HUMAN **RIGHTS.** One of the main purposes of every legal system is to protect the individual against oppression. Ordinarily the rights of individuals are protected on the local level; in federations there is, in addition, federal machinery for their protection. In some cases. if no protection can be found domestically, recourse may be had to appropriate international institutions.

History.— The first international rules and procedures for the protection of human rights were developed in order to protect foreigners against abuse by local authorities. Many international tribunals and claims commissions throughout the 19th century established certain minimum standards for all nations to follow in the treatment of aliens. If a citizen of one nation suffers an injury because of a violation of one of these standards by the government or an official of another nation, the violating nation has a duty to pay reparation to the alien's nation.

A series of treaties concluded after World War I imposed upon several European countries special obligations for the protection of racial, religious and national minorities, and authorized the League of Nations to supervise the execution of these obligations. *(See* MINORITIES.)

While international law does not usually deal with relations between a country and its citizens, this rule ceases to apply when a nation's treatment of its population violates the dictates of humanity and justice or shocks the conscience of mankind. Thus, in the course of the 19th century. trade in African slaves came to be generally condemned and following the massacre of minorities in the middle east various remedial measures were taken by western nations. It was, however, the ruthless tyranny of the Nazi regime and the wholesale slaughter by the Germans of minorities and inhabitants of occupied territories that brought about a widespread insistence that human rights must be internationally protected.

Charter of the United Nations.— At the San Francisco conference of 1945, many delegations urged the inclusion of provisions concerning human rights in the charter of the United Nations; some proposed even that a detailed declaration of essential human rights be appended to the charter. While the latter proposal was sidetracked on the ground that such a declaration required careful drafting and there was no time for it at the conference, the charter did contain seven specific references to human rights.

The preamble to the charter reaffirms faith in "fundamental human rights." and art. 1 lists among the purposes of the United Nations: "To achieve international cooperation . . . in promoting and encouraging respect for human rights and for the fundamental freedoms for all without distinction as to race, sex, language or religion"; similar provisions are contained in the additional statements of purposes in art. 55 and 76 of the charter, which deal, respectively, with economic and social co-operation and trusteeship. The general assembly was empowered to initiate studies and make recommendations for the purpose of "assisting in the realization" of these rights and freedoms; and the Economic and Social council was authorized to make recommendations for the purpose of "promoting respect for. and observance of" these rights and freedoms and to set up a special commission "for the promotion of human rights" (art. 13. 62 and 68).

Finally, all members pledged themselves "to take joint and separate action in cooperation with the organization for the achievement" of "universal respect for, and observance of, human rights and fundamental freedoms for all without distinction as to race, sex, language or religion" (art. 55 and 56).

It may be noted that none of these provisions defined in precise terms the meaning of the phrase "human rights and fundamental freedoms." and that the task of the United Nations was limited to "promoting" and "encouraging" respect for, and observance of, these rights and freedoms. Consequently, it was argued that these provisions did not create any definite obligations and that the United Nations might not enforce them until they had been properly defined by supplementary instruments. It became important therefore to prepare such a definition immediately, and the United Nations Commission on Human Rights was entrusted with the preparation of two separate instruments: a declaration of general principles and a treaty containing binding obligations (the so-called Covenant on Human Rights).

Universal Declaration of Human Rights.— The declaration completed by the commission in June 1948 was adopted, after a few changes, by the general assembly at its Paris session on Dec. 10. 1948, by unanimous vote (the six members of the Soviet bloc and Saudi Arabia and the Union of South Africa abstained). The declaration was proclaimed by the assembly as "a common standard of achievement for all peoples and all nations, to the end that every individual and every organ of society, keeping this Declaration constantly in mind, shall strive by teaching and education to promote respect for these rights and freedoms and by progressive measures, national and international, to secure their universal and effective recognition and observance."

The declaration contained general definitions not only of those principal civil and political rights recognized in democratic constitutions, but also of several so-called economic, social and cultural rights. To the first group belong such rights as: life. liberty and the security of person; freedom from arbitrary arrest, detention or exile; right to a fair and public hearing by an independent and impartial tribunal; freedom of thought, conscience and religion; and freedom of peaceful assembly and association. Among the new items in the declaration were: right to social security; right to work; right to education; right to participate in the cultural life of the community; and right to enjoy the arts and to share in scientific advancement and its benefits.

Effect of the Charter and the Declaration.— The effect of the declaration is not entirely clear. On the one hand Charles Malik of Lebanon, one of its chief draftsmen, stated that the principles embodied in the declaration represent "what my government pledged itself to promote, achieve and observe" when it signed the charter, and that "the declaration continued and in a way supplemented the charter, and could not therefore be considered a mere resolution." (United Nations. *These Rights and Freedoms,* p. 15 (1550); General Assembly, *Official Records of the Third Session,* pt. ii, "General Committee," p. 32.) On the other hand, another of its authors, Mrs. Franklin D Roosevelt (United States), expressed the view that the declaration "is not a treaty; it is not an international agreement. It is not and does not purport to be a statement of law or oi legal obligation." The middle view would seem to be that the declaration, though not a binding instrument itself, makes more precise the obligations previously contracted in the charter.

Whether the charter itself has any binding force within the nations which are members of the United Nations, and whether its effect was strengthened by the adoption of the declaration, were also disputed points. In *Sei Fujii* v. *California* (38 Cal. 2d 718, 242 p.2d 617, 1952), the supreme court of California held that the charter and the declaration were not self-executing and that they could not therefore invalidate the California Alien Land law which forbade the acquisition of land by aliens. (The court held the law invalid, however, on other grounds.)

On the other hand, the general assembly considered that the charter obliged members to "promote" human rights and condemned those who violated such rights. It held, for instance, that certain legislative acts of the Union of South Africa were "contrary to the charter and the Universal Declaration of Human Rights" (resolution 719 [viii] of 1953); and that measures taken

by the Soviet Union to prevent Russian wives of citizens of other nationalities from leaving the union with their husbands were "not in conformity with the charter" (resolution 285 [iii] of 1949).

Covenants on Human Rights.—To ensure further the enforcement of national obligations with respect to human rights, the UN general assembly requested the Commission on Human Rights to prepare in treaty form two covenants, one dealing with civil and political rights and the other with economic, social and cultural rights. While the primary purpose of both covenants was to spell out in great detail the rights outlined in the declaration, they were intended also to provide more effective enforcement. For instance, nations accepting the covenant on civil and political rights would be obliged to adopt such legislative measures as might be necessary to give effect to the rights recognized in that covenant; and to ensure that any person whose rights were violated should have an effective remedy and that the competent authorities should enforce such remedies when granted. On the other hand, a party to the covenant on economic, social and cultural rights would be bound only to take steps to the maximum of its available resources, with a view to achieving progressively the full realization of the rights recognized in that covenant. Many difficulties were encountered in the drafting of the two covenants.

