the Cnited States national A.A.U. championships were started in 1919 and national Y.N.C.A. championships in 1925, and the United States Handball association began conducting national championships in the early 1950s. The three organizations sponsored one combined national tournament 'in 19j8. In ,1959, the Y.M.C.A. and the A.A.U. again conducted a combined national tournament, but the C.S.H.A. sponsored a separate tournament.

When the first Helms Hall of Fame handball selections were made in 1954, Joe Platak, who died in that year, was chosen along with Al Banuet. Banuet was the leading player ior three years, 1929–31, but was disqualified as an amateur after a brief professional boxing career. Platak dominated singles championship play from 1935 to 1941 and returned in 1943 and 1945 to bring his total to nine national championships. Victor Hershkowitz of Brooklyn, N.Y., dominated modern tournament play. He had captured more than 20 national championships in one-wall, three-wall and four-wall play when he won another title in the national Y.M.C.A. championships in 19j7. Other outstanding players included Robert Brady of San Francisco, Calif.: Philip Collins of Chicago, Ill., and John Sloan (Chicago), the "over-all 19j8 champion."

Four-Wall Game.—This is the most popular version of the game in the Cnited States. The approved court should measure 20 ft. wide, 40 ft. long and 20 ft. high with the back wall 10 ft. high. under official unified handball rules (see diagram).

A game consists of 21 points. A match is the best two out of three games.

The ball is made of black rubber; it is $1\frac{7}{8}$ in. in diameter with not more than $\frac{1}{32}$ in. variation; it should weigh 2.3 oz. with not more than .2 oz. variation; when dropped from a height of 70 in. the ball must rebound not less than 42 nor more than 48 in. at a room-and-ball temperature of 68" F. Only one hand may be used in striking the ball; no other part of the body may be used. When attempting to return the ball, the player cannot strike it more than once. Gloves made of soft cloth or leather must be worn during all matches (to prevent moisture from the hands making the ball wet and slippery).

A service zone five feet wide is marked across the court; the back edge (called the short line) is exactly in the middle of the court (*e.g.*, in a court 20 ft. wide and 40 ft. long, the 20 ft. back edge of the zone, the short line, is parallel with and 20 ft. from the front wall; the front edge of the service zone, called the service line, is parallel with and 1j ft. from the front wall. To put the ball in play the server stands anywhere he chooses within the service zone, drops the ball to the floor and on the rebound strikes it with one hand so it travels directly to the front wall and rebounds in such a manner that it travels beyond the short line beiore striking the floor. A legally served ball that fails to rebound beyond the short line before it touches the floor, or one that hits two side walls beiore touching the floor is called a short serve. Two short serves retire the server. If the server steps outside the service zone, while in the act of serving, this is called a foot fault and is considered the same as a short service. Two foot faults retire the server.

After the ball is served the server's opponent (or one of the opponents in a doubles game) known as the receiver, must play the ball before it touches the floor twice, hitting it in such a manner that it travels from the striker's hand to the front wall without touching the floor. First the receiver then the server play the ball in alternate fashion until one or the other makes an error. If the receiver fails to return the ball legally a point is scored for the server. If the server makes an error, no point is scored, but he is "out" and the receiver comes "in" and has his opportunity to serve and while doing so may score points. A server continues to serve as long as he makes points.

In singles the receiver stations himself anywhere in the back court (but at least five feet behind the short line), where he waits for the service. In doubles the two receivers may stand anyn-here in the back court (at least five feet behind the short line), but the server's partner must stand in the service box with his back to the side wall, both feet on the floor, and remain there until the ball passes the short line. If a served ball strikes the server's partner while he is in the back-to-wall position, it is called a dead ball (the ball is out of play) and the serve is made over. If the server's partner leaves the service box position before the served ball crosses the short line, this is a short service and must be repeated.

GLASS-WALLED HANDBALL COURT

Court has full side walls of giass with a large glass insert in the back wall

Because of the many angle shots (side wall to front wall, ceiling to iront wall, recoveries from the back wall, and so on) many players and spectators consider the four-wall game more scientific and interesting than the one-wall game. The one-wall game supporters say their game requires more speed, stamina and control. It is generally conceded that a person who learns the one-wall game and then chahges to the four-wall game adapts more quickly than does a four-wall starter who goes to the one-wall game.

One-Wall Game.—The one-wall game is played in several sections of the Cnited States! but it achieved its greatest popularity in the New York city area. where an estimated 2,500 one-wall courts were built in parks and playgrounds. at beaches and elsewhere. The one-wall game is played with the ball described above for the four-wall game and is scored the same as the four-\?all game. The court dimensions differ; as specified by the Amateur Athletic union: they are length. 34 ft.; width, 20 ft.; and iront wall, 16 ft. high. The short line is 16 ft. from and parallel to the front wall. A "receiver restraining" line called the service line is indicated 9 ft. behind the short line (25 ft. from and parallel to the iront wall). In doubles the server's partner steps outside the court but in the space represented by a slight extension of the serving zone beyond the side line of the court.

Definitions.—A hinder is an accidental interference with or obstruction of flight of the ball: no penalty is involved. Fault refers to an infraction of the rules which involves a penalty. A ball returned to the front wall in such manner that it rebounds so close to the floor that it is impossible to get has been "killed." An ace is a service which completely eludes the receiver.

Other Versions.—Standard versions of the game in the United States have been described, but various adaptations have been introduced. Instead of two or four players. for example, three participants may engage in "cut-throat" handball. One player, while serving. engages the other two. He continues to serve as long as he makes points. When he is put "out." a move clockwise is made, the server pairs off with another, and a new server comes "in." The person scoring 21 points first is the game winner.

Sometimes a one-n-all court laid out on a gymnasium floor where the back line of the court is parallel to and near a gymnasium wall can be adapted for two-wall play. By agreement players are allowed to play legal balls off the wall, thus keeping in play balls that would not otherwise be returnable.

Some one-\+-allcourts are laid out in the corner of a gymnasium,

permitting corner shots and play on a side wall as well as the front wall. There are also courts with two folding triangular "wings" that swing out from the front wall of a one-wall court and fit into place on the side lines. The wings thus provide two front corners for angle corner shots. A further modification of this idea is a three-wall court (front, side and back wall), with one side open to accommodate a large group of spectators when contest matches are played. Two such courts were built by the New York department of parks and opened in Nov. 1959 with special exhibition matches. One is in Lincoln Terrace park, Brooklyn; the other is at Forrest park playground in Queens.

Glass-wall handball courts permit as many as 200 or 300 spectators to see tournament matches, but problems of materials, lighting. glare, variation in bounce and expense delayed development of such courts. The St. Louis Downtown Branch Y.M.C.A. built one of the first partial glass-mall courts. In 1958 the principal and final contests of the combined national four-wall handball tournament were played in a glass-enclosed court at the Y.M.C.A. in Aurora, Ill.

Irish Handball. — The game of Irish handball originated about 1,000 years ago and was played on a hard clay floor, with one wall, of stone, at the front of the court, against which the ball was struck. In the modern form of the game the court dimensions and rules are almost identical with those laid down in the 1880s, when the first Irish championships were played; the ball and the system of scoring go back to the 18th century, when handball was a popular pastime in many parts of Ireland.

The standard ball court is a four-wall structure, with concrete walls and floor. The playing floor is 60 ft. long and 30 ft. wide; the front wall is 30 ft. high and the back wall, 9 ft. high. The side walls are higher at the front than the back. The walls must be perpendicular and smooth. The short line, from which the ball is tossed (served). is drawn at or near halfway down the court. In the toss the ball must be hit against the front wall on the first bounce and must come out beyond the short line to be accepted. Returns count. as in all ball games; the game proceeds with return and counterreturn—the ball is "up" when it hits the front wall direct. The ball may be punched or hit with the open palm or kicked. Ambidexterity is most important in Irish handball. Players toss a coin for inside position which is held until the tosser (server) is beaten in the rally. A good tosser can score a considerable number of aces direct from service. The game is 21 aces and the rubber of games varies from five to seven or more games. Both single- and double-handed games are general.

The Irish ball has a cork or greenhart centre covered by woolen thread and thin pieces of cork or rubber. The outer cover is of thin sheepskin. This ball is called an alley cracker or hard ball. Some tournaments or championships are played with a soft, rubber ball, but the Irish ball is the recognized championship medium. The standard ball is $1\frac{7}{8}$ in. in diameter and weighs $1\frac{1}{2}$ to $1\frac{3}{4}$ oz.

For many years challenge and championship games for high wagers were common. Side bets amounting to £1,000 were not unusual. Many matches for big wagers were played between Ireland and the United States between 1895 and 1910. Then the Gaelic Athletic association took handball under its wing; wager matches were abolished in 1924 and handball became a truly amateur game in Ireland. Separate boards of handball control were subsidized by the Gaelic Athletic association, and regular county. provincial and all-Ireland championships were organized. There are many standard courts throughout Ireland and innumerable ball alleys, and every secondary school and college has its first-class handball court. The soft ball is generally used in schools.

(P. D. M.)

HANDCUFFS AND FETTERS are instruments for securing the hands and feet of prisoners under arrest, or as a means of punishment. The old names were manacles, shackbolts or shackles, gyves and swivels. Until modern times handcuffs were of two kinds, (1) the figure eight, which confined the hands close together either in front of or behind the prisoner; and (2) rings which fitted around the wrists and were connected by a short chain, the latter being somewhat like those used by the modern police forces. Handcuffs are made of steel, adjustable to the wrist size and equipped with an automatic locking device.

Thumb cuffs, made of lightweight, stainless steel also are used; these cuffs may be employed by juvenile officers and as an auxiliary restraining device by police officers and detectives. For transferring gangs of convicts an arrangement of handcuffs connected by a light chain has been used, the chain running through a ring on each fetter and made fast at both ends by what are known as endlocks.

Several appliances have been used as handcuffs; *e.g.*, snaps, nippers, twisters. They differ from handcuffs in being intended for one wrist only, the other portion being held by the captor. In the snap the smaller circlet is snapped onto the prisoner's wrist. The nippers can be instantly fastened on the wrist. The twister, which is liable to injure prisoners seriously, is a chain attached to two handles; the chain is put round the wrist and the two handles twisted until the chain is tight enough.

Leg irons are anklets of steel connected by light chains long enough to permit the wearer to walk with short steps. Modern leg irons are adjustable to the size of the leg or ankle and lock automatically when they are applied to the prisoner. Sometimes leg irons are combined with handcuffs, being attached to the latter by a chain.

An obsolete form of leg iron was an anklet and chain to the end of which was attached a heavy weight, usually a round shot. The Spanish used to secure prisoners in bilboes, shackles around the ankles secured by a long bar of iron. This form of leg iron was adopted by the English and was much employed by them during the 17th and 18th centuries. (R. *G.* CL.)

HANDEDNESS. It is the usual practice to classify individuals as right-handed, left-handed or ambidextrous. People differ considerably in the range of activities for which they prefer a given hand as well as in the degree of disparity in skill between their two manual members. Probably no one favours his right or left hand exclusively.

Origin and Development of Handedness.—There is no extensive agreement on the question of the origin of the manual preferences people show. Some authors believe laterality is inherited; others, that we are trained to it; and still others, that some organization of intrauterine forces, such as those producing twinning, or some extrauterine environmental influences initiate our biases. It is possible all three hypotheses are, in a measure, correct. It does seem clear that left-handed parents more frequently have left-handed offspring than do right-handed parents; that even at birth most babies tend to move one arm—usually the right—more than the other; and that, if a systematic effort is made to keep infants from being biased, they still come to favour one hand. It is equally apparent that most babies, if the hand used the more frequently in reaching or grasping is taken as the clue to their handedness, shift their preference a time or two during their first year. The consistency with which children use one hand in preference to the other increases with age, at least through the preschool years and probably longer. Although the incidence of left-handedness seems to vary with the way it is measured and with the population studied, it is probably not too far wrong to say that in the United States 18 to 24 children become right-handed for every one who persists in sinistral tendencies.

Effects of Interference with Handedness. — Most children can be trained to use and to prefer their right hand in any given operation and many have been so trained without obvious harmful effects. How wise it is to interfere with a child's spontaneous preference is, however, a question. There does seem to be some sort of relationship between left-handedness and stuttering. Some hold the view that a left-handed person in a right-handed society, by virtue of being disapproved, interfered with and inconvenienced, is under more emotional strain, on the average, than is a right-handed person, and this stress causes stuttering. Others believe that if a left-handed person has his hand preference

w changed, he does not develop the clear-cut dominance of one cerebral hemisphere over the other which is necessary for co-ordinated functioning. The individual's speech is a delicate indicator of this lack of co-ordination in neurological activity. Some workers maintain, on the other hand, that the cerebral organization which makes for a lack of consistent unilateral dominance is inherited.

Laterality in the Body.—There is good evidence that the speech centre tends to be in the hemisphere contralateral to the side of the dominant hand and that alpha waves from corresponding parts of the two cerebral hemispheres are more conspicuous on the nondominant side. Neither of these bits of evidence proves conclusively, however, that the cortical organization which an individual inherits is responsible for his hand preference. It is interesting in this connection that there is little support for the vie , as the theory of a dominant cerebral hemisphere might lead one to expect, that the body structures under the control of one hemisphere are uniformly more efficient than the other. The dominant hand is not always on the side of the dominant foot. About three-fourths of the dextrals and one-third of the sinistrals are right-eyed in sighting.

It is probable that a person's preference for a given hand is an expression of many influences. Since it is not a matter of great moment which manual member the individual uses, so long as he performs well, it seems a wise course to allow choice as to hand if a strong preference is indicated. Whatever the choice, however, there is evidence that it is desirable to work for a clear-cut dominance of one hand over the other.

HANDEL, GEORGE FREDERICK (1685–1759), musical composer, was born at Halle, in Lower Saxony, on Feb. 23, 1685. His name was Händel, but, like most 18th century musicians who travelled, he compromised with its pronunciation by foreigners, and when in Italy spelt it Hendel, and in England (where he became naturalized) accepted the version Handel, which is therefore correct for English writers, while Händel remains the correct version in Germany.

LIFE

Early Training.—Handel's father was a barber-surgeon, who disapproved of music and wished George Frederick to become a lawyer. A friend smuggled a clavichord into the attic. and on this instrument, which is inaudible behind a closed door, the little boy practised secretly. Before he was eight his father went to visit a son by a former marriage who was a valet-de-chambre to the duke of Saxe-Weissenfels. The little boy begged in vain to go also, and at last ran after the carriage on foot so far that he had to be taken. He made acquaintance with the court musicians and contrived to practise on the organ when he could be overheard by the duke, who, immediately recognizing his talent, spoke seriously to the father, who had to yield to his arguments.

On returning to Halle Handel became a pupil of Zachau, the cathedral organist, who gave him a thorough training as a composer and as a performer on keyed instruments, the oboe and the violin. Six very good trios for two oboes and bass, which Handel wrote in his 11th year, are extant; and when he himself was shown them by an English admirer who had discovered them, he was much amused and remarked, "I wrote like the devil in those days, and chiefly for the oboe, which was my favourite instrument." These trios were mere parerga beside the study and composition of vocal music, and he had to show Zachau a motet every week. By the time he was 12 Zachau thought he could teach him no more, and accordingly the boy was sent to Berlin, where he made a great impression at the court.

His father, however, thought fit to decline the proposal of the elector of Brandenburg, afterwards King Frederick I. of Prussia, to send the boy to Italy in order afterwards to attach him to the court at Berlin. German court musicians, as late as the time of Mozart, had hardly enough freedom to satisfy a man of independent character, and the elder Handel had not yet given up hope of his son becoming a lawyer. Young Handel, therefore, returned to Halle and resumed his work with Zachau. In 1697 his father died, but the boy with great filial piety, finished the ordinary course of his education, both general and musical, and entered the university of Halle in 1702 as a law student. Rut in that year he succeeded to the post of organist at the cathedral, and after his "probation" year in that capacity he departed to Hamburg, where the only German opera worthy of the name was flourishing under the direction of its founder, Reinhold Keiser.

Friendship *with* Matheson.—Here he became friends with Matheson, a prolific composer and writer on music. On one occasion they set out together to go to Liibeck, where a successor was to be appointed to the post left vacant on the retirement of the great organist Dietrich Buxtehude. Handel and Johann Matheson made much music on this occasion, but did not compete, because they found that the successful candidate was required to marry the retiring organist's daughter. Another adventure might have had even more serious consequences. At a performance of Matheson's opera Cleopatra at Hamburg, Handel refused to give up the conductor's seat to the composer when the latter returned to his usual post at the harpsichord after singing the part of Antony on the stage. The dispute led to a duel outside the theatre, and, but for a large button on Handel's coat which intercepted Matheson's sword, there would have been no *Messiah* or Israel in Egypt. But the young men remained friends, and Matheson's writings are full of the most valuable facts for Handel's biography. He relates in his Ehrenpforte that his friend at that time used to compose "interminable cantatas" of no great merit; but of these no traces now remain, unless we assume that a Passion according to St. John, the manuscript of which is in the royal library at Berlin, is among the works alluded to. But its authenticity, while strongly upheld by Chrysander, has since been as strongly assailed on internal evidence.

On Jan. 8, 1705, Handel's first opera, Almira, was performed at Hamburg with great success, and was followed a few weeks later by another work, entitled Nero. Nero is lost, but Almira, with its mixture of Italian and German language and form, is extant. It contains many themes used by Handel in well-known later works; but the current statement that the famous aria in *Rinaldo*, "Lascia ch'io pianga," comes from a saraband in Almira, is based upon nothing more definite than the common form of saraband-rhythm.

Three Years in Italy.—In 1706 Handel left Hamburg for Italy, where he remained for three years, rapidly acquiring the smooth Italian vocal style which thereafter always characterized his work. He had before this refused offers from noble patrons to send him there, but had now saved enough money not only to support his mother at home, but to travel as his own master. He divided his time in Italy between Florence, Rome, Naples, and Venice; and many anecdotes are preserved of his meetings with Corelli, Lotti, Alessandro Scarlatti, the founder of the Neapolitan school, or rather of the classical language of music as understood by Handel himself, and Alessandro's unacademic son Domenico, whose wonderful harpsichord technique still furnishes problems for the modern pianoforte virtuoso. Handel soon became famous as *Il Sassone* ("the Saxon"), and it is said that Domenico on first hearing him play incognito exclaimed, "It is either the devil or the Saxon!"

There is also a story of Corelli's coming to grief over a passage in Handel's overture to *Il* Trionfo del tempo, in which the violins went up to A in altissimo. Handel impatiently snatched away the violin to show Corelli how the passage ought to be played, and Corelli, who had never written or played beyond the third position in his life (this passage being in the seventh), said gently, "My dear Saxon, this music is in the French style, which I do not understand." The story becomes more interesting in view of the fact that Handel's later treatment of the violin is hardly less restrained than Corelli's, though he often wrote for the greatest players of the day.

In Italy he produced two operas, *Rodrigo* and *Agrippina,* the latter a very important work, of which the splendid overture was remodelled 44 years afterwards as that of his last original oratorio, *Jephtha*. He also produced two oratorios, *La Resurrezione,* and *Il Trionfo del tempo*. The latter, 46 years afterwards, formed the basis of his last work, *The Triumph of Time and Truth,* which contains no original matter. All Handel's early works contain material that he used often with very little alteration later on, and, though the famous "Lascia ch'io pianga" does not occur in *Almira,* it occurs note for note in *Agrippina* and the two Italian oratorios. On the other hand the cantata *Aci, Galatea e Polifemo* has nothing in common with *Acis and Galatea.*

Besides these larger works there are several choral and solo cantatas of which the earliest, such as the great *Dixit Dominus,* show in their extravagant vocal difficulty how radical was the change which Handel's Italian experience so rapidly effected in his methods. Handel's success in Italy established his fame and led to his receiving at Venice in 1709 the offer of the post of Kapellmeister to the elector of Hanover, transmitted to him by Baron Kielmansegge, his patron and staunch friend of later years.

Career in England.— Handel at the time contemplated a visit to England, and he accepted this offer on condition of leave of absence being granted to him for that purpose. To England accordingly Handel journeyed after a short stay at Hanover, arriving in London towards the close of 1710. He came as a composer of Italian opera, and earned his first success at the Haymarket with *Rinaldo,* composed, to the consternation of the hurried librettist, in a fortnight, and first performed on Feb. 24, 1711. In this opera the aria "Lascia ch'io pianga" found its final home. The work was produced with the utmost magnificence, and Addison's delightful reviews in the *Spectator* poked fun at it from an unmusical point of view in a way that would have pleased Gluck 50 years afterwards. The success was so great, especially for Walsh the publisher, that Handel proposed that Walsh should compose the next opera and that he (Handel) should publish it! He returned to Hanover at the close of the opera season and composed a good deal of vocal chamber music for the princess Caroline, the step-daughter of the elector, besides the instrumental works known to us as the "oboe concertos."

In 1712 Handel returned to London and spent a year with Andrews, a rich musical amateur, in Barn Elms, Surrey. Three more years were spent in Burlington, in the neighbourhood of London He evidently was but little inclined to return to Hanover, in spite of his duties to the court there. Two Italian operas and the Utrecht Te Deum, written by the command of Queen Anne, are the principal works of this period. It was awkward for the composer when his deserted master came to London in 1714 as George I. of England. For some time Handel did not venture to appear at court, and it was only at the intercession of Baron Kielmansegge that his pardon was obtained. The king received the composer into his good graces and granted him a salary of £400 a year

Later Handel became music master to the little princesses and was given an additional £200 by the princess Caroline. In 1716 he followed the king to Germany, uhere he wrote a second German Passion to the popular poem of Brockes, a text which, divested of its worst features, forms the basis of several of the arias in Bach's Passion according to St John This was Handel's last work to a German text A copy much more accurate than Handel's autograph exists in Bach's handwriting The Water Music was composed expressly for the occasion of a royal water picnic on the Thames in July 1717.

Composer and Impresario.—On his return to England he entered the srrvice of the duke of Chandos as conductor of his concerts, receiving a thousand pounds for his first oratorio *Esther.* The music which Handel wrote for performance at Cannons, the duke of Chandos's residence at Edgware, is comprised in the first version of *Esther, Acis and Galatea,* and the twelve Chandos Anthems, which are compositions approximately in the same form as Bach's church cantatas but without any systematic use of chorale tunes. The fashionable Londoner would travel nine miles in those days to the little chapel of Whitchurch to hear Handel's music; of the magnificent scene of these visits all that now remains is the church.

In 1720 Handel appeared again in a public capacity as impresario of the Italian opera at the Haymarket theatre, which he managed for the institution called the Royal Academy of Music. Senesino, a famous singer, to engage whom Handel especially journeyed to Dresden, was the mainstay of the enterprise, which opened with a highly successful performance of Handel's opera *Radamisto.* To this time belongs the famous rivalry between Handel and Buononcini, a melodious Italian composer whom many thought to be the greater of the two. The controversy has been perpetuated in John Byrom's well-known lines:

Some say, compared to Buononcini
That Mynheer Handel's but a ninny;
Others aver that he to Handel
Is scarcely fit to hold a candle.
Strange all this difference should be
Twixt tweedle-dum and tweedle-dee.

It must be remembered that at this time Handel had not yet asserted his greatness as a choral writer. The fashionable ideas of music and musicianship were based entirely upon success in Italian opera, and the contest between the rival composers was waged on the basis of works which have fallen into almost as complete oblivion in Handel's case as in Buononcini's. Apart from scholarly revivals, none of Handel's 41 Italian operas survives, except in some few detached arias out of each opera; arias which reveal their essential qualities far better in isolation than when performed in groups of between 20 and 30 on the stage, as interruptions to the action of a classical drama which was nothing but an interruption to them. But even under these conditions Handel's inexhaustible inventive power proved decisive; as was shown when he wrote the third act of an opera *Muzio Scevola,* of which Buononcini and Ariosti (Chrysander says Mattei) wrote the other two. Buononcini soon got into discredit by failing to defend himself against the charge of producing as a prize-madrigal of his own a composition which proved to be by Lotti. As a consequence Buononcini left London, and Handel for the next ten years was without a rival in his ventures as an operatic composer.

From Opera to Oratorio.—He was not, however, without a rival as an impresario; and the hostile competition of a rival company which obtained the services of the great Farinelli and also induced Senesino to desert him led to his bankruptcy in 1737, and to an attack of paralysis caused by anxiety and overwork. The rival company, it may be added, also had to be dissolved from want of support Handel's artistic conscience was that of an opportunist, or he would never have continued till 1741 to work in a field that gave so little scope for his genius. But operas were the only music that was known to pay, and at all events he could supply better operas more quickly and easily than any other living composer And this he naturally continued to do so long as it seemed the best way to keep up his reputation. But his opportunism did not include a readiness to stand any nonsense; and when the prima-donna Cuzzoni tried to give herself other airs than he had written for her, he held her at arm's length out of a window until she capitulated.

Already before his last opera, *Deidamia,* produced in 1741, Handel had been making a growing impression with his oratorios. In these, freed from the restrictions of the stage, he was able to give scope to his genius for choral writing, and so to develop, or rather revive, that art of chorus singing which is the normal outlet for English musical talent. In 1726 Handel had become a naturalized Englishman, and in 1733 he began his public career as a composer of English texts by producing the second and larger version of *Esther* at the *King's Theatre.* This was followed early in the same year by *Deborah,* in which the share of the chorus is much greater. In July he produced *Athalia* at Oxford, the first work in which his eight-part double choruses appear. The share of the chorus increases in *Saul* (1738); and *Israel in* Egypt (also 1738) is practically entirely a choral work, the solo movements being few and, in spite of their fame, perfunctory. The public, who still considered Italian opera the highest form of musical art, not unnaturally obliged Handel at subsequent per-

formances of this gigantic work to insert more solos.

The Messiah was produced at Dublin on April 13, 1742. *Samson* (which Handel preferred to *The Messiah)* appeared at Covent Garden on March 2, 1744; *Belshazzar* at the King's theatre, March 27, 1745; the *Occasional Oratorio* (chiefly a compilation of the earlier oratorios, but with a few important new numbers), on Feb. 14, 1746, at Covent Garden, where all his later oratorios were produced; *Judas Maccabaeus* on April 1, 1747; *Joshua* on March 9, 1748; *Alexander Balus* on March 23, 1748; *Solomon* on March 17, 1749; *Susanna,* spring of 1749; *Theodora,* a great favourite of Handel's, who was much disappointed by its cold reception, on March 16, 1750; *Jephtha* (strictly speaking, his last work) on Feb. 26, 1752, and *The Triumph of Time and Truth* (transcribed from *Il Trionfo del tempo* with the addition of many later favourite numbers), in 1757. Other important works, indistinguishable in artistic form from oratorios but on secular subjects, are *Alexander's Feast,* 1736; *Ode for St. Cecilia's Day* (words by Dryden); *L'Allegro, il pensieroso ed il moderato* (Milton, with a third part by Jennens), 1740; *Semele,* 1744; *Hercules,* 1745; and *The Choice of Hercules,* 1751.

Last Years.—By degrees the enmity against him died away, though he had many troubles. In 1745 he had again become bankrupt; for, although he had no rival as a composer of choral music, it was possible for his enemies to give balls and banquets on the nights of his oratorio performances. As with his first bankruptcy, so in his later years, he was scrupulously honourable in discharging his debts, and, like Scott, he continued to work hard to the end of his life. Unlike Scott, he not only completely recovered his financial position (by the year 1750) but he must have made a good deal of money, for he then presented an organ to the Foundling Hospital, and opened it with a performance of *The Messiah* on May 15.

In 1751 his sight began to trouble him; and the autograph of *Jephtha,* published in facsimile by the *Händelgesellschaft,* shows pathetic traces of this in his handwriting, and so greatly reveals his methods of composition, all the accompaniments, recitatives, and less essential portions of the work being evidently filled in long after the rest. By a dramatic coincidence Handel's blindness interrupted him during the writing of the chorus, "How dark, oh Lord, are Thy decrees, . . . all our joys to sorrow turning . . . as the night succeeds the day." He underwent unsuccessful operations, one of them by the same surgeon who had operated on Bach's eyes. He was able to see at intervals during his last years, but his sight practically never returned after May 1752.

He continued nevertheless superintending performances of his works and writing new arias for them, or inserting revised old ones, and he attended a performance of *The Messiah* a week before his death, which took place, according to the *Public Advertiser* of April 16, not on Good Friday, April 13, according to his own pious wish and according to common report, but on April 14, 1759. He was buried in Westminster Abbey; and his monument is by L. F. Roubilliac, the same sculptor who modelled the marble statue erected in 1739 in Vauxhall gardens, where his works had been frequently performed.

Handel was a man of high character and intelligence, and his interest was not confined to his own art exclusively. He liked the society of politicians and literary men, and he was also a collect~:of pictures and articles of *vertu.* His power of work was enormous, so that the *Handelgesellschaft's* edition of his complete works fills 100 volumes, forming a total bulk almost equal to the works of Bach and Beethoven together. (F. Hu.; D. F. *T.)*

MUSIC

Handelian Opera.—No one has more successfully popularized the greatest artistic ideals than Handel; no artist is more disconcerting to critics who expect to follow a great man's mental development easily. Not even Wagner effected a greater transformation in the possibilities of dramatic music than Handel effected in oratorio, yet we have seen that Handel was the very opposite of a reformer. Indeed he hardly took the pains to ascertain what an art-form was, so long as something externally like it would convey his idea. But he never failed to convey his idea, and, if the hybrid forms in which he conveyed it had no historic influence and no typical character, they were none the less fit for each case. The same aptness and the same absence of method are conspicuous in his style.

The popular idea that Handel's style is easily recognizable comes from the fact that he overshadows all his predecessors and contemporaries, except Bach, and so makes us regard typical 18th century Italian and English style as Handelian, instead of regarding Handel's style as typical Italian 18th century. Nothing in music requires more minute expert knowledge than the sifting of the real peculiarities of Handel's style from the mass of contemporary formulae which in his inspired pages he absorbed, and which in his uninspired pages absorbed him.

His easy mastery was acquired, like Mozart's, in childhood. The sonatas for two oboes and bass which he wrote in his 11th year are, except in their diffuseness and an occasional slip in grammar, indistinguishable from his later works, and they show a boyish inventiveness worthy of Mozart's work at the same age. Such early choral works, as the *Dixit Dominus* (1707), show the ill-regulated power of his choral writing before he assimilated Italian influences. Its practical difficulties are at least as great as Bach's though they are not as necessary; but the grandeur of the scheme and nobility of thought are already those for which Handel so often in later years found the simplest adequate means of expression that music has ever attained. His eminently practical genius soon formed his vocal style, and long before the period of his great oratorios such works as The Birthday Ode for Queen Anne (1713) and the Utrecht Te Deum show not a trace of extravagance.

Operatic Methods.—The only drawback to his practical genius was that it led him to bury perhaps half of his finest melodies, and nearly all the secular features of interest in his treatment of instruments and of the aria forms, in that limbo of vanity, the 18th century Italian opera. The allegation is untrue that his operas are no better than those of his contemporaries; but it is certainly true that he never stirred a finger to improve the condition of dramatic musical art. He was notoriously masterful with singers; and was not bound by the operatic conventions of the time. In *Teseo* he not only wrote an opera in five acts when custom prescribed three, but also broke a much more rational rule in arranging that each character should have two arias in succession.

He also showed a feeling for expression and style which led him to write arias of new kinds. But he never made any innovation which had the slightest bearing upon the stage-craft of opera, for he never concerned himself with any artistic question beyond the matter in hand; and the matter in hand was neither to create dramatic music nor to make the story intelligible, but simply to provide a concert of between some 20 and 30 Italian arias and duets, wherein singers could display their abilities and spectators find distraction from the monotony of so large a dose of the aria form (which was then the only opportunity for solo vocal music) in gorgeous costumes and scenery.

The Transition to Oratorio.—When the question arose how such musical entertainments could be managed in Lent without protests from the bishop of London, Handelian oratorio came into being as a matter of course. But though Handel was an opportunist he was not shallow. His artistic sense seized upon the natural possibilities which arose as soon as the music was transferred from the stage to the concert platform; and his first English oratorio, *Esther* (1720), beautifully shows the transition.

The subject is as nearly secular as any that can be extracted from the Bible, and the treatment was based on Racine's *Esther,* which was much discussed at the time. Handel's oratorio was reproduced in an enlarged version in 1732 at the King's theatre; the princess royal wished for scenery and action, but the bishop of London protested. And the choruses, of which in the first version there are already no fewer than ten, are on the one hand operatic and unecclesiastical in expression, until the last, where polyphonic work on a large scale first appears; but on the other hand they are all much too long to be sung by heart, as is neces-

sary on the stage. In fact, the turning-point in Handel's development is the emancipation of the chorus from theatrical limitations. This had as great an effect upon his few but important secular English works as upon his other oratorios. Acis and *Galatea,* Semele, and Hercules are in fact secular oratorios; the choral music in them is pagan, but it is large, independent, and polyphonic.

Handel's scheme of oratorio is, then, operatic in its origin and has no historic connection with the German Passion music of his time; and nothing is more significant than that the chorus should have so readily assumed its proper place in a scheme which the public at first certainly regarded as a sort of Lenten biblical opera. And, as the chorus gains its musical freedom by the disappearance of theatrical necessities, it becomes the more powerful as a means of dramatic expression (as opposed to dramatic action).

Already in Athalia the "Hallelujah" chorus at the end of the first act is a marvel of dramatic truth. It is sung by Israelites almost in despair beneath usurping tyranny; and accordingly it is a severe double fugue in a minor key, expressive of devout courage at a moment of depression. On purely musical grounds it is no less powerful in throwing into relief the ecstatic solemnity of the psalm with which the second act opens. Now this sombre "Hallelujah" chorus conveniently illustrates the real originality and creative power of Handel's art. It was not originally written for its situation in Athalia, but it was chosen for it. It was originally the last chorus of the second version of the anthem, "As pants the Hart," from the autograph of which it is missing because Handel cut out the last pages in order to insert them into the manuscript of *Athalia.* The inspiration in Athalia thus lies not in the creation of the chorus itself, but in the choice of it.

In choral music Handel made no more innovation than he made in arias. His sense of fitness in expression was of little use to him in opera, because opera could not become dramatic until musical forms broke with architectural and decorative limitations (*see* GLUCK; MUSIC; SONATA FORMS; and INSTRUMENTATION). But in oratorio there was no necessity for reforming any art-forms The ordinary choral resources of the time had perfect expressive possibilities where there were no actors and actions to keep waiting Moreover, when ordinary decorum dictated an attitude of reverent attention towards the subject of the oratorio, then the man of genius could find the true scope for his dramatic sense and base immortal music thereon.

Musical Borrowings. — Handel must be estimated in terms of Shakespearean criticism. Originality, in music as in other arts, lies in the uhole, and in a sense of the true meaning of every part. When Handel wrote a normal double fugue in a minor key on the word "Hallelujah" he showed that he enjoyed the vigour and dignity of good 18th century double fugues. In putting it at the end of a melancholy psalm he showed his sense of the value of the minor mode When he put it in its situation in Athalia he shed upon it the light of a truly conceived dramatic situation. Handel himself did not more often transfer old work to new contexts than the first and greatest reformer of dramatic music who thrust Handelian opera into limbo (*see* GLUCK) Such procedures are interesting enough in any case; but musical criticism is unused to the cases where the borrowed material is not the composer's own. Desperate efforts have been made to vindicate Handel or explain away the composers who were to Handel what Holinshed's Chronicles, Sidney's Arcadia, and North's Plutarch were to Shakespeare.

On such matters heat is unaccompanied by light. No apology for Handel can plausibly maintain that his enormous physical industry was not compensated for by the Johnsonian indolence of a well-stocked mind. One writer (P Robinson, *Handel* and his Orbit) tries to explain away Handel's Holinsheds and Plutarchs by pointing out that Urio and Erba, etc , are place-names around the Italian lakes which Handel visited. You cannot explain away Palestrina and half the Italian masters of painting by pointing out that their names are place-names; nor can you thus explain why Handel, who cares so little for art-forms, should faithfully imitate the minutest features of a style 50 years earlier than his own, or why his manuscript of the archaic Erba Magnificat should break off as a copyist breaks off, from the top of the page downwards. Besides, why explain away these Italian masters (whose existence as persons is attested by other evidence) when Handel borrowed a chorus in Esther from Graun?

This disposes, on the other hand, of attacks made on Handel's morality in plagiarising from sources that could never be traced in his lifetime. Within four years of Handel's death the child Mozart dedicated a set of sonatas to Queen Charlotte with the assurance that, inspired by her Majesty's protection "je deviendrai immortel comme Händel et Hasse"; and if he had substituted Graun, his patroness and his public would have missed no point but the alliteration. The only plausible reason why Handel did not plagiarise from Bach is that he would have thought any chorus of Bach quite impracticable in England. With the old Erba Magnificat the puzzle is that Handel should have thought such leaden vocal writing worth borrowing for Israel in Egypt. He could not add four chords, with the words "my fathers' God" without producing a vocal colour that aggravates rather than relieves the surrounding muddiness.

The most probable explanation is that Handel, who never thought of writing an original eight-part fugue, seriously imagined like an examiner for a university musical doctorate, that eight-part fugues were objects of veneration, and that the British public would be the better for hearing some old Italian masterpieces in this form. At all events he made no attempt to improve the Erba fugues, or even to assign them to texts that gave a tolerable declamation. A fugue on *Sicut* erat in principio et nunc et *semper* has to be sung to the words "THE earth swal . . . lowéd them."

Plagiarism or Transmutation? — Handel's plagiarisms begin to be interesting when we turn from these wholesale pilferings to his real transmutations of foreign elements. For English readers Sedley Taylor's volume of analysed illustrations (The Indebtedness of *Handel* to the works of other Composers, Cambridge 1906) is indispensable for a true understanding of the case. Its appearance gave rise to renewals of controversy which proved how dangerous it would have been to Handel if the matter had been raised in his lifetime. His rival Buononcini was finally discredited by the discovery that he had sent in as his own work for a prize competition a madrigal by Lotti. What, say the moralists, was one madrigal against Handel's wholesale thefts? This query overlooks the distinction between a single prize composition, which is nothing if not wholly original, and a four-hours' entertainment which was so seldom entirely new that it was specially advertised to be so when that statement was permissible.

Hardly any two performances of Handel's oratorios took place, during his lifetime, without the addition and substitution of many favourite airs from other works Later on, in the time of Mozart, performances of operas (which had become much tighter unities than Handelian oratorios) were often adorned with inserted arias by other composers; Mozart's own contributions to other men's operas fill two stout volumes. Music was in the same condition as architecture; and Handel was as indebted to other composers as Wren was to Palladian architects, and as Mozart was (especially in his Requiem) to Handel. And no fear that discovery might discredit him seems to have entered into Handel's mind, for he left his whole musical library to his copyist, and it was from this library that the sources of his work were discovered.

The true plagiarist is the man who does not know the meaning of the ideas he copies, and the true creator is he in whose hands they remain or become true ideas. The theme "He led them forth like sheep" in the chorus "But as for his people" is one of the most beautiful in Handel's works, and we may be shocked by the bare statement that it comes from a serenata by Stradella. But, to any one who knew Stradella's treatment of it first. Handel's would come as a greater revelation than if he had never heard the theme before. Stradella makes nothing more of it than an agreeably frivolous tune which lends itself to comedic purposes by repetition, throughout eight pages of patchy aria and ritornello, at an ever-increasing pace. What Handel sees in it is what he makes of it, one of the most solemn and poetic things

in music.

Again, how shocking that the famous opening of the "Hailstone chorus" comes from the patchy and facetious overture to this same serenata, with which it is identical for ten bars all in the tonic chord representing, according to Stradella, someone knocking at a door. And how yet more shocking that the chorus "He spake the word, and there came all manner of flies" contains no idea oi Handel's own; at least, none except the realistic swarming violin passages. the general structure, and the vocal colouring; whereas the rhythmic and melodic figures of the voice parts come from an equally patchy *sinfonia concertata* in Stradella's work.

The effects of Handel's original inspiration upon foreign material are really the best indication of the range oi his style. The comic intention of Stradella's door-knocking overture becomes Handel's inspiration in the "Hailstone chorus." In the theme of "He led them forth like sheep" what Stradella thought frivolous Handel makes sublime.

The converse process is equally instructive. In the short carillon choruses in *Saul,* where the Israelitish women welcome David after his victory over Goliath. Handel uses a delightiul instrumental tune which stands at the beginning of a Te Deum by Urio, from which he drew extensively in *Saul, L'Allegro,* the Dettingen Te Deum, and other works. Urio's idea is first to make a jubilant and melodious noise from the lower register oi the strings, and then to bring out a flourish of high trumpets as a contrast. The tune could not bear and does not receive any iurther development, beyond statement and counterstatement. It has none of the solemnity of church music, and its value as a contrast to the flourish of trumpets depends, not upon itseli, but upon its position in the orchestra. Handel did not see in it a fine opening for a Te Deum, but he saw in it a periect type of popular jubilation, and. taking it at its face value as a popular tune he raised it to a high dramatic level. So he used it as an instrumental interlude accompanied with a jingle of carillons, while the daughters of Israel sing to a square-cut tune those praises of David which aroused the jealousy of Saul.

But now turn to the opening of the Dettingen Te Deum and see realized the other side of Urio's idea, the contrast between a jubilant noise in the lowest part of the scale and the blaze of trumpets at an extreme height. In the fourth bar of the Dettingen Te Deum we find the same florid trumpet figures as we find in the fifth bar of Urio's, but at the first moment they are on oboes. The first iour bars beat a tattoo on the tonic and dominant, with the whole orchestra, including trumpets and drums, in the lowest possible position, with all the drastic power of Handel's genius. Then the oboes appear with Urio's trumpet flourishes; the momentary contrast is not less brilliant than Urio's; but when the oboes are immediately followed by the same figures on the trumpets themselves the contrast gains gradation and climax. Moreover, these flourishes are more melodious than the sledge hammer opening, whereas in Urio's scheme they were mere conventionalities coming after a good melody. Lastly, Handel's primitive opening rhythmic figures inevitably underlie every subsequent inner part and bass that occurs at every half close and full close throughout the movement, especially where the trumpets are used. And thus every detail of his scheme is rendered alive with a rhythmic significance like that of the themes of Beethoven's second period, whereby he obtains the liveliness of polyphony without fussiness.

Greatness of the Oratorios.—No other great composer has ever so overcrowded his life with occasional and mechanical work as Handel, and in no othet artist are the qualities that make the difference between inspired and uninspired pages more elusive. The libretti of his oratorios are full oi absurdities, except when they are derived in every detail from Scripture, as in *The Messiah* and *Israel in Egypt,* or irom the classics of English literature, as in *Samson* and *L'Allegro.* The absurdities, and the. way in which all Handel's works exist by taking in each other's washing, only serve to strengthen the conviction of sound musicians that Handel's originality and greatness consist in his grasp of the works as wholes. They would not matter but for the fact that in English oratorio Handel created a true art form on the largest possible scale.

Though drama, in the proper and Aristotelian sense of action, was inherently beyond the terms of Handel's art, the two main qualities of dramatic language, viz., rhetoric and characterization, are at their highest power in all his music, and are, in spite of all that an obscurantist piety has done to conceal them, a main source of his popularity. The 18th-century love affairs of the Israelite warriors and their Israelite maidens cease to resemble the Loves of the Triangles when Handel's music begins to discriminate. It cannot always save the situation, unless we are prepared (as the bishop of London in 1740 was not) to be amused at the contrast between the passionate Elder and the crafty Elder in their trio mith the chaste Susannah. But it leaves no part of the work altogether lifeless! even where the music is most perfunctory. Neither the chorus nor the solo parts admit any lay figures. The heathen are so delightfully pagan that Handel has often been praised for his sympathy with them; but it is a feebly man-about-townish view that thinks his orthodox Jews and Christians less true to their ideals and to life. Their music is the work of the man who hoped to die on Good Friday that he might rise mith his Christ on Easter Day.

The power oi Handel's English declamation is famous and might with advantage be used as a touchstone for the originality oi his setting of words. For instance, the theme of "For unto us a child is born" puts an awkward strain on the word "For"; whereas the next theme, "And the government shall be upon his shoulder," is magnificently suggestive oi the action symbolical of assuming the load of government. The rest of the chorus "Wonderful Counsellor," etc., obviously goes straight to the point. Now the first two themes come irom an earlier Italian duet, of which the first words are *No, da voi non più fidarmi,* so that the word "For" replaces the exclamation "No." The other theme was meant to scold blind Love for its lying cajoleries, the word "shoulder" coinciding with *lusinghie . . . re.* Handel, seeing in this theme the possibility of a majestic interpretation, put up with a slight inconvenience in the opening theme for the sake of the spacious general structure of the whole movement which was easily expanded to include the new material of "Wonderful Counsellor."

It can hardly be doubted that the melody of "He shall feed his flock like a shepherd" was originally composed to some text, now lost, which gave the awkward expansion and fall of the word "shepherd" (scarcely better on the word "weary") a meaning as convincing as the famous "sheds delicious death" in *Acis and Galatea.*

The Additional Accompaniments Question.—*There* never has been a time when Handel has been overrated, except in so far as other composers have been neglected. But this iavourite musician of the non-musician suffers grievously irom pious misinterpretation and the popular admiration of the wrong externals. Chrysander spoke true and winged words about the burial of Handel's art beneath "mammoth" Handel Festivals at the Crystal Palace; but greater damage has been done to periormances on a normal scale by the use of "additional accompaniments" in the style of a later symphonic art, started most unfortunately by Mozart (whose share in the work has been corrupted in its turn) and continued throughout the 19th century in progressive stages of insensibility until Handel's style has become as unrecognizable as Nash's Regent street.

But while it is obvious that in *The Messiah* Mozart's orchestral colouring is for the most part an intrusion, the desire for purity of style overreaches itself when it leads to a condemnation of Mozart's work in *Acis and Galatea* and the smaller *Ode to St. Cecilia's Day.* (The accompaniments to *Alexander's Feast,* published in Mozart's name, are obviously by no artist of even ordinary competence.) Handel's secular style is by no means remote from Mozart's, and he leaves so much to the discretion of the performer that it is no indiscretion to allow Mozart to convert Handel's often very perfunctory sketch into a perfect Mozart-Handel work of art.

The result is at all events less heterogeneous than the cadenzas inserted by recent *Musikgelehrte* who out of the fullness of research achieve a style which no real composer at any period would receive without derision.

For the rest, when the worst has been said concerning either his own weaknesses or the misdeeds of his editors, musicians mill never cease to love and revere Handel as one of the greatest of composers, whose inspired work is a marvel of architectonic power, perfect sense of style and the power to rise to the most sublime heights by the simplest means. (D.'F. T.)

Brenet, *Händel, Biographie critique* (1912); W. Newman Flower, *Georg Frideric Handel* (1923); H. Leichtentritt. *Händel* (1924); *W.* C. Smith, *Concerning Handel* (1949).

HANDEL-MAZZETTI, ENRICA, FREIIN VON (1871–1955). Austrian writer, was born in Vienna on Jan. 10, 1871. She is known primarily as the author of many historical novels markedly Roman Catholic in outlook. Her manner of depicting the customs and modes of thought of earlier times first aroused notice because her direct realism was unfamiliar to Austrian Roman Catholic circles.

Meinrad Helmpergers denkwürdiges Jahr (1900) treats the theme of an English boy's conversion to Roman Catholicism in 13th-century Austria after his father has been tortured and killed as a freethinker by Berlin Protestants. Clashes between Protestant and Catholic are central issues in *Jesse und Maria* (1906) and *Die arme Margaret* (1910). *Der deutsche Held* (1920) and the Karl Sand trilogy *Das Rosenwunder* (1924), *Deutsche Passion* (1925) and *Das Blutzeugnis* (1926) have a 19th-century setting, while *Frau Maria* (1929–31) is a trilogy centring upon the 18th-century poet Johann Christian Giinther. She died on April 8, 1955, at Linz.

HANDICRAFTS, manual skill, or skilled work with the hand, more generally designating those visual arts which are actually practised by hand and associated with wearing apparel or deco-

ration in the home. In a sense handicrafts may be considered as synonymous with arts and crafts only of a less broad meaning; arts and crafts including those arts which are practised by hand and those which are practised with the aid of a machine.

HANDL, JACOB, also HÄNDL or HÄHNEL (1550–1591), German composer, was born at Reifnitz, Carniola (Ribnica Slovenia), on July 31, 1jjo. The nickname of GALLUS, by which he was generally known, nas a play on his surname, Hahnel, "little cock." He is known to have been in the service of the bishop of Olmütz as master of the chapel about 1j79 but is principally associated with Prague. where he was for many years cantor of St. Johann am Ufer. He died at Prague, July 18, 1591.

Although he hardly merited the name, freely given to him, of "the German Palestrina," Handl was undoubtedly an important figure in his day. His music shows a definite leaning toward the homophonic style which was so soon to take the place of 16th-century polyphony.

Most of his works were published in his lifetime. the most important being a collection of motets found in his Opus *Musicum* (4 vol., Prague, 1j86–go). Me also wrote 16 masses and other church music. His motet Ecce *quomodo moritur justus* was borrowed by G. F. Handel for his "Funeral Anthem"

See a selection of his motets with biographical notes in *Denkmäler der Tonkunst in Österreich (1894 et seq.)*; Paul Pisk, *Die Messen von Jakobus Gallus* (1917).

HAND TREE (*Chiranthodendron pentadactylon*), a tree of the family Sterculiaceae, native to Mexico, which takes its name from the peculiar formation of the flowers, the five bright red stamens of the calyx projecting in such a way as to resemble somewhat the fingers of a human hand—the corolla being absent. It is related to the baobab (*q.v.*) of west Africa.

HANDWRITING, or. chirography, writing with the hand as distinguished from print, as a term has come to be more or less restricted to mean the form of writing peculiar to each person. Thus, in addition to the actual motor act and the resulting script, "handwriting" includes also handwriting identification and graphology. These are the aspects of the subject discussed in this article. Other related aspects are discussed in the separate articles on CALLIGRAPHY; PALAEOGRAPHY; and WRITING.

Before the introduction of the typewriter for general use, when handwriting had a greater utilitarian value, schools stressed handwriting instruction. In the United States scales were developed by E. L. Thorndike. L. Xyers and others for gauging the quality of the script from grade to grade in the elementary schools. and a series of careful investigations of the handwriting movements were undertaken. Studies showed that the pressure on the penholder (grip pressure) as well as the pressure of the pen point on the paper (point pressurej varies continuously during writing, and the speed of writing is not uniform but depends upon the type of stroke being made. For example, speed of movement usually rises slowly as the stroke begins, comes to a maximum in the middle and drops off toward the end. The direction of the stroke, turns and loops, complexity of stroke and the type of stroke that preceded will alter the speed of-a given writing movement. Speed is affected also by length of letter elements, since it usually takes more time to make long strokes than to make short ones. By comparing the handwriting movements of good and poor writers, F. N. Freeman found that these two groups differ in position of writing hand. speed and types of movements in fingers and hand. Considerable relationship was found to exist between the changes in speed and the form of letters, and good writers showed greater uniformity in the speed of formation of similar strokes. Later, other educators, experimenting with manuscript writing and printed script, maintained that the latter type of handwriting is learned and executed more speedily because it resembles printed type more. Scales were developed for evaluating quality of manuscript writing. which is taught increasingly in modern schools in the U.S.

The handwriting of adults is so individual that it is considered unlikely that any two people could really write identical hands. This high degree of individualization occurs even among those who learned to write from the same school copy under the same teacher. Investigations into the handwriting characteristics of children have indicated that individualization in graphomotor development begins very early in life. The scribblings of the preschool child as well as the early versions of the child's copy work are often found to show individual characteristics sufficient to identify the author of a handwriting specimen. Among the anomalies of early writing development is mirror writing; that is, reversed script which reads from right to left and is seen as ordinary writing only when reflected from a mirror. Reversal of individual letters to some degree is part of normal spatial and motor development in children, but students of the subject disagree on the physiological processes involved in mirror writing. Most agree that it is the left-handed child's natural form of writing; these children however, tend to conform to the school standard as they gradually assimilate the conventional left-right direction. Brain injuries may result in partial or total mirror writing, which in these instances is considered a regression to the earlier reversal state. The most famous instance of mirror writing is that of Leonardo da Vinci who allegedly did it to keep his scientific work secret.

Despite the highly individualized character of mature writing, it is not always possible to determine age, sex and intelligence from the script itself, although expert estimates are better than chance. Alfred Binet, the first to investigate graphological claims scientifically! carried out a series of experiments in which two graphologists. one the talented Crepieux-Jamin, and 1j untrained judges participated. Binet found that in estimating the sex of the writer of 180 envelopes, the graphologists scored higher than the untrained judges. However, the highest score: 79%, made by Crepieux-Jamin, left too wide a margin for error for practical application when certainty of sex is crucial, as in court proceedings. Similar experiments were made for evaluation of age and intelligence, and again, though the graphologists mere consistently better than the untrained judges, the percentage of error was too high for certainty of evaluation. Nevertheless, Binet considered these results proinising for the future of graphology. Investigations of resemblances in handwriting of blood relatives have indicated that similarity in handwriting is not so great as in other characteristics such as height, weight and intelligence.

Handwriting Identification. — Identification of handwriting assumes great importance in courts of law when the authenticity of signature is contested. Even when the handwriting itself is not to be doubted: the conditions under which it was written sometimes become of great moment. Such questions as whether the writer's hand was forced or guided and whether alterations were introduced after the completion of the document often have to be answered by the expert. One of the first steps in the investigation of a suspected or disputed writing is to find some genuine writing of the disputed author with which to make a comparison. The writing characteristics which experts use in determining authenticity presuppose that each handwriting has certain permanent characteristic features from \\-hich the available handwriting sample may vary, and the question is whether the observed variation is within expected limits or beyond them. Many ingenious methods have been developed to determine the authenticity of a given piece of writing: comparison of dates with age of paper, determining whether writing at the creases preceded or followed the creasing, and chemical and physical examination of the paper and the ink to determine its origin, date of manufacture: date of writing, etc. The presence of tremors, types of final strokes for ending words, and other characteristics of handwriting which graphologists utilize in personality evaluations are also utilized by handwriting experts for identification purposes. However, handwriting experts usually limit themselves to problems of identification only.

Graphology. — Handwriting in its relation to personality has interested observers for many centuries. Peculiarities in the handwriting of Octavius Xugustus were noted by C. Suetonius Tranquillus as early as the 2nd century. The Chinese called attention to the relationship between handwriting and personality as early as the 11th century. In Europe in 1622 Camillo Baldi observed that all persons have a recognizably characteristic way of writing. Baldi began the analysis of handwriting into its elements: which later gave impetus to the French school of Abbé Hippolyte Michon (originator of the term graphology) and Crepieux-Jamin, some-

times known as the founders of the school of "isolated'signs." Their purpose was to relate specific elements in the handwriting to specific personality traits. In contrast, the intuitive graphologists evaluated handwriting by the total impression it made on them, without always being able to indicate the exact basis of their evaluation. The Chinese philosopher of the 11th century and the European poets, artists and philosophers of the 19th century, among then Goethe, Poe, Madame de Stael, Leibnitz and Gainsborough, who were amateur graphologists may be classed with the intuitive graphologists. It was not until the close of the 19th century that an attempt at a unified approach to graphological theory was provided by a study of the handwriting movement itself —the graphomotor process rather than the end product. In this way handwriting joined speech, gait and facial expression as an expressive movement. The features of these expressive movements were assumed to be determined internally, reflecting the stresses and strains. rhythms and inhibitions which the individual characteristically experiences in his everyday life.

In attempting to assess personality from handwriting many investigations have been conducted in which the script is analyzed into its component elements. Factors such as size of letters, width, slant, spacing between letters, degree of connectedness of strokes and letters and many other measurable aspects of writing have been studied. Other aspects of handwriting which do not lend themselves to geometrical measurement can also be rated. Among these are the form level (over-all evaluation of the character and type of form used in writing), degree of ornamentation or simplification of the basic form of the school copy, degree of angularity v. curvature, and types of connecting forms between strokes and letters. There are definite indicators in the handwriting from which the pressure of writing and its speed can be estimated. For example, pressure can be gauged by comparing the width and degree of darkness of the upstrokes, which usually bear little pressure, with the width and degree of darkness of the downstrokes, in which pressure is usually more pronounced. Similarly, increased speed of writing may be gauged from the smoothness of the writing, trimness of the strokes, "i" dots and periods that assume the form of commas as speed increases, increase in right-tending forms, increasing left-hand margins. prolonged lively finishing strokes and infrequency of changes in direction after breaks or pauses.

One of the most fundamental problems in graphology is that of finding an underlying dimension for evaluating all handwriting elements in measurable or ratable scales. With the provision of such a dimension, size of letters, a measurable element, and form level, a ratable one, could be evaluated on the same continuum as could all the other characteristics which graphologists consider important. Though a start in this direction was made by L. Klages. who regarded handwriting as an expressive movement and who tried to provide a systematic procedure for analyzing this movement along a specified continuum, many graphologists continued to be either atomistically analytic or intuitive. The analytic graphologists have claimed that each of the hand riting elements has specific meaning. Thus, unusually large handwriting is said to characterize the ambitious, imaginative person; very small writing, the pedantic person. However, it is recognized that there may be more than one cause for the same effect. Minute writing may be due to myopia; magnification of script may mask loss of motor control. Empirical studies in which attempts are made to relate individual handwriting elements to personality traits in an atomistic fashion rarely yield positive results. Many graphologists claim that only when the isolated elements are integrated into patterns is it possible to find significant relationship with personality.

Klages, maintaining that healthy people express themselves rhythmically in all expressive movements and especially in writing, suggested that the degree of rhythm exhibited by handwriting is a good measure of the wholesomeness of the personality. However, he gave no specific system for classifying degrees of rhythm. T. S. Lewinson and J. Zubin tried to correct this deficiency by providing scales in which the degree of rhythm present in each writing element can be judged. These scales have two opposite poles, extreme contraction and extreme release, with rhythmic balance centred between them. Writing which lacks rhythm as a result of inhibited movement is placed at the contraction end of the scale, while that which lacks rhythm as a result of deficient control is placed at the release end of the scale. The intermediate steps in the scale show an increasing degree of rhythm (or a decreasing degree of contraction or release) up to the point of rhythmic balance in the centre. Each handwriting element is classified on the seven-point scale, and the handwriting of well-adjusted normal persons is expected to vary in a bell-shaped curve of distribution about the point of rhythmic balance. Standards for classifying a given handwriting element on the contraction-release scale have been developed. Rose Wolfson applied these scales to the writings of delinquent and nondelinquent boys. She found that the scales differentiated significantly between the two groups, reflecting less rhythm and more release for the delinquent than for the nondelinquent subjects. Moreover, statistical analysis revealed a cluster of handwriting elements, consisting of size of letter, spacing and curvature, etc., which seem to be the most important elements in the handwritings of delinquents and may also prove to be the most important in all handwriting.

Another development in graphology was Max Pulver's interpretation of the symbolic in handwriting. Following Klages, Pulver studied the entire writing, but he interpreted its symbolic character according to dream symbolism and the relations between symbols and personality according to psychoanalytic theory.

Some broad claims have been made for graphology in predicting and diagnosing various physical and mental ailments — liver, heart and gastrointestinal disease, cancer, accident proneness, numerous psychiatric diagnostic categories and tuberculosis. It is difficult to evaluate the validity of many of these claims because too often the data on which they are based lack sufficient control, but studies in which scientific controls are utilized do not invariably disprove the claims of graphology. Careful comparisons of group data on epileptics, schizophrenics and manic-depressives with data obtained from comparable normal persons have shown significant differences, but such group differences are not suitable for the diagnosis of individuals. Similarly, differences have been noted between the premorbid and morbid handwriting of patients. Other investigators, however, have shown that there are no observable differences between the premorbid handwriting of schizophrenics and suicides and the handwriting of comparable normal persons. Group differences have been reported for stutterers and for criminals, and the handwriting of mental patients has been found to be more variable in its rhythmic qualities on the contraction-release continuum proposed by Lewinson and Zubin. A study of neurotic patients was conducted in which the answers of each patient to a personality questionnaire were compared with the answers to the same questions given to him by a graphologist based on an analysis of the patient's writing. This study indicated that the graphologist was right significantly more often than she was wrong.

The specific basis for the graphological judgment, however, rather than the accuracy or validity of an interpretation, is the issue in the development of graphology as a scientific method. Methods which match graphological interpretations with different indices (such as personality test scores, self-appraisal estimates and friends' opinions) may show that graphologists can evaluate personality with better than chance success, but the exact method of analysis is left undefined. Moreover. judges' opinions as to the validity of an analysis are not always conclusive. F. E. Krueger and Karl Ziets obtained handwritings from 80 individuals, then, without referring to the handwriting specimens, concocted a universal personality sketch of the type that astrologists use; each of the 80 subjects accepted this sketch uncritically as applying to himself.

After the late 1940s the following trends were discernible in graphology: it became more amenable to experiment; it was used more professionally; experimenters worked with subjects about whom extensive personal data were available against which to check findings. An outstanding example of this is the extensive research on alcoholic patients in which the findings from the handwritings and biochemical findings conspicuously agreed.

Finally, there were efforts to modernize existing instruments electronically and in other ways in order to study pressure. speed and tension. The question of the ultimate scientific value of graphology remained unanswered. however. The answer will depend largely on the development of more adequate laboratory techniques and preparation of more objective rating scales, but also on deeper insight into the factors underlying personality so that graphological results can be related to stable criteria of personality measurement.

HANGAR: *see* **AIRPORT.**

HANGCHOW (HANG-CHOU), one of the notable historic cities of China and capital of Chekiang province. Pop. (1953) 696,600; (1957 est.) 784,000. Its importance is largely the product of its position. It lies at the mouth of the basin of the Ch'ien-T'ang river, which drains west Chekiang, and at the head of Hangchow bay. It is the natural link between the thickly peopled plains on either side of the bay and is the outlet of west Chekiang. Hangchow has a wider significance through its position on the south margin of the Yangtze delta and through its participation in the cultural development of the deltaic cities. It is the focal point for the southern ends of the waterways of the delta and is the southern terminus of the Grand canal (Yün Ho), which was from the time of the Mongols to the mid-19th century the main avenue of communication between the Yangtze delta and Peking. Yet the greatest days of Hangchow were before the completion of the Grand canal as a route between north and south. It was during the later Sung dynasty (A.D. 1127–1280), when the Chinese had retreated before the Mongols south of the Yangtze and had established their capital at Hangchow that the city reached the height of its importance. becoming the scene of intense literary activity of the period. Hangchow was then called Linan but popularly known as King-shih (the capital), from a corruption of which Marco Polo's *Kinsai* was derived.

Hangchow has been a commercial centre of great importance from the T'ang period onward. Although one of the points where the system of inland waterways which thread the Yangtze delta reaches the sea, Hangchow itself has never been a port for seagoing vessels, its port functions being restricted to inland navigational shipping. From the T'ang to the Yüan periods it utilized Kan-p'u farther down Hangchow bay, and with the continued silting of the bay, its seagoing trade has had to pass through Shanghai. The total trade of the port before World War II, was slightly less than that of Soochow or Chen-chiang, which are also within the delta and on the Grand canal. Hangchow is of some importance industrially, the most important industry being silk manufacture, based on the famous sericultural region of northwest Chekiang. Like Nanking, Hangchow is a silk-weaving rather than a silk-reeling centre.

After 1949, a jute-sack industry developed in Hangchow. A considerable number of rice-hulling and cleaning mills reflected the rice culture of the surrounding plains.

The city is built at the foot of a beautiful range of hills, the Hsi-t'ien-mu shan, or Eye of Heaven mountains, and by the shores of the famous Hsi Hu. the Western lake. The beauty of its buildings and gardens equals the charm of its situation among hills and valleys studded with some of the most famous monasteries in China. Hence the Chinese proverb: "There is Heaven above and Soochow and Hangchow below."

To Marco Polo it was incomparably the finest city in the world. This beauty was sadly tarnished in 1861 by terrible devastations during the Tai P'ing Rebellion, but the city, in a somewhat modernized form, largely recovered its prestige and still ranked as one of the leading cities of China.

After 1928, aith the establishment of the national government at Nanking. Hangchow gained new importance as the capital of the native province of Chiang Kai-shek. Emphasis on cleanliness of streets and buildings. and a model police force, were some of the accomplishments. No foreign treaty port rights were recognized in Hangchow itself where only foreigners in Chinese service or missionaries were permitted to reside.

The city became the home of the National Chekiang university and the Hangchow Christian college, which continued its work until 1941 in Shanghai.

Hangchow is linked by rail with Shanghai, Ningpo and Nanchang The city was held by the Japanese from 1937 until the end of World War II in 1945. In 1949 it was captured by Communist forces (T. SD.)

HANGING is one of five methods used in the western world for executing persons sentenced to death for crime. the others being electrocution, guillotining, gassing and shooting. Hanging is the method used in some U.S. states, in England, Scotland and the commonn ealth countries.

United States.—Execution by hanging was introduced early in colonial America by the English settlers In 1630, according to Joseph Dillaaay Sawyer in *History* of *Pilgrims and Puritans,* a John Billington was hanged at Plymouth in "ye first execution amongst them" for his murder of "one John New-comin" whom he "shote . . . with a gune, whereof he dyed."

Before the wide acceptance in the 19th century of the scaffold and the hangman's knot, which made possible a quick snapping of the spinal column, the victim often suffered slow strangulation before death.

In the United States the last public execution, a hanging, occurred in Kentucky in August. 1936. The number and type of witnesses attending executions are now highly restricted by law and administrative regulations. In the second part of the 20th century the lans of six states (New Hampshire. Iowa. Kansas. Montana Idaho and Washington) prescribed hanging as the method of execution. One other state, Utah, gave the prisoner the right to choose between hanging and shooting. The tendency in the United States to replace hanging with some other method of execution is reflected in the fact that of the 48 executions that took place during 1958, only one mas by hanging.

England and Scotland.—The procedure of an execution in England and Scotland is similar. The executioner and his assistant travel to the prison the day before that fixed for the execution. They observe the prisoner and are told his height and weight. They then go through the procedure of the execution using a sack of the same weight as the prisoner. The proper drop is calculated nith regard to the physical characteristics of the prisoner. The trap upon which the condemned person stands is formed of two hinged leaves held in position from below by bolts which are withdrawn when a lever is pulled. Above the trap a rope is attached to an overhead beam in such a way that it can be adjusted to the proper height.

The execution is carried out in the presence of the sheriff or undersheriff. At the time appointed the executioner enters the condemned "cell," pinions the prisoner's arms behind his back and leads him to the appropriate spot on the trap of the gallows. The assistant executioner then pinions the prisoner's legs, while the executioner puts a white cap over his head and the noose around his neck.

The knot of the noose is drawn tight on the left jaw where it is held in position by a sliding ring. The executioner then pulls the lever and the prisoner falls through the trap thereby suffering fracture or dislocation of the first three cervical vertebrae and so damaging the vital centres of the spinal cord. It is said that the dislocation of the vertebrae causes immediate unconsciousness and there is no chance of a later recovery since breathing is no longer

possible.

Apart from the sheriff the persons required to be present are the jailer, chaplain and prison surgeon and such other officers of the prison as the sheriff requires. Relatives and some other persons may be permitted to attend.

Hanging was derived by the Anglo-Saxons from their German ancestors (Tacitus, *Germ.*, 12). In England hanging was established as a punishment for homicide by the time of Henry II and in the middle ages every town, abbey and nearly all important manorial lords had the right of hanging. From the 12th century the jurisdiction of the royal courts became exclusive. Until 1868 hangings took place in public. During the early years of the modern period, the corpse was gibbeted (*i.e.*, hung in chains) and allowed to remain in a public place as a warning to evildoers.

HANK: *see* YARN.

HANKEY, MAURICE PASCAL ALERS HANKEY, 1ST BARON (1877–), British soldier and politician, the first holder of the office of secretary to the British cabinet, was born at Biarritz, France. on April 1. 1877. Educated at Rugby, Eng.. and at the Royal Naval college, Greenwich, he served in the royal marine artillery (1895–1901) and in the naval intelligence department (1902–06). He became secretary to the committee of imperial defense in 1912 and, after World War I, was given in addition the new appointment of secretary to the cabinet. a post which he occupied until 1938. when he was raised to the peerage on his retirement. At the outbreak of World War II he was recalled to service, and was a cabinet minister until 1942. His knowledge. wisdom and experience were used by a succession of prime ministers, and he was British secretary at several international conferences. notably at Versaillcs. Washington, Genoa. The Hague. Lausanne and London. His retirement from public service was the prelude to an independent and very full life as a regular speaker in the house of lords. as chairman of several scientific and technical committees and as British representative on the Suez Canal company. In his *Politics, Trials and Errors* (1949) he strongly opposed the war crimes trials after World War II. especially those in Tokyo. In 1951 he delivered the Romanes lecture at Oxford. (F. S. G. P.j

HANKOW (HAN-K'OU), a member city of the tri-city conurbation of Wu-han on the left bank of the Han river where it joins the Yangtze in Hupeh province, China. Hankow was merged in 1950 with the adjacent cities of Han-yang and Wu-chang to form the single metropolis of R'u-han. *See* WU-HAN.

HANN, JULIUS (1839–1921), Austrian meteorologist and climatologist, acquired a world-wide reputation for his works on atmospheric dynamics and thermodynamics, the "atmospheric pulse." cyclones and 'climatology. He was born near Linz, Upper Austria, on March 23, 1839. In 186j he became editor of the *Zeitschrift der Oesterreichischen Gesellschaft für Meteorologie*, and from 1877 was occupied in the Central Meteorological institute at Vienna. In 1873 he was appointed professor of physics at the University of Vienna.

He died in Vienna on Oct. 1. 1921.

Hann's principal works are *Die Erde als Ganzes; Die Atmosphäre und Hydrosphäre* (1872); *Handbuch der Klimatologie*, 3 vol. (1908; rev. ed. by Karl Knoch, 1932); *Lehrbuch der Meteorologie*, 3d ed. (1914) and many papers in his own *Zeitschrift* and the reports of the Akademie der Wissenschaften.

HANNA, MARCUS ALONZO (1837–1904), U.S. politician, was born at New Lisbon (now Lisbon), Columbia county. O.. on Sept. 24, 1837. In 1852 he moved with his father to Cleveland. He received his education in the public schools of that city and at the Western Reserve university. He was associated with his father in the wholesale grocery business and became a member of the firm. In 1867 he entered into partnership with his father-in-law. Daniel P. Rhodes. in the coal and iron business. In 1877 the firm became M. A. Hanna & Company and was extended to include the ownership of a fleet of lake steamships constructed in its own shipyards and the control and operation of valuable coal and iron mines. Hanna became largely interested in street railway properties and in various banking institutions. and after 1880 became prominent in the affairs of the Republican party in Cleveland. In 1884 and 1888 he was a delegate to the Republican national convention and was associated with William McKinley in the management of the John Sherman canvass. It was not, however, until 1896. when he personally managed the canvass that resulted in the Republican presidential nomination for William McKinley that he became known throughout the Cnited States as a political manager of great adroitness, tact, and resourcefulness. He was chosen chairman of the Republican national committee and managed with consummate skill the campaign of 1896 against William Jennings Bryan and "free-silver." In March 1897 he was appointed, by Governor Asa S. Bushnell (1834–1904), U.S. senator from Ohio. In the Senate: to which in Jan. 1898 he was elected for the short term ending March 3, 1899, and for the succeeding term, he was recognized as one of the principal advisers of the McKinley administration and his influence was large.

He took a deep and active interest in the problems of capital and labour, was one of the organizers (1901) and the first president of the National Civic Federation. whose purpose was to solve social and industrial problems. and in Dec. 1901 became chairman of a permanent board of conciliation and arbitration established by the Federation. After President Roosevelt's policies became defined Senator Hanna was regarded as the leader of the Conservative branch of his party and a possible presidential candidate in 1904. He died at Washington on Feb. 1j, 1904.

HANNIBAL (247–183 B.C.), Carthaginian general. The name of Hannibal was a very common one in Carthage, but the most illustrious of its bearers was the son of Hamilcar Barca. Born in 247 B.C., at the age of nine Hannibal was taken by his father to Spain, after swearing eternal hatred against the Romans. In Spain he was trained by his father in the art of war. He also accompanied him on the expedition in the course of which Hamilcar, having assured the safety of his young son, was killed by the rebellious Oretani (229). Hannibal remained in Spain during the term of government of his brother-in-law, Hasdrubal, who succeeded Hamilcar Barca, and he served under Hasdrubal for some years. On the latter's death (221), Hannibal, at the age of little more than 25, assumed command of the army and province of Spain. In 221 also, he conducted a campaign against the Holcades, and in 220 he moved against the Vaccaei, and overcame the Carpetani in a battle near the Tagus. In the following year, notwithstanding a warning received from Roman ambassadors, he laid siege to Saguntum, the only city in eastern Spain south of the Ebro which still resisted his armies, and he took it after an eight months' siege. The Romans, who had threatened war if Hannibal should attack Saguntum, now demanded satisfaction from Carthage and, failing to obtain it, declared war. Thus began one of the most terrible wars of antiquity, the Second Punic War.

Inasmuch as he rejected the Roman warning, it is beyond dispute that Hannibal must bear the responsibility in history for initiating the war. On legal grounds we may ask whether in virtue of the treaties, the Romans were entitled to intimate to Hannibal that he must not attack Saguntum, and there can be no doubt as to the answer, in view of what we learn from the very historians who consider that Hannibal's attack on Saguntum was a violation of the treaties. The treaty concluded by the Romans with Hasdrubal prohibited the latter from crossing the Ebro in arms. Saguntum, however, is south of that river, though certain ancient historians committed the gross geographical error of placing it to the north. Again, it is by no means certain that the treaty contained a clause excluding the Greek colonies from the Carthaginian sphere of influence; but even if there was any such clause it did not apply to Saguntum, for it is a mere fable, due to the likeness of names, that Saguntum was a colony of Zacyn-

thus; it was undoubtedly an Iberian city, as is shown by its coins. While, however, legally the Romans had no right to intervene on behalf of Saguntum — their own alliance with the Saguntines constituting a violation of Hasdrubal's treaty, which, at all events implicitly, assigned the region to the south of the Ebro to the Carthaginian sphere of influence — politically it is clear that by attacking Saguntum Hannibal accepted responsibility for the war and all its consequences. He did so because he thought it necessary in order to uphold the position of Carthage as a great power, and at the same time he thought that he could win — not realizing the granite solidity of the Italic confederation centred in Rome, which he hoped to dismember by the hammer-blows of his army. Thus Hannibal's whole action was based on a grave and fatal error of valuation; but this error was inevitable, because he could have no idea of the solidity of the Roman confederation, which had never yet been tested, except partially and not very thoroughly in the time of Pyrrhus; he could only draw a fallacious analogy with the other, infinitely weaker, confederations with which he was acquainted from history or by personal experience. Granted that Hannibal believed in the possibility of a victorious war with Rome, and thought that Carthage was bound to initiate it in order to retrieve the disasters of the First Punic War, we must then consider whether the moment Hannibal selected was a good one, and whether his preparations and his plan of campaign were suited to the exigencies of that moment.

The moment itself could not have been better chosen. Later on, a victorious war in Italy would have been almost impossible. The Romans had indeed, during recent years, discomfited the Boii, and crossing the Po had subjugated the Insubres, but the power of the Gauls was not yet broken; hatred of the victors was still extreme, and the Romans had scarcely begun to establish themselves in the conquered territory. At that juncture, therefore, the valley of the Po offered Hannibal an excellent base for a war against Rome, with abundant recruiting material. Had the Romans but been able to consolidate themselves in the Transpadane, he could have had no such hopes. Indeed, from then onwards it was already beginning to be a little too late, and Hasdrubal, by allowing the Romans to conquer the Cisalpine Gauls, had paid dearly for the truce during which he had been left free to consolidate the Punic empire in Spain.

With regard to the plan of campaign, modern writers have discussed whether Hannibal was really its author or whether it was not essentially due to Hamilcar Barca, who had entered upon the conquest of Spain with the precise object of subsequently preparing for an invasion of Italy across the Alps with the help of the Gauls, who at that time were still not under Roman dominion. There seems no doubt that such was really Hamilcar's intention. That he nourished a deadly hatred for the Romans, that he prepared for a war of revenge after having been forced to give up Sicily to them and watch them seize Sardinia, and that his whole object in founding the empire in Spain was to prepare for that war, is beyond question. But he could have made use in two ways of the strength and wealth which Carthage drew from her Spanish empire against the Romans: either in the way which Hannibal afterwards chose, or by preparing to regain the command of the sea, which had been lost in the First Punic War. As, however, he did not direct the policy of Carthage along this latter channel, it is perfectly legitimate to conclude that it was he who laid the foundation of the plan of campaign which Hannibal subsequently carried out Hannibal's merit consists in having adopted that plan and putting it into execution with unequalled genius.

Nevertheless, Hannibal's conduct of the war had two fundamental defects. One was that — as his father, Hamilcar Barca, had previously done in Sicily, when he tenaciously defended the last remnants of Carthaginian territory there — he failed to realize with sufficient clearness the absolute necessity of naval supremacy for a definitive victory in the great duel with Rome, and, taking the view that the predominance gained by the Romans in the First Punic War was unalterable, he made no serious attempt at preparing to dispute it. Thus he lessened the efficiency of his conduct of the war; for there is no doubt that the ultimate victory of Rome in the Second Punic War was essentially due to the fact that her naval supremacy was maintained throughout.

Moreover, Hannibal, having to entrust the command of the Spanish forces which were left to themselves when he started for Italy to a tried and faithful officer, selected his brother Hasdrubal, who was certainly in every way loyal, but was very young and quite unequal to his heavy responsibilities — so much so, that he was not merely unable to make head for a moment against a really good general like Scipio (afterwards called Africanus), but was repeatedly defeated by mediocre leaders like the brothers Publius and Gnaeus Scipio, who had small resources and few troops at their command.

Having gone into winter quarters at Cartagena (219–218), Hannibal started slowly towards the Ebro in the spring of 218, not crossing the river till nearly the end of May; he then spent two months in operations against the tribes between the Ebro and the Pyrenees. This slow progress was intentional. He was anxious that his opponents should not have the slightest suspicion of his contemplated invasion of the Po valley, and (thinking it possible to stop him near the Rhone with the strong allied city of Marseilles as their base) should not soon enough make efficient preparations in upper Italy for the defence of the passes of the western Alps. This must have been exactly what the consul Publius Cornelius Scipio planned when, in the late summer of 218 (he had been detained in Italy by an unexpected rebellion of the Boii), he transported his army of two legions by sea from Pisa to the mouths of the Rhone. Here Scipio learned that Hannibal was already north of him, near the right bank of the river. When, after a successful cavalry reconnaissance, he moved northward along the right bank of the Rhone with his legions, he found that Hannibal had crossed the river and was proceeding northward on the left bank with intentions that were not too clear. Hannibal had been anxious to avoid a battle for the time being, and by marching northward to leave Scipio uncertain through which Alpine pass he had chosen to descend into Italy. In these circumstances, Scipio returned to the sea, embarked his legions for Spain with the intention of campaigning against the Carthaginian forces that still remained there, and accordingly entrusted the command to his brother Gnaeus, while he himself sailed from Marseilles for Pisa, whence he hastened to the Po to take command of the two legions stationed there to guard the territory and protect the two recently-founded Roman colonies near the river — Placentia and Cremona. Hannibal, however, as soon as he was assured that the Romans were not contemplating either pursuing him or closing the Alpine passes against him, returned southward, and crossing the pass of Mont Genèvre descended into Italy, into the valley of Susa. There he rested his forces, and having taken by assault the city of the Taurini tribe of Gauls, which offered resistance, proceeded to take the offensive, moving so rapidly in the direction of the Po as to anticipate Scipio's offensive.

Hannibal's march was thus, strategically, entirely successful. The Romans, failing to anticipate his movements, had not awaited him where with strong forces they could easily have given an initial and perhaps decisive check to his war worn and unacclimatized Africans — that is to say, in Piedmont, between Ivrea and Turin. After wasting time in seeking him near the Rhone, they had not acted rapidly enough to encounter him near the passes of the western Alps. Nevertheless, according to our tradition, this strategic success was very dearly bought, for between the Ebro and the Po Hannibal is said to have lost more than 50,000 men — about two-thirds of his army — reaching Italy with 20,000 infantry and 6,000 cavalry. This estimate of his losses is, however, quite inadmissible, and a critical scrutiny must reduce the total Carthaginian losses during the long march to not more than 5,000 or 10,000. It is indeed inconceivable that any army, after undergoing such hardships and suffering such enormous losses, could at once enter upon a victorious campaign; nor can it be supposed that Hannibal made such havoc of the best army Carthage ever had

A cavalry skirmish between the Ticino and the Sesia, known as the battle of the Ticino, informed Scipio of the enemy's strength and led him to recross not only the Ticinc but also the Po, abandoning the Transpadane to Hannibal and organizing his defence to the south of the Po, with the colony of Placentia as its base.

Near Placentia the Romans also concentrated the legions of the other consul, Tiberius Sempronius, who had been recalled from Sicily, where he was making preparations for a descent on Africa. Hannibal, crossing the Po higher up, moved in the direction of Placentia and encamped on the left bank of the Trebia. Here, crossing the river, the four Roman legions attacked him by order of Sempronius. The victory of the Trebia (about Dec. 218) was the first of the three great victories that Hannibal owed to his supreme tactical skill. This battle caused the Romans to abandon the whole of northern Italy except the colonies of Placentia and Cremona, so that in the following year (217) they stood on the defensive in the peninsula, with one army commanded by Gaius Flaminius at Arretium, and the other under Gnaeus Servilius at Ariminum. Eluding the vigilance of Flaminius, Hannibal now succeeded in crossing the Apennines and proceeded to ravage north-eastern Etruria under his very eyes; he then moved unexpectedly from Cortona along the northern shore of Lake Trasimene in the direction of Perusia, as if he intended to attack the other consul, Servilius, who was coming down by forced marches from Ariminum to effect a junction with his colleague in Etruria. Flaminius, who was in the enemy's rear, allowed himself to be surprised on the northern shore of Lake Trasimene, between the pass of Borghetto and Passignano, giving Hannibal the opportunity to gain the second of his great victories (June 217).

The dilatory and cautious methods of the dictator Fabius gave the Romans every facility for preparing for what they thought was bound to be the decisive campaign in the following year, but did not hinder Hannibal from ravaging along the Adriatic as far as Apulia and crossing into Campania, where he Iaid waste the fertile Ager Falernus. Thereafter, exhibiting admirable judgment and amazing skill in manoeuvre, he evaded the ambushes laid for him with considerably superior forces by the dictator, and returned to northern Apulia to take up his winter quarters (217–216).

Here, skirmishes near Geronium, one of which went in the Romans' favour and the other against them, did not alter the situation. It was altered by Hannibal, who at the end of the winter, without interference from the Roman army that was watching him, suddenly moved further south near the Aufidus and there seized the fortress of Cannae, where the Romans had a large supply depot. He thus secured stores for his army and at the same time had the advantage of moving into an undevastated area well suited to his skilful manoeuvring. Here, near the Aufidus, he was overtaken by the consuls for the year 216, Lucius Aemilius Paulus and Gaius Terentius Varro, with one of the largest armies that Rome had ever put in the field, about 50,000 strong (allowing for the exaggerations of tradition, which sets it at 80,000); their intention was to engage the enemy in a decisive battle. The Romans had two camps, one on either bank of the river, connected by a bridge; Hannibal had a camp on the right bank, further downstream.

The Romans drew up in order of battle on the left bank of the Aufidus, with their front facing the sea and their right resting on the river. If they were defeated, they thought they could fall back either on the left bank towards Asculum or Aquilonia, or, crossing the bridge between the two camps, on the right bank towards Canusium or Venusia. If he gave battle on the Apulian plain, Hannibal had to be prepared to fight with his back to the sea and risk a complete disaster if defeated, since he had no line of retreat. He relied, however, on the efficacy of a manoeuvre that has made the battle of Cannae famous, and has been successfully imitated several times in modern warfare, including the recent World War. Drawing up, as usual, his infantry in the centre and his cavalry on both wings, he advanced impetuously against the enemy with the middle part of the infantry line, consisting of the Gauls and Spaniards, while the detachments of Libyan infantry on both flanks remained inactive. The Romans not merely withstood the attack, but, with the weight of their deep columns, forced the enemy to give back beyond his original position. Thus the Libyan detachments, which had not moved during the attack, were projecting on both sides of the front as it bent before the drive of the legionaries; and now, at a given signal, the Romans, who were penetrating like a wedge into the Carthaginian front, were assailed on either flank, while to complete the enveloping movement there came up from the rear the cavalry, who had routed the Roman cavalry on the wings, and half of whom, giving up the pursuit, had returned to the field of battle. Thus the enveloping movement was completely successful, and, notwithstanding its bravery and its superiority in numbers, the Roman army was utterly defeated. It will be realized that Hannibal's manoeuvre, which brought about the complete encirclement of the enemy, presupposes that the Romans were not so enormously superior in numbers as tradition would suggest. Otherwise, in order to surround them, he would have had to weaken his lines proportionately, to such an extent as to make it almost impossible for them to withstand the enemy's attacks.

This tremendous victory bore its natural fruits. After the battles of the Trebia and Lake Trasimene, the Italic confederation had remained intact. Not one of the confederate cities had passed over to the enemy. Now, however, this terrible hammer-blow detached from the granite mass of the confederation those parts that were least firmly joined to it—first northern Apulia with the powerful city of Arpi, then nearly all the territory of the Caudini and Hirpini, then most of the Lucanians and Bruttians, and lastly Capua, the second city in Italy.

Both by the ancients and in our own day Hannibal has been blamed for not profiting by his victory to march directly on Rome. The criticism is wholly unjustified. Defended by the strong and recently-repaired wall of Servius Tullius, inhabited by a warlike people not accustomed to quail, commanded by a senate that had always known how to face difficult moments, situated on a river that ensured its supplies even if Hannibal had succeeded in blockading it by land, Rome was in such a position that in all probability a move against it would not have had the very slightest hope of success, immediate or remote, and would have prevented Hannibal from exploiting his victory and gaining the practical benefit he obtained by inducing southern Italy to rebel. But at this point comes the end of Hannibal's wonderful series of successes, and the character of the war entirely changes. Legend ascribes this to the fact that Hannibal's troops went into winter quarters at Capua and thus lost the fighting spirit. In reality it was due to the new Roman strategy, which no longer allowed Hannibal to exploit that fighting spirit in great pitched battles. For the Romans now adopted the strategy suggested by Fabius, which earned him the name of *Cunctator,* the Delayer: never to accept battle when the enemy offered it, never to offer it on equal terms, never to attack him in his camp; but to destroy his army in detail as time and opportunity offered, to defend vigorously all the places that had remained loyal to Rome, to try to recover by force or fraud the places that had fallen into Hannibal's hands, profiting by Rome's numerical superiority and Hannibal's inability to keep the two theatres of war, Apulia and Campania, both uhder his own eye. This plan of campaign undoubtedly called on the Roman people and its allies for immense sacrifices in men and money, and for an indomitable tenacity. Hannibal, inferior in strength and not adequately supported by the Carthaginian Government because the Romans held permanent command of the sea, was obliged to substitute for his audacious and victorious offensives a cautious and not always successful defensive in which all the resources of his genius could not prevent the recovery by the Romans of one place after another that had fallen into his hands; for when superior Roman forces sat down before a city friendly to Carthage his only way of saving it was to give battle with inferior numbers, or to attack the Romans in their firmly-defended entrenchments, offering them the choice of easy victory.

Thus Hannibal's genius was nullified by the force of circumstances. It is not surprising that he lost ground and gained no more great victories in the field. Rather is it surprising that, always unconquered, threading his way among armies superior to his own, without any hope of adequate reinforcements, he succeeded for so many years in gaining still here and there a success, in winning here and there, even if not for long, another position, in retaining possession of a little Italian territory to the

end, and maintaining in it a strong and fairly large army. The weak point in the strategy of attrition adopted by the Romans was the immense effort for which it called, and it is doubtful whether the citizens and their allies would have been equal to such an effort year after year if they had not been comforted by visible successes, which raised their moral when it had been lowered by weariness. Nor must it be supposed that because he was reduced to passive resistance, Hannibal had any idea of allowing the Romans to dictate to him, or even of accepting the transformation of the war into a war of pure attrition, as Fabius desired. He was no longer, indeed, in a position to strike unaided such decisive blows as Cannae. But he could hope for some assistance that would change the aspect of the war in Italy — not so much from Africa, whence reinforcements could only reach him intermittently, as from Spain, if Hasdrubal had succeeded in destroying the small forces which the Romans could send there, or from Macedon, if King Philip V., who had been induced by news of Hannibal's success to take up arms against Rome in order to expel the Romans from their possessions in what is now Albania, had ventured to cross the Strait of Otrantq and conduct an offensive war in Italy. Hannibal might also hope for assistance from Sicily, which, impressed by the Carthaginian victories, also rebelled against Rome immediately upon the death of the old king Hieron (215); or, at any rate, he might hope that the rebellious Syracusans, with effective help from Carthage, would succeed in containing considerable Roman forces for a long period, and thus indirectly assist him in his war in the peninsula. For reasons over which Hannibal had absolutely no control, none of these hopes were realized except the hope of reinforcements from Spain, which however, as we shall see, arrived too late to change the course of the war in Italy.

Meanwhile, however, the effects of the tenacious Roman resistance and the war of attrition were making themselves inexorably felt. In 213, Casilinum fell into the hands of the Romans, and later they recovered Arpi. True, Hannibal succeeded in surprising the Greek colony of Tarentum, the third city in Italy. This was not in every way of advantage to him; for as he never succeeded in occupying the citadel he was obliged to disperse his forces in a very dangerous manner, and meanwhile in his absence the Romans, with six legions, laid siege to Capua and surrounded it entirely with lines of circumvallation. Hannibal was not deaf to his allies' appeal, and in the spring of 211 he broke into Campania and offered battle to the Romans. They, however, refused to leave their fortified positions, and Hannibal was unable to relieve the city because he could not, without very great risk, persevere in his efforts to break the lines of circumvallation. Accordingly he made a very bold move. Leaving behind him the armies which were besieging Capua, he marched on Rome, and encamped three miles from the walls, between the Anio and the Tiber. The Romans were not intimidated; lining the walls with defending troops, instead of offering battle they sent a force out of the city to encamp a mile from Hannibal. In such circumstances it was madness to attempt an assault upon the walls, and equal madness to delay in the heart of the enemy's country, with difficult communications and with the danger of being surrounded by superior forces. Consequently, after a few days, Hannibal was forced to retire towards Bruttium, without realizing his hope of drawing away to the relief of Rome the powerful armies which were surrounding Capua, and thus securing an opportunity for a pitched battle and giving the besieged the respite of which they stood in need. A slight success over the consul Sulpicious Galba, who was following him up, did not recompense Hannibal for the complete strategic failure of his march, marvellous — almost miraculous — as it was in itself. Merely by remaining firmly at their posts the besiegers of Capua had decided the fate of the city, which not long afterwards opened its gates and received terrible punishment for its treachery. The fall of Syracuse a little earlier had marked the final destruction of the Greek power in Sicily. In 209, Hannibal received another heavy blow in the occupation of Tarentum by Fabius through treachery. In Spain also, after many years of indecisive warfare and following the momentary success represented by the rout of the two Scipios (of which. however, the Carthaginians had not been capable of taking full advantage), their empire was breaking up under the blows of Scipio. At this juncture it occurred to Hasdrubal to go to help his brother in Italy with the troops which he could not usefully employ in the defence of Spain. In the fine season of 208, while Hasdrubal, retracing his brother's route, was descending the Alps and continuing in the direction of central Italy as far as the Metaurus, it would seem that Hannibal, with the object of effecting a junction with him, advanced as far as Larinum, in the country of the Frentani. Such, however, was the numerical superiority of the Romans that, while he himself was obliged to proceed northward with extreme slowness and caution, he was unable to prevent the concentration of considerable forces against his brother. The defeat of Hasdrubal at the Metaurus deprived Hannibal of his last hope of making a recovery in Italy, and the fatal news was conveyed to him by the severed head of his brother being cast by the Romans into his camp. Thereupon, abandoning all idea of an offensive, he retired into Bruttium, where he also concentrated the forces of those allies who had remained loyal to him. Here for four more years he withstood the Romans, fiercely contesting every step of their advance, and making them pay heavily for such successes as they gained by their strategy of attrition. Had they persevered in this strategy to the end, it is doubtful indeed whether they would have gained the final decisive victory, and even had they done so they would probably have paid for it by such immense sacrifices that they themselves would have fallen exhausted upon the corpses of their conquered adversaries. Now, however, Publius Cornelius Scipio, the young general who had displayed genius of such a high order in destroying, with very limited resources, the Carthaginian empire in Spain, was anxious to substitute a strategy consisting in boldly taking the offensive in Africa; and, despite the reluctance of the senate, in which a strong party headed by the aged Fabius was opposed to such an audacious policy, regarding it as dangerous and foolish, he succeeded in obtaining permission to carry out his design.

Scipio's marvellous victories, which broke Carthage's principal ally, Syphax, king of the Massaesylian Numidians, and threatened Carthage herself, ultimately compelled Hannibal to abandon Italy in the autumn of 203 in order to go to the help of his country. When he landed with his army at Leptis Minor and encamped near Hadrumetum, the Carthaginians, reduced to the last extremity, had already concluded an armistice and accepted preliminaries of peace with Scipio on extremely severe terms. Meanwhile the forces with which, a little earlier, Hannibal's other brother Mago had tried somewhat unsuccessfully to take the war into Liguria, also collected at Hadrumetum. Mago, recalled, had also embarked for Africa, but had died of wounds during the voyage. The large forces collected at Hadrumetum and the presence of their greatest general now induced the Carthaginians to try once more the test of arms. Almost at the very moment when the ambassadors were returning from Rome with the peace preliminaries approved, the Carthaginians — perhaps with Hannibal's connivance — violated the armistice concluded with Scipio, and the war broke out again. Scipio promptly recalled his faithful ally, Masinissa, king of the Massilian Numidians, whom he had sent into Numidia to fight against Vermina, son of Syphax, king of the Massaesylians, and allied like his father to the Carthaginians. Then, in the fine season of 202, he decided to climb the Bagrada in order to make a junction with the Numidians. Hannibal, who had likewise sent for Vermina, moved from Hadrumetum into the interior to join him, and encamped not far from Scipio, near Zama Regia. Scipio, instead of retiring towards his base, boldly moved forward towards Naraggara, between the Bagrada and the Muchtul, where he effected a satisfactory junction with the Numidian cavalry that Masinissa was bringing him. Hannibal, who had been following him, always in the vain hope of being joined by Vermina, now found himself in a serious position, being something like 125 miles from his base and in the presence of an enemy immensely his superior in cavalry. A meeting between the two commanders, at which Hannibal asked for peace, proved fruitless — because Scipio, realizing the strategic advantage he had

gained, insisted on terms more severe than those which had been agreed to before the breach of the armistice; so that there was nothing for it but battle. Scipio disposed the maniples of his legions in column, in three lines capable of operating independently, and defended his wings with the Italian and Numidian cavalry. Hannibal posted in his first line the Ligurian and Celtic mercenaries who had been under Mago's command, in his second line the native Libyans and the Carthaginian citizens, and in his third, further back as a true reserve, the flower of his army—the veterans of the Italian war. The front was protected by the elephants, the flanks by the cavalry. The elephants' assault was ineffectual owing to the able resistance of the Roman light troops, who succeeded in directing them through the columns of maniples, after passing which they were disposed of by other light troops without having done any serious damage. In the centre, the Carthaginian front line failed to resist the charge of the Roman *hastati,* and defeat seemed inevitable when Scipio, employing a manoeuvre which he himself had first used in the war in Spain, brought up the second- and third-line maniples, the *principes* and the *triarii,* on the flanks of the *hastati.* Hannibal had foreseen this manoeuvre, and countered it by bringing up the African infantry on either side of the mercenaries. But his tactical foresight was not crowned with success. The mercenaries, who were already giving ground, were routed, and the Africans with them. The reserve of Italian veterans remained intact, and Hannibal had disposed them on purpose to attack the legions if the latter should be victorious and should enter upon an undisciplined pursuit. As soon, however, as he perceived that Hannibal's third line was intact, Scipio recalled his men and re-formed them behind the natural breastwork afforded by the bodies of the casualties in the first two Carthaginian lines; having done so, he led them to the attack. Coming up from the rear at the same moment were the Italian and Numidian cavalry under Laelius and Masinissa, who had driven back the weaker Carthaginian cavalry with ease and, abandoning the pursuit in time, were returning to attack the infantry. Hannibal's veterans were thus surrounded and cut up, only very few escaping, among whom, however, was Hannibal himself (Oct. 202).

After this battle, in which, though not victorious, he had given a most wonderful exhibition of his tactical genius, Hannibal advised his fellow-citizens to make peace—indeed, almost forced them to do so—notwithstanding the very severe terms now dictated by the victor. After the conclusion of peace Carthage, despite her defeat, displayed the greatest confidence in Hannibal, and placed him at the head of the Government, thus enabling him to reorganize public affairs. Hannibal, great in administration as in war, speedily restored the State finances—to such an extent that in a short time the Carthaginians were able to make Rome an offer of payment in full of the heavy war indemnity that had been exacted. Rome, however, could not allow Carthage to recover; and so, a few years later, Roman envoys came to the city to accuse Hannibal of conspiring against the peace. He was forced to escape secretly, and took refuge (196) with Antiochus IV. the Great, king of Syria; who, having reunited the old Seleucid empire, was in diplomatic conflict with Rome, since the latter, after her victory in the Second Macedonian War, had established herself in the hegemony of the Balkan peninsula. The diplomatic conflict between Syria and Rome dragged on for some years until in the autumn of 192, in response to an appeal from the Aetolians, who had taken up arms against Rome, Antiochus landed in Greece and began the so-called Syrian War.

To this war he had been incited by the great Carthaginian refugee, who hoped that it might lead to the liberation of his country. Hannibal is said to have asked to be sent to the west with a hundred warships to prepare for a descent on Italy. This was a chimerical project, in view of the failure of the great expedition which he had so carefully prepared and ably conducted in the peninsula. It is much more likely that Hannibal simply asked Antiochus for a small land and sea force, with a view to preparing for a descent on Africa and inducing the Carthaginians to resume the war of independence against Rome and her ally Masinissa in Africa, thus causing a diversion which might also turn greatly to the advantage of the king of Syria. But even if such were the original plans of Hannibal and Antiochus, there was no possibility of carrying them out. When the Aetolians took up arms, intervention by Antiochus in Greece became urgent and could no longer be delayed; and he was obliged to employ all his available land and sea forces in strengthening and maintaining his expeditionary forces in the peninsula. Moreover, it is obvious that, since he could not even find adequate forces in 191 to resist the attack of the Romans and Philip in Greece, he could certainly have none available for a diversion in Africa. When, defeated at Thermopylae (191), he took refuge in Asia Minor, his only thought was—inevitably—to prepare to defend by land and sea his ancestral kingdom, which the Romans were getting ready to attack.

Already in the year 191 the naval battle of the Corycus gave the Romans the command of the Aegaean. It was essential for Antiochus to regain it in the following year. With this object, while his admiral Polyxenides was operating in the Aegaean, Hannibal was sent to Phoenicia to collect a fleet with which to help the principal Syrian squadron. In 190 Hannibal moved north from Phoenicia with 37 warships. Near the promontory of Side he encountered the fleet of the Rhodians, allies of Rome, who disputed his passage. After a fierce fight Hannibal was defeated and forced to retire; nor did he succeed either then or later, in joining with Polyxenides to take part in the decisive struggle. By land as by sea the fortune of war was against the Syrians, and after the defeat of Polyxenides at Myonessus and that of Antiochus at Magnesia (the latter battle took place late in 190 or early in 189) the king was obliged to accept the peace terms imposed by the Romans, which included the surrender of Hannibal.

Hannibal. however, effected his escape, and after many vicissitudes—tradition gives us anecdotes of varying degrees of authenticity—we find him at the court of Prusias, king of Bithynia, one of the few despots who had not yet become dependent on Rome. It was Hannibal who suggested to his protector the magnificent site which was chosen for the foundation of the city of Prusa, the modern Brussa. Later he took part in the war between Prusias and Eumenes II., king of Pergamus, in which he gained his last success, the naval victory of the Bithynian fleet over that of Pergamus, commanded by Eumenes himself, who narrowly escaped capture. The war ended when Rome imposed her mediation on the contending parties. These events, however, drew the attention of the Romans upon Hannibal, and, through Titus Quintius Flamininus, they demanded that Prusias, who also had now been forced by circumstances to become dependent upon them, should surrender him. Prusias was cowardly enough to arrange for the great refugee's arrest; Hannibal, however, seeing his house surrounded by soldiers, committed suicide by taking poison, which he always carried on his person in readiness for emergencies (183).

The great Carthaginian had thus witnessed the complete failure of what had been the whole purpose of his life—the war of revenge by Carthage against Rome. That war had not merely ended in the defeat and destruction of the Carthaginian power, but had made Rome so conscious of her strength, and given rise to such a development of the spirit of militarism and imperialism among the Romans, that they had by now firmly established their predominance over the Eastern Greek world as well. This complete failure can in no way be laid to the charge of Hannibal, who, with unshaken patriotism, until his death employed all the resources of his genius in the unequal struggle; nor would it be fair to impute it to Carthage, whose tenacious resistance was marvellous, having regard to the forces at her command, and was at any rate immensely superior to that of the Hellenic powers, though in many respects the latter were in a much more favourable position. The failure was due to the strength of the Roman people and the Italians so firmly bound to them, to the admirable political-military organization of the Italic confederation, to the almost superhuman spirit of sacrifice exhibited by the Italians during the war, to the strategy of their leaders—the policy of attrition adopted at the beginning by Fabius when it represented

the only possibility of resistance, and the bold offensive policy later adopted by Scipio, who proved himself such a talented pupil of his great adversary as to profit by his own teaching to frustrate his most wonderful tactical inspirations.

Of the great Carthaginian's personality we know but little, and the tradition that has come down to us is often vitiated by the partisan hatred of his adversaries; but all the ancient writers without exception pay homage to his incomparable military genius, and all but a few moderns regard him as one of the greatest warriors of all time. Roman tradition charged him with acts of cruelty, and his memory lived as that of a man "abominated by the fathers" of Italy for the slaughter of their sons. But those of his cruel acts of which there is reliable evidence do not exceed what the customary laws of war in ancient times were cruel enough to permit, and the terrible tragedy of Carthage's struggle for existence affords them an extenuation which is not forthcoming for some of the atrocities committed by the Roman commanders in the second century. Moreover, on more than one occasion he displayed generosity towards a fallen enemy. The "Punic faith" of which the Roman sources accuse him seems to have no more foundation than resides in the military stratagems of which he made free use, and these were certainly far more innocent than the somewhat dishonourable stratagem employed by Scipio Africanus to surprise the camps of Hasdrubal and Syphax. For the rest, Hannibal was a cultured man, acquainted with several languages; he spoke and wrote Greek, and probably had not omitted to study the military science of the Greeks. Many of his sayings are given us by the various sources, and, though not all authentic, taken as a whole they illustrate his rough, frank, soldierly spirit. Little or nothing is known of his private life. We are told that he married a Spanish woman from Castulo, by whom he does not seem to have had any children. The ancient writers, who manage to find more or less well-authenticated scandalous anecdotes about almost all the greatest men of antiquity, laud his morality to the skies, and, much as they hate him, they can find no least speck on his fair fame in this regard. There is only one reference to be found in certain sources to a love affair with a Bruttinn girl, but its authenticity is by no means sure, and it is in any case too vague to arouse curiosity. For the rest, certain charges of avarice found in the ancient sources can easily be explained hy his constant need of large resources for his political and military activities. Even in this matter, however. his prudent administration of the finances of Carthage bears witness to his integrity. Taken for all in all, he proved one of the noblest, as he was one of the most unfortunate, of the great men of action of antiquity.

BIBLIOGRAPHY.—The history of Hannibal was written very shortly afterward by Greeks who were in his camp, such as Sosilus and Silenus. Sosilus, as also another Greek historian of Hannibal, Chaereas, is reprimanded by Polybius (iii., 25) for his "barber's-shop anecdotes"; but a fragment discovered later dealing with the war in Spain (Wilcken, *Hermes,* xli., pp. 103 *sqq.)* does not seem to confirm the condemnation. In addition to these Greek sources, all or nearly all of which are pro-Carthaginian, the ancients had Roman primary sources, chief of which were the *Annales* of Fabius Pictor. Later a full general history of the Second Punic War was composed in Latin by L. Caelius Antipater; it is lost, but, to judge from the fragments, it was of little value. There has come down to us the Greek history of the Second Punic War composed about the middle of the second century B.C. by the Greek historian Polybius of Megalopolis; it is complete as far as the battle of Cannae (lib. iii.), fragmentary thereafter. Polybius combined Carthaginian and Roman sources—in what proportions it is difficult to say, but it is certainly a mistake to suppose that our tradition regarding the Second Punic War is wholly of Roman origin (Dessau, *Hermes,* li., pp. *355 sqq.),* or to try to make a mechanical separation of the Roman and Carthaginian passages in the text of Polybius (Beloch, *Hermes,* 1.). The full story of the Second Punic War has come down to us in the third decade of Livy; and here again, while we have passages of undoubted annalistic origin and others, particularly dealing with the wars in Sicily and the East, that are mere versions of Polybius, regarding the remainder there are strong differences of opinion among the critics. Of the copious bibliography mention need only be made of Wesselbarth's *Historisch-kritische Untersuchungen zur dritten Dekade des Livius,* and for the rest the student may be referred to the historical works cited below. Of the minor sources, apart from those derived from Livy (Florus, Orosius, etc.), we need only mention here Plutarch's lives of Fabius and Marcellus, Appian's *Hannibalica.* and the fragments of Diodorus and Dion Cassius, all of which narrations appear to be based on the vulgate of Polybius, with additions and errors in varying degrees.

The modern Hannibalic bibliography is enormous. On a single episode in his career—the crossing of the Alps--a whole shelf of monographs could be collected. Neglecting entirely the earlier writings and those that deal with too specialized subjects, we may mention in the first place Mommsen's passage on Hannibal and his wars *(Röm. Geschichte,* vol. i., book iii.), and Neumann's *Das Zeitalter der punischen Kriege* (1883). Acute and original, though frequently hypercritical, is U. Kahrstedt, *Geschichte der Karthager von 218–146* (1919; published as vol. iii. of O. Meltzer's *Geschichte der Karthager,* but entirely different in character from the first two volumes). On the military aspect two works are of fundamental importance: Delbriick's *Geschichte der Kriegskunst,* 2nd ed. (1908), book v., and Kromayer's *Antike Schlachtfelder,* iii (1912); in addition, K. Lehmann, *Die Angriffe der drei Barkiden auf Italien* (1905), may be read with profit. An attempt at a comprehensive political and military appreciation of the history of the Second Punic War is made in De Sanctis, *Storia dei Romani* (1917). Lastly, special mention must be made of the *Untersuchungen zur Geschichte des zweiten punischen Krieges* collected by *E.* Meyer in his *Kleine Schriften,* ii. (1924), and his drawings of medallions of Hannibal and Scipio in *Meister der Politik, I.,* 2nd ed. (1923).

(G. DE S.)

HANNIBAL, a city on the Mississippi river, in Marion county, Mo., U.S., 100 mi. N.W. of St. Louis. As the boyhood home of Mark Twain (*q.v.*), the town provided the setting for several of his finest books, including *The Adventures of Tom Sawyer* and *The Adventures of Huckleberry Finn.*

The site, part of old Spanish land grants, was given to Abraham Bird in 1818 as compensation for earthquake damage to his property in New Madrid, Mo. Hannibal's first settler, Moses Bates, arrived in 1819, and in 1845, with a population of about 1,000. it was incorporated as a city. A river landing in the Louisiana Purchase territory. the settlement took its name from the small stream (later Bear creek) flowing through the site, which was named in the classic tradition and mapped by a pioneer Spanish surveyor. The Mark Twain Memorial bridge (1935) spans the Mississippi river, linking Missouri and Illinois. The city lies between two peaks, Lovers' Leap (225 ft.) and Cardiff hill, on which rises the Mark Twain Memorial lighthouse. Beyond is Riverview park (250 ac.) with commanding views of the mile-wide Mississippi. Once an important steamboat port, Hannibal's industries include railroad repair yards; shoe, machinery and drill tools factories; cement and printing plants; food, dairy and building products. The surrounding farm land is devoted to dairying, corn and grain. The Hannibal-La Grange college (Baptist) was moved from La Grange, Mo., to Hannibal in 1929.

Memorials to Mark Twain include: his boyhood home at 208 Hill street. built by his father in 1844; the city-built Mark Twain museum (1937); Judge J. M. Clemens's law office; the Becky Thatcher house; and the house of the Pilasters. The famous Tom Sawyer cave is 2 mi. S. Discovered in 1819 by Jack Simms, a hunter, it is reputed to have been a hiding place of Jesse James, and in slavery days a station on the Underground Railroad (*q.v.*). Jackson's Island. an adventure ground of Tom Sawyer and Huck Finn, lies across the river near the Illinois shore. Mark Twain's two-room cabin birthplace is preserved in the Mark Twain State park at Florida. 25 mi. S.W. of Hannibal. For comparative population figures *see* table in MISSOURI: *Population.* (J. A)

HANNINGTON, JAMES (1847–1885), English missionary, was born at Hurstpierpoint, Sussex, on Sept. 3, 1847, and was educated at St. Mary's Hall, Oxford. He was curate in charge at Hurstpierpoint when his thoughts were turned to mission work by the murder of two missionaries on the shores of Victoria Nyanza. He sailed on May 17, 1882, at the head of a party of six, for Zanzibar, and thence set out for Uganda; but, prostrated by fever and dysentery, he was obliged to return to England in 1883. On his recovery he was consecrated bishop of Eastern Equatorial Africa (June 1884), and in January 1885 started again for the scene of his mission, and visited Palestine on the way. He reached a spot near Victoria Nyanza in safety. His arrival, however, roused the suspicion of the natives, and under King Mwanga's orders he was lodged in a filthy hut swarming with rats and vermin. After eight days his men were murdered, and on Oct. 29, 188j he himself was speared in both sides, his last words to the soldiers appointed to kill him being, "Go, tell Mwanga I

have purchased the road to Uganda with my blood."

His ***Last Journals*** were edited in 1888. ***See*** also ***Life*** by E. C. Dawson (1887); and W. G. Berry, ***Bishop Hannington*** (1908).

HANNINGTON, a shallow lake (7 mi. by 2 mi.) in Kenya colony, south of Lake Baringo, just north of the equator. It lies in the eastern rift-valley, in the shadow of the Laikipia escarpment. It was named after Bishop Hannington; its waters are brackish, its shores having on them remnants of an ancient forest which serve as an eyrie for storks, herons and eagles, while on the flat banks congregate thousands of flamingoes. There are valuable guano deposits.

HANNO, the name of many Carthaginian soldiers and statesmen, the most important of whom are:

1. HANNO, Carthaginian navigator, who flourished c. 500 B.C. He wrote an account of a coasting voyage on the west coast of Africa, undertaken for the purpose of exploration and colonization. The original, inscribed on a tablet in the Phoenician language, was hung up in the temple of Melkarth on his return to Carthage. A supposed Greek translation of this is still extant, under the title of *Periplus*, but its authenticity has been questioned. Hanno appears to have advanced beyond Sierra Leone as far as Cape Palmas.

Valuable editions by T. Falconer (1797, with translation and notes) and C. W. Miiller in ***Geographici Graeci minores,*** i.; ***see*** also ***E. H.*** Bunbury, ***History of Ancient Geography,*** i. and treatise by C. T. Fischer (1893), with bibliography.

2. HANNO (3rd century B C.), called "the Great," Carthaginian statesman and general, leader of the aristocratic party and the chief opponent of Hamilcar and Hannibal. He appears to have gained his title from military successes in Africa, but of these nothing is known. In 240 B.C. he drove Hamilcar's veteran mercenaries to rebellion by withholding their pay, and when invested with the command against them was so unsuccessful that Carthage might have been lost but for the exertions of Hamilcar (*q.v.*). Hanno subsequently remained at Carthage, exerting his influence against the democratic party. During the Second Punic War he advocated peace with Rome, and according tc Livy even advised that Hannibal should be given up to the Romans. After the battle of Zama (202) he was one of the ambassadors sent to Scipio to sue for peace. See also CARTHAGE; HANNIBAL; PUNIC WARS.

HANOI, the capital of the Democratic Republic of Vietnam (see VIETNAM: Partition), lies on the right bank of the Red (Koi) river, 80 mi. from the Gulf of Tonkin. Pop. (1953) 297,900. The town possesses several ancient monuments among which are the pagoda of the Great Buddha, so named because of the great bronze statue, 12 ft. high, that it contains, and the One Column pagoda, which dates from the 11th century. The Temple of Literature, also built in the 11th century, was dedicated to Confucius and 72 sages, and was once the seat of a university. The beautiful Sword lake lies in the centre of the town and the botanical gardens are near the palace of the president of the republic. There are two theatres, the Grand theatre built in 1901, and the open-air People's theatre, built in the 1950s, which has a seating capacity of 15,000. Hanoi has a university, several technical schools, a museum and a large public library. The Red river at Hanoi is spanned by the Long Bien bridge, which is more than a mile in length. Modern highuays extend from Hanoi to Haiphong, to Saigon and to three different points on the Chinese border. The town is also the junction for railway lines to Haiphong, Vinh, Dong Dang and Lao Kay. The Lao Kay and Dong Dang lines are connected with the Chinese lines to Kunming and Peking respectively. The Gia-Lam aerodrome (about 2½ mi. from the town) is one of the biggest in Vietnam. Hanoi has a large power station and a number of factories. Flourishing handicrafts include the making of carved and inlaid objects, bronze and other metalwork, and embroidery. (VN. T.)

HANOTAUX, ALBERT AUGUSTE GABRIEL (1853–1944), French statesman and historian, was born at Beaurevoir, Aisne, on Nov. 19, 1853. He studied at the École des Chartes, and became *maître* de *conférences* in the École des Hautes Études. In 1879 he entered the ministry of foreign affairs as archivist, and rose step by step through the diplomatic service, being appointed councillor of embassy at Constantinople in 1885. In 1886 he was elected Republican deputy for Aisne, but, defeated in 1889, he returned to his diplomatic career. On May 31, 1894 he became foreign minister in the Dupuy cabinet. With one interruption (during the Ribot ministry, Jan. 26–Nov. 2, 1895), he held this portfolio until June 14, 1898. During his ministry he developed the rapprochement of France with Russia, visiting St. Petersburg with the President, Félix Faure, and sent expeditions to delimit the French colonies in Africa. The Fashoda incident of July 1898 was a result of this policy, and Hanotaux's distrust of England is frankly stated in his literary works.

During the World War Hanotaux, who was already known as a distinguished historian, and had been elected to the French Academy on April 1, 1897, was active as propagandist. He was employed on more than one semi-official mission, notably to the Vatican. In 1921 he was the third French delegate to the League of Nations Assembly. He died April 11, 1944.

Hanotaux's works include: ***Origines de Pinstitution des intendants de provinces*** (1884), the authoritative study on the intendants; ***Etudes historiques sur les XVIe et XVIIe siècles en France*** (1886); ***Histoire de Rickelieu*** (2 vols. 1888); ***Histoire de la France contemporaine, 1871–1900*** (4 vols. 1903–8), the standard history of contemporary France; ***Histoire de la Guerre de 1914*** (9 vols. 1914 ff.); ***Le Traité de Versailles*** (1919); ***Histoire de la Nation française*** (15 vols. 1920–4); ***La Bataille de la Marne*** (2 vols. 1923). He also edited the ***Instructions des ambassadeurs de France à Rome, depuis les traités de Westphalie*** (1888).

HANOVER, an administrative district of Lower Saxony, formerly an independent kingdom, Germany, after 1866 a province of Prussia bounded on the north by the North sea, Schleswig-Holstein, Hamburg and Mecklenburg-Schwerin, east and south-east by Prussian Saxony, Brandenburg and Brunswick, southwest by Lippe and the Prussian provinces of Hesse-Nassau and Westphalia, and west by Holland. These boundaries included after 1919 the German *Lands* of Oldenburg and Bremen, the former stretching southward from the North sea nearly to the southern boundary of Hanover. A small part of the province in the south was separated from Hanover proper by the interposition of part of Brunswick. In 1873 the province was increased by the addition of the Jade territory (purchased by Prussia from Oldenburg), southwest of the Elbe, with the naval station and arsenal of Wilhelmshaven.

The area of the former province was 14,983 sq.mi., of the present department, 2,535 sq.mi.

The plain of Hanover is mainly sandhills, heath and moor. On the Elbe and near the North Sea, rich meadows are preserved from encroachment of the sea by dikes and ditches. The so-called *Lüneburger* Heide in the north is an expanse of moor and fen, with oases of beech and oak woods, extending almost due north from the city of Hanover to the southern arm of the Elbe at Harburg. The south part of the province is hilly, rising to the forested Harz mountains. The east part of the northern plain is covered with fir forests. The Elbe forms the north-east boundary and receives the navigable Jeetze, Ilmenau, Lühe, Seve, Este, Schwinge and Medem; the Weser drains the centre, with its tributary the Aller (navigable from Celle downwards); and the Ems, the west, with its tributaries Aa and Leda. Numerous canals connect these river systems. A few small lakes are found here and there in the province.

The climate in the coastal lowlands is moist and foggy, in the plains mild, on the Harz mountains severe and variable. In spring the prevailing winds are easterly, in summer they blow from the south-west. In the town of Hanover the average monthly temperature ranges from 32° F in January to 63° F in July, and the average annual rainfall is about 23.5 in. In the west the Herauch, a thick fog arising from the burning of the moors, is frequent.

The population of the former Prussian province was 5,114,910 in 1950, giving a density of 341 to the sq.mi. The province had been divided into the six *Regierungsbezirke* (or departments) of Hanover, Hildesheim, Luneburg, Stade, Osnabriick and Aurich, and these again into Kreise (circles, or local government districts) —82 in all. The chief towns are Hanover, Osnabruck, Hildesheim, Wesermünde, Wilhelmshaven, Harburg, Liineburg, Celle, Göttingen and Emden. Above 80% of the population are Protestant.

The province has the university of Göttingen, a technical college in Hanover, an academy of forestry in Münden, a mining college in Clausthal, and a veterinary college in Hanover.

The greater part of the soil is of inferior quality, and one-third of the province is uncultivated moor and heath; about half the remainder is arable and the rest pasture and forest. The best agriculture is to be found in the districts of Hildesheim, Calenberg, Gottingen and Grubenhagen, on the banks of the Weser and Elbe, and in East Friesland. Rye is widely grown for bread. Flax is extensively cultivated and exported, chiefly in the form of yarn. Potatoes, hemp, turnips, hops, tobacco and beets are also grown, the latter in connection with the sugar industry. Apples, pears, plums and cherries are the principal fruits cultivated, while the wild red cranberries from the Harz and the black bilberries from the Luneburger Heide form an important article of export.

Hanover is renowned for its cattle and live stock. The Lüneburger Heide yields excellent sheep, while horses are reared in Aurich and Stade, in Hildesheim, Hanover and in Celle. Bees are principally kept on the Luneburger Heide, and the yield of honey is considerable. Large flocks of geese are kept in the moist lowlands. The rivers yield trout, salmon (in the Weser) and crayfish. The sea fisheries are important and have their chief centre at Wesermiinde.

The Harz mountains are rich in silver, lead, iron and copper; coal is found around Osnabruck, on the Deister, at Osterwald, etc., lignite in various places; salt-springs exist at Egestorfshall and Neuhall near Hanover, and at Luneburg; and petroleum is obtained south of Celle. In the northern lowlands peat occurs. Low-grade iron ore is extensively mined at Salzgitter.

Works for the manufacture of iron, copper, silver, lead, vitriol and sulphur are carried on. The iron works are important: smelting is carried on in the Harz and near Osnabruck; there are extensive foundries and machine factories at Hanover, Linden, Osnabruck, Hameln, Wesermunde, Harburg, Osterode, etc., and manufactories of cutlery in the towns of the Harz and in the Sollinger Forest. Linen yarn and cloth are largely manufactured, and bleaching is engaged in extensively; woollen cloths are made in the south about Einbeck, Gottingen and Hameln; cotton-spinning and weaving have their seats at Hanover and Linden. Glass houses, paper-mills, potteries, tile works and tobacco-pipe works are numerous. There are numerous tobacco factories, tanneries, breweries, vinegar works and brandy distilleries. Shipbuilding is an important industry, especially at Wilhelmshaven, Papenburg, Leer, Stade and Harburg; and at Munden river-barges are built.

The carrying trade of Hanover is largely absorbed by Hamburg and Bremen, while the Weser forms the chief commercial artery of the province. The province has good roads connecting the chief towns and is intersected by trunk lines of railway; notably the lines from Berlin to Cologne, from Hamburg to Frankfort-on-Main, from Hamburg to Bremen and Cologne, and from Berlin to Amsterdam.

HISTORY

The name Hanover (*Hohenufer*=high bank), originally confined to the town which became the capital of the duchy of Liineburg-Calenberg, came gradually into use to designate, first, the duchy itself, and secondly, the electorate of Brunswick-Lüneburg; and it was officially recognized as the name of the state when in 1814 the electorate was raised to the rank of a kingdom.

The early history of Hanover is merged in that of the duchy of Brunswick (*q.v.*), from which the duchy of Brunswick-Luneburg and its offshoots, the duchies of Luneburg-Celle and Lüneburg-Calenberg, have sprung. In 1692, in return for lavish promises of assistance to the empire and the Habsburgs, the emperor granted Duke Ernest Augustus of Calenberg the rank and title of elector of Brunswick-Luneburg with the office of standard bearer in the Holy Roman empire. Indignant protests followed, but in 1708 George Louis, the son and successor of Ernest Augustus, was recognized as an elector by the imperial diet. Through his mother, the elector George Louis became, by the terms of the Act of Settlement of 1701, king of Great Britain and Ireland in 1714.

Under British Sovereignty. — From this time until the death of William IV. in 1837, Luneburg or Hanover, was ruled by the same sovereign as Great Britain. Both George I. and George II. preferred Hanover to England as a place of residence, and it was a frequent and perhaps justifiable cause of complaint that the interests of Great Britain were sacrificed to those of the smaller country. But George III. was more British than either his grandfather or his great-grandfather, and owing to a variety of causes the foreign policies of the two countries began to diverge in the later years of his reign. During the Napoleonic wars Hanover was occupied by Prussia in 1805, but after the battle of Jena (1807) became part of the kingdom of Westphalia. The northern portion was added to France in 1810. The elector was granted the title of king by the Vienna Congress, which restored the independence of Hanover. On the conclusion of peace in 1814 the estates of the several provinces of the kingdom were fused into one body, consisting of 85 members, but the chief power was exercised as before by the members of a few noble families. In 1819, however, this feudal relic was supplanted by a new constitution. Two chambers were established, the one formed of nobles and the other of elected representatives; but although they were authorized to control the finances, their power with regard to legislation was very circumscribed. This constitution was sanctioned by the prince regent, afterwards King George IV.; but it was out of harmony with the new and liberal ideas which prevailed in Europe, and it hardly survived George's decease in 1830. The revolution of that year compelled George's brother and successor, William, to dismiss Count Munster, who had been the actual ruler of the country, and to name his own brother, Adolphus Frederick, duke of Cambridge, a viceroy of Hanover, one of the viceroy's earliest duties being to appoint a commission to draw up a new constitution. This was done, and after William had insisted upon certain alterations, it was accepted and promulgated in 1833. Representation was granted to the peasants; the two chambers were empowered to initiate legislation; ministers were made responsible for all acts of government; a civil list was given to the king in return for the surrender of the Crown lands; and, in short, the new constitution was similar to that of Great Britain.

King Ernest Augustus. — By the law of Hanover a woman could not ascend the throne, and accordingly Ernest Augustus, duke of Cumberland, the fifth son of George III., and not Victoria, succeeded William as sovereign in 1837, thus separating the crowns of Great Britain and Hanover after a union of 123 years. Ernest, a prince with very autocratic ideas, had disapproved of the constitution of 1833, and his first important act as king was to declare it invalid. He appears to have been especially chagrined because the Crown lands were not his personal property, but the new arrangements were quite repugnant to him. Seven Göttingen professors who protested against this proceeding were deprived of their chairs; and some of them, including F. C. Dahlmann and Jakob Grimm, were banished from the country for publishing their protest. To save the constitution an appeal was made to the German Confederation, which Hanover had joined in 1815; but the federal diet declined to interfere, and in 1840 Ernest altered the constitution to suit his own illiberal views. Recovering the Crown lands, he abolished the principle of ministerial responsibility, the legislative power of the two chambers, and other reforms, virtually restoring affairs to their condition before 1833. The inevitable crisis was delayed until the stormy year 1848, when the king probably saved his crown by hastily giving back the constitution of 1833. Order, however, having been restored in 1850 he dismissed the Liberal ministry and attempted to evade his concessions; a bitter struggle had just broken out when Ernest Augustus died in Nov. 1851. During this reign the foreign policy of Hanover both within and without Germany had been coloured by jealousy of Prussia and by the king's autocratic ideas. Refusing to join the Prussian Zollverein, Hanover had become a member of the rival commercial union, the Steuerverein, three years before Ernest's accession; but as this union was not a great success the Zollverein was joined in 1851. In 1849, after the

failure of the German parliament at Frankfort, the king had joined with the sovereigns of Prussia and Saxony to form the "three kings' alliance"; but this union with Prussia was unreal, and with the king of Saxony he soon transferred his support to Austria and became a member of the "four kings' alliance."

Annexation to **Prussia.**—George V., the new king of Hanover, who was unfortunately blind, sharing his father's political ideas, at once appointed a ministry whose aim was to sweep away the constitution of 1848. This project, however, was resisted by the second chamber of the *Landtag*, or parliament; and after several changes of government a new ministry advised the king in 1855 to appeal to the diet of the German Confederation. This was done, and the diet declared the constitution of 1848 to be invalid. Acting on this verdict, not only was a ministry formed to restore the constitution of 1840, but after some trouble a body of members fully in sympathy with this object was returned to parliament in 1857. But these members were so far from representing the opinions of the people that popular resentment compelled George to dismiss his advisers in 1862, and the more liberal government which succeeded did not enjoy his complete confidence. In 1865 a ministry was once more formed which was more in accord with his own ideas. This contest soon lost both interest and importance owing to the condition of affairs in Germany. Bismarck, the director of the policy of Prussia, was devising methods for the realization of his schemes, and it became clear after the war over the duchies of Schleswig and Holstein that the smaller German states would soon be obliged to decide definitely between Austria and Prussia. After a period of vacillation Hanover threw in its lot with Austria, the decisive step being taken when the question of the mobilization of the federal army was voted upon in the diet on June 14, 1866. At once Prussia requested Hanover to remain unarmed and neutral during the war, and with equal promptness King George refused to assent to these demands. Prussian troops then crossed his frontier and took possession of his capital. The Hanoverians, however, were victorious at the battle of Langensalza on June 27, 1866, but the advance of fresh bodies of the enemy compelled them to capitulate two days later. By the terms of this surrender the king was not to reside in Hanover, his officers were to take no further part in the war, and his ammunition and stores became the property of Prussia. The decree of Sept. 20, 1866, formally annexed Hanover to Prussia.

HANOVER, capital of the *Land* of Lower Saxony, in a sandy, fertile plain on the Leine, which there receives the Ihme. Pop. (1950) 444,296. Hanover is first mentioned in the 12th century, when it belonged to the Welf family, later dukes of Brunswick. It joined the Hanseatic League, and was later the residence of the electors of Hanover. In 1866 it was annexed by Prussia, after having been the capital of the kingdom of Hanover since its foundation in 1815. The Leine flows through the city. having the old town, with narrow streets and old-fashioned gabled houses, on its right. In its centre lies the Markt Kirche, a red-brick edifice of the 14th century, with its interior restored in 1855, and containing fine stained-glass windows. On the market square is the red-brick medieval town hall (Rathaus), containing the civic archives and museum. The new town surrounds the old on the north and east. Among the other churches are the Neustadterkirche, with a shrine containing the tomb of Leibnitz; the Kreuzkirche, built about 1300, with a curious steeple; and the Aegidienkirche. Of secular buildings the most remarkable is the royal palace—Schloss—built 1636–40. In its chapel are preserved the relics of saints which Henry the Lion brought from Palestine. Its museums have important art collections. The Welfenschloss has been occupied since 1875 by the technical high school, an academy with university privileges. Close to it lies Herrenhausen, the summer palace of the former kings of Hanover, with fine gardens, an open-air theatre, a museum and an orangery.

Almost all industries are represented; chief among them are machine-building, the manufacture of indiarubber, cotton, cork, hardware, chemicals, cocoa, asphalt, tobacco. pianos, furniture and groceries. The commerce consists principally in wine, hides, horses, coal, wood and cereals. There are extensive printing establishments. It is the birthplace of Sir William Herschel, the astronomer, and the philosopher Leibnitz died there in 1716.

HANOVER, a village in Grafton county, west New Hampshire, U.S., is located on the east bank of the Connecticut river 5 mi. N. of White River Junction, Vt. The village precinct of Hanover was organized in 1885 by state legislative action as a subdivision of the "town" of Hanover (chartered 1761). Since the village's first settlement in 1770 it has existed primarily as the seat of Dartmouth college. The college was an outgrowth of Moor's Indian Charity school organized in the 1750s by the Rev. Eleazar Wheelock in Lebanon (now Columbia), Conn. It was chartered as a college in 1769 under authority of George III, taking the name of the 2nd earl of Dartmouth, president of the trustees of English funds, and located on Hanover plain in 1770.

The college is a men's liberal arts institution with an undergraduate enrollment of approximately 3,000. It has three associated professional graduate schools: the Dartmouth medical school (1797); the Thayer school of engineering (1871); and the Amos Tuck school of business administration (1900). Baker library contains more than 800,000 volumes, and while it functions mainly for undergraduates, visiting scholars make it their headquarters for research every summer. A notable holding is the extensive Vilhjalmur Stefansson collection of Arctic material. the chief American collection in this field. On the walls of the reading rooms are 3,000 sq.ft. of frescoes, "An Epic of American Civilization," a series of panels by the Mexican artist José Clemente Orozco. Located in the foothills of the White mountains, Dartmouth is nationally known for its pioneering in skiing and other winter sports and has attained fame as an "outdoor college."

Connected with the Mary Hitchcock Memorial hospital, the largest medical installation in northern New England, are the Hitchcock clinic with about 150 resident medical and surgical specialists, the Hitchcock foundation, a research organization, and the Dartmouth medical school. The village is primarily residential. For comparative population figures *see* table in NEW HAMPSHIRE: *Population.*

See Leon *B.* Richardson, *History of Dartmouth College (1932).*

(W. H. McCR.)

HANRIOT, FRANÇOIS (1761–1794). French revolutionist, was born at Nanterre (Seine) of poor parentage. He became one of the orators of the sans-culottes, and commanded the armed force of that section during the insurrection on Aug. 10, 1792, and the massacres of September. He was appointed by the Commune to the command of the armed forces of Paris on May 30–31, from June 2 to June 11, and again after the failure of his impeachment in the Convention, from July 1 until the revolution of the 9th Thermidor (July 27, 1794). He was then arrested, after a vain attempt to rescue Robespierre, and was guillotined with Robespierre and his friends on the 10th Thermidor of the year II (July 28, 1794).

HANSARD, LUKE (1752–1828), English printer, was born in St. Mary's parish, Norwich, educated at Boston grammar school, and apprenticed to Stephen White. a Norwich printer. As soon as his apprenticeship had expired Hansard started for London with only a guinea in his pocket and became a compositor in the office of John Hughs (1703–71), printer to the House of Commons. In 1774 he was made a partner, and in 1800 the business went completely into his hands. He printed the *Journals of the House of Commons* from 1774 until his death. The promptitude and accuracy with which he printed parliamentary papers were often of the greatest service to the government—notably on one occasion when the proof sheets of the report of the secret committee on the French Revolution were submitted to Pitt 24 hours after the draft had left his hands. He devised numerous expedients for reducing the expense of publishing the reports; and in 1805, when his workmen struck at a time of great pressure, he and his sons themselves set to work as compositors. Luke Hansard died on Oct. 29, 1828.

His son, THOMAS CURSON HANSARD (1776–1833), established a press of his own in Paternoster row, and began in 1803 to print the *Parliamentary Debates,* which were not at first independent reports, but were taken from the newspapers. After 1889

the debates were published by the Hansard Publishing Union, Ltd. The original business remained in the hands of his younger brothers, James and Luke Graves Hansard (1777–1851). The firm was prosecuted in 1837 by John Joseph Stockwell for printing by order of the House of Commons, in an official report of the inspector of prisons, statements regarded by the plaintiff as libellous. Hansard sheltered himself on the ground of privilege, but it was not until after much litigation that the security of the printers of government reports was guaranteed by statute in 1840.

HANSARD is the name given to the official report of the debates of both houses of the British parliament. It is so called after T. C. Hansard (1776–1833), the first printer. and later publisher, of the unofficial series of parliamentary debates inaugurated by William Cobbett in 1803. The series known as the fifth, dating from 1909, when the report first became both official and verbatim, comprised more than 200 vol. for the lords and over 600 for the commons by the end of the 1950s. The daily parts, of which these volumes are composed, are produced in the lords by an editor, assistant editor and six reporters and in the commons by an editor. assistant editor, 2 subeditors and 18 reporters. The complete report of the lords debate is generally in print by first post the following morning. The commons report, as published by that time, always covers the debate up to approximately 10:30 P.M. the previous evening but, should the house have sat later. the report of the subsequent proceedings precedes the report of the following day. The reports of both houses are printed, and sold to the public, by the stationery office, which also issues a Weekly Hansard consisting of several daily parts. Printing is expressly sanctioned by both houses, for either, if it so desired, could uithhold its proceedings from the public. (E. *C.* TN.)

HANSEATIC LEAGUE. It is impossible to assign any precise date for the beginning of the Hanseatic League or to name any single factor which explains the origin of that loose but effective federation of north German towns. Associated action and partial union among these towns can be traced back to the 13th century. In 1241 we find Lubeck and Hamburg agreeing to safeguard the important road connecting the Baltic and the North sea. The first known meeting of the "maritime towns," later known as the Wendish group and including Lubeck, Hamburg, Luneburg, Wismar, Rostock and Stralsund, took place in 1256. The Saxon towns, during the following century, were joining to protect their common interests, and indeed at this period town confederacies in Germany, both north and south, were so considerable as to call for declaration against them in the Golden Bull of 1356. The decline of the imperial power and the growing opposition between the towns and the territorial princes justified these defensive town alliances, which in south Germany took on a peculiarly political character. The relative weakness of territorial power in the north, after the fall of Henry the Lion of Saxony, diminished without however removing this motive for union, but the comparative immunity from princely aggression on land left the towns more free to combine in a stronger and more permanent union for the defence of their commerce by sea and for the control of the Baltic.

While the political element in the development of the Hanseatic League must not be underestimated, it was not so formative as the economic. The foundation was laid for the growth of German towns along the southern shore of the Baltic by the great movement of German colonization of Slavic territory east of the Elbe. This movement, extending in time from about the middle of the 11th to the middle of the 13th century and carrying a stream of settlers and traders from the north-west, resulted not only in the Germanization of a wide territory but in the extension of German influence along the sea-coast far to the east of actual territorial settlement. The German trading towns, at the mouths of the numerous streams which drain the north European plain, were stimulated or created by the unifying impulse of a common and long-continued advance of conquest and colonization.

The impetus of this remarkable movement of expansion not only carried German trade to the east and north within the Baltic basin, but reanimated the older trade from the lower Rhine region to Flanders and England in the west. Cologne and the Westphalian towns, the most important of which were Dortmund, Soest and Munster, had long controlled this commerce but now began to feel the competition of the active traders of the Baltic, opening up that direct communication by sea from the Baltic to western Europe which became the essential feature in the history of the League. The necessity of seeking protection from the sea-rovers and pirates who infested these waters during the whole period of Hanseatic supremacy, the legal customs, substantially alike in the towns of north Germany, which governed the groups of traders in the outlying trading posts, the establishment of common factories, or "counters" (Komtors) at these points, with aldermen to administer justice and to secure trading privileges for the community of German merchants — such were some of the unifying influences which preceded the gradual formation of the League. In the century of energetic commercial development before 1350 the German merchants abroad led the way.

The **Gothland** Association. — Germans were early pushing as permanent settlers into the Scandinavian towns, and in Wisby, on the island of Gothland, the Scandinavian centre of Baltic trade, equal rights as citizens in the town government were possessed by the German settlers as early as the beginning of the 13th century. There also came into existence at Wisby the first association of German traders abroad, which united the merchants of over 30 towns, from Cologne and Utrecht in the west to Reval in the east. We find the Gothland association making in 1229 a treaty with a Russian prince and securing privileges for their branch trading station at Novgorod. According to the "Skra," the by-laws of the Novgorod branch, the four aldermen of the community of Germans, who among other duties held the keys of the common chest, deposited in Wisby, were to be chosen from the merchants of the Gothland association and of the towns of Lubeck, Soest and Dortmund. The Gothland association received in 1237 trading rights in England, and shortly after the middle of the century it also secured privileges in Flanders. It legislated on matters relating to common trade interests, and, in the case of the regulation of 1287 concerning shipwrecked goods, we find it imposing this legislation on the towns under the penalty of exclusion from the association. But with the extension of the east and west trade beyond the confines of the Baltic, this association by the end of the century was losing its position of leadership. Its inheritance passed to the gradually forming union of towns, chiefly those known as Wendish, which looked to Lubeck as their head. In 1293 the Saxon and Wendish merchants at Rostock decided that all appeals from Novgorod be taken to Lubeck instead of to Wisby, and six years later the Wendish and Westphalian towns, meeting at Lubeck, ordered that the Gothland association should no longer use a common seal. Though Lubeck's right as court of appeal from the Hanseatic counter at Novgorod was not recognized by the general assembly of the League until 1373, the long-existing practice had simply accorded with the actual shifting of commercial power. The union of merchants abroad was beginning to come under the control of the partial union of towns at home.

A similar and contemporary extension of the influence of the Baltic traders under Lübeck's leadership may be witnessed in the west. As a consequence of the close commercial relations early existing between England and the Rhenish-Westphalian towns, the merchants of Cologne were the first to possess a gild-hall in London and to form a "hansa" with the right of admitting other German merchants on payment of a fee. The charter of 1226, however, by which Emperor Frederick II. created Lubeck a free imperial city, expressly declared that Lubeck citizens trading in England should be free from the dues imposed by the merchants of Cologne and should enjoy equal rights and privileges. In 1266 and 1267 the merchants of Hamburg and Lubeck received from Henry III. the right to establish their own hansas in London, like that of Cologne. The situation thus created led by 1282 to the coalescence of the rival associations in the "Gild-hall of the Germans," but though the Baltic traders had secured a recognized foothold in the enlarged and unified organization, Cologne retained the controlling interest in the London settlement until 1476. Lubeck and Hamburg, however, dominated the German trade in the ports of the east coast, notably in Lynn and Boston,

while they were strong in the organized trading settlements at York, Hull, Ipswich, Norwich, Yarmouth and Bristol. The counter at London, first called the Steelyard in a parliamentary petition of 1422, claimed jurisdiction over the other factories in England.

The Counter of **Bruges.**—In Flanders, also, the German merchants from the west had long been trading, but here had later to endure not only the rivalry but the pre-eminence of those from the east. In 1252 the first treaty privileges for German trade in Flanders show two men of Lubeck and Hamburg heading the "Merchants of the Roman Empire," and in the later organization of the counter at Bruges four or five of the six aldermen were chosen from towns east of the Elbe, with Lubeck steadily predominant. The Germans recognized the staple rights of Bruges for a number of commodities, such as wool, wax, furs, copper and grain, and in return for this material contribution to the growing commercial importance of the town, they received in 1309 freedom from the compulsory brokerage which Bruges imposed on foreign merchants. The importance and independence of the German trading settlements abroad were exemplified in the statutes of the "Company of German merchants at Bruges," drawn up in 1347, where for the first time appears the grouping of towns in three sections (the "Drittel"), the Wendish-Saxon, the Prussian-Westphalian and those of Gothland and Livland. Even more important than the assistance which the concentration of the German trade at Bruges gave to that leading mart of European commerce was the service rendered by the German counter of Bruges to the cause of Hanseatic unity. Not merely because of its central commercial position, but because of its width of view, its political insight and its constant insistence on the necessity of union, this counter played a leading part in Hanseatic policy. It was more Hanse than the Hanse towns.

The last of the chief trading settlements, both in importance and in date of organization. was that at Bergen in Norway, where in 1343 the Hanseatics obtained special trade privileges. Scandinavia had early been sought for its copper and iron, its forest products and its valuable fisheries, especially of herring at Schonen, but it was backward in its industrial development and its own commerce had seriously declined in the 14th century. It had come to depend largely upon the Germans for the importation of all its luxuries and of many of its necessities, as well as for the exportation of its products, but regular trade with the three kingdoms was confined for the most part to the Wendish towns, with Lubeck steadily asserting an exclusive ascendancy. The fishing centre at Schonen was important as a market, though, like Novgorod, its trade was seasonal, but it did not acquire the position of a regularly organized counter, reserved alone, in the north, for Bergen. The commercial relations with the north cannot be regarded as an important element in the union of the Kanse towns, but the geographical position of the Scandinavian countries, especially that of Denmark, commanding the Sound which gives access to the Baltic, compelled a close attention to Scandinavian politics on the part of Lubeck and the League and thus by necessitating combined political action in defence of Hanseatic sea-power exercised a unifying influence.

Energetic and successful though the scattered trading settlements had been in establishing German trade connections and in securing valuable trade privileges, the middle of the 14th century found them powerless to meet difficulties arising from internal dissension and still more from the political rivalries and trade jealousies of nascent nationalities. Flanders became a battle-field in the great struggle between France and England, and the war of trade prohibitions led to infractions of the German privileges in Bruges. An embargo on trade with Flanders, voted in 1358 by a general assembly, resulted by 1360 in the full restoration of German privileges in Flanders, but reduced the counter at Bruges to an executive organ of a united town policy. It is worth noting that in a document connected with this action the union of towns, borrowing the term from English usage, was first called the "German Hansa." In 1361 representatives from Lubeck and Wisby visited Novgorod to recodify the by-laws of the counter and to admonish it that new statutes required the consent of Lubeck, Wisby, Riga, Dorpat and Reval. This action was confirmed in 1366 by an assembly of the Hansa which at the same time, on the occasion of a regulation made by the Bruges counter and of statutes drawn up by the young Bergen counter, ordered that in future the approval of the towns must be obtained for all new regulations.

Hanseatics in England. — The counter at London was soon forced to follow the example of the other counters at Bruges, Novgorod and Bergen. After the failure of the Italians, the Hanseatics remained the strongest group of alien merchants in England, and, as such, claimed the exclusive enjoyment of the privileges granted by the *Carta Mercatoria* of 1303. Their highly favoured position in England, contrasting markedly with their refusal of trade facilities to the English in some of the Baltic towns and their evident policy of monopoly in the Baltic trade, incensed the English mercantile classes, and doubtless influenced the increases in customs duties which were regarded by the Germans as contrary to their treaty rights. Unsuccessful in obtaining redress from the English Government, the German merchants finally, in 1374, appealed for aid to the home towns, especially to Lubeck. The result of Hanseatic representations was the confirmation by Richard II. in 1377 of all their privileges, which accorded them the preferential treatment they had claimed and became the foundation of the Hanseatic position in England.

In the meanwhile, the conquest of Wisby by Waldemar IV. of Denmark in 1361 had disclosed his ambition for the political control of the Baltic. He was promptly opposed by an alliance of Hanse towns, led by Lubeck. The defeat of the Germans at Helsingborg only called into being the stronger town and territorial alliance of 1367, known as the Cologne Confederation, and its final victory, with the peace of Stralsund in 1370, which gave for a limited period the four chief castles on the Sound into the hands of the Hanseatic towns, greatly enhanced the prestige of the League.

The assertion of Hanseatic influence in the two decades, 1356 to 1377, marks the zenith of the League's power and the completion of the long process of unification. Under the pressure of commercial and political necessity, authority was definitely transferred from the Hansas of merchants abroad to the Hansa of towns at home, and the sense of unity had become such that in 1380 a Lubeck official could declare that "whatever touches one town touches all." But even at the time when union was most important, this statement went further than the facts would warrant, and in the course of the following century it became less and less true.. Dortmund held aloof from the Cologne Confederation on the ground that it had no concern in Scandinavian politics. It became, indeed, increasingly difficult to obtain the support of the inland towns for a policy of sea-power in the Baltic. Cologne sent no representatives to the regular Hanseatic assemblies until 1383, and during the 15th century its independence was frequently manifested. It rebelled at the authority of the counter at Bruges, and at the time of the war with England (1469–74) openly defied the League. In the east, the German Order, while enjoying Hanseatic privileges, frequently opposed the policy of the League abroad, and was only prevented by domestic troubles and its Hinterland enemies from playing its own hand in the Baltic. After the fall of the order in 1467, the towns of Prussia and Livland, especially Danzig and Riga, pursued an exclusive trade policy even against their Hanseatic confederates. Lubeck, however, supported by the Bruges counter, despite the disaffection and jealousy on all sides hampering and sometimes thwarting its efforts, stood steadfastly for union and the necessity of obedience to the decrees of the assemblies. Its headship of the League, hitherto tacitly accepted, was definitely recognized in 1418.

The League Assembly. — The governing body of the Hansa was the assembly of town representatives, the "Hansetage," held irregularly as occasion required at the summons of Liibeck, and, with few exceptions, attended but scantily. The delegates were bound by instructions from their towns and had to report home the decisions of the assembly for acceptance or rejection. In 1469 the League declared that the English use of the terms "societas," "collegium" and "universitas" was inappropriate to so loose an organization. It preferred to call itself a "firma con-

federatio" for trade purposes only. It had no common seal, though that of Liibeck was accepted, particularly by foreigners, on behalf of the League. Disputes between the confederate towns were brought for adjudication before the general assembly, but the League had no recognized federal judiciary. Lubeck, with the counters abroad, watched over the execution of the measures voted by the assembly, but there was no regular administrative organization. Money for common purposes was raised from time to time, as necessity demanded, by the imposition on Hanse merchandise of poundage dues, introduced in 1361, while the counters relied upon a small levy of like nature and upon fines to meet current needs. Even this slender financial provision met with opposition. The German Order in 1398 converted the Hanseatic poundage to a territorial tax for its own purposes, and one of the chief causes for Cologne's disaffection a half-century. later was the extension from Flanders to other parts of the Netherlands of the levy made by the counter at Bruges. Since the authority of the League rested primarily on the moral support of its members, allied in common trade interests and acquiescing in the able leadership of Lubeck, its only means of compulsion was the "Verhansung," or exclusion of a recalcitrant town from the benefits of the trade privileges of the League. A conspicuous instance was the exclusion of Cologne from 1471 until its obedience in 1476, but the penalty had been earlier imposed, as in the case of Brunswick, on towns which overthrew their patrician Governments. It was obviously, however, a measure to be used only in the last resort and with extreme reluctance.

The decisive factor in determining membership in the League was the historical right of the citizens of a town to participate in Hanseatic privileges abroad. At first the merchant Hansas had shared these privileges with almost any German merchant, and thus many little villages, notably those in Westphalia, ultimately claimed membership. Later, under the Hansa of the towns, the struggle for the maintenance of a coveted position abroad led to a more exclusive policy. A few new members were admitted, mainly from the westernmost sphere of Hanseatic influence, but membership was refused to some important applicants. In 1447 it was voted that admission be granted only by unanimous consent. No complete list of members was ever drawn up, despite frequent requests from foreign powers. Contemporaries usually spoke of 70, 72, 73 or 77 members, and perhaps the list is complete with Daenell's recent count of 72, but the obscurity on so vital a point is significant of the amorphous character of the organization.

The towns of the League, stretching from Thorn and Krakow on the east to the towns of the Zuider Zee on the west, and from Wisby and Reval in the north to Gottingen in the south, were arranged in groups, following in the main the territorial divisions. Separate assemblies were held in the groups for the discussion both of local and Hanseatic affairs, and gradually, but not fully until the 16th century, the groups became recognized as the lowest stage of Hanse organization. The further grouping into "Thirds," later "Quarters," under head-towns, was also more emphasized in that century.

Decline **of** the League.—In the 15th century the League, with increasing difficulty, held a defensive position against the competition of strong rivals and new trade-routes. In England the inevitable conflict of interests between the new mercantile power, growing conscious of its national strength, and the old, standing insistent on the letter of its privileges, was postponed by the factional discord out of which the Hansa in 1474 dexterously snatched a renewal of its rights. Under Elizabeth, however, the English Merchant Adventures could finally rejoice at the withdrawal of privileges from the Hanseatics and their concession to England, in return for the retention of the Steelyard, of a factory in Hamburg. In the Netherlands the Hanseatics clung to their position in Bruges until 1540, while trade was migrating to the ports of Antwerp and Amsterdam. By the peace of Copenhagen in 1441, after the unsuccessful war of the League with Holland, the attempted monopoly of the Baltic was broken, and, though the Hanseatic trade regulations were maintained on paper, the Dutch with their larger ships increased their hold on the herring fisheries, the French salt trade and the Baltic grain trade. For the Russian trade new competitors were emerging in southern Germany. The Hanseatic embargo against Bruges from 1451 to 1457, its later war and embargo against England, the Turkish advance closing the Italian Black sea trade with southern Russia, all were utilized by Nuremberg and its fellows to secure a land-trade outside the sphere of Hanseatic influence. The fairs of Leipzig and Frankfurt-on-Main rose in importance as Novgorod, the stronghold of Hanse trade in the east, was weakened by the attacks of Ivan III. The closing of the Novgorod counter in 1494 was due not only to the development of the Russian State but to the exclusive Hanseatic policy which had stimulated the opening of competing trade routes.

Within the League itself increasing restiveness was shown under the restrictions of its trade policy. At the Hanseatic assembly of 1469, Danzig, Hamburg and Breslau opposed the maintenance of a compulsory staple at Bruges in the face of the new conditions produced by a widening commerce and more advantageous markets. Complaint was made of south German competition in the Netherlands. "Those in the Hansa," protested Breslau, "are fettered and must decline and those outside the Hansa are free and prosper." By 1477 ,even Lubeck had become convinced that a continuance of the effort to maintain the compulsory staple against Holland was futile and should be abandoned. But while it was found impossible to enforce the staple or to close the Sound against the Dutch, other features of the monopolistic system of trade regulations were still upheld. It was forbidden to admit an outsider to partnership or to co-ownership of ships, to trade in non-Hanseatic goods, to buy or sell on credit in a foreign mart or to enter into contracts for future delivery. The trade of foreigners outside the gates of Hanse towns or with others than Hanseatics was forbidden in 1417, and in the eastern towns the retail trade of strangers was strictly limited. The whole system was designed to suppress the competition of outsiders, but the divergent interests of individuals and towns, the pressure of competition and changing commercial conditions, in part the reactionary character of the legislation, made enforcement difficult. The measures were those of the late-mediaeval town economy applied to the wide region of the German Baltic trade, but not supported, as was the analogous mercantilist system, by a strong central government.

Among the factors, economic, geographic, political and social, which combined to bring about the decline of the Hanseatic League, none was probably more influential than the absence of a German political power comparable in unity and energy with those of France and England, which could quell particularism at home, and abroad maintain in its vigour the trade which these towns had developed and defended with their imperfect union. Nothing was to be expected from the declining empire. Still less was any co-operation possible between the towns and the territorial princes. The fatal result of conflict between town autonomy and territorial power had been taught in Flanders. The Hanseatics regarded the princes with a growing and exaggerated fear and found some relief in the formation in 1418 of a thrice-renewed alliance, known as the "Tohopesate," against princely aggression. But no territorial power had as yet arisen in north Germany capable of subjugating and utilizing the towns, though it could detach the inland towns from the League. The last wars of the League with the Scandinavian powers in the 16th century, which left it shorn of many of its privileges and of any pretension to control of the Baltic basin eliminated it as a factor in the later struggle of the Thirty Years' War for that control. At an assembly of 1629, Liibeck, Bremen and Hamburg were entrusted with the task of safeguarding the general welfare, and after an effort to revive the League in the last general assembly of 1669, these three towns were left alone to preserve the name and small inheritance of the Hansa which in Germany's disunion had upheld the honour of her commerce. Under their protection, the three remaining counters lingered on until their buildings were sold at Bergen in 1775, at London in 1852 and at Antwerp in 1863.

HANSEN, EMIL CHRISTIAN (1842–1909), Danish botanist, whose pure-culture studies on yeasts revolutionized the brewing industry, was born on May 8, 1842, at Ribe, Jutland. He studied art at Copenhagen but in 1871 turned to science. From 1879 he was head of the physiological department of the Carlsberg institute. Hansen's researches were concerned chiefly with fungi and alcoholic fermenting yeasts. He perfected the methods of culture and isolation begun by Pasteur. He devised a method of sowing cultures with a single cell and so isolating one species from another. He defined with precision the morphological and physiological characters of different species and crowned his work by devising a system of classification which is still universally used. The yeast grown from single cells was largely adopted in the bottom-fermentation breweries of the continent. Hansen died at Copenhagen on Aug. 27,1909,

He wrote *Untersuchungen aus der Praxis der Gärungsindustrie,* 2 vol., 3rd ed. (1892–95; Eng. trans., 1896) and *Gesammelte theoretische Abhandlungen über Gärungsorganismen* (1911).

See BREWING: *Fermentation.*

HANSEN, PETER ANDREAS (1795–1874), Danish astronomer, whose most important work was for the specific purpose of improving the theories and tables of the motion of the principal bodies in the solar system, was born on Dec. 8, 1795, at Tondern, in the duchy of Schleswig. He learned the trade of a watchmaker but in 1820 went to Copenhagen, where he won the patronage of H. C. Schumacher. He acted as Schumacher's assistant in work connected with the Danish survey, chiefly at the new observatory of Altona, 1821–25. He then went to Gotha as director of the Seeberg observatory, where he worked until his death there on March 28, 1874.

Hansen had great practical talents but the observatory was poorly equipped and it was not until 1857 that a new observatory was built for him. In the meantime he had made investigations into the theory of instruments and devised improvements in their construction and use. He also worked on theoretical geodesy, on optics and on the theory of probability. A paper on the mutual perturbations of Jupiter and Saturn won for him a prize of the Berlin academy in 1830. His two most important works on the theory of the motion of the moon are the *Fundamenta* (1838) and the *Darlegung* (1862–64). The tables based on his theory were printed in Great Britain in 1857 at the expense of the British government, the author receiving a gratuity of £1,000. These tables were used for the *Nautical Almanac.* A few errors had been corrected, but as the difference between theory and observation continued to grow, empirical terms calculated by S. Newcomb were introduced to bridge the gap. These terms had no theoretical foundation and it was later recognized that the discordances are largely due to irregular fluctuations in the rate of rotation of the earth. Hansen's tables remained in use until they were replaced by Brown's tables in 1923. From his theory of the moon Hansen deduced that the accepted distance of the sun must be reduced by about 3% and so obtained a value close to that now accepted. Hansen, assisted by Christian Olufsen, compiled new tables of the sun in 1854. He received world-wide recognition for his work, being twice awarded the gold medal of the Royal Astronomical society; in 1850 the Copley medal of the Royal society was awarded to him. (J. JN.)

HANSON, JOHN (1721–1783), American Revolutionary leader, was the first president under the Articles of Confederation. Born in Charles county, Md., on April 13, 1721, he became a political leader of note in Maryland, serving in the general assembly from 1757, upon many important committees during the Revolutionary War, and as a representative of Maryland in the Continental Congress elected Dec. 22, 1779. On Kov. 5, 1781, he was elected by the Continental Congress "President of the United States in Congress Assembled," which office he held one year. He is sometimes referred to as "the first president of the United States," but he was a congressional presiding officer and had none of the powers of the first president under the constitution. Hanson died on Nov. 22. 1783, at Oxon Hill, Prince Georges county. Md.

HANSSON, OLA (1860–1925), Swedish poet, prose-writer and critic, belatedly recognized as one of the most original modern Swedish writers, was born at Gronby, Skbne, Nov. 12, 1860. After studying at Lund, he went to Copenhagen where he met many Danish writers. He was enormously influenced by foreign literature, especially by contemporary psychological writers who fostered his almost morbid sensitivity; yet, a descendant of a long line of Skbne farmers, he felt kinship with the placid plains of his native province. Out of this fundamental dichotomy came the conflict in his personality. His first publication, *Dikter* (1884), contains some poems describing nature and others inspired by social injustice. In *Notturno* (1885) he had already achieved poetic mastery, expressing in exquisite lyrics complex, subjective moods. His prose sketches, *Sensitiva Amorosa* (1887), in which he explored the "physiology of the soul," shocked contemporary Sweden and, embittered by their reception, from 1889 he lived abroad. first in Germany, and later in France, Switzerland and Turkey. In 1889 he married Laura Marholm, herself a writer, and they worked to make Scandinavian authors, especially Strindberg. known abroad and to introduce contemporary foreign writers to Sweden. Hansson's admiration for Kietszche was reflected in *Ung Ofegs visor* (1892; Eng. trans., *Young Ofeg's Ditties,* 1895). This was followed by remarkable short stories, the autobiographical novel *Resan hem* ("The Journey Home"; 1895), and numerous critical essays. Hansson later became a Roman Catholic for a time. His opinions became more violent and bizarre with age, but he continued to write, sometimes recapturing the lyrical beauty of his early poetry, until his death at Buyukdere, Turkey, Sept. 26, 1925.

His collected works were published in 17 vol. (1919–22); a further selection was edited by H. Gullberg, 5 vol. (1928–31).

HANSTEEN, CHRISTOPHER (1784–1873), Norwegian astronomer and physicist, associated with the study of terrestrial magnetism, was born at Christiania (Oslo) on Sept. 26, 1784. From the cathedral school he went to the University of Copenhagen, where he studied mathematics. In 1807 he began his inquiries into terrestrial magnetism. He was appointed lecturer at the University of Christiania in 1814 and two years later, professor of astronomy and applied mathematics. An astronomical observatory was erected in 1833, to which a magnetic observatory was added in 1839. To further his researches in terrestrial magnetism he traveled not only throughout Norway and Finland but in 1828–30 undertook an expedition to western Siberia with G. A. Erman. Various publications gave an account of his expeditions and the final results were published in 1863 *(Resultate magnetischer Beobachtungcn).* He especially wrote on the magnetic poles and axes. Hansteen also supervised survey and topographical work in Norway begun in 1837. He continued his studies in magnetism after his retirement in 1861. He died at Oslo on April 11, 1873. (J. JN.)

HANSWURST, a comic character in Viennese plays created

by the Austrian playwright Joseph Anton Stranitzky (1676–1726), who replaced the somewhat tired Italianate Harlequin (*q.v.*) with a homebred clown type. Hanswurst sported the modified costume of a Salzburg peasant and supposedly embarrassed Lady Mary Wortley Montagu, who, in her letters, gave an account of the coarseness of his speech and gestures after she saw him perform in Vienna in 1716. In nontheatrical usage the name Hanswurst occurs first in 1519 in Sebastian Brant's satire *Das Narrenschiff* (1494). (A. M. N.

HANTHAWADDY, a district in the Pegu division of Lower Burma, the home district of Rangoon, from which the town was detached to make a separate district in 1880. It has an area of 1,931 sq.mi., with a population in 1941 of 459,522, of whom about 50,000 lived in the towns of Syriam, where the oil refineries are situated, and Thongwa. Maubin and Hanthawaddy are the two most densely populated districts in the province. It consists of a vast plain stretching up from the sea, and lies on either side of the Rangoon river by which the port of Rangoon is approached from the sea. The country is intersected by numerous tidal creeks, many navigable by large boats and some, like the Bassein creek which connects the Rangoon river with the To or China Bakir mouth of the Irrawaddy, by steamers. The Twante canal affords a more direct communication between the Rangoon and China Bakir rivers, and is used by the regular steamer services between Rangoon and Bassein across the delta.

The British admiralty oiling base, constructed between 1922 and 1927, lies on the east bank of the Rangoon river in the Hanthawaddy district. Cultivation in, the district is almost wholly confined to rice, and there are considerable tracts of unreclaimed marshland.

HANTZSCH, ARTHUR (1857–1935), German theoretical chemist, won fame at the age of 25 by devising the celebrated synthesis of substituted pyridines from β-ketonic esters, aldehydes and ammonia. Born in Dresden, March 7, 1857, Hantzsch studied at Dresden and Wiirzburg universities. He became a professor at Zürich (1885), at Wiirzburg (1893) and at Leipzig (1903).

With his pupil, Alfred Werner (*q.v.*), Hantzsch founded the stereochemistry of nitrogen, enunciating the theory that the three valences of nitrogen are not coplanar, and elucidating and proving the configurations of the stereoisomeric oximes and hydrazones. An attempt to extend the work to diazo compounds led to the discovery that many diazonium compounds are salts or bases. Hantzsch demonstrated the transformation $ArN_2+OH \rightleftharpoons Ar NNOH$, whereby a strong base is changed into a nonelectrolyte and showed that similar transformations occur between the aciforms and normal forms of nitro compounds and in the triphenylmethane dyes.

In the last case, the transformation is accompanied by a colour change, the investigation of which led Hantzsch to make pioneer studies in spectrophotometry and in the relationship between colour and constitution. He advanced a theory of indicators, emphasizing that the amount of the dissociable form present, and not the extent of dissociation, determines the colour.

Hantzsch conducted an extensive study of the dissociation of acids at all concentrations and in various solvents. He demonstrated the formation of oxonium salts with water and ether and came to the conclusion that acid dissociation does not occur except after solvation or association of the acid molecules.

Hantzsch was a man full of ideas; he was responsible for nearly 1,000 papers. He was remarkable for his early adoption of the methods of the science of physical chemistry.

He wrote *Grundriss der Stereochemie,* 2nd ed. (1904); *Diazoverbindungen,* 2nd ed., with S. Reddelien (1921); and *Theorie der ionogenen Bindungen* (1923). He died in Dresden, March 14, 1935.

HANUKKAH (lit. "dedication," *cf.* Num. vii), the feast instituted by Judas Maccabaeus on 25 Kislew, 165 B.C., for the purification of the Temple, on the third anniversary of the setting up of the "Abomination of Desolation" (Dan. xi. 31; 1 Macc. i, 41–64, iv, 59; 2 Macc. vi, 2; Mark xiii, 14) by Antiochus Epiphanes. The name ἐγκαίνια corresponds to ἐγκαίνια (John x, 22). Wellhausen maintained that Hanukkah represents a primitive winter solstice festival. On this *see* ch. xii of C. C. Keet, *Liturgical Use of Psalter* (London, 1928). The feast lasts eight days, but the legend in 2 Macc. i, 18, is probably not the reason for this. One light is kindled on the first night, an extra one being added on each successive night, Hillel's rule thus prevailing over that of Shammai. The scroll of Antiochus still survives in some liturgies. For the service *see* the prayer books of S. Singer (Ashkenazic rite, London, 1928, and I. Abraham's notes in the annotated edition) and M. Gaster (Sephardic rite, with variants, Oxford, 1901); I. Elbogen in *Jüd. Gottesdienst* (Frankfurt-am-Main, 1924); and G. F. Moore, *Judaism,* ii, 49 (Harvard, 1927). The *Jewish Encyclopedia* (*s.v.*) article contains numerous illustrations of Hanukkah lamps. *See* also the catalogue of the Anglo-Jewish Historical exhibition of 1887 (published by the *Jewish Chronicle,* London). Specimens are in museums and private collections.

HANUMAN, in Hindu mythology the monkey god, a central figure in the Ramayana. Child of a nymph by the wind god, he aided Rama to recover his wife, Sita, from the demon Ravana, bridging the strait between India and Ceylon with boulders brought from the Himalayas with the help of a host of monkeys. Temples in his honour are numerous, especially in southern India. He is also a popular deity in Japan, where many temples are erected to his honour and districts of towns bear his name. The hanuman monkey (*Semnopithecus entellus),* called after the god, is one of the commonest Indian monkeys. *See* PRIMATES.