Protection of Human Rights in Europe.—Enforcement of human rights does not depend solely on the United Nations. Under the auspices of the Council of Europe, for instance. the nations of western Europe put into force the European Convention on Human Rights of Nov. 4, 1950 (together with a supplementary protocol of March 20, 1952). A European court of human rights was established in 1959 to enforce this convention, and individuals were allowed to bring complaints in the form of petitions to a European commission of human rights. Effective measures were thus provided for direct international protection of human rights.

HUMAYUN (1508–1556), Mogul emperor of Delhi, succeeded his father, Baber, in India in 1530, while his brother Kamran obtained the sovereignty of Kabul and Lahore. Humayun was thus left in possession of his father's recent conquests, which were in dispute with the Indian Afghans under Sher Shah, governor of Bengal. After ten years of fighting, Humayun was driven out of India and compelled to flee to Persia through the desert of Sind, where his famous son, Akbar the Great, was born in the petty fort of Umarkot (1542). Sher Shah was killed at the storming of Kalinjar (1545); and Humayun, returning to India with Akbar, then only 13 years of age, defeated the Indo-Afghan army and reoccupied Delhi (1555). India thus passed again from the Afghans to the Moguls, but six months afterward Humayun was killed by a fall from the parapet of his palace (1556) and left his kingdom to Akbar. The tomb of Humayun is one of the finest Mogul monuments in the neighbourhood of Delhi.

See S. Ray, *Humayun in* Persia, Royal Asiatic Society of Bengal monograph series, vol. 6 (Calcutta, 1948).

HUMBER, an estuary on the east coast of England between the counties of Yorkshire and Lincolnshire and forming the outlet of the Ouse and Trent rivers. It consists of two sections, one running east for 18 mi. and a second southeast for 19 mi. to the North sea. The first is clearly the submerged course of a river which had cut its way across the chalk ridge near Hessle and entered the sea in Bridlington bay. The lower Humber follows a channel excavated by melt water through glacial deposits at a late stage in the Ice Age. The waters of the Humber are notoriously muddy, and much deposition is taking place along its shores, material washed southward from the clay cliffs of the Holderness coast being carried inland by the flood tide and dropped at slack water. The deep-water channel swings from shore to shore through the mud shoals. and its close approach to the north bank fixed the site of Kingston upon Hull as its major port. Grimsby (on the south bank) is less well placed in this respect, as the main channel is there well offshore. It comes closer at the coal port of Immingham, a few miles farther inland but also on the south bank. Goole, at the mouth of the Ouse and west of the Trent mouth, can be reached by a 22-ft. dredged channel and is the terminal of the Aire and Calder canal system which links Goole with Leeds and other west Yorkshire centres. In 1955 a wildfowl refuge of about 20 sq.mi. of water and tidal flats was made on the Humber to protect the roosting area of the pinkfoot geese. (T. HER.)

HUMBERT I (UMBERTO RANIERI CARLO-EMANUELE GIOVANNI-MARIA FERDINANDO EUGENIO) (1844–1900), king of Italy, son of Victor Emmanuel II and Adelaide, archduchess of Austria, was born at Turin, capital of the kingdom of Sardinia, on March 14, 1844. He had some education in constitutional law from the celebrated jurist P. S. Mancini, but for the most part he received the usual severe and rigid military education of his house. All his life he was first and foremost a soldier. Ignorant and untutored in all matters of culture, his early training left him predisposed toward the authoritarian and imperialist policy of a minister such as Francesco Crispi. Entering the army on March 14, 1858, as a captain, he was present at Solferino in 1859, and in 1866 commanded a division at Custozza. In April 1868 he married his cousin Margherita Teresa Giovanna, princess of Savoy, so carrying one stage farther the unwise tendency of his family toward intermarriage. On Nov. 11, 1869, Margherita gave birth to Victor Emmanuel, prince of Naples, afterward Victor Emmanuel III of Italy.

Ascending the throne on the death of his father (Jan. 9, 1878), Humbert adopted the style "Humbert I of Italy" instead of Humbert IV. The same sensible policy of making the monarchy more Roman and less Piedmontese led him to go against his father's wishes and bury the body of the *re galantuomo* at Rome in the Pantheon and not in the royal mausoleum of Superga. He himself always spoke with a strong Piedmontese accent, and indeed preferred to use not Italian but his own northern dialect, but he did much more than his parents to visit other areas of Italy and come in contact with other classes than the narrow court aristocracy; for a time he even lived in Naples, and there his son was born. Just after his accession, on entering Naples (Nov. 17, 1878), he was attacked by a fanatic named G. Passanante The king warded off the blow with his sabre, but Benedetto Cairoli, the prime minister, in attempting to defend him, was severely wounded.

Compared with the reigns of his grandfather, Charles Albert, and of his father, Victor Emmanuel, the reign of Humbert was tranquil, at least in its early years. Despite his father's great popularity, a popularity to which the less colourful character of Humbert could never aspire, there was a strong antimonarchical opposition which was inherited by the new king. On the left were the republicans and near-republicans who derived from Mazzini and Garibaldi; on the right were the clericals who were completely unreconciled to the Italian capture of Rome and the Papal States in 1870. Humbert maintained a firm attitude toward the Vatican and repeatedly asserted Italy's right to permanent possession of the Holy City. He and Queen Margherita did their best, with moderate success, to set up a sociable court life in Rome such as had been lacking in the previous reign, and so to win over Catholic society to the new order. Margherita was a strong and ambitious personality, indeed the only uncontestably regal character in modern Italian history. Although much neglected by her husband, she had a strong influence over him, and used this influence to make the monarchy a powerful ally in politics of the conservative right.

The royal prerogative was allowed special play in foreign policy and in the appointment of a foreign minister. Humbert approved the conclusion of the triple alliance, and in repeated visits to Vienna and Berlin established and consolidated the pact. He also refused to let his governments reduce the money spent on armaments. Latterly he tried to override parliament in his choice of prime ministers and became associated with a harsh policy of ruling by martial law. At one point the premiership and five ministries were in the hands of generals or admirals who had a sworn al-

legiance to the king personally. This was met by a dangerous upsurge of republicanism, and on July 29, 1900, Humbert was assassinated at Monza by the anarchist G. Bresci. (D. M. SH.)

HUMBLEBEE: *see* BUMBLEBEE.

HUMBLE PETITION AND ADVICE. This was a constitution devised by the second parliament of the English Protectorate (1656) to replace the Instrument of Government (*q.v.*). It was inspired by resentment at the rule of the major generals and marked a further return toward the ancient constitution. In its original form (March 1657) it offered the title of king to the protector, Oliver Cromwell, but this he refused after much hesitation. In its final form, with the modifications introduced by the Additional Petition and Advice (June 1657), it left him the title of lord protector, with power to name his successor. It vested authority in the protector, a privy council and a parliament of two houses, and gave the government an annual revenue of £1,300,000 of which £1,000,000 was assigned to the upkeep of the army and navy. Parliament was to meet at least once in every three years. Those who had abetted the rebellion in Ireland, who professed the Roman Catholic religion or who had fought against parliament and had not afterward given good testimony of their affection to the commonwealth were excluded from sitting in either house and from voting in the elections for the commons. No one elected to the commons was to be excluded except by a decision of the house itself. The "other house" was to consist of from 40 to 70 members nominated by the protector. The 21 members of the privy council were to be approved by both houses of parliament, whose approval was also required for the dismissal of a councilor and for appointments to most of the great offices of state. The control of the standing forces by land and sea was shared between the protector and parliament or, when parliament was not sitting, between protector and council; and the treasury was to account to parliament for the £1,000,000 allotted to these forces. The revenue of £1,300,000 per annum was not to be altered, nor were any other taxes to be raised, without consent of parliament. Finally, protector and parliament were to agree upon and "recommend" to the people a confession of faith "according to the rule and warrant of the scriptures"; but religious toleration was promised to all, with the serious qualification "that this liberty be not extended to Popery or Prelacy or to the countenancing such who publish . . . blasphemies or practise or hold forth licentiousness or profaneness under the profession of Christ." (R. B. WM.)

HUMBOLDT, ALEXANDER (FRIEDRICH HEINRICH ALEXANDER) BARON VON (1769–1859), German naturalist and traveler, was born at Berlin, on Sept. 14, 1769, son of a major in the Prussian army. His education devolved upon his mother, who was left a widow in 1779. His researches into the vegetation of the mines of Freiberg led to the publication in 1793 of his *Florae Fribergensis Specimen;* and the results of prolonged experiments on the phenomena of muscular irritability, then recently discovered by L. Galvani, were contained in his *Versuche über die gereizte Muskel- und Nervenfaser* (Berlin, 1797), enriched in the French translation with notes by Johann Blumenbach.

In 1794 he was admitted to the intimacy of the famous Weimar coterie, and contributed (June 1795) to Johann Schiller's new periodical, *Die Horen,* a philosophical allegory entitled *Die Lebenskraft, oder der rhodische Genius.* In 1790 he visited England with Georg Forster, the companion of Cook on his second voyage. In 1792 and 1797 he was in Vienna; in 1795 he made a geological and botanical tour through Switzerland and Italy. Meanwhile he had been appointed assessor of mines at Berlin, in 1792. He rapidly rose to the highest post in his department, and was entrusted with important diplomatic missions. After the death of his mother in 1796 he severed his official connections, to fulfill his desire to travel. He left for Marseilles with Aimé Bonpland, the botanist. hoping to join Napoleon in Egypt, but the two travelers eventually went to Madrid, where the unexpected patronage of the minister d'Urquijo determined them to make Spanish America the scene of their explorations.

They sailed in the "Pizarro" from Corunna, in 1799, stopped six days at Teneriffe for the ascent of the peak, and landed at Cumana. There Humboldt observed, on the night of Nov. 12–13, that meteor shower which forms the starting point of our knowledge of the periodicity of the phenomenon; thence he proceeded with Bonpland to Caracas; and in 1800 he left to explore the course of the Orinoco. He covered in four months 1,725 mi. of wild and uninhabited country, established the existence of a communication between the water systems of the Orinoco and Amazon and the exact position of the bifurcation. On Nov. 24 the two friends set sail for Cuba, and after a stay of several months regained the mainland at Cartagena. Ascending the Magdalena and crossing the Cordilleras, they reached Quito on Jan. 6, 1802. They made the ascent of Pichincha and Chimborazo, and an expedition to the sources of the Amazon en route for Lima. At Callao Humboldt observed (*c.* Nov. 9) the transit of Mercury, and studied the fertilizing properties of guano. the introduction of which into Europe was mainly due to his writings. After a year spent in Mexico, and a short visit to the United States, they returned (1804) to Europe.

In this expedition Humboldt laid the foundation in their larger bearings of the sciences of physical geography and meteorology. By his delineation (in 1817) of isothermal lines, he suggested the idea and devised the means of comparing the climatic conditions of various countries. He first investigated the rate of decrease in mean temperature with increase of elevation above the sea level, and afforded, by his inquiries into the origin of tropical storms, the earliest clue to the detection of the more complicated law governing atmospheric disturbances in higher latitudes; while his essay on the geography of plants was based on the then novel idea of studying the distribution of organic life as affected by varying physical conditions. His discovery of the decrease in intensity of the earth's magnetic force from the poles to the equator was communicated (Dec. 7, 1804) to the Paris institute. His services to geology were mainly based on his study of the volcanoes of the new world. He showed that they fell naturally into linear groups, presumably corresponding with vast subterranean fissures; and by his demonstration of the igneous origin of rocks previously held to be of aqueous formation, he contributed largely to the elimination of erroneous views.

After a short trip to Italy with Joseph Gay-Lussac to investigate the law of magnetic declination. and a sojourn of two and a half years in Berlin. he settled (1808) in Paris for the purpose of securing the scientific co-operation required for the arrangement of the material he had collected on his travels. This colossal task occupied him for 21 years, and even then remained incomplete. With the exception of Napoleon Bonaparte, he was the most famous man in Europe. Academies, both native and foreign, were eager to enroll him among their members. Frederick William III of Prussia gave him a court sinecure. He refused the appointment of Prussian minister of public instruction in 1810. In 1814 he accompanied the allied sovereigns to London. Three years later he was summoned by the king of Prussia to attend him at the congress of Aix-la-Chapelle. Again in the autumn of 1822 he accompanied the king to the congress of Verona, proceeded to Rome and Naples and returned to Paris in the spring of 1823.

In Paris Humboldt found scientific sympathy, and the social stimulus which his mind craved. When at last he received a summons to join the court at Berlin he obeyed regretfully. He never ceased to rail against the bigotry without religion, aestheticism without culture and philosophy without common sense, which he found dominant in Berlin. At first he sought relief from the "nebulous atmosphere" of his new abode by frequent visits to Paris; but as years advanced his excursions were reduced to accompanying the monotonous oscillations of the court between Potsdam and Berlin. On May 12, 1827. he settled permanently in the Prussian capital, where his first efforts were directed toward the investigation of the nature and law of "magnetic storms"—a term invented by him to designate abnormal disturbances of the earth's magnetism. His appeal to the Russian government in 1829 led to the establishment of a line of magnetic and meteorological stations across northern Asia; while his letter to the duke of Sussex, then (April 1836) president of the Royal society, secured for the undertaking the wide basis of the British dominions. Thus that scientific conspiracy of nations which is one of the noblest

fruits of modern civilization was by his exertions first successfully organized.