HAN-YANG, a member city of the tri-city conurbation of Wu-han on the north bank of the Yangtze at the mouth of the Han river in Hupeh province, China. It was merged in 1950 with the adjacent cities of Hankow and Wu-chang to form the single metropolis of Wu-han. *See* WU-HAN.

HAN YU (HAN WEN-KUNG) (768–824), Chinese poet and essayist of the T'ang dynasty, was born in Teng-chou, Honan, in 768. He regarded himself as a transmitter of Confucianism in the orthodox tradition of Mencius. As part of his program of returning to antiquity, he revived the literary style practised by the Confucians of the 4th and 3rd centuries B.C. The style he advocated was a free, simple prose unencumbered by the mannerisms and elaborate verselike regularity of parallel prose, the style then prevalent. In his poetry he reveals a tendency toward experimentation and unconventionality. His frequently polemical writings led him to be banished on two occasions, once in 803, when, as a member of the Censorate, he protested to the throne against overtaxation and the economic abuses of the eunuchs, and again in 819, when, in his famous Buddha-bone memorial, he attacked the veneration of a Buddhist relic on the grounds that Buddhism was a foreign religion. This memorial, together with the short essays "On the Way," "On Man," "On Spirits" and "On Inborn Qualities," became the most famous models of the prose style he espoused. His initial failure to find examiners sympathetic to his style kept him from embarking on the official career to which he aspired. He presented himself to the ministry of rites four times before being admitted to its examinations for the degree of Doctor of Letters. Having earned it at the age of 24, he spent the following three years attempting unsuccessfully to pass other qualifying examinations until, at the age of 28, he accepted his first post under a provincial governor. Later, as a compiler in the office of historiography, he edited the official record of the brief reign of the emperor Shun-tsung, which survives as the earliest example, and only T'ang specimen, of its genre. He served at times as vice-president in each of the ministries of justice, war and personnel. The prestige of his high office lent respectability to his literary reforms. At his death, in 824. the title of president of the ministry of rites was posthumously conferred upon him, as well as the epithet "Prince of Letters." *See* also CHINESE LITERATURE.

HARA KEI (HARA TAKASHI) (1856–1921), Japanese politician, the first untitled prime minister of that nation and the first authentic Japanese party boss, was born at Morioka on Feb. 9, 1856.

Hara was educated in the justice ministry law school and entered the foreign service in 1882. Like many Japanese politicians of his era, he used the journalistic as well as the bureaucratic road to power, becoming chief editor of the ***Osaka Mainichi*** in 1897. When Prince Ito Hirobumi organized the Seiyukai party in 1900, however, Hara returned to politics as minister of communications. Elected to the house of representatives in 1902, he rose rapidly to become home minister in two Saionji cabinets (1905 and 1911) and Seiyukai president in 1914. Astute, often ruthless strategy brought him not only firm party control but the premiership on Sept. 29, 1918. This broke the hold of the Meiji oligarchy and ushered in almost two decades of "normal constitutional government" in which the Seiyukai party machine and its Mitsui business allies dominated civilian politics.

As prime minister, Hara pushed through a small-district electoral reform that gave the Seiyukai an absolute majority in the 1920 diet election. He failed to obtain approval of a racial equality clause in the covenant of the League of Nations or withdrawal of Japanese troops from Siberia.

Hara's administration opposed the universal suffrage movement and promoted the spoils system, primarily the close alliance of the Seiyukai with the Mitsui, and this corruption eventually helped to destroy public confidence in the party system. It inspired the young assassin who killed Hara in front of Tokyo station on Nov. 4, 1921. (D. H. ML.)

HARA-KIRI, self-disembowelment (Japanese ***hara,*** belly, and ***kiri,*** cutting), the method of suicide permitted to offenders of the noble class in feudal Japan and later the national form of honourable suicide. The more commonly used modern term is ***Seppuku,*** the Chinese reading of the same characters. Hara-kiri was a growth of mediaeval militarism, prompted by the desire of the noble to escape the humiliation of falling into an enemy's hands. By the end of the 14th century the custom had become a valued privilege. Hara-kiri was of two kinds, obligatory and voluntary. The first is the more ancient. An official or noble, who had broken the law or been disloyal, received a message from the mikado, couched always in gracious terms, courteously intimating that he must die. The mikado usually sent a jewelled dagger with which the deed might be done. The suicide made dignified preparations for the ceremony. In his own baronial hall, or in a temple, a dais, 3 or 4 in. from the ground, was constructed. Upon this was laid a rug of red felt. The suicide, clothed in his ceremonial dress, and accompanied by his second (Kaishaku), took his place on the mat, the officials and his friends ranging themselves in a semi-circle. The weapon was then handed to him with many obeisances by the mikado's representative, and he made a public confession of his fault. A moment later he plunged the dagger into his stomach below the waist on the left side, drew it slowly across to the right and, turning it, gave a slight cut upward. At the same moment the Kaishaku, who crouched at his friend's side, leaping up, brought his sword down on the outstretched neck. The bloodstained dagger was taken to the mikado as a proof of the consummation of the act. The performance of hara-kiri carried with it certain privileges. If it was by order of the mikado half only of a traitor's property was forfeited to the State. If the gnawings of conscience drove the disloyal noble to voluntary suicide, his dishonour was wiped out, and his family inherited all his fortune.

Voluntary hara-kiri was the refuge of men rendered desperate by private misfortunes, or was committed from loyalty to a dead superior, or as a protest against what was deemed a false national policy. This voluntary suicide still survives, a characteristic case being that of the citizen who despatched himself in 1925 as a protest against the Government's foreign policy. The popularity of this self-immolation is testified to by the fact that for centuries no fewer than 1,500 hara-kiris are said to have taken place annually, at least half being entirely voluntary. Stories of amazing heroism are told in connection with the performance of the act. Obligatory hara-kiri was actually abolished in 1868.

See A. B. Mitford, ***Tales*** of ***Old Japan;*** Basil Hall Chamberlain, ***Things Japanese*** (1898).

HARALD I. (85—33), surnamed Haarfager ("Fairhair"), first king over Norway, succeeded on the death of his father Halfdan the Black in A.D. 860 to the sovereignty of several small and somewhat scattered kingdoms, which had come into his father's hands through conquest and inheritance and lay chiefly in south-east Norway. (***See*** NORWAY.) In 866 he made the first of a series of conquests over the many petty kingdoms which then composed Norway; and in 872, after a great victory at Hafrsfjord near Stavanger, he found himself king over the whole country. His realm was, however, threatened by dangers from without, as large numbers of his opponents had taken refuge, not only in Iceland, then recently discovered, but also in the Orkneys, Shetlands, Hebrides and Faeroes, and in Scotland itself; and from these winter quarters sallied forth to harry Norway as well as the rest of northern Europe. Their numbers were increased by malcontents from Norway, who resented Harald's claim of rights of taxation over lands which the possessors appear to have previously held in absolute ownership. At last Harald was forced to make an expedition to the west to clear the islands and Scottish mainland of Vikings. Numbers of them fled to Iceland, which grew into independent commonwealth, while the Scottish isles fell under Norwegian rule. The latter part of Harald's reign was disturbed by the strife of his many sons. He gave them all the royal title and assigned lands to them which they were to govern as his representatives; but this arrangement did not put an end to the discord, which continued into the next reign. When he grew old he handed over the supreme power to his favourite son Erik "Bloody Axe," whom he intended to be his successor. Harald died in 933, in his 84th year.

The tale goes that the scorn of the daughter of a neighbouring king induced Harald to take a vow not to cut or comb his hair until he was sole king of Norway and that ten years later he was justified in trimming it whereupon he exchanged the epithet "Shockhead" for the one by which he is usually known.

HARALD II., surnamed Graafeld, a grandson of Harald I., became, with his brothers, ruler of the western part of Norway in 961; he was murdered in Denmark in 969.

See H. Hermannson, ***Islandica III.*** (Bibliography of ***the*** Sagas of the Kings of Norway) (1910). A. Bugge, *Norges Historie* Vol. I. part II. (1909–10).

HARALD III. (1015–1066), king of Norway, surnamed Haardraade, which might be translated "ruthless," was the son of King Sigurd and half-brother of King Olaf the Saint. At the age of fifteen he was obliged to flee from Norway, having taken part in the battle of Stiklestad (1030), at which King Olaf met his death. He took refuge for a short time with Prince Yaroslav of Novgorod (a kingdom founded by Scandinavians), and thence went to Constantinople, where he took service under the empress Zoe, whose Varangian guard he led to frequent victory in Italy, Sicily and North Africa, also penetrating to Jerusalem. In the year 1042 he left Constantinople, the story says because he was refused the hand of a princess, and on his way back to his own country he married Ellisif or Elizabeth, daughter of Yaroslav of Novgorod. In Sweden he allied himself with the defeated Sven of Denmark against his nephew Magnus, now king of Norway, but soon broke faith with Sven and accepted an offer from Magnus of half his kingdom. In return for this gift Harald is said to have shared with Magnus the enormous treasure which he had amassed in the East. The death of Magnus in 1047 put an end to the growing jealousies between the two kings, and Harald turned his attention to subjugating Denmark, which he ravaged year after year; but in 1064 he gave up the attempt and made peace. In 1066, possibly instigated by the banished Earl Tostig, he invaded England. In September 1066 he landed in Yorkshire with a large army, reinforced from Scotland, Ireland and the Orkneys; took Scarborough by casting flaming brands into the town from the high ground above it; defeated the Northumbrian forces at Fulford; and entered York on Sept. 24. But

on the 25th the English Harold arrived from the south. and routed his forces at Stamford bridge after the fall of their king. His many victories in the face of great odds prove him to have been a remarkable general, of never-failing resourcefulness and indomitable courage, in spite of the fact that he was an unpopular king

HARALD IV (d 1136), king of Norway, surnamed Gylle (probably from *Gylle Krist, i.e.*, servant of Christ), was born in Ireland about 1103 About 1127 he went to Norway and declared he was the son of King Magnus III (Barefoot), who had visited Ireland just before his death in 1103, and consequently a half-brother of the reigning king, Sigurd. He appears to have submitted successfully to the ordeal of fire, and the alleged relationship was acknowledged by Sigurd on condition that Harald did not claim any shdre in the government of the kingdom during his lifetime or that of his son Magnus.

Harald kept this agreement *until* Sigurd's death in 1130. Then war broke out between himself and Magnus. who was captured in 1134. blinded, and imprisoned. Harald now ruled the country until 1136, when he was murdered by Sigurd Slembi-Diakn, another bastard son of Magnus Barefoot. Four of Harald's sons, Sigurd. Ingi, Eysteinn and Magnus, were subsequently kings of Norway

HARAR, a province and city of Ethiopia. The province is one of the most fertile in the country, situated at an elevation of some 4.000 to 5,000 ft. above sea level, enjoying a pleasant climate and a rainfall of between 35–60 in, and rich in varied cultivation. Area 156,000 sq.mi.

The duke of Harar is its governor, although the emperor takes a personal interest in its affairs since it was as governor of Harar he arose to power

Harar is famous for its excellent coffee, which is grown extensively and largely exported

Along its northern extremity runs the Franco-Ethiopian railway from Jibuti to Addis Ababa, on which 193 mi. from Jibuti is the town of Diredawa, the most progressive town in Ethiopia (population about 30 000), with roads. a water supply and electricity; it was for many years the terminus of the railway. Thirty-five miles southwest of Diredawa lies the town of Harar, the capital of the province and for long its most important centre until the advent of the railway transferred its commercial predominance to Diredawa. It remains the centre of the caravan trade of the province and in addition to coffee there is considerable trade in durra, chat (used as a drug), ghee. cattle, mules and camels. skins and hides and gums. Cotton and metal goods form the bulk of the import trade. Harar is built on the slopes of a hill at an elevation of more than 5 000 ft. A lofty stone wall, pierced by five gates and flanked by 24 towers, encloses the city, which has a population (1956 est.) of 40.500. The streets are steep, narrow. dirty and unpaved, the roadways consisting of rough boulders. The houses in general are made of undressed stone and mud and are flat-topped, the general aspect of the city non-Ethiopian.

A few houses, including the palace of the governor and the foreign consulates, are of more elaborate and solid construction.

Harar is believed to owe its founddtion to Arab immigrants from Yemen in the 7th century of the Christian era. In the region of Somaliland, the Arabs established the Muslim state of Adel or Zaila, with their capital at Zaila, Harar becoming the seat of government in 1521. A subsequent amir of Harar Mohammed surnamed Grañ (left-handed), probably a Somali, is famous for his invasion of Ethiopia, of which country he was virtual master until his defeat and death in 1541. It was first visited by a European in 1854 when (Sir) Richard Burton spent ten days there in the guise of an Arab. In 1875 Harar was occupied by an Egyptian force and remained in the possession of Egypt until 1885, when the garrison was withdrawn in consequence of the rising of the Mahdi in the Sudan. A son of the ruler who had been deposed by Egypt was installed as amir, the arrangement being carried out under the superintendence of British officers. The new amir held power until Jan. 1887, in which month Harar was conquered by Menelek II, king of Shoa (afterward emperor of Ethiopia). The governorship of Harar was by Menelek entrusted to Ras Makonnen, who held the post until the time of his death in 1906.

The Harari proper are of a stock distinct from the neighbouring peoples. and speak a special language. Hararese is "a Semitic graft inserted into an indigenous stock" (Sir R. Burton, *First Footsteps in East Africa*). The Harari are Muslims of the Shafa'i or Persian sect, and they employ the solar year and the Persian calendar. In addition to the native population there are in Harar colonies of Amharas, Somalis and Gallas By the Somalis the place is called Adari, by the Gallas Adaray. *See* also ETHIOPIA (ABYSSINIA).

See P Paulitschke, *Harar: Forschungreise nach den Somâl- und Galla-Landern Ost-Afrikas (1888).* (C F. R.; X.)

HARBIN, the chief city of Heilungkiang province, central Manchuria, China. It lies on the right bank of the Sungari river in latitude 45° 30' N and longitude 126° 40' E.. 220 mi. N N.E. of Mukden and 250 mi W N W. of Vladivostok, with both of which towns it is connected by railway.

The gronth of the town has been phenomenal. In 1898 Harbin was only a local wheat market, but it was developed by the Chinese Eastern railway and became rapidly a populous industrial city and a centre of former tsarist activities in Manchuria in the generation after the Russian October Revolution of 1917. Because of this origin it has remained a city of outspoken Russian character although the Russian population has declined.

In 1911 the city had 40,500 inhabitants. The population increased to 332.000 in 1931 and to 662,000 in 1940; in 1953 (census) it was 1,163.000 and increased to an estimated 1,552,000 in 1957. The city is divided into various sections: the "new town." the mart, Machiakou, Chuanchiatien and the Russian town, one of the colourful sections of the metropolis. On Dec. 1, 1934, after the creation of the puppet state of Manchoukuo, Harbin became the seat of the provincial government of the new province of Pinkiang

Harbin has been an important commercial centre. The surrounding plain, composed mainly of fertile black loam and some yellow clays, is very suitable for the growth of wheat, maize (corn) and that very adaptable plant, the soybean. Harbin is also well situated in relation to markets.

Five railway lines converge in the city. The northwest-southeast line of the former Chinese Eastern railway connects Harbin with Manchouli in the west and—through Mutankiang from where a branch line leads to the Korean border—with Vladivostok in the east. The line to Hsinking (Ch'ang-ch'un) leads to Mukden Dairen and to the Korean border. Another southern line from Harbin connects at Lafachan uith the railroad from Hsinking via Kirin to the Korean border; a northern line leads to Hailun and Ai-Hun (Aigun) on the Amur river.

These lines make Harbin the strategic centre of the Manchurian railway system. Harbin is also connected by steamships and junks with all important towns on the Sungari river and its tributaries. Airlines connect the city nith Manchouli via Tsitsihar and with Dairen and Shingishu (Korea) via Hsinking and Mukden. In the city itself street cars. omnibuses and automobiles and the regular rickshas and sleds (in winter) provide an elaborate transportation system.

Harbin had a number of industries on an agricultural basis, as flour milling, soybean factories, distilleries, leather industries, etc. It exported soybeans, bean oil, bean cake, wheat flour, tobacco, cotton piece goods, furs, leather, beer, beet sugar, veneer, lumber, woolens, soap, candles, jewelry and confectionery. After 1936 the exports declined rapidly while at the same time the import of Japanese goods connected with the Japanese economic development of north Manchuria increased very strongly.

After 1939 Harbin was developed into a major industrial base of northeast China. In addition to the traditional food-processing industries. new enterprises included production of ball bearings, wire and cable, film projectors, tractors, electric-power generators, nylon and plastics.

HARBINGER, originally one who provided shelter for an army (from M.E. *herbergere,* formed from O.H. Ger. *heri,* an

army, and *bergen,* shelter). The meaning was enlarged to include any place where travellers could be lodged, and also the person who provided lodgings or one who went on before a party to secure lodgings; hence, figuratively, in literature a forerunner. A harbinger was also the herald sent to announce the king's coming, and until 1846 a knight harbinger was an officer in the royal household.

HARBINGER-OF-SPRING *(Erigenia bulbosa),* a small North American plant of the parsley family (Umbelliferae), native to moist low woods from southern Ontario to Minnesota and southward to Pennsylvania, Alabama and Missouri. It is a low, smooth, almost stemless perennial, rising from a deep round tuber and bearing near the ground from two to four compound leaves thrice divided into narrow leaflets and a flower stalk (scape), three to nine inches high, terminating in small umbellate clusters of white flowers.

In the southern part of its range the plant blooms as early as February, and at the north in April, whence its name. It is somewhat rare and local in many sections but is especially abundant in the vicinity of Washington, D.C.

HARBORD, JAMES GUTHRIE (1866–1947), U.S. army officer, was Gen. John J. Pershing's chief of staff during World War I. Born at Bloomington, Ill., March 21, 1866, he graduated from the Kansas State Agricultural college, Manhattan, in 1886. He joined the 4th infantry as a private in 1889 and was commissioned in the cavalry in 1891. Thereafter he was promoted through the grades and in 1917 became brigadier general. He was chief of staff of the American Expeditionary force in France, May 1917–May 1918, and again from May 1919. He commanded the marine brigade near Chateau-Thierry, June 1918, and the 2nd division of the A. E. F. in the Soissons offensive, July 1918, after which he was placed in command of the service of supply. He served as deputy chief of staff, U.S. army, 1921–22, and retired from the army as lieutenant general.

He became president (1923) and later chairman of the board (1930) of the Radio Corporation of America. Harbord died Aug. 20, 1947, in Rye, N.Y.

HARBOURS. A harbour is a refuge for ships, a port or haven, and is taken from the old English *hereberge* meaning protection or shelter. From the very earliest understanding of the term, a harbour was a sheltered arm of the sea in which vessels could be built and launched and taken for repair, or seek refuge in time of storm. One of the requisites was a good anchorage or holding ground. Such cargo as was carried by the vessel was transported to the shore by smaller craft or carried to the vessel by hand.

Natural harbours are those which, in themselves, are usable without resort to engineering works of improvement. Primitive harbours were almost always of this character. With the increase in size and draught of vessels, most of the so-called natural harbours have required works of extension and improvement. As a distinctive term, a natural harbour may now be considered as one located on an estuary or an enclosed bay.

Artificial harbours, in a more restricted sense, are those requiring construction of extensive engineering works, such as breakwaters for protection of the shipping from wave action, or harbours in which shallow or otherwise unsuitable areas have been excavated and deepened and other improvements made in order to make them available for the purpose intended.

The present article describes some of the more important and typical examples, both natural and artificial, the principles on which artificial harbours are—or should be—planned and the means by which natural facilities have been improved and supplemented by artificial works. The guiding principles to be followed in the making of small harbours are the same, *mutatis mutandis,* as those which are applicable to the great achievements of maritime engineering construction on which millions of money have been expended.

Breakwaters, which constitute the principal protection works of most artificial harbours, are described in a separate article; for the interior works and facilities of a port *see* DOCKS; river and estuarine harbours are also referred to in the article RIVER AND RIVER ENGINEERING; and for the lighting and buoying of harbours *see* LIGHTHOUSES and BUOY. *See* DREDGES AND DREDGING and JETTY and further particulars of individual harbours under place names; *e.g.,* CHERBOURG; RIO DE JANEIRO.

Classification. — Harbours may be classified in several ways:

1. Natural harbours, possessing, in a large degree, natural shelter. These require only the provision of such facilities as docks or piers, and sometimes deepening by artificial means, to make them serviceable as shipping ports. Such are the landlocked harbours of Hong Kong, Rio de Janeiro, New York city, Portsmouth and Sydney.

Some estuarine harbours, such as those formed by the lower tidal compartments of the Thames, Mersey and Yangtze, also come under this heading.

2. Harbours possessing partial natural shelter improved by artificial means; *e.g.,* Plymouth and Table bay.

3. Harbours entirely (or almost entirely) of an artificial nature formed on open sea coasts. A notable example of this class is Madras harbour (fig. 2).

Another classification, of an arbitrary and somewhat artificial nature, divides harbours according to their respective purposes; *e.g.,* harbours of refuge, commercial harbours, naval harbours and fishery harbours. It may be explained here that the term "harbour of refuge" (now almost obsolete) ordinarily denotes a harbour constructed specifically and primarily for the purposes of shelter (usually for small craft) and not as an essential factor of a naval or commercial port.

Still another method classifies harbours according to their physical characteristics and the nature of the artificial works employed for their creation or improvement; as for instance: (1) lagoon harbours; (2) jetty harbours; (3) harbours formed by converging breakwaters projected from the shore; (4) those protected by breakwaters parallel with the shore; (5) those formed by the projection of breakwaters from one or both horns of a bay; (6) harbours where island breakwaters cover and protect embayments; and (7) prefabricated harbours.

EARLY HISTORY

There is no conclusive evidence as to the date or the locality of the first artificial harbour construction. The use of natural havens and places of shelter must, of course, have been contemporary with the origins of navigation, and there are evidences of intercourse between Egypt and Crete in the predynastic period of Egypt more than 6,000 years ago. It is recorded on the Palermo stone that about 3000 B.C. King Seneferu built 60 great ships to go to the Syrian coast to bring cedarwood for his works. Gaston Jondet claimed, in *Les ports submerge's de l'ancienne Ile* de *Pharos* (Institut Egyptien, 1916) to have discovered on the seaward side of the island of Pharos an ancient harbour in the Cretan manner dating to 2000 B.C.; but the date and origin of these remains were disputed. The Phoenicians built harbours at Sidon and Tyre in the 13th century B.C. The second city of Tyre was built on a small island off the coast. T o harbours were built on the island, the Sidonian harbour on the north end and the Egyptian on the south end. The Sidonian harbour was built about 1100 B.C. and the Egyptian harbour was constructed by Hiram, king of Tyre, about 940 B.C. A main feature of this harbour was a 2,500-ft. mole formed of rubble stone surmounted by masonry walls. The true location of the southern or Egyptian harbour was not known until 1934–36, when Père A. Poidebard determined it by means of extensive investigation. (*See* L. H. Savilles, "Ancient Harbours," *Journal Inst. C.E.,* 1940.) Almost 600 years after the death of Hiram, Alexander the Great attacked the island from the land (332 B.C.) by building a 100-ft.-wide mole, one-half mile long in three fathoms of water, and captured and destroyed the city. The mole stopped the drifting sands and Sur, the ancient Tyre, became connected to Syria by a broad neck of land.

It was after the capture of Tyre that Alexander founded Alexandria and built the second harbour. He connected the Island of Pharos with the mainland by a causeway, called the Heptastadion—one mile long and 600 ft. wide. The two harbours lying east and west of the causeway were the Great Harbour and Eu-

nostos or the haven of happy return. The Great Harbour was protected on three sides by the mainland, the Heptastadion and the eastern end of the Island of Pharos. On the open or eastward side it was protected by a pier built out from the mainland and by a line of reefs which made entrance to the harbour difficult. It was for this reason that Ptolemy built the famous lighthouse of Pharos.

Many other Mediterranean harbours, both natural and artificial, were of considerable commercial or military importance in Greek and Roman times. The natural harbours of Tarentum (Taranto) and Brundisium (Brindisi) are still in use. Ostia, once the port of Rome, is said by some classical writers to have been founded in the 7th century B.C., but the port of the empire was built by Claudius and extended by Trajan about 100 A.D. (See *Proc.* Inst. C.E., vol. iv, 1845.) In Trajan's reign Centum Cellae (modern Civitavecchia) was founded 30 mi. N. of the Tiber mouth. As the name implies the harbour was provided with 100 covered *cellae* or dock for warships. Ostia, abandoned because of silting up of the approaches, is now more than one mile from the sea.

In mediaeval times the prosperity of such Mediterranean cities as Venice and Genoa led to the building of harbour works for the accommodation of their seaborne trade. Some of the early works at Genoa and on the Venetian lagoons remain to this day. Natural harbours suitable to the needs of the trade of the middle ages are more numerous in northern Europe than in the tideless Mediterranean sea, and for many centuries these natural facilities, combined in some cases with artificial works of the simplest character, sufficed for the shipping of the times.

One of the earliest protection works built at a seaport in England was the Cobb at Lyme Regis dating from the 14th century. This was a pier or jetty constructed of rough boulders held in place between rows of oak piles. A pier occupying the same site still bears its name. Harbour works are said to have existed about 1250 at Hartlepool and at Arbroath in Scotland *c.* 1394. Dover was a busy port in the time of Henry VIII., and a stone and timber breakwater was built there in his reign. Towards the end of the 16th century the first of the jetties at the entrance to the Yare at Yarmouth was constructed; and in the 17th century protection piers were built at Whitby and Scarborough, portions of which still exist. It was not, however, until the second half of the 18th century when John Smeaton (*q.v.*) began his career, that the building of harbour works on any considerable scale was undertaken in England, Smeaton must be regarded as the founder in England of the science of harbour engineering. His work and that of his successors, Thomas Telford and John Rennie, permanently established British seaports in the forefront of progress in harbour construction.

On the other side of the channel, Le Havre, Dieppe, Rochelle and Dunkirk were among the earliest ports to embark on harbour construction; in Bélidor's *Architecture Hydraulique* (Paris, 1737–53) is a detailed account of the early harbour at Dunkirk as well as of other ancient port works.

PRINCIPLES OF DESIGN

In designing the works of a harbour one of the most important considerations is that of exposure. Such information as can be obtained from reliable charts must be supplemented by more detailed marine surveys and soundings, and the nature of the sea bed must be ascertained by borings and probings. Among the points to be noted are:—the geological and other physical characteristics of the site; the slope of the sea bed; the depth of water seaward of the proposed site as well as over it; the presence of any outlying reefs, rocks, shoals or islands of which advantage can be taken as affording protection, or as good foundations for sheltering works; and the tidal phenomena, such as the vertical range. Investigation must be made of the nature and directions of the currents and tidal streams; the effect of littoral drift; the nature and extent of natural shelter; the directions of the prevailing and of the strongest winds; the line of maximum exposure, or the greatest fetch or reach of the sea in any unobstructed line of direction; the probable maximum height of the waves due to the exposure; and the direction from which the heaviest seas come. These and other considerations determine the character of the works to be constructed. In the case of harbours proposed to be made at the mouths of rivers or in estuaries, many other problems relating to river flow, bars, the maintenance of channels, etc., call for investigation.

There is a great diversity in the height of waves experienced in different positions on the same coastline. In some places shores lie open to the full force of the ocean waves while other parts of the same coast are protected by projecting headlands or islands, or by outlying reefs or sandbanks. Then again, inlets and enclosed arms of the sea, creeks, and river mouths, estuaries and land-locked lagoons provide sites more or less sheltered from wind and waves according to the degree of natural protection afforded them. At the other extreme is the exposed open site where breakwaters are necessary to protect an anchorage harbour, and where secondary breakwaters or piers may be required to provide local and complete shelter for the inner works of the port.

In planning a harbour to be formed in an exposed situation, certain important points must be kept in view, *e.g.*, (1) The entrance should be so placed as to afford ample sea room, free from rocks and shoals on a lee shore, for a vessel when on the point of entering or immediately after leaving the shelter of the outer and covering breakwater or breakwaters. (2) The alignment of the works should be such as to minimize the wheeling effect of waves around a breakwater head and the projection of seas across the entrance. (3) If possible the entrance should be so placed that one breakwater overlaps the other in such a way that some shelter from the direction of the heaviest seas is afforded to a ship when passing the harbour entrance. (4) The entrance should be planned so as to avoid strong currents sweeping across it. (5) Ample expending beaches or wave traps should be provided inside a harbour whose entrance is exposed, to allow the waves that pass the entrance to spend and break themselves. For this reason such a harbour surrounded with vertical walls, where there is not ample spending room, becomes a "boiling pot" of reflected waves; and in these circumstances sloping walls are preferable.

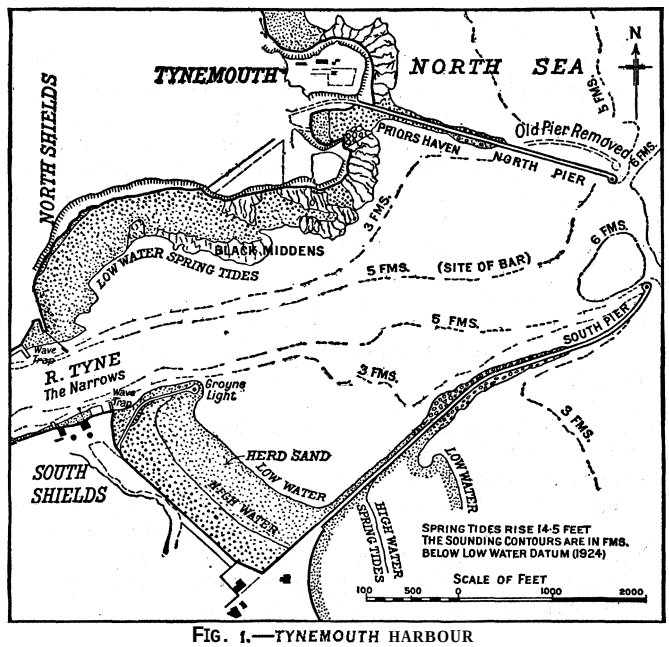

FIG. 1.—*TYNEMOUTH* HARBOUR

(6) The width of entrance, while being sufficient for the safe passage of ships, should be restricted as much as practicable, for upon the relation of the entrance width to the internal width and area of the harbour largely depends the reduction of range[1] of sea waves particularly when they are propagated into a harbour; *windlop* describes the short wind waves generated in narrow waters as distinct from the ocean wave. The amplitude of the vertical motion of a ship due to range of waves is known as *scend; tidal range* is the vertical rise and fall of a tide; *tidal rise* the height of a tide at high-water above the chart datum which is usually the level of the lowest low-water.

[1] *Range*, applied to waves, denotes the vertical rise and fall of

BAY, ESTUARY AND DEEPWATER RIVER-HARBOURS

1. The inner harbour, entrance lock and docks at Le Havre, France, before World War II. The port works suffered considerable damage during the war. Originally constructed in sheltered water at the mouth of the Seine estuary, the port was later extended into more exposed water
2. View of New York harbour showing the Upper and Lower bays and the harbour entrance with the Atlantic ocean in the extreme background. The East and Hudson rivers, important arteries of coastwise and inland commerce, are in the left and right foregrounds respectively
3. Hone Kong harbour as seen from the heights above Victoria, capital of the island of Hong Kong. The naturally sheltered harbour, 10 sq.mi. in area and possessing an east and a west entrance, is one of the chief ports on the coast of China
4. Group of the older docks at Liverpool, England, including the Sandon entrance and half-tide dock entered from the river Mersey. The docks at Liverpool and at Birkenhead on the opposite side of the Mersey cover an enclosed water area of more than 650 ac. and are provided with more than 37 mi. of quayage
5. The harbour at Alexandria, Egypt. The city occupies a strip of land between the Mediterranean and Lake Mareatis, also a peninsula which forms two harbours
6. Palermo, Italy, bay and harbour. The harbour has a water area of 144 ac. and quayage of about 9,000 ft.

NATURAL AND JETTY HARBOURS OF EUROPE AND AMERICA

1. View of Gibraltar harbour on the bay of Algeciras. The commercial moles are used as a wharf for naval destroyers. There are three breakwaters, two of which are connected with the shore on the north and south. The third is on the west. The port has been valued chiefly as a naval harbour
2. The harbour at Hampton Roads, Va., a natural harbour large enough to accommodate 1,000 ships. Newport News is in the foreground
3. Aerial view of Dieppe, France, on the English channel. The entrance from the outer harbour is protected by jetties (background) and leads into the winding Arques river, along which are quays for the accommodation of vessels drawing up to 20 ft.
4. View of waterfront, San Francisco, Calif., showing the Golden Gate bridge, and in the background the San Francisco-Oakland Bay bridge
5. Grand harbour of Valletta. Malta. a bav harbour further protected by two breakwaters. It affords anchorage-for the largest war vessels
6. Vancouver, B.C., Canada's chief western port and one of the finest natural harbours on the Pacific coast. Situated on Burrard inlet, an arm of the Strait of Georgia, it is the principal westward outlet of Alberta's wheat crop and is served by many steamship lines

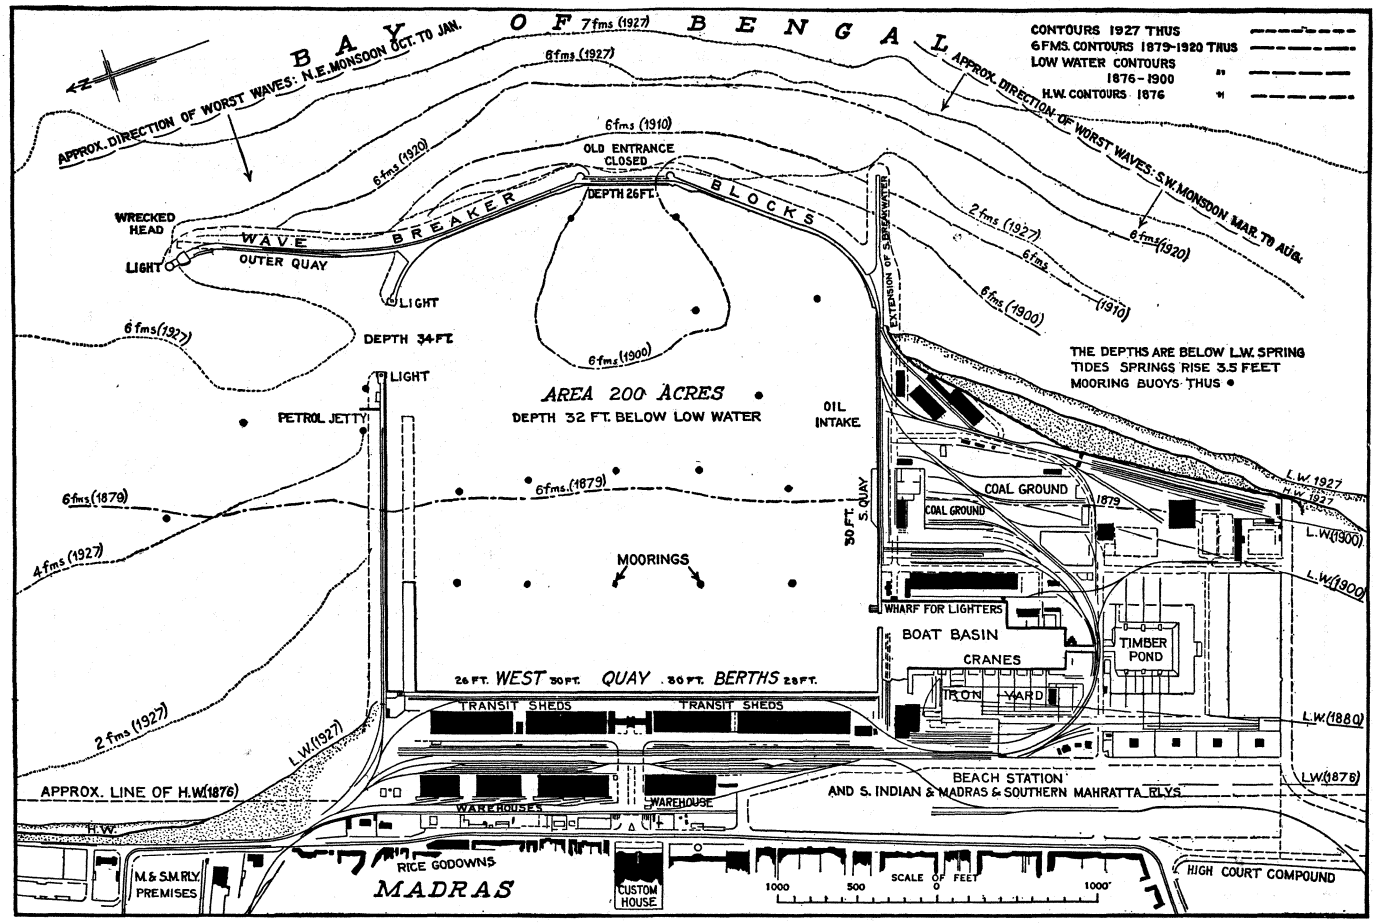

FIG. 2.—MADRAS HARBOUR

in the latter. (7) The entrance width to a tidal harbour must not however be so restricted as to produce through the opening a current interfering with safe navigation. (8) The approaches to the entrance from seaward should not be obstructed by submerged dangers in or close to the recognized channel. If there be any such dangers in the vicinity of the harbour entrance they must be removed or, at least, suitably marked. (9) There should be sufficient extra depth of water (over the nominal depth of the harbour) in the approaches and at and near the entrance to allow for the effect of range.

Waves.—The action of waves on solid structures is discussed under BREAKWATER (*q.v.*), and for theories concerning them and their phenomena *see* WAVES OF *THE* SEA; the writings of the authorities mentioned in those articles should also be consulted. Here we will mention one matter closely connected with the selection of harbour sites.

The height of waves depends mainly on the strength and duration of the wind, and the fetch or distance the waves have run. The importance of this last factor can be realized when it is considered that the sea is always smooth under the windward shore, regardless of how strong the wind may be, or for how long it has been blowing. Studies at the Scripps Institute of Oceanography, Woods Hole, Mass., of the basic energy relationships between wind and waves made by H. U. Sverdrup and W. H. Monk, showed that a 40-knot wind blowing for a sufficient duration to generate the highest waves will produce a 7-ft. wave when the fetch is 10 mi., a 19-ft. wave when the fetch is 100 mi., and a 36-ft. wave when the fetch is 1,000 mi. This relationship presupposes unobstructed deep water, for waves of great height cannot reach any coast line or artificial obstruction unless there is an unbroken stretch of deep water for their propagation. Reefs and sandbanks, even though entirely submerged, materially reduce the range of undulation; and a sudden change in the level of the sea bed, even in comparatively deep water, may produce a breaking wave. The heights of waves are increased when they are propagated up tunnel shaped or converging channels and are decreased when they pass into expanding channels.

Effect of the Angle of Incidence of Waves.—*If* the line of the outer face of a harbour work, such as a breakwater, is at right angles to the direction of the waves, the blow delivered by a wave against the solid structure will be at its maximum. When, however, seas strike the face in an oblique direction so as to be deflected towards the breakwater head and harbour entrance, the waves will sweep across the entrance, or wheel round the head, thus causing a turbulent cross sea at the point where vessels enter or leave the harbour. It is an advantage when the face of the breakwater can be aligned so that the heaviest seas assail it obliquely at such an angle that the waves are deflected away from the entrance and towards the inner or shore end of the structure. But in such cases the shore must be adequately protected, naturally or artificially, against scour.

It is a matter of common observation that the direction of waves is sometimes changed on passing a headland and that they will wheel round and enter a bay on the lee side of the head and break on a lee shore. A similar effect is often noticed in the case of islands and it frequently occurs at the head of breakwaters. The phenomenon is no doubt due to the frictional retardation of the inshore portion of the wave in shallow water. The deflection of waves during their passage up a wide channel between two shores is susceptible of similar explanation. Even if the wind is blowing and the waves are travelling up the channel in the direction of the centre line, the waves will be deflected and curve round so as to approach the shore on lines almost parallel with it.

Spending Beaches and Range.—*The* best method of quickly reducing the height of waves entering a harbour is to secure their lateral expansion. This may be effected by widening the harbour immediately inside the entrance and providing for expending beaches; or by intercepting, by means of spurs, groynes or wave traps, the ends of the entering waves, thus admitting of endwise expansion after the interception has taken place; or by a com-

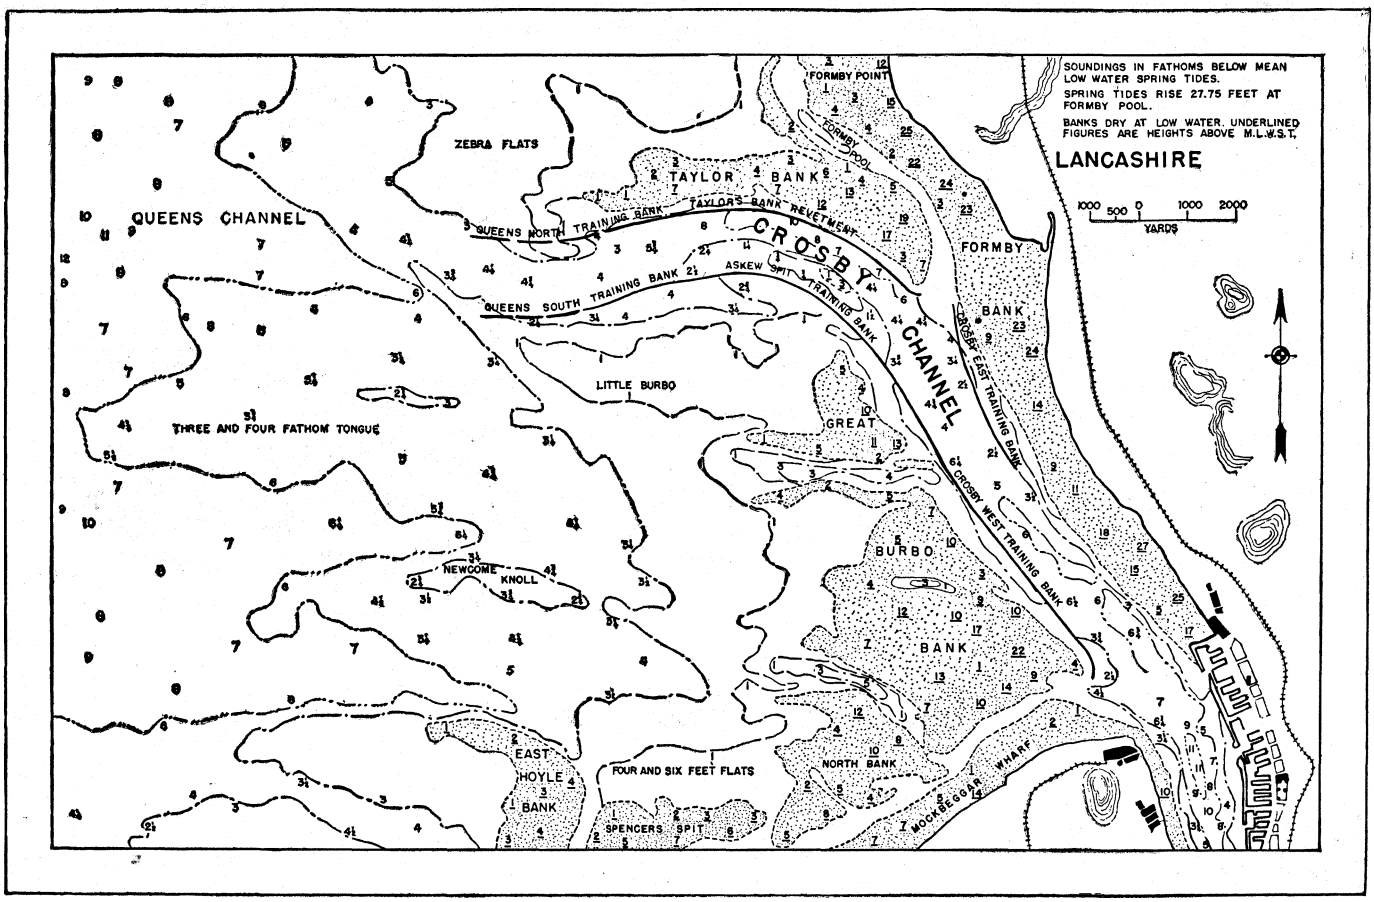

FIG. 3.— LIVERPOOL BAY AND MERSEY ENTRANCE CHANNELS

bination of these means. (See *Proc.* Inst. C.E. vol. CCIX, **1921.**) The first method is the more effective and is to be preferred for harbours whose entrances are exposed to heavy seas. The harbour at the Tyne entrance (fig. 1) illustrates the combined effect of widening within the breakwater heads, expending beaches and wave traps. Waves **30** ft. in height have been observed just outside the entrance during a sustained gale from the northeast. The reduction of range between the pierheads and the Narrows at Shields, a mile inshore, is more than 90%. The entrance between the outer pierheads is 1,180 ft., and the greatest width in the outer harbour is about 5,000 ft. The arrangement of breakwaters and spending beaches in the outer harbour at Sunderland, Eng., and in that at Ymuiden, Neth., is somewhat similar to the Tyne. Wave traps are frequently introduced in the planning of jetty harbours. (See below.)

TYPES OF HARBOURS

Natural Harbours.— A sheltered anchorage in its simplest form is sometimes found under the lee of outlying reefs, sandbanks or islands. Where there is good holding ground and the shelter afforded is sufficient to give protection from heavy seas, such an anchorage is termed a roadstead. Examples are the Downs under the shelter of the Goodwin sands; Dunkirk road, under the lee of the Braekbank sand; Yarmouth roads and the anchorages in sheltered positions in some wide estuaries such as that of the Thames. Others are found in deep embayments where shelter is afforded from the worst winds by projecting headlands, as in Weymouth and Portland roads. A well-known example of a roadstead protected by an island is that sheltered by the Isle of Wight.

Natural havens to which the term harbour is ordinarily applied are those inlets or arms of the sea which are almost completely landlocked. Where such natural shelter is found combined with ample depth of water, both in the approaches and in the anchorage, and in positions convenient for sea-borne trade, it is of great value to shipping; such havens, even without artificial works, serve as harbours of refuge, and the necessary interior works of a port can usually be constructed in them without difficulty and at much less cost than in an exposed and open situation. Well-known examples in addition to those already mentioned are the harbours of Port Royal and Kingston in Jamaica, Southampton Water, Eng., the landlocked sea inlets of San Francisco, Calif., Cromarty Firth and Scapa Flow, Scot., Milford Haven, Wales, Queenstown, Ire., Falmouth, Eng., and Kiel, Ger. In many situations, however, there are large enclosed water areas having openings into the sea which are either obstructed by a bar at the entrance, as in the lagoon harbour of Venice and the enclosed bay harbour of Durban, or are shallow. Works of considerable magnitude are often required for the improvement and maintenance of such harbours.

Estuary Harbours and Entrances.— Some rivers which possess sufficient depth of water in the tidal compartment for the navigation of vessels of considerable draught up to the docks or wharves of the port are obstructed in the estuary, or where they discharge into the open sea, by banks of sand or silt which, sometimes, are liable to change of position. In other estuaries the approach channels from the open sea to the river proper may be sufficient for all the requirements of shipping while the river channels are of insufficient depth.

Not only are such obstructions or bars met with in the estuaries of rivers which discharge into seas that are either tideless or of small tidal range, but they are frequently present when the rise and fall of the tide is considerable, as in the Mersey (fig. **3**). Rivers opening out into large expanding estuaries, such as the Severn, Scheldt and Clyde, are usually free from bars; and rivers which gradually widen out as they approach the sea are not ordinarily impeded by bars, though they may be obstructed by sandbanks, as in the Thames and Humber, through which the tidal streams form good channels to the sea. The formation of a navigable channel through a bar, or the improvement of natural channels to provide for the increased draught of vessels. has been effected in a few cases by dredging alone, in some by training

works or jetties, and in many cases by a combination of the two methods. The Mersey at Liverpool and the harbour of New York city are notable examples of the first case of estuarine conditions embracing the presence of a bar with deep water in the river above it.

The Mersey Entrance.—The inner estuary of the Mersey has a depth in some places of about 63 ft. at low water; however, by 1890 the bar in the principal channel maintained a depth of 10 ft. to 12 ft. at low tide. In 1890 dredging started which was later carried on continuously and there was no difficulty in maintaining a go-ft. depth over the bar. By 1906, 105,000,000 tons of material had been removed. However, despite the dredging the Queen's and Crosby's channels were becoming more and more distorted and growth of what later was named Taylor's spit continued. (See fig. 3.) To fix the channel and prevent its encroachment on Taylor's bank, and in an effort to lessen the dredging required, building of the various submerged revetments and rubble stone training walls was begun in 1909 and proceeded almost continuously except for interruptions during World Wars I and II. As many as 22,000,000 tons were dredged from the sea channels in one year (1936), but after World War II this quantity was less than 10,000,000 tons annually. Construction of the Queens training banks was still proceeding at mid-century. It was hoped that when the training works had reached their full length, the tides would work together and drain the river automatically. For the complete history of revetments and training walls in the sea channel approaches, see J. A. Cashin, "Engineering Works for the Improvement of the Mersey," (Journal *Inst.* C.E., May 1949).

New York Harbour Entrance.—Until 1885 the natural channels in the southern approach to New York harbour sufficed for all the requirements of shipping. The Gedney channel had then a depth of about 24 ft. at low water and about 28 ft. at high water neap tides. Above the sandbanks which obstruct the lower bay there was ample natural depth—more than 44 ft. at low water—in the harbour (fig. 4).

In 1885 the deepening of the Gedney channel by suction dredging was commenced and by 1892 30 ft. at low water had been obtained over a channel width of 1,000 ft.

In 1899 Ambrose channel, an entirely artificial and shorter dredged cut through the sand banks, 40 ft. deep and 2,000 ft. wide, was started. In 1939 both channels were deepened an additional five feet. The dredging of the Gedney channel was the earliest successful attempt to mainain an open channel through exposed sandbanks by means of dredging alone.

Such attempts had been made, for instance, at the bar at the mouth of the practically tideless Mississippi where, for years before the training works were commenced (see RIVER AND RIVER ENGINEERING), a dredger was employed for forming a channel for the waiting vessels, the channel, however, silting up almost as rapidly as it was made.

Other Instances of Dredging.—Suction dredging of the open sea channels of many estuaries has been carried out with success, as for instance. in the Scheldt which gives access to Antwerp, Belg.; in the Rio de la Plata in the approaches to Buenos Aires, Arg., and Montevideo, Urug.; in the sea approaches to Brisbane, Queensland, and through the sea bar known as the Fairy Flats at the mouth of the Yangtze. The success of these operations has only been made possible by the improvements effected in the construction of large and powerful sand pump dredgers (see DREDGERS AND DREDGING).

Lagoon and Jetty Harbours.—The formation or improvement of harbours on the sea coast by the construction of jetties across the beach and foreshore, at points where river mouths or lagoons or, in some cases, low marshy land afforded suitable sites, has been practised for more than 200 years.

Lagoons.—A marine lagoon is a shallow lake separated from the sea by a narrow belt of coast formed of deposit from a deltaic river or of sand dunes heaped up by onshore winds along a sandy shore. Many such lagoons possessing good natural shelter have outlets which are maintained through the fringe of coast, even when the tidal rise is quite small, by the scour of the water flowing into and out of the large expanse at each tide, aided by the discharge from any rivers falling into it. These outlets afford navigable access to the lagoon in which, moreover, natural channels are formed by the action of the currents. Because of the scour of the issuing current becoming gradually too enfeebled, on entering the open sea, to overcome the heaping up action of the waves along the shore, the sea entrance to a lagoon is however usually obstructed by a bar which tends to form a continuous beach across the opening.

The depth over the bar in front of a lagoon entrance can sometimes be improved by concentrating the current through the outlet by jetties on each side. This has been done with success and, up to a point, without recourse to dredging, in the cases of the three entrances to the lagoon harbour of Venice at Malamocco, Lido and Chioggia, where the tidal range at springs is no more than three and one-half ft. (fig. 5). At Malamocco the low-water depth on the bar was increased from $11\frac{1}{2}$ to 31 ft., and at the Lido entrance from 8 to more than 22 ft. The two training jetties at Chioggia, completed in 1934, resulted in the channel over the bar being scoured to a depth of 20 ft. Since 1921, however, the Lido entrance has been dredged in order to maintain a low-water depth of 30 ft.

Dredging, in combination with the scour induced by jetties constructed after 1909, provided a deep entrance channel through the bar at Rio Grande do Sul on the southeast coast of Brazil which formerly obstructed the access to a series of deep landlocked lagoons of very large area. On the other hand dredging alone is relied on to form and maintain a channel 40 ft. deep through the bar which fronts the narrow entrance to a lagoon of great extent and depth at Cochin on the southwest coast of India, and the construction of jetties is not intended.

Jetty Harbours in English Channel, *etc.*—On the sandy shores of the English channel and North sea there are several well-known harbours where, formerly, flat marshy ground, lying below

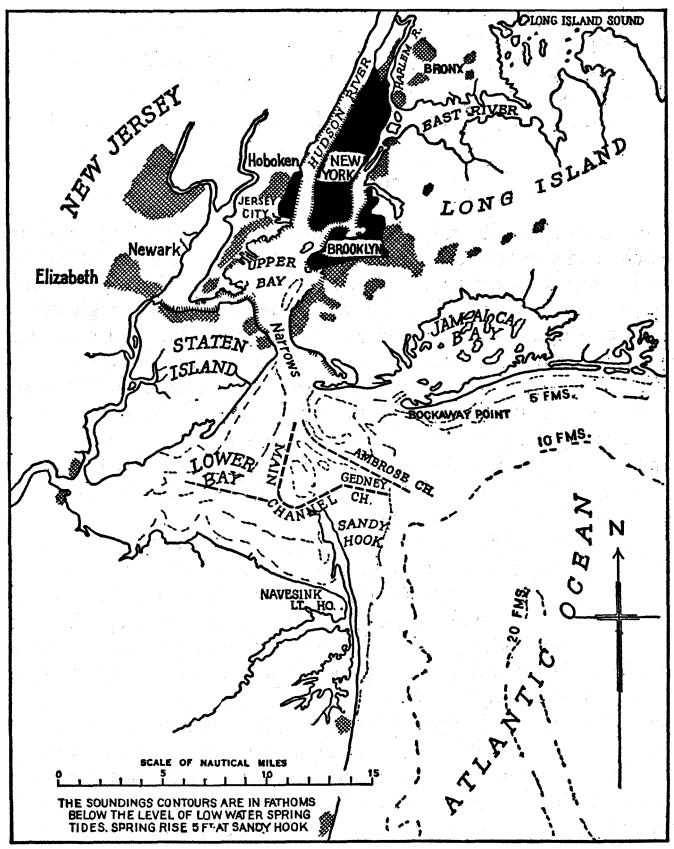

FIG. 4.—NEW YORK HARBOUR

the level of high water and shut off from the beach by dikes or sand dunes, was connected with the sea by a small creek or river. In their original condition these ports presented some resemblance, although on a very small scale, to lagoons. Such are the old harbours of Dieppe, Boulogne, Calais and Dunkirk, Fr.,

and Nieuport and Ostend, Belg. The passage of water from these tidal areas through a narrow opening served to maintain a shallow channel to the sea. When deeper channels were required the scour was concentrated by erecting jetties across the beach. This obstruction to the littoral drift of sand caused a building-up of the beach, and as a reclamation of the low-lying areas was effected, the tidal scour was reduced. Sluicing basins were therefore formed into which the tide flowed; the water, being shut in at high tide by gates or sluices, was released at low water producing a rapid current through the channel. The sluicing current, however, gradually lost its velocity in passing down the channel and was not effective in maintaining the full length of the channel. The introduction of powerful mechanical dredging appliances, particularly the improved suction dredgers, led to the substitution of dredging for artificial sluicing, and made it possible to form and maintain channels of uniform depth.

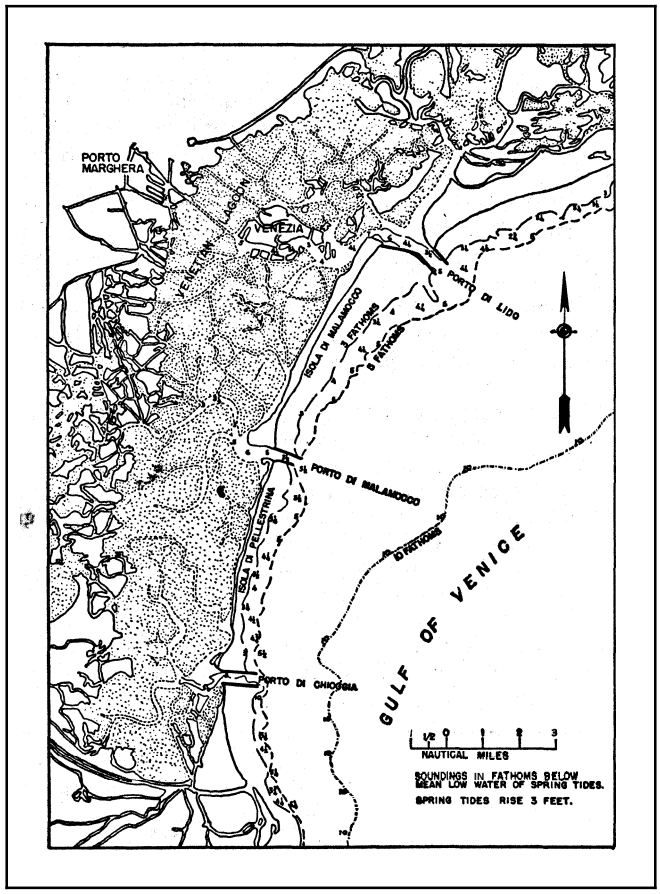

FIG. 5—THE VENETIAN LAGOON

During the past half century jetty construction has been applied with varying success to the improvement of harbour entrances on a much larger scale than in the channel ports, not only in Europe but in America and other parts of the world, particularly where a river having a considerable flow or an extensive backwater provides the means for effective scour. Instances where scour alone has been effective in securing depths sufficient for large vessels are rare, and dredging has generally to be resorted to for this purpose. It should be noted here that entrances formed by jetties with a narrow channel between them are, from the point of view of the navigator, unsatisfactory in positions of considerable exposure on the open coast, particularly at ports used by large vessels.

Jetty Harbours in North America.—In the United States there are many examples of jetty harbours. At Charleston, S.C., for instance, a landlocked bay 15 sq.mi. in extent and with ample depth of water, provides an adequate harbour, but the narrow entrance was obstructed by a bar. Converging entrance jetties, each more than two miles long, with openings at their inner ends, were constructed to concentrate the scour, caused by the tidal range of about five and one-half feet at springs, and to protect the channel from littoral drift. The jetties, however, caused an advance of the foreshore and a corresponding progression seaward of the bar with the result that extensive dredging is required to maintain a low-water depth of 30 ft. beyond the ends of the jetties and in the channel. At Aransas Pass, Tex., in the Gulf of Mexico, two jetties have been constructed at the narrow sea entrance to a lagoon or enclosed bay through which a dredged channel, 21 mi. long, and 32 ft. deep has been made between the pass and the port of Corpus Christi. In addition a 25½-ft. channel, seven miles long, branches off from this channel to Encial. In this case the channel between the jetties was formed and maintained entirely by dredging.

Among other jetty entrances to lagoon harbours in the Gulf of Mexico are those at Sabine pass and Galveston bay. Sabine pass is the outlet into the Gulf of Mexico for Sabine lake and its two important tributaries, the Sabine and Neches rivers. The ports of Port Arthur, Orange and Beaumont are on the lake and the two rivers respectively. The bar and pass were improved by dredging and by the construction of two jetties extending from the entrances about four miles across the bar and into the Gulf. The pass was dredged to 34 ft. below mean low water. Bolivar channel, the outlet of Galveston bay on which lie the ports of Galveston and Texas City, also marks the end of the so-mi. channel to the inland port of Houston. Converging jetties from Galveston Island and Bolivar peninsula extend about four miles into the Gulf, and are one and one-half miles apart at their end. The bar was improved by the jetties, and by dredging to 34 ft., and extends nearly four miles into the Gulf of Mexico.

Lagoons of Coral Formation.—Lagoons of coral formation and waters sheltered by coral reefs often furnish valuable natural harbours as in many of the islands of Oceania; examples are Pago-Pago in the Samoan Islands and Honolulu in the Hawaiian group. In them the problems presented by sandy bars and entrance channels do not as a rule arise. Port Sudan in the Red sea is an example of a deepwater inlet, bordered by coral reefs rising to just above water level, which has been converted into a useful commercial port by the construction of low quay walls along the margin of the steep-to coral. The entrance is a natural opening 900 ft. in width through the coral reef.

Other Jetty and Bar Harbours.—The physical features of semiartificial harbours formed in lagoons, backwaters, enclosed bays and at the mouths of barred rivers, differ so much that they exhibit an almost endless variety of works applied to their formation and improvement. A few examples only can be mentioned here.

Hook of Holland.—When the artificial channel for the river Maas was cut, during the 1870s, from Rotterdam to the North sea at the Hook, the sea entrance was flanked by diverging jetties. Rapid silting in the entrance led to the construction of a third and internal jetty to contract the channel to a width of 2,100 ft., and thereby increase the scour. The low water depth of 30 ft. at mid-century was maintained chiefly by the tidal action, although some dredging was performed.

Durban.—The entrance to the landlocked harbour of Durban, U. of S. Af., (see Proc. Inst. C.E., vol. clxvi, 1906; cxciii, 1914; cxcvi, 1914) is between two nearly parallel breakwaters or jetties about 600 ft. apart, though the channel is no more than 400 ft. wide (fig. 6). Before 1883, when the first breakwater was begun, the bar at the entrance often shoaled so much that there was sometimes less than three feet of water over it. The constant travel of littoral drift from south to north across the harbour mouth almost completely neutralized the scour induced by the great volume of water flowing between the piers every tide, into and out of the large landlocked bay; and it was not until intensive suction dredging was employed, about 1896, that the low-water depth in the entrance was increased beyond 16 ft. It has since been steadily improved by continuous dredging until now a depth of about 42 ft. is available. Narrowness of the channel between the jetties has always made the entrance a difficult one.

Karachi *and Vizagapatam.*—Karachi, capital of Pakistan, is a natural harbour, with an ample backwater, extensive creeks, and

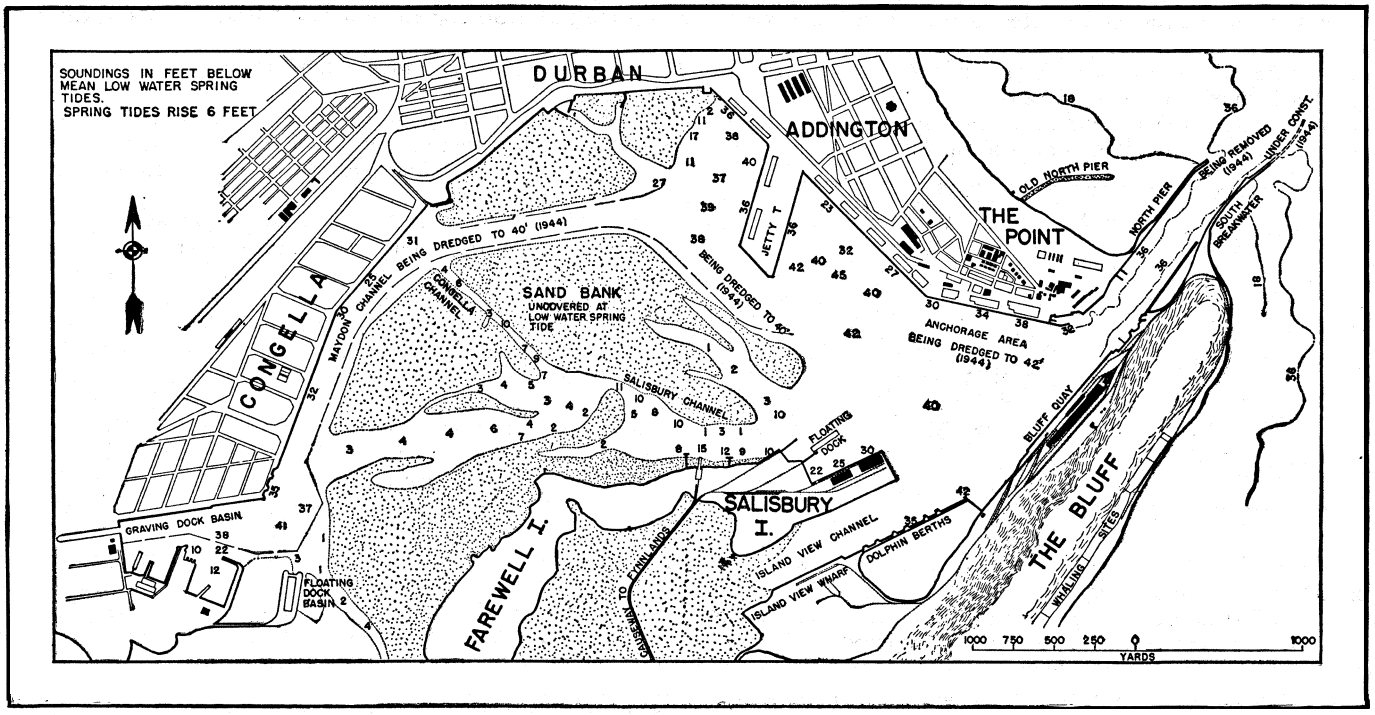

FIG. 6.—DURBAN HARBOUR ENTRANCE

a tidal range of eight and one-half feet, which has been developed by building entrance jetties and dredging, and by the construction of deepwater quays within the harbour. Somewhat similar natural conditions exist at Vizagapatam (spring rise, four and one-half feet), a port halfway between Madras and Calcutta, where there is a tidal creek and backwater of lagoon character with a narrow and shallow entrance in an exposed position on the coast line. Deepwater internal port works were begun in 1928 and an interesting and bold attempt was made to form and maintain, by dredging, a channel of 30 ft. at low water through the narrow entrance and into the backwater, protected by a rubble stone jetty on its northern side only. This attempt was attended with success and the least depth in the entrance channel in 1940 was 37 ft. This depth was maintained without difficulty for several years.

The channel leading to the harbour entrance was, in 1933, further protected on its south or weather side by the construction of an island breakwater about 1,000 ft. long of stone rubble, the nucleus of which was formed by sinking two old ships filled with stone in the desired position.

Lagos, the principal port of southern Nigeria, has an entrance 1,700 ft. wide, formed by dredging between converging jetties of rubble stone.

Australian Bar Herbours.—The harbour of Newcastle, N.S.W., the principal coal port of Australia, is in a backwater into which flows the Hunter river. The entrance was obstructed by a sand bar with less than 13 ft. over it at low water. Jetties constructed to shelter and improve the passage over the bar, where the spring rise is 5 ft., had little effect in the latter direction, but since 1905 dredging has increased the depth to about 26 ft., and a moderate amount of sand dredging suffices to maintain the channel depths. The width of channel between the jetties at the entrance, about 1,400 ft., is larger, on account of the exposure, than is usual in jetty harbours. Range in the harbour is considerable and the slight divergence of the jetties tends to increase it. Wave traps have been formed at the sides of the channel between the jetties.

Fremantle harbour, the principal port of Western Australia, at the mouth of the Swan river, has been made by the removal of a bar of rock and sand which completely blocked the entrance to the river. At the site of this bar and within it there is now a harbour 36 ft. deep at low water protected by jetty breakwaters. The river mouth is sheltered by outlying islands and shoals and the sand travel is not a serious problem.

New Zealand Bar Harbours.—Otago harbour, one of the few New Zealand natural harbours at which improvement works in the entrance have been necessary, is in the South Island. A training mole at the bar entrance, training works in the inner channel and a moderate amount of dredging have been effective in providing a channel with a least depth of 30 ft. at low water where formerly a sandy bar and inner shoals restricted it to about 15 ft. (See Proc. Inst. C.E., vol. cx, 1892; cxxi, 1895; and cc, 1915.) The harbour is a long narrow sea inlet at the head of which, about 11 mi. from the entrance, is situated the town of Dunedin.

Westport, on the west coast of the South Island and the principal coal port of the dominion, furnishes an example of the provision of wave traps (fig. 7) in an entrance between converging training jetties or breakwaters built in 1886–93. The position is one of moderate exposure, the entrance being open to the Pacific. The combined effect of the contracted river and tidal scour and a moderate amount of dredging has increased the low-water depth over the bar from 4 to about 18 ft., the rise of springs being $9\frac{1}{2}$ ft. (See Proc. Inst. C.E., vol. cxii, 1893; cxxxvi, 1899.) For other examples of jetty harbours at river mouths see JETTY and for harbours at river outlets see RIVER AND RIVER ENGINEERING.

Bay Harbours Protected by a Single Breakwater.—The adoption of a deepwater bay for a harbour reduces the necessity for providing artificial shelter and, in most situations, secures a site not exposed to silting, where sheltering works do not interfere with any littoral drift along the open coast. In favourable situations a deep and narrow bay or inlet may be sheltered by a single breakwater extended out from one shore across the outlet of the bay, having a single entrance between its extremity and the opposite shore. Sometimes—where the exposure is from one direction only approximately parallel with the coast line at the site, and there is some natural shelter in the opposite direction—a single breakwater extending at right angles to the shore, with a bend or curve inward at its outer end, suffices to afford the necessary shelter. An example of this form of harbour construction is Newhaven breakwater, Eng., protecting, on the west side, the approach to the river port which is somewhat sheltered from the moderate easterly storms by Beachy head. Other examples are Holyhead and Fishguard, Wales, Brixham, Eng., Victoria, B.C., and Valparaiso and other harbours on the Chilean coast. The Folkestone harbour pier is an example of a single curved breakwater, sheltering the harbour formed on its east and north sides,

which also has berths on its outer face used in heavy weather from the east or northeast.

Fishguard.—The harbour here was made by the building (1900–18) of a breakwater across Fishguard bay. The internal shelter was increased by the subsequent construction of a second breakwater thrown out from the shore in the middle of the bay.

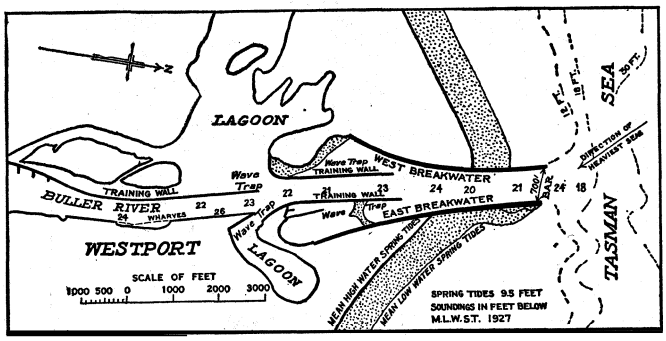

FIG. 7.— WESTPORT HARBOUR. NEW ZEALAND

Chilean Ports.—The breakwater at Valparaiso (see BREAKWATER) is a remarkable structure projecting from the western shore of Valparaiso bay. The seaward termination is in a depth of 180 ft. of water. The water area, fully sheltered by the breakwater approximately 3,230 ft. long, is small and the cost (reported to be almost £800 per lineal foot) very large in proportion to the benefit.

Single breakwaters were also built in the bays of San Antonio (1911–18) and Antofagasta (1918–27). In each of these cases the breakwater is bent in plan having two straight arms connected by a curved portion. The sites are somewhat more sheltered than Valparaiso bay and the depths of water considerably less. The outer arm of the Antofagasta breakwater was almost completely demolished within a few hours on Aug. 9, 1929; but the work was later rebuilt. At both harbours piers and other inner port works were reconstructed under the lee of the breakwater.

Island Breakwaters Protecting *Embayments*.—A well-known example is the breakwater converting the natural harbour of Plymouth, Eng., into a place of almost perfect shelter. Plymouth sound, one of the most famous and historic roadsteads of the world, and the deep inlets or creeks above it, form a harbour into which fall the rivers Tamar and Plym. The breakwater is one mile in length, stretching across the middle part of the sound. Begun by John Rennie in 1812, it was completed about 1827. In the harbour itself are the naval dockyard establishments at Devonport and Keyham, and a small commercial dock and port works at Millbay and in the Cattewater.

Cherbourg.—The breakwater across the wider but shallower bay forming Cherbourg harbour and roadstead, in France, is another example of an island structure but in a more open and exposed position than Plymouth. Begun in 1784, its construction was continued under Napoleon, but it was not completed until 1858. More than $2\frac{1}{4}$ mi. in length it is built, for the most part, in a depth of about 42 ft. at low water. It is of composite construction, a solid superstructure surmounting a rubble stone mound. The sheltered water area is more than 2,000 ac. in extent, but less than one-half of this is of sufficient depth for large vessels. The two entrances on the east and west are between the breakwater ends and islands which are joined to the mainland by breakwater walls. In 1933, deepwater quays were brought into use, having a depth alongside of 46 ft. at low water.

Delaware Bay.—The Delaware breakwaters at Cape Henlopen, Del., the south horn of the entrance to Delaware bay, are both of the island type. The first, built (1828–69) inshore under the shelter of the headland, is the prototype of American rubble-mound breakwaters. The national harbour of refuge of about 800 ac. formed outside the old breakwater by the U.S. government (1897–1901) is protected by a rubble-mound breakwater 8,025 ft. in length built in a depth at low water of about 30 ft.

Another excellent example of island breakwaters is that at Duck Island harbour, near Grove Beach, Conn. Two breakwaters projecting at right angles from Duck Island partially enclose a 16-ft. anchorage basin and a third breakwater one and one-half miles to the southwest protects the anchorage from the remaining exposure.

Island breakwaters frequently form portions of the artificial protection of harbours in conjunction with breakwaters projected from the shore line. Some examples of this combination are referred to hereunder.

Bay Harbours with Two or More Breakwaters.—The method most generally adopted for the completion of the shelter of deeply indented bay harbours is the construction of a breakwater extended across the outlet from each shore, leaving a single entrance between their ends, where usually the deepest water is found as at Peterhead, Scot., and Monaco. If one breakwater placed somewhat farther out is made to overlap an inner one, and so cover it to some extent from the direction of the heaviest seas, a more sheltered entrance is sometimes obtained. This arrangement was adopted when additional protection works were built at the entrance to the old bay harbour at Genoa (fig. 8) and for the harbour in Bilbao bay, Sp., at the mouth of the Nervion. The breakwaters at Valletta, Malta, and those at the entrance to the almost landlocked Spanish naval harbour at Cartagena are also planned in this way. Many harbours formed in wide or open bays, and in other positions where some abrupt projection from the coast line has been utilized as providing shelter from one quarter, have their protection completed by two or more breakwaters enclosing the site. Dover (fig. 9) and Colombo, Ceylon, (fig. 10) furnish typical and somewhat similar examples. Both of these were begun

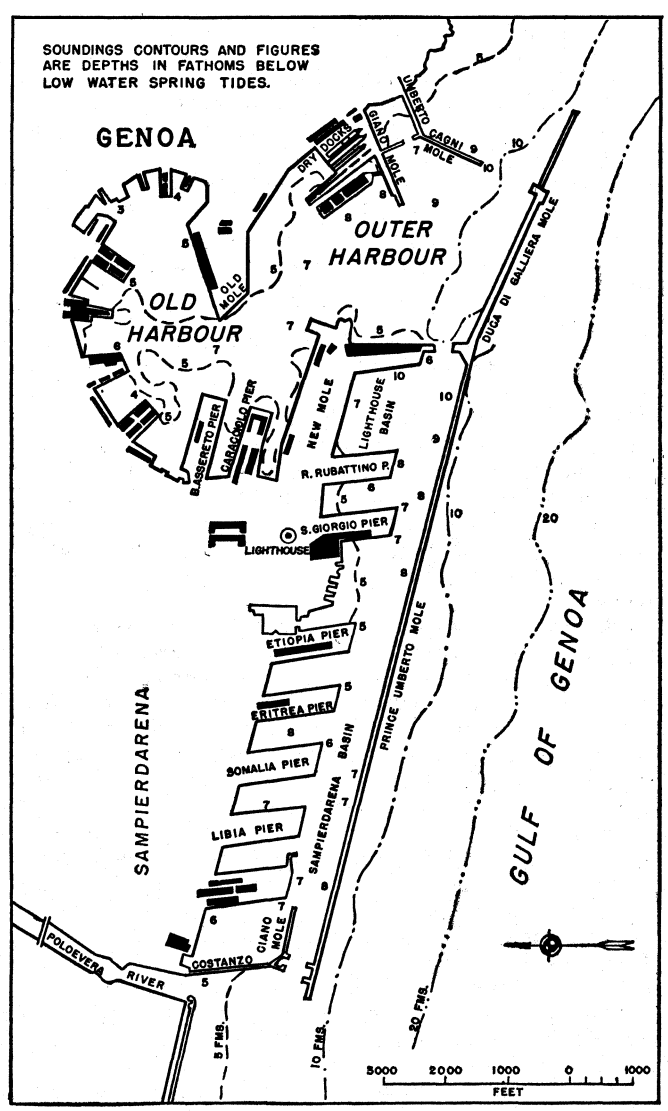

FIG. 8.—GENOA HARBOUR

as single breakwater harbours, and their conversion into enclosed harbours was not completed until many years later.

The extension of artificial shelter has often been brought about not only by the demand for more complete protection against heavy seas and consequent range in a harbour, but also by the growth in the dimensions of ships and the increase in the trade of a port. Thus, greater depth of water and extended accommodation have been obtained at one and the same time with the improvement of the shelter by building additional breakwaters.

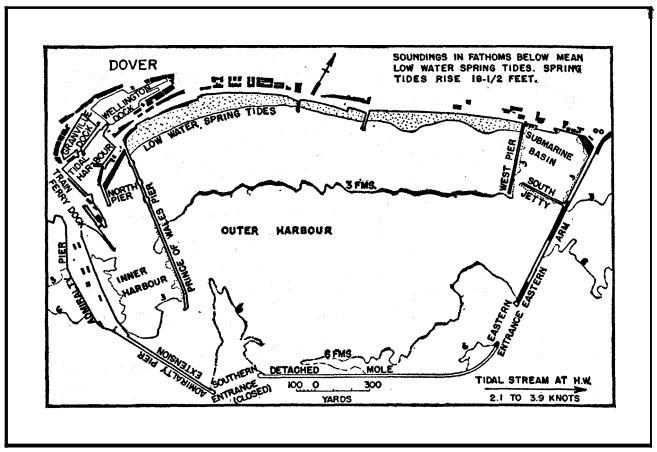

FIG. 9.— DOVER HARBOUR

In some instances a wide or exposed entrance to a harbour formed by breakwaters thrown out from the shore has been sheltered by an island breakwater built in front of the opening and thus providing two entrances, one at each end of the island structure; Bizerta, Tunisia, and Cette, Fr., furnish examples. In other cases, as at Dover, Portland and Colombo, the line of breakwaters enclosing the harbour has been made discontinuous, two, and in some cases more, openings being formed between them. The Gibraltar harbour works (1893–1904), made in the sheltered Bay of Algeciras on the west of the rock, include a detached mole with two entrances between it and the breakwaters which are connected with the shore.

Dover.—This is an example of an artificial harbour formed on a coast of moderate exposure—the narrowest part of the Straits of Dover. The nucleus of the harbour which exists today was the Admiralty pier, commenced in 1844 and extended to form the western arm of the outer harbour. The pier afforded shelter from the south and west, and protection from the north is given by the coast line and was increased later by the building of the Prince of Wales pier. The works carried out between 1897 and 1909 enclose a low-water area of 690 ac. and comprise, in addition to the Admiralty pier, now 4,000ft. long, an island breakwater of 4,212 ft. and an eastern arm of 2,942 ft. connected with the shore (*see* BREAKWATER). The harbour was handed over by the admiralty to the Dover harbour board in 1923 for commercial use, and it has been proposed, with the object of reducing the severe range in the harbour, to close the western entrance (740 ft.), leaving only the eastern opening (650 ft.) available for shipping.

Portland.—The refuge and admiralty harbour of Portland furnishes an instance of the conversion of a naturally sheltered roadstead into an enclosed harbour by the construction of breakwaters projecting from the horns of a bay. The Isle of Portland—actually a peninsula joined to the mainland of Dorset by the Chesil bank—shelters the roads from the south and the anchorage is exposed to storms only from east to south. The southern, or inner, and the eastern, or outer, breakwaters were begun in 1849 and completed in 1872, the latter being in eight to ten fathoms at low water. Later two additional breakwaters were added, one projecting from the Bincleave rocks near Weymouth on the north side, and the other, an island structure, on the northeast of the harbour. The last was finished in 1904, the building of the later breakwaters being carried out, partly at any rate, as a protection against torpedo attack. There are three entrances between the four breakwaters; but one of them, the southern, was closed in 1914 by sinking a blockship in it, and it is not proposed to reopen it. The breakwaters have a total length of three and one-fourth miles and shelter a water area of four square miles. Portland is one of the largest artificially enclosed harbours in existence.