In 1811, and again in 1818, projects of Asiatic exploration were proposed to Humboldt, first by the Russian, and afterward by the Prussian government; but it was not until he had entered upon his 60th year that he resumed his early role of a traveler. Between May and Nov. 1829 he with Gustav Rose and C. G. Ehrenberg, traversed the Russian empire from the Neva to the Yenesei, traveling 9,614 mi. in 25 weeks. The journey was too rapid to be profitable. Its most important fruits were the correction of the prevalent exaggerated estimate of the height of the central Asian plateau, and the discovery of diamonds in the gold washings of the Ural.

Between 1830 and 1848 Humboldt was frequently sent on diplomatic missions to the court of Louis Philippe, with whom he always maintained cordial personal relations. The death of his brother. Wilhelm von Humboldt (*q.v.*), saddened the later years of his life. After the accession (1840) of Frederick William IV, Humboldt was more and more in demand at court, and was much hindered in his own work.

The first two volumes of the *Kosmos,* the great work of his life, were published, and in the main composed, between 1845 and 1847, the third and fourth between 1850 and 1858; a fifth appeared posthumously in 1862. The idea of a work which should convey not only a graphic description but an imaginative conception of the physical world—which should support generalization by details, and dignify details by generalization—had first taken shape in lectures in 1827–28. These formed. as his biographer expresses it, "the cartoon for the great fresco of the *Kosmos,*" and cover the whole scientific knowledge of the time. The supreme and abiding value of his work consists in its faithful reflection of the mind of a great man.

In 1857 Humboldt had a stroke. He died on May 6, 1859. Humboldt's early zeal for the improvement of the condition of the miners in Galicia and Franconia, his consistent detestation of slavery, his earnest patronage of rising men of science, bear witness to the large humanity which formed the groundwork of his character. The faults of his old age are shown in his letters to Varnhagen von Ense. The chief of these was his habit of smooth speaking, almost amounting to flattery, which contrasted with the caustic sarcasm of his confidential utterances. After every deduction has been made Humboldt was a great representative of the scientific side of the culture of his country.

The *Voyage aux régions équinoxiales du Nouveau Continent, fait en 1799–1804, par Alexandre de Humboldt et Aimé Bonpland* (Paris, 1807, etc.), consisted of 30 vol., and comprised subordinate but important works. Among these may be enumerated *Vue des Cordillères et monuments des peuples indigènes de l'Amérique,* 2 vol. folio (1810); *Examen critique de l'histoire de la ge'ographie du Nouveau Continent* (1814–34); *Atlas géographique et physique du royaume de la Nouvelle Espagne* (1811); *Essai politique sur le royaume de la Nouvelle Espagne* (1811); *Essai sur la géographie des plantes* (1805, now very rare); and *Relation historique* (1814–25), an unfinished narrative of his travels, including the *Essai politique sur l'île de Cuba.* The *Nova genera et species plantarum,* 7 vol. folio (1815–25), containing descriptions of above 4,500 species of plants collected by Humboldt and Bonpland, was mainly compiled by C. S. Kunth; J. Oltmanns assisted in preparing the *Recueil d'observations astronomiques* (1808); G. Cuvier, P. Latreille, A. Valenciennes and Gay-Lussac co-operated in the *Recueil d'observations de zoologie et d'anatomie comparée* (1805–33). Humboldt's *Ansichten der Natur* (Stuttgart and Tiibingen. 1808) went through three editions in his lifetime, and was translated into nearly every European language. The results of his Asiatic journey were published in *Fragments de géologie et de climatologie asiatiques,* 2 vol. (1831), and the *Asie centrale,* 3 vol. (1843)—an enlargement of the earlier work.

The publication of his *Briefe an Varnhagen von Ense* (Leipzig, 1860) was followed by *Briefwechsel mit einem jungen Freunde* (Berlin, 1861); *Briefwechsel mit Heinrich Berghaus,* 3 vol. (Jena, 1863); *Correspondance scientifique et littéraire,* 2 vol. (Paris, 1865–69); "Lettres à Marc-Aug. Pictet," published in *Le Globe,* tome vii (Geneva, 1868); *Briefe an Bunsen* (Leipzig, 1869); *Briefe zwischen Humboldt und Gauss* (1877); *Briefe an seinen Bruder Wilhelm* (Stuttgart, 1880); *Jugendbriefe an W. G. Wegener* (Leipzig, 1896); besides some other collections of less note. An edition of Humboldt's principal works was published in Paris by T. Morgand (1864–66). *See* also Karl Bruhns (and others), *Alexander von Humboldt, eine wissenschaftliche Biographie,* 3 vol. (1872, with bibliography, Eng. trans. by Lassell, 1873); Karl von Baer, *Bulletin de l'acad. des sciences de St.-Pétersbourg,* xvii, 529 (1859); R. Murchison, *Proceedings, Geog. Society of London,* vi (1859); L. Agassiz, *American Jour. of Science,* xxviii. 96 (1859); *Proc. Roy. Society,* x, xxxix; 4. Quetelet. *Annuaire de l'acad. des sciences,* p. 97 (Brussels. 1860); J. Madler, *Geschichte der Himmelskunde,* ii, 113; J. C. Houzeau, *Bibl. astronomique,* ii, 168. (A. M. C.; X.)

HUMBOLDT, WILHELM VON, BARON (1767–1835), German philologist, diplomat and man of letters, who mas the first to state clearly that the character and structure of a language express the inner life and knowledge of its speakers and that languages differ from one another in the same way and to the same extent as those who use them. He was born at Potsdam on June 22, 1767, the elder brother of Alexander von Humboldt. After studying at Berlin, Gottingen and Jena, in the last of which places he formed a close and lifelong friendship with Schiller, he married Karoline von Dacheroden, and in 1802 was appointed by the Prussian government first resident and then minister plenipotentiary at Rome. While there he published a poem entitled *Rom.* His critical essay on Johann Wolfgang von Goethe's *Hermann und Dorothea,* published in 1799, had already placed him in the first rank of authorities on aesthetics, and, together with his family connections, had much to do with his appointment at Rome. In the years 1795 and 1797 he had brought out translations of several of the odes of Pindar, which were also held in high esteem. On quitting his post at Rome he was made councillor of state and minister of public instruction. (*See* EDUCATION, HISTORY OF: *Germany.*) He soon, however, retired to his estate at Tegel, near Berlin, but was recalled and sent as ambassador to Vienna in 1812.

In 1813, as Prussian plenipotentiary at the congress of Prague, he was instrumental in inducing Austria to unite with Prussia and Russia against France; in 1815 he was one of the signatories of the capitulation of Paris, and drafted the treaty between Prussia and Saxony, by which Prussian territory was largely increased. In 1816 he was at Frankfurt, but was summoned to London in the midst of his work, and in 1818 had to attend the congress at Aix-la-Chapelle. The reactionary policy of the Prussian government made him resign his office of privy councillor and give up political life in 1819; and from that time forward he devoted himself solely to literature and study.

In 1816 he had published a translation of the *Agamemnon* of Aeschylus, and in 1817 corrections and additions to J. Adelung's *Mithridates,* that famous collection of specimens of the various languages and dialects of the world. Among these additions that on the Basque language is the longest and most important, Basque having for some time specially attracted his attention. Wilhelm von Humboldt introduced Basque to the notice of European philologists, and made a scientific study of it possible. He visited the Basque country itself, the result of his visit being the valuable "Researches Into the Early Inhabitants of Spain by the Help of the Basque Language" (*Prüfung der Untersuchungen über die Urbewohner Hispaniens vermittelst der vaskischen Sprache,* 1821). Another work on what has sometimes been termed the metaphysics of language was published in 1828 under the title of *Über den Dualis.*

The great work of his life, on the ancient Kawi language of Java, was interrupted by his death on April 8, 1835. The imperfect fragment was edited by his brother and J. Buschmann in 1836, and contains the introduction on "The Heterogeneity of Language and Its Influence on the Intellectual Development of Mankind," which was afterward edited and defended against H. Steinthal's criticisms by A. Pott (2 vol., 1876). This essay has been called the textbook of the philosophy of speech. Other linguistic publications of Humboldt, which had appeared in the *Transactions* of the Berlin Academy, the *Journal* of the Royal Asiatic society or elsewhere. were republished by his brother in a seven volume edition (1841–52). These volumes also contain poems, essays on aesthetic subjects and other creations of his prolific mind.

Many volumes of Humboldt's interesting correspondence with his contemporaries have been published, among them: with Schiller (1830), new ed. by A. Leitzmann (1880); with Goethe, ed. by F. Bratranek (1876); with J. R. Forster, ed. by Forster (1889); with F. H. Jacobi, ed. by A. Leitzmann (1892); with A. W. von Schlegel, ed. by A. Leitzmann (1908); with Karoline von Hum-

boldt. ed. by **A.** von Sydow, 3 vol. (1906–09); and a selection of letters to various correspondents, ed. by K. Sell (1924). A new edition of his *Gesammelte Werke,* 7 vol. (1841–52) was prepared for the Prussian Academy, 15 vol. (1903–18).

HUME, ALEXANDER (*c.* 1560–1609), Scottish poet, one of the "last of the makaris," or native Scottish poets, of the 16th century. He was the second son of Patrick Hume of Polwarth, Berwicksbire. He probably studied at St. Andrews university, spent some years in France and, after practising law in Edinburgh and trying his fortune at court, was finally ordained, becoming minister of Logie, near Stirling, in 1597. He remained there until his death, Dec. 4, 1609. He wrote a few religious tracts and published his meagre collection of poems, *Hymnes, or Sacred Songs,* "written in rude Scottish," in 1599. Although he is remembered chiefly by one poem, the evocatively descriptive "Of the Day Estivall," his autobiographical "Epistle to Maister Gilbert Mont-Crief" is an interesting early example of the genre.

See *Poems of Alexander Hume,* ed by A. Lawson for the Scottish Text Society (1902), which also contains his prose tracts; R. M. Fergusson, *Alexander Hume . . . and His Intimates* (1899). G. M.)

HUME, ALLAN OCTAVIAN (1829–1912), English ornithologist and Indian administrator, son of Joseph Hume (*q.v.*), was born on June 6, 1829, and educated at Haileybury and London university. He had a distinguished career in the Indian civil service (1849–82). After his retirement he devoted himself to furthering the aspirations of Indians. The Indian National Congress (*see* INDIA: *History*), which first met at Bombay in 1885, owes its existence to him. He was the author of several works on ornithology and presented his collections to the British museum. He died at Norwood on July 31, 1912.

See W. Wedderburn, *Allan Octavian Hume C.B.; Father of the Indian National Congress* (1913); *Allan O. Hume: a Sketch of His Life and Services to India* (1912); and **H.** V. Lovett, *A History* of *the Indian Nationalist Movement* (1920).

HUME, DAVID (1711–1776), British philosopher, historian, economist and essayist who conceived of philosophy as the inductive science of human nature. He was the younger son of Joseph Hume, the modestly circumstanced laird of Ninewells, a small estate adjoining the village of Chirnside, about nine miles distant on the Scottish side from Berwick-upon-Tweed. The family seems to have had some remote connection with the earls of Home. David's mother, Catherine, daughter of Sir David Falconer, president of the Scottish court of session, was in Edinburgh when he was born, on April 26 (Old Style), 1711. In his third year death robbed him of his father. He entered Edinburgh university when he was about 12 years old and left it at 14 or 15, as was then usual. Pressed a little later to study law (in the family tradition on both sides), he found it distasteful. read voraciously in the wider sphere of letters and, through this intensity and the excitement of intellectual discovery, had a nervous breakdown in 1729 from which it took him a few years to recover.

In 1734, after trying his hand in a merchant's office in Bristol, he took the turning-point of his life, retiring to France for three years. Most of this time he spent at La Flèche in Maine, studying and composing *A Treatise of Human Nature.* Returning to England in 1737, he set about publishing the *Treatise* (books i and ii, 2 vol., London, 1739; book iii, 1740). The negligent reception of this his first and very ambitious work depressed him, but his next venture, *Essays, Moral and Political,* 2 vol. (Edinburgh, 1741–42), won some success. Perhaps encouraged by this, he became a candidate for the chair of moral philosophy at Edinburgh in 1744. Objectors alleged heresy and even atheism, pointing to the *Treatise* for evidence. Unsuccessful, he left the city, where he had been living since 1740, and began a period of wandering: a sorry year near St. Albans as tutor to the mad marquess of Annandale (1745–46); a few months as secretary to Gen. James Sinclair (d. 1762) throughout an abortive expedition to Brittany (1746); a little tarrying in London and at Ninewells; and then some further months with General Sinclair on an embassy to the courts of Vienna and Turin (1748–49). He was earning the money that he needed to get leisure for his studies. Some fruits of these studies had already appeared before the end of his travels: namely, a further *Three Essays Moral and Political* (London, 1748) and *Philosophical Essays Concerning Human Understanding* (London, 1748), the latter a rewriting of book i of the *Treatise* (with the addition of his notorious essay "Of Miracles") and better known as *An Enquiry Concerning Human Understanding,* the title that Hume gave to it in a revision of 1758. The *Enquiry Concerning the Principles of Morals* (London, 1751) was a rewriting of book iii of the *Treatzse.*

A settled spell followed (1751–63), spent in Edinburgh, with two breaks in London. It opened with an attempt to get him appointed as successor to Adam Smith (later to be his close friend) in the chair of logic at Glasgow. The rumour of atheism prevailed again. In 1752, however. he was made keeper of the Advocates' library at Edinburgh. There, "master of 30.000 volumes," he could indulge a desire of some years to turn to historical writing. His *History of England,* extending from Caesar's invasion to 1688, came out in six quarto volumes between 1754 and 1762, preceded by *Polztical Discourses* (Edinburgh, 1752). His recent writings had begun to make him known, but these two brought him fame, abroad as well as at home: there were two French translations of the *Discourses* as early as 1754; and of the *History* a French version was begun in 1760 and a German in 1762. In this period he also produced *Four Dissertations* (London, 1757), which he regarded as a trifle, although it included a rewriting of book ii of the *Treatise* (completing his purged restatement of this work) and an able study of "the natural history of religion." In 1762 James Boswell called Hume "the greatest writer in Britain," and Rome paid him the attention of putting all his writings on the *Index* in 1761.