Colombo.—The artificial harbour at Colombo (fig. 10) begun in 1875, occupies an exposed situation in an embayment on the west coast of Ceylon. The site is sheltered to some extent from southerly winds and to a lesser degree from the north. The breakwaters are fully exposed to westerly gales from the Indian ocean. The southwest breakwater, the first to be constructed, is 4,212ft. long and was completed in 1885 (see BREAKWATER). Two additional breakwaters, the northwest and northeast, 2,670 ft. and 1,080ft. respectively, were built between 1892 and 1906, thus completing the enclosure of the harbour except for two openings of 800 and 700 ft. respectively. The shelter afforded was still in-

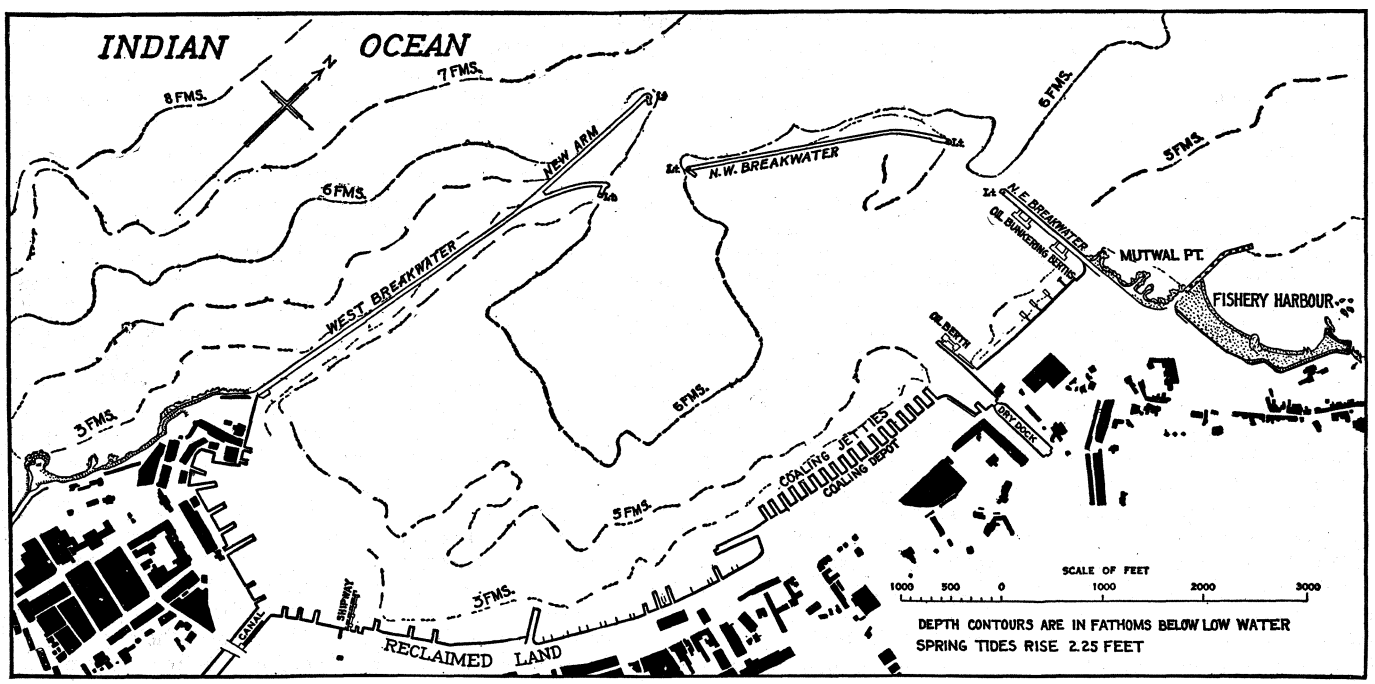

FIG. 10.— COLOMBO HARBOUR. CEYLOW

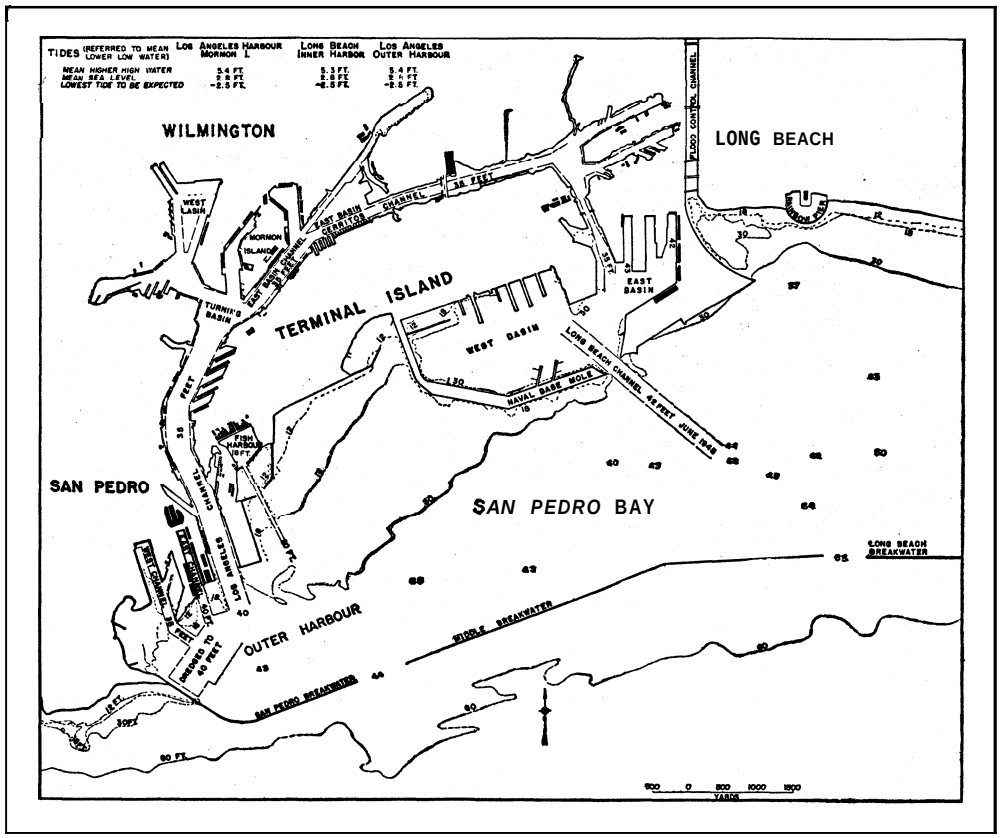

FIG. 11.—LOS ANGELES HARBOUR

sufficient to tranquilize the northern part of the water area, where are situated most of the coaling and oil berths, during the southwest monsoon. Consequently a sheltering arm, 1,800 ft. in length, was completed in 1912 as an extension of the original southwest breakwater. The harbour has an area of 643 ac. Of this 246 ac. are dredged to greater than 36 ft.; another 246 ac. are dredged to 30 to 36 ft., and the remainder is less than 30 ft. deep. The western entrance has a navigable depth of 36 ft. above low water and the navigable depth at the northern extrance is 30 ft.

Le *Havre.*—The outer harbour at Le Havre furnishes an example of a port, originally formed in a sheltered embayment along the margin of an estuary, where it has been necessary to build long breakwaters extended into more exposed waters, in order to provide the additional accommodation demanded by its increasing trade. The modern deepwater quays in the tidal outer harbour are situated on areas which have been reclaimed from the sea under the shelter of the breakwater walls.

Los Angeles and Long Beach.—The outer harbours of Los Angeles and Long Beach on San Pedro bay furnish examples of ports, originally protected by a single embayment, later protected by several breakwaters. From 1912–37 the outer harbour of Los Angeles, on the western side of San Pedro breakwater (fig. 11), was protected by the 11,152-ft.-long San Pedro breakwater extending eastward from Point Fermin. In 1937 a 12,500-ft. section of island breakwater, separated from the San Pedro breakwater by a 2,200-ft. opening, was completed. This island breakwater has been extended in the easterly direction an additional 6,000 ft. A second island breakwater separated from the first island breakwater by a 1,800 ft. opening was to extend due east an additional 13,350 ft. The total protected area in the Los Angeles-Long Beach outer harbours would amount to approximately 6,000 ac. upon completion of the island breakwater. The entrance channel to the Los Angeles harbour is dredged to 40 ft. and the channel to Long Beach is dredged to 45 ft.

The inner harbour at Los Angeles contains a water area of approximately 900 ac. dredged to 35 ft., and consists of a series of channels with turning basins and numerous slips. Cerritos channel, 400 ft. wide and 35 ft. deep connects the inner harbour of Los Angeles with the inner harbour at Long Beach.

The harbour at Long Beach was originally protected by the 7,300-ft. curved breakwater sheltering the area known as the East Basin. The series of breakwaters extending eastward from Point Fermin now afford protection to the Long Beach outer harbour, and a second curved earth-mole-type breakwater now protects the West Basin in the outer harbour. The inner harbour is reached by a channel 35 ft. deep and 300-500 ft. wide.

Artificial Harbours on **Open** Coasts.—It sometimes happens that harbours have to be constructed where little or no natural shelter exists. When, in such cases, the only possible site is an open sandy shore, considerable littoral drift may occur. Breakwaters, carried out from the shore at some distance apart, and converging to a central entrance of suitable width, provide the requisite shelter. Such works may be necessary, not only on open unindented coasts, but also to afford increased shelter at a river mouth on an unprotected coast line. Harbours of this description have, for instance, been made at Madras, Ind., and Ymuiden on open shores; while the breakwaters at the mouth of the Tyne and those at Sunderland, Eng., furnish examples of the protection of river entrances.

If there is little littoral drift from the most exposed quarter, the amount of sand brought into the harbour during storms can be readily removed by dredging. The quantity is, moreover, smaller in proportion to the depth into which the entrance is carried; and the scour across the projecting ends of the breakwaters tends, in some cases, to keep the outlet free from deposit. If a river discharges into the harbour the detritus and matter in suspension brought down by it must also be taken into consideration.

Where there is littoral drift in both directions on an open sandy coast, caused by winds blowing alternately from opposite quarters, sand accumulates in the sheltered angles outside the harbour on both sides at the junction of the breakwater with the shore line. This has occurred at Ymuiden. Silting also frequently occurs just inside the breakwater heads under the shelter of the arms. The worst results occur when the littoral drift is mainly in one direction, so that the projection of a solid breakwater out from the shore causes a very large accretion on the side facing the exposed quarter, while, because of the arrest of the travel of sand, erosion of the beach occurs beyond the lee breakwater (see COAST PROTECTION). Such effects have been produced by the works at Port Said. Egy., and Madras. The harbour of Salina Cruz, Mex., on the Pacific coast of the Isthmus of Tehuantepec, where two breakwaters projecting from the shore were built (1900–06), rapidly sanded up and narrow channels to the berths are maintained only by constant dredging.

Madras and *Ymuiden Harbours.*—Considering first of all harbours formed by converging breakwaters on an open unindented coast, the two examples mentioned above are both typical and instructive. Madras furnishes an instance of difficulties and unforeseen happenings overcome by continuous effort and drastic modification of the original plans. At Ymuiden the original forecast of the designers has been more nearly, but not entirely, realized. The harbour of Madras, begun in 1877, comprised, when

first completed, two breakwaters 3,000 ft. apart carried straight out to sea at right angles to the shore for 3,000 ft. with two return arms inclined slightly to seaward. The breakwaters originally enclosed an area of 220 ac. and left a central entrance, 515 ft. wide, facing the Indian ocean in a depth of about eight fathoms. The position and form of this entrance were determined mainly on navigational grounds as suitable to the needs of the sailing vessels, still at that time largely employed in the eastern trade. The breakwaters, in a position of extreme exposure on an open coast without any natural shelter, have suffered severe damage from the sea on many occasions necessitating rebuilding from time to time. The great drift of sand from south to north resulted in an advance of the shore against the outside of the south breakwater as it was projected seaward (fig. 2), and erosion, but to a lesser extent, occurred beyond the north breakwater. The progress of the foreshore in course of time extended so far seaward as to produce shoaling at the entrance; so rapidly in fact that in the ten years from 1893 the depth was diminished by ten feet. Moreover, the original entrance, facing east, was exposed to the full force of waves during both the northeast and the southwest monsoons. At these seasons the range within the harbour was severe and at times vessels could not ride at moorings in safety. A new entrance was therefore constructed by forming an opening in the breakwater on the north side of the harbour, protected by a sheltering arm, the original eastern entrance being closed when the new entrance had been made (1906–11). The harbour is now comparatively tranquil and vessels are able at all times to lie at the quays in safety.

The advance of the shore line seaward on the south side of the harbour still appears to average more than 25 ft. a year, but the rate of progression tends to decrease as the sand deposit extends into deeper water. The drift of sand along the outside face of the eastern breakwater wall has been checked, at any rate temporarily, by the construction of an extension seaward of the south breakwater 700 ft. in length which was begun in 1924. This spur breakwater or groyne is protected by concrete blocks placed pell mell on each side. Incidentally the accretion of sand on the south side of the harbour is not an unmixed evil for the value of the land so formed is increasing with the expansion of the city and much of it has been sold for over £3,000 per acre. Since the tranquilizing of the water area in 1911, the quay accommodation has been largely increased (see *Proc.* Inst. C.E., *Passim*).

The harbour at Ymuiden, constructed during the 1870s, is an entirely artificial one formed, on the open sandy shore and bed of the North sea, to serve as the entrance to the Amsterdam ship canal. The breakwaters, each about a mile in length, are converging and the entrance faces west. A dredged channel extends from deep water outside the breakwaters to the canal locks. This channel has been deepened to more than 40 ft. below mean sea level (spring rise, five and one-half feet). The actual entrance to the canal channel is between parallel jetties built on the original foreshore where the cut through the sand dunes was first made. The entrance between the breakwater heads is about 800 ft. in width, the harbour widening to 3,800 ft. at the shore line, thus providing broad expending beaches on either side of the canal entrance. The construction of the large entrance lock (*see* WATERWAYS, INLAND) necessitated the sacrifice of a part of the northern spending beach to the formation of an additional and wider canal entrance. In order to compensate for this loss the inner portion of the north breakwater was reconstructed so as to form a large wave trap on the north side of the new channel jetties. The advance of the shore on both sides of the harbour at Ymuiden appears to have reached its limit only a short distance out from the old shore line on each side. The only evidence of drift consists in the advance seaward of the line of soundings alongside, and in the considerable amount of sand which enters the harbour and has to be removed by bucket dredging. For dredging outside the breakwaters suction dredgers are employed. A condition of balance has now been reached. Dredging operations, fairly uniform and continuous in amount (about 1,700,000 cu.yd. per annum), but not economically burdensome in proportion to the commercial importance of the harbour, serve to maintain the required depths of water. It is interesting to note here that an early instance of the employment of sand-pump dredgers was in connection with the construction of the harbour by British engineers about 1874 (see *Proc.* Inst. C.E., vol. lxii, 1880).

Port Said Harbour, at the Mediterranean entrance of the Suez canal, is interesting as an example of the successful formation of an artificial harbour on an open shore where the littoral drift is almost wholly in one direction. The exposure is moderate and the sea bed slopes very slowly toward deep water. Because of the prevalence of northwest winds, the drift is from west to east, and is augmented by the alluvium issuing from the Nile. The original harbour was formed by two converging breakwaters or jetties, of which the western has been extended seaward from time to time as successive deepenings of the canal were effected. Its total length in 1939 was 8,100 yd. and its termination in a depth of water of 38 ft. (*see* E. Quellennec, *Breakwaters of Egyptian Harbours,* Paper *31* bis., and P. Solente, Paper 54; xiv, Int. Congress of Navigation, Cairo, 1926). The outer portion is a submerged mound serving merely to prevent sand and silt from entering the dredged channel except around the seaward extremity. The east breakwater, on the less exposed side, is 2,625 yd, long (fig. 12). The shore has advanced considerably against the outer face of the west breakwater and at the same time erosion has taken place on the east side of the east breakwater. The advance on the western side between 1858 and 1939 was about 5,200 ft., but the rate of progress has decreased in recent years. Though the progress seaward of the lines of soundings close to the harbour continues, a depth of about 40 ft. below normal low water is main-

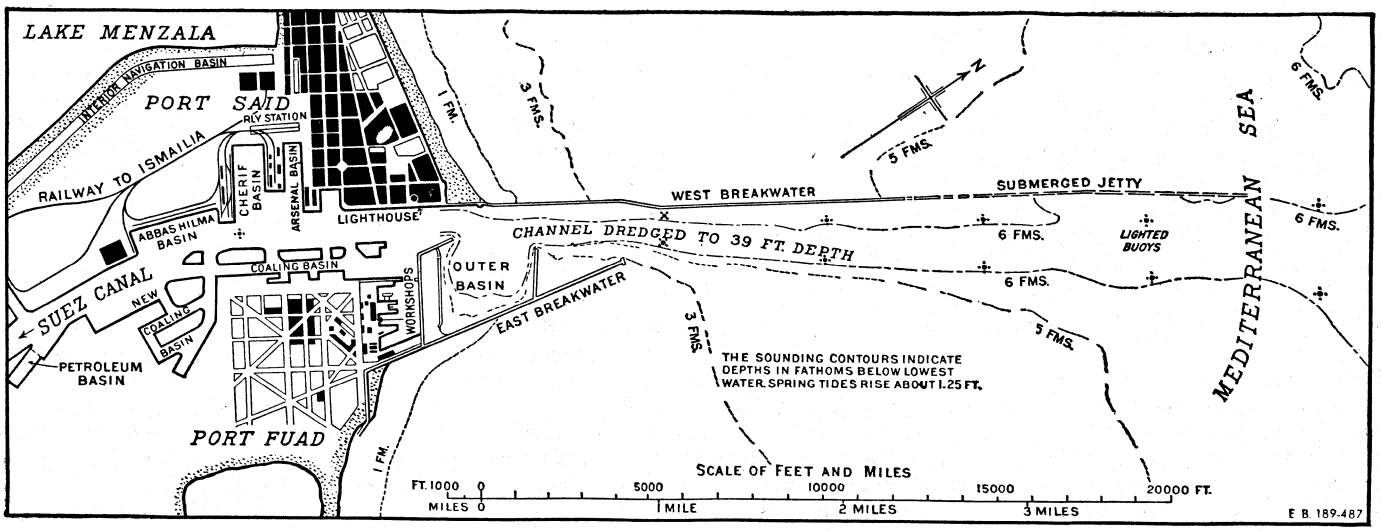

FIG. 12.—PORT SAID HARBOUR AND SUEZ CANAL ENTRANCE

tained without difficulty by the continuous working of powerful bucket and suction dredgers in the channel and outer approaches. Since 1938, the powerful suction dredger "Pierre-Lefort" has been employed in dredging the approach channel.

The Tyne and Sunderland.—The breakwaters at the mouths of the Tyne and Wear furnish outstanding instances of the successful adoption of the converging plan in situations where a river outfalls on an exposed coast line and there is no protecting estuary or sheltered sea inlet (see Proc. Inst. C.E., vol. clxxv, 1910 and cclx, 1921). In the case of the Tyne sand travel has occasioned no difficulty, neither has erosion taken place on the lee side of the harbour, a small rocky headland less than a mile south forming a natural groyne which has trapped sand and shingle in the embayment between it and the south pier. At Sunderland some accumulation, though not to a serious extent, has occurred on the north side of the harbour works and erosion of the foreshore to the south has necessitated the carrying out of costly protection works. The building of the Tyne breakwaters (fig. 1) was commenced in 1855; they were originally designed to terminate in a depth of 15 ft. at low water, but when more than half finished it was decided to extend them seaward to near the six-fathom contour. This involved changes in the plan of the harbour and accounts for the somewhat peculiar curved form of the south pier. The north pier was originally completed in a similar manner but the outer portion was partially destroyed (1895–6) and subsequently rebuilt on a straight line (see BREAKWATER). The formation of the outer harbour at Tynemouth has provided a safe deepwater approach to the river whose mouth was, about the middle of the last century, obstructed by a sand bar with no more than five-feet depth at low water and was, moreover, notorious on account of the difficulty of entrance and the frequency of wrecks. The channel from harbour to docks is being dredged to 35 ft. at low water spring tides (see RIVER AND RIVER ENGINEERING).

Casablanca.—An example of harbour construction carried out on a large scale on an exposed shore is the making of this artificial port on the Atlantic, the largest and most important harbour in French Morocco (fig. 13). The construction of a small

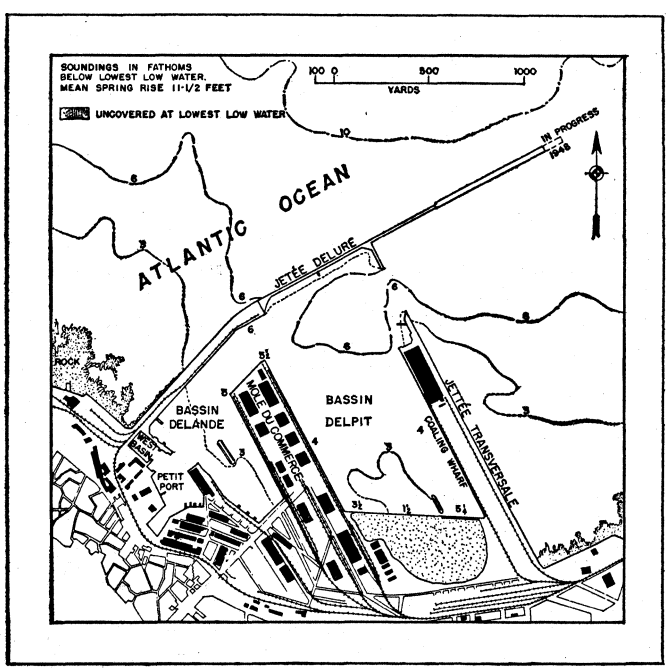

FIG. 13.—CASABLANCA HARBOUR

inshore harbour and jetty was commenced in 1907; the sheltering harbour enclosing about 350 ac., for the most part having a depth of 30 ft. or more at low water, was begun in 1913, and the main harbour works were completed in 1927. Later the northern breakwater, more exposed, was further extended to more than 8,000 ft. The works are fully exposed to the Atlantic swell.

Takoradi.—The artificial deepwater harbour of Takoradi, on the Gold Coast (constructed 1921–28), affords an instance of advantage being taken of a rocky reef extending out from the shore to form the foundation for a large part of the main protecting breakwater, which is of the rubble mound type. The plan of the harbour is in some ways similar to that of Casablanca, the main breakwater affording shelter on the side exposed to the prevailing winds and heaviest seas, while a transverse breakwater built under its lee has wharves constructed along its side, and the deepwater entrance between the breakwater heads is well sheltered. The site selected for the harbour is on an open coast, but is free from the trouble of littoral drift.

Boulogne.—The old harbour of Boulogne is of the conventional jetty type common to the French and Belgian ports of the English channel and North sea. The formation of a large outer harbour sheltered by breakwaters projected from the shore was commenced as far back as the 1880s. The south or Carnot breakwater was completed in 1938, its length being more than one and three-quarters miles. The north breakwater was begun in 1935. When completed, the enclosed low-water area would be more than one and one-half square miles. The Carnot breakwater is L shaped in plan; its shore end is more than 6,000 ft. south of the jetty entrance to the inner harbour, the intervening foreshore forming an ample expending beach. Boulogne harbour is not free from the troubles arising from littoral drift. The sand travel along the shore from south to north led to considerable accretion along the outer face of the Carnot breakwater and the depth contours are being gradually pushed seaward. The channel through the outer harbour is being dredged to 45 ft.

Prefabricated Harbours.—Prefabricated harbours were installed on the flat, sandy beaches of the invasion coast of Normandy (1944) to maintain supply lines of the Allied expeditionary force. They consisted of a series of breakwaters manufactured in England in sections, towed across the channel with the invading forces and installed at the time of assault. Three types of breakwaters were used: floating steel units anchored far out to break surface waves; the main or open concrete caissons, "Phoenixes," sunk in about 33 ft. of water forming the deepwater harbour; and a line of sunken ships in 12 ft. of water forming the shallow harbour. Behind the protection of the breakwaters, prefabricated "Lobnitz" pierheads, floating steel platforms steadied by spuds, were fixed in position. These pierheads, in turn, were connected to the beach high-water line by means of prefabricated and assembled pontoon bridge structures.

Breakwaters Connected with the Shore by an Open Viaduct.—Proposals have been brought forward from time to time to evade the advance of the foreshore against a solid obstacle by extending an open viaduct across the zone of littoral drift inshore, and forming a closed harbour or a sheltering breakwater against which vessels can lie, farther seaward and beyond the influence of accretion. It should, however, be pointed out that the single curved arm breakwater can afford adequate protection only in situations of moderate exposure and where the harbour is naturally sheltered on its open side.

Zeebrugge Harbour.—This principle was carried out on a fairly large scale at the port of call formed by the sheltering breakwater constructed (1900–09) in front of the entrance to the Bruges ship canal at Zeebrugge on the sandy North sea coast. A solid breakwater, provided with a wide quay furnished with sidings and sheds, and curving round toward the east so as to overlap the entrance to the canal and shelter an ample water area, is approached by an open steel and iron viaduct extending out 1,000 ft. from low water into a depth of 20 ft. The solid breakwater is carried out into a depth of 33 ft. at low water near the head. It was hoped that by thus avoiding interference with the littoral drift close to the shore, coming mainly from the west, the accumulation of silt and sand to the west of the harbour, and also in the harbour itself, would be prevented, or at any rate reduced to a very moderate amount. These hopes have not, however, been realized, and considerable dredging is necessary in the harbour and at the entrance to the canal in order to maintain the required depths. The probable explanation of the failure to avoid the troubles of sand accretion and silting is, in this as in other similar cases where

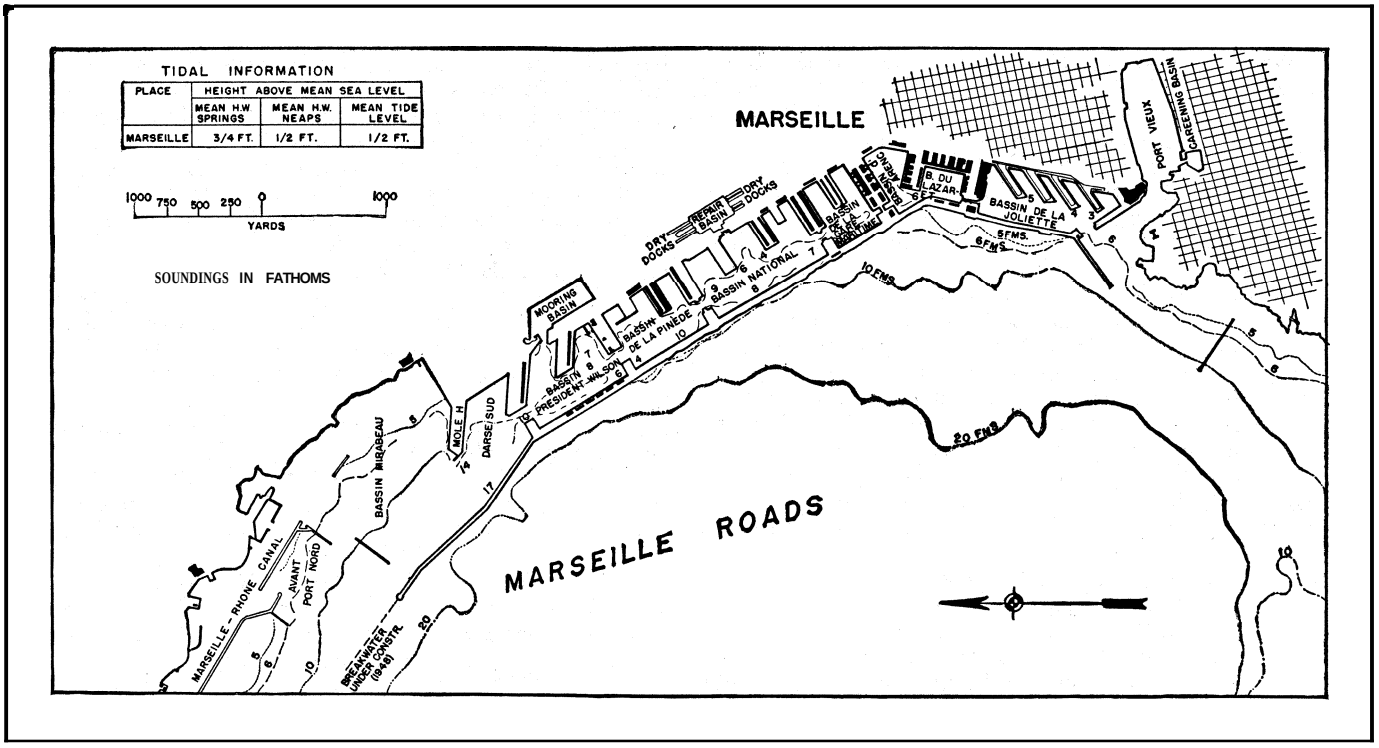

FIG. 14.—PORT OF MARSEILLE

the accretion has been still more serious, that the shelter caused by anything in the nature of an island near the shore must result in interference with the natural littoral current and drift and consequent stoppage of the travelling material.

Ceará and Rosslare: A plan somewhat similar to that adopted later at Zeebrugge was carried into effect at Ceará on the northeast coast of Brazil about 1886. Sand accumulated very rapidly both inside and outside the harbour; in a few years the low-water line had receded as far as the breakwater head and the harbour was ultimately abandoned. Work on a new port of Ceará or Fortaleza was started in Aug. 1938; the site chosen was the natural shelter formed by the spur of land running out to the Mucuripe lighthouse. This spur, extending roughly at right angles from the coast, is composed of a low reef on which very high sand dunes had formed, and is about six miles from the old port. Rosslare harbour, near Wexford, on the southeast coast of Ireland, is another and more favourable example of this type of construction. Here also dredging must be carried on periodically to maintain adequate depths for navigation.

Port Elizabeth.—Construction of the harbour of Port Elizabeth, S. Af., was started in 1933 when it was proposed to enclose about 700 ac. between two curved breakwaters. Only one breakwater had been constructed by mid-century. The south breakwater which extends about 2,300 ft. northeast from the old 1,400-it. Dom Pedro jetty, then curves and runs an additional length of approximately 2,300 ft. to the northwest, was constructed between 1919–38. The inner harbour is afforded additional protection by a 4,000-ft. pier extending at nearly right angles from the coast at a point approximately parallel with the end of the south breakwater. Another solid pier approximately 1,200 ft. long extends into the 314-ac. harbour protected by the south breakwater and the north pier. A northern breakwater was intended to complete the scheme.

Harbours Sheltered by Works Parallel to Coast.—Many important modern harbours of artificial construction in the Mediterranean and other tideless seas have been formed by building sheltering breakwaters in deep water at some distance from the shore and more or less parallel with it, leaving openings at one or both ends, or at intervals. Under the shelter of these breakwaters inner port works have been constructed (see DOCK). This characteristic of Mediterranean harbours is caused. first of all, by the absence of good river harbours; for in tideless seas the rivers are usually barred by deltas at their outlets, as the Rhone and Tiber. Secondly, many ancient ports were formed in narrow sheltered sea inlets as, for instance, the old harbour of Marseille; or in small bays as at Genoa, Naples and Trieste. In course of time the maritime commerce of such ports outgrew the limited resources of the old harbours and it became necessary to provide enlarged accommodation near by and in deeper water. The only sites available for such extensions have usually been in more open and exposed situations in deep water fronting the adjacent coast line. Moreover, the great depths of water near the shore at many Mediterranean ports, as for example. Marseille and Naples, make lateral extensions more economical and practically convenient than seaward enlargements. (See BREAKWATER.)

Marseille.—The great breakwater at Marseille has a total length of more than three and one-half miles along the shore (fig. 14), and the range of basins enclosed by it is still being extended both north and south.

Genoa, Italy's second port, was a centre of maritime trade long before the days of Columbus, whose statue overlooks the harbour and who was a native of the city. The old harbour is in a semicircular bay less than three-quarters of a mile in width at its entrance. Around its shores moles and jetties were built from time to time, first in sheltered positions and later in more exposed parts of the bay open to the south; still later protection moles were thrown out from the two horns of the bay, and the continued expansion of the port has necessitated the construction of an island breakwater—the Galliera mole—(begun in 1877 and subsequently extended) stretching east and west in front of the old harbour. Under its shelter port works have been constructed which are further sheltered by subsidiary moles projected more or less at right angles to the shore. With its eastern and western extensions, the latter named Principe Umberto mole, it was in 1940 nearly three miles long.

Trieste.—The Adriatic port of Trieste furnishes another example of lateral expansion. The old port, situated in a small sheltered bay, called the Doganale basin, is now used mainly for coastwise shipping. Along the coast to the northward and again to the southward across the entrance to the Bay of Muggia, several island breakwaters, having an aggregate length of more than two miles have been built to shelter the port works which stretch

along the coast line.

Naples. — The old harbour of Naples was formed by building small moles or breakwaters in sheltered positions on the western side of the bay. The San Vincenzo breakwater, which is the nucleus of the modern harbour, was begun in 1836. The harbour now reaches across the wide bay from west to east for a distance of more than two and one-half miles and is protected by a series of breakwaters parallel with the shore. Practically the whole of the modern harbour, having a sheltered area of more than one square mile, is in deep water and little dredging has been required except alongside some of the quays.

Lateral Breakwaters in Sheltered Positions. — In large landlocked natural harbours and arms of the sea lateral breakwaters parallel with the shore form convenient and effective means of providing shelter from the short wind waves which are generated in them and protection from as much of the ocean swell as may be propagated into the enclosed water area. Behind the shelter of such works, wharves and other port works can be constructed where vessels may berth without risk of damage.

In this manner the naval and commercial harbours in the landlocked Rade at Brest are protected by island breakwaters fronting them.

Another example is the harbour of Kobe, situated in a sheltered part of the inland sea of Japan, where wide, solid and well equipped piers, projecting 1,000 to 1,500 ft. from the shore, have been afforded additional protection by the construction of a series of island breakwaters generally parallel with the shore in depths of 35 to 45 ft.

Many of the ports on the shores of the Great Lakes of North America also furnish examples of lateral breakwater protection as, for instance, Chicago, Ill., Buffalo, N.Y., Port Arthur and Toronto, Ont. American lake breakwaters are commonly formed of rubble stone mounds or of timber cribwork filled with stone (see BREAKWATER). Breakwaters made in comparatively sheltered positions such as these are naturally of less massive construction than those required in situations exposed to the full force of ocean waves.

Entrances. — Seamen always wish for a wide entrance to a harbour as giving greater facility for safe access; on the other hand, it is important to keep the width as narrow as practicable consistent with easy access, to exclude waves and swell as much as possible and secure tranquillity inside. The result of this conflict is often a compromise. Examples which illustrate the divergence of practice in the dimensions of entrances to artificial harbours have already been mentioned; these differences are mainly the result of the equally wide variations in circumstances and exposure, and no generally applicable rule or guiding principle can be formulated, though some authorities maintain that the space between breakwater heads should never be less than the over-all length of the largest vessel expected to enter the port. The advantages which can sometimes be secured by overlapping breakwaters, covering island breakwaters and double entrances, have already been mentioned; on one point, however, there can be no difference of opinion; that is, the increasing length and beam of ocean-going vessels require the provision of entrances of ample width, and the more exposed such entrances are to heavy cross seas and strong cross-currents the wider they must be in the interests of the navigator. The difficult nature of the present Durban entrance is an example of this. In tidal harbours, and in those with a large volume of river water discharge, an undue restriction of the width of the entrance may produce a current unsafe for navigation. A strong outgoing stream meeting onshore waves at an entrance is bound to increase the turbulence and create a dangerous sea at a critical point.

The Natural Harbours of America. — The North American continent is well endowed with naturally sheltered harbours in positions where they serve the necessities of sea-borne trade. In the United States deepwater river harbours meet these needs at such ports as New York city, at the mouth of the Hudson; Philadelphia, Pa., on the Delaware, 88 nautical miles from the sea entrance to Delaware bay; Portland and Astoria, Ore., on the Columbia, where, however, dredging has been necessary to deepen parts of the river; and Newport News and other places on the James river, Va. Deep landlocked bays or sea inlets provide the harbours of Baltimore, Md., at the head of Chesapeake bay; Portland, Me.; Boston, Mass.; and San Francisco, Calif.; and those at Seattle and Tacoma, Wash., and other ports in Puget sound.

Two of the most important Canadian ports, Montreal and Quebec, are situated on the magnificent St. Lawrence river, the former 1100 mi. from the Gulf of St. Lawrence. Halifax in Nova Scotia is in a large landlocked, deepwater harbour free from ice all the year round. Vancouver harbour, in the sheltered Burrard inlet, is one of the finest on the Pacific coast and is capable of internal development on a large scale. Victoria and Esquimalt harbours are in well protected inlets at the southern end of Vancouver Island; and Prince Rupert, in British Columbia, is a comparatively new deepwater port on a narrow and well sheltered arm of the sea.

The finest and most beautifully situated natural harbour in South America is that formed by the landlocked bay of Rio de Janeiro, Braz. Buenos Aires, Montevideo and Bahia Blanca, Arg., are all estuary ports in sheltered positions, but where dredging operations are necessary to form and maintain deep water channels.

New York Harbour. — The harbour of New York (fig. 4) is one of the most perfect natural havens in the world. It enjoys the advantages of ample water area and depth, shelter, good access, a small tidal range — no more than five feet at springs — and moderate tidal streams. The outer harbour, or Lower bay, is sheltered by the New Jersey shore and Sandy Hook on one side, and by Long Island on the other. The inner harbour is entered through a channel, called the Narrows, between Staten Island on the west or New Jersey shore, and Brooklyn on the east. It comprises the deep Upper bay, the rivers which isolate Manhattan Island, namely, the Hudson, East and Harlem, and numerous bays and creeks of which Newark bay is the most important. The shore lines have a combined length of more than 480 mi. and, if the total berthing space of the piers be added, this figure is increased by about 150 mi. Excluding the Lower bay, the sheltered water area within the harbour is approximately 150 sq.mi. In recent years the development of the trade of the port has led to the building of shipping piers on an extensive scale in positions remote from the old centre of trade in Manhattan Island. In this way Staten Island, Jersey City, Newark and the Long Island shores have become busy centres of maritime trade. More recently still, Jamaica bay, a sheltered inlet on the south side of Long Island with access direct from the Lower bay, has been developed as a new centre of port activity.

The entrance to the Lower bay is open to the Atlantic, but shelter is afforded by outlying sandbanks. Sandy Hook itself is a long, low spit of sand. Until about 1885 the natural channels through the banks afforded, when suitably marked and buoyed, ample depth and width for all ships using the port. The subsequent deepening of the sea channels, consequent on the growth in the dimensions of transatlantic vessels, has already been referred to. The depths in the sea approaches are now maintained by periodical suction dredging.

The entrance to the harbour through Long Island sound from the north and east is sheltered, but the channel is obstructed by rocky islets and reefs. The navigation of this approach was at one time difficult and even dangerous, but it has been improved by the removal of many of the rocks by blasting and dredging, notably in the neighbourhood of Hell Gate, to provide a channel 35 ft. deep from Throgs Neck to the Brooklyn navy yard and 40 ft. thence to the Upper bay with widths from 300 ft. to 1,000 ft. The Hudson river channel has been dredged to a low-water depth of 40 ft. for full river width from Upper bay to W. 59th street, and in 1940 the construction of a channel 45 ft. deep to W. 40th street, thence 48 ft. to W. 30th street over a width of 2,000 ft. was in progress. Many berths alongside piers and wharves in New York harbour have depths of 40 ft. or more at low water.

San Francisco. — The landlocked bay of San Francisco is 11 mi. long and has a water area of about 420 sq.mi. with about 200 mi. of shore line. Two large rivers, the Sacramento and San Joaquin,

flow into it. The entrance to the bay, known as the Golden Gate, is a mile wide and has a greatest depth of 360 ft. Outside the Golden Gate a semicircular bar obstructs the entrance. The northern portion of this bar, the Four Fathom bank, has a minimum depth of 22 ft. and the depths over the remainder range from 31 to 36 ft.

The main channel is dredged to a minimum of 46 ft., and the comparatively narrow Bonita channel, paralleling the coast north of the Golden Gate, is 54 ft. deep. These channels afford entrance to the harbour having a natural depth of 54 ft. The ports of San Francisco, Oakland, Richmond and Alameda all lie on San Francisco bay.

The Natural Harbours of Australasia.— Some of the most important harbours of Australia and most of the frequented harbours in New Zealand are of natural formation. Pre-eminent is the great landlocked harbour of *Sydney*, one of the finest and most beautiful in the world. No artificial protection is required and no deepening or enlargement of its entrance channel has been necessary to meet the needs of the largest ships. The outer entrance, facing southeast between two bluffs, known as the north and south heads, is less than a mile in width at its narrowest part and has a minimum depth in the channel, nearly one-half mile wide, of 84 ft. The outer part of the harbour is known as Port Jackson, so named by Capt. James Cook in 1770. Its shores, as well as those of the upper harbour near and above Sydney, are indented by many sheltered coves. The tidal rise is about five feet at springs and shipping is berthed at open piers. The trade of the port is large, Sydney ranking fifth among the commonwealth ports in this respect. Although only 12 mi. in a straight line from the heads to the upper limit of the harbour, the length of the indented shore line is 188 mi. Of its water area of 23 sq.mi., nearly 5 sq.mi. have a depth of more than 35 ft. at low water. Channels 40 ft. deep have been dredged where necessary to give access to the overseas piers some of which have berths 45 it. deep at low water.

Melbourne is less fortunately placed than is Sydney, for the city itself is situated on the shallow Yarra river, which discharges into the large landlocked Port Phillip bay. In its natural state the river had a depth of little more than 13 ft. The approach channels to the wharves on Hobsons bay were dredged to 34 ft., and the river channel up to Melbourne was dredged to 26–30 ft.

Tasmania has several fine natural harbours. *Hobart* is a port on the wide 60-ft.-deep Derwent river. There is a perfect approach to the river entrance; no dredging is required; open jetties furnish all the needs of shipping and the capacity for extension is almost unlimited. The Tamar provides in its lower reaches a sheltered deepwater harbour for the port of *Launceston*.

New Zealand is rich in good natural harbours. *Port Lyttleton* in the South Island is a sheltered deepwater inlet with no bar. Dredging has been required only to deepen and maintain a channel in the approaches to the inner harbour. *Wellington*, at the southern end of the North Island, is a splendid landlocked harbour with more than 30 sq.mi. of sheltered water, from 6 to 14 fm. in depth. The entrance is 3,600 ft. in width with a depth of 42 ft. at low water. Open wharves, most of which have a low-water depth of more than 30 ft., and some as much as 41 ft., project from the shores of the inner or Lambton harbour. *Auckland* harbour, also in the North Island, is an arm of the sea, with an entrance over one-half mi. wide, well protected by outlying islands, providing deepwater accommodation for the largest vessels.

The Harbours of the East.—The great majority of the important harbours east of Suez are natural havens. Some possess such advantages of depth and shelter that little more than the provision of wharves and other internal port works has been necessary to convert them into first class ports. In others dredging and river training works have been required. Great artificial harbour works in exposed situations such as these at Colombo and Madras are rare in the east; but harbour works on a very large scale have been made in recent years in sheltered waters, particularly in Japan and Indonesia and at Singapore. A few only of the more important harbours not already referred to can be mentioned here. The harbour of *Bombay* is a well-sheltered arm of the sea situated between the island of Bombay and the mainland. *Calcutta* and *Rangoon* are river ports in both of which sand bars and shoals are serious problems *(see* RIVER AND RIVER ENGINEERING); *Singapore*, one of the greatest trading ports of the east, occupies a sheltered position, protected by outlying islands and shoals, with a deepwater anchorage. The principal British naval base in the east, completed in 1938, is on the channel separating Singapore from the mainland of Johore. *Hong Kong* Island is situated at the mouth of the Canton river. Between it and the mainland at Kowloon is a natural and well-sheltered deepwater harbour of great extent.

Kobe and *Osaka* are large breakwater harbours in sheltered positions in the inland sea of Japan. *Yokohama*, the principal port of Japan, is in the bay of Tokyo. At mid-century there were about 27.000 ft. of breakwater protecting the harbour. *Darien*, the principal port of Manchuria, was energetically developed when it was in the hands of the Japanese. It is in a sheltered bay where two island breakwaters projected from the shore, having a total length of more than two and one-half mi., cover a protected water area of 780 ac. At *Manila* in the Philippines, breakwaters were made in an almost landlocked bay to protect a harbour of 1,250 ac.

HARBURG, former seaport town of Germany, on the left hank of the southern arm of the Elbe, 6 mi. S. of Hamburg by rail. In 1927 Harburg was united with the city of Wilhelmsburg and in 1938 was incorporated into the city of Hamburg (*q.v.*) as the district of Harburg-Wilhelmsburg.

Harburg belonged originally to the bishopric of Bremen, and received municipal rights in 1297. In 1376 it was united to the principality of Liineburg, along with which it fell in 1705 to Hanover, and in 1866 to Prussia. It possesses a palace, which from 1524 to 1642 was the residence of the Harburg line of the house of Brunswick. The leading industries of Harburg were the crushing of palm-kernels, for which it was famous, and linseed and the manufacture of india-rubber, gutta-percha, phosphates, nitrate and jute.

HARCOURT, a noble French family which took its name from the village of Hal-court (Eure), and traces its origin back to the 11th century. The fief of Harcourt was raised to a countship in 1338, and passed in the 15th century, by a marriage, into the house of Lorraine. HENRI DE LORRAINE, COMTE D'HARCOURT (1601–1666), nicknamed Cadet la perle, fought in Italy against Spain in 1639, and captured Turin. He took sides with Condé in the Fronde, but made his submission in 1654.

The most distinguished among the younger branches of the family are those of Montgomery and of Beuvron. To the former belonged Jean d'Harcourt (d. 1452), bishop of Amiens and Tournai, archbishop of Narbonne and patriarch of Antioch; and Guillaume d'Harcourt, count of Tancarville, and viscount of Melun (d. 1487), who was head of the administration of the woods and forests in the royal domain.

From the branch of the marquises of Beuvron sprang Henri d'Harcourt, marshal of France, and ambassador at the Spanish court, who was made duke of Harcourt (1700) and a peer of France (1709); also François Eugène Gabriel, count, and afterwards duke, of Harcourt, who was ambassador first in Spain, and later at Rome, and died in 1865.

The English family of Harcourts trace their descent to Ivo de Harcourt, son of William de Harcourt who acquired English land at the date of the Conquest.

See G. *A.* de la Rogne, *Histoire généalogique de la maison d'Harcourt* (4 vols., *1662)*; P. Anselme, *Histoire généalogique de la maison de France,* v. 114, etc.; and Dom le Noir, *Preuves généalogiques et historiques de la maison de Harcourt* (1907); and the *Harcourt Papers.*

HARCOURT, LEWIS VERNON HARCOURT, 1ST VISCOUNT (1863–1922), British politician, was born in London on Feb. 1, 1863, the elder son of Sir William Harcourt (*q.v.*). He was educated at Eton and afterwards travelled, becoming well known for his interest in art. In 1899 he married the only daughter of Walter H. Burns, of New York. From 1904 to 1916 he was Liberal M.P. for the Rossendale division of Lancs., and on the formation of Sir Henry Campbell-Bannerman's Government (1905) he became first commissioner of works. In 1910 he became secretary of State for the colonies in the Asquith Cabinet, and on the formation of the Coalition Government in 1915 again became first commissioner of works. In 1917 he was raised to the peerage. He died in London on Feb. 24, 1922, being succeeded in the title by his son, William Edward Harcourt (b. 1908).

HARCOURT, SIMON HARCOURT (c. 1661–1727), 1ST VISCOUNT, lord chancellor of England, only son of Sir Philip Harcourt of Stanton Harcourt, Oxfordshire. On the accession of George I he was deprived of office and retired to Cokethorpe, where he enjoyed the society of men of letters, Swift, Pope, Prior and other famous writers being among his frequent guests. With Swift, however, he had occasional quarrels, during one of which the great satirist bestowed on him the sobriquet of "Trimming Harcourt." In 1721 Harcourt was created a viscount and returned

to the privy council; and on several occasions during the king's absences from England he was on the council of regency. He died in London on July 23, 1727.

HARCOURT, SIR WILLIAM GEORGE GRANVILLE VENABLES VERNON (1827–1904), English statesman, was the second son of Canon William Vernon. The family name was changed to Harcourt in 1831 on the succession of Edward Vernon, archbishop of York and father of William Vernon, to the Harcourt estates. Canon Harcourt is separately noticed. William was born at the Old Residence, York, on Oct. 14, 1827. He was educated privately at Dumford, near Salisbury, and at Preston, where he witnessed the bread riots of 1842. From his tutor at Preston he went up to Trinity college. Cambridge. He was a member of the famous Society of the Apostles at Cambridge, and among his close friends were Fitzjames Stephen and Julian Fane. He was called to the bar at the Inner Temple in 1854, became a Q.C. in 1866, and was appointed Whewell professor of international law, Cambridge, 1869. He quickly made his mark in London society as a brilliant talker; he wrote for *The Morning Chronicle* and *Saturday Review*, and began in 1862 to write letters to *The Times* over the signature of "Historicus" on questions of international law arising out of the American Civil War. The earlier letters were directed against the recognition of the Southern States as belligerents in the American Civil War and towards defining the duties of neutrality on the part of England. These letters had a profound effect on public opinion. He maintained that the launching of the "Alabama" was an illegal act, and throughout the period was in close touch with Lord John Russell and Lord Clarendon.

He entered parliament as Liberal member for Oxford, and sat from 1868 to 1880, when, upon seeking re-election after acceptance of office, he was defeated by Hall. A seat was, however, found for him at Derby, by the voluntary retirement of Plimsoll, and he continued to represent that constituency until 1895, when, having been defeated at the general election, he found a seat in West Monmouthshire. He was appointed solicitor-general and knighted in 1873; and, although he had not shown himself a very strenuous supporter of Gladstone during that statesman's exclusion from power, he became secretary of state for the home department on the return of the Liberals to office in 1880. His name was connected at that time with the passing of the Ground Game Act (1880), the Arms (Ireland) Act (1881), and the Explosives Act (1883). As home secretary at the time of the dynamite outrages he acted promptly, and the Explosives Act was passed through all its stages in the shortest time on record. He was constantly in conflict with the Irish members in the House of Commons. In 1884 he introduced an abortive bill for unifying the municipal administration of London. He was indeed at that time recognized as one of the ablest and most effective leaders of the Liberal party; and when, after a brief interval in 1885, Gladstone returned to office in 1886, he was made chancellor of the exchequer. The government fell on the Home Rule queston in July. In Jan. 1887 Harcourt, who had been a close ally of Joseph Chamberlain before the split in the Liberal party over Home Rule, now made an effortto secure reunion, and the Round Table Conference of Herschell, Harcourt, Morley, Chamberlain and Trevelyan met at his house. It failed disastrously.

Between 1880 and 1892 Harcourt acted as Gladstone's loyal and indefatigable lieutenant in political life. In 1892 he became chancellor of the exchequer for the second time. In 1894 he introduced and carried a memorable budget, which equalized the death duties on real and personal property and put the budget on a basis which enabled it to stand the strain of the South African War. After Gladstone's retirement in 1894 and Lord Rosebery's selection as prime minister, Sir William became the leader of the Liberal party in the House of Commons, but it was never probable that he would work comfortably in the new conditions. His title to be regarded as Gladstene's successor had been too lightly ignored, and from the first it was evident that Lord Rosebery's ideas of Liberalism and of the policy of the Liberal party were not those of Harcourt. Their acute differences were patched up from time to time, but the combination could not last. At the general election of 1895 the divisions in the party were obvious. The effect of Harcourt's abortive Local Veto Bill on the election was seen in his defeat at Derby, which gave the signal for the Liberal rout. In Dec. 1898 the crisis arrived, and he resigned his leadership of the opposition, alleging as his reason, in letters exchanged between John Morley and himself, the cross-currents of opinion among his old supporters and former colleagues.

Harcourt strongly condemned the government's financial policy and their attitude towards the Transvaal in 1899–1900; and was a constant critic of Chamberlain's policy. At this time he engaged in a violent controversy, conducted in letters to *The* **Times,** against ritualism in the Church of England. His last great political effort was against Chamberlain's tariff reform proposals. In March 1904, just after he had announced his intention not to seek election again to parliament, he succeeded, by the death of his nephew, to the family estates at Nuneham. But he died suddenly there on Oct. 1 in the same year. He married, first, in 1859, Thérèse Lister (d. 1863), a niece of the 4th Lord Clarendon (*q.v.*), by whom he had one son, Lewis Vernon Harcourt (*q.v.*); and secondly, in 1876, Elizabeth, widow of T. Ives and daughter of J. L. Motley, the historian, by whom he had another son, Robert (b. 1878). Lady Harcourt survived until 1928.

Sir William Harcourt was one of the great parliamentary figures of the Gladstonian Liberal period. He was essentially an aristocratic type of the late 19th century Whig, with a remarkable capacity for popular campaign fighting. He had been, and remained, a brilliant journalist in the non-professional sense. He was one of those who really made the *Saturday Review* in its palmy days, and the "Historicus" letters on international law published in *The Times* showed him to be a great international lawyer. In later years he found himself somewhat isolated and disappointed. A tall, fine man, with the grand manner, he was a great personality in the life of his time.

See A. G. Gardiner, ***The Life*** of *Sir William* ***Harcourt,*** 2 vol. (1923).

HARCOURT, WILLIAM VERNON (1789–1871), founder of the British association, was born at Sudbury, Derbyshire. in 1789, a younger son of Edward Harcourt, archbishop of York, youngest son of George Vernon, 1st Lord Vernon (Edward took the name Harcourt in 1831). William Harcourt served for five years in the British navy and then went to Christ Church, Oxford, took holy orders and held a living at Bishopthorpe, Yorkshire. He was one of the founders of the Yorkshire Philosophical society and its first president.

The laws and the plan of proceedings for the British Association for the Advancement of Science were drawn up by him, and Harcourt was elected president in 1839. In 1824 he became canon of York and in 1837 rector of Bolton Percy. His spare time until quite late in life was occupied with scientific experiments. Inheriting the Harcourt estates in Oxfordshire from his brother in 1861, he moved to Nuneham, where he died in April 1871.

HARDANGER FJORD, an inlet on the west coast of Norway, penetrating 70 m. inland apart from the deep fringe of islands off its mouth, the distance from the sea to the head of the fjord being 114 miles. Its extreme depth is about 350 fathoms. With Toro at the entrance, the general direction is north-east from that point. Magnificent mountains, from which pour many waterfalls flank the fjord. The main fjord is divided into parts under different names, and there are many fine branch fjords. The fjord is frequented by tourists, and the principal stations have hotels. The outer fjord is called the Kvindherredsfjord, flanked by the Melderskin (4,680 ft.); then follow Sildefjord and Bonde Sund, separated by Varalds island. Here Mauranger-fjord opens on the east; from Sundal on this inlet the great Folgefond snowfield may be crossed. Bakke and Vikingnaes are stations on Hisfjord, Nordheimsund and Östensö on Ytre Samlen, which throws off a fine narrow branch northward, the Fikensund. There follow Indre Samlen and Gtnefjord, with the station of Utne opposite Oxen (4,120 ft.), and its northward branch, Gravenfjord, with the beautiful station of Eide at its head, uhence a road runs north-west to Vossevangen. From the Utne terminal branches of the fjord run south and east; the

Sorfjord, steeply walled by the heights of the Folgefond, with the frequented resort of Odde at its head; and the Eidfjord, with its branch Osefjord. terminating beneath a tremendous rampart of mountains, through which the sombre Simedal penetrates. Vik is the principal station on Eidfjord, and Ulvik on a branch of the Ose, with a road to Vossevangen. A small stream entering Sorfjord forms in its upper course the Skjaeggedalsfos, of equal height with the Voringfos, and hardly less beautiful.

HARDEE, WILLIAM JOSEPH (1815–1873), U.S. soldier, was born in Savannah, Ga., on Nov. 10, 1815 and graduated from West Point in 1838. As a subaltern of cavalry he was employed in 1839 on a special mission to Europe to study the cavalry methods in vogue. He was promoted captain in 1844 and served aith distinction under Generals Taylor and Scott in the Mexican War. After the war he served as a substantive major of cavalry under Col. Sidney Johnston and Lieut. Col. Robert E. Lee. For some time before 1856 he was engaged in compiling the official manual of infantry drill and tactics which. familiarly called "Hardee's Tactics," afterward formed the textbook for the infantry arm in both the Federal and the Confederate armies. From 1856 to 1861 he was commandant of West Point, resigning his commission on the secession of his state in the latter year. Entering the Confederate service as a colonel, he was shortly promoted brigadier general. He distinguished himself greatly by his tactical leadership on the field of Shiloh, and was immediately promoted major general. As a corps commander he fought under Gen. Braxton Bragg at Perryville and Stone river, and for his distinguished services in these battles was promoted lieutenant general. He served in the latter part of the campaign of 1863 under Bragg and in that of 1864 under J. E. Johnston. When the Civil War came to an end in 1865 he retired to his plantation near Selma, Ala. He died at Wytheville, Va., on Nov. 6, 1873.

See James Kendall Hosmer, *Outcome of the Civil War,* "American Nation" series, vol xxi (1907).

HARDEN, SIR ARTHUR (1865–1940), English biochemist, was awarded the Nobel prize in chemistry for 1929 jointly with Hans von Euler-Chelpin (*q.v.*) for work on the fermentation of sugar and the enzyme action in the process. He was born Oct. 12, 1865, at Manchester, Eng. He studied chemistry at Owens college (later the Victoria University of Manchester) and at the University of Erlangen in Germany. After serving as lecturer and demonstrator in chemistry at the University of Manchester (1888–97), he took charge of the chemical and water laboratory at the Jenner Institute of Preventive Medicine (later Lister institute). From 1907 to 1930 he was head of the department of biochemistry. In 1912 he received the title of professor of biochemistry from the University of London. Harden applied the knowledge of a trained chemist to the investigation of biological phenomena. His studies of the fermentation of sugar by expressed yeast juice occupied most of his working time for over 30 years, and advanced the knowledge of the processes of intermediary metabolism in all living forms. He pioneered also in studies of bacterial enzymes and metabolism. His best-known work, *Alcoholic Fermentation,* appeared in four editions. He was co-author (with Sir Henry Enfield Roscoe) of a history of John Dalton's theories of atomic structure, published several chemical texts and numerous scientific papers and served as joint editor of *The Biochemical Journal* irom 1913 to 1937. Recipient of the Davy medal in 1935, he was knighted in 1936. He continued his scientific work from the time of his retirement from the Lister institute in 1930 until his death at Bourne End, June 17, 1940.

(B. V.)

HARDEN, MAXIMILIAN (1861–1927), German journalist, founder and editor of *Die Zukunft,* was born at Berlin on Oct. 20, 1861. He commenced journalism as a keen admirer of Bismarck, and *Die Zukunft,* founded in 1892, made its name by its attacks on the court camarilla, which resulted in a prosecution for libel in 1907. Harden's statements proved to be justified. and Count Kuno von Moltke, who had instituted the prosecution, withdrew from the case and Prince P. Eulenburg fled the country. During World War I Harden was a candid critic of the German government and the German high command. He was just as unsparing in his criticisms of the German revolutionary government and of subsequent administrations. He died on Oct. 30, 1927.

Many of his writings and essays were published under the title of *"Kopfe," 4* vol. (1910–24). See *Kautsky and Harden,* by *H.* Delbriick (1920).

HARDENBERG, KARL AUGUST VON, PRINCE (1750–1822), Prussian statesman, was born at Essenroda, Hanover, on May 31, 1750. He studied at Leipzig and Gottingen, and entered the Hanoverian civil service in 1770. Finding the promotion slow, he spent some time in travel, visiting the South German courts and those of France, Holland and England. On his return he married the countess Reventlow, became privy councillor and a count. He then went to London in the hope of obtaining the post of Hanoverian envoy there, but his wife formed a liaison with the prince of Wales, and he was forced to leave the Hanoverian service. He entered (1782) that of Brunswick, but there again his wife's conduct made his position untenable. They were divorced, and he then married a divorced woman. In 1792 Hardenberg was made administrator of the principalities of Ansbach and Bayreuth, which had just fallen to Prussia. He filled this difficult office with great skill, and used it to expand Prussian influence in south Germany. He then received a rising commission as Prussian envoy to the Rhenish courts, and presently succeeded Count Goltz as Prussian plenipotentiary at Basle where he signed (Feb. 28, 1795) the treaty with France.

In 1797, on the accession of Frederick William III, Hardenberg became a member of the Prussian cabinet. He acted as deputy for the foreign minister, Hangwitz, in 1803, and in 1804 succeeded him. The king desired to continue the policy of Prussian neutrality, though he had made an agreement with Russia to take up arms in case of further aggression by Napoleon in north Germany. If there was to be war, Hardenberg would have preferred the French alliance, which was the price Napoleon demanded for the cession of Hanover to Prussia; for the eastern powers would scarcely have conceded, of their free will, so great an augmentation of Prussian power. But he still hoped to gain the coveted prize by diplomacy, backed by the veiled threat of an armed neutrality. Napoleon's contemptuous violation of Prussian territory by marching three French corps through Ansbach turned the scale, and the king signed (Nov. 3) with the tsar Alexander the terms of an ultimatum to be laid before the French emperor. The battle of Austerlitz, however, compelled submission. Prussia, indeed, by the treaty signed at Schonbrunn on Dec. 15, 1805, received Hanover, but in return for all its territories in south Germany. One condition of this arrangement was the retirement of Hardenberg, whom Napoleon disliked. He was again foreign minister after the crisis of 1806 (April–July 1807); but Napoleon's resentment was implacable, and one of the conditions of the terms granted to Prussia by the treaty of Tilsit was Hardenberg's dismissal.

After the enforced retirement of Baron Heinrich von Stein in 1808 and the interlude of the feeble Altenstein ministry, Hardenberg was again summoned to Berlin, this time as chancellor (June 6, 1810). The campaign of Jena had profoundly affected him. He broke with the old diplomacy, and was inspired with a passionate desire to restore the position of Prussia and crush its oppressors. In his retirement at Riga he had worked out a plan for reconstructing the monarchy on Liberal lines; and though circumstances did not admit of his pursuing an independent foreign policy, he prepared for the struggle with France by carrying out Stein's far-reaching schemes of social and political reorganization. The military system was completely reformed, serfdom was abolished, municipal institutions were fostered, the civil service was thrown open to all classes, and great attention was devoted to the educational needs of every section of the community.

After the Moscow campaign of 1812, Hardenberg, supported by the noble Queen Louise, determined Frederick William to take advantage of Gen. Yorck's loyal disloyalty, and declare against France. He was rightly regarded by German patriots as the statesman who had done most to encourage the spirit of national independence; and immediately after he had signed the first peace of Paris he was raised to the rank of prince (June 3, 1814) in

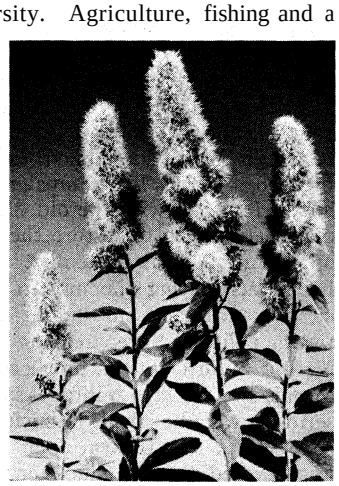
recognition of the part he had played in the War of Liberation.

Hardenberg now had an assured position in that close corporation of sovereigns and statesmen by whom Europe, during the next few years, was to be governed. He accompanied the allied sovereigns to England, and at the congress of Vienna (1814–15) was the chief plenipotentiary of Prussia. But from this time the zenith of his influence, if not of his fame, was passed. In diplomacy he was no match for Metternich. At Vienna, in spite of the powerful backing of Alexander of Russia. he failed to secure the annexation of the whole of Saxony to Prussia; at Paris. after Waterloo, he failed to carry through his views as to the further dismemberment of France; he had weakly allowed Metternich to forestall him in making terms with the States of the Confederation of the Rhine, which secured to Austria the preponderance in the German federal diet; on the eve of the conference of Carlsbad (1819) he signed a convention with Metternich, by which—to quote the historian Treitschke—"like a penitent sinner, without any formal *quid* pro *quo,* the monarchy of Frederick the Great yielded to a foreign Power a voice in her internal affairs." At the congresses of Aix-la-Chapelle, Troppau, Laibach and Verona the voice of Hardenberg was but an echo of that of Metternich. The cause lay partly in the difficult circumstances of the loosely-knit Prussian monarchy, but partly in Hardenberg's character, which had deteriorated with age. He continued amiable, charming and enlightened as ever; but the excesses which had been pardonable in a young diplomatist were a scandal in an elderly chancellor, and could not but weaken his influence with so pious a *Landesvater* as Frederick William III. Hardenberg clung to office, and when the tide turned strongly against Liberalism he allowed himself to drift with it. He died at Genoa, on Nov. 26, 1822.

Hardenberg* (Leipzig, 1904); F. Hartung, *Hardenberg und die preussische Verwaltung in Ansbach-Bayreuth, 1792–1806* (1906); P. Haake, *Der preussische Verfassungskampf vor hundert Jahren* (1921).

HARDERWYK, a seaport in the province of Gelderland, Netherlands, on the shores of the Ijsselmeer, 17 mi. by rail N.N.E. of Amersfoort. Population (1957 est.) 15,484 (mun.).

The principal buildings are the town hall, with some ancient furniture, and a large 15th century church with a notable square tower, named after the famous botanist Linnaeus. In the 17th century Harder~vykhad a university. Agriculture, fishing and a few ddmestic industries form the only employment of the inhabitants. As a seaport its trade was confined exclusively to the Zuider Zee. Plans for the draining of the major part of this sea reduced Harderwyk to a rather unimportant town.



ROCHE

HARDHACK (SPIRAEA TOMENTOSA)

HARDHACK (Spiraea *tomentosa*), a North American shrub of the rose family (Rosaceae, *q.v.*), called also steeplebush, native to open grounds from Nova Scotia to Manitoba and southward to Georgia and Kansas. It has an upright, woolly, reddish-brown stem, 2 to 4 ft. high, bearing, oval. pointed, sharply-toothed leaves, which are grayish or yellowish and woolly beneath. and a slender, steeple-like flower spike crowded with tiny deep-pink flowers, blooming in late summer. The hardhack, which is sometimes planted for ornament, is especially abundant in eastern New York and New England, where in many localities it occurs in weedlike profusion, becoming pestiferous in meadows and pastures. See SPIRAEA.

HARDICANUTE (more correctly HARTHACNUT) (*c.* 1019–1042), son of Canute, king of England, by his wife Emma. On the death of Canute in 1035 the claims of Hardicanute were supported by Emma and her ally, Godwine, earl of the West Saxons, in opposition to those of Harold, Canute's illegitimate son, who was backed by the Mercian earl Leofric and the chief men of the north. Godwine held Wessex for a time on Hardicanute's behalf. Harold's party rapidly increased; and early in 1037 he was definitely elected king. Emma was driven out and took refuge at Bruges. In 1039 Hardicanute joined her, and together they concerted an attack on England. Next year Harold died; and Hardicanute succeeded. His short reign was marked by great oppression and cruelty. He caused the dead body of Harold to be dug up and thrown into a fen; the exaction of a heavy geld for the support of his foreign fleet in Worcestershire, provoked a rising whereupon he burned the city of Worcester to the ground and devastated the surrounding country; in 1041 he permitted Edwulf, earl of Northumbria, to be treacherously murdered after having granted him a safe-conduct.

Hardicanute died on June 8, 1042.

HARDIE, JAMES KEIR (1856–1915), British Labour leader, was born on Aug. 15, 1856, at Legbrannock, Lanarkshire. His early life was one of great hardship; he was employed in the mines from the age of ten. Originally a Liberal in politics, he started, with some friends, in 1887 the Miner, afterwards the *Labour* Leader, the first Socialist paper in western Scotland. In the same year he opened the attack, as delegate of the Ayrshire miners at the Trades Union congress. upon the dominant Liberal members of the parliamentary committee, and continued this struggle, in which his chief allies were John Burns and Tom Mann, up to the decisive defeat of Henry Broadhurst, M.P.. his chief opponent, at the Liverpool congress in 1890. In 1888 he entered politics as an "Independent Labour" candidate for Mid-Lanark, polling only 617 votes; in 1892 he was elected on the same program for South West Ham, but did not retain the seat in 1895. In 1900 he was elected for Merthyr. He was very largely responsible for the foundation of the Scottish Labour party in 1888, and the Independent Labour party (I.L.P.) in 1893. His first great triumph came in 1899, when the Trades Union congress was induced to authorize the formation of labour representation committees in conjunction with the I.L.P. and other Socialist bodies. Socialist-Labour candidates were, for the first time, run systematically at the ensuing election, and at the 1906 election 29 were returned to parliament.

This number was raised to more than 40, but the Socialist character of the party was diluted by the adhesion en bloc of most of the Liberal miners' M P.'s. Hardie was selected as first chairman, and during the years before World War I had as chief tasks firstly, the persuading of the Liberal trade union representatives to advance further on the Socialist path; secondly, the extension of Socialism by public propaganda outside. In attempting these, he was severely criticized by the Social-Democrats as compromising and muddled in theory; for the right wing of the Labour party he was too rugged. But there was no doubt of his success, as chief propagandist for the I.L.P., in spreading Socialist tenets in every manufacturing and mining district, until, in 1914, there was scarcely a big industrial town in which there was not a powerful and active I.L.P. or other Socialist branch.

For such pioneering work Hardie's strong personality, his unquestioned honesty and his lovable character notably fitted him.

In concert with Edouard Vaillant he had made a vain endeavour to bind the Socialist international to calling a general strike in the event of war. The complete failure of this body to act in 1914 was a great disappointment to Hardie; the progress of the war seemed to be undoing his life's work; depression and dejection hastened his death in 1915.

See W. Stewart, *J. Keir Hardie* (1921); *D.* Lowe, *From Pit to Parliament* (1923).

HARDING, CHESTER (1792–1866), U.S. portrait painter, was born at Conway, Mass., on Sept. 1, 1792. He marched as a drummer nith the militia to the St. Lawrence in 1813 and became

subsequently chairmaker, peddler. innkeeper and house painter, painting signs in Pittsburgh. Pa.. and eventually going on the road. self-taught. as an itinerant portrait painter. He soon became proficient. and in the early 1820s had such a vogue in Boston—80 portraits in six months—that he could afford a trip to England. He set up a studio' in London and there met with great success. painting royalty and the nobility, and becoming. despite his lack of education and social experience. a favourite in all circles. Returning to the United States. he settled in Boston and painted portraits of many of the prominent men and women of his time. He died on April 1. 1866.

Harding's portraits may be seen at many galleries in the U.S., including the Essex institute. Salem. Mass.; the National Gallery of Art. Washington. D.C.; the Boston Athenaeum; and the Philadelphia Museum of Art.

HARDING, WARREN GAMALIEL (1865–1923), 29th President of the United States, was born at Corsica (then Blooming Grove), Morrow county, Ohio, on Nov. 2, 1865, son of George Tryon Harding, a farmer and country doctor, and Phebe Elizabeth Dickerson. He studied in the common schools, and from 14 to 17 at the Ohio Central college at Iberia. He taught in a country school for a year, read law for a short time, worked in a newspaper office and in 1884 became editor and proprietor of the Marion *Star*. On July 8, 1891, he married Florence Kling. Having attracted the notice of Senator Joseph B. Foraker, he was encouraged to enter State politics, and was early recognized as an effective speaker. He served two terms in the Ohio senate (1900–04), and during the second was influential in securing Senator Foraker's re-election to the U.S. Senate. From 1904 to 1906 he was lieutenant-governor of Ohio, but in 1910, when nominated for governor by the Republicans, was defeated by a plurality of 100,000. In the campaign of 1912 his paper supported President Taft. In 1914 he defeated Foraker in the Republican primaries as candidate for the U.S. Senate, and was elected with a majority of 100,000 for the term of 1915–21; his friendship with Foraker remained unchanged.

In 1916 Mr. Harding was delegate-at-large from Ohio to the Republican National Convention, of which he was chosen permanent chairman. In the Senate he was regarded as a "safe" man, who could be relied upon to support orthodox Republican policies. In 1915 he urged "preparedness" for naval defence. In 1916 he voted against the confirmation of Louis D. Brandeis as associate justice of the U.S. Supreme Court. In 1917 he gave his support to the declaration of war against Germany, and also to all the war measures, including the Selective Draft and Espionage bills. He favoured the death penalty for spies, but after the war advocated amnesty for political prisoners. He opposed the suggested Federal control of food and fuel. He favoured the Prohibition amendment and voted for the Volstead Act over the President's veto. He favoured the anti-strike clause of the Cummins Railway bill, and voted for return of the lines to their owners within a year after the end of the war. He was for exempting American shipping from Panama Canal tolls and also supported woman suffrage. He was opposed to the Covenant of the League of Nations, holding that "either the Covenant involves a surrender of national sovereignty and submits our future destiny to the League, or it is an empty thing, big in name, and will ultimately disappoint all of humanity that hinges its hopes upon it." He voted for the Lodge resolution of ratification of the Versailles Treaty, with reservations, and against the Underwood resolution of unconditional ratification. He maintained that Americans should show chief concern for America, and opposed all tendencies toward internationalism. He supported the Knox resolution declaring that war with Germany was ended.

At the Republican National Convention in 1920 Mr. Harding was not at first among the prominent candidates for president. On the first ballot he received 65½ votes (493 being necessary for choice), 39 of these being from his own State. On the eighth ballot he received 133½ votes, on the ninth 374½ votes, and on the tenth he secured the nomination with 6923 votes, the result being due largely to the support of certain influential U.S. Senators, deiegates to the convention, who hoped that as president he would be amenable to the Senate. He did not "stump" the country, but conducted his campaign from the "front porch" of his own home. Mr. Harding based his campaign chiefly upon criticism of the Wilson administration, denouncing especially the excessive power that, as he maintained, had been exercised by the executive as a result of war centralization; he demanded as speedy as possible a return to normal conditions, political and industrial.

While opposing the Covenant of the League of Nations, Mr. Harding gave to many of his supporters the impression that he desired an "association of nations," which, without the characteristics of a super-state (such as he believed the League to be), might safeguard peace. But he retained the political support of many who were opposed, like Senators Borah and Johnson, to any sort of international association. In the November elections he won an overwhelming victory over James M. Cox, the Democratic nominee, also from Ohio; he carried, generally by immense majorities, all the northern States and all but one of the States on the border between North and South, and he cut down materially the Democratic majorities in the South. The electoral vote was 404 for Harding against 127 for Cox. The popular vote was 16,133,000 for Harding against 9,142,000 for Cox. In Ohio the popular vote was 1,182,000 for Harding against 780,000 for Cox. The sweeping character of his victory was due less to his own personal strength than to the national reaction against the Democratic Party and the popular feeling against President Wilson. Mr. Harding resigned from the C.S. Senate in Dec. 1920, and was inaugurated on March 4, 1921, the sixth President to come from Ohio.

President Harding's cabinet, like most cabinets, was a *mélange* of men of native ability and political or industrial experience and Party leaders who claimed office as a reward for services rendered the new President. The outstanding names were those of Charles E. Hughes and Herbert C. Hoover, who became Secretary of State and of Commerce respectively. The distinguished career of the former and the widespread confidence in his ability and political integrity had marked him for the most important position in the Cabinet; and there had been a general demand that the new administration should utilize the organizing ability displayed by Hoover in many fields. The choice of Andrew W. Mellon, a wealthy banker and ironmaster of Pittsburgh, as Secretary of the Treasury, was welcomed by men of business. Political and personal debts were paid by the choice of Albert B. Fall as Secretary of the Interior, Harry M. Daugherty as Attorney General and Will H. Hays as Postmaster General. The conduct of administrative and political affairs by these and others less prominent in the new administration, later brought intense criticism upon the President and the Republican Party.

Mr. Harding's inaugural address, and his first message to Congress, delivered in person on April 12, voiced his desire to return to "normalcy," as he expressed it. Retrenchment in expenditure formed a major item in his programme, together with a prompt and thorough revision of taxation. He advocated the adoption of a national budget system, and the Congress having passed a Budget bill similar to that vetoed by Wilson in 1920, he approved it on June 10, 1921; it provided for a Budget Bureau in the Treasury Department and the appointment of a director of the budget, the first being Charles G. Dawes, formerly general purchasing agent of the American Expeditionary Force. President Harding's first budget was presented on Dec. 5, 1921. The President was insistent upon the need of repealing the excess profits taxes and reducing transportation taxes and income surtaxes. The need of financial retrenchment led to his opposing the proposal that war veterans should receive a cash bonus In this matter, as in others, he proved his ability at this early stage to resist political pressure. As regards the tariff he advocated, as a temporary stop-gap, the passing of the emergency tariff, which had been vetoed by President Wilson, but which with slight alteration was approved by Harding on May 27, 1921. He urged the need of adopting a permanent tariff policy, and on Dec. 5. 1921, suggested a "flexible tariff" which might provide for the adjustment of rates to meet unusual and changing conditions. Such

adjustments might be made, in his opinion, by the executive on the advice of the Tariff Commission.

As regards domestic legislation, the President, in general, assumed the rôle of moderator. He disclaimed any desire to enlarge the powers and responsibilities of the executive, which, he declared, were already too large; and he aimed at close co-operation with Congress.

Foreign policy was largely determined by Hughes, financial by Mellon, and the problem of unemployment was thrown upon Hoover. The President, however, frequently played an active rôle in the conferences necessary to secure general agreement, as on Aug. 9, 1921, when an accord was reached between the Treasury and the Representatives on the taxation plan.

The foreign policy of the administration at first seemed likely to emphasize independence of action, in contradistinction to that of President Wilson; the threatened war between Panama and Costa Rica was prevented by a sharp note from Secretary Hughes; the claims of the Japanese to a mandate over Yap were stoutly denied; the administration refused to follow Great Britain in resuming trade relations with Soviet Russia. President Harding made plain in his first message that the United States would not enter the League of Nations.

In rejecting the League Covenant, he said, "we make no surrender of our hope and aim for an association to promote peace, in which we would most heartily join." The President advocated a declaration of peace with Germany by resolution, and the immediate negotiation of a treaty. This policy was adopted by Congress, which agreed upon a joint peace resolution, signed by him on July 2. On Aug. 25, 1921, a treaty with Germany was signed, embodying the President's plan of including most of the stipulations of the Versailles Treaty, but repudiating adherence by the United States to any clause referring to the League of Nations. This treaty and similar pacts with Austria and Hungary were ratified by the Senate on Oct. 18. 1921.

The most important step taken by President Harding during the first year of his administration was the calling of an international conference on the limitation of armaments. On May 25, 1921, the Senate adopted an amendment of Senator Borah to the Navy bill, authorizing and inviting the President to call such a conference.

Mr. Harding's preliminary invitations to the principal naval Powers (Great Britain, Japan, France and Italy) were sent July 10, and formal invitations Aug. 11. He indicated his belief that the question mas closely connected with the problems of the Pacific and Far East, and invitations were also sent accordingly to China and to the smaller European Powers with Far-Eastern interests—Holland. Belgium and Portugal.

The invitations were accepted. and the conference assembled at Washington on Nov. 12. The President made it clear that he regarded the conference merely as a step in securing international understanding and good-will; he advocated the convening of succeeding conferences as a possible means of securing an international association for the promotion of peace, and he approved the principle of substituting an understanding between the United States, Great Britain, France and Japan regarding Far-Eastern problems for the existing Anglo-Japanese Treaty. See WASHINGTON CONFERENCE.

The Washington Conference was the highwater mark of the Harding Administration. Thereafter he faced the development of blocs in the Republican Party which destroyed its solidarity, and the growth of criticism which was manifested in the elections of 1922, as a result of which the Republican majority in the House was reduced. The administrative incompetency of office-holders in Washington was widely heralded and there was more than a suspicion of corrupt dealing on the part of cabinet members and their political followers, who were known to be close to the President. Government investigations later verified such suspicions and revealed an extent of political immorality in Washington such as had no parallel in recent times. Harding himself enjoyed personal popularity; his nature was kindly and genial, and there was general confidence in his honesty and devotion to his duties; but he was regarded as easy-going in his relations with friends and disinclined to scrutinize their activities critically. Resentment was voiced against the Republican national organization controlled by the Old Guard; there was outspoken criticism of the new tariff; keen discontent among the farmers led to the election to the Senate of Shipstead and Magnus Johnson. Again the threat of a Third Party became imminent.

In the summer of 1923 Mr. Harding set forth on a tour across the United States and to Alaska, designed to reassure the farmers and reawaken enthusiasm for the administration. The President, already tired, became ill on the trip back from Alaska and was stricken with pneumonia in San Francisco. On Aug. 2, 1923, he died suddenly. (C. SEY.)

HARDINGE, HENRY HARDINGE, VISCOUNT (1785–1856), British field marshal and governor general of India, was born at Wrotham, Kent, on March 30, 1785. He entered the army in 1799 as an ensign in the queen's rangers, a corps then stationed in Upper Canada. He served right through the peninsular campaigns, and in the Waterloo campaign was British commissioner at Prussian headquarters. He was wounded at Ligny on June 16, 1815, where he lost his left hand by a shot, and thus was not present at Waterloo, fought two days later. He received a pension of £300, a knight commander of the Bath and Wellington presented him with a sword that had belonged to Napoleon.

In 1820 and 1826 Sir Henry Hardinge was returned to parliament as member for Durham; and in 1828 became secretary for war in Wellington's ministry, a post which he also filled in Peel's cabinet in 1841–44. In 1830 and 1834–35 he was chief secretary for Ireland. He succeeded Lord Ellenborough as governor general of India. During his term of office (1844–48) the first Sikh War broke out; and Hardinge, waiving his right to the supreme command, magnanimously offered to serve as second in command under Sir Hugh Gough; but disagreeing with the latter's plan of campaign at Ferozeshah, he temporarily reasserted his authority as governor general (see SIKH WARS). After the Sobraon campaign he was created a viscount, and received a pension of £3,000 for three lives.

Hardinge's term of office in India was marked by many social and educational reforms. In 1852 he succeeded Wellington as commander-in-chief of the British army. In the Crimean War he endeavoured to direct the army on Wellington's principles—a system not altogether suited to the changed mode of warfare. In 1855 he was promoted field marshal.

Hardinge resigned in July 1856, and died on Sept. 24, of the same year at South Park near Tunbridge Wells.

HARDINGE OF PENSHURST, CHARLES HARDINGE, 1ST BARON (1858–1944), British diplomat, was born in London on June 20, 1858, second son of the 2nd Viscount Hardinge. He was educated at Harrow and Trinity college, Cambridge, and in 1880 entered the diplomatic service. He became secretary of legation at Tehran in 1896, and in 1898 went to St. Petersburg (Leningrad) as secretary of embassy. In 1903 he returned to England and became assistant undersecretary for foreign affairs. Later (1906–10) he became permanent undersecretary and accompanied Edward VII on his foreign visits.