The most colourful episode of his life ensued: in 1763 he left England to become secretary to the British embassy in Paris under the earl of Hertford. The society of Paris accepted him, despite his ungainly figure and gauche manner. He was honoured as eminent in width of learning, in acuteness of thought and in elegance of pen, and taken to heart for his simple goodness and cheerfulness. The salons threw open their doors to him, and he was even given a distinguished reception at court. For four months in 1765 he acted as chargé d'affaires at the embassy. When he returned to London at the beginning of 1766 (to become a year later undersecretary of state there) he brought Jean Jacques Rousseau with him and found him a refuge from persecution in a country house at Wootton in Staffordshire. This pathetic genius, under one of his delusions, suspected a plot, took secret flight back to France and spread a report of Hume's bad faith (*see* ROUSSEAU, JEAN JACQUES). Hume was partly stung and partly persuaded into publishing the relevant correspondence between them with a connecting narrative (*A Concise and Genuine Account of the Dispute between Mr. Hume and M. Rousseau,* London, 1766).

In 1769, somewhat tired of public life and of England too, he established a residence (he never married) in his beloved Edinburgh again, deeply enjoying the company, at once intellectual and convivial, of friends old and new and revising the text of his writings. He issued five further editions of his *History* between 1762 and 1773 (there was also a Dublin one, perhaps without his leave) and eight editions of his collected writings (omitting the *Treatise, History* and ephemera) under the title *Essays and Treatises* between 1753 and 1772, besides preparing the final edition of this collection, which appeared posthumously (1777), and *Dialogues Concerning Natural Religion,* held back under pressure from friends and not published until 1779. His curiously detached autobiography, *The Life* of *David Hume, written by Himself* (London. 1777; the title is his own) is dated 18 April 1776. After a long illness he died in his Edinburgh house on Aug. 25, 1776, and was buried on Calton hill. Adam Smith, his literary executor, added to the *Life* a letter that concludes with his judgment on his friend as "approaching as nearly to the idea of a perfectly wise and virtuous man as perhaps the nature of human frailty will

permit." His distinguished friends, with ministers of religion among them, certainly admired and loved him, and there were younger men indebted either to his influence or to his pocket. The mob had heard only that he was an atheist and simply wondered how such an ogre would manage his dying. How he did, Boswell, who visited him in his last illness, has told us.

Place in History. — That Hume was one of the major figures of his century can hardly be doubted. So his contemporaries thought, and his achievement, as seen in historical perspective, confirms that judgment, though with a shift of emphasis. Some hints of the reasons for the assessment may be given under four heads:

As a Writer. — Hume's style was praised in his lifetime and has often been praised since; but not so much in the 20th century. It seems in retrospect to be little, if anything, more than the style of his day at a high level of competence. It lacks individuality and the pulse of variety and power. Hume's quill never becomes a wing, nor does it ever plunge into depths; and the pathetic was beyond him, for he was always proudly on guard against his emotions. The touch is light, except on slight subjects, where it is rather heavy. Yet in his philosophical works — those later than the Treatise — he gives an unsought pleasure. Here his detachment, levelness (all on one plane), smoothness and daylight clearness are proper merits. It is as one of the best writers of scientific prose in English that he stands in the history of style.

As a Historian. — Library catalogues still list Hume as "Hume, David, the Historian." Between his death and 1894 there were at least 50 editions of his History; and an abridgement, The Student's *Hume* (London, 1859; often reprinted), remained in common use for 50 years. Though now outdated, its generations of readers entitle the History to be regarded as an event of cultural importance. Moreover, in its own day it was an innovation! soaring high above its very few predecessors. It was fuller and set a higher standard of impartiality. It saw in the nation the mental interests of the educated citizens as well as the deeds of kings and statesmen, as may be seen, for instance, in the pages on literature and science at the end of ch. iii under the Commonwealth and at the end of ch. ii under James II. It was unprecedentedly readable, in structure as well as in phrasing, persons and events being woven into causal patterns that furnished a narrative with the goals and resting points of recurrent climaxes. That was to be the plan and march of future history books for the general reader. No one. however, would place Hume near to Gibbon.

As an Economist. — Hame steps forward as an economist in the Political Discourses incorporated in Essays and Treatises as part ii of Essays *Moral,* Political and Literary. How far he influenced his friend Adam Smith, 12 years his junior, remains uncertain: they have broadly similar principles and both have the excellent habit of illustrating and supporting these from history. How far he was original is also uncertain: George Berkeley's Querist (1735–37) and some of the private correspondence of the period leave the impression that there was more economic sense alive than the histories of economic thought suggest. Still, in the eliciting of general principles, in sense of evidence and in lucidity of exposition. Hume wrote ahead of his day, though. unlike Smith. whose Wealth *of* Nations he just lived to see, he did not work out a system. His level of insight can be gathered from his main contentions: that wealth consists not of money but of commodities; that the amount of money in circulation should be kept related to the amount of goods in the market (two points made by Berkeley) ; that a low rate of interest is a symptom not of superabundance of money but of booming trade; that no nation can go on exporting only for bullion; that each nation has special advantages of raw materials, climate and skill, so that a free interchange of products (with some exceptions) is mutually beneficial; and that poor nations impoverish the rest just because they do not produce enough to be able to take much part in that exchange. He welcomed advance beyond an agricultural to an industrial economy as a precondition of any but the barer forms of civilization.

As a Philosopher. — This is the essential Hume, for even outside his philosophy all his serious work is either the seed or the fruit of his conception of philosophy as the inductive science of human nature, as well as of his philosophical conclusion that man is more a creature of sensitive and practical sentiment than of reason. It is also the Hume that has been most vigorously alive since his physical death. On the continent of Europe he is seen as one of the few classical philosophers of Great Britain, with only Francis Bacon and John Locke for company. For some Germans his title to fame is that by putting the problem of causal inference devastatingly he stung Immanuel Kant into creating the "critical" philosophy. He was one of the factors that led Auguste Comte to positivism. In Great Britain he has been and remains the symbol of a cause, of a type of philosophy that must be either exalted or disgraced. The Scottish school, from its beginning in his lifetime under Thomas Reid until Thomas Brown, recoiled from his sceptical treatment of belief in causality and in a material world, and the British Hegelian idealists attacked his empiricism and naturalism generally. His positive influence is instanced in Jeremy Bentham, confessedly moved to utilitarianism by book iii of the Treatise, and more extensively in J. S. Mill. By the middle of the 20th century he was again on his pedestal, regarded by the anti-metaphysicians in England as one of the few philosophers of the past still worth reading.