He was created knight commander of the order of St. Michael and St. George in 1904, knight of the grand cross of the order of St. Michael and St. George in 1905 and knight of the garter in 1916. From 1904 to 1906 he was ambassador to Russia, and in 1910 was appointed viceroy of India and raised to the peerage. Lord Hardinge returned to England in 1916 and was reappointed to the post of permanent undersecretary of foreign affairs. In Nov. 1920 he succeeded Lord Derby as ambassador in Paris, retiring in 1923. He died Aug. 2, 1944, in London.

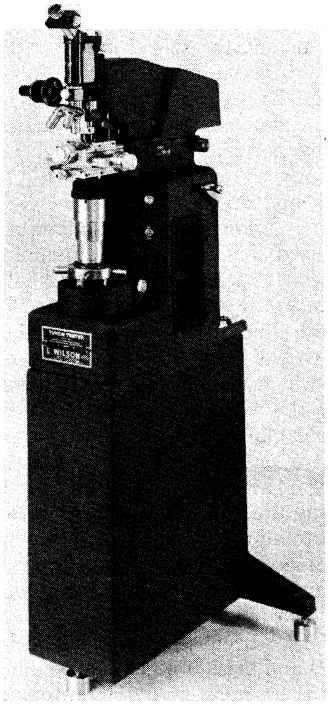
HARD MONEY, a term used in the United States, but not in Great Britain, to designate metallic money and to distinguish it from paper money. It came into existence in the days of the Greenback party. See GREENBACKS.

HARDNESS TESTING. History is replete with references to the preoccupation of man with tools, that is, materials hard enough to cut or otherwise deform softer materials. Attempts to evaluate relative resistance to deformation are noted in early

historical records, for example, the use of a file test in 1640 is recorded.

Although others anticipated it, F. Mohs' scale of resistance to indentation as judged by which material will scratch another has been widely accepted and is used by mineralogists. His scale first described in 1812 assigns numbers to natural minerals.

With development of the arts, there was an increasing demand for more precise evaluation of hardness, particularly of metals, characterized by some ability to deform without fracture. J A. Brinell met this demand very effectively about 1900 with his test for hardness. As commonly used, a load of 3.000 kg. is applied to a hardened steel ball 10 mm. in diameter which is in contact with the plane surface of the metal. The load is maintained for 10 seconds or more and then removed. The diameter of the impression remaining is measured and its spherical area calculated, assuming the same radius for the ball indenter and the indentation. The Brinell hardness number is then obtained by dividing the load in kilograms by the area in square millimetres.



COURTESY OF THE WILSON MECHANICAL INSTRUMENT DIVISION OF AMERICAN CHAIN AND CABLE COMPANY

THE "TUKON" HARDNESS TESTER

A limitation of the Brinell test is that its use is restricted to metals softer than the indenter. Metals used in tools frequently attain this level of hardness. Rockwell introduced about 1920 a test applicable to high levels. It employs a diamond cone indenter nith a spherical point. A hardness number isobtained from the difference between the depth of the impression in millimetres for the major load and that for a minor load. This number is read directly from a dial on the machine. Since fast and reliable readings are readily obtained, it is widely used in industrial inspection. The hardness scale used, however, is nonlinear relative to the Brinell scale and. moreover: has a limited range of high sensitivity, so a variety of other scales are in use and are described in the literature. These scales embrace a range of major loads from 15 to 150 kg. applied to spherical hardened steel indenters from $\frac{1}{16}$ to $\frac{1}{2}$ in. diameter, as well as to the diamond cone. Low loads and large indenters are used to test soft materials such as bearing metals and plastics.

The first hardness tester to meet acceptably the demand for a continuous sequence of comparable numbers over the very aide range of hardness found in metals was the Vickers hardness tester, apparently invented by R. L. Smith and C. E. Sandland. In this method a square-based diamond pyramid indenter is used with 136° angle between opposite faces. This angle was chosen as the mean for the range of penetrations recommended with the Brinell test. At this angle, identical hardness numbers are obtained on relatively soft metals with both the Brinell and Vickers tests. Loads from 10 to 100 kg. are used and the length of the impression diagonals is measured with a micrometer ocular in a microscope that swings over the work after the impression is made. While this machine is much preferred for laboratory work, its operation is rather slow for routine inspection.

There still remain many materials such as glass and minerals whose hardness is of interest but which will crack under the diamond indenters already described. The Knoop hardness test overcomes this limitation by use of an elongated diamond-shaped indenter. An undistorted impression has a length 7.1 times its width and go.j times its depth. With this indenter. the hardness of extremely brittle materials, including glass and even diamonds, can be measured without cracking or spalling either the indenter or the test piece.

The Knoop hardness test number embodies several important departures from conventional hardness testing practice. First, the hardness number is defined as the ratio of the load to the unrecovered lateral area of the indentation in kilograms per square millimetre. The unrecovered area, as distinct from the recovered contact area measured in the Brinell method! is the theoretical lateral area of the indentation while the load is being applied. The Knoop hardness number is found by measuring the length of the impression which is sharply defined and calculating the lateral area from the known ratio of width to length of the indenter. This area is equivalent to that under load because there is lateral spring back. However, width of the unloaded impression relative to length varies widely among the materials tested as a result of differences, among other things, in elastic deformation. A measure of this effect is taken as the ratio of the recovered impression width to that as loaded.

This concept of hardness evaluation found much support when the Brinell test was introduced though Brinell promulgated the use of the ratio of applied load to recovered contact area for an assumed unloaded ball diameter. In the late 1950s this was still current. Knoop *et al.* effectively justified their break with precedent in the following words:

The use of areas which depend upon the elastic recovery of a material is rejected as a method of expressing the results of indentation tests because this associates an applied load with an area other than that involved at the time the load was applied. Furthermore, an unrecovered area is chosen to express the indentation number because it seems to afford the most rational interpretation of the results, placing as it does, vastly different materials such as rubber, copper, glass, and hardened steel in some logical order; whereas, no reasonable sequence results from the use of recovered areas. (F. Knoop, C. G. Peters and W. B. Emerson, "A Sensitive Pyramidal-Diamond Tool for Indentation Measurements," J. *Res. Sat. Bur. Stand.*, 23:39–61, July 1939.)

The merit of the Knoop test. as applied to brittle materials, is well attested to by the evaluation of minerals of the Mohs' hardness scale shown in the table.

Material	Hardness Number	
	Mohs	Knoop
Pitch (for optical polishers)	...	1–22
Gypsum	2	32
Calcite	3	135
Fluorite	4	163
Flint glass	...	180–390
Apatite (parallel to axis)	5	360
Apatite (perpendicular to axis)	5	430
Crown glass	...	420–470
Fused quartz	...	475
Albite	6	490
Orthoclase	6	560
Crystalline quartz (parallel to axis)	7	710
Crystalline quartz (perpendicular to axis)	7	790
Nitrided annealed high-speed steel	...	800
Chromium plate	...	850–900
Carboloy	...	1,050
Nitrided hardened high-speed steel	...	1,100
Topaz	8	1,250
Alundum	...	1,635
Silicon carbide		2,000
Boron carbide (molded)	...	2,230
Diamond	...	8,000–8,100

BIBLIOGRAPHY.—General information on hardness testing is given in the *Metals Handbook*, pp. 93–105 (1948 ed.) and in Hugh O'Neil, *The Hardness of Metals and Its Measurement* (1934). Basic historical works are F. Mohs, *Grundriss der Mineralogie* (1822) and J. A. Brinell, *II Congres Int. des Methodes d'essai* (1900). The original description of the Vickers hardness tester is given in "Accurate Determination of the Hardness of Metals," *Engineering*, p. 518 (April 25, 1924). Also on the Vickers method is R. L. Smith and G. E. Sandland: "Some Notes on the Use of a Diamond Pyramid for Hardness Testing," J. *Iron St. Inst.*, 111:285–294 (1925). Detailed experience with the Knoop tester, including evaluations of many materials, is given in F. Knoop, C. G. Peters and W. B. Emerson: "A Sensitive Pyramidal-Diamond Tool for Indentation Measurements," J. *Res. Nat. Bur. Stand.*, 23: 39–61 (July 1939). (HD. S.)

HARDOI, a municipality. tehsil (subdivision) and district in the Lucknow division of Uttar Pradesh. India. The town is 63 mi. N.W. of Lucknow. Population in 1951 was 29,881. It has a wood-carving industry, saltpetre works and conducts trade in

grain. HARDOI TEHSIL (632 sq.mi.) had a population in 1951 of 387,734.

HARDOI DISTRICT has an area of 2,320 sq.mi. It is a level district watered by the Ganges, Ramganga, Deoha or Garra, Sukheta, Sai, Baita and Gumti rivers—the first three being navigable by local boats. Toward the Ganges the land is uneven, and often rises in hillocks of sand cultivated at the base, and their slopes covered with lofty munj grass. There are several large *jhils* or swampy meres in the district, the largest being that of Sandi, 3 mi. long by ¾ mi. broad.

Large tracts of forest jungle still exist. Leopards, black buck, spotted deer and nilgai are common; the mallard, teal, gray duck, common goose and all kinds of waterfowl abound. In 1951 the population of the district was 1,361,562.

The first authentic records of Hardoi are connected with the Mohammedan colonization. Bawan was occupied by Salar Masaud in 1028, but permanent occupation did not begin until 1217 Between Bilgram and Sandi was fought the great battle between Humayun and Sher Shah, in which the former was utterly defeated. Hardoi, along with the rest of Oudh, became British territory under Lord Dalhousie's proclamation of Feb. 1856.

HARDOUIN, JEAN (1646–1729), French classical scholar, was born at Quimper in Brittany. About the age of 16 he was admitted into the order of the Jesuits. He eventually became librarian of the Collège Louis le Grand in Paris, and died there on Sept. 3, 1729.

He edited Pliny's *Natural History* for the Delphin series and in the course of this work became interested in numismatics. His work in this department was marred, 'like the rest of his work, by a passion for originality. It includes *Nummi antiqui populorum et urbium illustrati* (1684), and *Antirrheticus de nummis antiquis* (1689). He also supervised the *Conciliorum collectio regia maxima* (1715), holding the view that all councils prior to the council of Trent were fictitious.

Among his many paradoxical theories, the most remarkable is that contained in *Prolegomena ad censuram veterum scriptorum*, to the effect that the vast majority of the existing classical works are spurious productions of the monks of the 13th century.

HARDT, THE, a mountainous district of Bavaria, forming the northern end of the Vosges range. It is, in the main, an undulating plateau of sandstone, of a mean elevation of 1,300 ft., and the highest point is the Donnersberg (2,254 ft.).

The eastern slope, toward the Rhine, is diversified by deep well-wooded valleys, such as the Lauter and the Queich, and by conical hills surmounted by ruins of feudal castles and monasteries; *e.g.*, the Madenburg near Eschbach, the Trifels (long the dungeon of Richard I of England), and the Maxburg near Neustadt.

Three-fifths of the area is occupied by forests, principally oak, beech and fir. The lower eastern slope is highly cultivated and produces excellent wine.

HARDWAR, an ancient town and Hindu place of pilgrimage, in the Saharanpur district of Uttar Pradesh, India, on the right bank of the Ganges at the point where the Ganges debouches from the foothills of the Himalayas into the plains. Pop. (1951) 56,175.

The position is of great natural beauty, and the river at this point has special sanctity. The town is of great antiquity and has borne many names. It was originally known as Kapila from the sage Kapila. Hsuan Tsang, the Chinese Buddhist pilgrim, in the 7th century visited a city which he calls Mo-yu-lo, the remains of which still exist at Mayapur, a little to the south of the modern town.

Among the ruins are a fort and three temples, decorated with broken stone sculptures. The goal of the vast numbers of Hindus who visit Hardwar is the Hari-ka-charan, or bathing ghat. with the adjoining temple of Gangadmara. The *charan* or footmark of Vishnu, imprinted on a stone let into the upper wall of the ghat, forms an object of special reverence; and water from the pool below is carried off all over India, for use on solemn occasions. A great assemblage takes place annually, at the beginning of the Hindu solar year (April–May), when the sun enters Aries.

After 1892 many sanitary improvements were made for the benefit of the annual concourse of pilgrims. In early days riots and also outbreaks of cholera were of common occurrence. It is at Hardwar that the main Ganges canal takes off from the river; and the headworks are an engineering feat of much interest.

HARDWARE, a term applied to a large variety of metal goods, especially domestic ironmongery and appliances. hand tools, small metal manufactures such as stoves used in building, garden appliances, etc. There are millions spent annually on builder's hardnare for new buildings of all kinds, and by gas and electricity supply undertakings on lighting, cooking and heating appliances.

Inventive genius is constantly widening the scope of the trade, and the tendency is specially marked in the multiplicity of modern laboursaving appliances for the house. It is impossible to indicate accurately the relative importance of various sections of the trade, but the furnishing side covers a large part of it.

Birmingham, "the city of a thousand trades," is known the world over as the great hardware metropolis, practically every class being made there. One leading branch is the manufacture of hollow ware—cast-iron, galvanized, enameled and aluminum products for domestic and other uses. Cast-iron pots are still sold both for home and export, but the trade has suffered from the competition of enameled goods and aluminum ware. A notable development in the enameled branch has been the introduction of colours. Aluminum hollow ware—which may be cast, deep-drawn under heavy pressure or spun from the flat disk of metal—enjoys great popularity, on account of its cleanliness, lightness and purity. Cast aluminum ware is the most expensive kind and is largely used for ships and hotel kitchens. The manufacture of hearth suites, curbs and companion sets, and fire screens, is another great industry. New metals and finishes to eliminate labour of cleaning have been adopted; the goods are made in copper, Grecian bronze, satin brass. oxidized silver and stainless steel. Birmingham is a centre for electroplated ware, and also for brass foundry.

Cutlery and electroplate trades have been centred in Sheffield for generations. Machine processes and mass production methods are increasingly applied in the cutlery industry. Hand-forged crucible steel blades are still made, but machine processes have been brought to a fine pitch of perfection, and the tradition for quality products is well maintained. The manufacture of stainless steel (*q v.*) by Harry Brearley in the Brown-Firth Research laboratory prior to World War I was one of the most far-reaching developments in the history of steel; not only did it largely revolutionize the cutlery trade, but it proved of great value in the engineering and allied industries. Great improvements have been made in precision grinding, and especially in measures for safeguarding the health of the workers engaged in grinding operations. Safety razor blades are produced—millions per week—in the United States, Great Britain and Germany.

In plated goods, chromium plating applied to base metal is used for flatware like spoons and forks, and for hollow ware, plumbers' fittings, bathroom taps. plugs and wastes, and other goods for domestic and industrial uses where the stainless requisite is desirable.

Builders' Hardware.—This is produced in many centres. Light castings—stoves, ranges, grates, baths and rainwater pipes—are staple manufactures of Falkirk, where the industry was established in 1759. Stoves and ranges for solid fuel have long been made; now, in addition, the industry is meeting needs for cooking and heating appliances using gas or electricity. Here again stainless steel is being more extensively utilized. Mechanical methods are rapidly superseding old laborious hand practice. Machine molding, for instance, is extending. Large outputs of light castings are made from foundries at Rotherham, Leeds, Warrington, Birmingham. in the Black Country and at Luton. Wire manufacture is the chief industry of Warrington; and wire netting works are situated there and also in Manchester, Norwich, and London.

Willenhall and Wolverhampton are the most important centres for locks and latches. Corrugated iron is largely produced in London. Ellesmere Port. Glasgow and South Wales, and in the West Riding of Yorkshire; metal casements are made in Essex;

plumbers' brass foundry and fittings in various centres. but largely in Birmingham. and screws and nails also in the Midlands. Sheffield manufacturers produce saws and woodworking tools, engineering tools and appliances, tools for road making and agricultural work and garden requisites In the Midlands there are norks devoted to the manufacture of edge tools. Agricultural implement making is carried on in Scotland, Yorkshire and the eastern counties. The domestic washing machine trade is carried on in Lancashire, Torkshire and in Glasgow; and Keighley (Yorks) is the leading centre of production for laundry machinery. Carpet sweepers and domestic mops are largely produced in Lancashire; and brushes of all kinds at Oldham, St. Albans. London and Wymondham. An outstanding feature of the hardware trade is its tremendous scope and its varied range of patterns. However. the trend is now toward simplification by the elimination of many patterns and sizes. (N. F.; X)

THE UNITED STATES

At the beginning of the 19th century this term meant chiefly mechanics' tools and builders' hardware. but, in the United States. it has come to mean all small metal articles used in the construction of houses or for household purposes, tools of mechanics' trades, furnishing goods for kitchen and dining room service, tin plate, sheet iron, nails, screws, fence wire, etc.

In the early American colonial period supplies were brought from the mother countries of Europe. As the colonies assumed a definite shape, the village blacksmith established the foundation of American hardware manufacture. Immigrants brought their own tools. the patterns of which were at once copied and improved. Village blacksmiths in Connecticut and thereabouts began to make farm implements and simple hand tools about 1850, and in 1860 American manufacturers began to pull trade away from competitors by virtue of higher quality goods.

The hardware-manufacturing industry began in New England. The business gradually spread into the Middle Atlantic states. especially New Pork and Pennsylvania. In the latter part of the 19th century New York became the undisputed centre of the trade. Here were located the majority of the great importing houses. and here also were founded and flourished the jobbers who distributed to the retail trade. With the growth of the country new advance manufacturing centres were created, and New Pork was no longer the pre-eminent trade centre. (W. H. SIE.; X.)

HARDWICKE, PHILIP YORKE, 1ST EARL OF (1690–1764), English lord chancellor, whose grasp of legal principle and study of the historical foundations of equity, combined with his knowledge of Roman civil law. enabled him to establish the principles and limits of the English system of equity. He was born at Dover on Dec. 1, 1690. Called to the bar at the Middle Temple in 1715, he afterward joined Lincoln's Inn, of which he was bencher and treasurer in 1724. He sat in parliament for Lewes (1719) and Seaford (1722–34); was solicitor general (1720), attorney general (1724), lord chief justice and baron Hardwicke (1733) and lord chancellor (1737).

For many years from 1740 onward Hardwicke held the controlling power in the government. Duripg the king's absences on the continent he was an influential member of the council of regency, and he had to cope with the Jacobite rising of 1745. After Culloden he presided at the trial of the Scottish Jacobite peers. He carried out the great reform of 1746, which swept away the private heritable jurisdictions of the Scottish landed gentry; among his other great legal services was the reform of the English marriage laws (1753).

Hardwicke, who was created earl in 1754, retired with Newcastle in Nov. 1756, but helped to secure the coalition between Newcastle and Pitt in 1757. He died in London on March 6, 1764.

Hardwicke was not a statesman of the first rank, but he was one of the greatest judges who ever sat on the English bench. Lord Campbell pronounces him "the most consummate judge who ever sat in the court of chancery, being distinguished not only for his rapid and satisfactory decision of the causes which came before him, but for the profound and enlightened principles which he laid down, and for perfecting English equity into a systematic science."

Born within two years of the death of Chief Justice Jeffreys, Hardwicke had a powerful influence in obliterating the evil traditions of the judicial bench under the Stuart monarchy.

BIBLIOGRAPHY.—The contemporary authorities for the life of Hardwicke are voluminous, being contained in the memoirs of the period and in numerous collections of correspondence in the British museum. *See,* especially, the *Hardwicke Papers;* Horace Walpole, *Letters,* ed. by *P.* Cunningham, 9 vol. (1857–59); *see* also Lord Campbell, *Lives* of *the Lord Chancellors,* 8 vol., vol. v (1845). (W. T. Ws.; X.)

HARDWOODS. A trade term employed by lumbermen to designate timbers obtained from broad-leaved trees. Coniferous trees, in turn. produce the softwoods of the trade. These two terms often lead to confusion: they should be used only to indicate classes of material rather than specific mechanical properties exhibited by either class. Actually there are several hardwoods, such as yellow poplar, aspen or balsa. which in the mechanical sense are much softer than softwoods of the order of longleaf pine. Douglas fir or yew.

Many beautiful hardnoods are known to the trade, and to this group are traceable such renowned cabinet timbers as American black walnut, Indian rosenood. teak, ebony, primavera, maple, satinwood. American and African mahoganies. greenheart and vermilion. *See* TIMBER.

HARDY, ALEXANDRE (1569?–1631), French dramatist, was born in Paris. He was one of the most fertile of all dramatic authors, and himself claimed to have written some 600 plays. of which, however, only 34 are preserved. He seems to have been connected all his life with a troupe of actors headed by a clever comedian named Valleran-Lecomte, whom he provided with plays. Hardy toured the provinces with this company, which gave some representations in Paris in 1599 at the Hôtel de Bourgogne.

Valleran-Lecomte occupied the same theatre in 1600–03, and again in 1607. apparently for some years. In consequence of disputes with the Confrérie de la Passion. who owned the privilege of the theatre. they played elsewhere in Paris and in the provinces for some years; but in 1628, when they had long borne the title of "royal," they were definitely established at the Hôtel de Bourgogne. Hardy's numerous dedications never seem to have brought him riches or patrons. His most powerful friend was Isaac de Laffemas (d. 1657), one of Richelieu's most unscrupulous agents, and he was on friendly terms with the poet Theophile, who addressed him in some verses placed at the head of his *Théâtre* (1632), and Tristran l'Hermite had a similar admiration for him. Hardy's plays were written for the stage, not to be read; and it was in the interest of the company that they should not be printed and thus fall into the common stock. But in 1623 he published *Les Chastes et loyales amours de Théagène et Cariclée,* a tragi-comedy in eight "days" or dramatic poems; and in 1624 he began a collected edition of his works, *Le Théâtre d'Alexandre Hardy, parisien,* of which five volumes (1624–28) were published, one at Rouen and the rest in Paris. These comprise eleven tragedies: *Didon se sacrifiant, Scédase ou l'hospitalité violée, Panthée, Méléagre, La Mort d' Achille, Coriolan, Marianne,* a trilogy on the history of Alexander, *Alcméon, ou la vengeance féminine;* five mythological pieces; 13 tragi-comedies, among them *Gésippe,* drawn from Boccaccio; *Phraarte,* taken from Giraldi's *Cent excellentes nouvelles* (1584); *Cornélie, La Force du sang, Félismène, La Belle Égyptienne,* taken from Spanish subjects; and five pastorals, of which the best is *Alphée, ou la justice d'amour.*

Hardy's importance in the history of the French theatre can hardly be overestimated. Up to the end of the 16th century mediaeval farce and spectacle kept their hold on the stage in Paris. The French classical tragedy of Étienne Jodelle and his followers had been written for the learned, and in 1628 when Hardy's work was nearly over and Rotrou was on the threshold of his career, very few literary dramas by any other author are known to have been publicly represented. Hardy educated the popular taste, and made possible the dramatic activity of the 17th century. He had abundant practical experience of the stage, and modified tragedy accordingly, suppressing chorus and monologue,

and providing the action and variety which was denied to the literary drama. He was the father in France of tragi-comedy, but cannot fairly be called a disciple of the romantic school of England and Spain. It is impossible to know how much later dramatists were indebted to him in detail, since only a fraction of his work is preserved, but their general obligation is amply established.

See Le Théâtre d'Alexandre Hardy, edited by *E.* Stengel (1883–84, 5 vol.); E. Lombard, "Étude sur Alexandre Hardy," in *Zeitschr. für neufranz. Spr. u. Lit.* (vol. i and ii, 1880–81); K. Nagel, *A. Hardy's Einfluss auf Pierre Corneille* (1884); and especially E. Rigal, *Alexandre Hardy . . .* (1889) and *Le Théâtre français avant la période classique* (1901).

HARDY, SIR GODFREY HAROLD (1877–1947), English mathematician, one of the leading mathematicians of his time, was born at Cranleigh, Surrey, on Feb. 7, 1877, and died on Dec. 1, 1947. He was educated in Cranleigh school, Winchester college and at Trinity college, Cambridge, where he became a Prize fellow (1900–06). From 1906 to 1919 he was a lecturer in mathematics in Trinity college. In 1910 he was elected a fellow of the Royal society and in 1914 was made Cayley lecturer in Cambridge university. In 1919 he was appointed to the Savilian chair of geometry at Oxford university. He returned to Cambridge in 1931 as Sadleirian professor of pure mathematics, a post which he occupied until his retirement in 1942. He received a royal medal of the Royal society in 1920, the society's Sylvester medal in 1940 and its Copley medal in 1947. Many other distinctions and honorary degrees were bestowed upon him. His main mathematical interests lay in analysis and he wrote a number of treatises. contributing more than 300 papers to mathematical periodicals.

(ID. McK.)

HARDY, THOMAS (1840–1928), English novelist and poet, was born at Upper Bockhampton, near Stinsford in Dorset, on June 2, 1540. His father was a master mason, of a family originally connected with the Le Hardys of Jersey, who had settled in the west of England in the 1 jth century. His mother also came of a family long established in Dorset: smallholders in the parish of Melbury Osmond. Hardy owed much to his parents and their rural background, inheriting from his father a love of music, from his mother a love of reading, and from both strength of personality as well as the stability which connected him in an age of change with a world already vanishing.

He went first to the village school and then to a school in Dorchester, and added to the good grounding they provided by his own studies, teaching himself Greek and reading thoughtfully. In 1856 he was articled to John Hicks, an ecclesiastical architect in Dorchester; he continued his own reading, encouraged by William Barnes, the Dorset poet, who kept a school next door to Hicks's office, and by Horace Moule, the brilliant son of the vicar of Fordingbridge, to whose friendship he owed much intellectual stimulus. He continued to live at home, and to find in the life of the small rural community the refreshment and strength which were always necessary to him. In about 1857 he began to write verse and essays but, advised by Moule, decided not to give up architecture. After spending some time sketching and measuring many old Dorset churches with a view to their restoration, he went in 1862 to look for work in London. He became assistant to Arthur (later Sir Arthur) Blomfield, and worked hard at his profession (in 1863 winning both the medal of the Royal Institute of British Architects for an essay, *The Application of Coloured Bricks and Terra Cotta in Modern Architecture,* and the Architectural association's prize for design), although uncertain whether literature or architecture should be his life's work. He read and wrote, attended evening classes and went to art galleries and concerts. In March 186 j his first prose work, a humorous sketch. was published in *Chambers's Journal,* but he was more interested in poetry. Often lonely and depressed, he became ill, and in 1867 he returned to Dorset, working again for John Hicks. and. at Weymouth, for the architect who took over the business when Hicks died. During 1867 and 1868 he wrote a "purpose" story, *The Poor Man and the Lady,* which in 1869 was accepted by Chapman and Hall. It had been read by George Meredith, who asked the writer to call on him, and advised him not to print it, but to try another with more plot. The manuscript was withdrawn and rewritten, but never published, and although Hardy made use of parts of it later, he destroyed the original.

In 1870 Hardy took Meredith's advice too literally, and constructed a novel that was all plot, nhich was published in 1871 under the title *Desperate Remedies.* In 1872 appeared *Under the Greenwood Tree,* subtitled "a Rural Painting of the Dutch School," in which Hardy found himself, and which he never surpassed in delicate perfection of art. *A Pair of Blue Eyes,* in which tragedy and irony come into his work together. was published in 1873. In 1874 Hardy married Emma Lavinia Gifford, whom he had met when working on a church in Cornwall His first popular success was *Far From tlze Madding Crowd* (1874), which, on its appearance anonymously in the *Cornhill Magazzne,* was attributed by many to George Eliot. Then came *The Hand of Ethelberta* (1876) subtitled not inaptly, as "a Comedy in Chapters"; *Tlze Return of the Native* (1878), the most sombre and, in some ways. the most powerful and characteristic of Hardy's novels; *The Trumpet-Major* (1880); *A Laodicean* (1881); *Two on* a *Tower* (1882), a long excursion in constructive irony; *The Mayor of Casterbridge* (1886); *The Woodlanders* (1887); a collection of *Wessex Tales* (1888); *A Group of Noble Dames* (1891); *Tess of tlze D'Urbervilles* (1891), Hardy's most famous novel; *Life's Little Ironies* (1894); *Jude tlze Obscure* (1896), his most thoughtful and least popular book; *Tlze Well-Beloved* (1897), a reprint, with some revision, of a story originally published in the *Illustrated London News* in 1892.

In all his novels Hardy is concerned with one thing, under tno aspects; not civilization, nor manners, but the principle of life itself, invisibly realized in humanity as sex, seen visibly in the world as what we call nature. He is a fatalist, perhaps rather a determinist, and he studies the workings of fate or law (ruling through inexorable moods or humours) in the chief vivifying and disturbing influence in life, women. His view of women is more French than English; it is subtle, a little cruel. not as tolerant as it seems. thoroughly a man's point of view, and not, as with Meredith, man's and woman's at once. He sees all that is irresponsible for good and evil in a woman's character. all that is untrustnorthy in her brain and will, all that is alluring in her variability. He is her apologist. but always with a reserve of private judgment. No one has created more attractive women of a certain class, women whom a man would have been more likely to love or to regret loving. In his earlier books he is somewhat careful over the reputation of his heroines; gradually he allows them more liberty, with a franker treatment of instinct and its consequences. *Jude the Obscure* is, perhaps. the most unbiased consideration in English fiction of the more complicated questions of sex. There is almost no passion in his work. neither the author nor his characters ever seeming able to pass beyond the state of curiosity, the most intellectually interesting of limitations, under the influence of any emotion. In his feeling for nature. curiosity sometimes seems to broaden into a more intimate communion. The heath, the village with its peasants, the change of every hour among the fields and on the roads of that English countryside which he has made his own—the Dorsetshire and Wiltshire "Wessex"—mean more to him, in a sense. than even the spectacle of man and woman in their blind and painful and absorbing struggle for existence. His knowledge of women confirms him in a suspension of judgment; his knowledge of nature brings him nearer to the unchanging and consoling element in the world. All the entertainment which he gets out of life comes to him from his contemplation of the peasant, as himself a rooted part of the earth, translating the dumbness of the fields into humour. His peasants have been compared with Shakespeare's; he has the Shakespearean sense of their placid vegetation by the side of hurrying animal life, to which they act the part of chorus, with an unconscious wisdom in their close, narrow and undistracted view of things.

The order of merit was conferred upon Hardy in July 1910, and in his later years he received increasing recognition, not only as a great novelist but also as a poet, until by common consent he was admitted the undisputed sovereign of English letters. His great epic-drama *The Dynasts,* in three parts (1903–04, 1906,

1908), a chronicle play of England's struggle against Napoleon, with an accompaniment of philosophic comment chanted by a chorus of "phantom intelligences," was in part produced by Harley Granville-Barker in the early months of World War I, and again at Oxford in 1920 Several volumes of lyric poetry followed. His first nife died in 1912, and in 1914 he married Florence Emily Dugdale, herself a writer of children's books and articles in periodicals.

Both on his 70th and his 80th birthday he received at Max Gate (the house he had built himself near Dorchester in 1883, and from which, latterly, he seldom moved) tributes of respect and admiration from the whole English-speaking world. When he died there, on Jan. 11, 1928, his death was felt as a loss, not only of a figure unique in literature because of his great age and of his eminence, but also as a snapping of the last link with the 19th century, and he was mourned as "the last of the great Victorians." His ashes were buried in Westminster abbey, but in consideration of his deep affection for his native Wessex and the peculiar inspiration it gave him, his heart was buried in his parish churchyard.

Aspects of Hardy's Genius. — Thomas Hardy's career naturally divides itself into three periods. The first of these contains his work as a novelist: and ends with *Jude* the *Obscure.* Throughout the series of the novels there gradually become more and more insistent — first as an element of irony, but later as the tragic essence of the narrative — a characteristic metaphysic, in which the strivings and passions of individuals are in fruitless conflict with the inexorable process of the world. *Jude the Obscure,* despite its splendid qualities, made it clear that such a theme could not be adequately developed in the form of the novel; a form was required in which the author could speak out his own convictions without violating aesthetic propriety.

Accordingly! the second period consists of Tlze Dynasts; no doubt the greatest single achievement of his career. It may be said that this great poem was written in order to give full utterance. in artistic form, to his peculiar metaphysic. That, however, was not its originating intention. which was simply to celebrate in a chronicle play England's part in the Napoleonic wars. But as the conception grew and deepened, and as to the human action the superhuman comment of "phantom intelligences" was added. the poem became the summation of Hardy's vision of life; and thereby achieved a unity which. in its intrinsic grandeur and in its perfect command over immense wealth of matter. can only be compared nith such monuments of man's destiny as Faust and Paradise Lost. In diction, honever, Tlze *Dynasts* will not bear any such comparison.

The third period may be said to begin with *Time's Laughing* Stocks in 1909, and is devoted to lyric poetry. It is not often that an artist's life can be divided so definitely into separate stages, each stage characterized by the use of a difierent form; and, next to its length and plenty, and consistently noble idiosyncrasy, this tripartite division is, perhaps, the most remarkable feature of Hardy's career as a whole. The lyrical period. however. does not give us an entirely new development of his genius While he nas nriting novels. he had occasionally experimented with poetry and some of the results were published in *Wessex Poems* (1898) and Poems of *the* Past and *the* Present (1901), between *Jude the Obscure* and *The* Dynasts. The volumes published after The Dynasts also contained a good many more of these earlier poems. But after 1909 Hardy wrote little but lyrical poetry. and this may therefore be truly called his lyrical period. (A Changed *Man.* 1913, merely rescued from the periodicals of former years several stray pieces of minor fiction; Tlze *Queen oj Cornwall,* 1923, was a mummers' play written for a local group of players.) It represents a new concentration of his poner, but certainly no diminution of it.

Devotion to lyrical expression produced a mastery almost as signal in its kind as his command of the art of fiction; and his 70th year san hitn beginning, with Time's *Laughing* Stocks, the series of volumes — Satzres of *Circumstance* (1914), *Moments of Vision* (1917), Latr Lyrics and Earlier (1922), *Human Shows, Far* Phantasies (192j), and the posthumous volume *Winter Words* (1928), which revealed him as the most original, the most poignant and also the most copious of contemporary lyric poets.

The originality of the technique in these volumes did not by any means consist in a mere breach with the accepted conventions, but rather in its highly individual — to some, perhaps, rather disconcerting — compound of the conventional and the unconventional. Most of these lyrics maintain an exact and even rigid formality of stanza. in which a scheme of rhymes is imposed, as it seems, arbitrarily and at all costs. The effect is sometimes justified by its music; but more often by the compact force its pressure gives to language almost conversational in its idiom and choice of words. Yet the diction which defies poetic tradition and seems to despise the magic of elaborated verbal suggestion, is oddly blended with stiff literary phrases and even with words one might expect only lexicographers to think of. The truth seems to be that, in lyrical technique. Hardy had no prejudices either for or against the conventions. He is simply concerned with the matter which intense feeling and profound understanding have enabled him to imagine in a way peculiarly his own. and to express this faithfully he has iorged a technique peculiarly his own, out of whatever the language of literature or of speech could offer him. Readers who are willing to allow him this liberty can hardly fail to be impressed by the subtlety. depth and variety of his versions of the experiences common to humanity; the commonplace becomes in his hands something rich and strange. Naturally. the habits of thought and outlook on the world, which we find progressively insistent in the series of the Wessex novels, and which inspire the turbulent matter and monumental structure of The *Dynasts,* are evident also in the lyrics; which, indeed, are often in the nature of marginal comments on themes previously used.

But something like the quintessence of his tragic power may be found in such ballads as "A Trampwoman's Tragedy," or such keen discrimination of pathos as "Near Lanivet," and something too like the quintessence of his irony to be altogether comfortable in Satires of *Circumstance* or "Ah, Are You Digging on My Grave?" Nor is the rustic humour of his beloved Dorset villagers wanting, nor the vivid delight in nature. in the extraordinary range of his lyrical art. It is. in fact, the same Hardy in the lyrics as in the novels and *The* Dynasts; but a Hardy who, if his lyrics were all me had of him, would surely, by virtue of them alone, hold a secure, indeed a unique, position in modern English literature.

(L. A.; X.)

BIBLIOGRAPHY.—*Editions* and life: There have been several editions of Hardy's complete prose and verse; the Library edition (1953–) will comprise all the novels. The Short Stories *of* Thomas Hardy appeared in 1928; Collected *Poems* (1932) contains all the poetry except The Dynasts and The *Queen* of *Cornwall.* The Letters of Hardy were edited by C. J. Weber (1954) and the Notebooks of Hardy by E. Hardy (1955); F. E. Hardy's The Early Life of *Thomas* Hardy, *1840–1891* (1928) and Tlze Later Years of *Thomas Hardy, 1892–1928* (1930) provided the essential material for later biographies and studies and contained extracts from the letters and notebooks and Hardy's own personal memoirs, recorded by his wife. They are supplemented by E. Hardy's biography, *Thomas* Hardy (1954). R. L. Purdy's *Hardy:* a *Bibliographical* Study (1954) is indispensable. Critical studies include L. Johnson, The Art *of Thomas Hardy* (1894; rev. ed. 1923); L. Abercrombic, Thonzas Hardy: a Critical Study (1912); W. R. Rutland, *Thomas Hardy* (1938); Lord David Cecil, Hardy, the *Novelist* (1943); H. C. Webster, *On a Darkling Plain* (1947); A. J. Guérard, *Thomas* Hardy, tlze *Novels* and Stories (1949); C. Day Len-is, The Lyrical Poetry *of* Thonzas Hardy (1953); J. 1. M. Stewart, "The Integrity of Hardy," in *English* Studies, New Series, vol. i (1948); J. Holloway in The *Victorian* Sage (1953). (X.)

HARDY, SIR THOMAS DUFFUS (1804–1878), English antiquary, belonged to a family famous in the annals of the British navy. Born at Port Royal in Jamaica on May 22. 1804, he crossed over to England and in 1819 entered the Record Office in the Tower of London. Trained under Henry Petrie (1768–1842) he gained a sound knowledge of palaeography. and soon began to edit selections of the public records. From 1861 until his death on June 15, 1878, he was deputy-keeper of the Record Office. which just before his appointment had been transferred to its new London headquarters in Chancery Lane. Hardy. who was knighted in 1873, had much to do with the appointment of the I-listorical Manuscripts Commission in 1869. Sir T. Hardy edited the Close Rolls, *Rotuli* litterarum *clausarum, 1204–1227* (2 vols.,

1833–44), and the Patent Rolls, *Rotuli litterarum patentium, 1201–1216* (1835) with introduction, "A Description of the Patent Rolls, to which is added an Itinerary of King John." He also edited the *Rotuli de oblatis et finibus* (1833), which deal also with the time of King John. He edited many other important series of documents. His best known work is the invaluable *Descriptive Catalogue of Materials relating to the History of Great Britain and Ireland* (3 vols., 1862–71).

HARDY, SIR THOMAS MASTERMAN, Bart. (1769–1839), British vice-admiral, of the Portisham (Dorsetshire) family of Hardy, was born on April 5, **1769,** and in 1781 began his career as a sailor. He became lieutenant in 1793, and in **1796,** being then attached to the "Minerve" frigate, attracted the attention of Nelson by his gallant conduct. He continued to serve with distinction, and in 1798 was promoted to be captain of the "Vanguard," Nelson's flagship. In the "St. George" he did valuable work before the battle of Copenhagen in 1801. He was Nelson's flag-captain on the "Victory" at the battle of Trafalgar in 1805, witnessed Nelson's will, and was in close attendance on him at his death. Hardy was created a baronet in **1806.** He was then employed on the North American station, and later (1819), was made commodore and commander-in-chief on the South American station. In **182j** he became rear-admiral, and in December **1826** escorted the expeditionary force to Lisbon. In **1830** he was made first sea lord of the admiralty, being created G.C.B. in **1831.** In **1834** he was appointed governor of Greenwich hospital, where he died on Sept. **20, 1839.**

See Broadley and Bartelot, *The Three Dorset Captains at Trafalgar* (1906), and *Nelson's Hardy, his Life, Letters and Friends* (1909).

HARDYNG or **HARDING, JOHN** (1378–1465), English chronicler, was born in the north, and as a boy entered the service of Sir Henry Percy (Hotspur), with whom he was present at the battle of Shrewsbury (1403). He then passed into the service of Sir Robert Umfraville, under whom he was constable of Warkworth Castle, and served in the campaign of Agincourt in 1415 and in the sea-fight before Harfleur in **1416.** In 1424 he was on a diplomatic mission at Rome, where at the instance of Cardinal Beaufort he consulted the chronicle of Trogus Pompeius. Umfraville, who died in **1436,** had made Hardyng constable at Kyme in Lincolnshire, where he probably lived till his death about **1465.** Under Henry V. Hardyng was employed to investigate the feudal relations of Scotland to the English Crown. For this purpose he visited Scotland, at much expense and hardship. For his services he says that Henry V. promised him the manor of Geddington in Northamptonshire. Many years after, in 1439, he had a grant of £10 a year for similar services. In 1457 there is a record of the delivery of documents relating to Scotland by Hardyng to the earl of Shrewsbury, and his reward by a further pension of £20. It is clear that Hardyng was well acquainted with Scotland, and James I. of Scotland is said to have offered him a bribe to surrender his papers. But the documents, which are still preserved in the Record Office, have been shown to be forgeries and were probably manufactured by Hardyng himself. Hardyng spent many years on the composition of a rhyming chronicle of England. The original edition ending in **1436** had a Lancastrian bias and was dedicated to Henry VI. Afterwards he prepared a version for Richard, duke of York (d. 1460), and the chronicle in its final form was presented to Edward IV. after his marriage to Elizabeth Woodville in **1464.**

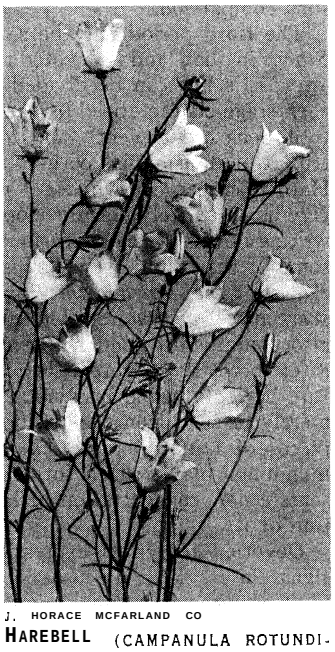
The version of **1436** is preserved in Lansdowne ms. 204, and the best of the later versions in Harley ms. **661,** both in the British Museum. Richard Grafton printed two editions in Jan. **1543,** which differ much from one another and from the now extant manuscripts. Sir Henry Ellis published the longer version of Grafton with some additions from the Harley ms. in **1812.**

See Ellis's preface to Hardyng's *Chronicle,* and Sir *F.* Palgrave's *Documents illustrating the History of Scotland* (for an account of Hardyng's forgeries).

HARE, SIR JOHN (JOHN FAIRS) (1844–1921), English actor-manager especially closely associated with the Garrick theatre, was born at Giggleswick, Yorkshire, on May **16, 1844** He appeared first in Liverpool in **1864,** and in London in 1865, where he was for ten years with the Bancrofts, succeeding in T. W. Robertson's comedies. In 1875 he became actor-manager at the Court theatre and from **1879** to **1888.** in association with the Kendals, brought success to the hitherto unlucky St. James's theatre. He became actor-manager of the Garrick theatre in **1889.** producing Sir Arthur Pinero's *The Profligate* and *The Notorious Mrs. Ebbsmith* and making a personal success in Sydney Grundy's *A Pair of Spectacles,* and later at the old Globe theatre in *Tlte* Gay *Lord Quex.* A fine character actor. Hare was popular in the United States, which he visited between 189j and 1901. Knighted in 1907, he appeared for the last time in 1917 in **A** *Pair of Spectacles.* He died in London on Dec. **28, 1921.** (W. J. M.-P.)

HARE, the name of the well-known English rodent now designated *Lepus europaeus.* The name includes all the numerous allied species which do not come under the designation of rabbits. *(See* RABBIT.) In parts of Europe, where the ordinary species does not occur, its place is taken by the closely allied blue. or mountain hare. the true *L. timidus* of Linnaeus, and the type of the genus *Lepus* and the family Leporidae. *(See* RODEWTIA.) The blue hare is a smaller animal with a more rounded and relatively smaller head. and the ears, hind legs and tail shorter. In southern Sweden it is permanently of a light fulvous gray, with black tips to the ears. but in more northerly districts the fur—except the black ear-tips—changes to white in winter, and still farther north the animal appears to be white at all seasons. In Ireland there is an allied species, *L. hibernicus,* distinguished by its more russet colouring, and the partial or complete absence of the white winter coat. The range of the common hare extends from England across southern and central Europe to the Caucasus; while that of the blue or mountain species reaches from Scotland and Scandinavia through northern Europe and Asia to Japan and Kamchatka. The North American varying hares are closely related to this form. These. the arctic hare (*L. arcticus*) and the Greenland hare (*L. groenlanicus*), turn white in winter.

The hare takes readily to the water. where it swims well; an instance having been recorded in which one was observed crossing an arm of the sea about a mile in width. Hares are remarkably prolific, pairing when scarcely a year old. and the female bringing forth several broods in the year. The young are born covered with hair and with the eyes open, and after being suckled for a month are able to look after themselves. In Europe this species has seldom bred in confinement: although an instance has recently been recorded. It will interbreed with the blue hare. Hares (and rabbits) have a cosmopolitan distribution with the exception of Madagascar and Australasia; and are now divided into numerous genera mentioned in the article RODENTIA. The most important of these groups is the typical genus which contains many different species, distributed over Europe, Asia, North America and Africa. In America several hares are wrongly called rabbits: the "jack rabbits" (*Lepus californicus* and *L townsendii*) and the "snow-shoe rabbits" (*L. americanus). Sylvilagus,* the cottontail, is called rabbit with more reason; it resembles the true rabbit, often lives in holes. and its young are helpless, nearly naked at birth. Several southern species, with less white on the tail, are also placed in this genus.



J. HORACE MCFARLAND CO

HAREBELL (CAMPANULA ROTUNDIFOLIA)

HAREBELL or BLCEBELL is a)$ell-known perennial wild flouer, *Campanula rotundifolia,* a member of the bellflower family (Campanulaceae), found throughout boreal Eurasia and in North America from the

arctic to the mountains of Pennsylvania, the Rockies and Sierra Nevada. The harebell has a very slender slightly creeping rootstock, and a wiry, erect stem. The leaves at the base of the stem, to which the specific name rotundijolia refers, have long stalks, and are roundish or heart-shaped with a wavy or toothed margin; the lower stem leaves are ovate or lance-shaped, and the upper ones linear, almost stalkless, acute and entire. The flowers are slightly drooping, usually solitary or in sparse clusters, and have a smooth calyx. with narrow pointed erect segments, the corolla bell-shaped, with slightly recurved segments, and the capsule nodding, and opening by pores at the base. The plant is found on heaths and pastures throughout Great Britain and flowers in late summer and in autumn. It is there called bluebell of Scotland and witches thimbles, but as bluebell is also applied to a squill (*Scilla*), the vernaculars are often confused. Cultivated in gardens are the blue-flowered form, and double-flowered and white varieties. See CAMPANULA. (N. TR.)

HAREM (Arabic *harīm,* "forbidden"), a name applied to that part of a house in Moslem countries which is set apart for the women; it is also used collectively for the women themselves. Zenana (strictly *zanāna,* from Persian zan, "woman") is the term used in India; *andarūn* (Persian "inner part," *sc.* of a house) in Persia. The Indian harem system is also known as *pardah* or purdah, literally the name of the curtain used to separate the women's quarters from the rest of the house. In Mohammedan countries theoretically a woman must veil her face to all men except her father, her brother and her husband; but among certain Moslem communities (*e.g.,* in parts of Albania) women of the poorer classes may appear in public unveiled.

Turkish Harems.—The Turkish republic in 1926 made polygamy illegal; but even before that date it was not common, for, though the Koran permits four wives, the man of average possessions was perforce content with one wife and a small number of female servants.

The imperial seraglio was a unique institution, an elaborately organized community with a complete system of officers, disciplinary and administrative, and strict distinctions of status. The real ruler of this society was the sultan's mother, the *validé* sultan, who exercised her authority through a female superintendent, the kyahya *kadini.* She had also a large retinue of subordinate officials (kalfas) ranging downward from the *hasnadar* ousta (lady of the treasury) to the "mistress of the sherbets" and the "chief coffee server." Each of these officials had under her a number of pupil-slaves (alaik), whom she trained to succeed her if need be and from whom the service was recruited. After the validk sultan ranked the mother of the heir apparent, called the bash kadin effendi (her excellency the chief lady). Next came the ladies who had borne the younger children of the sultan, the hanum effendis, and after them the so-called odalisques (a perversion of odalik, from odah, "chamber"). Every odalisque who had been promoted to the royal couch received a *daïra,* consisting of an allowance of money, a suite of apartments and a retinue, in proportion to her status. Since all the harem women were slaves, the sultans, with practically no exceptions, never entered into legal marriage contracts.

The security of the harem was in the hands of a body of eunuchs both black and white. The chief of the white eunuchs, the kapu *aghasi* (master of the gates), had part control over the ecclesiastical possessions, and even the vizier could not enter the royal apartments without his permission. The chief of the black eunuchs, usually called the *kizlar* aghasi (master of the maidens), though his true title was darus *se'ādet* aga (chief of the abode of felicity), was an official of high importance. His secretary kept count of the revenues of the mosques built by the sultans. The number of eunuchs was always a large one. The validk sultan and the bash *kadin* effendi each had 50 at their service, and others were assigned to the favourite odalisques.

The ordinary middle-class household was naturally on a very different scale. The selamlik (or men's quarters) was on the ground floor with a separate entrance, and there the master of the house received his male guests; the rest of the ground floor was occupied by the kitchen and perhaps the stables. The *haremlik* (or women's quarters) was generally (in towns at least) on the upper floor fronting on and slightly overhanging the street; it had a separate entrance, courtyard and garden. Communication with the *haremlik* was effected by a locked door, of which the effendi kept the key, and also by a sort of revolving cupboard (*dulap*) for the conveyance of meals.

The presence of a second wife was the exception, and was generally attributable to the absence of children by the first wife. The expense of marrying a free woman led many Turks to prefer a slave woman who was much more likely to be an amenable partner. If a slave woman bore a child she was often set free and then the marriage ceremony was gone through.

The harem ladies frequently drove into the country and visited the shops and public baths. Their seclusion had very considerable compensations and from the moment when a woman, free or slave, entered into any kind of wifely relation with a man, she had a legally enforceable right against him both for her own and for her children's maintenance. She had absolute control over her personal property whether in money, slaves or goods; and, if divorce was far easier in Islam than in Christendom, still the marriage settlement had to be of such amount as would provide suitable maintenance in that event.

On the other hand, of course, the system was open to the gravest abuse, and in countries like Persia, Morocco and India the life of Moslem women and slaves was often far different from that of middle-class women of European Turkey, where law was strict and culture advanced.

After the middle of the 19th century familiarity with European customs and the direct influence of European administrators brought about a certain change in the attitude of orientals to the harem system, and in "progressive" circles those with more than one wife came to be spoken ill of; but Turkey was the only Mohammedan country that abolished polygamy altogether.

India.—In India various attempts were made by societies, missionary and other, as well as by private individuals, to improve the lot of the zenana women. *Zenana* schools and hospitals were founded, and a few women were trained as doctors and lawyers for the special purposes of protecting the women against their own ignorance and inertia. Similarly, trained medical women were introduced into zenanas by the Lady Dufferin association for medical aid to Indian women. In India, as in Egypt, the influence of western education had a considerable effect in relaxing the restrictions formerly placed upon women in the upper and middle classes, and feminist associations began to play a part in political life.

(J. M. M.; X.)

HARFLEUR, a port of France in the *département* of Seine-Maritime, about 6 mi. E. of Le Havre by rail. Population (1954) 7,474. It lies in the valley of the Lézarde, near the estuary of the Seine.

Harfleur is identified with Caracotinum, the principal port of the ancient Calates. In the middle ages, when its name, Herosfloth, Harofluet or Hareflot, still indicated its Norman derivation, it was the principal seaport of northwestern France. In 1415 it was captured by Henry V of England, but in 1435 the people of the district of Caux rose against the English, and got rid of the foreign yoke. Between 1445 and 1449 the English were again in possession; but the town was recovered for the French by Jean, Comte de Dunois. In the 16th century the port began to dwindle in importance because of the silting up of the Seine estuary and the rise of Le Havre. In 1562 the Huguenots put Harfleur to pillage, and its registers and charters were destroyed; but its privileges were restored by Charles IX in 1568, and it was not till 1710 that it was subjected to the "taille." The port was improved on the opening of the Tancarville canal (1887) connecting it with the port of Le

Havre and with the Seine. Vessels drawing 18 ft. can moor alongside the quays of the new port, which is on a branch of the canal, has some trade in coal, timber and grain, and carries on fishing. The church of St. Martin with its lofty stone steeple forms a landmark for the pilots of the river. It dates from the 15th and 16th centuries. Of the old castle there are only insignificant ruins. The industries include distilling, metal founding, flour milling and the manufacture of oil and grease.

HARGEISA, the capital of former British Somaliland (from 1960 part of the Somali republic) in Hargeisa district, lies in a valley, 4.000 ft. above sea level, which runs from west to east and is enclosed by steep hills. Because of its altitude the climate is fairly equable. Pop. (1956 est.) 45,000. Originally the summer capital, Hargeisa became the permanent capital in 1941. Most of the houses are single storied, and there are areas in which nomadic hutments may be erected. Among the public buildings are the offices of the central and local governments. the meeting hall of the legislative council, schools, a broadcasting station and a power station. A network of roads connects Hargeisa with other towns in the former protectorate and with Berbera, the chief port, which lies on the Gulf of Aden, 117 mi. N.E. Frequent air services from Hargeisa airport to Aden and Nairobi link it to the rest of the world. There are no industries but the town is an important watering and trading centre for the nomadic stock herders who form the majority of the population.

The principal exports are fresh meat, sent by air to Aden, and livestock, skins and ghee (clarified butter), which are shipped from Berbera. Imports are mainly confined to tea, sugar. cotton cloth and other consumer goods. (J. A. BN.)

HARGREAVES, JAMES (1834–1915), prolific English inventor of industrial chemical processes, was born at Hoarstones, Lancashire. In 1856 an attempt to devise a method of recovering sulfur from alkali waste brought him in contact with W. Gossage, the soap manufacturer, who employed him until 1865; during this period he discovered a method of bleaching the brown soap in common use, invented blue mottled soap. and devised a method of recovering chromates from the fats and oils used in soap manufacture. Hargreaves also worked out a process for the recovery of phosphates from the slag of blast furnaces. In 1873 he erected works for the manufacture of hydrochloric acid by the action of the gases from pyrites burners on common salt; these works were eventually acquired by the United Alkali company. In conjunction with one of his employees, Bird. he invented the Hargreaves-Bird process for the manufacture of soda by the electrolytic decomposition of salt. This method was extensively adopted in Europe and the United States. In addition to his chemical investigations. Hargreaves invented an engine which ran on gas tar and was called the Hargreaves thermomotor; this was the forerunner of the diesel engine. Hargreaves died at Widnes, Lancashire. on April 4, 1915. (RT. S. C.)

HARINGTON, SIR JOHN (1562–1612), Elizabethan courtier, translator. author and wit. provides through his career and writings a unique insight into the life of the Elizabethan age. His father. John Harington of Stepney, enriched the family by marrying an illegitimate daughter of Henry VIII; his second wife was an attendant on Princess Elizabeth, who later stood as godmother for Sir John, born in 1562. Sir John was educated at Eton, Cambridge and Lincoln's Inn, London. In 1583 he married Mary Rogers, who bore him many children. Because he translated and circulated among the ladies a wanton tale from Ariosto, Elizabeth banished him from court until he should translate Ariosto's entire *Orlando Furioso.* Published in 1591, this remains one of the major translations of the age. more faithful to the spirit and style of the original than to accurate line-by-line reproduction. Probably while working on the Ariosto, Harington invented the flush lavatory (toilet') and installed one for the queen in her palace at Richmond, Surrey. In 1596 in *The Metamorphosis of Ajax* (a jakes, or privy) he described his invention in terms more Rabelaisian than mechanical. Again he was banished from court. In 1599 he accompanied the earl of Essex on his expedition to Ireland, where he won his knighthood. Harington was included in the queen's fury with Essex upon their return, hut he softened her anger with the account he had written of the expedition (published in *Nugae Antiquae,* 1769–7j).

Although active in his county of Somersetshire, Harington made his real career the court. The wantonness of his writings and the barbed wit of his personal epigrams won him a reputation as the queen's "saucy godson," a sort of jester about court, but he gained no advancement thereby. He met with even less success under James I, although he continued to write tracts and epigrams until he died at Kelston, Somerset, on Nov. 20. 1612.

His miscellaneous writings were collected by H. Harington in *Nugae Antiquae,* 2 vol. (1769–75). His *Letters and Epigrams* were edited by N. E. McClure (1930). For a study of the man and his work *see* T. Rich, *Harington and Ariosto* (1940). (T. RH.)

HARIRI, AL- (ABU MOHAMMED AL-QASIM AL-HARIRI) (1054–1122), Arab writer regarded as one of the supreme masters of style in Arabic literature, was born at Mahsan near Basra in 1054. His name denotes "the manufacturer or seller of silk." He is said to have held a government post, but devoted much of his life to studying the niceties of the Arabic language. On this subject he wrote a poem, *Mulhat al-'Irab* (French trans. by L. Pinto and A. Destrées, 1911); a work on the faults of the educated. *Durrat al-Ghawwas* (ed. by H. Thorbecke, 1871); and some smaller treatises (ed. by F. A. Arnold in *Chrestomathia Arabica,* pp. 202–209, 1853). His fame rests mainly on his 50 *maqamat* (ed. by F. Steingass, with English notes! 1896; Eng. trans. by T. Chenery, 1867, and by F. Steingass with valuable introduction. 1898).

The *maqamat* take the form of romances or anecdotes in rhymed prose and are of the same type as those of Hamadhani (*q.v.*), though far surpassing them in command of language. As a model of Arabic writing they came to rank next only to the Koran. They tell of the adventures of a fictional character, the rascally Abu Zayd, and are full of allusions to Arab history, poetry and tradition and to problems of grammar. The dialogue form adopted in them was the Arab's nearest approach to drama.

HARI RUD, the ancient Arius river of Afghanistan. It rises in the northern slopes of the Koh-i-Baba to the west of Kabul and finally loses itself in the Tejend oasis north of the Trans-Caspian railway and west of Merv. It runs a remarkably straight course westward through a narrow trough from Daolatyar to Obeh, amid the bleak wind-swept uplands of the highest central elevations in Afghanistan. From Obeh to Kuhsan, 50 mi. W. of Herat, it forms a valley of great fertility, densely populated and highly cultivated; practically all its waters are drawn off for purposes of irrigation. It is the contrast between the cultivated aspect of the valley of Herat and the surrounding desert that has given Herat its great reputation for fertility. It turns due north and breaks through the Paropamisan hills. Below Kuhsan it receives fresh tributaries from the west. Between Kuhsan and Zulfikar it forms the boundary between Afghanistan and Iran, and from Zulfikar to Sarakhs between Iran and the U.S.S.R. North of Sarakhs it diminishes rapidly till it is lost in the sands of the Turkman desert. The Hari Rud marks the only important break in the continuity of the central water parting of Asia.

HARITH IBN HILLIZA AL-YASHKURI, pre-Islamic Arab poet. was the author of one of the poems generally included among the *Mu'allaqat* (*q.v.*). He was a chieftain of the tribe of Bakr, but nothing is known of the details of his life.

HARIZI, JUDAH BEN SOLOMON (*c.* 1170–1235), a Spanish Hebrew man of letters. During a life of wanderings he translated several scientific works from the Arabic, including Maimonides' *Guide;* his rendering of the latter is more artistic than that of Ibn Tibbon. With his adaptation of the *Maqamat* of Hariri (*q.v.*), which he called *Mahberoth Ithi'el,* he was the only Hebrew writer to attempt translating Arabic poetry. He also produced original Hebrew *Maqamas,* the famous *Tahkemoni* (named after 2 Sam. xxiii, 8), partly translated by S. I. Kaempf in *Nicht-andalusische Poesie andalusischer Dichter* (1858).

See K. Albrecht, *Die . . . Angaben über Harîzîs Leben . . .,* (1890); J. Schirmann, *Die hebräischen Übersetzungen der Maqamen des Hariri* (1930). (C. RN.)

HARKER, ALFRED (1859–1939), British petrologist whose investigations of igneous rock complexes in the isles of Inverness-shire were pioneering achievements in igneous geology, was born at

Kingston-upon-Hull, Feb. 19, 1859. He was educated at St. John's college, Cambridge, where he was elected a fellow in 1885. In Yorkshire, where he spent part of his school days, he became interested in the geology of his native county; this interest in rocks grew at the university and led him to make petrology his life work at Cambridge, where he became, in 1918, reader in the subject.

His early work was on slaty cleavage in rocks, the result of these studies being published in a notable report to the British association (1886). Later, through his study of the mineral complex that girdles the Shap granites in Westmorland, he was able to offer a new interpretation of the thermal metamorphism of rocks. In 1895, at the instance of Sir Archibald Geikie. he was seconded to the Geological Survey of Scotland for summer work in Skye, where he made detailed geological maps of the Cuillins and the Red hills of central Skye.

His standard work, *The Natural History of Igneous Rocks* (1909), treating of the broad aspects of magmatic descent and the controlling influence of tectonic environment, had a strong influence on petrology and, with his later treatise *Metamorphism* (1932), fills an important place in the literature of petrology. He was elected a fellow of the Royal society in 1902 and was awarded its royal medal in 1933. He died at Cambridge, July 28, 1939.

(C. E. T.)

HARLAN, JOHN MARSHALL (1833–1911), associate justice of the U.S. supreme court, best known for his part in decisions involving amendments of the reconstruction period, was born in Boyle county, Ky., on June 1, 1833. He was the grandfather of John M. Harlan (1899–). also a member of the U.S. supreme court. The elder Harlan graduated from Centre college (Danville, Ky.) and studied law at Transylvania university (Lexington, Ky.). He served as county judge of Franklin county, Ky., in 1858–59. The following year he was a presidential elector for the Constitutional Union party. At the outbreak of the Civil War he recruited the 10th Kentucky U.S. volunteer infantry regiment and served as its colonel through numerous engagements. He resigned his commission in 1863 and in the same year was elected attorney general of Kentucky by the Union party. He was re-elected to the office in 1863. In the presidential campaign of 1864 Harlan emerged as a strong critic of the Lincoln administration and supported the candidacy of Gen. George B. McClellan. He later cast his lot with the Republican party and twice, in 1871 and 1875, was that party's unsuccessful candidate for governor. In 1877 he was appointed by Pres. Rutherford B. Hayes to a commission instructed to resolve the competing claims of two rival state governments in Louisiana. On Nov. 29 of the same year he was appointed to the U.S. supreme court by President Hayes. He remained a member of the court until his death almost 34 years later, a period of tenure exceeded by only two other justices in the court's history. In 1892 he was appointed by Pres. Benjamin Harrison to serve in the arbitration of the Bering Sea controversy with Great Britain. He died in Washington, D.C., on Oct. 14, 1911.

Although Harlan had opposed ratification of the 13th amendment. which prohibits slavery and involuntary servitude, as an undue infringement of state powers, as a judge he vigorously urged a broader interpretation of the amendments than any of his colleagues on the bench. His position is well illustrated by his notable dissent in the *Civil Rights Cases*, 109 U.S. 3 (1883). The majority of the court held that congress could not authorize punishment of private individuals who had discriminated against Negroes, since the 14th amendment applies only to "official" or "state" action. Harlan found congressional authority in both the 13th and 14th amendments and advanced a broader concept of "state action" than the court was or has since been willing to accept. In a series of cases involving state criminal procedures, Harlan. in dissent, urged that the 14th amendment imposed on the states the same limitations as are placed on the federal government by the first nine amendments of the U.S. constitution. This view, although never taken by the court, missed acceptance in 1947 by the narrow margin of one vote. The decision of *Plessy* v. *Ferguson*, 163 U.S. 537 (1896), upholding the validity of segregated seating on common carriers. inspired Harlan's eloquent protest and the assertion that "our constitution is colour-blind." His view was vindicated by the 1954 decision of the court in the school segregation cases. While rejecting the "natural rights" theories of Justice Stephen J. Field, Harlan nevertheless frequently voted to invalidate state regulation of economic activity. In *Adair* v. *United States*, 208 U.S. 161 (1908), his opinion for the court invalidated a congressional statute outlawing the so-called "yellow-dog" clause in labour contracts. Other notable opinions include his dissents in the Insular cases in which Harlan opposed withholding the federal bill of rights from unincorporated territories of the U.S. and argued that the constitution "follows the flag." One of his most famous dissents is his opinion in *Pollock* v. *Farmers' Loan and Trust Co.*, 158 U.S. 601 (1895), in which the court invalidated the federal income-tax and necessitated adoption of the 16th amendment.

Harlan's opinions are not distinguished by subtlety or fine discrimination. He was at his best in dissent, and many of these opinions are notable for their great power and conviction and their capacity to expose fundamental issues. He was not one to suppress his disagreements with the majority of the court, and the vigour of his language sometimes bordered on harshness. Harlan is one of the most distinctive figures in the history of the court. Many of his views, rejected by the court on which he sat, attained renewed importance in the years after his death. (F. A. A.)

HARLECH, ancient capital of Merionethshire, Wales, 38 mi. from Aberystwyth by rail. Population (1951) 1,206. (Parish of Llandanwg.) Ruins of a fortress crown the rock of Harlech, about half a mile from the sea. Roman coins have been discovered in the neighbourhood and there are associations with Bronwen, daughter of Bran Fendigaid, and the Mabinogion generally. In the 10th century, Harlech castle was, apparently, repaired by Colwyn, lord of Ardudwy, and thence called Caer Colwyn. The present structure dates from 1285 and is a good example of an Edwardian concentric castle. Edward made Harlech a free borough. Owain Glyn Dwr held it for four years. Dafydd ap Ieuan ap Einion held it for the Lancastrians, until famine made him surrender to Edward IV. From this time is said to date the air *Rhyfelgyrch gwyr Harlech*. The castle was the last to be held for the king in the civil war. The town is a tourist centre.

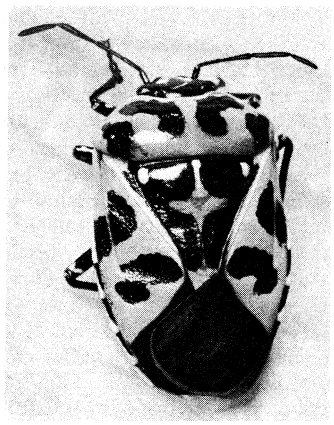
HARLEQUIN, the English name for one of the comic masks of the *commedia dell' arte*. The Italian name Arlecchino has been traced back to the medieval French Herlequin, which denoted a jester with devilish features who had found his way into the mystery plays. The Italian actor Tristano Martinelli (*c.* 1557–1630) is commonly regarded as the creator of the Arlecchino mask in improvised comedy. As a member of various traveling *commedia* companies he specialized as a witty comic servant under the stage name of Arlecchino. The standard Harlequin costume consisted of breeches and a jacket with multicoloured triangular patches sewn onto the garment. The actor carried a lath, the slapstick, which his English descendant in the 18th century used in the Harlequinades as a magic wand for the enactment of transformation scenes. As a rule, Harlequin (and Arlecchino before him) was in love with Columbine. *See* also CLOWN; PANTOMIME. (A. M. N.)

HARLEQUIN BUG, in North America, a hemipterous insect of tropical or subtropical origin, *Murgantia histrionica*, belonging to the stink bug family (Pentatomidae). It is about half an inch in length, shield-shaped and coloured brilliantly with red and black. First observed in Texas in 1864, it thereafter spread rapidly over the United States, reaching New Jersey in 1892 and Long Island in 1894. Now ranging from the Atlantic to the Pacific, the bug is rarely injurious north of about the 40th parallel.

It sucks sap from the leaves and veins of cabbage and other cruciferous crops, causing the plants to wilt and die. Fifty or sixty mature individuals may be found feeding on a large plant. The adult overwinters in sheltered sites. The barrel-shaped white eggs ringed with black are usually laid in double rows on the undersides of leaves. Within a month the eggs hatch, and the active young—wingless, but otherwise resembling the adults—molt five times before reaching full growth. In the south there may be four or five generations annually. Clean culture methods, especially thorough removal of host plants when a crop is harvested and the use of trap crops such as mustard on which the bug can concentrate in the spring and subsequently be killed by insecticides, will reduce losses

of cabbage, Brussels sprouts and others. In small plantings hand-picking is an effective means of control. Many insecticides are injurious to the plants or leave dangerous residues in the cabbage heads. A rotenone dust or spray applied according to manufacturer's directions will provide safe and eiiective control.

In South America the name has been used for a longhorn beetle (*Acrocinus longimanus*); and in Australia a hemipterous insect (*Dindymus versicolor*) injurious to apples and other fruits is called the harlequin fruit bug. (R. I. SR.)



ROSS E. HUTCHINS

HARLEQUIN BUG (MURGANTIA HISTRIONICA), PEST ON CABBAGES AND OTHER CRUCIFEROUS CROPS IN THE SOUTHERN U.S.

HARLEQUIN FLY, the popular name of small flies of the genus *Chironomus*. The larvae, known as bloodworms, are aquatic and live in foul or very deep water where there is little oxygen. To enable them to utilize fully the scant supply of oxygen, these larvae possess in their blood the same red pigment, hemoglobin, that is found in vertebrates. See DIPTERA; ANIMAL COLORATION; PIGMENT, ANIMAL; ANIMALS, DISTRIBUTION OF.

HARLINGEN, a city of Cameron county in southern Texas. U.S., is 28 mi. N.W. of Brownsville. It was founded in the early 1900s and was named for Harlingen. Netherlands. hy its pioneer settler. Lon C. Hill, Sr.. when it became a station (once known as Six-shooter Junction) of the St. Louis. Brownsville and Mexico railroad.

Harlingen was incorporated as a city in 1910, and adopted a city-manager form of local government in 1947.

The city, modern and well planned, is located in the centre of an intensively cultivated agricultural region. It has food-processing plants and is a major transportation and distribution hub of the Lower Rio Grande valley for citrus fruits and vegetables. Port Harlingen. with a grain elevator, oil terminals, chemical plants and other industries. is on a spur of the Intracoastal canal ancl is thus linked with more than 30,000 mi. of inland waterways. There is a Valley Mid-Winter fair. mainly for citrus fruits.

For comparative population figures *see* table in TEXAS: *Population.* (O. MO.)

HARLOW, an urban district created in 1955 after the development of the New Town (designated according to the New Towns act, 1946, to relieve the congestion in London) in the Epping parliamentary division of Essex (with a small part of the New Town in Hertfordshire), Eng., 25 mi. N.N.E. from Charing Cross. London, by road. The population of the area before development (1951) was 5,829; in 1961 it had reached 53,475 and its proposed final figure is 80.000. (See NEW TOWNS.)

Harlow village lies on the main London-Cambridge road and the New Town is to the west of it. A railway line runs through the north of the town. with a new station close to the east industrial estate and the town park, and beyond is the navigable river Stort, a tributary of the Lea. In 1955 a helicopter landing ground was opened.

Wheeled traffic is not allowed in the market square. where markets are held twice a week and which is one of several enclosed spaces for pedestrians only. There are special cycle tracks and footpaths with underpasses beneath main roads. Between the town centre and the residential areas is a belt of carparks and in the centre itself are two tower blocks of flats. Industries in Harlow New Town include the making of glass, surgical equipmen!. scientific apparatus, tools and furniture; printing and metallurgy.

HARMATTAN, a hot, dry wind over the southern Sahara desert that blows from the northeast, primarily in winter. It is a trade wind which is strengthened by the low-pressure area over the north coast of the Gulf of Guinea. The harmattan is accompanied by blowing sand in the desert. reducing visibility and making travel extremely uncomfortable. Suspensions of fine dust are noticeable along and off the west coast of North Africa, where aircraft operations are handicapped by lowered visibilities. At the height of the winter season. the harmattan reaches the Guinea coast. carrying with it clouds of red dust which form a dense haze and impede river navigation.

Locally, the wind is termed "the doctor" for, notwithstanding its disadvantages. it forms a welcome relief from the damp heat of the previous season. (E. M. Bs.)

HARMODIUS, a handsome Athenian youth, friend of Aristogiton. Hipparchus, the younger brother of the tyrant Hippias. endeavoured to supplant Xristogiton in the good graces of Harmodius. but. failing in the attempt, revenged himself by putting a public affront on Harmodius' sister at a solemn festival. Thereupon the two friends conspired with a few others to murder both Hipparchus and Hippias during the armed procession at the Panathenaic festival (514 B.C.). Seeing one of their accomplices speaking to Hippias, and imagining that they were being betrayed, they prematurely attacked and slew Hipparchus alone. Harmodius was cut down on the spot by the guards. and Xristogiton was soon captured and tortured to death. When Hippias was expelled (510), Harlnodius and Xristogiton became the most popular of Athenian heroes; their descendants were exempted from public burdens and had the right of public entertainment in the Prytaneum. The friends' names were celebrated in popular songs and scolia (after-dinner songs) as the deliverers of Athens. One of these songs, attributed to a certain Callistratus, is preserved in Athenaeus. Their statues by Antenor in the agora were carried off by Xerxes and replaced by new ones by Critius and Nesiotes. Alexander the Great afterward sent back the originals to Athens. It is not agreed which of these was the original of the marble tyrannicide group in the museum at Naples.

HARMON, MILLARD FILLMORE (1888–1945). U.S. army officer, military commander in Pacific theatres during World War II, was born on Jan. 19, 1888, at Fort Mason. Calif. In July 1942, after 30 years in the army — most of it as a flyer, staff officer and commander in the air corps — Harmon became commanding general of all U.S. army forces. both ground and air. in the South Pacific. He showed great skill and tact in co-ordinating his operations with those of the navy, which exercised over-all command of the area. A lieutenant general. he exercised supervision over army troops engaged in the air and ground campaigns that reconquered Guadalcanal and the other major islands in the Solomons from the Japanese. Harmon moved to the central Pacific in July 1944 as commanding general of the army air forces, Pacific ocean area. There he made an invaluable contribution to the war against Japan by pressing ahead vigorously with construction of air bases for B-29 bombers in the Marianas. After directing the launching of the strategic air war against Japan by the 20th air force in Nov. 1944, he was lost on a flight between Kwajalein and Johnston islands in the Pacific on Feb. 26–27: 1945. His plane n-as never found. (A. GG.)

HARMONIA, in Creek mythology, the daughter of Ares and Xphrodite. according to the Theban account; in Samothrace, daughter of Zeus and the Pleiad Electra. When Cadmus (*q.v.*) came to Samothrace in search of Europa. he carried off Harmonia; or, in Thebes. she was given him by the gods as his wife. In either case. all the gods honoured the wedding with their presence. Cadmus or one of the gods presented the bride n-ith a robe and necklace. the work of Hephaestus. This necklace brought misfortune to all nho possessed it: it led to the death of Amphiaraus (*q.v.*), of Eriphyle, of Alcmaeon (*q.v.*), of Phegeus ancl his sons. (Even in historic times its baleful influence continued. Phayllus, one of the Phocian leaders in the Sacred War, 352 B.C., carried it off and gave it to his mistress. After she had worn it for a time her son was seized with madness and set fire to the house, and she perished in the flames.) Both Harmonia and Cadmus were ultimately metamorphosed to snakes.

Harmonia is also the name given to the Greek personification of order and symmetry, and according to Euripides (*Medea,* 824) is daughter of the nine Muses. (T. V. B.)

HARMONICA, a generic term applied to musical instruments in which sound is produced by friction upon glass bells. The word is also used to designate instruments of percussion of the glockenspiel type, made of steel and struck by hammers (Ger. *Stahlharmonika*).

The origin of the glass-harmonica tribe is to be found in the fashionable 18th-century instrument known as musical glasses (Fr. *verrillon*), the principle of which was known already in the 17th century. The *verrillon* or *Glasspiel* consisted of 18 beer glasses arranged on a board covered with cloth, water being poured in whenever it was found necessary in order to alter the pitch, and the sound being produced by passing the moistened finger round the rims. (Or sometimes the sides of the glasses were struck instead by wooden sticks.) Gluck gave a concert at the "little theatre in the Haymarket" (London) in April 1746 at which he performed on musical glasses a concerto of his composition with full orchestral accompaniment.

When Benjamin Franklin visited London, in 1757, he was so much struck by the possibilities of the glasses as musical instruments that he set to work on a mechanical application of the principle involved, the result being the glass harmonica finished in 1762. The instrument was for many years in great vogue. Mozart, Beethoven, Naumann and Hasse composed music for it, while it had its celebrated virtuosos, such as Marianne Davies and Marianna Kirchgessner.

The curious vogue of the instrument, as sudden as it was ephemeral, produced emulation in a generation unsurpassed for zeal in the invention of musical instruments. The most notable of its offspring were Carl Leopold Rollig's improved harmonica with a keyboard in 1786, Chladni's euphon in 1791 and clavicylinder in 1799, Ruffelsen's melodicon in 1800 and 1803, Franz Leppich's panmelodicon in 1810. Most of these have long since completely disappeared.

The name, harmonica, is applied also to the aeolina, a small mouth organ, invented by Sir Charles Wheatstone in 1829. A few free reeds, each supplied with wind separately from the mouth of the player, are fastened in a small metal box. The tune is made by moving the instrument to and fro across the mouth, simple tunes being the result.

For the steel harmonica *see* GLOCKENSPIEL.

HARMONIC ANALYSIS is a mathematical procedure by which phenomena of a periodically recurrent nature can be subjected to measurement. Problems of great intricacy have been reduced to manageable terms by its technique of breaking complicated mathematical curves into comparatively simple components. Its applications range from analysis of the vibrations of machines to the study of sunspots.

A description of this versatile science was given by one of its pioneers. Jean Baptiste Joseph Fourier, in his classic thesis, *Analytical Theory of Heat* (1822):

> The analytical equations, unknown to the ancient geometers, which Descartes was the first to introduce into the study of curves and surfaces, are not restricted to the properties of figures . . . they extend to all general phenomena. . . . If matter escapes us, as that of air and light, by its extreme tenuity, if bodies are placed far from us by the immensity of space, if man wishes to know the aspect of the heavens at successive epochs separated by a great number of centuries, if the actions of gravity and of heat are exerted in the interior of the earth at depths which will be always inaccessible, mathematical analysis can yet lay hold of the laws of these phenomena. It makes them present and measurable.

Historical Background. — Much of the history of harmonic analysis is the story of the strange marriage of mysticism and mathematics.

In the 6th century B.C., Pythagoras taught that the essence of harmony was inherent in the miraculous power of numbers; but his mysticism was allied with keen observation and deduction. For example, he knew that the musical note produced by a string of fixed tension was converted into its octave when the length was reduced one-half, and its fifth when reduced two-thirds.

The great astronomer Johannes Kepler (*q.v.*) in the 16th and 17th centuries was imbued with the mysticism of Pythagoras, which was enjoying a revival in the centres of learning. particularly in the Italian universities. Kepler, while not accepting in a physical sense the "music of the spheres" of Pythagoras, believed it was possible to represent the motion of every planet in terms of musical notation. Stimulated by the quest for a basic harmony in arithmetic, geometry and music, Kepler opened a new era of mathematics with his discovery of the laws of planetary motion. Even in his lyrical moods, Kepler maintained the mathematician's quest for precision. For example, his staff notation of the tune appropriate to Mercury indicated, in strongly accented arpeggios, that its orbit is more elliptical than that of the other planets.

Another scientist who drew his inspiration from mysticism and his technique from mathematics was Isaac Newton. Newton, who was a disciple of the mystic Jakob Boehme, wrote in the *Principia,* published in 1687: "Nature is pleased with simplicity, and affects not the pomp of superfluous causes." But it is the hardheaded mathematician who is speaking in this excerpt from one of Newton's letters: "For the best and safest method of philosophizing seems to be, first diligently to investigate the properties of things, and establish them by experiment, and then to seek hypotheses to explain them."

Newton gave the first mathematical treatment of wave motion in the *Principia.* His calculations gave the ellipticity of the earth as 1/230; the figure accepted today is 1/297.

In connection with the study of the vibration of musical strings Daniel Bernoulli and Leonhard Euler laid the groundwork for Fourier's elaborate mathematical structure. The equations known as the Fourier series were first published by Bernoulli in 1728.

In keeping with the ancient traditions of harmonic analysis, James Clerk Maxwell in the 19th century pronounced Fourier's *Analytical Theory of Heat* "a great mathematical poem."

In *Science and the Modern World* (1925), Alfred North Whitehead notes that "we have in the end come back to a version of the doctrine of old Pythagoras, from whom mathematics, and mathematical physics: took their rise. He . . . directed attention to numbers as characterizing the periodicity of notes of music. . . . And now in the 20th century we find physicists largely engaged in analyzing the periodicities of atoms."

Basic Theory. — Many physical phenomena, such as sound waves, alternating electric currents, tides, machine motions, etc., may be periodic in character. Such motions can be measured at a number of successive values of the independent variable, usually the time; and these data, or a curve plotted from these data, will represent a function of that independent variable. Thus the ordinate of the curve at any point is $y=f(x)$. Generally the mathematical expression for f(x) will be unknown.

However, with the periodic functions found in nature, $f(x)$ can be expressed as the sum of a number of sine and cosine terms. Such a sum is known as a Fourier series (*q.v.*) and the determination of the coefficients of these terms is called harmonic analysis. The term harmonic analysis can also be used in the broader sense of the analysis into any kind of periodic components, such as spherical harmonics, cylindrical harmonics, tesseral harmonics. etc. However. this article shall be confined to the development into Fourier series, which development has found more extensive practical application than any of the others. One of the terms of such a series has a period equal to that of $f(x)$ and is called the fundamental. Other terms have shorter periods, which are integral submultiples of the fundamental. These are called harmonics.

Applications. — Harmonic analysis is of great value in mathematics. in physics and in engineering. A sound wave, for instance, can cause the vibration of a thin diaphragm, whose motion is photographed in the form of a continuous curve by the use of the Phonodeik of D. C. Miller, or by other methods such as the cathode ray oscilloscope. The shape of the resulting curve will depend on the quality of the sound and will generally be quite complicated. However, it can be analyzed into its fundamental and harmonics or overtones by use of Fourier series. It is the number and magnitude of these harmonics which determine the quality of the sound, and therefore such investigations are of great value in the scientific study of music and speech. Similar methods are used extensively by the electrical engineer in the study of alternating currents. In mechanical engineering they can be used

in the investigation of valve motion and other mechanical movements.

Harmonic analysis may be also used in the study of tidal records; and. by the use of such information as it affords, the prediction of tides is possible. (*See* TIDES.)

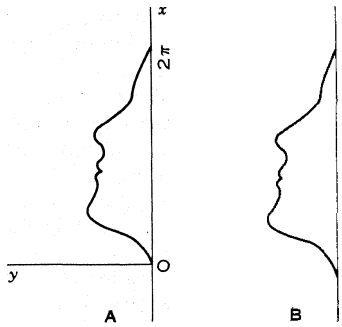


FIG. 1

All the above applications have been for cases where the movements are truly periodic. In a large class of other phenomena, such as the weather, sunspots, magnetic deviations, river flow, atmospheric strays in radio reception. etc.. the fundamental period is usually not evident and the periods of the harmonics are not simple submultiples of the fundamental. Even in such cases, however. modified methods can be used to some extent to give an analysis into a series of sine or cosine terms.

Any ordinary nonperiodic curve of finite length can also be analyzed by the harmonic method. the scale being changed in the x-direction so that the length is 2π units. An example taken from D. C. Miller's excellent book, The *Science* of *Musical Sounds*, is shown in fig. I(A), where a profile of a face is analyzed and found to have the equation:

$$\begin{aligned} y = {} & 49.6 \sin(\theta+302^\circ)+17.4 \sin(2\theta+298^\circ) \\ & +13.8 \sin(3\theta+195^\circ)+7.1 \sin(4\theta+215^\circ) \\ & +4.5 \sin(5\theta+80^\circ)+0.6 \sin(6\theta+171^\circ) \\ & +2.7 \sin(7\theta+34^\circ)+0.6 \sin(8\theta+242^\circ) \\ & +1.6 \sin(9\theta+331^\circ)+1.3 \sin(10\theta+208^\circ) \\ & +0.3 \sin(11\theta+89^\circ)+0.5 \sin(12\theta+229^\circ) \\ & +0.7 \sin(13\theta+103^\circ)+0.3 \sin(14\theta+305^\circ) \\ & +0.4 \sin(15\theta+169^\circ)+0.5 \sin(16\theta+230^\circ) \\ & +0.5 \sin(17\theta+207^\circ)+0.4 \sin(18\theta+64^\circ). \end{aligned}$$

These harmonics were then combined, giving the result shown in fig. I(B).

Numerical Methods. — In 1822 Fourier stated that a function $y=f(x)$ could be expressed between the limits of $x=0$ and $x=2\pi$ by the series:

$$y = a_1 \sin x + a_2 \sin 2x + a_3 \sin 3x + \cdots + b_0 + b_1 \cos x + b_2 \cos 2x + \cdots \quad (1)$$

provided the function is single-valued, finite and continuous except for a finite number of discontinuities. The coefficients are

$$\left.\begin{aligned} b_0 &= \frac{1}{2\pi}\int_0^{2\pi} y\,dx \\ b_k &= \frac{1}{\pi}\int_0^{2\pi} y \cos kx\,dx \\ a_k &= \frac{1}{\pi}\int_0^{2\pi} y \sin kx\,dx \end{aligned}\right\} \quad (2)$$

where $k=1, 2, 3, \cdots$

With the further restriction that there be only a finite number of maxima and minima, the theorem was proved by Lejeune Dirichlet in 1829.

Equation (1) can be written in the alternate form:

$$y = c_1 \sin(x+\phi_1)+c_2 \sin(2x+\phi_2)+c_3 \sin(3x+\phi_3)+\cdots, \quad (3)$$

where

$$c_k = \sqrt{(a_k^2+b_k^2)}, \qquad \phi_k = \tan^{-1}\frac{b_k}{a_k} \quad (4)$$

Assume that a record has been obtained of some periodic phenomenon expressed as a curve or as a set of data which can be plotted and called $f(x)$. Even although $f(x)$ cannot be expressed as a simple function. equation (1) can be used to approximate it, and the coefficients a, and b_k can be determined. It will be necessary first to find the period of the function; that is, the distance between corresponding points on successive waves. This distance will be called 2π radians or 360°, and can then be divided into any convenient number of parts, say n. The first n ordinates are measured and their values substituted in equation (1), giving n equations in the n undetermined coefficients. These equations can be solved to obtain a, and b_k. The n equations have the form:

$$y_k = b_0 + b_1 \cos x_k + b_2 \cos 2x_k + \cdots + a_1 \sin x_k + a_2 \sin 2x_k + \cdots,$$

where k = 0, 1, 2, 3, . . . (n−1) successively; y_k is the kth ordinate of the curve, and x_k is the corresponding abscissa expressed in degrees. From these it can be shown that

$$\left.\begin{aligned} b_0 &= \frac{1}{n}(y_0+y_1+y_2+\cdots+y_{n-1}), \\ b_k &= \frac{2}{n}(y_0 \cos kx_0+y_1 \cos kx_1+\cdots+y_{n-1} \cos kx_{n-1}), \\ a_k &= \frac{2}{n}(y_0 \sin kx_0+y_1 \sin kx_1+\cdots+y_{n-1} \sin kx_{n-1}). \end{aligned}\right\} \quad (5)$$

A curve plotted from (1) using the coefficients (5) will pass through all the values y_k exactly, but probably will not coincide with the experimental curve at other points. Obviously, the use of a larger number of terms will increase the accuracy. In some applications the function can be very closely approximated by a few terms. In other cases, particularly if the wave has sharp corners. a large number of terms is necessary to get a sufficiently accurate expression. It is often possible to tell something about the coefficients by inspection, thus simplifying the mathematical work of analysis. If positive and negative loops of the curve are the same, then even harmonics are absent. This is practically always the case with alternating currents. Also, if the curve for $x<0$ is the reflection in the y-axis of the curve for $x>0$, there will be no sine terms; while if the curve is symmetric about the origin, there are no cosine terms.

Schedule Methods. — The use of equation (5) is the basis of numerous so-called schedule methods of analysis. These are merely short cuts for solving this equation, many of the routine multiplications being combined and tabulated in a schedule. Of these, the best-known is probably that of C. Runge. It can best be explained by an example. For this a six-point schedule has been selected. Only odd harmonics are considered, and the zero is taken where the curve crosses the x-axis. Then the six equations are:

$$\begin{aligned} 3b_1 &= y_1 \cos 30^\circ + y_2 \cos 60^\circ + y_3 \cos 90^\circ + y_4 \cos 120^\circ + y_5 \cos 150^\circ, \\ 3b_3 &= y_1 \cos 90^\circ + y_2 \cos 180^\circ + y_3 \cos 270^\circ + y_4 \cos 360^\circ + y_5 \cos 450^\circ, \\ 3b_5 &= y_1 \cos 150^\circ + y_2 \cos 300^\circ + y_3 \cos 450^\circ + y_4 \cos 600^\circ + y_5 \cos 750^\circ, \\ 3a_1 &= y_1 \sin 30^\circ + y_2 \sin 60^\circ + y_3 \sin 90^\circ + y_4 \sin 120^\circ + y_5 \sin 150^\circ, \\ 3a_3 &= y_1 \sin 90^\circ + y_2 \sin 180^\circ + y_3 \sin 270^\circ + y_4 \sin 360^\circ + y_5 \sin 450^\circ, \\ 3a_5 &= y_1 \sin 150^\circ + y_2 \sin 300^\circ + y_3 \sin 450^\circ + y_4 \sin 600^\circ + y_5 \sin 750^\circ. \end{aligned}$$

All can be expressed as functions of 30°, 60° and 90°:

$$\begin{aligned} 3b_1 &= (y_2-y_4) \sin 30^\circ + (y_1-y_5) \sin 60^\circ, \\ 3b_3 &= -(y_2-y_4) \sin 90^\circ, \\ 3b_5 &= (y_2-y_4) \sin 30^\circ - (y_1-y_5) \sin 60^\circ, \\ 3a_1 &= (y_1+y_5) \sin 30^\circ + (y_2+y_4) \sin 60^\circ + y_3 \sin 90^\circ, \\ 3a_3 &= (y_1-y_3+y_5) \sin 90^\circ, \\ 3a_5 &= (y_1+y_5) \sin 30^\circ - (y_2+y_4) \sin 60^\circ + y_3 \sin 90^\circ. \end{aligned}$$

It will be noticed that, except for y_3, all the coefficients occur as sums or differences. In the schedule given above, y_0 has been added so that the curve does not have to cross the x-axis at $x=0$. If $f(x)=0$ when $x=0$, as in the previous equations, then of course y_0 disappears. The work can be tabulated as shown in Table I. Table II is a numerical example given by F. W. Grover. This has been plotted in fig. 2. The heavy curve is the one to be analyzed. The six points used in the above schedule are enclosed by circles. Since the wave is nearly sinusoidal, the analysis results in a large fundamental sine curve and very small higher harmonics. Synthesis gives the light curve of fig. 2. It will be noted that this passes through all six points, but does not exactly coincide with the original curve throughout. By taking a larger number of points and, therefore, a different schedule, a much closer approximation would be obtained.

TABLE I.—General Schedule

Measured ordinates	Sums	Differences		Sine terms: 1st and 5th	Sine terms: 3rd	Cosine terms: 1st and 5th	Cosine terms: 3rd
y_0		d_0					
y_1 y_5	S_1	d_1	sin 30°	S_1		d_2	
y_2 y_4	S_2	d_2	sin 60°	S_2		d_1	
y_3	S_3		sin 90°	S_3	S_1-S_3	d_0	d_0-d_2
				S_0 S_e	S	D_0 D_e	D
				$a_1=\frac{S_0+S_e}{3}$	$a_3=\frac{S}{3}$	$b_1=\frac{D_0+D_e}{3}$	$b_3=\frac{D}{3}$
				$a_5=\frac{S_0-S_e}{3}$		$b_5=\frac{D_0-D_e}{3}$	

A method of selected ordinates has been devised by J. Fischer-Hinnen. This appears to require slightly less computation than the Runge method, but has the disadvantage that a new set of equally spaced ordinates must be measured for each pair of coefficients. Other methods of computation of the coefficients have been worked out by C. P. Steinmetz. S. P. Thompson and others. Various graphical methods have also been devised. C. S. Slichter, for instance, uses a special graph paper which introduces the sine or cosine factor without computation. The area under the curve is measured with an ordinary planimeter. It requires the replotting of the curve for each coefficient, and it is doubtful if any time is saved over the schedule method. Other graphical methods have been used by W. K. Clifford, J. Perry, Harrison, Ashworth. Beattie and Rottenburg.

Mechanical Methods.— The above methods all require a large amount of labour, especially if many coefficients are to be determined. If much of the work is to be done, therefore, some machine method is advisable. Equation (2) is used in most of the mechanical analyzers.

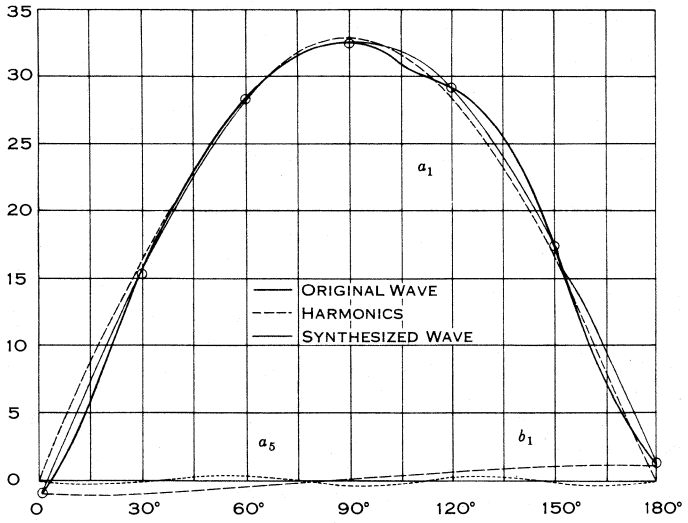

FIG. 2

If the curve $y=f(x)$ of fig. 3(A) is to be analyzed, it is merely necessary to multiply the ordinates by sin x (fig. 3[B]) and obtain the area under the resulting curve (fig. 3[C]). This gives

$$\int f(x) \sin x\, dx,$$

which is proportional to a_1. The other coefficients are obtained similarly. Most of the machines, therefore, consist of some means of multiplying the ordinates of the curve by sin kx or cos kx and integrating the product.

The first mechanical harmonic analyzer was invented in 1876 by Lord Kelvin. Another machine working on a similar principle is that invented in 1894 by O. Henrici and A. Sharp. For descriptions and illustrations of these early machines see MATHEMATICAL INSTRUMENTS. The Henrici machine was improved by G. Coradi. This very beautiful instrument makes use of a number of glass spheres which are moved an amount equal to the ordinate of the curve. The readings are obtained by two Amsler integrating wheels bearing on each sphere, one reading sine components, and the other cosine components. A five-sphere machine will thus give ten coefficients for one trace of the curve. The machine is speedy and accurate, but its expense and delicacy have limited its use to some extent. The Michelson and Stratton analyzer will handle up to 80 coefficients at once. It works equally well as a synthesizer and has been extensively used in tide prediction. The Chubb analyzer differs from all others in that it uses a polar graph instead of a rectangular one. The curve, in the form of a cardboard template, is fastened to the table of the machine. The table moves back and forth with a sinusoidal motion as it turns, and the result is integrated by an ordinary planimeter. The machine can evaluate only one coefficient at a time and is therefore slow. It is very rugged, and finds considerable use in connection with polar oscillograms.

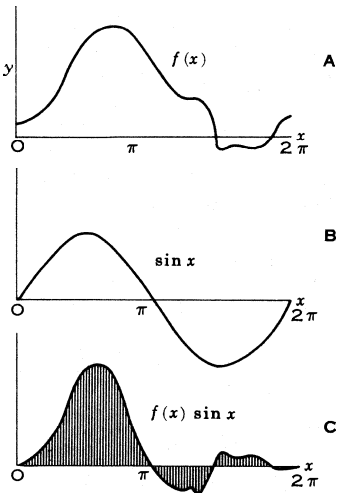

FIG. 3

A product integraph developed at the Massachusetts Institute of Technology can obtain the integral of the product of any two functions. Its primary use is in the mechanical solution of differential equations, but it can be used for harmonic analysis. In fact, it will develop curves in terms of various other series as well as the harmonic series of Fourier. Many other machines have been proposed, notably by O. Mader, Rowe, Wiechert and A. Sommerfeld, Bashforth, G. U. Yule, J. Le Conte, Terada. F. S. Dellenbaugh and D. O. Woodbury. Most of these machines work on the principle previously mentioned, though the Dellen-

TABLE II.—Schedule with Numerical Example

	Ordinates	Sums	Differences		Sine terms: 1st and 5th	Sine terms: 3rd	Cosine terms: 1st and 5th	Cosine terms: 3rd
0	−1·3 . . .		−1·3					
1	15·1 17·3 . . .	32·4	−2.2	0·50	+16·200		−0·425	
2	28·0 28·85 . . .	56·85	−0·85	0·86		−49·233		−1·905 −1·300
3	32·35	32·35		1·00	32·350	32·400	−1·300	0·850
				Sums	48·550	49·233	0·050	1·725 1·905 −0·450
				S_e	49·233			1·905
					97·783	−0·683		−3·630 0·180
				$a_1=$	32·594			$b_1=-1·210$ $b_3=-0·150$
					$a_5=-0·228$		$a_3=0·017$ $b_5=0·060$	

baugh uses the schedule method, while the Woodbury is based on the Fischer-Hinnen method.

Direct Analysis.— The above methods make use of an experimentally determined curve or set of data. In the case of electric currents or voltages. an entirely different method is possible. This direct method was suggested by M. I. Pupin in 1894. and was developed by the Bell System laboratories. Instead of first getting an oscillographic record of the voltage or current and analyzing it mathematically. the analysis is performed directly on the electric quantity by making a record of the response when the natural frequency of a tuned circuit is varied through a wide range.

A large number of methods are available for the harmonic analysis of complex waves. The direct mathematical method is unnecessarily long and arduous. This has been simplified by schedules which are fairly quick and are the methods generally used if only a small amount of such work is to be done, or if a punched card system or some other form of digital computer is available. If much harmonic analysis is required, it may be advisable to use a machine analyzer, such as the Henrici-Coradi, the Michelson and Stratton, or the Chubb. Of these the first appears to offer advantages if five or ten coefficients are sufficient. If a very large number of terms is required, the Michelson and Stratton is advisable.

The reverse process of synthesis is also used to a considerable extent. particularly in tide prediction. Various machines have been built for this purpose. the first being designed by Kelvin. An extremely compact form of Kelvin synthesizer was built by D. C. Miller for use in his work on the theory of musical sounds. The Michelson and Stratton machine is also very good for synthesis. In fact. any of the analyzers can be used for this purpose, though some are much more convenient than others. Some synthesizers display the sum of suitable voltages on an oscilloscope. See also FOURIER SERIES; SOUND; TIDES.

(V. BU.; P. FN.)

HARMONICHORD, an ingenious kind of upright piano, in which the strings were set in vibration not by the blow of a hammer but by friction. One of the many attempts to fuse piano and violin, the harmonichord was invented by Johann Gottfried and Johann Friedrich Kaufmann (father and son) in Saxony at the beginning of the 19th century. The space under the keyboard was enclosed, a knee-hole being left in which were two pedals used to set in rotation a large wooden cylinder fixed just behind the keyboard over the levers. The cylinder (in some specimens covered with chamois leather) tapered towards the treble-end. When a key was depressed, a little tongue of wood, one end of which stopped the string, was pressed against the revolving cylinder, and the vibrations produced by friction were transmitted to the string and reinforced as in piano and violin by the soundboard. Carl Maria von Weber must have had some opinion of the possibilities of the harmonichord. since he composed for it a concerto with orchestral accompaniment.

HARMONIUM, a wind, keyboard instrument, otherwise a small organ without pipes, furnished with free reeds. Both the harmonium and its later development, the American organ, are known as free-reed instruments, the musical tones being produced by tongues of bra-s. technically termed "vibrators." The vibrator is fixed over an oblong, rectangular frame. through which it swings freely backwards and forwards like a pendulum while vibrating, whereas the beating reeds (similar to those of the clarinet family), used in church organs, cover the entire orifice, beating against the sides at each vibration. A reed or vibrator, set in periodic motion by impact of a current of air, produces a corresponding succession of air puffs, the rapidity of which determines the pitch of the musical note. There is an essential difference between the harmonium and the American organ in the direction of this current; in the former the wind apparatus forces the current upwards, and in the latter sucks it downwards, whence it becomes desirable to separate in description these varieties of free-reed instruments.

Harmonium.—This has a keyboard of five octaves compass when complete, and a simple action controlling the valves, etc. The necessary pressure of wind is generated by bellows worked by the feet of the performer upon foot-boards or treadles. The air is thus forced up the wind-trunks into an air-chamber called the wind-chest, the pressure of it being equalized by a reservoir, which receives the excess of wind through an aperture, and permits escape, when above a certain pressure, by a discharge valve or pallet. The aperture admitting air to the reservoir may be closed by a drawstop named "expression." The air being thus cut off, the performer depends for his supply entirely upon the management of the bellows worked by the treadles, whereby he regulates the compression of the wind. The character of the resulting tone is then entirely changed from a mechanical response to the player's touch to an expressive one, varying in correspondence with the increase or diminution of sound through the greater or less pressure of wind to which the reeds may be submitted. The drawstops bearing the names of the different registers in imitation of the organ, admit, when drawn, the wind from the wind-chest to the corresponding reed compartments, shutting them off when closed.

American Organ.—This acts by wind exhaustion. A vacuum is practically created in the air-chamber by the exhausting power of the footboards, and a current of air thus drawn downwards passes through any reeds that are left open, setting them in vibration. Valves in the board above the air-chamber give communication to reeds made more slender than those of the harmonium and more or less bent, while the frames in which they are fixed are also differently shaped, being hollowed rather in spoon fashion. The channels, the resonators above the reeds. are not varied in size or shape as in the harmonium; they exactly correspond with the reeds, and are collectively known as the "tubeboard." The American organ has a softer tone than the harmonium. The "automatic swell" in the instruments of Mason and Hamlin (of Boston. Mass.) is a contrivance which assists expression. Another very clever improvement introduced by these makers. who were the originators of the instrument itself. is the "vox humana." effected by a fan, made to revolve rapidly by a wind pressure; its rotation, disturbing the air near the reeds, causes interferences of vibration that produce a tremulous effect not unlike the beatings heard from combined voices, whence the name.

History. — The start in the instrument's invention was due to Prof. Christian Gottlieb Kratzenstein of Copenhagen. who, having had the opportunity of examining a Chinese cheng sent to his native city, invented about 1779 a small pneumatic organ fitted with free reeds which appears to have been the first instrument of its kind.

During the first half of the 19th century numerous efforts in France and Germany, and subsequently in England. were made to produce new keyboard instruments with free reeds, the most notable of these being the physharmonica of Anton Häckel. invented in Vienna in 1818. which, improved and enlarged, has retained its hold on the German people. The modern physharmonica is a harmonium without stops or percussion action; it does not therefore speak readily or clearly. It has a range of five or six octaves. Other instruments of similar type are the French melophone and the English seraphine. a keyboard harmonica with bellows but no channels for the tongues; for which a patent was granted to Myers and Storer in 1839; the aeoline or aelodicon of Eschenbach; the melodicon of Dietz: the melodica of Rieffelson; the apollonicon; the new cheng of Reichstein; the terpodion of Buschmann, etc. But none of these has survived.

HARMONY, in broad musical terms, is the science of combined sounds. Theoretically. it is distinct from melody in that it is the result of the creation of a musical texture in at least two parts: from counterpoint in that these parts need have no melodic life of their own; and from rhythm in that harmony implies pitch. In practice, however. melody. counterpoint and rhythm each have a function in harmony. (In the course of this article the system of figured hass [*see* THOROUGH BASS] employed for *continuo* parts in the 17th and 18th centuries is used, since it is the best shorthand notation for harmony. The figures under any bass note show the intervals between each note of the parts above and the bass. The following conventions are employed: (1) Any unfigured hass note signifies $\overset{(8)}{5}$ (the octave is always understood); an accidental alone refers to the third. (2) Movement of parts is shown by intermediate figures)

In this article the letter name of a note is printed followed by a figure; the note so named is presumed to be the bass.

HARMONY BEFORE 1550

The earliest known harmony in western European music is called "parallel organum" (*see* ORGANUM) and dates from the 9th century. In this a plain chant melody was doubled at the octave, fifth or fourth below, and examples of organum occur in two, three or four parts. In England the interval of the third is recorded. In the 11th century a free organum style was introduced, so called because the chant was doubled at a variety of intervals. Although the voices sang note against note. the intervals varied so that contrary motion occurred as well as parallel movement. The plain chant was usually the lower part, In this style the ieeling of a cadence emerges since both parts end on the "final" of the mode. A new development occurs in the first half of the 12th century. In the added part two or more note; were sung to one note of the plain chant. At the same time the octave and the fifth emerge as characteristic intervals marking the beginning and end. In ex. 1 octaves and fifths occur at important points oi rest.

Ex. 1

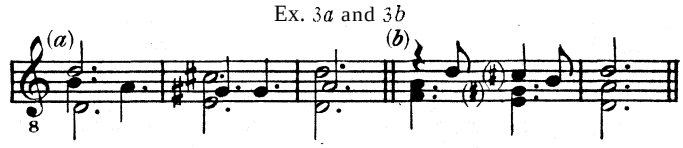
The harmonic collisions in bars 2 and 5 in the above example were doubtless the result of methods of composition whereby each extra part was added to the original plain chant., as opposed to the much later methods of considering the parts as a whole. The counterpoint, however, was not entirely independent since the mode determined some sort of correlation between the parts. In ex. 2, irom a motet, c. 1250, decorated movement between fifths and octaves produce a $\frac{7}{3}$ $\frac{6}{3}$ progression on the last beat of bar 7, and the feeling of a cadential approach to the octave by contrary motion (bar 8). establishing a form of the cadence that persisted until the Renaissance and beyond (*see* CADENCE).

Ex. 2

This example shows the systematic movement of fifths and octaves as a harmonic basis of counterpoint. Polyphonic music of the immediately succeeding period differed little harmonically, though it developed greater rhythmic and melodic complexities. The interval of the third. however, was used more often, notably in the well-known rota (round) "Sumer Is icumen in" (*q.v.*).

The innovations of the Ars Nova (*q.v.*), concerned chiefly with form. melodic design and counterpoint, did not greatly affect the existing harmonic technique. Two related features are; however, connected with these innovations. To avoid the tritone (the inter\-a1 of three whole tones written as an augmented fourth. F-B, or, in the form of its inversion B-F, as a diminished fifth) the procedure in ex. 3*a* was evolved; and the cadence in ex. 3*b*, probably motivated bv the desire to resolve the sixth to what was held to be the more consonant fifth. became commoner a little later.

Ex. 3*a* and 3*b*



Ex. 3*b*, in which the cadence note D is preceded by notes a second and third below, is called the "Landini cadence," though it is not first found in. nor confined to. the work of Francesco Landini, being current all over Europe at this period.

The 15th-century practice of ia-burden. consisting of three-part harmony in which a melody is accompanied by two lower parts in parallel fourths and sixths, was a distinctly harmonic system. This was again a type of organum, deriving perhaps from the earlier English fondness for thirds. The English style at this period was in any case inclined to be harmonic — a *Kyrie* in the Old Hall manuscript consists almost entirely of $\frac{6}{3}$ chords — and these harmonic tendencies were incorporated in the work of John Dunstable (*q.v.*). Sot only do certain cadence progressions become systematic in Dunstable's work but the third ceases to be merely part of a chord of the fifth, becoming an important interval in its own right. The sixth becomes commoner and the seventh and fourth are often treated as dissonances by suspension. Pausing on one point or another of the mode with evident design, Dunstable appears to have differentiated between various forms of cadences, and he also anticipated a ieeling of tonality.

These features are also illustrated in the works of the Burgundians, Guillaume Dufay and Gilles Binchois. and in the later Flemish school of Jean d'Okeghem and Jakob Obrecht. Though their general style differs from that oi Dunstable the systematization of cadences in their work becomes more marked. The Landini cadence, though still appearing. was gradually replaced by one in which the sixth did not fall to the fifth before moving upward, and the $\frac{6}{3}$ chord became a commonly used feature of the musical language. A fuller harmony was obtained by the Flemish composers since they normally urote in four parts as opposed to the typical three-voice texture of Dunstable's time.

With Heinrich Isaak, Josyuin Desprès and Pierre de la Rue harmonic methods were established that were to remain. with iew changes, until the end of the 16th century. The treatment of dissonance by Josquin became more systematic. In the works of

Ex. 4

Okeghem leaps from dissonant notes were not uncommon, as ex. 4 shows. In Josquin only the first instance of such leaps (known as the *notu cambiata*) was normal. In fact. Josquin's treatment of dissonance differed only in detail from that of Palestrina.

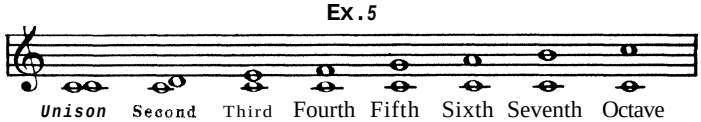
The most important changes of harmonic style in the century and a half culminating in Josquin were thus: (1) the replacement of parallel movement between perfect concords (fifths, octaves and fourths) by imperfect concord movement (thirds and sixths), though in Dunstable consecutive fourths are not uncommon and were even used, between upper parts, by Tomas Luis de Victoria a century later; (2) the systematization of dissonance treatment and cadences. From this system. with its delicate relation between dissonance and pulse, arose the whole conception of modern harmonic rhythm. See *Tonality* below.

HARMONY *c.* 1550-1900

Late 16th-Century Style. — From about 1550 onward the main elements of the harmonic method in use to the end of the 19th century are discernible. This method is based on the movement of parts and the intervals resulting from their relation to each other. After the modes were discarded, new chromatic possibilities of the diatonic system arose (*see* SCALE: *Diatonic Scale*). But the harmonic and contrapuntal method remained fundamentally unchanged. The main principles of this method are:

Harmony is reducible to the effect of intervals. Intervals from the note C are as follows:

Ex. 5



Unisons, fourths, fifths and octaves are perfect intervals and perfect concords. Since Dunstable the fourth, while remaining a perfect concord in theory, has been treated as dissonant when it occurs between the bass and another part and as concordant between upper parts.

Thirds and sixths are imperfect concords.

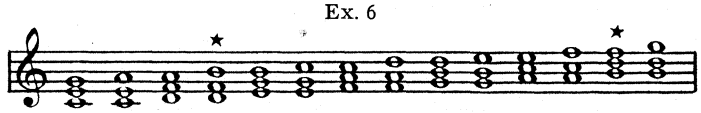
Seconds, fourths (*see* above) and sevenths are discords.

The properties of intervals are repeated in each octave, *i.e.,* a ninth has the harmonic properties of a second. etc.

Imperfect concords and discords, excepting the fourth, are further designated major or minor. In ex. 5, all are major and may be made minor by flattening the upper or sharpening the lower note. Minor and perfect intervals may similarly be diminished by flattening the upper or sharpening the lower note, and major and perfect intervals may be augmented by a reverse process. Whatever its quality, and interval's numerical name is derived from counting the number of note names, *i.e.,* C-G remains a fifth whatever accidentals are added. The change from major to minor does not affect consonance, but all augmented and diminished intervals are dissonant.

Hence the following three-note chords (in C major) are concordant, their constituent notes being concordant with each other. The chords marked * containing the tritone (F-B and B-F), a dissonant interval, were treated as essential discords in the 16th century and so in one sense are concordant. (See *Essential Discords* below.) As with octave multiples of intervals, inversion of the upper notes of triads (three-note chords) does not alter their harmonic significance.

Ex. 6



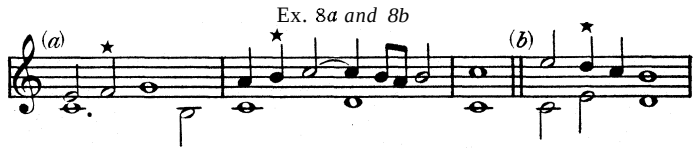
Treatment of Dissonance. — Practice in the late 16th century confines dissonance treatment to the following:

(1) Suspensions. Notes prepared as concords on weak beats are tied to dissonances on succeeding strong beats and resolved on the following weak beats to concords one note below (ex. 7*a*). The only exception to this treatment on a strong beat is the dissonant preparation called the consonant seventh or fourth, the latter being commoner in three- and four-part writing. The consonant seventh (D-C) occurs over a pedal (a held or reiterated note) bass in ex. 7b.

Ex. 7*a and 7b*

(2) Passing notes. Unaccented passing notes are discords "passing" between concords by step and between pulse beats (ex. 8*a*). Accented passing notes occur on weak beats and in this period are nearly always descending (ex. 8b).

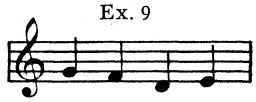
Ex. 8*a and 8b*



Ex. 8*a* shows, at the conclusion of bar 2, one of the common methods of decorating the resolution of a suspension.

Dissonances were quitted by step except in the following pattern where the second note is often dissonant:

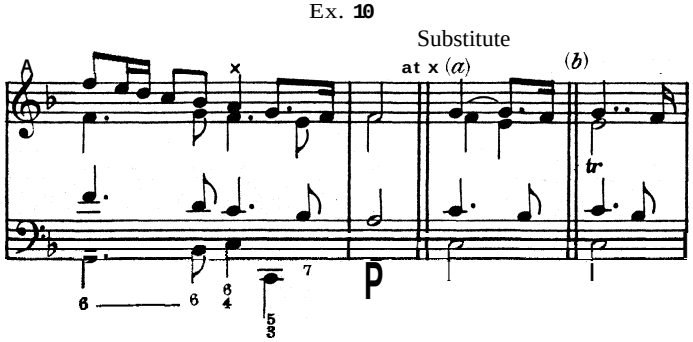
Ex. 9



These principles of 16th-century method are discussed fully in books concerning the style of the period, notably in those by Knud Jeppesen and Tillman Merritt, but perhaps most interestingly by the 16th-century composer, Thomas Morley, though he curiously omits mention, except by implication, of the relationship between dissonance and pulse. Particularly interesting to the modern reader is Morley's insistence on the interval structure of harmony, a conception that descends directly from the ancient methods of adding parts to an existing part.

Opposed to Morley's treatise was the inversion system of the 18th-century composer. Jean Rameau (*q.v.*). This system, widely used by pedagogues from the middle of the 19th century onward. is derived from Rameau's theory of the "fundamental bass." It teaches that all three-note and other chords are derived from fundamental triads; a $\frac{6}{3}$ chord having, for instance, an imaginary bass on the note figured as 6 and a $\frac{6}{4}$ chord on its fourth. Such a system fails to explain the augmented sixth, cannot effectively explain the diminished seventh as a fundamental discord and complicates the explanation of quite simple phenomena such as appoggiatura. Its explanation of the $\frac{6}{4}$ is perhaps its weakest point, since it argues that a $\frac{6}{4}$ on the dominant is the second inversion of the tonic chord. though usage always demonstrated this chord to be a dissonant version of the dominant chord. In the following example of a typical final cadence by Handel, the reduction of the

Ex. 10



cadential $\frac{6}{4}$ to its original dominant meaning is shown. It must be stressed that this passage is meaningless unless the bass note at that point is C (the dominant).

Neither does the system explain how $\frac{6}{3}$s on succeeding notes of the scale were held to be satisfactory while the fundamental triads of these same chords were prohibited. The system is mentioned here because of its almost universal dissemination up to the middle of the 20th century. Despite its fallacies, most 20th-century harmony textbooks were based on it.

The Diatonic Age

Under this heading further developments, most of them dating from the 17th and early 18th centuries, may be approached. In this period concords remain as before. Though style changed greatly between 1650 and 1900 the fundamentals of harmonic method did not, though their application varied. The main features of this new application will now be classified.

Treatment of Dissonance. — As a general principle any dissonant note, however approached, resolves by falling or rising one note to a consonance, though there may be intervening notes decorating the resolution. Upward resolutions of accented discords are normally of a semitone, rarely a tone, although the resolution of a tone is common when moving in thirds or sixths. Different types of accented dissonance are given below. They are so called because of the nature of the approach to the dissonant note.

(1) Accented passing note. (2) Suspension. (3) Changing

Ex. 11

note (a harmony note approached through notes on each side). (4) Appoggiatura (a dissonance approached by leap).

The above example is a simplified skeleton, slightly altered to make certain dissonances appear more obvious, of a passage from Beethoven's "Hammerklavier" Sonata, Opus 106. This includes the fifth type of dissonance of fairly frequent occurrence, the note *échappée*, or changing note (5 in ex. 12), a two-note descending figure, which, usually leaping a third, is the only normal exception to the principle of quitting a dissonance by step (apart from decorated resolutions). Its dissonant note is always unaccented. Ex. 12 is altogether highly decorated and affords many examples of dissonance treatment, in particular of changing notes.

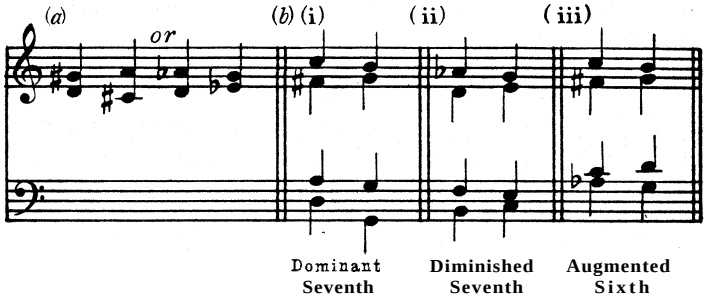
Essential Discords. — In modal usage the tritone was handled with care. Where its effect was ambiguous it was usually made into a perfect interval by an added accidental. Certain chords containing the tritone are known as essential discords. They are said to be essential when they can resolve to new harmony. An essential discord is therefore, a multiple discord requiring multiple resolutions. The tritone's ambiguity is shown in ex. 13*a*. In 13b are shown the three essential discords with their normal

Ex. 12

resolutions. The augmented sixth often contains a fourth harmony note (which could be a D or an E♭ in ex. 13*b*, iii) which would not affect the essential harmonic and tonal meaning of the chord.

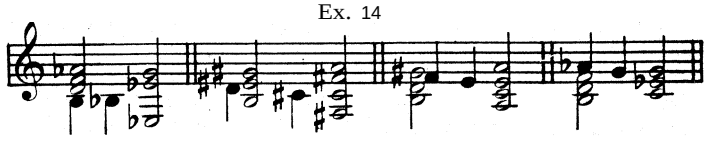
Kith the rise of diatonicism the strong leading properties of the tritone encouraged the use of it wherever a tonal sense was required. The term "leading note" is commonly used in a limited sense to mean the seventh note of the scale, the semitone leading to the tonic. But the fourth note also tends to lead down a semi-

Ex. 13*a* and *13b*



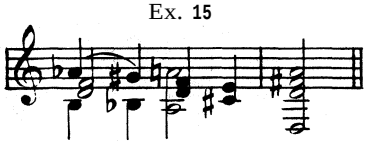
tone to the third. The tritone consists of both these notes, and this fact, coupled with its dissonant quality, gives it its motive power. As the tritone itself can be ambiguous, so the chords it contains can be altered enharmonically. Ex. 136, ii can be altered as follows:

Ex. 14



Furthermore, depending on the arrangement of the notes. the dominant seventh harmony on the second crotchet of all these may become an augmented sixth by enharmonic means (*i.e.*, A♭ = G♯) as shown in ex. 15.

Ex. 15



Part Writing. — Normally, simultaneous passing notes in different parts are concordant with each other but much depends on the texture of the harmonic progressions. on tempo and on whether the parts are in similar or contrary motion.

In similar motion, movement is by imperfect concord (thirds and sixths) and not by periect concord (unisons, fourths, fiiths and octaves) though similar movement of fourths between upper parts is usual; consecutive or parallel octaves and fiiths produce the effect of mixture stops on the organ, a doubling rather than the addition of parts, so that in part writing consecutives reduce the number of real parts, giving undue prominence to the parts so doubled. Deliberate doublings oi whole phrases at the octave are, of course, commonplace (they occur in ex. 12), and although such doubling was extended to fifths in the 20th century, it rarely occurred between 1650 and 1900. In Bach's *St. John Passion*, "If this man were not a malefactor" (no. 23), flutes doubling the vocal tenor line at the octave move in fifths with the first oboe and first violins in bar 3 of the chorus. The ear, horvever. perceives the tenor line in fourths below the upper voices. There are isolated examples of consecutives in the works of great masters in this period, but they are rare. and they usually are placed so that either their effect is inconsiderable or the harmony or figuration forces the ear to disregard them as contrapuntal progressions. More common types of consecutives can be found in Bach's chorale *Freuet euch, ihr Christen* (cantata no. 40) in four of the cadences between soprano and tenor; in Mozart's Violin Sonata in A, K. 526, in the opening notes of the last movement between top and bass; in Handel's Violin Sonata in E in the opening notes between violin and bass; and in Beethoven's Pianoiorte Sonata, Opus 31, no. 1 (second movement. bars 109, 111 and 113).

This discussion is made necessary by the fact that forbidden consecutives have long dominated the teaching of harmony. It is necessary ior students to distinguish between doublings that are a sign of impoverished part writing and those that are legitimately used for added sonority. As a rule parallel octaves are found less oiten than parallel fifths. The common syncopated avoidance of direct fiiths, as in ex. 16 irom Thomas Morley, is never found with octaves.

Ex. 16

Chromatic Harmony. — Chromatic harmony presents no difficulty once the harmonic principles of diatonic harmony have been grasped Ex 11 shows the use of chromatic dissonance and certain aspects of transitory modulation. Most chromatic chords are normal diatonic chords with one or more notes altered chromatically, very oiten in thia way producing a species of artificial leading note.

Tonality, Time Scale, Movement and Modulation. — The chief problem of composition has always been the problem of the extension of an idea. Renaissance composers discovered means of composing without using an existing *cantus firmus* (see COUNTERPOINT), and as a result various methods became standard: (1) canon and fugue; (2) *ostinato* methods including the device of isorhythm; (3) sectional vocal forms allied to the continuity of the text. All of these depended on the extension of an existing melodic or literary feature.

The monodists of the *nuove musiche* had to find other methods since imitative devices were hardly possible in truly monodic works. Hence the 17th-century predilection for forms of ground bass. This device was borrowed from dance music as bass and harmony patterns already existed for decorated repetitions in dance music; *e.g.*, the *passamezzo antico*. Such patterns were related to previous *ostinato* methods in that once a pattern was composed (like an isorhythmic talea) it was merely repeated.

But variation patterns alone could produce only one kind of extension. The other great factor that enabled composers to expand the time scale of music was the emergence of diatonic tonality. The modes ,provided a distinctive character and colour but little movement and few possibilities of extension. In the succeeding major and minor key system, horvever. the tonal centre or tonic became such a strong characteristic that any movement away from it forced continuation. since the piece was felt to be incomplete until it rested again on the tonic. This is. of course, a simplified view oi a process that took considerable time to evolve, especially as modal methods were in use until the 17th century; works by Dietrich Buxtehude and John Blow, for example, contain final cadences that 100 years later would not have been thought to establish tonics.

In spite oi the relation between dissonance and pulse (rhythmical beating) in 16th-century style, melodic rhythms themselves only partly depended upon the pulse; *i.e.*, insofar as they were related to other melodic parts. The rhythmic independence of various parts gradually disappeared with the development of tonality, and as a result the bass came into prominence as support of the harmonic structure. This led to the so-called "tyranny of the bar line." But this was no more tyrannical than the tyranny of modal thought or of pulse in 16th-century dissonance treatment. The real tyranny was one of a homophonic nature, namely that of the "top" and "bottom" parts with harmonic support in the inner parts.

By compensation there arose the delicate balance of movement, harmonic rhythm and time scale. Time scale may be illustrated in the fact that it is scarcely possible to tell from the first 20 bars of a madrigal or motet of the 16th century whether the whole piece will last two, five or ten minutes, but that this is usually possible after a few bars of a work by Beethoven.

Harmonic rhythm is the name given to the pulse rhythm of harmony changes. While the 16th-century treatment of accented discords was considerably widened in scope and became less rigidly applied, the principles remained, if only because dissonance produces accent and resolution repose. In addition, the tonal meaning of harmonies in the diatonic system enabled composers to use, instead of discords, other chords that had more or less motive power.

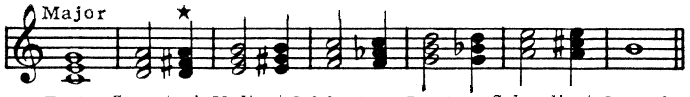
Extension of movement can be obtained in various ways, not all of them tonal. Among the non-tonal means extending movement are: (1) overlapping of melodic phrases, *i.e.*, one phrase starting at the point at which the previous one ends; (2) contrapuntal overlapping; (3j use of suspensions and other dissonances; the need of resolution, often delayed by further decoration, compels a forward movement; (4) use of non-final chords and progressions, such as interrupted cadences.

The most important voice in all harmonic progression is the bass. The bass must provide good counterpoint with the upper parts, and it also determines the tonal movement oi every phrase. At the end of a piece in C major, for example, a melody has as its last two notes B and C. A normal bass to these notes would be G C—the dominant followed by the tonic. This progression is called the periect cadence or full close. A bass that had D C, though periectly feasible (and indeed formed the basic final cadence long before the G C progression); would not sound so final. A bass E C would be distinctly unusual. Such considerations necessarily apply to the movement of the bass, especially regarding the approach to the aptly named dominant. In music that constantly moves dominant harmony is likely to be much commoner than tonic harmony, since the dominant always requires some movement at least to return to the tonic for finality.

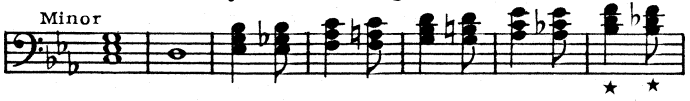
One of the phenomena of the diatonic style is that once a key is established, progressions involving directly related keys do not alter the tonic. Key relations to C major may be shown by the keys of the triads involving the perfect fifth on each degree of the scale. Direct relations are shown as minims (half notes); indirect relations are shown as crotchets (quarter notes); and doubly indirect relations as quavers (eighth notes). Relations to the minor tonic may be found by reversing the process; similarly, the direct relation to C minor is triads based on notes of the minor key. All relations are reciprocal. So relationships involve a third key; *e.g.*, in G major in a modulation to B♭ and E♭ minor the last key is the flat submediant of G major. It is not related through B♭.

Ex. 17

Direct and indirect through major scale



Indirect and doubly indirect through tonic minor



Keys marked* are ambiguous in effect; the chromatic supertonic insists on becoming the dominant of the dominant, and the seventh chords in the minor insist on leading to the minor mediants.

An understanding of the principles of tonal relations will make the apparent complesities of chromatic harmony clear. Hence in an analysis of Beethoven's First Symphony there is a transitory modulation to the supertonic of C in bar 7 of the allegro con brio of the first movement. It would be misleading to call this supertonic D minor because that would encourage the misbeliei that the D was a new tonic. This may be tested by adding as many perfect cadences in D minor as are desired and then stopping altogether. It will be iound that C is still the tonic. Such a test is useless, however, unless C is established as a tonic at the outset, as it is by Beethoven. If before playing those seven bars B♭ major were established then the D minor chord would be the mediant of B♭.

Thus transitory modulation differs from real modulation in that real modulation denotes movement to a new tonic, whereas transitory modulation moves to a tonal relation of the established tonic. Real modulation occurs in tn-o ways: (1) over a distance in time involving various modulations, as in the exposition of a sonata movement; and (2) where no properly established tonic exists, as in parts of development sections of sonata movements.

In the early 18th century nearly all modulation was transitory, except in movements on the largest scale like the first *Kyrie* of Bach's B minor Mass. A good illustration oi Bach's method in detail may be found in bar 11 onward of Fugue XIV of Book I of *Das Wohltemperierte* **Klavier** (ex. 18).

Ex. 18

If these bars are played omitting all accidentals except those specifically concerned with F ♯ minor (marked below and above) the tonal meaning of the whole passage is not altered, though from chord to chord the differences are huge. Oi course, some of the counterpoint becomes ugly, ii not nonsensical, showing that artificial leading notes produce their own melody and counterpoint. Nevertheless, the lesson is a tonal one; *i.e.*, Bach making artificial leading notes colour more strongly progressions to chords directly relative to F♯ minor.

The question of tonal and real answers in fugue (*q.v.*) was earlier bedeviled by pedagogues who iailed to distinguish between different kinds of modulation. The most real oi Bach's answers does not leave the tonic established by the subject. The episode between the second and third entries in Fugue XIV is not necessary for modulatory purposes, however vital it may be to the melodic extension and phrasing at that point; omission of bar 7 proves this.

The new style adopted by Bach's sons mas associated with a dramatic element in music rather than with melodic and contrapuntal development and ornamentation. The Viennese style of the late 18th century concentrates on changes oi key and texture rather than on extension of melody. The natural result of this change of style was the expansion of time scale. A movement lasting ten minutes will contain more real modulation than a piece lasting two minutes. Likewise, if there is much real modulation the time scale will be greater than in pieces with little or no real modulation. The reason for this is that the human ear normally refuses to listen to music without movement. From time to time a composer achieves the improbable by compelling interest in a deliberately static movement. But this is rare and is the nature of a tour de iorce. The second movement of Beethoven's Violin Concerto is a triumph of this kind. Of course many successiul sets of variations stay in the same key, or the listener's interest may be held by the composer's decorative skill, as in this particular movement. Larger sets of variations use the tonic minor, with a variety of transitory modulation, or a variety of basic progressions within the variations themselves. In the early baroque period, the great age of variation writing, composers normally used modulating ground basses ior longer movements and, even so, often took pains to conceal the final cadence of the ground bass pattern by unequal phrases, suspensions and so iorth.

The possibility of establishing a new tonic by real modulation led to the rise of the sonata iorm (*q.v.*). Sonata iorm sprang from simple binary iorms, such as are common in the dance movements oi Bach's suites ior keyboard. As soon as the time scale and modulatory scheme mas large enough to make the close at the double bar a full close in a new tonic, some sort of modulatory process was necessary to prepare ior the return to the original tonic—hence, the development section. Nineteenth-century textbooks obscured matters by inventing the term "shortened sonata form" to describe those movements where a development section is unnecessary. But the reason for its omission is the absence of real modulation to a new tonic. Thus, the exposition of the second movement of Beethoven's Piano Sonata, Opus 2, no. 1, ends with a dominant chord of F, not a tonic chord of C, and in this case the return to F presents no problem. The term "shortened sonata iorm" is misleading because binary form without a development section preceded full compound binary form. The latter is an expanded version of the former, and not vice versa.

In movements in binary form without a development section the second group of subjects is usually shorter, and certainly not longer, than the first group. In a compound binary movement the reverse is true. the second group being usually at least twice as long as the first group. This is because it is difficult to establish a second key without preparation over a considerable time, whereas at the beginning of a piece a key can be established by a single chord.

The development sections of compound binary movements differ in detail. Some oi them are contrapuntal, some homophonic, some consist largely of passage work and some do not even use material from the exposition at all, while many introduce much new material. But they do not differ in their general tonal method, which is to avoid all sense of the new tonic reached at the end of the exposition by means of wide modulation. Many development sections are more complex in that they contain large episodes in some new tonic; *e.g.*, Beethoven's *Eroica Symphony*, first movement, and his *Appassionata* sonata. In cases like the first movement of Beethoven's Piano Sonata, Opus 14, no. 2, a new tonic is introduced as if it were the original tonic—a false recapitulation, so to speak; further modulation and very long dominant preparation occur beiore the real recapitulation starts in the original tonic.

Methods of modulation vary according to the scale of the work. In the exposition of compound binary movements, the enhanced dominant (the dominant of the dominant) is often used to herald the second group of subjects in the second key. This is not to say that the second key becomes an established tonic at the beginning of the second group. Rarely is such the case and, as Beethoven's style developed, the so-called transition section gradually becomes indistinguishable from the second group. If, indeed. the second group were to start in an already established new tonic, it would need to be a very short second group or it would become static. One of Beethoven's favourite devices in establishing a second key is to modulate widely just aiter the beginning of the second group, using the same methods as in the development section, only not so drastically, *e.g.*, the first movement oi his Piano Sonata, Opus 2, no. 2. Certain concepts are common to development modula-

tion, namely, the use of tritone chords with their inherently ambiguous properties, and the principle that most chords will be compatible if they have a common note. The chord structure of Beethoven's Piano Sonata, Opus 57, first movement, bars 79–88, is as follows:

Ex. 19

This type of procedure can be described as a pedal link. Other methods of development modulation are the alteration of the quality of triads from major to minor or vice versa, producing different sets of relations, and, related to this procedure, the effect of certain notes on the aural imagination. If the note G is reiterated 20 times, the listener may still hear it as a tonic, but ii Ab s are introduced the G tends to become a dominant, an effect strengthened by the subsequent introduction oi an F♯ Whatever the explanation, such phenomena exist. Another example of this kind of note behaviour is shown in the alteration of a dominant chord from major to minor: the minor chord has less dominant and more tonic character than it had before, *e.g.,* the third bar of the introduction to the rondo of Beethoven's Piano Sonata, Opus 53. Such note behaviour is an important part of a composer's resources, since he is often concerned with modulation from dominant to dominant in the course oi development. Certain procedures establish new dominants fairly easily. The following progression

Ex. 20

shows how the function of certain notes together with a succeeding $\frac{6}{4}$ causes a strong presumption of a tonality of the dominant of G. In general it may be said that if, at a moment of no discernible tonality (as at the proionged diminished seventh chord just beiore the return to the tonic in the first movement of Beethoven's *Appassionata* sonata), a pedal or one of the dominant-ward progressions shown above is introduced, there is no difficulty in establishing a key. This procedure forms the tonal basis of many development sections that obliterate previous tonics with wide modulation, preparing for the return of the original tonic. Finally, there are types of motlulation that are repeated on different degrees; these types are common from the 17th century onward and are used in sonata developments throughout the period.

The 19th Century

Several factors combined, during the great romantic age, to alter some of the characteristic methods of diatonic harmony. First, since tonal principles were essentially abstract, forms arising from them became less common. Increasingly, themes symbolizing moods determined musical designs. An important factor in this development was the emergence of the solo song as a genre. Earlier developments of the solo song had sometimes been bound to specific musical forms or to lyrics designed for musical setting and therefore symmetrical or repetitive.

From the early middle ages to the Renaissance, songs used a structure containing a repeat, a refrain or an *envoi* in the iorm of paired lines, or forms of a ternary or rondo (*q.v.*) pattern. This was inevitable at periods when poets were closely identified with music. The early Italian cantata, however, mas built on a ground bass and on various rondo structures, the less formal sections being set in recitative, or arioso, and later in the form of the *da* capo aria. A pattern of libretto writing was evolved to conform to the demands of the musician, leading to the opera librettos of P. Metastasio (1698–1782).

The poems of the romantic period were generally literary achievements in their own right. The revolt against formal designs, as part of the romantic ideal, ensured a wide formal independence in the settings of these poems in the form of the German Lied (see Song: *German* Song). A Lied may begin in one key and end in another and it is even common to find quite short songs displaying bold changes of texture and tempo. Not surprisingly, Goethe preferred Carl Friedrich Zelter's settings of his poems to those by Schubert. Schubert recreated Goethe's poems, producing a new art iorm, while Zelter, whose settings seem stilted, merely served them.

The miniature scale of the typical song focused attention on the expressive rather than the functional qualities of harmony; hence the use of suspensions and appoggiaturas, single and multiple. with delayed resolutions, changing notes, chromatic decorations and the wide variety of romantic dissonance. It is not surprising that Bach was rediscovered in the early 19th century since his style, though disguised in contrapuntal forms, contained many features beloved by the romantics. It is interesting, since his chromatically colourful style was new to the romantics, that they regarded Bach as revolutionary. a view still widely held in the middle of the 20th century, though the chromaticisms and other contrapuntal decorations of Bach and, indeed, of Purcell were actually old-fashioned features of their style.

At the same time dramatic forms were adapted or enlarged to illustrate lyrical or poetic concepts. The symphonic field divides into the categories of abstract and program music. In the abstract field the procedures of Schubert and Brahms were typical. Their problem was to introduce (into forms based on the tonal schemes of Beethoven) longer and more lyrical melodic ideas in place of the shorter themes of the earlier Viennese composers. This resulted in the change of certain features of compound binary form but not of its essentials. By their very nature program symphonies and symphonic poems introduced new designs and, compensating for the partial absence of compound binary patterns, certain iormal features became prominent, among them the *Leitmotiv* (*q.v.*) and the metamorphosis of themes. Thus emphasis in design lay in melodic and textural variation and in repetition rather than on key structure.

As with the Lied the iunction of harmony became more decorative and impressionistic. With the development of the late 19th-century taste for fully saturated sound, harmonic colours became rich and complex and, while the basis of harmonic progression was still contrapuntal, the irequent doublings and complexities of texture tended to obscure this contrapuntal basis. Pedagogically, harmony was perceived more and more as the iunction oi vertical chords.

Nineteenth-century opera is dominated by the figures of Wagner and Verdi, whose conceptions of harmony were not dissimilar. They differed, of course, in their treatment of the voice, the orchestra, the time scale and in their conception of the theatre. But their forms and treatment of harmony and tonality were fundamentally melodic in outlook, Wagner placing emphasis on the orchestra and developing his concept of the Leitmotiv; Verdi giving prominence to the vocal line. It is significant that in his later, orchestrally richer operas Verdi used the Wagnerian Leitnzotiv technique. The harmonic detail of both composers was decorative and fluid, in Verdi's later work particularly, loosely based on the modulatory principle oi moving from dominant, or other related key, to dominant rather than from tonic to tonic. A well-known illustration of this harmonic fluidity is the opening oi Tristan und *Isolde* (ex. 21).

The key suggestions in the extract are as follows: bar 3, dominant of A minor; bar 7, dominant of C (major or minor); bar 11, dominant of E (the enhanced dominant of A in view of bars 1–3); bar 16–17, what looks like the eventual close in A minor is interrupted and steered through the dominant of C (18), the supertonic of C (20–21) becoming more like the subdominant oi A minor (D minor) in the last half of 21, and in 22 and 23 returning obliquely to the dominant of A minor (recognizable only from the effect of the previous A minor).

Wagner's complex harmonic counterpoint is well illustrated in this example. There was at one time much discussion of the first chord in *Tristan,* and Donald Tovey showed its origin in a well-known but overcomplex series of examples. This chord is simply an augmented sixth in a common enough form (the so-called French sixth), with an appoggiatura, G♯, resolving normally to A. The dissonance is unprepared but represents nothing new. The novelty of the opening of Tristan derives from the fact that, unlike the opening of Haydn's Creation, it has no tonic unison establishing tonality in the listener's mind. In this it does not differ fundamentally from the opening of Beethoven's First and Ninth Symphonies, both of which proclaim the nature of their opening chords after their first appearance. There are few chords in Wagner that cannot be explained in simple harmonic-contrapuntal terms, though his constant use of chromatic detail engendered the belief, widely held, that his harmonic methods were revolutionary.

The iunction oi tonality in opera is necessarily different from that in symphonic movements. The capacity for tonal memory over long periods is limited. Critics who postulate tonal theories depending on the possession of the iaculty of absolute pitch (a form of acute and permanent musical memory that, like other forms of memory, becomes less acute with age) assume that composers have written their music for enjoyment by the few possessed of this iaculty. The facts of history are otherwise. The very length of an opera, or even of one act of an opera, precludes the normal symphonic usage oi tonality, except on rare occasions. Instead, key is used for dramatic emphasis, bright and dark keys being contrasted to underline dramatic action. Act II of Tristan provides many instances of the methods of Wagner: the change from B♭ to C major at Tristan's arrival; the changes from A♭ to G♭, from A♭ to G major and to the much brighter B major at various stages in the love music; and particularly the use of the much darker D minor at King Mark's entrance, becoming D major at the words "Dies wundervolle Weib," a moving use of tonal word illustration.

POST-WAGNERIAN HARMONY

Widely different methods characterize the symphonic schools at the turn of the 19th century, although all of them used the harmonic resources of Wagner to some degree. Mahler stressed the lyrical aspects of the symphony, Sihelius, the architectural, while the Russian schools mere preoccupied with harmonic colour. The harmonic technique of these composers added little to Wagner's language despite their different applications. Richard Strauss, believed in his

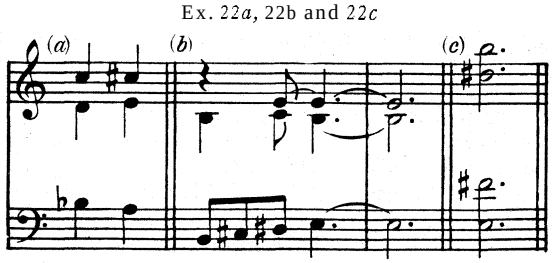
Ex. 21

youth to be a revolutionary, was later seen as a complicator of Wagner's language.

The 19th–century harmonic language was particularly extended by Debussy. Much of Debussy's harmony may be analyzed as tritone discords with additional and altered notes, and its departure irom traditional methods was later seen to be less fundamental than was at first supposed. Certain new elements. however, were introduced: consecutive-fifth chord movement, a more common use of modal elements and, following the example of Liszt and others, the use of the augmented triad with added notes in the form of the whole-tone scale. Some of these elements blurred tonality and made movement more difficult. a consideration that sometimes caused Debussy to use more traditional methods, encouraging also the use of pedal figures. Pedals were also used freely by Sibelius and, indeed, became an increasingly important feature of 20th-century music.

Nationalist schools, developing their own variations of harmonic technique, produced a number of different styles. Often, consecutive triads. iourths and seconds were used, and novel scales and modes were introduced, resulting largely irom the study oi folk music. No system of harmony was, however, codified, except one by Hindemith based on a new view of traditional methods. Scriabin's system of chords quickly proved its limitations. Schönberg's system oi dodecaphony (*q.v.*) was designed to provide the composer with a method oi composing in place of the connecting thread of tonality. but it was not basically a harmonic system since the harmony of each piece differs according to its "row."

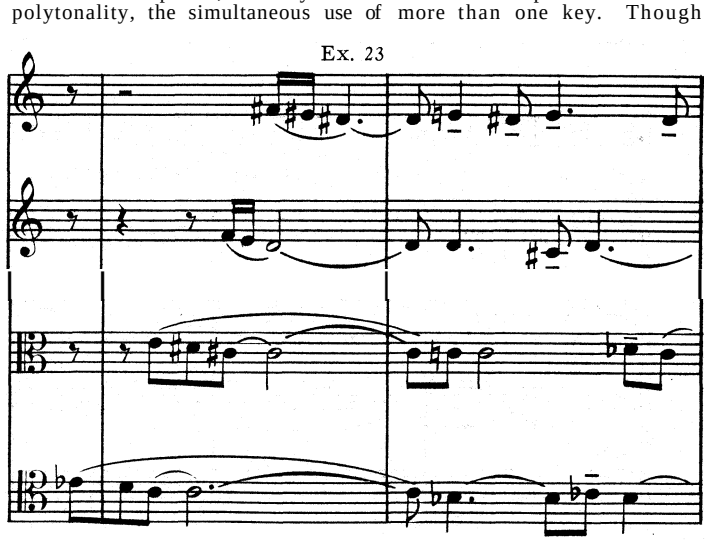
Ex. *22a,* 22b and *22c*



Nevertheless, certain methods were common to 20th-century composers whose music was based on tonality of some kind. In avoiding traditional cadences and progressions new uses were made of artificial leading notes such as in ex. *22a,* an instance as contrapuntal as the two-part cadence of the 16th century, and ex. *22b* irom Lennox Berkeley's String Trio. The combination of certain upper harmonies mas viewed as concordant; this view is the basis for the most probable explanation of Stravinsky's predilection for chords such as ex. *22c.* Another addition to the language was the doubling of melodic lines at various intervals to produce chordal polyphony. False relations mere used in increasing complexity and nonresolving acciaccature were used in the form of note clusters. The resolution of such acciaccature has the effect of a cadence.

Certain composers, notably Darius Milhaud. experimented with polytonality, the simultaneous use of more than one key. Though

Ex. 23



Ex. 23—contd.

it produced interesting by-products, polytonality itself proved disappointing, possibly because of the limitations of the human ear.

Extensions of traditional methods of colour variation through harmony were used. In Béla Bartok's music harmonies are associated with intervals occurring in the thematic material. His fondness for seconds is generally attributable to a combination of contrapuntal cadence methods and highly rhythmic forms of harmony. This combination is used in conjunction with numerous scale patterns, sometimes derived from Balkan folk music. His Fourth String Quartet concentrates on the interval of the second not only thematically but also contrapuntally and harmonically. Ex. 23 demonstrates the thesis of this work.

The second movement of Bartók's *Concerto for Orchestra* affords a striking demonitration of his methods. Pairs of instruments enter using parallel motion as follows: (1) bassoons in sixths (supporting harmony traditional); (2) oboes in thirds (harmony traditional with much use of thirds; *e.g.*, bars 33–39); (3) clarinets in sevenths (harmony almost exclusively in sevenths); (4) flutes in fifths (many fifths in harmony); (5) trumpets in seconds (harmony largely combinations of seconds).

Ex. 24

Such harmony is, of course, contrapuntal in origin and thus has some resemblance to serial methods. An illustration of the serial technique appears in ex. 24, taken from Humphrey Searle's *Put Away the Flutes*. Here (a) is the opening melody (row); (b) is the start of the final section. The voice continues (from the previous section) with an inverted backward presentation of the row while the instrumental harmony is an inversion of the row. The figures show the relationship of the individual notes to the row.

The resemblance between Bartók's contrapuntal harmony and Schönberg's serial technique is, however, not more than superficial. Bartók's music is fundamentally tonal even though it is highly coloured by the use oi unusual scales. Moreover, contrapuntal methods oi harmonic structure, though characteristic of much modern tonal music, do not necessarily constitute the whole of its harmony. On the other hand, though contrapuntal possibilities exist in serialism, the serial technique is not, properly speaking, contrapuntal. In ex. 23 the harmony of seconds arises out of successive imitative entries at the second. not from the seconds in the thematic material. In contrast, Searle's harmony derives from the intervals occurring in a single melodic line. *See* also references under "Harmony" in the Index volume.

HARNACK, ADOLF VON (1851–1930). German theologian and church historian, the leading patristic scholar of his time, was born on May 7, 1851, at Dorpat. Estonia, where his father. Theodosius Harnack (1817–89), was professor of practical theology. Adolf studied at Dorpat and at Leipzig, becoming *Privatdozent* in church history in 1874 and professor *extraordinarius* in 1876. As full professor he occupied chairs at Giessen (1879–86), Marburg (1886–89) and the University of Berlin (1889–1921). Harnack was a member of the Prussian Academy of Science (of which he prepared a three-volume history in 1900), founder and president (1902–12) of the Evangelical-Social congress. director of the Royal library (1905–21) and president of the Kaiser Wilhelm Society for the Advancement of Science. He was ennobled in 1914 and died at Heidelberg on June 10, 1930.

Harnack's intellectual career led him through the orthodoxy of Dorpat and Erlangen and the historical-critical approach of the Tübingen school to the liberal position set forth bv Albrecht Ritschl (*q.v.*). The Ritschlians were primarily concerned to relate Christianity and culture, and Harnack believed this could be achieved only by a historical understanding of Christianity where the essence is separated from the dogma. This essence could be isolated by employing a scientific historical method that abjured all metaphysical speculation and included source study (hence his initiation, with O. von Gebhardt, of the important *Texte und Untersuchungen zur Geschichte der altchristlichen Literatur* series [Leipzig, 1882 *et seq.*], to which Harnack contributed 49 monographs); analysis of the cultural factors that help to shape historical events; the assessing of historical institutions and their relation to the *Geist* that produces them; and faithful representation of the facts.

Harnack's greatest work is his *Lehrbuch der Dogmengeschichte* (3 vol., 1886–89; Eng. trans. *History of* Dogma, 7 vol., 1894–99), universally acclaimed as brilliant in conception and a monument of liberal historiography. Christian dogma, by which Harnack means the authoritative doctrinal system of the 4th century, is traced in its origin and development through the Protestant Reformation. His thesis is that Christian dogma in its conception and development is a work of the Greek spirit on the ground of the Gospel. The process begun at the Reformation—viz., the overcoming of dogma by a recovery of the essence of the Gospel—should be completed, and it is the historical-critical approach that will achieve this. Harnack defended this value-judgment in his most famous work, *Das Wesen des Christentums* (1900 and many later eds.; Eng. trans., *What* Is *Christianity?,* 1901), which evoked

violent and prolonged opposition.

Harnack's other major works include *Geschichte der altchristlichen Literatzcr bis Eusebius* (3 vol., 1893–1904), incomplete; *Die Mission und Ausbreitung des Christentums in den ersten drei Jahrhunderten* (1902; Eng. trans., 2 vol., 1904–05; 2nd Ger. ed. 1924); a collection of papers, *Beiträge zur Einleitung in das Neue Testament* (7 parts, 1906–16; Eng. trans. of 6 parts. 1907–25); a collection of speeches and articles, *Reden und Aufsätze* (7 vol., 1904–30, vol. vii edited by Axel Harnack); *Marcion, das Evangelium vom fremden Gott* (1921). A complete bibliography of Harnack's writings, listing 1,611 items. was prepared by Friedrich Smend under the title *Adolf von Harnack: Verzeichnis seiner Schriften* (1931).

See *Adolj von Harnack,* a biography by his daughter, Agnes von Zahn-Harnack (1936). (G. W. GL.)

HARNESS AND SADDLERY, the equipment for any animal used for packing, traction or riding. Harness is the general term for the gear and tackle for such animals. Saddlery in the sense used in this article applies to articles produced by a saddler, a person who makes, repairs or sells saddles and related equipment, such as bridles, bits. stirrups and hames.

Bridles and Other Head Gear.—The bridle, a harness of horses and mules, is a set of straps that make the bit secure in the animal's mouth and thus ensure human control. The headstall portion of the bridle consists of the headpiece passing behind the ears and joining the head band over the forehead; the cheek straps run down the sides of the head to the bit, to which they are fastened; in the blind type of driving bridle the blinkers, rectangular or round leather flaps that prevent the animal from seeing anything except what lies in front, are attached to the cheek straps; the noseband passes around the front of the nose just above the nostrils; and the throatlatch extends from the top of the cheek straps underneath the head.

The martingale, sometimes used on riding horses, passes between the horse's forelegs with one end fastened to the saddle girth and the other to the head harness. It keeps the horse from throwing back its head.

The bit is the metal contrivance inserted in the mouth to which the reins are attached. There are three general types of bits: the straight bar, snaffle and curb. The snaffle has a jointed steel mouthpiece with straight cheek bars, the rings for the reins and cheekpieces of the headstall being fixed in the bars at the junction with the mouthpiece. The bars prevent the horse from pulling the bit through its mouth. The snaffle without bars is termed a bridoon. The curb bit is one to which a curb chain or strap is generally attached, fastened to hooks on the upper ends of the cheek bars of the bit and passing under the horse's lower jaw in the chin groove. The reins are attached to rings at the lower ends of the cheek bars, the leverage thus pressing the curb chain against the jam. The mouthpiece of the curb bit is unjointed and in the centre commonly has a port, *i.e.,* a raised curve, allowing liberty for the tongue and bringing the pressure on the base of the horse's jaw. The curb bit and the bridoon can be used together with separate headstalls and reins, and there are many combination bits.

Saddles. — The skeleton of the riding saddle is composed of the tree, or framework, the parts of which are the pommel or head. the projection that fits over the animal's withers, and the side bars that curve around to the back to form the cantle, or hind bow. The rigid parts are almost always covered with leather. To the tree are fastened the stirrup bars. On either side of the saddle are a leather skirt and hanging flaps to protect the rider from the mount's sweat. In saddles to be used with unbroken or unruly horses, knee rolls are often placed on either side behind the cantle.

The saddles of Asia, Africa and continental Europe tend to be heavy and high. But the English saddle, removed from all utilitarian purpose, has developed extreme lightness for sport, racing and fox hunting; the pommel and cantle are greatly reduced, and. provision is made for clinging with the knees in jumps.

The saddles of Latin America and of western North America are highly diversified but largely are derived from equipment developed in the cattle industry of Spain during the middle ages. On the pommel is a sturdy metal horn to which the lariat or lasso is tied when cattle are being roped. The cantle is high to prevent the rider from slipping off the seat when the horse sits back on its haunches at the moment of roping. The saddle is made secure by one or two surcingles called cinches, or girths; these are held to the tree rings by latigos, long leather straps. The sides and front of the stirrups are covered by leather taps (Sp. tapaderos), a casing that prevents them from snagging in brush.

Harness. — Many types of harness are used in different parts of the world for oxen. zebus. asses. reindeer, elephants, camels, water-buffaloes, yaks and dogs. In the basic occidental harness for horses and mules, a leather collar, heavily padded, passes over the head and rests firmly on the shoulders; two hames, rigid curved pieces of metal, rest on this collar and are fastened at top and bottom by hame straps. To the hames are attached the traces, straps that pass along the animal's sides and are connected to the ends of the whippletree (also called whiffletree, singletree or swingletree), a horizontal bar connected to the load by a centre link.

When the animal is harnessed between shafts, the shafts are usually supported by a back pad; the pad is a narrow leather cushion resting on the hack, attached to the shaft by straps and held in position by a girth or bellyband as well as by a backband and crupper. a loop strap passing under the tail. Reins pass through terrets, or rings. on the hames and pad. The other harness on the animal's hindquarters consists of the breeching. straps passing around behind the haunches to help in backing, braking and stopping the vehicle, and the hip strap fastened to the breeching and passing over the hindquarters.

The checkrein (bearing rein). a device sometimes used to add to the elegant arch of a horse's neck, consists of a separate bridoon bit with the reins passing through rings on the collar and then attached to a hook on the pad.

Historical **Sketch.**—With the possible exception of the sail, harness represents man's first attempt to employ nonhuman power fnr his purposes. In pre-Columbian times, the new world knew no harness except for llamas and dogs carrying packs, dogs pulling travois on the Torth American plains and dog sleds among the Eskimos. The Indian failure to develop much harness map be due both to the scarcity in America of animals anatomically suited to it and to the failure to observe systematically the effects of gelding.

The earliest old world form of harness, which presupposes gelding, is the yoke resting on the withers of two animals, first used in the near east perhaps by 4000 B.C. to attach a pair of oxen to a plow. By about 3000 B.C. the yoke was employed in Mesopotamia with onagers to draw light wagons and chariots, and by about 2000 B.C. it was applied to horses, then newly arrived from central Asia. Asses were used as pack animals in Egypt by 3000 B.C., but there is no evidence that any animal was ridden until about 1300 B.C.

The first use of the camel for labour is of very uncertain date. Presumably it is early. since the single-humped camel appears as a pack animal by 1000 B.C. in Mesopotamia. In the regioa north of the Altai mountains reindeer were used for traction earlier than horses, to judge from the fact that horses drawing the funeral sled of a chieftain buried at Pazirik about 400 B.C., which were sacrificed and buried with him, wore reindeer masks.

Bits. — Both oxen and onagers were controlled by rings through the nose. The horse, however, appears from the beginning to have been governed normally by a bridle and bit, sometimes of bone but generally of metal. At first this was a simple bar with a ring at each end for reins, although by 1400 B.C. the jointed snaffle was known throughout the near east. While there were many variations of both bar and snaffle bit, no basic innovation appeared for a thousand years; in the 4th century B.C. Xenophon speaks of the curb bit. During the European middle ages the development of mounted shock combat demanded that the knight have absolute control of his charger. with the result that heavy and very severe curbs were produced. But no basic new idea in bits has appeared for the past 23 centuries.

Spurs.—The simple prickspur appears in Celtic graves of about 400 B C. Although its use became habitual in Europe and eventually in the Americas, it seems not to have spread widely in the orient or Africa. Rowel spurs which replaced the single prick with a wheel of radiating points first were found in 9th-century Spain.

Saddles. — For at least 12 centuries after horses were first ridden there were no saddles but only saddle cloths attached by surcingles or bellybands. These cloths were gradually supplemented by cushions or rolls that improved the rider's comfort but did not add greatly to his stability. Saddles with rigid frames, pommels and cantles but without stirrups appear in China during the Han dynasty (206 B.C.–A D. 220) and are found in Roman Gaul in the 1st century AD., probably as an introduction from the barbarian world. The development of mounted shock combat in the middle ages required that the saddle become a large seat giving maximum support to the knight. In early modern times as shock combat in warfare and the tournament as sport went out of fashion, saddles steadily grew lighter. The decline of the saddle into the so-called English saddle of the late 19th and 20th century is a sign of the technological obsolescence of the horse among those using such saddles. Herdsmen continued to use very substantial saddles.

The sidesaddle developed from an ancient pack saddle with a pannier, a board suspended on one side upon which the woman rider could rest her feet for support. By Frankish times the term astreba referred specifically to the footrest of such a saddle, and the word conveniently labeled the stirrup when it came from central Asia.

During the middle ages and early modern times, the sidesaddle was varied in many ways from the basic device.

Stirrups.—The first stirrups appeared as big-toe stirrups in India in the late 2nd century B C. These were diffused nherever Hindu culture had contact with barefoot aristocracies, from Timor and the southern Philippines on the east to Ethiopia on the west. The wave of Indian culture that took Buddhism to China likewise carried the idea of the stirrup which the booted Chinese, in their chillier climate, expanded into the foot stirrup by the 5th century A.D.

The foot stirrup reached Korea in the 5th century and Japan and some of the central Asian countries in the 6th century. In A.D. 694 Moslem armies in northern Iran received the stirrup from Turkestan. Shortly afterward it was found in Byzantium. and by the early 730s it had arrived in the Frankish realm

Before the support of the stirrup supplemented that of pommel and cantle, a mounted warrior could thrust his spear only with the strength of his own arm. With stirrups he could lay the spear at rest under the upper arm while his hand guided the blow that was now delivered by the force of his charging horse. The increase of violence was immense. Since it made possible mounted shock combat, the stirrup is the most significant invention in the history of warfare prior to gunpowder. In the early 730s Charles Martel saw the military potentialities of the stirrup, seized great areas of church lands, distributed them to retainers as endoament on condition that they serve him by fighting in the new manner and thus instituted the feudal regime.

Modern Harness. — The Bronze Age transfer of the yoke from oxen to onagers, horses, etc., was not successful for anatomical reasons: a horse, ass or similar animal could be attached to such a yoke only by two straps running from the end of the yoke around the animal's neck and under its belly. The neck strap pressed on the windpipe and jugular vein in proportion to the pull of the animal, while the withers were so high a point of traction as to be mechanically inefficient. The modern harness, with its padded collar supporting rigid hames on the shoulders in a way that does not interfere with breathing or blood circulation, enables the animal to throw all its neight into pulling. It has been shown experimentally that a team of horses equipped with modern harness can pull a load between four and five times heavier than the same team can pull with the ancient yoke harness

Modern harness appears to have been introduced into Europe from Asia China under the Hans developed a type of single-horse chariot drawn by lateral shafts, and the modern harness is found in frescoes of about 500 A.D. in Kansu. The first modern harness in Europe was seen about 800 A.D

Animals and teams could not be harnessed tandem, or in sequence. until the 1st or 2nd century A D.. when suddenly the evidence of such harness is found in Gaul, Italy and China. When this was later combined with horse collar and traces, horsepower became available for plowing and heavy hauling. The first evidence of habitual plowing with horses comes from Norway toward the end of the 9th century. Two hundred years later plow horses nere common over much of northern Europe. from the Ukraine to Normandy. In the 11th century the nhippletree began to equalize the pull of traces on the load, and the pivoted front axle. knonn in Roman times. became common. By the 12th century the big four-wheeled wagon drawn by several teams of horses was revolutionizing land transport. It was the ancestor of all later European coaches and wagons, including the Conestoga wagons of the American frontier and the railroad coach.

See DRIVING AND COACHING; HORSEMANSHIP AND RIDING.

HARNESS HORSE RACING: see HORSE RACING AND BREEDING.

HARNEY, GEORGE JULIAN (1817–1897), English socialist and Chartist agitator, was born at Deptford on Feb. 17, 1817. His education was rudimentary and as a youth he was several times imprisoned for selling unstamped radical newspapers. He became leader of the London Democratic association, the largest left-wing Chartist body in the capital, editor of the unstamped *Democrat* and a strong physical-force Chartist agitator (see CHARTISM). Although he saw that this agitation required an organized mass backing, he never secured it. Harney twice stood for parliament, for the West Riding of Yorkshire in 1841 and against Lord Palmerston at Tiverton in 1847. without success in either case. He edited *The Northern* Star from 1815 to 1850 and through it came to know Friedrich Engels and Karl Marx. sorne of whose ideas he shared. The ineffectiveness of the Chartist petition of 1848 convinced him that a successful working-class movement must be socialist as well as democratic. He helped Marx in the early days of the Communist International, but quarreled with him in 1851, for he was too independent-minded to follow hfarx's lead in everything. Thereafter Harney's influence waned. He moved to Jersey in 1855 and to Massachusetts in 1863, where he worked as a clerk. He returned to England in 1888 and died at Richmond, Surrey. on Dec. 9, 1897.

See A. R. Schoyen, *The Chartist Challenge* (1958). (M. R. D. **F.**)

HARO, LUIS DE (1598–1661), Spanish statesman. who governed Spain; as the favourite of Philip IV, during the critical years between the defeat of Rocroi (1643) and the peace of the Pyrénées (1659), was born at Valladolid, the son of Diego de Haro, marqués del Carpio (whose title he inherited in 1648), and of Francisca de Guzmán, sister of the conde-duque de Olivares. He went to court at an early age and quickly gained the friendship of Philip IV, whose amity Haro was able to reconcile with opposition to the king's minister Olivares, whom he succeeded in 1643. Less able and less ambitious than his uncle. Luis de Haro was unable to improve his country's situation: for most of his administration the war with France continued and the economic crisis worsened. When he led the Spanish delegation to negotiate the treaty of the Pyrénées he was no match for Mazarin, but for his services in arranging the peace his marquessate was raised to a dukedom. Haro died in Madrid in 1661.

HARO (CLAMEUR DE), the ancient Norman custom of "crying for justice," still surviving in the Channel islands. The wronged party must on his knees and before witnesses cry: "Haro! Haro! Haro! a l'aide, mon prince. on me fait tort." This appeal has to be respected. and the alleged trespass or tort must cease till the matter has been thrashed out in the courts. The "cry" thus acts as an interim injunction, and no inhabitant of the Channel islands would think of resisting it.

This method of appeal is said to be identical with the "Legatro of the Bavarians and the Thuringians," and the first mention of it in France is to be found in the "Grand coutumier de Normandie." A similar custom, only observed in criminal charges, was recognized by the Saxon lams under the name of "Clamor Violentiae." Thus there is reason to think that William the Conqueror on his arrival in England found the "cry" fully established as far as criminal matters were concerned. Later the "cry" was made applicable to civil wrongs; and, when the administration of justice became systematized, disappeared altogether in criminal cases. It was long retained in northwestern France in cases of disputed possession. and was not actually repealed until the close of the 18th century. See HUE AND CRY.

HAROLD I (HAREFOOT) (d. 1040), king of the English from 1037 to 1030. an illegitimate son of Canute by Aelfgifu of Northampton. He was made regent of England after his father's death in 1035, until the legitimate son, Hardicanute (*q.v.*), should arrive. Because the latter delayed in Denmark, Harold was made king in 1037, and banished Emma, Canute's widow. In 1036 he was responsible for the cruel treatment of a party brought from Normandy by a son of Aethelred II the Unready, Alfred, who was blinded and soon died.

A Welsh raid in 1039, when Earl Leofric's brother Edwin was killed. and an unsuccessful Scottish attack on Durham c. 1040 are the only other recorded events of this reign. Harold died at Oxford on March 17, 1040.

See F. M. Stenton, *Anglo-Saxon England,* 2nd ed. (1947). (D. WK.)