PHILOSOPHY

Theory of **Knowledge.**—Hume's conclusion is that no theory of reality is possible. His way to this conclusion is in both the Treatise (book i) and the Enquiry concerning *Human Understandzng.* The custom of expositors is to follow the former. on the true ground that it is more thorough and on the questionable supposition that the latter is merely a popular version of the former. Hume himself at the end of his life vehemently repudiated the Treatzse as juvenile, avowing that only his later writings presented his considered views. A brief summary can only follow the clearer lines of the *Enquiry.*

The basis is a twofold classification of objects of awareness, both classifications being derived from Locke and the second sharpened by Leibniz. In the first place, all such objects are either "impressions." ultimate data of sensation or of internal consciousness. or "ideas," derived from the data by compounding, transposing, augmenting or diminishing. That is to say, we do not create any ideas. From this Hume. again with Locke, infers a theory of meaning: a word that does not stand directly for an impression has meaning only if it brings before the mind an object that can be gathered from an impression by one of the mental processes mentioned. In this short way he dismisses the terms of metaphysics: all talk of a realm beyond experience has no content. Secondly, all objects of awareness are either "relations of ideas" or "matters of fact." Ideas can be held before the mind simply as meanings, and their logical relations to one another can then bedetected by rational inspection. The idea of a plane triangle, for example, entails the equality of its internal angles to two right angles, and the idea of motion entails the ideas of space and time. irrespective of whether there really are such things as triangles and motions. Only on this level of mere meanings, Hume asserts. is there room for demonstrative knowledge, which (unlike Locke) he arbitrarily restricts to ideas of quantity; *i.e.,* to mathematics. Matters of fact, on the other hand, objects believed to exist, come before us merely as they are, revealing no logical relations; their properties and connections have to be accepted as they are given. That primroses are yellow, that lead is heavy and that fire burns things are facts, each shut up in itself, logically barren. Each, so far as reason is concerned, could be different: the contradictory of every matter of fact is conceivable. Therefore, any demonstrative science of fact is impossible — as Locke had said, with less crispness and less relish.

From this unoriginal basis Hume takes his own way, developing his distinctive doctrine about causality. singled out because of its importance both in natural science and in practical thinking. The idea of causality is alleged to be of a necessary connection among matters of fact. From what impression. then, is it derived? But no logically necessary relation is discoverable among matters of fact. What, then, is the nature of causal inference? The two questions are obviously intertwined.

On the first question, Hume concurs with the occasionalists, with Locke and with Berkeley in observing no causal relation among the data of the "external" senses; in his own terms, the idea of causality has no impressional source there. Locke had found this internally, in the experience of willing: here we are directly aware of putting forth power, necessitating the next event. Hume disagrees: causal power is nowhere observed, for when we regard any events as causally connected, all that we do and can observe is that they frequently and uniformly go together. Now in this sort of togetherness it is a fact that the impression or idea of the one event brings with it the idea of the other. A habitual association is set up in the mind; and as in other forms of habit, so in this one, the working of the association is felt as compulsion. This *feeling,* Hume concludes, is the only discoverable impressional source of the idea of causality: in other words, when we assert, however carefully (as in natural science), a causal connection between any two objects, the sole experience or evidenced necessitation is not in them but in the habituated mind.

The second question has already been partly answered: causal inference is not rational detection but a habit-determined movement from one object to another. But there is a residual question, namely, the movement also of belief. When we see a glass fall, we not only think of its breaking but expect and believe this, or, starting from an effect, when we see the ground to be generally wet, besides thinking of rain we believe that there has been rain. Hume claims that he was the first to investigate the nature of belief. He uses this term in the narrowed sense of belief in matter of fact, in anything as existing. Belief is not, he notes, part of the content of ideas, since if it were it would be itself an idea and could then be joined at will to any other idea. He describes it as a sort of liveliness or vividness possessed by some of the immediate objects of awareness: originally by impressions and the simple memory-images of these. How does it come to belong to certain ideas? By association. Now this is the essence of causal inference: we pass from an impression to an idea regularly associated with it. Hume confidently asserts that in the process the aspect of liveliness proper to the impression infects the idea. He is almost thinking by analogy with the communication of motion by impetus. It is an odd theory that makes belief consist in a vividness of what is thought of instead of an attitude of the thinker (one consequence of it should be that "existing" means being believed) but, taken with his view of it as transferable by association. it enables him to formulate a theory of probability. Transferred belief varies in strength with the frequency and regularity of the association. The degrees of probability are the degrees of transferred belief.

What Hume was doing falls within what we would now call the psychology of cognition: he has been trying to describe how the mind works in acquiring what passes for knowledge, or, more particularly, how it derives ideas from impressions and infers from given facts to ideas believed also to be facts. He claimed to have shown that there can be no knowledge of anything beyond experience; that reason can work only with bare meanings, not with facts. or, in other words, cannot infer anything from any facts. since no particular causal law, nor the general law of causality (that every event has a cause), nor the law of uniformity (that every cause always has the same effect) has a shred of logic in it; that causality can be known only as a feeling attending frequent and regular association; and that causal inference is merely such association. What he has not claimed to prove is that the propositions (1) that events themselves are causally related and (2) that they will be related in the future in the same ways as they were in the past are false. He firmly believed both these propositions and insisted that everybody else does, will continue to do and must do in order to survive. They are natural beliefs, inextinguishable propensities (here Hume slips back into taking belief as an attitude) of our nature, madness apart. What he has claimed to prove is that they are not got and cannot be illuminated either by empirical observation or by reason whether intuitive or inferential. Reflection shows that there is no evidence for them and shows also both that we are bound to believe them and that it is sensible or sane to do so. This is Hume's scepticism: it is an affirmation of that tension. a denial not of belief but of evidence. Some of our knowledge of what exists is merely given, the rest of it is not logically inferred, yet it is believed and deserves to be believed. He was fond of saying that we should be grateful to nature for giving us the knowledge we need through "a species of instinct or mechanical power" (association) instead of leaving us to so narrow a faculty as reason.