HAROLD II (1022?–1066), king of the English. the second son of Earl Godwine, was born about 1022. While still very young (before 1045) he was appointed. through his father's influence with Edward the Confessor, to the earldom of the East Angles. He shared his father's outlawry and banishment in 1051, but while Godwine went to Flanders, Harold with his brother Leofwine took refuge in Ireland. In 1052 the uneasiness felt at the visit to England of William, Duke of Normandy, who was known to covet the English throne, caused a reaction in favour of Godwine, who returned to England with his sons, under arms. The witan finally decreed that their lands should be restored. Harold therefore received his earldom of the East Angles, and on his father's death in 1053 succeeded him in the greater earldom of the West Saxons, Sweyn having died while on a pilgrimage to Jerusalem. Harold was now the chief man in the kingdom, and the latter part of Edward's reign was virtually the reign of Harold. On the death (1055) of Siward, earl of Yorthumbria. Edward. at the instigation of Harold. appointed his brother Tostig earl of Sorthumbria: Earl Aelfgar looked upon this appointment as a menace to the Mercian house. and his opposition led Harold to procure his outlawry by the witan. Aelfgar then joined Gruffydd. Prince of North Wales, in an attack on Hereford, as the result of which Aelfgar regained his position as earl of East Xnglia. In 1057. with the exception of Lfercia. Harold and his brothers held all the earldoms throughout England. Aelfgar, in order to secure a useful ally. married his daughter Ealdgyth to Gruffydd. Xelfgar died in 1062, and was succeeded by his son Edwin. In spite of the alliance between the hfercians and the Welsh, Harold and Tostig raided Wales in 1063. and forced Gruffydd, who was eventually killed by his own men, to flee. In 1063 Harold was shipwrecked on the French coast, and captured by the Normans. who only released him on his oath on sacred relics (though at the time he was unaware of their nature) to support William in any claim for the English throne. Probably on his return to England. though the date is uncertain. Harold married Ealdgyth (Edith), sister of Edwin, and widow of Gruffydd, thus conciliating the powerful earl of Mercia. His mistress. Eadgyth of the Swan-neck, the mother of his children. was still living. In 1065 the Northumbrians revolted against Tostig's rule. choosing Morkere, brother of Edwin of Mercia, in his place. Harold acted as mediator, but was compelled to agree to the banishment of Tostig, who was thenceforth his bitterest enemy.

On Jan. 6, 1066, Edward died, recommending Harold as his successor. He was accordingly elected at once and crowned. He won over the men of Northumbria. and prepared against the attacks which threatened on both sides. William challenged the crown, alleging both a bequest of Edward in his favour and Harold's oath, and prepared to invade England. From May to September: Harold kept men and ships in readiness on the south coast. but at last provisions failed and he returned to London. At this time Harald Hardrada of Norway, supported by Tostig in the north, invaded England. Together they sailed up the Humber, defeated Edwin and Morkere, and received the submission of York. Harold hurried northward, and on Sept. 25 won a complete victory over the Northmen at Stamford Bridge, in which Tostig and Harald Hardrada were slain. Two days later Harold received news that William had landed at Pevensey, and he marched southward as fast as possible. He gathered his army in London from all southern and eastern England, while Edwin and Morkere held the north. The king then marched into Sussex, and engaged the Normans (Oct. 14, 1066) on the hill of Senlac near Battle (see HASTINGS: The *Battle of Hastings*). After a fight lasting all day the Normans had the victory; Harold. wounded by an arrow in the eye, and his two brothers Gyrth and Leofwine, lay dead on the field.

Harold had three sons. Godwine, Edmund and Magnus, and two daughters. probably the children of Eadgyth of the Swan-neck. Another son mas named Ulf. By his wife Ealdgyth, who was sent for safety to Chester in 1066, he had a posthumous son. Harold, who took part in the expedition of Magnus Barefoot to the Scottish Isles in 1098. Harold's body is said to have been taken from the cairn of stones on the sea shore where it was originally buried to Waltham.

See E. A. Freeman, *History of the Norman Conquest of England* 6 vol. (1871–79), in which the existing sources are fully utilized; Lytton's *Harold* is a brilliant historical novel, though not an impartial record.

HARO STRAIT, a channel forming part of the international boundary between Canada and the United States, is located east of the southern end of Vancouver Island: B.C., and joins the straits of Juan de Fuca and Georgia. The San Juan islands of Washington state lie east of Haro strait. Depths in mid-channel average between 100 and 150 fathoms, but at its southern end where there are submerged islands the water is only about 10 to 50 fathoms deep. Deep-sea vessels approaching Vancouver usually follow the Haro strait through the islands in the gulf of Georgia.

Throughout the strait the ebb or south-going tidal stream has a much greater rate than the flood or north-going tide. Tide rips are common off headlands. The ebbing tides carry surface water from the Fraser river, which is warmer than the deeper water which comes from Juan de Fuca strait. (J. L. R.)

HARP, a plucked stringed instrument of great antiquity. Typically, the harp is either triangular or bow-shaped, with one string for each note and with a resonator to which the plane of the strings is perpendicular or nearly so. The gradation of string length from short to long corresponds to the gradation from high to low pitch. The word harp is often used inaccurately to describe instruments that are properly zithers or lyres.

The modern harp is a combination of the basic structure and method of sound production of the ancient harps, with a complex mechanism to obtain a full chromatic range.

The modern double-action pedal harpcovers 63 octaves (3 below and $3\frac{1}{2}$ above middle Ci and consists of (1) a hollow sound box, rectangular or semicircular in section to which the belly, or sounding board is attached; (2) the harmonic curve, or neck, carrying the tuning pins, a set of wrest pins and two sets of rotating brass disks; (3) the forepillar. which joins the end of the neck to the base; (4) the strings, of gut or nylon and, in the bass, bound wire, which. at the upper end. are fixed through the tuning pins and, at the lower end, are pegged to holes in the belly; (5) the mechanism, concealed inside the forepillar and the deep metal plates that run along both sides of the neck. This mechanism is worked from seven pedals (one for each string in the harp's 7-note octave) set in the base of the harp; each of these pedals acts upon all the strings of a certain pitch name throughout the harp's compass. Depression of the pedal to the first notch (single ac-

tion) shortens the appropriate strings by a semitone; to the second notch (double action) by a whole tone; the shortening is effected by means of the rotating disks on the neck that grip the string at the appropriate point. This harp is normally tuned diatonically in C♭; thus, depression of all pedals to the first notch puts it into C, and to the second notch into C♯. Its technique demands skilled co-ordination between the hands, which pluck the strings with the fleshy part of the finger tips, and the feet, which, with the pedals, select the necessary pitch changes on the strings.

True harps of great size are depicted in the tomb of Ramses III (c. 1200 B.C.) and harps of various forms and sizes were much used in the ancient Mediterranean civilizations, the exceptions being Greece and Rome, where the lyre and cithara were more important. There are few extant specimens of these ancient harps. but their use ultimately spread to Africa and the far east and the form of the small Egyptian bow harp survives in the tribal harps of east Africa and the old Burmese harp. Ancient harps had no forepillar and, presumably. were strung at rather low tension.

The frame harp. with a forepillar joining the forward ends of neck and sound box. appears to have developed in northern Europe during the 10th and 11th centuries of the Christian era. From the 12th century two main forms are recognizable, one Irish and one European. The characteristic features of the Irish harp. or *clarsach*, were a huge sound box carved from a solid block of wood, a heavy neck and a deeply curved forepillar. It was designed to bear great tension from thick brass strings, which were plucked by long fingernails to produce a ringing, bell-like sound. It belonged to the world of strongly coloured medieval instruments, but, because of the static nature of the aristocratic Irish society into which it was integrated, it survived almost unchanged to the end of the 17th century. Its long resonance was out of keeping with the harmonic nature of 18th-century music! and by the end of that century it had disappeared.

The modern harp is derived from the more delicate European harp, which differed from the Irish in having a thin, shallow sound box, slender neck and forepillar and, at least from the 16th century. gut strings plucked with the finger tips. The simple 16th century form is preserved in the rustic harps of Latin America, taken there by the Spaniards and adopted by the Indians, who still play vivacious dance music on them, together with drums, guitars and maracas.

FIG. I.— SMALL IRISH HARP. PROBABLY 14TH CENTURY

From the 17th century onward, the harp was progressively mechanized to give it the chromatic notes demanded by changing musical styles. The first attempt was made by Tirolean harp makers,, who placed a number of hooks on the neck close to the strings, to be turned by hand when required. Although this mechanism made it possible to sharpen the pitch by a semitone, it also pulled the hooked strings out of plane, and its operation left only one hand free to play. In 1720. Celestin Hochbrucker. a Bavarian. attached the hooks to a series of levers in the forepillar (which henceforth became hollow) controlled by seven pedals. In 17.50. Cousineau of Paris replaced the hooks by metal plates that gripped the strings while leaving them in plane. In 1792, Sébastien Érard substituted the rotating disk for the metal plate and in 1810 added a second disk for each string and produced the double action for the pedals; Érard's changes virtually established the modern form of the harp.

FIG. 2.— DOUBLE-ACTION PEDAL HARP

The Welsh triple harp with three parallel ranks of strings, and the chromatic harp invented and improved by members of the Pleyel firm in Paris in the late 19th century. were attempts to chromaticize the harp without using mechanism. The so-called Irish harp of the 19th and 20th centuries is derived from the gut strung pedal harp and has little connection in construction or technique with the historic Irish harp.

In the absence of exact instrumentation, medieval harp music can only be inferred. Much 17th- and 18th-century solo music is alternatively for harp or keyboard instruments and is. with the exception of Mozart's concerto for flute and harp, unremarkable. The tonal and technical possibilities of the modern harp, particularly its sweeping glissandi and mysterious harmonics, make it most effective in impressionist or "atmosphere" music, and its. solo and ensemble repertoire is largely modern.

Parts specifically written for the harp are rare in early concerted music. Rlonteverdi's opera *Orfeo* (1607) and Handel's oratorio *Esther* (1730) being notable exceptions; the double-action pedal harp. however, became a standard part of the orchestra from 1830 onn ard.

HARPENDEN, an urban district in the Hemel Hempstead parliamentary division of Hcrtfordshire. Eng., 3 mi. N.N.W. of St. Albans. Pop. (1951) 14,244. Area 4.9 sq.mi. It is a residential district from which many people travel daily to London. West of Harpenden common (238 ac.) is Rothamsted Experimental station (*q.v.*), a centre for agricultural research founded by J. B. Lawes and opened in 1843. It covers about 527 ac. and includes laboratories, an. experimental farm and the historic Rothamsted Manor house, now used as a hostel. Harpenden hall, dating from the 17th century, was acquired by the district council in 1932 for offices. About 4 mi. E. of Harpenden is Wheathampstead, where are the huge earthworks of Cassivellaunus' stand against Caesar.

HARPER, JAMES (1795–1869), founder of the U.S. publishing firm of Harper and Brothers, was born in Newton, Long Island, N.Y., on April 13, 1795. At the age of 16, after a country school education. he was apprenticed to a printer in New York city. In 1817. with his younger brother John, he established in New York a printing business that soon became a publishing firm. The business was successful and two younger brothers, Joseph Wesley and Fletcher, were brought into the firm. In 1833 Harper and Brothers was adopted as the name of the firm. The abilities of each of the brothers supplemented those of the others and the firm attained an eminent position in the publishing business. James was elected mayor of New York city in 1844 but declined offers thereafter to run for public office. He died in New York on March 27, 1869.

See J. *H.* Harper, *The House* of *Harper (1912).* (H. J. Sc.)

HARPER, ROBERT ALMER (1862–1946), U.S. botanist, whose early research on the cytology of reproduction in the fungi and later work on fundamental problems of morphogenesis came to be considered classic contributions to the understanding of living things. was born in Le Claire, Ia., Jan. 21, 1862. He was graduated from Oberlin (O.) college in 1886. From 1889 to 1898 he was at Lake Forest (Ill.) college, where he became professor of botany and geology. In 1898 he was appointed professor and head of the department of botany at the University of Wisconsin, Madison; he remained there until 1911, when he accepted the chair of Torrey professor of botany at Columbia university. He died on May 12. 1946. in Bedford, Va. (R. Bd.)

HARPER, WILLIAM RAINEY (1856–1906), U.S. Hebraist and first president of The University of Chicago, was born on July 26, 1856, at New Concord, O. His interest in Hebraic studies began in Muskingum college, New Concord, at which he graduated in 1870. In 1875, when only 19 years of age, he received his Ph.D. at Yale for studies in the Indo-Iranian and Semitic languages. In 1880. after several years of academy teaching, he was given a professorship in Hebrew at the Baptist Union Theological seminary in Chicago. There he founded *The Hebrew Student* and *Hebraica* and organized the American Institute of Hebrew. He published a number of textbooks and study helps for the teaching of Hebrew which found wide use. In 1886 he accepted a professorship in Semitic languages at Yale, and in 1889 was appointed also Woolsey professor of biblical literature, filling both positions simultaneously. In 1891 he became president of the nearly established University of Chicago (*q.v.*). His liberal aims and comprehensive plans for the new university attracted wide attention. Harper remained its president and head of the department of Semitic languages until his death on Jan. 10. 1906.

Among his more important books are *Religion and the Higher Life* (1904); *A Critical and Exegefical Commentary on Amos and Hosea* (1905); *The Prophetic Element in the Old Testament* (1905); *The Trend in Higher Education* (1905).

HARPERS FERRY, scene of John Brown's dramatic raid, Oct. 16–18, 1859, has become a quiet residential town in Jefferson county. W.Va., U.S., located at the confluence of the Potomac and Shcnandoah rivers where the states of West Virginia. Virginia and Maryland converge, about 60 mi. N.W. of Washington, D.C., and 70 mi. E. of Baltimore, Md. (For details of the raid *see* Brown, John [1800–1859].)

In 1747 Robert Harper established a ferry across the Potomac river and a grist mill on the bank of the Shenandoah river. The purchase of land from Harper's heirs in 1796 for the establishment of a federal armoury provided economic stimulus needed for the growth of the town. Pres. George Washington selected the site, recognizing the water-power potential of the rivers. The armoury attracted workmen whose need for goods resulted in the expansion of mercantile operations.

In the mid-1830s the Chesapeake and Ohio canal, Baltimore and Ohio railroad. and Winchester and Potomac railroad all were completed as far as Harpers Ferry. Gradually the town became a commercial. industrial and transportation centre for northern Virginia. Confederate forces under Gen. Thomas J. "Stonewall" Jackson captured the town, Sept. 13–15, 1862. and took more than 12,500 prisoners, the largest surrender of Union forces in the American Civil War. War-battered and flood-damaged Harpers Ferry never fully recovered and became a virtual ghost town.

Recognizing the scenic beauty and historical importance of Harpers Ferry. the national park service embarked on a program, authorized in 1944, of development and restoration. The old business section of the town and surrounding Civil War sites comprise Harpers Ferry National monument. *See* also Index references under "Harpers Ferry" in the Index volume. (H. H. K.)

HARPIES, the Greek *harpyiai,* or snatchers, were fabulous creatures, probably wind spirits. Their presence as tomb figures, however, as on the famous Harpy tomb of Xanthus in Lycia, makes it not impossible that they were ghosts; the two ideas are not wholly contradictory. In Homer's *Odyssey* they are plainly winds that carry people away; for example, they have carried off Odysseus (*i.e.,* he has been lost at sea). They are sometimes connected with the powers of the underworld; thus they carried off two orphan sisters whose marriage was being arranged by Aphrodite and gave them to the Erinyes, the deities of vengeance, as servants. Homer mentions one Harpy, Podarge (Swiftfoot), who seems to be of equine nature, since, according to the *Iliad,* she became by the West Wind the dam of Achilles' horses. Hesiod mentions two, Aello and Okypete (Stormwind and Swiftwing), daughters of Thaumas and of Electra, the daughter of Oceanus.

These harpies were in no way disgusting. Later, especially in the Argonautic saga, they were represented as birds with the faces of women, horribly foul and loathsome. They are sent to punish the Thracian king Phineus for his ill-treatment of his children, or for some other offense, and nearly starve him to death by carrying off most of his food and befouling the rest. Calais and Zetes, the sons of Boreas, deliver him and chase the harpies away. Virgil imitates the episode in the *Aeneid;* he calls the chief harpy Celaeno (Dark).

HARPIGNIES, HENRI (1819–1916), French landscape painter and engraver, was born at Valenciennes on June 28. 1819. He took to painting comparatively late in life, entering Achard's atelier in Paris at the age of 27. Between 1850 and 1865 he studied and painted in Italy and France, coming more and more under the influence of Corot. and the water colours executed during this period are among his finest work. Harpignies scored his first great success at the Salon. in 1861, with his "Lisière de bois sur les bords de l'Allier," and after that year he was a regular exhibitor at the old Salon. In 1886 he received his first medal for "Le Soir dans la campagne de Rome." which was acquired for the Luxembourg gallery. Many of his best works were painted at Hérisson in the Bourbonnais, as well as in the Nivernais and the Auvergne. He died on Aug. 28, 1916, at St. Privé (Yonne), where he had settled in 1878.

Harpignies's landscapes are distinguished for constructive drawing and breadth of treatment; a silvery tone pervades them. They may be seen in several galleries in the United State's, including the Toledo Museum of Art and the Boston Museum of Fine Arts.

HARPOCRATES, originally an Egyptian deity, adopted by the Greeks and worshiped in later times by both Greeks and Romans. In Egypt, Harpa-khruti, Horus the child. was one of the forms of Horus. the sun-god, the child of Osiris. He was supposed to carry on war against the powers of darkness, and hence Herodotus considers him the same as the Greek Apollo. He was represented in statues with his finger on his mouth, a symbol of childhood. The Greeks and Romans, not understanding the meaning of this attitude, made him the god of silence.

HARPOCRATION, VALERIUS (?2nd century A.D.), Greek grammarian, whose lexicon provides valuable information on a variety of subjects, was born in Alexandria. Two works were attributed to him, an anthology which has not survived. and the *Lexeis ton deca rhetoron* ("Lexicon of the Ten Orators") which survives in two forms—one virtually complete and an epitome made from an earlier and better version of the text which is now lost. The *Lexicon rhetoricum Cantabrigiense* edited by P. P. Dobree in 1834 contains a series of extra articles from the margin of a Cambridge manuscript of the fuller version. The lexicon of Harpocration explains words, phrases. names and events mainly from the works of the canonical ten Athenian orators and is arranged in alphabetical order. It is valuable both for its explanations of technical 'terms and Athenian institutions, and for the numerous quotations it preserves from tragic and comic poets, from the Atthidographers and other historical writers, and from Alexandrian scholars such as Didymus and Callimachus. It gives the fullest known explanation of many points in Xthenian law and has notes of great interest on religious and architectural matters.

See **edition** *by* W. **Dindorf,** 2 **vol. (1853)**; **J. E. Sandys,** *History of Classical Scholarship,* vol. *1, 3rd* **ed. (1921).** (G. B. KD.)

HARPOON, a barbed spear used mainly for spearing whales or large fish, and either thrown by hand or fired from a gun *(see* WHALE FISHERIES).

HARPSICHORD, a large keyboard instrument, belonging to the same family as the virginal and spinet, but having two, three or even four strings to each note, and a case of the harp or wing shape, afterward adopted for the grand pianoforte. J. S. Bach's harpsichord, in the museum of the Hochschule für Musik at Charlottenburg, has two manuals and four strings to each note, one 16 ft., two 8 ft. and one 4 ft. By means of stops the performer has a number of combinations for varying the tone and dynamic power. In all instruments of this family the strings, instead of being struck by tangents as in the clavichord, or by hammers as in the pianoforte, are plucked by means of a quill firmly embedded in' the centred tongue of a jack or upright placed on the back end of the keylever. This plucking of the string produces the incisive tone peculiar to the harpsichord family, What these instruments gain in brilliancy of tone, however, they lose in power of expression and of accent.

See also PIANOFORTE.

HARPY EAGLE, powerful eagles named after the mythological half-bird. half-woman monsters *(see* HARPIES). They are largely South American. and include the great harpy or Mexican imperial eagle (*Harpia harpyja*), most powerful of eagles, ranging to southern Brazil, and the crowned harpy (*Harpyhaliaetus*). Elsewhere are found the New Guinea harpy (*Harpyopsis*) and the large Philippine monkey-eating forest eagle (*Pithecophaga jefferyi*).

BY COURTESY OF NEW YORK ZOOLOGICAL SOCIETY

HARPY EAGLE (HARPIA HARPYJA)

Most harpy eagles stand over three feet high and present a formidable appearance. Although slow of flight, they are powerfully armed with hooked beak and large talons. *See* also EAGLE.

HARQUEBUS: *see* ARQUEBUS.

HARRAN (HARAN; Rom. CARRHAE), a historic site of strategic importance on the Belikh river, is in modern times a small town 23 mi. S.S.E. of Urfa (Edessa) in the Urfa *il* of Turkey. The ancient town lay on the road that ran westward from Nineveh to the crossing of the Euphrates at Carchemish and was regarded as of considerable consequence by the Assyrian kings. Its chief cult in Assyrian times was that of the moon-god. As Haran, the town is frequently mentioned in the Bible. It was there that Abraham's father. Terah. settled with Abraham and all his family when they had left Ur of the Chaldeans (Gen. xi, 31–32). The story of this migration. and of Abraham's further migration from Haran after Terah's death. is told again in Acts vii, 2–4.

In Roman times Harran, as Carrhae. mas the scene of the disastrous defeat of Crassus by the Parthians (53 B.C.). Three and a half centuries later the emperor Galerius was defeated at Carrhae by the Persian king Narses (A.D. 296). Meanwhile the emperor Caracalla had been murdered there in 217 while preparing for a campaign against the Parthians.

Still a place of importance in the 12th century, Harran was again the scene of a battle when Bohemund, the Norman prince of Xntioch, was defeated there by the Turks in a decisive battle (0 Later in the century Harran formed part of the principality of the atabeg Zangi.

HARRATIN, black Berbers, dwelling In Tidikelt and other Saharan oases. Many, though blacker than the average Negro, are of the Berber type, with European features and well-proportioned bodies. They are the result of an early crossing with the Sudanese Negro. They have all the pride of the Berbers (*q.v.*) and do not live with or intermarry among Negroes.

HARRIER, any hawk (*q.v.*) in the genus *Circus,* subfamily Circinae, with face feathers arranged into a disc and oval nostrils. They are moderate in size (17–23 in., females larger and usually much different in colour) and. in most species! display a distinct white rump-patch. These predators. with wings somewhat angled up. fly low over open country) particularly marshes, in search of small mammals. reptiles, insects; frogs and sometimes birds. The nest is usually on the ground in marshes, or in tall grass, with four to six dull whitish or bluish eggs; the spotted harrier (*Circus assimilis*) oi .Australia and Celebes is remarkable for its tree-nesting habits.

The best knonn is the hen harrier (*C. cyaneus*). ranging across Europe and Asia from the arctic tundras-south to the Pyrenees, Italy, Turkestan and Tibet. An allied form, the marsh hawk (*C. c. hudsonius*) lives in North America. from Alaska and Newfoundland south to California, Texas, Ohio and Virginia; in winter it shifts southward. Females and young are brown; the bluish-ash males, whitish below, are known as blue hawks. Also common is the marsh harrier (C. *aeruginosus*), over most of Europe and the Mediterranean shores of north Africa to Mongolia, and Montagu's harrier (C. *pygargus*), having the same temperate range but with longer wings, more slender body and darker colours. The pallid harrier (*C. macrourus*) breeds from the Baltic to southeastern Europe and central Asia. Allied species are the cinereous harrier (*C. cinereus*), Peru to the Straits oi Magellan; long-winged harrier (*C. buffoni*), over all of South America, especially east of the .Andes ; South African marsh harrier (C. *ranivorus*), ranging north to Uganda on the east; pied harrier (C. *melanoleucus*), central eastern Asia from Lake Baikal to northeastern China; allied harrier (*C. approximans*), Australia, New Zealand. New Guinea, New Caledonia and the Fijis; eastern marsh harrier (*C. spilonotus*), central Asia and Madagascar; and black harrier (C. *maurus*), southern South Africa. (G. F. Ss.)

HARRPGAN, EDWARD (NED) (1845–1911), U.S. actor, producer and playwright, was born in New York city on Oct. 26, 1845. His theatrical career began in San Francisco, Calif.. where, in 1861, he was singing with Lotta Crabtree at the Bella Union. After developing his skill as a comedian, Harrigan formed a team with Sam Rickey and returned to New York. In 1872 he formed a new partnership with Tony Hart (original name Anthony Cannon), and Harrigan and Hart remained a team until 1885. In 1876 they became co-managers of the Theatre Comique, After a new theatre was destroyed by tire in 1884, Harrigan became sole manager or' Harrigan's Park theatre.

During his long career Harrigan wrote several hundred sketches and plays, mostly burlesques. His most popular creation was *The Mulligan Guard,* first produced in 1873. Harrigan died on June 6, 1911. (S. W. H.)

HARRIMAN, EDWARD HENRY (1848–1909), U.S. financier and railroad magnate, was born at Hempstead. N.Y.,

Feb. 25, 1848. He became a broker's clerk in New York at an early age. and in 1870 was able to buy a seat on the New York Stock exchange on his own account. Harriman's career in railroad management started with executive positions with the Illinois Central. In 1898, his career as a great railway organizer began with his formation, by the aid of the bankers, Kuhn. Loeb & Co., of a syndicate to acquire the Union Pacific line, which was then in the hands of a receiver. Having brought the Union Pacific out of bankruptcy into prosperity, he utilized his position to draw other lines within his control, notably the Southern Pacific in 1901. His abortive contest in 1901 with James J. Hill for the control of the Northern Pacific led to one of the most serious financial crises ever known on Wall Street. At his death. on Sept. 9, 1909, his influence was estimated to extend over 60,000 mi. of track. Harriman's methods excited the bitterest criticism, culminating in a stern denunciation from Pres. Theodore Roosevelt in 1907.

His son, WILLIAM AVERELL HARRIMAN (1891–), entered the employment of the Union Pacific in 1915 and was board chairman. 1932–46. Although he held numerous positions in the business world, Averell Harriman was best known for his governmental service: beginning with an administrative position with the N.R.A. in 1934. He was ambassador to the U.S.S.R. (1943–46) and to Great Britain (1946); secretary of commerce (1946–48); and director of the Mutual Security agency (1951–53). In 1954 he was elected governor of the state of New York; in 1958 he was defeated for re-election. (W. H. D.)

HARRINGTON, EARLS OF. The English title earl of Harrington was first created for the diplomatist and politician, WILLIAM STANHOPE (*c.* 1683–1756), a distant cousin of the more famous statesman James Stanhope (1673–1721), 1st Earl Stanhope. Educated at Eton, William Stanhope was British ambassador in Spain 1721–27, and 1729–30 and was created Baron Harrington in Jan. 1730. He was secretary of state for the northern department from 1730 to 1746 except for a short interval (1742–44), when he was president of the council. He was created earl of Harrington in 1742. He was lord lieutenant of Ireland (1746–50) and died in London on Dec. 8. 1756.

LEICESTER (1784–1862), 5th earl. was a soldier and a politician of advanced views, who worked with Lord Byron in the cause of Greek independence. although his later speeches in the house of lords displayed a much more conservative temper. WILLIAM (1922–). 11th earl. succeeded his father in 1929, and is also heir presumptive to the viscountcy of Stanhope.

HARRINGTON (HARINGTON), **JAMES** (1611–1677), English political philosopher, best known for his major work *Oceana,* a treatise on the ideal state mhich must be understood in terms of the political and economic conditions of 17th-century England, but which contains ideas that have gained importance far beyond their historical context. Harrington, a member of the English nohility. was born at Upton on Jan. 7, 1611. (He should not be confused with his cousin. Sir James Harrington, a member of the commission which tried Charles I.) He studied at Trinity college. Oxford. and traveled extensively in continental Europe. Although he was a devoted exponent of the ideas of republican government, he won the esteem of Charles I, whom he served and whose execution he deeply deplored. Moreover, Harrington's ideas initially failed to gain Cromwell's approval. *Oceana* was confiscated while it was being printed; only after the intervention of Cromwell's daughter was it published in 1656, dedicated to Cromwell.

Harrington's persistence in his republican views after the restoration of the monarchy led to his imprisonment in 1661, from which he was released after he had become physically and mentally ill. He died on Sept. 11, 1637 at Westminster.

"Oceana" is the name of the ideal state which Harrington envisaged for England. Olphaus Megaletor, a pseudonym for Oliver Cromwell, is its protector, who retires into private life after a republican government under a constitution has been firmly established. The treatise *Oceana* has been regarded as a Utopia. However. such developments in American political history as the adoption of written constitutions. the reliance on bicameral legislatures, rotation in office, the use of the secret ballot and the provision for indirect election of the president must be understood, in part, in terms of the influence of Harrington's ideas; his ideas did not remain confined to their Utopian context.

Of particular interest is Harrington's idea that political power follows economic power. This idea, which was extensively developed in *Oceana,* may be regarded as the first important restatement of Aristotle's theory of constitutional stability and revolution. In his *Politics,* Aristotle emphasized that constitutional stability in a polity is attained by a unification of political and economic power. The contemporary version of this aspect of Xristotle's theory is that democracy is most stable where there is a strong middle class. The other, corresponding aspect of Aristotle's theory is that whenever political and economic power are separated, a revolution is likely to occur. Through Harrington's influence this theory appears in American political thought in such diversified forms as Jefferson's defense of an agrarian democracy and the antitrust policies of Roosevelt and Wilson.

In 20th-century research in the social sciences, the Pareto-Davis theory of income distribution and political disturbances has provided a mathematical index for measuring the concentration of economic power and its relation to civil wars and revolutions. In terms of such a wide perspective, it may be suggested that Harrington's idea of the relation of political and economic power represents a fusing link between classical Greek thought, modern political history and contemporary research.

John Toland's edition of Harrington's *Works* was first published in 1700; subsequent editions appeared in 1747 and 1771. *Oceana* has been edited by Henry Morley (1887) and S. B. Liljegren (1924).

(F. KT.)

HARRIOT (HARRIOTT), **THOMAS** (1560–1621). English scientist, who specialized in mathematics and astronomy. was born and educated at Oxford. Sir Walter Raleigh made him scientific adviser on the expedition of 1585–86 to Roanoke, Va. Harriot's observations are found in A *Brief and True Report* (1588), often reprinted. *e.g.,* in Richard Hakluyt's *Voyages* (1600). He became the leading scientist of the circle around Raleigh and received a pension from the earl of Northumberland. In his algebra. *Artis analyticae praxis ad aequationes algebraicas resolvendas* (1631) he improved the theory of equations. noting the relation between coefficients and roots, and also improved notation, introducing the signs > (greater than) and < (less than). The book was influenced by François Vieta and. in turn, influenced John Wallis. Harriot constructed telescopes — the first one contemporaneously with Galileo—studied sunspots and comets and corresponded with Kepler on the refraction of light. He died July 2, 1621, in London.

HARRIS, SIR ARTHUR TRAVERS, 1ST BART. (1892–). British air marshal. best known for his outstanding work as air officer commander in chief, bomber command, was born at Cheltenham, Gloucestershire. on April 13, 1892, and was educated at Gore court. Sittingbourne. In World War I he first served with a Rhodesian regiment in German West Africa, and then, commissioned in the Royal Flying Corps, flew as a pilot in France and with the home defense command. Afterward he served in India and the middle east and on the planning staff in England before commanding a bomber group.

From 1940 to 1941 he was deputy chief of air staff, and in the latter year headed a delegation to the United States. He held the most important and arduous post of commander in chief of bomber

command with the greatest resolution between Feb. 1942 and Sept. 1945. During his command the bombing offensive against Germany was developed on an immense scale and is generally thought to have contributed greatly to the defeat of that country. Sir Arthur Harris was created a baronet in 1953. (E. B. BN.)

HARRIS, GEORGE, 1ST BARON. cr. 1815 (1746–1829), British general, was the son of the Rev. George Harris. curate of Brasted, Kent, and was born on March 18, 1746. Educated at Westminster school and at the Royal Military academy, Woolwich, he was commissioned to the royal artillery in 1760, transferring to an ensigncy in the 5th foot (Northumberland fusiliers) in 1762. His first active service was in the American War of Independence, his next under Major General Medows at Santa Lucia in 1778–1779, after which his regiment served as marines in Rodney's fleet. After commanding the 5th in Ireland for some years. he exchanged and went with General Medows to Bombay, and served in India until 1792. In 1794 he was again in India, and in 1796 became local lieutenant genera1 in Madras. Up to 1800 he commanded the troops in the presidency, and for a short time he exercised the civil government as well. In Dec. 1798 he was appointed by Lord Wellesley, the governor-general, to command the field army against Tipu Sahib (*q.v.*), and in a few months Harris reduced the Mysore country and stormed the great stronghold of Seringapatam. He returned home in 1800, and attained the rank of full general in 1812. Lord Harris died at Belmont in May 1829.

See Kt. Hon. S. Lushinpton, *Life of Lord Harris* (London, 1840).

HARRIS, GEORGE WASHINGTON (1814–1869). U.S. humorist. was born in Allegheny City. Pa.. on March 20. 1814, and lived most of his life at Knoxville. Tenn., and in the surrounding Great Smoky mountains. From the early 1840s until his death. Dec. 11. 1869, he wrote humorous tales for Tennessee newspapers. the New York *Spirit of the Times* and other publications which were reprinted widely over the entire country. The best of his tales. published in a hook. *Sut Lovingood's Yarns* (1867), surpasses.anything before Mark Twain, in the words of a leading critic. "for vivid imagination. comic plot. Rabelaisian touch, and sheer *fun.*" Harris achieves this high level of excellence by being an oral storyteller with a rare kind of dramatic imagination. He gets his tales going by introducing his comic narrator Sut Lovingood, a "long-legged. short-bodied. small-headed. hog-eyed. natral-born durn'd fool" who takes the reader into a wonderful world of fantasy where anything can happen—and does. There camp meetings. quiltings. frolics. horse races and even political gatherings spring to life in scent, sound, form, colour and motion that are hilariously comic. Mark Twain knew his work and was influenced by it. 'The manuscript of another hook. accepted by the publishers, was lost when Harris died on the train returning home. (D. DY.)

HARRIS, JAMES RENDEL (1852–1941), English scholar, was born at Plymouth in 1852 and studied at Clare college. Cambridge. From 1882 to 1892 he held professorships at Johns Hopkins university. Baltimore. Md., and Haverford (Pa.) college. He was professor of paleography (1893–1903) at Cambridge, spent a year at Leyden as professor of theology. and was director of studies at the Friends' Settlement at Woodbrooke. near Birmingham (1903–18). From 1918 to 1925 he was curator of manuscripts at the John Rylands library. Manchester. He died in Birmingham on March 1, 1941.

Harris wrote a long series of works dealing with textual criticism of the biblical and other sacred books. He also wrote on various Mediterranean cults. His works include *Biblical Fragments from Mount Sinai* (1890); *The Diatessaron* (1890); *Origin of the Cult of Dionysos* (1915); *Further Traces of Hittite Migration* (1927): *Josephus and His Testimony* (1931); *The Magi* (1932); *The Builders of Stonehenge* (1933): *Who Discovered North America?* (1934); *A Temple in Tennessee, Emendations to the Greek of the New Testament* (1935); *The Migration of Culture* (1936); and *An Egyptian Cat Goddess in Britain* (1938).

HARRIS, JOEL CHANDLER (1848–1908), U.S. author, creator of the American folk character. Uncle Remus. was born in Eatonton, Ga.. Dec. 9, 1848. As apprentice on a weekly plantation paper, *The Countryman*, he obtained the real basis for his later work. He established a reputation as a brilliant paragrapher, humorist and writer of dialect while employed on newspapers at Macon, Ga.. New Orleans. La., Forsyth and Savannah. Ga.. and finally on the staff of the *Atlanta* (Ga.) *Constitution* for 24 years. In 1879 the "Tar-Baby Story" appeared in the *Atlanta Constitution* and created a vogue for a distinctive type of dialect literature. This and successive Uncle Remus stories won for Harris a secure place in American literature. The pattern was new: Uncle Remus. the wise, genial old Negro tells animal stories to the little boy, son of a plantation owner, and inter\\-eaves his philosophy of the world about him. Harris recorded the speech of the plantation Negro faithfully. Speaking through Uncle Remus. he captured not only what the Negro said. but how he said it—the poetic impulse, gift for narrative and condensation, humour and pictorial language. *Uncle Remus: His Songs and Sayings* was published in hook form in 1880, followed by *Nights With Uncle Remus* (1883), *Daddy Jake, the Runaway* (1889), *Uncle Remus and His Friends* (1892), *The Tar Baby* (1904), *Uncle Remus and Brer Rabbit* (1906) and other volumes of a similar type. Included in a series of children's books were: *Little Mr. Thimblefinger and His Queer Country* (1894), *The Story of Aaron* (1896) and *Aaron in the Wildwoods* (1897). *Mingo, and Other Sketches in Black and White* (1884), *Free Joe and Other Georgian Sketches* (1887), *Sister Jane, Her Friends and Acquaintances* (1896) and *Gabriel Tolliver* (1902) reveal Harris' ability to vitalize other southern types. *On the Plantation* (1892) is valuable because of its autobiographic nature. From 1907 until his death in Atlanta. on July 3, 1908, he edited *Uncle Remus's Magazine.*

Harris' works are arnong the finest examples of the "local colour" literature that flourished in the 1870s and 80s. With an unerring instinct fur dialect and a firm grasp of character. he depicted the vanishing plantation life with charm and sympathy.

HARRIS, JOHN (*c.* 1666–1719), English writer, best known as the editor of the *Lexicon technicum,* or *Dictionary of the Arts and Sciences* (1103), which is the earliest English encyclopaedia (*see* also ENCYCLOPAEDIA), and as the compiler of a *Collection of Voyages and Travels* (1705). Harris was a scholar of Trinity college, Oxford. and afterward took orders. In 1698, at St. Paul's cathedral, he delivered the seventh series oi the Boyle lectures—*Atheistical Objections Against the Being of God and His Attributes Fairly Considered and Fully Refuted.* Between 1702 and 1704 he gave st the Marine coffee house. Birchin lane, London. the mathematical lectures founded hy Sir Charles Cox. The friendship of Sir William Cowper, afterward lord chancellor, secured for him a series of church preferments. He showed himself an ardent supporter of the government and engaged in a bitter quarrel with the Rev. Charles Humphreys, afterward chaplain to Henry Sacheverell, who held him up to ridicule in *The Picture of a High-Flying Clergyman* (1716). Harris was one of the early members of the Royal society and for a time acted as vice-president. He died on Sept. 7, 1719.

HARRIS, ROY (1898–), U.S. composer who helped establish the distinctive features of the modern American school. He was born in Lincoln county. Okla.. on Feb. 12. 1898. His musical development came relatively late. After studying in California with Arthur Farwell, Arthur Bliss and others, he went to Paris in 1926 to study with Nadia Boulanger. His first significant work was a concerto for clarinet. piano and string quartet (1927). Returning to the U.S. in 1929, he accepted various teaching positions. and was also active as organizer of music festivals. In 1062 he was living in California.

Harris' works are marked by broad tonal melodies and asymmetrical rhythms. Some of his works reflect scenes of American life: *When Johnny Comes Marching Home,* a symphonic overture on a Civil War song (1935); *Folksong Symphony* with

chorus (1940); *Kentucky* **Spring** (1949). His Sixth Symphony (1944) bears the subtitle *Gettysburg Address*, its four movements inspired by Lincoln's ideals.

Of his seven symphonies, the best known is the third (1939), written in a single movement with contrasting sections of lyrical and dramatic nature. His Fifth Symphony (1943) has a vigorous proclamatory quality and his seventh, performed in 1952, shows his characteristic harmonic, melodic and rhythmic features to be further strengthened and developed.

In chamber music Harris follows classical models. He wrote three string quartets, a piano trio, a piano quintet and a string quintet. Particularly interesting is his third string quartet (1939) in the form of four preludes and fugues in modal harmony.

See N. Slonimsky, "Roy Harris," in ***The*** *Musical Quarterly*, Jan. 1947. (N. Sy.)

HARRIS, WILLIAM TORREY (1835–1909), U.S. educator, probably the most widely known public school educator and philosopher in the United States during the late 19th century, was born in North Killingley. Conn.. on Sept. 10, 1835. He attended Yale college and then worked as a teacher and later superintendent of schools in St. Louis. Mo. (1868–80). He served as U.S. commissioner of education from 1889 to 1906. As a practical school man, Harris was an effective administrator and innovator. He introduced into the curriculum such studies as art, music, science and manual arts, and he iavoured the professional study of education for teachers in training. He worked to extend the public high school and incorporated the kindergarten into the regular school system of St. Louis. As a philosopher and psychologist, Harris was conservative and synthetic rather than original, embracing German idealism, American transcendentalism. Christianity, phrenology and mental discipline. He lectured for several summers at the Concord School of Philosophy, but Hegelian idealism was retreating and Harris was not creative enough to stem the tide of Naturalism.

A prolific writer of several hundred philosophical and educational articles, Harris was also editor of the *Journal of Speculative Philosophy*, Appleton's International Education Series and Webster's *New International Dictionary*.

Harris died at I'rovidence, R.I., on Nov. 5, 1909.

See Kurt Leidecker, *Yankee Teacher* (1946). (R. F. Bs.)

HARRISBURG, capital city of Pennsylvania. U.S., and seat of Dauphin county, lies on the east bank of the Susquehanna river, 101 mi. W.N.W. of Philadelphia.

The population of the city proper was 79.697 in 1960; 69,544 in 1950; and 83.893 in 1940 by the federal census. Ringed by independent boroughs and townships. Harrisburg was unable to expand its boundaries, and the central city lost population. The national trend toward suburban living was aggravated in Harrisburg by slum clearance and public works projects that reduced housing in once thickly settled downtown sections. A truer picture of the community's growth is reflected in the population figures for the metropolitan area. The standard metropolitan statistical area comprising Dauphin and Cumberland counties had a population of 345.071 in 1960; 292,241 in 1950; and 252,219 in 1910.

Incorporated boroughs adjacent to the city include Steelton, Paxtang and Penbrook in Dauphin county; Camp Hill. Lemoyne, New Cumberland, Shiremanstown, West Fairview and Wormleysburg in Cumberland county. Other significant communities in the metropolitan area are Middletown, Hummelstown and Hershey in Dauphin county; and Mechanicsburg, Carlisle and Shippensburg in Cumberland county.

Located at the head of the Cumberland and Lebanon valleys and at the site of one of the best fords on the Susquehanna. the Harrisburg area has been a communications crossroads since Indian times. John Harris, an Englishman from Yorkshire, received a licence to trade with the Indians in 1705; and about 1715 he established a trading post on the site of Harrisburg and soon began to operate a ferry. The settlement. known as Harris' Ferry, grew and in 1785 when Dauphin county was created, a town mas laid out by John Harris. Jr., assisted by William Maclay, which for a time was called Louisbourg in honour of Louis XVI. This title was never widely used, being first set forth in commissions issued by the supreme executive council to justices of the peace for the town in 1786; the borough charter of 1791 used the name Harrisburg as did the city charter of 1860.

With the removal of the state capital to Harrisburg in 1812, it became a political and governmental centre as well as the hub of interior transportation. Among the notable political events in the city were the national tariff convention of 1827, the Buckshot War of 1838, and the first national Whig nominating convention in 1839, which named William Henry Harrison for U.S. president. In transportation. key events included the laying of the first lock in the famous Pennsylvania canal in 1827, the establishment of the first railroad in 1836, and the building in 1847 of the first link in the main line of the Pennsylvania railroad from Harrisburg to Pittsburgh.

Harrisburg's role as a governmental and communications centre made it the first major objective of the Confederate army when Gen. Robert E. Lee invaded Pennsylvania in June 1863. Confederate forces occupied Carlislc on June 27, and two days later a skirmish between Confederate and Union outposts was fought at a point about 3 mi. W. of Harrisburg in present Camp Hill. The invading forces then withdrew to concentrate at Gettysburg, where they were defeated in a three-day battle on July 1–3, 1863.

In the period aiter the Civil War. Harrisburg continued to be an important transportation centre and also enjoyed growing industrial development. Civic planning and improvement kept pace with 20th-century progress; and by mid-20th century the city had become the metropolis for an expanding group of industrial and residential suburbs.

Harrisburg has a diversified economy based upon manufacturing, transportation, wholesale and retail trade and governmental activities. The leading types of manufacture are steel and steel products, food products, airplane parts, clothing and shoes. Both the Reading and the Pennsylvania railroads maintain large freight classification yards. Many people in Harrisburg are employed by the stare government. while others work at the nearby Olmsted air force base at Middletown, the naval supply depot at Mechanicsburg, and the New Cumberland army general depot.

The city is dominated by the group of state capitol buildings, which occupy a 68-ac. park in the downtown section. The main capitoi. completed in 1906, was built to replace the first capitol which was completed in 1822 and destroyed by fire in 1697. The 272-ft. capitol dome, patterned after St. Peter's in Rome, is the most prominent feature of the Harrisburg landscape. The paintings, statuary and other decorative features of the capitol are justly famous. Eight other major buildings, including the Pennsylvania State museum, are in the capitol group.

Cultural facilities in the Harrisburg area are excellent and include a symphony orchestra, a community theatre, an art association, a historical society and the state library. Parks. golf courses and other recreational facilities are numerous in Harrisburg and vicinity. An outstanding scenic attraction is the five-mile-long parkway along the Susquehanna. (S. W. Hm.)

HARRISON, (THOMAS) ALEXANDER (1853–1930), U.S. painter. whose reputation rests primarily on his marine pictures, was born in Philadelphia, Pa., on Jan. 17, 1853, and studied at the Pennsylvania Academy of Fine Arts and the Ecole des Beaux Arts. Paris, where he went in 1873. Chafing under the restraints of the schools, he went into Brittany, and at Pont Aven and Concarneau turned his attention to marine painting and landscape. In 1882 he sent a figure piece to the Salon, a fisher boy on the beach. which he called "Châteaux en Espagne." This piece attracted much attention. He received many awards, including the Temple gold medal, Philadelphia (1887), first medal, Paris exhibition (1889) and medals in Munich, Brussels, Ghent, Vienna and elsewhere. Harrison died in Paris on Oct. 13, 1930.

Harrison's brother, (Lovell) Birge Harrison (1854–1929), was also a painter. He is identified especially with the Woodstock (N.Y.) art colony.

HARRISON, BENJAMIN (1833–1901), 23rd president of the United States, was born at North Bend, near Cincinnati, O., Aug. 20, 1833. His great-grandfather, Benjamin Harrison of Vir-

ginia, mas a signer of the Declaration of Independence and three times governor of Virginia (1781–84). His grandfather, William Henry Harrison (*q.v.*) (1773–1841), was the 9th president of the United States. His father, John Scott Harrison (1804–78), served as Whig congressman from the second Ohio district in the national house of representatives from *1853* to 1857.

Benjamin was born of his father's marriage to Elizabeth Irwin of Mercersburg, Pa., and was one of eight children by this marriage, only six of whom grew to maturity. He spent his youth on his father's farm at the junction of the Big Miami and Ohio rivers. He was prepared for college by private tutors, studied for three years at the Farmers' college in Walnut Hills near Cincinnati, and in *1852* graduated from Miami university at Oxford. O. He was a diligent student, leaning particularly to political science and history, and during his college life showed a marked talent for extemporaneous speaking. After graduation he devoted himself to the study of law and in *1854* was admitted to the Ohio bar.

At the age of *21,* Harrison moved from Ohio to Indianapolis, then a town of only *16.000* inhabitants but the fast-growing capital of Indiana. While engaged in building up his law practice he became active in the new Republican party and was elected city attorney of Indianapolis in *1857* and reporter of the supreme court of Indiana in *1860.* But both his legal and his political careers were interrupted by the Civil War. In *1862* he helped to recruit the 70th regiment of Indiana volunteers, becoming its colonel. For the next year and a half his regiment guarded railroads and engaged in minor skirmishes in Kentucky and Tennessee. It was then attached to Gen. William T. Sherman's command and participated in hard fighting in the Atlanta campaign. In recognition of his "ability and manifest energy and gallantry in command of a brigade" he was promoted to the brevet rank of brigadier general.

At the close of the Civil War, Harrison resumed the practice of law in Indianapolis. He also worked diligently to advance the interests of the Republican party, publicly castigating the Democratic party as the party of treason and supporting the program of the Radical Republicans toward the South. He opposed the Liberal Republican schism of *1872,* spoke out against the inflation advocated by the Greenback party (*q.v.*), and played a leading role in bringing about a peaceful solution of a strike in *1877* in Indianapolis. Becoming a candidate for the Republican nomination lor governor of Indiana in *1872* he failed of nomination, and when nominated in *1876* failed of election.

His energetic campaign for the governorship brought him national prominence. As chairman of the Indiana delegation to the Republican national convention in 1880 he swung his delegation to James A. Garfield (*q.v.*) and later campaigned for Garfield's election. In Jan. *1881* he was elected by the Indiana legislature as C.S. senator and chose to fulfill the duties of his new position rather than accept a cabinet post that was offered him. His influence with the White House waned after Garfield's assassination and his Indiana rival, Walter Q. Gresham (*q.v.*), was appointed to the cabinet of Pres. Chester A. Arthur (*q.v.*).

Senator Harrison favoured the merit system for federal appointments and supported the Pendleton act of *1883.* He served on committees dealing with military affairs, Indian affairs. transportation routes to the seaboard, foreign relations and territories. As chairman of the last-named committee he sponsored a hill establishing civil government in Alaska, worked to preserve and enlarge the national parks and took an active part in urging the admission of new states. Six states—North Dakota, South Dakota, Washington, Montana, Idaho and Wyoming—were later admitted during Harrison's term as president. He opposed President Cleveland's vetoes of pension bills, helped to enact the Interstate Commerce act in *1887* for the regulation of the nation's railroads, and throughout his senatorial term supported the protection principle in the tariff legislation of his party.

He failed of re-election by the Democratic state legislature in *1887* but became Indiana's "favourite son" for the Republican presidential nomination at the Chicago convention in the following year. Indiana's position as a doubtful state, the support of his devoted friends there and the endorsement of James G. Blaine (*q.v.*) gave him the nomination. In the ensuing election he defeated Cleveland, receiving *233* electoral votes to Cleveland's *168.*

Harrison's presidency (1889–93) was marked by new ventures in foreign policy and a deteriorating domestic situation. During his administration the United States participated in the first International Conference of American States (*see* PAN AMERICAN CONFERENCES) presided over by Secretary of State Blaine: was represented in the Berlin conference concerning the Samoan Islands; convoked an international monetary conference; concluded treaties of commercial reciprocity with many foreign countries; resolved peaceably a bitter controversy with Chile; and negotiated a convention for the arbitration of a troublesome dispute with Great Britain involving fur seals in the Bering sea. In domestic affairs enactment of the Sherman anti-trust act in 1890 was to have far-reaching results in the iuture. Of more immediate importance were the beneficial effects of the McKinley tariff bill on .American industry. but they were partly offset by the .inflationary results of the Sherman Silver Purchase act. The Democrats won a majority in the house of representatives in the election of 1890. The growing Populist discontent and the Homestead and other strikes that occurred after Harrison's renomination at the Minneapolis convention in *1892* largely accounted for his defeat for a second term by an electoral vote of *145* to *277* for Cleveland. (See also UNITED STATES (OF AMERICA) : History.)

After leaving the White House. Harrison returned to his law practice in Indianapolis. He contributed articles to magazines and wrote two books. This *Country* of *Ours (1397)* and *Views of an Ex-President* (1901). In 1898–99 he served as leading counsel for Venezuela in the arbitration of its boundary dispute with Great Britain at I'aris.

Harrison's outstanding traits displayed in his public career were his legal acumen. industry. high moral principles, devotion to duty and loyalty to the principles of the Republican party. As president he accepted the constitutional limitations of his office. Conceiving himself as the legal advocate of the American people he discharged his duties conscientiously and with dignity and ability but failed to provide magnetic leadership. After the war with Spain *11898)* he criticized the policy of denying full constitutional rights to the newly acquired territories.

Harrison was married twice. first in 1853 to Caroline Lavinia Scott. by whom he had a son and a daughter and who died in the White House in Oct. *1892.* and second to Mrs. Mary Scott Lord Dimmick in *1896,* by whom he had a daughter. He died at Indianapolis on blarch *13. 1901.*

BIBLIOGRAPHY.—Harry J. Sievers, S.J.. *Benjamin Harrison, Hoosier Warrior, 1833–1865* (1952) and *Benjamin Harrison, Hoosier Statesman; From the Civil War to the White House, 1865–1888 (19.59).* A campaign biography of Harrison was published in 1888 by Gen. Lew Wallace and another in 1892 by Col. Thomas W. Knox. The Harrison papers are in the Library of Congress, Washington, D.C. (D. M. D.)

HARRISON, FREDERIC (1831–1923), English jurist and man of letters, one of the founders of the Sociological society in London and a leader of the positivist movement in England. was horn in London on Oct. *18. 1831.* He was educated at King's college school. London. and at Wadham college. Oxford. where, after taking classical first-class honours in 1853, he became a fellow. In 1855 in I'aris he talked with Auguste Comte and became a devoted follower of his thought and writings.

Harrison was called to the bar in 1858 and practised in equity. His interest in the betterment of the workers led to his appointment on the Royal Commission on Trade Unions. 1867–69, and through its reports he had a paramount influence on the shape of trade union law between *1868* and 1906. In *1369* he was secretary to the Royal Commission for Digesting the Law. From 1877 to 1889 he was professor of jurisprudence and international law under the Council of Legal Education. In 1889 he became an alderman of the newly formed London County council, resigning in 1893.

Harrison's life may best be understood. however, as an attempt to introduce the sociology of Auguste Comte into England. As president of the English Positivist committee from 1880 to 1905, he lectured and wrote extensively on these principles and on the religion of humanity. *The Positivist Review* carried his views beyond the audience of Newton hall, the London centre of the English positivists. In addition to this work he also took an active

part with Sir Patrick Geddes in the foundation of the Sociological society (later: the Institute of Sociology) in 1903; this society attempted to combine the philosophical and historical approach oi Comte with that of the practical held enquiry into social problems.

In mid-life he virtually retired from political life and legal practice to devote himself to writing. From 1900 onward books and essays flowed from his pen; he wrote on famous men, on history, on morals and on religion. as well as on the political issues of the day. He died at Bath. Somerset, on Jan. 14, 1923.

Harrison's principal works include *Oliver Cromwell* (1888); *Humanity: Religious Systems of the World* (1890); *Positivism: Its Position, Aims and Ideals* (1901); *Ruskin* (1902); *The Creed of a Layman* (1907); *National and Social Problems* (1908); *Autobiographical Memoirs,* 2 vol. (1911); *Tlze Positive Evolution of Religion: Its Moral and Social Reaction*(1913)

See Austin Harrison, *Frederic Harrison* (1927). (J. My.)

HARRISON, JANE ELLEN (1850–1928), English classical scholar whose view of the ritualistic origin of mythology has been endorsed by modern anthropologists. was horn at Cottingham, I'orkshire. Sept. 9, 1850. Overcoming the obstacles of a conventional upbringing, she went to Newnham college, Cambridge. to read classics. later studying Greek archaeology and art at London and Athens, and becoming a lecturer in Greek at Newnham. 1898-1914, and in Russian. which she learned during World War I, 191;-22. She died in London. April 15, 1928.

The Mythology and Monuments of Ancient Athens (1890) had won her recognition as a scholar, but her chief work is *Prolegomena to the Study of Greek Religion* (1903), which altered the approach to the subject. In it she investigated the actual ritual of Greek festivals. to discover what underlay the Olympic theogony. In *Themis* (1912) h e went further, using evidence from anthropology to illuminate the whole field of Greek religion. Her *Epilegomena* (1921) also considered modern religion in the light oi psychology.

BIBLIOGRAPHY.—J. E. Harrison, *Reminiscences of a Student's Life* (1925); Gilbert A. Murray, J. E. *Harrison* (1928); D. P. Svyatopolk-Mirsky, J. E. *Harrison and Russia* (1930); J. G. Stewart, J. E. *Harrison* (1959).

HARRISON, JOHN (1693–1776), British horologist, the inventor oi the hrst practical marine chronometer, was born at Foulby, near Pontefract. Yorkshire. He lived at Barrow-upon-Humber. Lincolnshire, from 1700 to 1736, when he settled permanently in London.

In 1714 the British government offered an award of £20,000 for a timekeeper which would enable longitude to be determined within an accuracy of half a degree at the end of a voyage to the West Indies. Harrison set himself to solve this difficult problem and by 1; 59 had constructed a large watch. In this. compensation lor the change of stiffness of the balance spring with temperature change, which affects the rate of the watch. was achieved with the aid of a bimetallic strip, the two metals enabling the effective length of the strip to vary. Harrison's expectations of accuracy were realized, for when tested at sea in 1761–62 his watch erred by only five seconds on arrival in Jamaica. corresponding to an error in longitude of only $1\frac{1}{4}'$. Harrison claimed the award of £20,000, but though he occasionally received sums on account it was not until 1773 that he was paid in full.

Earlier in his career Harrison made two other important inventions, since widely applied: his "gridiron" pendulum, devised about 1726, whose effective length does not vary with temperature. and a simple device which keeps a clock going while it is being wound up and the normal weight or spring drive is not in operation. He died in London on March 24. 1776.

See R. T. Gould, *The Marine Chronometer* (1923). (F. A. . W.)

HARRISON, ROSS GRANVILLE (1870–1959), U.S. biologist, was the first to employ tissue culture methods. In one important experiment he demonstrated the outgrowth of nerve fibers in culture medium thereby providing the foundation for modern nerve physiology and neurology. He also performed early experimental studies of embryological asymmetry. He was born in Germantown, Pa.. and after receiving his schooling in that area went to the Johns Hopkins university where he took his baccalaureate degree and began his zoological studies. He completed his nork for the degree of doctor of philosophy under the guidance of A'. K. Brooks. After teaching at Bryn Mawr college. he returned to the Johns Hopkins medical school where he taught anatomy. He went to Bonn where he worked with Moritz Nussbaum and took his degree in medicine in 1899. He came to Yale in 1907 and assumed the headship of the department of zoology which he held until his retirement in 1938.

Using amphibian material he was able to show that the three axes oi the limb become fixed at different times in development. During embryonic development, when material which normally would form a left limb is moved to the animal's right side but turned upside down, it will develop a right limb. From this and other experiments, Harrison was able to formulate the rules for the development of asymmetry which hold for all the vertebrate forms so far tested. The same material also provided the information that the middle germ layer is predominantly responsible for the formation of the limbs.

Upon retirement in 1938, Harrison became chairman of the National Research council, a position which he held throughout World War II. In association with Frank B. Jewett, then president of the National Academy of Sciences, the council and the academy were combined in essential services to the country. Harrison's work in administration was characterized by the extreme deliberation and logical analysis which he employed in his scientific approach. (J. S. Ns.)

HARRISON, THOMAS (1606–1660), English parliamentarian. a native of Newcastle-under-Lyme, Staffordshire, the son of a butcher and mayor of that town, enlisted in 1642 in Essex's lifeguards. became major in Fleetwood's regiment of horse under the earl of Manchester, was present at Marston Moor, at Naseby, Langport and at the taking of Winchester and Basing. as well as at the siege of Oxford. In 1646he was returned to parliament for Wendover, and served in Ireland in 1647 under Lord Lisle, returning to England in May, when he took the side of the army in the dispute with the parliament and obtained irom Fairiax a regiment of horse. In November he opposed the negotiations with the king, whom he styled "a man of blood" to be called to account, and he declaimed against the House of Lords. At the surprise of Lambert's quarters at Appleby on July 18.1648, in the second civil war, he was severely wounded. He showed a special zeal in bringing about the trial of the king. Charles was entrusted to his care on being brought up from Hurst Castle to London. Harrison was assiduous in his attendance at the trial, and signed the death-warrant. He took part in suppressing the royalist rising in the midlands in May 1649, and in July was appointed to the chief command in South Wales, where he is said to have exercised his powers with exceptional severity. On Feb. 20, 1651, he became a member of the council of state, and during Cromwell's absence in Scotland held the supreme military command in England. He failed to stop the march of the royalists into England at Knutsford on Aug. 16, 1651, but after the battle of Worcester he pursued the fugitives. Later he pressed on Cromwell the necessity of dismissing the Long Parliament, and it was he who at Cromwell's bidding, on April 20, 1653, laid hands on Speaker Lenthall and compelled him to vacate the chair. He was president of the council of thirteen which now exercised authority. Harrison belonged to the faction of Fifth Monarchy men, whose political ideals were entirely destroyed by Cromwell's assumption of the protectorate. He was deprived of his commission on Dec. 22, 1653, and on Feb. 3, 1654, was ordered to confine himself to his father's house in Staffordshire. He was imprisoned for a short time-in September, and on Feb. 1;, 1655, he was imprisoned in Carisbrooke Castie, being liberated in March 1656. At the Restoration, Harrison, who was excepted from the Act of Indemnity, refused to take any steps to save his life. to give any undertaking not to conspire against the government or to flee. He was arrested in Staffordshire in May 1660, and executed at Charing Cross on Oct. 13, 1660.

Richard Baxter. who was acquainted with him. describes Harrison as "a man of excellent natural parts for affection and oratory. but not well seen in the principles of his religion; of a sanguine complexion. naturally of such a vivacity, hilarity and

alacrity as another man hath when he hath drunken a cup too much, but naturally also so far from humble thoughts of himself that it was his ruin." Cromwell also complained of his excessive eagerness. "Harrison is an honest man and aims at good things, yet from the impatience of his spirit will not wait the Lord's leisure but hurries me on to that which he and all honest men will have cause to repent."

See C. H. Simpkinson, ***Life*** of ***Harrison*** (1905).

HARRISON, WILLIAM (1534-1593), English topographer and social historian, whose valuable and entertaining *Description of England* forms an important part of *The Chronicles of England* . . . of Raphael Holinshed (*q.v.*), was born, by his own account. in London on April 18. 1534. He was inducted early in 1559 to the rectory of Radwinter, Essex. on the presentation of Sir William Brooke. Lord Cobham, to whom he had formerly acted as chaplain; and from 1571 to 1581 he held the living of Wimbish in the same county. He became canon of Windsor in 1586, and died there in 1593.

His *Description of England* was undertaken for the queen's printer. Reginald Rolfe. who designed the publication of "an universall cosmographie of the whole world . . . with particular histories of every knowne nation." After Wolfe's death in 1576, this comprehensive plan was reduced to descriptions and histories of England, Scotland and Ireland. The historical section was to be supplied by Holinshed. the topographical by Harrison. The work was published in 1577 as *The Chronicles of England, Scotland and Ireland* . . . by Raphael Holinshed and others. Harrison's final share consisted of one book of topographical description of the island of Britain. two books of description of England's institutions and a translation from the Scots of John Bellenden's version of Hector Boece's Latin description of Scotland.

The *Description of England* is an exhaustive survey of the political, religious and social condition of Elizabethan England. Although Harrison was ill-qualified as a topographer, his insatiable spirit of inquiry enabled him to produce a vivid and detailed portrait of his countrymen and their institutions. His work throws particular light on the economic changes and consequent social upheavals of his time. His famous contemptuous account of "how gentlemen are made in England" reveals how rapidly the redistribution of wealth was altering the traditional structures of society. Harrison wrote in a voluhle and homely style; he apologized that his "foule frizeled treatise" was "scrambled up." but its very lack of literary polish enahles it to reflect not only current colloquial speech but also the pronounced individuality of its author.

The second and third hooks of Harrison's *Description of England* were edited by F. J. Furnivall for the New Shakespere society, with extracts from his unpublished "Chronologie" from the creation to Feb. 1593 and also from other contemporary writers. as *Shakespere's England* (4 vol., 1877-1908).

HARRISON, WILLIAM HENRY (1773-1841), 9th president of the United States. was born at the plantation of Berkeley in Charles City county. Va., on Feb. 9, 1773, the third son of Benjamin Harrison. His father. long prominent in Virginia politics. served his state in a number of capacities: as a member of the Virginia house of burgesses; as a delegate to the Continental Congress (1774–77); as a signer of the Declaration of Independence; and as governor of Virginia (1781–84). William Henry Harrison attended Hampden-Sidney college from 1787 to 1790, and later enrolled at the College of Physicians and Surgeons in Philadelphia. He withdrew in 1791 to enter the army as an ensign in the First Regiment at Ft. Washington, Cincinnati. Promoted to lieutenant the following year, he later acted as aide-de-camp to Gen. Anthony Wayne (*q.v.*) in the campaign against the Indians that ended in the battle of Fallen Timbers on Aug. 20. 1794. In 1797 Harrison received his captaincy but elected to resign his commission the next year. Soon afterward he was inade secretary oi the northwest territory. In 1799 the Jeffersonian party there sent him to congress as territorial delegate.

In May, 1800. Pres. John Adams appointed Harriron governor of the newly created Indiana territory. Sworn into office on Jan. 10. 1801. he served as governor until Sept. 1812. In 1803 he became a special commissioner to the Indians and in this role negotiated a number of treaties that opened new areas of land to white settlement. Greatly dissatisfied with these treaties. the Indians. led by Tecumseh (*q.v.*) and his brother. "The Prophet." and undoubtedly encouraged by the British, began the hostilities that terminated at the Tippecanoe river on Kov. 7. 1811. Here. Harrison, leading a force of regulars and militia, won the victory that not only established his military reputation but also gained for him the national prestige which made possible, in part, his subsequent election to the presidency.

When war broke out with Great Britain in the summer of 1812, Harrison was appointed a major general in the Kentucky militia. A few weeks later he was made a brigadier general in the regular army of the United States and placed in command of all the troops in the northwest. On Oct. 5. 1813. after reoccupying American territory previously surrendered to the enemy. troops under his command defeated the British at the battle of the Thames. *(See* WAR OF 1812.)

Harrison resigned his commission in 1814 and shortly afterward was appointed to negotiate a second treaty of Greenville with the Indians (July 22. 1814). Settling at this time in Ohio, Harrison quickly became important in the politics of his adopted state. He served in congress from 1816 to 1819 and in the Ohio senate from 1819 to 1821. From 1825 to 1828 he served in the U.S. senate. In 1828 he was appointed the first U.S. minister to Colombia. but retained this position for less than a year. For the next several years he lived in semiretirement at Korth Bend. Ohio.

Early in 1835 Harrison began to receive favourable mention as a candidate for president on the Whig ticket and was later "nominated" at large public meetings in Pennsylvania. New York and Maryland. In the election of 1836 he led the candidates running against Martin Van Buren (*q.v.*), but received only 73 electoral votes. while the "Little Magician" won 170 electoral votes. Harrison's military record and his noncommittal political views made him the most "available" candidate for the Rhig party nomination in the election of 1840. He received the Whig nomination at the party's convention in Harrisburg. Pa., in Dec. 1839. Largely to attract the votes of discontented and anti-Jacksonian Democrats, the Whigs nominated John Tyler, lately identified with the Democrats. for the vice-presidency. The campaign of 1840 was notable for the use of campaign songs, political slogans and party insignia. When the Democrats derisively referred to Harrison as the "log cabin and hard cider" candidate. the Whigs quickly adopted miniature log cabins and cider jugs as their major identifying symbols. The cry of "Tippecanoe and Tyler too!!" echoed throughout the land. In the November election Harrison overwhelmingly deieated his Democratic opponent, receiving 234 electoral votes to Van Buren's 60.

William Henry Harrison took his oath of office on March 4. 1841, and delivered a long inaugural address for the occasion. One month later. on April 4. 1841. he died, the first president to die in office. Vice-president John Tyler (*q.v.*) succeeded him. It is generally agreed that Harrison died of pneumonia. but his illness was complicated by the excitement and fatigue brought on by the innumerable demands of office seekers n-ho plagued him incessantly. His body was permanently interred at North Bend, O.

In 1795 Harrison married Anna Syinmes (1775–1864), daughter of John Cleves Symmes. Their grandson. Benjamin Harrison (*q.v.*), became the 23rd president of the United States (1889-93). *See* also UNITED STATES (OF AMERICA): *History.*

Harrison* (1824); Dorothy Burne Goebel, *William Henry Harrison: A Political Biography (1926)*; Freeman Cleaves, *Old Tippecanoe: William Henry Harrison and his Time* (1919); James A. Green, *William Henry Harrison: His Life and Times* (1941). Several campaign biographies were written by Richard Hildreth (1839), Caleb Cushing (1840), Isaac Jackson (1840) and Samuel Burr (1810). (M. M. Ro.)

HARRIS TWEED, a distinctive cloth originally handspun, warped, woven and finished by the inhabitants of Lewis-and-Harris. North and South Uist, Barra and other islands of the Outer Hebrides off the northwest coast oi Scotland, from the virgin fleece of native sheep.

Harris tweeds are relatively coarse and open in appearance but strongly characterized by a soft texture with excellent tailoring and wearing properties. Because of the steady increase in demand, most of them are now made from machine-spun yarns. Cloths spun and woven on the islands have an unmistakably peaty odour. The superiority claimed for the homespun and woven cloth is attributed to the incorporation of longer fibres in the yarn as compared with the shorter fibred machine-spun yarn employing more twist. The Harris tweed industry has been affected by the competition from cheaper imitation cloths manufactured on the mainland, in Europe and in the far east. These may be made from wool-cotton or wool-shoddy blends containing other fibres.

Two organizations—the Harris Tweed Association Ltd. and Independent Harris Tweed Producers Ltd.—watch over the interests of the trade. The first controls the "orb" mark. while the second employs arms that form the basic design for hanging tickets and woven labels. Both marks are affixed only to tweeds handwoven in the Outer Hebrides. (A. DR.)

HARROGATE, a municipal borough (1884) in the Harrogate parliamentary division of the West Riding of Yorkshire. Eng., 15½ mi. N. of Leeds and 21½ mi. W. of York by road. Pop. (1961) 56,332. It stands about 400 ft. above sea level, on the Pennine foothills. Harrogate is the principal inland watering place in the north of England, containing 88 known mineral springs. It owes its rise and development, which started in the 17th century (the Queen hotel was built in 1687), to the presence of these chalybeate and sulphur springs. There is some light industry but the chief employment is catering for visitors to the spa, delegates to conferences and tourists to the moorlands and dales of Yorkshire and to Knaresborough, Fountains abbey. Bolton abbey, etc. Harrogate consisted of two scattered townships. now united—Low Harrogate and High Harrogate. A common, the Stray. secured by act of parliament from ever being built upon, covers 200 ac in front of the main lines of houses. The chief of the many beautifully laid-out gardens is the Valley gardens (17½ ac.) adjoining the Royal Pump room (1842). There were 540 ac. of open spaces by the latter 1950s. At Harlow Car are the Northern Horticultural Trial grounds.

There were "holy wells" in Harrogate from early times, the best-known being that of St. Mungo. There are five main chalybeate springs: Tewit well, discovered in 1571 by William Slingsby and called the "English Spaw" by Timothy Bright; the Royal chalybeate spa or John's nell, discovered in 1631; Muspratt's chalybeate spring or the Chloride of Iron nell, discovered in 1819; Kissingen (Royal Baths Iron) wells; and the Pure Chalybeate spring. The chief sulphur springs are the Old Sulphur well, discovered about 1656; the Magnesia well; and the Montpellier or Royal Baths wells, the chief of which was discovered in 1822 on the grounds of the Crown hotel. The first account of the Harrogate springs was written by Edmund Deane of York in 1626 and called *Spadacrene Anglica or the English Spaw Fountain.* The Royal baths (1897, greatly extended in 1939) are owned by the corporation and are on the site of the old Victoria baths. The municipal offices were built in 1930 on the site of the new Victoria baths. The spa is equipped with apparatus for thermal, electrical and other kinds of treatment to supplement hydrological treatment. Harrogate also contains the Royal hall, opened in 1903, and the Royal Bath hospital. founded in 1824.

HARROW, a municipal borough (1954) in Middlesex. Eng., 11 mi. N.W. of Hyde Park corner, London, by road. Pop. (1961) 208.963. It includes Harrow-on-the-Hill. Wealdstone Pinner, Hatch End, Harrow Weald. Stanmore and parts of Edguare. Harrow-on-the-Hill, which stands on an isolated hill cap of Bagshot sands and gravels resting on the London Clay. rises to 408 ft. On the summit is the church of St. Mary, founded by Lanfranc, archbishop of Canterbury, and containing Norman work. Harrow is first mentioned in 7b7 and at Wealdstone is a moated house, a residence of the archbishops of Canterbury until 1545. Though a great extension of Harrow as a residential suburb of London has taken place north of the hill, the borough retains more than 1,100 ac. of open spaces which include Stanmore and Harrow Weald commons. Grim's dike runs across the northwest of the borough. There are photographic, optical. glass and printing works. The borough returns three members to parliament.

Harrow School.—The school was founded in 1571 by John Lyon (d. 1592). whose brass is in the church. A yeoman of the neighbouring village of Preston, he had yearly during his life set aside 20 marks for the education of poor children of Harrow. The charter was granted by Elizabeth I in 1571 and the statutes drawn up by Lyon in 1590, but it was not till 1611 that the first building was opened. In about 1660 the headmaster began to receive "foreigners," *i.e.,* boys from other parishes, who were to pay for their education. Control was originally vested in six persons of standing in the parish. but under the Public Schools act of 1868 the governing body consists of six members nho are elected respectively by the lord chancellor, the universities of Oxford, Cambridge and London, the Royal society and the assistant masters of the school. The principal buildings are of the 19th century but the fourth form room dates from 1611 and on its panels are cut the names of many eminent alumni among whom are Robert Peel, H. J. Temple (Lord Palmerston), R. B. Sheridan, Lord Byron and Henry Cardinal Manning. Other famous pupils include Lord Rodney, Anthony Trollope, Lord Shaftesbury and Sir Winston S. Churchill. The Vaughan library. named after the distinguished headmaster C. J. Vaughan (1844–59), was built by Sir George Gilbert Scott who also built the chapel. The war memorial building, near the chapel, is the nork of Sir Herbert Baker. Some features peculiar to the school are the Harrow songs illustrating its history and traditions; the ceremony of Bill (roll call) in the schoolyard; Harrow football, specially adapted to the heavy clay soil; and the Harrow hats, of straw uith shallow crowns and broad brims, worn all the year round. The Eton and Harrow cricket match takes place yearly at Lord's Cricket ground in London.

HARROWBY, DUDLEY RYDER, 1ST EARL OF (1762–1847), English statesman, was unobtrusively in office for most of the first quarter of the 19th century. The eldest son of Nathaniel Ryder, 1st Baron Harrowby, he was born on Dec. 22, 1762. and educated at St. John's college. Cambridge. Entering parliament in 1784, he held various minor offices: undersecretary for foreign affairs (1789–90); member of the India Board (1790); paymaster general (1791–1800); vice-president of the board of trade (1790–1801); treasurer of the navy (1800–01). He succeeded his father as 2nd Baron Harrow-by in 1803 and joined the Younger Pitt's second ministry in 1804 as foreign secretary. An accident compelled him to resign in 1805, but later in the year Pitt appointed him chancellor of the duchy of Lancaster. In the duke of Portland's ministry he was president of the board of control (July–Nov. 1809), and given an earldom and was subsequently in the cabinet without portfolio (1809–12). Like Lord Liverpool, under whom he served (1812–27) as lord president of the council, he was one of the least ambitious of politicians; three times he refused an offer of the premiership and never again held office after Aug. 1827. It was at Harrowby's London house that the cabinet was to have been assassinated by the Cato Street conspirators in Feb. 1820 (*see* THISTLEWOOD, ARTHUR). He died on Dec. 26, 1847. (A. AL.)

HARRY (OR HENRY) THE MINSTREL (BLIND HARRY) (fl. 1470–1495), author of the Scottish historical romance *The Actis and Deidis of the Illustere and Vailyeand Campioun Schir William Wallace Knicht of Ellerslie.* He has been traditionally identified with the Blind Harry named among the poets in William Dunbar's *Timor mortis conturbat me* and among recipients of the royal bounty in the treasurer's accounts for 1490–92. and with the blind minstrel described in John Major's famous *Hzstory* as a gatherer and itinerant reciter of legends about Wallace. He was no mere beggarly rhymer: his work shows his acquaintance with the poetry of John Barbour and Chaucer, and with Scots, Latin and French chronicles. He imitates Barbour's claim to historicity, citing as his main authority a Latin life of Wallace by Wallace's comrade-in-arms. John Blair; but Blair and his book have not been identified, and may be literary fictions.

The *Wallace,* ahich runs to 11 books and nearly 12,000 lines in decasyllabic couplets, is a historical novel in verse, fabricated from the events of the War of Independence, a mass of popular

legend about Wallace and earlier romances. It is not improbable that the poem in its present form is an edited and improved version of a series of *gestis* on the hero's exploits, gathered up by the minstrel into his repertoire; and the improver may have been John Ramsay, the Perth scribe who wrote the one surviving manuscript and also transcribed Barbour's *Bruce*. Judged simply as a romance, the *Wallace* is inferior to the *Bruce* in arrangement and literary finish. It has, however, great energy and patriotic spirit and its author is readier than Barbour both with tears and a rather grim laughter.

On external evidence the *Wallace* may be dated between *1474* and *1479;* the manuscript in the National Library of Scotland is dated *1488.* There seems to have been an edition printed at Edinburgh by W. Chepman and A. Myllar about *1508;* but the earliest surviving edition was printed by R. Lekprevik for Henry Charteris in 1570 Reprints are numerous. The poem was modernized by William Hamilton of Gilbertfield in *1722—the* version which provoked so much patriotic fervour in Burns. The first critical edition is J. Jamieson's *(1820);* the standard edition is by J. Moir for the Scottish Text society, *3* vol. *(1885-89).*

Kinsley, in *Scottish Poetry: A Critical Survey* (1955); M. P. McDiarmid, "The Date of the *Wallace,*" in *Scottish Historical Review,* vol. xxxiv (1955); A. M. Kinghorn, "Romantic History and Poetry in Mediaeval Scotland," in *Dalhousie Review* (1956). (J. Ky.)

HARSDÖRFER, GEORG PHILIPP *(1607–1658),* German poet, who, with Johann Klaj, founded in Niirnberg in *1644* the literary society of the *Pegnitzschäfer* ("Pegnitz Shepherds"), for the purification of the German language. He was born in Niirnberg, Nov. *1, 1607,* and died there, Sept. *22,* 1658. His best-known works are his *Frauenzimmer-gesprächspiele, 8* vol. *(1641-49).* a collection of entertaining anecdotes, and his *Poetischer Trichter, 3* vol. (1647–53), a treatise on poetry written in an euphuistic style. He also wrote religious and secular lyrics, numerous collections of stories and a novel, *Dianea (1634).* There is a selection of his poems in *Bibliothek deutscher Dichter des 17 Jahrhunderts,* vol. ix *(1826),* ed. by W. Müller.

BIBLIOGRAPHY.—J. Tittmann, *Die Nürnberger Dichterschule* (1847); A. Krapp, *Die asthetischen Tendenzen Harsdörffers* (1903); *W.* Kayser, *Die Klangmalerei bei Harsdörffer* (1932).

HARSHA (HARSHAVARDHANA) (reigned A.D. 606–647), emperor of northern India. Son of Prabhakaravardhana, king of Sthanvisvara (Thanesar, Punjab), he came to the throne at the age of *16,* after the assassination of his elder brother. Rajyavardhana. His accession occurred in the midst of a great war, in which the king of Magadha and Malwa and Sasanka, king of Bengal. were attacking Grahavarman, the Maukhari king of Kannauj with whom Harsha's line had a matrimonial alliance. Grahavarman was killed, and. as he left no heirs, Harsha became king of Kannauj, which was henceforth the capital of his empire.

For some years the young king waged war in many parts of India and succeeded in bringing most of the north under his hegemony. He appears to have made no attempt at building a centralized empire but ruled according to the traditional pattern, leaving conquered kings on their thrones and contenting himself with tribute and homage. His influence extended from Gujarat to Assam, but the area directly under his control probably comprised no more than the modern Uttar Pradesh, with parts of Punjab and Rajasthan. He attempted to conquer the Deccan (c. 620), but was driven back to the Narmada river by the Chalukya emperor Pulakesin II.

Harsha is known mainly through the works of Bana, whose *Harshaclzarita* describes his early career in flowery language, and of the Chinese pilgrim Hsuan Tsang (*q.v.*), who became a personal friend of the king. The pilgrim depicts Harsha as a convinced Buddhist, though in the earlier part of his reign he appears chiefly to have supported orthodox Hinduism. Hsuan Tsang describes Harsha as a model ruler, benevolent, energetic and just, and praises the efficiency and mildness of his administration and the prosperity of his empire.

In the pattern of Indian history Harsha's reign seems to mark a transition from the ancient to the medieval period, when decentralized regional empires continually struggled for hegemony. (*See* INDIA: *History.*) Like many other Indian kings, Harsha was a patron of literature and the arts and was himself an author. Three Sanskrit dramas attributed to his pen have survived. *See* SANSKRIT LANGUAGE AND LITERATURE.

HART, ALBERT BUSHNELL *(1854-1943),* U.S. historian, who was the author. joint author or editor of about *100* volumes. was born at Clarksville, Pa., on July 1, *1854.* He graduated from Harvard college in *1880,* and studied in Europe at Paris, Berlin and Freiburg. After receiving a Ph.D. at Freiburg in *1883,* Hart taught at Harvard. where he was professor of history. 1897–*1910,* and of government, 1910–26. He edited the "American Nation" series. published in *28* volumes, *1904-18,* for which he wrote *Slavery and Abolition (1906)* and *National Ideals Historically Tvaced (1907).*

Of particular note are his studies of U.S. foreign policy: *The Monroe Doctrine: an Interpretation (1917),* and *The Foundations of American Foreign Policy (1901).* In addition, he wrote several biographies, among them *Salmon Portland Chase (1899). Abraham Lincoln (1914)* and *George Washington (1927).* Hart also edited numerous collections of documents giving contemporary data on historical events; they include *American History told by Contemporaries,* 5 vol. *(1897-1929);* *American Patriots and Statesmen from Washington to Lincoln, Revealed in . . . Letters, Addresses, State Papers, 5* vol. *(1916);* and *Source Book of American History (1899,* frequently revised). These, along with his *Introduction to the Study of Federal Government* (1891), were widely used as college texts, as was *Formation of the Union, 1750–1829 (1892).* Beginning in *1925* Hart edited the *American Year Book.* He participated in numerous studies and committees on reform in government and was historian from *1926* of the U.S. commission for the celebration *(1932)* of the *200th* anniversary of the birth of George Washington. He served as president of the American Historical association *(1909)* and of the American Political Science association *(1912).* He died June *16, 1943.*

HART, CHARLES (d. 1683), English actor, grandson of Shakespeare's sister Joan, is first heard of as playing women's parts at Blackfriars theatre, London, as an apprentice of the actor Richard Robinson. In the Civil War he was a lieutenant of horse in Prince Rupert's regiment, and after the king's defeat he played surreptitiously at the Cockpit and at Holland House and other noblemen's residences. After the Restoration he is known to have been in *1660* the original Dorante in *The Mistaken Beauty,* adapted from Corneille's *Le Menteur.* In *1663* he went to the Theatre Royal in Thomas Killigrew's company, with which he remained until *1682,* taking leading parts in plays by Dryden, Jonson, Beaumont and Fletcher. He is highly spoken of by contemporaries in such Shakespearean parts as Othello and Brutus. He is often mentioned by Samuel Pepys. Thomas Betterton praised him, and would not himself play the part of Hotspur until after Hart's retirement. Hart is said to have been the first lover of Nell Gwyn (*q.v.*) and to have trained her for the stage. He died at Stanmore, Middlesex, in Aug. *1683.*

HART, HEINRICH *(1855-1906)* and **JULIUS** *(1859–1930),* brothers, who collaborated in critical work leading to the development of naturalism in German literature. Heinrich was born on Dec. *30, 1855,* in Wesel, studied history, philosophy and modern languages at the universities of Halle, Munich and Münster, and died at Tecklenburg, Westphalia, on June *11, 1906.* His brother Julius was born at Miinster on April *9, 1859,* studied law at the university of Berlin, and died in Berlin on July *7, 1930.* Heinrich, in collaboration with his brother, edited a number of short-lived periodicals *(Deutsche Monatsblätter, 1878 et seq., Deutscher Literatur-Kalender,* 1879–82), which were followed by his *Kritisclze Waffengänge (1882-84).* The publication of this last periodical created a sensation and started the new literary

movement of naturalism. Gerhart Hauptmann and Arno Holz. in particular, were indebted to the Harts' critical work. The brothers had poems published in *Moderne Dichtercharaktere,* an anthology of lyrical poetry introducing social themes which was published by W. Arent in 1884. Later both brothers were active as theatre critics. but after the death of Heinrich. Julius opposed the literary trends he had helped to initiate and adopted a pantheistic philosophy.

See L. H. Wolf, *Die Kritische Waffengänge der Brüder Hart* (1922); K. Tillmann, *Die Zeitschriften der Gebrüder Hart* (1923).

(W. I. L.)

HART, MOSS (1904-61). playwright and stage director whose own life was a rags-to-riches drama. was born Oct. 24, 1904, in a New York city tenement. At the age of 17 he obtained a job as office boy for the theatrical producer Augustus Pitou. He wrote his first play at 18, and the critics found in it approximately that degree of maturity. He then worked as director of amateur theatre groups. spending his summers as entertainment director of vacation resorts in the Catskills that were known to the theatrical world as "the borscht circuit." In 1929 he wrote the first draft of *Once in a Lifetime,* a satire on Hollywood that became a hit the following year after its exuberant humor had been tempered by the sardonic skill of George S. Kaufman. He then wrote books for musicals for Irving Berlin and Cole Porter, but until 1941 he continued his collaboration with Kaufman. a collaboration that produced such popular comedies as *You Can't Take It With You* and *The Man Who Came to Dinner.* His affinity for success continued with his musical play *Lady in the Dark,* which he himself directed in 1941. Among the plays he directed was *My Fair Lady.* In 1959 he published *Act One,* the story of his theatrical apprenticeship. He died at Palm Springs, Calif.. Dec. 20, 1961. (J. Ay.)

HART, ERNEST ABRAHAM (1835–1898), English medical journalist. was born in London on June 26, 1835. Beginning on the *Lancet* in 1857, he was made editor of the *British Medical Journal* in 1866. He took a leading part in the exposures which led to the reform of the treatment of sick poor throughout England, and the Infant Life Protection act of 1872, aimed at the evils of baby farming, was largely the result of his efforts. The record of his public work covers nearly the whole field of sanitary legislation during the last 30 years of his life: the amendments of the Public Health and of the Medical acts, the measures relating to notification of infectious disease and to vaccination and the improvement of factory legislation, etc. From 1872 to 1897 he was chairman of the parliamentary bill committee of the British Medical association. Hart died on Jan. 7, 1898.

See Alienist and Neurologist, vol. xiv, pp. 488–493 (1893).

HART, SIR ROBERT, 1ST BARONET (1835–1911), who developed the imperial maritime customs service of China to its full stature, was born at Portadown. County Armagh, Ire., on Feb. 20, 1835. He graduated from Queen's college, Belfast, in 1853 and became a student interpreter in the consular service in China. In 1863 he succeeded H. N. Lay as inspector general of the customs. He founded the postal service that later passed to French control.

Hart was unique as an organizer, a diplomat and the confidant of both Chinese and foreign governments. In three serious crises (one in 1875 and two in 1885) Hart's skillful mediation restored peace. His loyalty to China was strikingly shown in his book, *These From the Land of Sinim* (1901), a scathing criticism of foreign dealings with China; he wrote it when a refugee in the British legation after the Boxers had burned down his house.

He was despotic; he had his favourites (nicknamed "the Royal Family"); but his appointments were always sound. Toward the end his influence declined with the Chinese government, which created the department of customs over his head in 1906. Hart showed no resentment, but in 1908 went home and remained nominally on leave until his death at Great Marlow, Buckinghamshire, Sept. 20, 1911. He was created baronet in 1893.

See Juliet Bredon, *Sir Robert Hart* (1909); S. F. Wright, *Hart and the Chinese Customs* (1950).

(O. M. G.)

HART, THOMAS CHARLES (1877–), U.S. naval officer of World War II, was born at Davidson, Mich., June 12, 1877, and graduated from the United States Naval academy in 1897. He became a rear admiral in 1929 and between that year and 1931 commanded the submarine force. Hart was superintendent of the Naval academy, 1931–34, a cruiser commander, 1934–36, and from 1936 to 1939 served as a member of the general board of the navy. Appointed commander in chief of the Asiatic fleet, with rank of admiral, in July 1939, he served in that post, acting for a brief period also as commander of the Allied naval forces in the far east. until June 1942, when he was retired. He was immediately recalled to active service. however, to serve again on the general board. from which he finally mas relieved in 1945. Appointed U.S. senator from Connecticut, he served until Dec. 1946, and was not a candidate for election. (J. B. HN.)

HART, WILLIAM S. (1870–1946), U.S. film and stage actor, the greatest of the early "western" heroes, was born Dec. 6, 1870, in Newburgh. N.Y., and was brought up in the Dakotas, where he lived until he was 16. He first appeared on the stage in 1889, and in 1905 his role in the play *The Squaw Man* made him a western hero. After playing in *The Virginian* and *The Trail of the Lonesome Pine* he went to Hollywood, where his portrayals of stern, taciturn westerners became enormously successful. Among his many films were *The Passing of Two-Gun Hicks, Hell's Hinds, The Captive God, The Dawnmaker, Truthful Tulliver, The Gunfighter, The Square Deal Man, Tumbleweeds* and *Desert Dust.* In 1923, after two years of retirement, he made nine pictures, including *Wild Bill Hickok, Singer McKee* and *A Lighter of Flames.* Later Hart turned to writing, producing several volumes of fiction and an autobiography, *My Life East and West* (1929). He died in Newhall, Calif.. June 24, 1946. (M. S. BY.)

HARTE, BRET (FRANCIS BRETT HARTE) (1836–1902), U.S. author. was the creator of a new genre in the short story and a new movement in American literature — the local colour school. Originally named Francis Brett Harte. he was born in Albany, N.Y., on Aug. 2j. 1836. His paternal grandfather was Jewish; his father was Roman Catholic; and his mother, low-church Episcopalian. The family lived a somewhat nomadic life until the death of the elder Harte in 1845, after which they settled in New Tork and Brooklyn. The education of young Frank. as he was then known, was spotty and' irregular. but he inherited a love of books and managed to get some juvenile verses published at the age of 11. Two years later he was forced to leave school and seek work.

In 1854 Harte left for California. where the previous year his mother had remarried. He taught one year in a rural school. made a brief trip into the mining country which legend has expanded into a lengthy participation in and intimate knowledge of camp life, and worked for a few days or weeks as a Wells Fargo expressman. In 1857 he went to Union, Calif.. on Humbolt bay, where for two years he was employed b y the *Northern Californian,* a weekly paper. There his support of minority groups. particularly Indians and Mexicans, proved unpopular; and after the massacre of Indians at Mad river, Feb. 26, 1860, which he editorially deplored, he found it advisable to leave town.

Returning to San Francisco. he married. worked in the office of the surveyor general. and began to write for the *Golden Era,* which soon published the first of his *Condensed Novels,* brilliant parodies of James Fenimore Cooper. Charles Dickens. Victor Hugo and others. which revealed him as one of the masters of that form. He then became clerk to the superintendent of the U.S. branch mint, a position which permitted a certain freedom to pursue his literary interests, including the editorship of the *Californian,* for which he engaged Mark Twain to write an article a week.

In 1868, after having written a series of Spanish legends like those used by Washington Irving in *The Alhambra,* he was virtually pushed into his rightful field when Anton Roman named him as first editor of the *Overland Monthly* and charged him with working up a group of local sketches. He wrote "The Luck of Roaring Camp," followed it with "The Outcasts of Poker Flat." and, as one of his idols. Byron. awoke one day to find himself world famous. His brisk reportorial style. his mastery of picturesque narrative, and his shrewd understanding of the universal appeal of an artful blending of sentiment and wit. proved to be a combination of qualities that won immediate praise. A further

fillip was given to his reputation by "Plain Language From Truthful James" (better known as "The Heathen Chinee"), a poem which attracted national attention.

Eastern publishers began to bid against one another for the literary services of the brilliant meteor out of the west; and, flushed with success, Harte signed a contract with the Atlantic Monthly calling for 12 monthly contributions at a stipend of $10,000, the highest figure until then ever offered an American r t e r Resigning a professorship at the newly founded University of California. Harte left for the east, never to return. In New England he was greeted as an equal by Henry Wadsmorth Longfellow, James Russell Lowell. Oliver Wendell Holmes and William Dean Howells, and in the best social circles he was lionized and toasted to the point of spiritual and moral breakdown. Moreover, he was soon to learn that the vein he had discovered was a shallow one. It was with difficulty that he tardily fulfilled his contract, which mas not renewed. Personality difficulties developed. the domestic scene was not quiet, and his work slumped further. After several years of indifferent success on the lecture circuit. Harte took the advice of friends and in 1878 accepted a consulship in Crefeld. Ger. Two years later he was moved to Glasgow, Scot.. where he served as consul for five years. In 1885 he retired to London. where he continued to live for 17 busy but uneventful writing years. His wife and family. whom he always supported generously, joined him for reunions at wide intervals, but he never returned to the U.S. Harte died on Nay 5, 1902.

During his London years Bret Harte was something of an anachronism. telling and retelling stories of a California which did not then exist and which perhaps had never existed. But he found in England a ready audience long after American readers had tired of his formula. It is inaccurate. however, to say that Harte burned himself out in a few sensational years and did no first-rate work thereafter. His "An Ingénue of the Sierras" and "A Protégée of Jack Hamlin's," both written in 1893, are perhaps better than his earlier stories, for they are dryly and ironically humorous, avoiding the emotional dilution and the sentimentality that mar so many of his more familiar stories.

Harte was driven all his life by hard economic necessity and never had the leisure to do the work of which he was capable. This is unfortunate because his talent, though limited in range, was susceptible of high artistic polish. He had a remarkably discerning journalistic eye for mannerisms and a usually reliable ear for habits of speech, and he was clever enough to pour old wine into new bottles, to take conventional story formulas and give them the aura of novelty that goes with an unusual setting. He was a master of small effects in narrative technique; his style, richly humorous, is ever graceful, ever charming. If his world is a fairyland of make-believe. the illusion is well sustained.

Harte's most successful books were The Luck *of* Roaring Camp, and *Other Sketches* (1570) and Tales of the *Argonauts* (1875). His best play was *Ah* Sin (1877), which was written in collaboration with Mark Twain. and was based on his famous poem, "Plain Language From Truthful James" (1870).

HARTEBEEST, a large South African antelope. *Alcelaphus caama,* characterized by its red colour. long face with naked muzzle, and sharply angulated lyrate horns. present in both sexes. This graceful animal. one of the swiftest of African antelopes, but grotesque appearing. formerly occurred in great herds from Cape Colony to Rhodesia. but is now comparatively rare and restricted to remote districts. It stands about 4 ft. high at the withers, with heavy forequarters. which are much higher than the narrow and drooping hindquarters. The name is usually extended to include all members of the genus. *See* ANTELOPE.

HARTFORD, a city and the capital of Connecticut; U.S., in Hartford county is a port of entry at the head of navigation on the Connecticut river, 38 mi. from Long Island sound and 100 mi. N.E. of New York city.

The city is well-planned with many parks and squares, and a planning commission has functioned since 1907. The state capitol, which stands on a hill in centrally located Bushnell park. is a handsome building of marble and granite, designed by R. M. Upjohn. Completed in 1879, it contains many objects of historic interest, including the tombstone of Israel Putnam and a carved chair made for the senate chamber from wood of the Charter Oak (see belo). In the park is the Corning Memorial fountain (1899), designed by J. Massey Rhind, and the memorial arch and bridge erected by the city in 1884 in tribute to the Civil War dead. Facing the capitol on the south is the supreme court and state library building (1910), and across the west lawn is the state armoury and arsenal, and Bushnell Memorial hall. Between the capitol and the Connecticut river stands the old three-story brick statehouse (1796), a gem of colonial architecture. designed by Charles Bulfinch. This was turned over to the city, and for a generation was used as a city hall, but after 1915 it was restored as a historic shrine. The city stands at 40 ft. above sea level. and an extensive system of dikes along the lower meadows form a protection against flood hazards.

Insurance, the outstanding business of Hartford and an outgrowth of its banks. dates from Feb. 8, 1794, when the first fire insurance policy was issued. Principal industries are the manufacture of brushes: mechanical counters, electrical equipment. tools, automatic machines, automobile parts, precision machines, chucks. firearms, plastics. marine engines. typewriters and glass-making machinery.

Hartford is the seat of Trinity college (Episcopalian) founded in 1823 as Washington college, and the Hartford Seminary foundation (Congregational), founded at East Windsor Hill in 1834 and moved to Hartford in 1865. Also located in the city are La Salette Missionary college and St. Mary's seminary (Roman Catholic), the University of Connecticut's schools of law, social work and college of insurance and the University of Hartford (Hartford Art school. Hartt College of Music and Hillyer college). The *Hartford Courant*, established in 1763. is one of the oldest surviving newspapers published in the United States. The Hartford Times, edited by Gideon Welles from 1826 to 1836, mas once one of the nation's most influential Democratic newspapers. The city has many literary associations, such as those with Lemuel Hopkins, John Trumbull, Timothy Dwight. Joel Barlow and David Humphrey~known as the Hartford Wits (see AMERICAN LITERATURE: Eighteenth Century). It is the birthplace of Noah Webster and was at one time the home of Harriet Beecher Stowe. Charles Dudley Warner and Samuel L. Clemens (Mark Twain).

History. — The first settlement was made by Dutch from New Amsterdam. who built a fort in 1633 at the mouth of Park river. a narrow and muddy branch of the Connecticut, which they held until 1654. In 1635, 60 English settlers came from New Towne (now Cambridge), Massachusetts. In 1636 the First Church of Christ (Centre Congregational), which was organized in New Towne (1632) moved to Hartford with most of its congregation under the leadership of Thomas Hooker (*q.v.*) and Samuel Stone. (The present building [1807] stands near the site of the original meetinghouse, and adjoins the graveyard where Hooker. William Leete, John Haynes and their contemporaries were buried.) In 1637 the settlement adopted its present name from Hertford. England, the birthplace of Stone.

Of interest is the monument marking the site of an oak tree on Charter Oak avenue. where, according to tradition. Capt. Joseph Wadsworth secreted the royal charter when New England colonial Gov. Sir Edmund Andros attempted to seize it in 1687. The city was chartered in 1784 and the town and city were consolidated in 1881. Hartford was the scene of the famous convention of 1814–15 called by New England Federalists to protest against the war policies of Pres. James Madison. (See UNITED STATES [OF AMERICA]: History.) Shipping reached a peak in the 18th century but never recovered from the depression caused by the War of 1812. After the American Civil War, the city prospered through better transport facilities and industries rapidly developed in the late 19th century.

Hartford adopted the city-manager form of government in 1948. The nature of the community was profoundly altered by

mid-20th century at which time Hartford had become the focus of a large and growing metropolitan district, completely surrounded by suburban towns and an even larger urbanized area. The chaotic condition of local government produced by this development is suggested by the fact that there are 32 local governments in the metropolitan district. Pop. (1960) 162,178; metropolitan population, 522,735. (E. E. Sr.)

HARTLAND, EDWIN SIDNEY (1848–1927), British anthropologist, was born at Islington, a borough of London, on July 23, 1848. He was a solicitor at Swansea from 1871 to 1890, and a charter member of the Folk-lore society, which he served as president in 1899. He was mayor of Gloucester in 1902. In 1922 he gave the first Frazer lecture at Oxford. His interest in folk tales and mythology (he was chairman of the folktale section of the International Folklore congress in 1891) led him to undertake research into primitive culture. He served as head of many British anthropological organizations and died on June 19, 1927.

He wrote *English Fairy and Other Folk Tales* (1890); *The Science of Fairy Tales* (1891); *The Legend of Perseus,* 3 vol. (1894–96); *Primitive Paternity* (1910); *Ritual and Belief* (1914); *Primitive Society* (1921); and *Primitive Law* (1924).

HARTLEBEN, OTTO ERICH (1864–1905), German poet, dramatist and short-story writer, was born in Clausthal, Hanover, on June 3, 1864. He studied law at the University of Berlin and later at the University of Tübingen. Hartleben soon abandoned the study of law, however.

Hartleben, who followed Nietzsche in rejecting morality, led a bohemian life and wrote intermittently between drinking bouts with friends. After his health failed, he retired to Salò, It., where he lived on a large country estate on the shores of Lake Garda which he named Halkyone and where he hoped to found a poetry centre. He died at Salò at the age of 41, on Feb. 11, 1905.

His writings are filled with humour and satire; he delighted in taunting the *bourgeoisie* and presenting militarism in a ridiculous light. Because of his storytelling genius he has been likened to Guy de Maupassant (*q.v.*); his verses are lyrical and excellent in form. He wrote: *Der Frosch, Familiendrama nach Henrik Ipse* (1891); *Der Geschichte vom abgerissenen Knopf* (1893); *Meine Verse* (1895); *Vom gastfreien Pastor* (1895); *Meiner Verse Zweiter Teil* (1904); *Hanna Jagert* (1892); *Rosenmontag* (1900; Eng. trans., "Love's Carnival," 1904), a play about the Prussian military system; *Das Ehefest* (1906); *Tagebuch* (1906). His *Collected Works* were published in three volumes (1909).

See W. Mahrholz, *Deutsche Literatur der Gegenwart* (1930); J. Bithell, *Modern German Literature, 1880–1938,* 2nd ed. (1946); H. Lücke, *Otto Erich Hartleben* (1941).

HARTLEPOOL, a municipal borough in the Hartlepools parliamentary division of County Durham, Eng., on a peninsula at the northern point of Hartlepool bay, 2 mi. N.N.W. of West Hartlepool (*q.v.*) and 18 mi. E.S.E. of Durham by road. Pop. (1951) 17,219. Area 2.3 sq.mi. This ancient market town and port, to which John gave a charter in 1201, is now an industrial centre, mainly for shipbuilding, marine engineering and fishing, and also a residential and holiday town with miles of sandy beach. On Heugh point is a lighthouse and along the coast to the northwest is a lifeboat station. The large parish church of St. Hilda was begun in the late 12th century and restored in 1925–30.

HARTLEY, DAVID (1705–1757), English physician and philosopher, known for his advocacy of a physiological psychology in place of a psychology based on the concept of a soul, was born on Aug. 30, 1705. Educated at Bradford grammar school and Jesus college, Cambridge, he practised medicine at Newark, London and Bath, where he died on Aug. 28, 1757.

Hartley's chief work, *Observations on Man, His Frame, His Duty, and His Expectations* (2 vol., 1749), aimed to overcome "the great difficulty of supposing that the Soul, an immaterial Substance, exerts and receives a physical influence upon and from the Body." The preface states that he had been "informed that the Rev. Mr. Gay had asserted the possibility of deducing our intellectual pleasures and pains from Association." From Isaac Newton's *Opticks* (1704) he derived the idea that sensory stimuli might operate by producing "vibrations," propagated through the nerves, like "the trembling of particles in sounding bodies": in the brain the occurrence of vibrations in a certain order sets up a readiness for similar vibrations to recur in the same order. Part II explains how the more complex processes—imagination, memory, reasoning—may thus be analyzed into clusters or sequences of elementary sense impressions formed by individual experience, so that all mental phenomena can be explained by a single law of association. Part III seeks to show how the idea of God develops in the human mind. Hartley's theory had little influence until the early 19th century, when it was taken up and elaborated by James Mill and other members of the associationist school.

Bibliography.—The *Observations* were published by his son with a life of Hartley, 3 vol. (1801). *See* also G. S. Bower, *Hartley and James Mill* (1881) and B. Schönlank, *Hartley and Priestley die Begründer des Assoziationismus in England* (1882). (Cy. B.)

HARTLEY, DAVID, the younger (1731–1813), parliamentarian, pamphleteer and inventor, son of the philosopher David Hartley (*q.v.*), was a fellow of Merton college, Oxford, and member of parliament for Hull (Kingston-upon-Hull), 1774–80 and 1782–84. He gained fame about 1776 by a discovery intended to protect buildings against fire, and attracted gatherings to his experimental house on Putney common where an obelisk stands in his honour. He was the friend and correspondent of Benjamin Franklin, with whom he shared many interests; he devoted a great part of his political career to opposing the American War, speaking frequently in the commons and publishing in 1778 his vigorous *Letters on the American War.* He was appointed by the Fox-North ministry as plenipotentiary to treat with the Americans in 1783, and signed the definitive treaty in Paris.

See G. H. Guttridge, *David Hartley, M.P.,* with bibliography (1926).

HARTLIB, SAMUEL (*c.* 1599–*c.* 1662), educational reformer and agriculturalist, was born at Elbing (then a Hanseatic city under Polish protection). His father was a refugee merchant from Poland, but his mother was English. He was at Cambridge before 1625, and when in 1628 he settled in England he associated himself with the reforming ideas of John Dury. He was an admirer of J. A. Comenius, many of whose works he translated, including *A Reformation of Schools* (1642). He wrote more than 30 tracts and treatises among which were *Macaria* (1641), a description of the ideal state, and *A True and Readie Way to Learn the Latine Tongue* (1654). In 1651, in *An Essay for Advancement of Husbandry-Learning,* he advocated the foundation of an agricultural college. Milton dedicated his tractate *On Education* to Hartlib. He was also concerned with the educational legislation of the Long parliament and the visit to England of Comenius (1641). For his services Cromwell awarded him a pension of £300 a year which ended with the Restoration. It is supposed that Hartlib died in poverty and, according to J. W. Adamson, was buried at St. Martin-in-the-Fields, London, on March 12, 1662.

Turnbull, *Hartlib, Dury and Comenius* (1947); W. A. L. Vincent, *The State and School Education, 1640–1660* (1950); S. J. Curtis and M. E. A. Boultwood, *A Short History of Educational Ideas,* 2nd ed. (1956). (S. J. C.)

HARTMANN, JOHANNES FRANZ (1865–1936), German astronomer and inventor of scientific instruments, was born at Erfurt on Jan. 11, 1865. From 1886 to 1891 he studied mathematics at Tübingen, Berlin and Leipzig. In 1891 he was appointed assistant in Leipzig observatory. In 1909 he became professor of astronomy and director of the observatory in Göttingen, and in 1921 director of the university observatory at La Plata, Arg. He worked on spectrographs and dispersion curves and wrote numerous papers on his spectral observations. He edited the volume on astronomy in the series *Die Kultur der Gegenwart* (1921). Hartmann invented the microphotometer (1899), and the spectrocomparator (1904). With John Plaskett and Otto Struve, he discovered and investigated the calcium clouds in space.

HARTMANN, KARL ROBERT EDUARD VON (1842–1906), German philosopher who based his metaphysical system on the unconscious, was born at Berlin on Feb. 23, 1842. Educated for the army, he turned to philosophy after an injury

to his knee in 1865.

In 1867 the university of Rostock conferred on him the degree of Ph.D. He subsequently returned to Berlin and died at Grosslichterfelde on June 5, 1906.

Eduard von Hartmann's reputation was established by his second book, Die Philosophie des *Unbewussten,* 3 vol. (Berlin, 1869; 12th ed., with supp. texts, 1923; Eng. trans., The Philosophy of the *Unconscious,* London, 1884). Its success was due to the diversity of its contents (Hartmann professing to obtain his speculative results by the methods of inductive science and using many concrete illustrations), to its apparent pessimism and to the vigour and lucidity of its style. The unconscious is both reason and will and the absolute all-embracing ground of all existence, the spiritual principle required by nature. At the fall of man, will and reason were separated, and the former, as blind impulse, determines the melancholy career of the unconscious in the world process.

Reason is in constant strife against will; and only when it is emancipated from this strife in the conscious reason of the enlightened pessimist can the world be redeemed. When the greater part of the will in existence is so far enlightened by reason as to perceive the inevitable misery of existence, a collective effort to will nonexistence will be made, and the world will relapse into nothingness, the unconscious into quiescence. Civilization, like the happiness of the individual, means the annulment of the will to live and the gradual releasing of the unconscious from its sufferings.

Meanwhile mankind must provisionally affirm life and devote itself to social evolution, instead of striving after a happiness which is impossible; in so doing man will find that morality renders life less unhappy. Suicide, and all other forms of selfishness, are highly reprehensible.

BIBLIOGRAPHY.—Eduard von Hartmann's numerous other works include *Neukantianismus, Schopenhauerianismus und Hegelianismus* (1877); *Phanomenologie des sittlichen Bewusstseins* (1879); *Zur Geschichte und Begrundung des Pessimismus* (1880); *Das religiose Bewusstsein der Menschheit* (1882); *Moderne Probleme* (1886); *Zwei Jahrzehnte deutscher Politik* (1889); *Das Grundproblem der Erkenntnistheorie* (1889); *Die soziale Kernfragen* (1894); *Kants Erkenntnistheorie und Metaphysik* (1894); *Kategorienlehre* (1896); *Geschichte der Metaphysik,* 2 vol. (1899–1900); *Die moderne Psychologie* (1901); *Das Problem des Lebens* (1906); and *System der Philosophie im Grundriss,* 8 vol. (1906–09). Under the pseudonym Karl Robert he published *Dramatische Dichtungen: Tristan und Isolde, David und Bathseba* (1871).

HARTMANN, NICOLAI (1882–1950), one of the dominant figures of German philosophy between World Wars I and II, was born in Riga, Latvia. on Feb. 20, 1882. Educated at St. Petersburg, Dorpat and Marburg, he served in World War I and was successively appointed professor at Marburg (1920), at Cologne (1925), at Berlin (1931) and at Gottingen (1945), where he died on Oct. 9, 1950.

Originally a disciple of Marburg Neo-Kantianism, Hartmann reversed the Kantian conception of the object as a construct of the mind and developed what he himself called "a new ontology" (cf. his Neue *Wege* der Ontologie, 1942; Eng. trans. by R. C. Kuhn, *New* Ways of Ontology, Chicago, Ill., 1953), a theory of unitary though diversified being which is in and by itself. Intelligent beings have the privilege of taking cognizance, within the narrow compass of their faculties, of things existing. But this awareness of reality must in its turn be regarded primarily as forming part and parcel of reality, as an event among other events, and by no means as fundamental to being or to reality as such. According to Hartmann it is an error to hold that the basic forms of human thought, the "subjective categories," are identical with the basic structure of reality, the "objective categories." All that scientists or philosophers can hope to achieve is a partial assimilation of their subjective categories to those of the object. The element of the irrational will always loom large in their field of vision, and the restricted circle of light in which they move will be forever encompassed by the vast expanse of unobjectifiable being.

In conceiving his realist ontology Hartmann was influenced by Edmund Husserl's phenomenology, but whereas Husserl supplemented the intuitive grasp of essential forms by a reflexive study of the mental acts which give rise to the realm of intuited essences, Hartmann insisted on viewing philosophy as an object-centred research, a prolongation, as it were, of the scientist's approach to reality.

Reality, for him, revealed a hierarchy of layers, each of them structured in accordance with certain regional "categories," the bottom layer, the region of inanimate matter, supporting the rest, the top layer, the mind, forming a superstructure in no way anticipated by realities further below. Hartmann's conception of the scale of being differed radically from the hierarchical vision of classical metaphysics. He adopted Max Scheler's thesis of the relative weakness of the higher categories. Reality, though orderly and partly rational, is for him void of meaning, and man has to perform the heroic feat of living a human life in a world entirely alien from his human aspirations. In this he is assisted by an intuition of values which are believed to form an imposing firmament of ideal entities. In developing this "material" ethics, so styled in contradistinction to Kant's formalism, Hartmann again followed Scheler's example.

His work, remarkable for its scope and for the consistency with which ontological principles are brought to bear upon all areas of philosophical thought, shows a genius for systematic synopsis rather than for original vision or for disclosure of hidden traits of reality.

BIBLIOGRAPHY.—Hartmann's chief writings are *Grundzüge einer Metaphysik der Erkenntnis* (1921; 2nd ed., 1925); *Die Philosophie des deutschen Idealismus,* 2 vol. (1923–29); *Ethik* (1926; 2nd ed., 1935; Eng. trans., *Ethics,* 3 vol., 1932); *Zur Grundlegung der Ontologie* (1935); *Moglichkeit und Wirklichkeit* (1938); *Der Aufbau der realen Welt* (1940); *Philosophie und Natur* (1950); *Asthetik* (1953). *See* further *Nicolai Hartmann, der Denker und das Werk,* ed. by H. Heimsoeth and R. Heiss (1952); H. Kuhn, "Nicolai Hartmann's Ontology," *The Philosophical Quarterly,* vol. i, iv (1951); O. Samuels, *Foundation of Ontology: A Critical Analysis of Nicolai Hartmann,* Eng. trans. (1954). (HT. K.)

HARTMANN VON AUE (*fl.* 1190–1210), Middle High German poet, was one of the masters of the courtly epic. There are no documentary references to him, but it emerges from his works that he received a learned education at a monastery school, that he was a ministerialis at a Swabian court and that he took part in Henry VI's ill-fated crusade of 1197. There are in existence by Hartmann four extended narrative poems (Erec, Gregorius, Der *arme* Heinrich, Iwein), two shorter allegorical love poems (Biichlein I and 11) and 16 lyrics (13 love songs and three crusading songs). The lyrical poems and the two Biichlein appear to have been written first, followed by the narrative poems—his most important works—in the above order. Gregorius and *Der* arme *Heinrich* are religious works with an openly didactic purpose. The former is a version of the Oedipan legend of Pope Gregory, a popular medieval theme. The latter, Hartmann's most perfect poem, tells the story of a leper who is healed by the readiness of a pure young girl to sacrifice her life for him. The two secular epics Erec and Iwein, both based on works by Chrétien de Troyes and belonging to the Arthurian cycle, enshrine Hartmann's ethical ideal of restraint and moderation (*mâze*) in human conduct, and are complementary in that they depict the return to grace of knights who have defected from this ideal—Erec by subordinating the duties of the man of action to those of the chivalrous servant of woman, Iwein by neglecting the claims of family life for the pursuit of heroism and adventure.

Hartmann regarded his works as instruments of a moral purpose. Edifying content mattered more to him than elegance of style, and his narratives are characterized by clarity and directness, and by the avoidance of rhetorical devices and displays of poetic virtuosity.

The best short account of Hartmann and his works is in the introduction to F. Neumann's edition of *Der arme Heinrich* and *Gregorius* (1958). *See* also G Ehrismann, *Geschichte der deutschen Literatur bis zum Ausgang des Mittelalters* II, 2, 1, pp. 141–212 (1954), which contains detailed bibliographies on specific topics. (RD. J. T.)

HART'S-TONGUE (Phyllitis) is the name given to a genus of ferns, formerly known as *Scolopendrium,* meaning "like a centipede," from the numerous lines of fructification on the leaves.

Typical P. *scolopendrium* (S. *vulgare)* is common in Europe, including Great Britain, and in eastern Asia. Variety *americana* grows in the U.S. and southern Canada but is very rare, occurring only locally in central New York. Tennessee, Ontario and New Brunswick. Var. *Lindeni* grows in Chiapas, Mexico. The thick, leathery, glossy fronds reach a length of 18 in. There are eight species of *Phyllitis,* mainly tropical and subtropical. *See* PTERIDOPHYTA.

HARTY, SIR HERBERT HAMILTON (1880–1941), Irish conductor and composer, was born at Hillsborough, County Down, Ireland, on Dec. 4, 1880. He was an organist in Belfast and in Dublin before he went to London in 1900. As an accompanist he was soon in great demand and his compositions also received recognition. His *Comedy Overture* was played at a promenade concert at Queen's Hall in 1907 and in the same year his *Ode to a Nightingale* was produced at the Cardiff festival with Madame Agnes Nicholls, his wife, in the solo part. In 1920, after gaining considerable experience by conducting the London Symphony orchestra, he was appointed permanent conductor of the Halle orchestra in Manchester.

In 1925 Harty was knighted and also received the degree of Mus.D. from Dublin university. In January 1927 he visited London with the Halle orchestra and chorus and gave a notable performance of Berlioz's *Requiem* at a British Broadcasting Corporation's Albert Hall concert.

Harty's compositions include a violin concerto; *With the Wild Geese,* tone poem for orchestra; *The Mystic Trumpeter* for voices and orchestra; an "Irish" symphony; songs and settings of folk-songs. In 1931 and again in 1934 he conducted orchestras in the United States. Harty died on Feb. 19, 1941, at Brighton, Eng.

HARTZENBUSCH, JUAN EUGENIO (1806–1880), one of the most successful of the Spanish romantic dramatists, editor of standard editions of Spanish classics and author of fanciful poetry in a traditional style, was born in Madrid. Sept. 6, 1806, the son of a German cabinetmaker. Early tribulations ended with the production of *Los amantes de Teruel* (1837), a vivid dramatization of a legend, followed by successes with *comedias de magia* (*e.g., Los polvos de la madre Celestina,* 1840) and adaptations of Golden Age plays. He entered the Spanish Academy (1847) and became director of the national library (1862). He died in Madrid. Aug. 2, 1880. (R. F. B.)

HARUN AL-RASHID (766–809), fifth Abbasid caliph, who reigned from 786 to 809, when the caliphate (*q.v.*) was at its zenith. Son of the caliph al-Mahdi and the princess Khaizuran, he was born at Rayy (beside modern Teheran) in Feb. 766. From the age of 14 he was given military commands, subject to the advice of his guardian, Yahya the Barmecide, in the wars against the Byzantine empire. His efficiency in these gained him the honorific name of al-Rashid, "the rightly guided," and nomination as second in succession to the throne. After his father's death in 785 his brother al-Hadi tried to alter the succession, to the dismay of Yahya the Barmecide and Khaizuran, but in Sept. 786, before he had taken any definite steps, al-Hadi died under suspicious circumstances and Harun was at once proclaimed caliph. Frankish historians say that he and his contemporary Charlemagne were on friendly terms and exchanged embassies on several occasions. His reign marked the flowering of culture in the new social and political structure created by the Abbasids. The merging of Arab and non-Arab elements and the consequent growth of industry and commerce set free some of the energies of the caliphate for the pursuit of intellectual culture, and Harun proved an enthusiastic and discerning patron. *The Arabian Nights (see* THOUSAND AND ONE NIGHTS) gives impressions, perhaps somewhat romanticized, of the brilliance of the court at Baghdad at that period. Despite expenditure on luxury, however, the affairs of the caliphate were prudently administered by Harun's viziers, Yahya the Barmecide and his son Fadl, who greatly increased administrative efficiency. Nevertheless the strains of the vast empire were not eliminated. It was probably the rivalry of different groups at court supporting different policies that. led to the fall of the Barmecides (*q.v.*) in 803; but a change of administration did not improve matters, and troubles increased during the remainder of Harun's reign. He died at Tus (near modern Meshed) on March 24, 809, on his way to quell a rebellion in Transoxiana. The war between his sons. which broke out in 811, is an indication of the strength of the unresolved tensions.

HARUSPICES, ancient Etruscan diviners, "entrail observers" whose art (*disciplina*) consisted especially in deducing the will of the gods from the appearance presented by the entrails of the slain victim. They also interpreted all portents or unusual phenomena of nature, especially thunder and lightning, and prescribed the expiatory ceremonies after such events. This formed a most complicated pseudo science. in sharp contrast to native Italian divination, which consisted of asking the approval of the gods for a proposed action and deducing a "yes" or "no" from such omens as the flight of birds *(see* AUGURS; DIVINATION; ORACLE) and in simple inspection of the entrails of a victim to see if the beast were normal and therefore acceptable. The Etruscans were said to have learned it from a being named Tages (*q.v.*). Instructions were contained in certain books called *libri haruspicini fulgurales, rituales.* The art was practised in Rome chiefly by Etruscans, occasionally by native-born Romans who had studied in the priestly schools of Etruria. Though of great importance under the early republic, it never became a part of the state religion. In this respect the haruspices contrast with the augurs, who were an ancient and purely Roman institution, and were a most important element in the political organization of the city. In later times the art fell into disrepute. Gnder the empire, however, there existed a collegium of 60 haruspices; however, it was never a state priesthood but a body of salaried expert advisers.

HARVARD UNIVERSITY, the oldest and one of the foremost U.S. educational institutions, situated chiefly in Cambridge, Mass., but also in Boston and other places. Of its student body, drawn from all parts of the Cnited States and from many other countries, somewhat less than one half are undergraduates in Harvard college; the rest study in the graduate schools of arts and sciences (which includes engineering and applied physics) business administration. dental medicine, design, divinity, education, law, medicine, public administration and public health.

In 1636 the general court of the Colony voted £400 toward "a schoale or colledge," which in the next year was ordered to be at "Newetowne." In memory of the English university where many (probably some 70) of the leading men of the Colony had been educated. the township was named Cambridge in 1638 In the same year John Harvard (1607–38), an immigrant Puritan minister to America, a bachelor and master of arts of Emmanuel college, Cambridge, dying in Charlestown. Mass.. bequeathed to the wilderness seminary £780 (half his estate) and 260 books; and the college, until then unorganized. was named Harvard college (1639) in his honour.

The history of Harvard is unbroken from 1640, and its first commencement was held in 1642. The spirit of the founders is beautifully expressed in the words taken from *New England's First Fruits* (1643) and carved on the college gates: "After God had carried us safe to *New-England,* and wee had builded our houses, provided necessaries for our liveli-hood. rear'd convenient places for Gods worship and settled the Civill Government; One of the next things we longed for, and looked after was to advance *Learning* and perpetuate it to Posterity; dreading to leave an illiterate Ministry to the Churches, when our present Ministers shall lie in the Dust." The charter of 1650 dedicated the college to "the advancement of all good literature, arts, and sciences." and "the education of the English and Indian youth . . . in knowledge and godlynes." The second building (1654) on the college grounds was called the "Indian College." In it was set up the college press, which since 1638 had been in the president's house, and there, it is believed, was printed the translation of the Bible (1661–63) by John Eliot into the language of the natives, with his primer, catechisms, grammars, tracts, etc. A fair number of Indians were students, but only one, Caleb Cheeshahteaumuck, took a bachelor's degree (1665). By generous aid received from abroad for this spe-

cial object. the college was greatly helped in its infancy.

The charter of 16jo has been in the main, and uninterruptedly since 1707, the fundamental source of authority in administration. It created a self-perpetuating corporation consisting of the president, the treasurer and five fellows, who formally initiate administrative measures, control the college funds, and appoint officers of instruction and government, subject, however, to confirmation by the board of overseers (established in 1642), which has a revisory power over all acts of the corporation. Circumstances gradually necessitated ordinary government by the resident teachers; and today the various faculties. elaborately organized, exercise immediate government and discipline over all the students. The board of overseers was at first jointly representative of state and church. The former, as founder and patron, long regarded Harvard as a state institution; but the controversies and embarrassments incident to legislative action proved prejudicial to the best interests of the college, and an act of 1865 severed the connection with the state. Financial aid and practical dependence had ceased some time earlier; indeed, from the very beginning, and with steadily increasing preponderance, Harvard has been sustained and fostered by private munificence. The last direct subsidy from the state terminated in 1824, although state aid was afterward given to the Agassiz museum, later united with the university.

The church was naturally sponsor for the early college. The changing composition of its board of overseers marked its liberation first from clerical and later from political control; since 186j the board has been chosen by the alumni who therefore really control the university. When in the first half of the 17th century the unity of Puritanism, in religion and in politics, gave way to a variety of intense sectarianisms, this, as also the incoming of Anglican churchmen, made the old iaith of the college insecure. The conservatives, who clung to pristine and undiluted Calvinism, sought to entrench themselves in the board of overseers. The history of the college from about 1673 to 1725 was exceedingly troubled. One episode in the struggle was the foundation of Yale college by the conservatives of New England as a truer "school of the prophets" after they had failed to secure control of the government of Harvard. In 1792 the first layman mas chosen to the corporation; in 1805 a Unitarian became professor of theology; in 1843 the board of overseers was opened to cle gymen of all denominations; in 1886 attendance on prayers ceased to be compulsory. Thus Harvard, in response to changing conditions. grew away from the ideas of its founders.

Harvard and its alumni and faculty have been closely associated with the intellectual development of the United States in many spheres. Especially in the field of letters, its influence was felt in colonial times through Increase Mather, Cotton Mather, Samuel Sewall and others, and in the revolutionary and early national epoch through men such as the Adamses and Robert 'Treat Paine. Henry Wadsworth Longfellow taught there and the graduates included such men as Ralph Waldo Emerson, Oliver Wendell Holmes, Henry Thoreau, James Russell Lowell, Henry James, Henry Adams, and, later, Robert Frost (who was a special student for two years and taught at Harvard. 1939–43), T. S. Eliot, E. A. Robinson, Walter Lippmann and J. P. Marquand.

The first course in American history was introduced in 1838 by Jared Sparks. The writing of history, given impetus by George Bancroft. William Prescott, John L. Motley, Francis Parkman, John Fiske and others, continued through the works of such teachers and graduates as Albert B. Hart, James Ford Rhodes, Theodore Roosevelt, Frederick J. Turner and Vernon L. Parrington. By the 1960s, Harvard had provided six presidents of the United States—John Adams, John Quincy Adams, Rutherford B. Hayes, Theodore Roosevelt, Franklin D. Roosevelt and John F. Kennedy—and a number of justices, cabinet officers and congressional leaders, as well as business and financial figures of importance. Science was taught at Harvard in the 18th century (astronomy almost from the beginning of the college) but the modern growth of investigation was led by such men as Benjamin Pierce in astronomy, Wolcott Gibbs and Theodore W. Richards in chemistry, and Nathaniel S. Shaler in geology. In the debate of the 1860s over Darwin's theories, the botanist Asa Gray was ranged against the anti-Darwinian naturalist Louis Agassiz. At Harvard, William James introduced the experimental study of psychology into the United States in the 1870s. In other fields, too—the ministry, the law, medicine, music, philosophy—Harvard teachers and graduates took a leading role.

In organization and scope of effort Harvard became, especially after 1869. in the highest sense a university; but the "college" proper, whose end is the liberal culture of undergraduates. continues to be the centre of university life, as it is the embodiment of university traditions. In this period of development the university was led by three outstanding presidents—Charles W. Eliot (1869–1909), A. Lawrence Lowell (1909–1933) and James B. Conant (1933–1953). Another forceful leader, Nathan M. Pusey, became president in 1953. The medical school (in Boston) dates from 1782, the law school from 1817, the divinity school (although instruction in theology was of course given from the foundation of the college) from 1819; but in all of these schools the selection and instruction of students had been lax. Under Eliot these schools were raised to the graduate level in admissions and instruction, the laboratory investigation of disease was added to the clinical practice of medicine, the historical study of religions was provided for the ministry, and the case method of studying the law was introduced. (The graduate school of business administration was formed in 1908. and after 1920 teaching by discussion of actual cases was applied to training for business as well.) The graduate school of arts and sciences was formed in 1872. After 1949 it included the fields of engineering and applied physics, which had first been offered in 1847 in the Lawrence scientific school, and later in a school of engineering. Graduate schools also were developed in dental medicine, design, education, public administration and public health. In addition to its laboratories, museums and research groups in Cambridge and Boston, such as the Museum of Comparative Zoology founded by Louis Agassiz in 1859, the Gray herbarium (1864), the Peabody Museum of Archaeology and Ethnology (1866), the Arnold arboretum (1872), the Semitic museum (1889), the William Hayes Fogg Art museum (1895) and the Busch-Reisinger Museum of Germanic Culture (1902), the university maintained several institutions distant from Cambridge. These included an institute of Italian art and culture at the villa I Tatti in Florence; the Dumbarton Oaks Research library and collection in Byzantine and medieval humanities at Washington, D.C.; astronomical and seismographic observatories at Harvard, Mass. and an additional radio-telescope at Ft. Davis, Tex. The Harvard forest of about 2,300 ac. is at Petersham, Mass., and the Black Rock forest of 3,700 ac. at Cornwall, N.Y.

At the outset: Harvard students were given the classical tongues—Greek, Latin and Hebrew. In the early 19th century, a young graduate, George Ticknor, returned from Germany to urge the modern languages. and after 1825 instruction was offered in French, Spanish, German and Italian. Longfellow was the first Smith professor of French and Spanish languages, and he was followed by James Russell Lowell. Other languages were added from time to time—Russian in 1896, for instance, and in the 20th century Chinese. Japanese and the Indic languages. After World War II research centres on various regions of the world were established. Combining language skills and social science methods, they included the Russian research center (1948), the center for middle eastern studies (1954) and the center for east Asian studies (195j). In the law school, where international law had been taught for several decades, an international legal studies program was also established after World War II. In addition, the university created a center for international affairs (1957).

Harvard's library is the largest university library in the United States, if not in the world. Among all libraries of the United States it is the oldest and one of the foremost. Three adjoining buildings house nearly half the collection: advanced study and research centres in the Harry Elkins Widener Memorial library (1915); rare books and manuscripts are kept in the Houghton library (1942); and the Lamont library (1949) serves undergraduates. The New England Deposit library in Boston provides storage for little-used materials. The other half of the university's books are in scores of departmental and special libraries, of which

the most outstanding are those covering law, business, biological sciences, Chinese and Japanese, astronomy, anthropology and ethnology. The Houghton library houses remarkable collections of books and manuscripts by John Keats and Emily Dickinson, Emerson, Lowell, Holmes and others; the Theatre collection is unique in 18th- and 19th-century British and American materials. In Widener there is a special Theodore Roosevelt collection, and other particularly strong areas include the Italian Risorgimento, Celtic, the fine arts, the French Revolution, Hebraica, linguistics, and Portuguese language and literature. The university publishes, mainly through the Harvard University Press, a distinguished series of scholarly studies and journals in a variety of fields.

The central faculty of arts and sciences and seven separate professional faculties control admissions, set curricula and prescribe educational policy. Teaching fellows, instructors and assistant professors are appointed for a term, but associate professors and professors are appointed for life. To assure the highest quality in these posts, a system of ad *hoc* committees was instituted in 1941 with, typically, a special committee of scholars drawn both from Harvard and from other institutions, led by the president, sitting to review each appointment. The office of university professor was created in 1935 to free a few outstanding scholars for work "on the frontiers of knowledge" without commitment to any single school or faculty.

Among the students are a number of mature men established in their careers who come to the university for background study under programs developed since 1935—the Littauer fellows in public administration, the Nieman fellows in journalism, fellows in international affairs, post-doctoral fellows in the sciences, medicine, dental medicine and public health, conservation fellows, members of the trade union program, and the advanced management group (about 140 business executives twice yearly). Beginning in 1933 the Society of Fellows provided an opportunity for a limited number of outstanding young scholars, on three-year appointment as junior fellows, to pursue research and study in fields of their own choosing without academic limitations. Women students, who were first admitted to the school of education in 1920, by the mid-1950s were accepted in all divisions of the university not provided through Radcliffe college.

A strong development toward the university ideal marked the last half of the 19th century. especially in the widening of courses, the betterment of instruction and the progress of university freedom; and this was consolidated in the 20th century, bringing Harvard to the forefront among higher institutions of learning. This had its effect on the undergraduate college as well as in the developing graduate schools, and Harvard became a leader both in setting high standards for admission and in seeking change in the rigid, traditional curriculum. In the search for a college curriculum to meet the needs both of general education and specialized learning, Harvard has been bold in experiment and innovation. The ideas of recognizing special students and introducing the elective system were suggested in 1824, attaining establishment even for freshmen by 1885, the movement characterizing particularly the years 1865–85. The basis of the elective system is freedom in choice of studies within liberal limits. This freedom was modified in 1910 by requiring each student to choose enough courses in one field to enable him to gain considerable knowledge of that subject, and by distributing a certain number of courses among other fundamental subjects to round out his view of the world. Dissatisfaction with the distribution requirement as a means to a well-rounded education, however, led in 1946 to the report of a special faculty committee, under the chairmanship of Paul H. Buck, on "General Education in a Free Society." After several years of trial the general education program was put into full effect in the fall of 1951. This provided that each student should take, during his first two years, one course in each of the three great fields of learning—the natural sciences, the social sciences and the humanities. Rather than offer a single "core" course, however. the faculty gave the student a choice among four or five offerings in each of these fields, each prepared by outstanding scholars especially for the instruction of nonspecialists. Optional advanced courses also were offered under the same program. In this way, it was felt, all students would gain a common appreciation of the western heritage. In 1910 the degree with distinction was established for high attainment in general, coupled with distinguished success in the subject to which the student had given most attention. Beginning with 1916, general final examinations on the student's field of concentration were introduced; the plan was later extended to almost all departments.

In the years following 1916 a system of tutors was developed to direct the private reading of the students. The tutor met his men individually each week and advised as to their private study. In later years, especially after World War II. this tutoring became limited in the larger departments to the abler students. Feeling that tutorial instruction had value for all students, the faculty introduced in the fall of 1952 a system of tutoring in groups of six or less to cover all students in these larger departments, while continuing individual tutoring as before. First-year students in Harvard college live in dormitories in the Harvard Yard, and since 1931 students in the three upper classes have lived under the house plan. The several houses, each with about 400 students with tutors, a senior tutor and a master, became the centres of undergraduate life, each house having its own library, common rooms, social and intellectual activities and athletic teams. It is believed that in this way any advantage that a small college may have is united with those of the university college. In 1950 a somewhat similar arrangement for communal living mas provided for graduate students in Cambridge.

With an increase in the number of persons of college age and an increasing demand for college and university education in the United States after mid-century, Harvard sought to make its special contribution by maintaining quality and by providing increasing numbers of well-equipped college and university teachers in several fields through its graduate programs.

RADCLIFFE COLLEGE, an institution of higher education for women, dates from the beginning of instruction of women by members of the Harvard faculty in 1879. the Society for the Collegiate Instruction of Women being formally organized in 1882. The present name was adopted in 1894 in honour of Ann Radcliffe, Lady Mowlson (d. *c.* 1661), widow of Sir Thomas Mowlson, alderman and (1634) lord mayor of London. She was the founder (1643) of the first scholarship in Harvard college. From 1394 also dates the present official connection of Radcliffe with Harvard. The requirements for admission and for degrees are the same as in Harvard. and all diplomas are countersigned by an authorized official of Harvard and bear the university seal. Instruction has always been given by members of the Harvard faculty, and after World War II Radcliffe students were introduced into Harvard classes. Although instruction was joined, Radcliffe maintained its own deans and administration, continued its own student activities and maintained its own library, recreational facilities and tutorial hall. Radcliffe. with the Harvard graduate school of business administration, maintains a one-year graduate management training program for women intending a career in business.

HARVEST, the season of the ingathering of crops (A.S. *haerfest* "autumn." O.H. Ger. *herbist*). Harvest has been a season of rejoicing from the remotest ages. The Romans had their Cerealia or feasts in honour of Ceres. The Druids celebrated their harvest on Nov. 1. In pre-Reformation England Lammas day (Aug. 1, O.S.) was observed as the beginning of the harvest festival. Throughout the world harvest has always been the occasion for many queer customs which all have their origin in the animistic belief in the corn spirit or corn mother. This per-

sonification of the crops has left its impress upon the harvest customs of modern Europe. In West Russia, for example, the figure made out of the last sheaf of corn is called the bastard, and a boy is wrapped up in it. The woman who binds this sheaf represents the "corn-mother," and an elaborate simulation of childbirth takes place, the boy in the sheaf squalling like a newborn child, and being, on his liberation, wrapped in swaddling bands. Even in England vestiges of sympathetic magic can be detected. In Northumberland, an image formed of a wheatsheaf, and dressed in a white frock and coloured ribbons, is hoisted on a pole. This is the "kern-baby" or harvest-queen, and is set up in a prominent place during the harvest supper. In Scotland, the last sheaf, if cut before Hallowmas, is called the "maiden," and the youngest girl in the harvest-field is given the privilege of cutting it.

Throughout the world. as Sir J. G. Frazer shows, the semi-worship of the last sheaf is or has been the great feature of the harvest-home. Among harvest customs none is more interesting than harvest cries; the Devonshire reapers go through a ceremony which in its main features is a counterpart of pagan worship. "After the wheat is cut they . . . pick out a bundle of the best ears . . . ; this bundle is called 'the neck'; the harvest hands then stand round in a ring, an old man holding 'the neck' in the centre. At a signal from him they take off their hats, then all together they utter in a prolonged cry 'the neck!' three times, raising themselves upright with their hats held above their heads. Then they change their cry to 'Wee yen! way yen!' or, as some report, 'we haven!'" On a fine, still autumn evening "crying the neck" has a wonderful effect at a distance.

For a very full discussion of harvest customs see Sir J. G. Frazer, *The Golden* ***Bough.***

HARVEST BUG, the familiar name for mites of the family *Trombidiidae*. belonging to the order Acari of the class Arachnida. Harvest bugs are the six-legged larval forms of several species of *Trombicula.* They are minute, rusty-brown organisms, barely visible to the naked eye, which swarm in grass and low herbage in the summer and early autumn, and cause considerable irritation by piercing the skin, often lodging themselves in some part where the clothing is tight. They may be destroyed, and the irritation allayed, by rubbing the affected area with some insecticide like turpentine or benzine. They are not permanently parasitic, and if left alone will leave their temporary host to assume the active life characteristic of the adult mite, which preys upon minute animal organisms. In the United States they are called "chiggers."

HARVESTER. HARVEST SPIDER or HARVESTMAN, names given to arachnids'of the order Opiliones. Harvest spiders or harvestmen, so-called on account of their abundance in the late summer and early autumn, may be distinguished from all true spiders by the extreme length and thinness of their legs, and by the small size and spherical or oval shape of the body, which is not divided into two regions by a constriction. The French name *faucheurs* given to these arachnids alludes to the ability of detached legs to contract and extend in a fashion reminiscent of the mower swinging the scythe. They may be met with in a great variety of situations. They are predacious, feeding upon small insects, mites, and spiders. The males are smaller than the females, and often differ markedly from them. The male is furnished with a long protrusible penis. The sexes pair in the autumn, and the female, by means of her long, protrusible ovipositor, lays her eggs in some cleft or hole in the soil. After breeding, the parents die. The eggs hatch with the warmth of spring. The adults are provided with a pair of glands, situated one on each side of the carapace, which secrete an evil-smelling fluid believed to be protective. Harvestmen are very widely distributed and are abundant in temperate countries of both hemispheres. They are also common in the tropics. The long legs of harvestmen serve them not only as organs of rapid locomotion, but also as props to raise the body well off the ground, thus enabling the animals to stalk unmolested from the midst of an army of raiding ants. Harvester is sometimes, but erroneously, used as a synonym for harvest bug (*q.v.*). (See ARACHNIDA.)

HARVESTING MACHINERY. Each machine on the farm has its important purpose, but harvesting machines have a special place in the over-all picture because the farmer depends upon them to get his crops safely in after they have survived the hazards of drought, flood, hail, frost and pests. For the history of harvesting machinery, see FARM MACHINERY. For other types of agricultural machinery, see PLANTING MACHINERY; TILLAGE MACHINERY; CROP-PROCESSING MACHINERY. *See* also CROP DRYING AND PROCESSING.

Haymaking Machinery.—The variety of machines used is limited only by the diversity of crops grown, but many farmers grow some hay and this is usually the first harvest of the season. The first operation in making hay is to cut the grass (or legume) which will be made into hay by drying so it will keep for many months without spoiling. The grass is cut off, close to the ground, usually with a mower.

The *Mower.*—The cutting mechanism consists of a cutter bar, a long flat bar of strong steel to which slotted fingers or guards are attached to point forward, and a reciprocating knife, a thin strip of steel to which triangular steel blades or knife sections are riveted. The cutter bar runs close to the ground and the guards comb through the grass, which is cut off by the knife sections working against ledger (*i.e.*, stationary) plates mounted in the guards. The action is very similar to having many pairs of scissors mounted along the front of the cutter bar. The guards provide the scissors' action with the reciprocating knife sections and they also give some protection to the knife against stones.

The cutter bar is fastened to a frame which may be carried directly on a tractor or may be mounted on wheels and pulled by a tractor or by horses, mules, oxen or water buffalo. The reciprocating knife is usually driven by a crank and connecting rod (pitman). The crank of a horse-drawn mower is normally driven through gears from the wheels, but tractor mowers are driven by the tractor engine through a flexible drive system which permits the mower to follow the ground independently of the tractor. This drive is more satisfactory than one through the wheels, because there is no slippage and cutting can be done more rapidly.

The width of cut for horse mowers may vary from three and one-half to five feet while tractor mowers are usually six or seven feet except for a few narrower ones designed for very small tractors. As the crop is cut by the mower, it falls in a continuous swath on the ground, where it is usually left to cure until dry enough to rake for stacking or baling.

Dump Rake.—The next machine to be used depends upon whether the hay is to be stored as loose hay in a stack, stored in a haymow as loose chopped hay. or baled. If to be stacked as loose hay, the grass will be allowed to dry almost to the safe storage point in the swath and then it will be raked into windrows and bunches with a dump rake. This machine consists of a number of long, semicircular spring teeth spaced across the entire machine. They are carried at the upper end in a beam nhich, in turn, is supported by a wheel at each end. The teeth form a basket into which the hay is raked by the forward motion of the machine and which can be dumped by rotating the beam which carries the teeth.

Hay Chopper.—If the hay is to be stored loose for mow curing, the grass is raked into windrows and then picked up and chopped by a hay chopper soon after cutting. The advantage of this system is that a very fine quality hay is secured by avoiding the loss of leaves and certain food elements through field drying. The hay chopper is a form of forage harvester which will be described later under forage harvesting machines.

Side-Delivery Rake.--Often hay is baled to make it more compact and economical to handle. When this is to be done, the hay is raked from the swath into a windrow by a side-delivery rake while the moisture content is still quite high so that the leaves will not fall off too badly. The windrow is kept sufficiently loose for air circulation to continue the drying process to the point where the hay can be baled safely.

The side-delivery rake consists essentially of a rotating cylinder with spring teeth which, because of the oblique position of the cylinder in reiation to the direction of travel, rakes or rolls the hay forward and laterally until it escapes from the rake to form

a windrow. The cylinder is counterbalanced so that it can follow the contour of the ground.

Sweep Rake.—For loose hay. side-delivery rakes together with sweep rakes are sometimes used. The latter are used to gather up the windrowed hay and carry it to the stackar. The sweep rake consists essentially of a number of wooden teeth, several feet long. carried at the rear on wheels or directly by a tractor or truck. As the rake moves forward, the hay slides back onto, and collects on, the teeth, nhich are then lifted at the front for transport to the stack when the rake is full.

Loaders *and Stackers.*—For handling loose hay, loaders and stackers are also used. By means of toothed pick-up cylinders, the loader picks up the hay from the windrow and delivers it to the wagon or truck body by means of a slat-and-rope carrier or a raker-bar mechanism. Most stackers are of the overshot type. The hay is placed by a sweep rake onto a large "floor" of wooden teeth mounted on the end of a boom which is pivoted at the opposite end. A winch rotates the boom and its load of hay upward, past the vertical, and "shoots" the hay over onto the stack. The boom is then returned to its position flat on the ground for the next load.

Hay Conditioners.—These are used to accelerate the rate of drying when field curing. The machines consist of pairs of smooth rolls ahich may be of steel or rubber (to split the stems) or meshing fluted rolls (to crimp the stems) between which the swath of cut crop is passed. Splitting or breaking stems of leguminous crops allows moisture to escape quickly so that leaves and stems dry at more nearly the same rate. and drying time is cut about half.

Pick-Up Balers—Used to bale hay directly from the windrow in the field when it has been allowed to dry to safe storage moisture content, the baler has a rotary toothed pick-up mechanism. This lifts the windrow and delivers it to an auger or other feeding device which, nith the help of packer fingers or a "wadboard packer." places a charge of hay in the bale chamber on each stroke of the compressing plunger. Two twines or wires are automatically tied around a length of hay compressed into the bale chamber to form a bale. The density and length of the bale can be adjusted. Some balers are driven by power-take-off (PTO) shaft while those of greater capacity, used for custom baling. are usually driven by a gasoline engine mounted on the baler. Twine is tied in a conventional knot. "Wire-tie" machines usually twist the ends of the wires together, but both twine and wire are joined mechanically and automatically.

Hay *Pelleters.*—The next step beyond hay baling is hay pelleting in which the hay is compacted approximately eight times in place of about two and one-half times as in baling. In the late 1950s this system appeared to offer promise from the standpoint of feeding and handling efficiency but only stationary machines for the commercial pelleting of ground alfalfa were generally available.

Forage Harvesting Machines.—Grass, legumes, corn (maize) and other crops are often ensiled to keep them in a succulent and fermented state rather than in the dry condition in which they are called hay. To make silage, they must be cut up so as to permit packing in the silo sufficiently well to expel most of the air and so produce anaerobic fermentation and prevent mold formation. (See ENSILAGE.)

Almost all silage crops are now cut in the field with a forage harvester nhich cuts the crop and chops it immediately or picks up and chops a windrow which has been cut and raked earlier. Forage harvesters have a basic cutting or chopping unit consisting of rotating knives which shear the crop against a cutter bar or shear plate. The length of cut is adjusted by varying the feed speed or by changing the number of knives. The knife holder, whether it be flywheel or cylinder type, includes impeller devices which fling the chopped hay through a pipe into a wagon hauled behind the machine. In some cases the knives are shaped so as to provide the impelling action to transport the chopped material. These machines. like balers, may have a separate engine or be driven by a tractor through a PTO shaft. They usually handle one row of corn or up to seven feet of grass or legume crop.

Forage harvesters can be equipped with alternate attachments. They may have a cutter bar similar to that of a mower or combine, in nhich case the crop is chopped immediately. They may be equipped with a pick-up mechanism like that of a baler. This is used where it is wished to allow the crop to wilt or dry a little before it is chopped for ensilage or placement in the mow for curing as hay. The third attachment is a row-crop device making it suitable for harvesting corn for silage. A knife cuts the stalks close to the ground while gathering chains grasp them and carry them to the feed rolls or apron which delivers the material to the cutter wheel and meters it.

So-called economy-type forage harvesters which perform both the cutting and chopping operations are also used where acreages to be harvested are small. They consist of a stalk beater or shredder to which is fitted a blower to deliver the chopped fodder to a wagon. Beaters which have their axis of rotation parallel to the ground often use an auger to collect the chopped material from the rotor knives or hammers and carry it to the blower.

Grain Harvesting Machinery.—Grain or cereal crops are harvested when their seeds have reached maturity and have dried to some degree. The crop may be threshed as it is harvested (by a combine or reaper-thresher), in which case the grain is usually allowed to dry to a safe storage level of moisture before harvesting. If the crop is not threshed as cut it is harvested with a grain binder and left to dry in bundles, with a windrower or swather, in which case it is dried in the windrow, or with a mower with dropper or buncher attachment, to be dried in hand-tied bundles.

Grain Binder.—This is used to harvest small grains in localities where the combine harvester-thresher is unsuitable or not available. It cuts the grain, binds it and drops the bundles or sheaves on the ground singly or in bunches to be shocked or hauled for stacking or storing in the barn until threshing. The cutting mechanism is very similar to that of the mower. A slatted cylindrical reel mounted parallel to and above the knife pushes the cut grain back onto a canvas conveyer which moves it laterally to and between a pair of counter-rotating inclined canvas conveyers or elevators. These deliver the grain to the binding deck where a butter evens the butts of the cut straw, and a set of packer fingers in the binding attachment compresses the straw to form a bundle of the required size and density. A trip mechanism engages the pouer to operate the binding attachment and the knotter ties a loop of twine around the bundle before it is ejected.

When pulled by horses or other draft animals, binders secure their mechanical motions and power from a large lugged traction wheel, and cut a swath from four and one-half to eight feet wide. When pulled by tractors, they are usually PTO driven and cut from six to ten feet. Binders with special drive wheels are sometimes used for rice harvesting but have been largely replaced by combines.

Buncher.—On very small farms, grain may be harvested with a mower using a dropper attachment or buncher, a slat device mounted behind the cutter bar and permitting the operator to collect the grain in bunches for later hand tying.

Combine.—As early as 1950 practically all of the small grains, soybeans and similar crops in the western hemisphere and Great Britain were harvested by means of the combine or combined harvester-thresher. This machine cuts, threshes and cleans the grain as it moves over the field. In design, it is essentially a regular binder-type cutting device with a gathering-conveying mechanism that delivers the cut grain to a conventional thresher that has been modified to make it work satisfactorily when in motion over the fields. In combine harvesting the aim is usually to take the heads of grain with a minimum of straw. Hence, the cutting-gathering device is sometimes called the header. However, if the crop is lodged. that is, bent down, or if the straw is to be saved, the crop is cut close to the ground.

From the threshing cylinder, which rubs the grain out of the heads against a curved "concave," some of the grain and chaff goes directly to the cleaning "shoe" where sieves and a blast of air are used to separate and clean the grain. Some of the grain and chaff go with the straw to the straw deck or to walkers which serve to shake the grain from the straw. This grain too is delivered to the cleaning shoe and thence, after passing through the air blast, it drops into the clean-grain auger which conveys it to an

elevator and on into the storage tank or to the bags as the case may be. The straw drops out the back of the machine and is left in a windrow for later baling, is baled directly by a baling attachment or press, or is scattered over the ground by means of a fan-like straw spreader.

While combines were used as early as about 1875 in California and the Pacific northwest of the United States, it was not really until the 1920s and 1930s that they made themselves generally felt. They were then shown to be the only practical way to harvest soybeans and this impetus together with the introduction of the small (five and six foot cut) PTO-driven combine made them popular throughout almost the entire United States. The self-propelled combine, introduced in 1940, with its own traction power made the large combine a much more flexible unit and for large farms this machine became standard equipment. Combines became established in Great Britain during World War II when labour shortage forced their adoption and justified the auxiliary drying equipment needed in that climate. After World War II, several European combines were produced to embody cleaning and separating principles peculiar to those countries and, above all, to provide means for saving the straw, which is valued highly.

Power-take-off-driven combines cut from j to 7 ft. wide while self-propelled and pull-type machines with auxiliary engine range in size from 8 to 18 ft. On self-propelled and other large models the cut grain is gathered behind the cutter bar by a large auger which replaces the canvas conveyer used on earlier models. A chain-type conveyer carries the grain to the threshing cylinder except on some "straight-through" pull-type combines where a canvas conveyer moves the material directly from cutter bar to cylinder. V-belt and roller-chain drives are used to power the various elements of the machine and a generous use of sealed-for-life ball bearings on models appearing in the late 1950s typified the trend of the farm machinery industry toward higher standards of materials and workmanship. Combines are made with means for regulating the speed of the threshing cylinder to suit the various crops to be harvested, and self-propelled machines are usually equipped with means for fine adjustment of the travel speed to suit field and crop conditions.

Hillside combines of the self-propelled type are available for use on steeply rolling land. The body of the machine is supported in the frame by hydraulic cylinders which are automatically adjusted to keep the body level.

Pick-Up Attachments.—Combines may be fitted with pick-up attachments that mount ahead of the cutter bar. These are used to pick up, for threshing, windrows of grain that have been cut and allowed to dry for several days.

Windrow-Harvesters, *Windrowers* or Swathers.—These are used in some sections of the U.S. and Canada where weather and crop conditions at harvest time are unfavourable for direct combining of the grain. Uneven ripening of the grain. and heavy, green weed conditions both favour windrow harvesting. Green patches and green weeds both dry out in the windrow and permit satisiactory threshing, whereas if left standing until green spots and weeds were ripe, the crop might all be lost by storms and windy conditions.

Windrowers.—These consist essentially of a cutter bar with a canvas-type conveyer behind it to move the cut grain to one point and to deposit it gently on the top of the stubble so the air can circulate beneath and through it. A reel is used to push the cut grain back onto the canvas. Most windrowers are pulled by a tractor, cut a swath width up to 16 ft. and are PTO driven, but in the second half of the 20th century there appeared to be an increasing preference for self-propelled models.

Pick-Up Reels.—Used on combines and windrowers when the crop is very badly lodged or flattened by wind or due to straw weakness, these reels have rows of spring teeth in place of the usual bats. The teeth are eccentrically controlled to get under and lift the crop before it is cut, but to retract smoothly after the grain is into the header. This action is necessary to prevent the straw from wrapping on the reel.

Combines may also be fitted with corn harvesting attachments (see below).

Corn (Maize) Harvesting Machinery.—When corn is grown for grain it may be cut with a corn binder and stored in shocks while the grain dries to shelling and storing moisture. However, the usual practice is to use a mechanical corn picker which jerks or "snaps" the ears from the stalks so that only the grain and cobs are harvested. The standing stalks are guided by two shields or snouts to pass between two counterrotating rollers which pull the stalks down and through very sharply. The ears strike either a snapping bar located above the rolls or the rolls themselves and this breaks the shanks which attach the ears to the stalk. The ears then travel by means of an elevator to the husking mechanism, consisting of closely spaced, counterrotating rollers which tear the husks away. The ears are carried by means of a chain-type elevator to a trailed wagon.

Some pickers are pulled behind a tractor and are PTO driven, but most are mounted directly on a tractor, one unit on each side, to form a two-row harvester.

Picker-Shellers.—Pickers may be fitted with shelling units (see FARM MACHINERY) and are then known as picker-shellers. By shelling the corn as it is harvested, a separate operation is eliminated. Cob hauling and storage are avoided with considerable saving and the corn may be harvested early to reduce field losses. Similar advantages can be secured by equipping a combine with a corn attachment. In t is case, the combine shells and cleans the corn. The attachment consists of a two-row snapping unit similar to a picker. or of a two-row cut-off and conveying unit which delivers the whole corn plant to the combine. See also CORN.

Mechanical Cotton Harvesters.—The hand harvesting of cotton is an excessively laborious operation, which has stimulated the development of many patents on machines to do the job. In the U.S. more and more cotton was being picked mechanically in the second half of the 20th century.

Regular open-boll cotton is commonly harvested by machines which utilize rotating moistened spindles. The plants are guided between banks or drums of rapidly rotating, automatically cleaned and dampened spindles. The cotton is wrapped around the moistened spindles, to which the fibres tend to adhere, and then doffed or stripped by a special device. When barbed spindles are used a doffing wheel unrolls the cotton to get it free of the spindle. From the strippers or doffers the cotton is delivered by conveyer or suction to a large basket carried above the machine.

In some areas such as the high plains of Texas a stormproof cotton, in which the cotton is kept close within the protective boll, is grown. Strippers are used to harvest this type of cotton. The plants pass between stationary strippers or counterrotating rollers or brushes which tear the bolls from the stalks. Both cotton strippers and pickers are usually mounted on tractors. A few are self-propelled. See also COTTON AND THE COTTON INDUSTRY: Cotton Cultivation.

Potato Harvesting Machinery.—One of the simplest mechanical devices for lifting potatoes is the potato plow provided with a share to which are attached a series of rods for raising the tubers as the implement is drawn through the ground. A middle buster, or double plow with right- and left-hand bottom mounted back to back, fitted with rods as above is another simple device for this purpose. Still another consists of a flat diamond-shaped plow, for lifting the potatoes, and an agitated pivoted grate, actuated by a small star wheel underneath, which shakes off most of the earth, leaving clean potatoes lying on the surface of the ground.

More elaborate machines, designed to both raise and separate the tubers from the soil, are of two distinct types, the spinner and the elevator. The spinner type is carried on two wheels and has a broad scoop share which runs under the ridge and loosens the earth around the tubers. Immediately behind the share is the spinner, consisting of a series of forks rotating at right angles to the path of the machine. The forks, set to work at about the same depths as the share, throw the potatoes to one side, leaving them more or less in compact rows. This type is commonly used in Great Britain and Europe.

The elevator type comprises a broad share with an agitating rod-link conveyer directly behind it to carry the earth and potatoes upward and backward. As they are moved the agitation shakes a

large part of the earth free and it drops through the conveyer. At the end of this conveyer the potatoes may be dropped off onto the ground. In some they are delivered to cleaning devices and sorting tables. In these more complicated machines various mechanisms are used to prepare the potatoes for direct sacking. Rods and deflectors are used to separate the vines. Rollers may be used to move the potatoes and remove earth and small stones. Finally the potatoes move onto moving picking tables where men. riding on the machine. pick out rocks and other foreign objects before the potatoes are delivered to bags or bulk transportation. Most diggers are PTO driven and are made in one- and two-row models. The digging depth is regulated from a forward truck or gauge wheel that runs on the row.

Beet Harvesting Machinery. — In sugar beet harvesting the object is to lift the whole root from the ground, clean the earth off it and deliver it to a wagon accompanying the machine. In the process the tops, together with a small portion of the root itself. must be removed and separated from the root as it travels to the wagon. Some machines have stationary blades that lift the beets together with some earth onto a kicker-wheel cleaner-conveyer; others perform the lifting by means of two tilted wheels whose action, rolling together, lifts the beets out of the soil.

In these machines the beets are first topped by a revolving inclined disk, the cutting height of which is regulated by a finder wheel or shoe. These machines are semimounted on a tractor and lift one row at a time.

Other types of beet harvesters top the beets after they have been lifted. One of these actually lifts the beets by their tops. The second type employs a two-blade lifter to do the lifting. At the same time a large spiked wheel rolling over the beets impales them on the spikes and subsequently elevates them to a rod-chain conveyer. They are removed from the spikes by strippers after being topped by rotary disk-type knives.

A part of the U.S. beet crop and much in other beet-growing countries is lifted by hand after mechanical loosening. A subsoiler type of standard with a blade or small share projecting under the row is sometimes used. Others employ the two-blade design which straddles and lifts the beet, the device used on some complete harvesters. Some are single-row units drawn by horses; others drawn by tractors loosen several rows at a time. *See* also BEET.

Peanut Harvesting Machines. — Peanuts are an important crop and mechanical harvesting is considered essential. The tubers are usually lifted and allowed to dry for three to ten days before picking or removal from the vines. They are lifted. vines and all. with units similar to potato diggers. Side-delivery rakes may be used to windrow the vines for drying, but special shaker-windrowers that clean and windrow the vines more loosely and gently are more generally used. After drying, the threshing is done with a combine or a special peanut harvester. These employ intermeshing spike tooth cylinders or similar devices to comb the peanuts out of the vines. All peanut harvesters require stemmer saws to remove the piece of stem that remains on the peanut when it is broken from the vine. *See* also PEANUT.

Sugar Cane Harvesting Machinery. — Sugar cane is harvested by hand in those parts of the world where labour costs are very low, hut in the mainland U.S. and Hawaii it has been necessary to mechanize. Harvest of the one-year cane grown in Louisiana is not excessively difficult. The specially designed cane harvester which straddles one row cuts the cane off close to the ground, removes the useless leafy top and conveys the cut stalk or cane to an accompanying truck or wagon.

The much heavier two-year cane grown in Hawaii is far more difficult to mechanize since at harvest time it is completely lodged and tangled. .Although much effort was made in the late 1950s to develop harvesters to cut. detrash and deliver two-year cane to an accompanying truck. most such cane was harvested by means of push rakes mounted on crawler tractors which push the cane into piles to be grab-loaded onto trucks for hauling to the mill. In being pushed into piles many canes are torn up by the roots, necessitating replanting for the following crop. Much of the balance of Hawaiian cane is grab harvested. A grab. similar to a clamshell bucket, is used literally to tear the cane loose from the ground, two or three tons at a time, and load it directly into trucks. This method, too, damages the stools. or stumps, badly. Some unirrigated cane. which therefore does not grow in furrows. is harvested with a V-cutter which consists of a modified snow plow having sharp knives along the lower edges to shear off the cane, which is then pushed into windrows and bunched for grab loading. *See* also SUGAR.

HARVEY, GABRIEL (1550?–1630), English writer and a friend of Edmund Spenser, was the eldest son of John Harvey, a yeoman of considerable means and a ropemaker. In 1566 Harvey matriculated at Christ's college, Cambridge, and in 1570 received his B.A. and became. through the influence of Sir Thomas Smith, a fellow of Pembroke hall (later Pembroke college). When in 1573 he was ready to take his M.A., some students protested that he was arrogant, overcritical and inclined to defend paradoxes. The degree was conferred only after the intervention of John Young. master of Pembroke hall. The next year Harvey was appointed praelector or professor of rhetoric. and in this capacity delivered annual lectures, two of which were published. *Ciceronianus* (1577) and *Rhetor* (1577). Both works revealed the scope of Harvey's learning. his thorough knowledge of classical authors and his admiration of writings in the vernacular. On the death of Sir Thomas Smith in 1577, Harvey composed a series of Latin elegies, published as *Smithus: vel Musarum lachrymae* (1578). On July 26. 1578 Harvey disputed before Queen Elizabeth I when she visited at Audley End, Essex. There is a biased but entertaining account of this in Thomas Nashe's *Haoe With You to Saffron-Walden* (1596). Harvey himself celebrated this significant event in his career with another collection of facile Latin verse. *Gratulationes Valdinenses* (1578). His fellonship at Pembroke was not renewed, but he was elected on Dec. 18, 1578, to a new fellowship at Trinity hall. Cambridge. where he began the study of civil law.

At Pembroke Harvey had become an intimate friend of Edmund Spenser. Spenser celebrated this friendship in *Thr Shepheards Calender* (1579) through the characters of Colin Clout (Spenserj and Hobbinol (Harvey). The June eclogue in particular expresses the deep affection between them. In 1j80 appeared *Three Proper, and Wittie, Familiar Letters* containing two letters by Spenser and three by Harvey. The letters revealed that Spenser had temporarily succumbed to Harvey's advocacy of classical metres, but that authorship was not Harvey's main aim. Unfortunately for Harvey's ambitious plans. his epistles caused trouble. Cambridge demanded and received a retraction of the criticism that the university failed to honour learning and granted preferential treatment to wealthy students. Edward de Vere. earl of Oxford, at the instigation of John Lyly, interpreted personally Harvey's satire of an Italianate Englishman in "Speculum Tuscanismi." Harvey denied that the poem was an attack upon the ear!. and that he went.. as Nashe alleged, to the Fleet prison. Further humiliation was heaped on Harvey in the Latin comedy *Pedantius*, performed at Trinity college in 1581, which satirized him as. in Nashe's words, "the concise and firking finicaldo fine Schoole-master."

In 1585 he failed to be elected master of Trinity hall, and though he had completed his study of civil law, he was not admitted to the doctor's degree. In 1585, however, he became doctor of civil law at Oxford. Except for Lyly's criticism in *Pap With a Hatchet* (1589), nothing is known of Harvey's activities until 1592, when he published *Foure Letters, and Certaine Sonnets*. This pamphlet detailed accurately, but mercilessiy, the pathetic death of Robert Greene and replied to the indictment of himself and his brothers John and Richard in Greene's *A Quip for an Upstart Courtier* (1592) and Nashe's *Pierce Penilesse* (1592). The origins of this dispute are hidden in mysterious animosities, undoubtedly including the attack on "Speculum Tuscanismi" and the personal associations of the antagonists at Cambridge. Richard Harvey in *Lamb of God* (1590) had abused Nashe as a "piperly makeplay or makebate." but unaccountably the latter did not reply for two

years. Then Harvey and he carried on a lengthy fliting, in Nashe's *Strange Newes* (1592) and *Have With You to Saffron-Walden* and in Harvey's *Pierces Supererogation* (1593) to ivhich he appended a reply to Lyly written four years earlier. Both writers were evidently at the time in the employ of stationers, Nashe with John Danter and Harvey with John Wolfe; and since neither appeared enthusiastic to prolong the feud, it is plausible that the controversy was artificially stimulated by printers interested in sales. It was officially terminated in 1599 when the archbishop of Canterbury ordered the satires of the two men burned.

In 1598 Harvey petitioned Sir Robert Cecil to be elected master of Trinity hall; once again he was not appointed. About this time, or earlier, he retired to Saffron Walden. In 1608 his sister, Mary Collins, instituted a legal suit against him. On his mother's death in 1613 he evidently succeeded to his inheritance, and died in Saffron Walden in 1630. The picture posterity has of Harvey is based on Nashe's devastating burlesque, and on his malicious account of Greene's death. Though Harvey was sometimes tasteless and certainly pompous, he should be judged neither by his books, since he came into print reluctantly, nor by his desire to introduce hexameters into English. His marginalia in the books he read, many of which are extant, demonstrate that rather than a pedant, he was, like Francis Bacon, a man who made all learning his province.