In the *Treatise* (book i) the arguings of the *Enquiry* had proceeded with divagations and applications which do indeed exhibit Hume's flair for seeing problems and his acuteness in following them out (making it a fertile textbook for students) but leave the reader wondering where Hume stands. The *Treatise* is badly constructed, in parts over-subtle, confusing because of ambiguity in important terms (especially "reason") and marred by willful extravagance of statement and rather theatrical personal avowals. His mature condemnation of it was only severe, not misplaced. Since, however, that single book i has been more read in academic circles than any other of his writings, a summary must be given of its treatment of some topics that are omitted from. or merely hinted at, in the *Enquiry.* First, on the relation of the impressions of the "external" senses to reality, Hume, convinced by the current doctrine that such impressions are all within the sensing mind, rejects as fruitless all attempts to argue from them to continuing material things outside the mind: the sensations are our ultimates; and the theories that pretend to justify our belief in an external world are incoherent and unverifiable, whereas the belief itself is indispensable for practice and in fact ineradicable. Secondly, he continues Berkeley's polemic against the possibility of abstract ideas and general entities and (at much length) against the infinite divisibility of space and time. Thirdly, the idea of substance, as something underlying, producing and holding together all the observable properties of a thing, is discarded. Locke had exposed the extreme thinness of the idea of material substance; Berkeley had dismissed it as empty; Hume dismissed along with it the idea of mental substance. As for a self, if there is one it should be observable, but nothing is observable except particular and momentary impressions and ideas. A mind is known only as a "bundle" of punctual experiences; we suppose it to be a unity because of the felt smoothness of the transitions which imagination effects from point to point. In an appendix published a year later (at the end of book iii) Hume frankly condemns as one-sided his treatment of the problem of the self, summarizes the opposite side as equally cogent and claims the right of a sceptic to leave the matter there. He never returned to it in print. Once more he finds critical reflection at variance with itself. Surprisingly. in book ii, on the "passions," he openly uses the idea of a self: and in book iii he seems to take it for granted.

Theory of Morals.—When Hume passes from the study of knowing to the study of living, another character seems to come into play. He is still whittling down the pretensions of reason, but no longer enjoying the business of displaying reason as divided against itself. He writes as a man having the same engagements as his fellows, anxious both to elucidate and to defend them. The subject occupies book iii of the *Treatise,* more than half of the space being given to justice. The substance of the book was re-expressed in a more balanced form in the *Enquiry concerning the Principles of Morals.* If we take his confession about this two years later, "I have a partiality for that work," and his judgment at the end of his life, "Of all my writings incomparably the best," along with many other indications in his *History,* essays and letters: we may well suspect that he regarded himself chiefly as a moralist.

The total evidence strongly suggests that the traditional view of his character (a detached scoffer, everywhere a sceptic) and of his ruling purpose (desire for literary fame) is deeply wrong. The priority of his moral interest has been shown by N. K. Smith to provide an illuminating clue to some of the glaring inconsistencies within the *Treatise* as a whole.

In ethics Francis Hutcheson is Hume's general guide, behind whom stands the 3rd earl of Shaftesbury. and the impress of

Joseph Butler is evident: but he achieves, as in his theory of knowledge, a striking originality. He keeps to his rule of studying what human nature can be observed to be. Defining morality as those qualities that are approved (1) in whomsoever they happen to be and (2) by virtually everybody, he sets himself to discover the broadest grounds of the approvals. He finds them, as he found the grounds of belief, in "feelings," not in "knowings." No single *summum bonum* or single faculty of moral reason or sense, or single moral propulsion, emerges, but four types of human merit and four corresponding "moral sentiments." Qualities are valued either for their utility or for their agreeableness, in each case either to their owners or to others.

Utility or usefulness means the fitness or natural tendency of anything to serve an end, if the end is regarded as good. Hume takes special pains to prove that justice—still taken in Locke's sense as the honouring of property-rights—owes its merit entirely to its "public utility"; *i.e.*, to its being conducive to the weal of society. It might be rhetorically, but is not scientifically ultimate: it is not to be set among the original biases which Hume is trying to track down as the general sources of behaviour and judgment. It cannot be original because property is not; because it would be unrequired if nature's bounty were so great that everybody could take what he pleased without robbing anybody else; and because it would be impossible if the weal of society were not itself desired or admired as an end. It has an external condition (the distinction of property) and an internal condition (esteem for the public good), and when these are present it arises so naturally that it is not to be classified as merely conventional. Within our nature; then, the irreducible source is concern for the good of others, of which justice is an impersonal and institutionalized form and benevolence a freer form, operating among individuals and over a sphere wider than property. This regard for others, according to Hume, accounts for the greater part of morality. He was continuing the reaction of Shaftesbury, Butler and Hutcheson against the egoism of Hobbes. Altruism is not analyzable into a covert care for oneself.

A second group of esteemed qualities is characterized by usefulness to those who have them; *e.g.*, diligence and frugality. Our approval of them cannot be attributed to self-love, since we approve them in others even when we ourselves are not beneficiaries—another stream from the spring of concern for others. True, some of them, for example honesty and truthfulness, are praised for their usefulness to others as well as to those who have them. The doubleness here of the ground for esteem is a general fact of experience, not to be argued away with a theoretical preconception that one of the grounds must be collapsible into the other: we do like a man to be industrious for his own sake. In this group Hume includes such goods as advantages of birth, wealth and figure (handsomeness), expostulating that the distinction of virtues and what he calls "talents" is merely verbal. If he is wrong here, it is because his starting-point, the qualities that we admire, is too wide for ethics.

Further, Hume records, there are some qualities, such as cheerfulness and courage, which we approve because they are felt as pleasant by their owners, again whether these be ourselves or others. Like the preceding type, this third one also benefits others, but our esteem is irrespective of this fact. Benevolence is an instance: Hume says that our chief reason for regarding it as good is its utility to others, but that we do as well find it intrinsically attractive. However, their tendency to benefit others leads Hume to refer the first and third types to a common source, which he calls "a sentiment of humanity," linking with this "social sympathy."

The fourth type consists of qualities, for instance modesty and good manners, which are approved, whether in ourselves or in others, simply because they are agreeable or attractive to others. Of this type, Hume remarks, nothing more can be said than that it "must be trusted entirely to the sure but blind testimony of taste and sentiment! and must be considered as a part of ethics left by nature to baffle all the pride of philosophy, and make her sensible of her narrow boundaries and slender acquisitions."

Hume is clearly not a utilitarian in the Benthamite sense. His system is more nearly eudaemonism—the happiness of others (without any such formula as "the greatest happiness of the greatest number") *and* the happiness of self. Like Butler: he contends that these two do not conflict. His emphasis is on altruism: of the four moral sentiments which he claims to find by inductive classification, he traces the first three to a sentiment for and a sympathy with our fellows. It is our nature, he maintains, to laugh with the laughing and to grieve with the grieved and to seek the good of others as well as our own. It is also our nature to find certain human qualities intrinsically good, and this takes him beyond eudaemonism. How is this nature to be accounted for? It cannot be, is his reply, since any attempt would take us into the vacuum of metaphysics.

HUME, JOSEPH (1777–1855), British politician, was born on Jan. 22, 1777, of humble parents, at Montrose, Scot. After completing his course of medical study at the university of Edinburgh he sailed in 1797 for India, where he made a fortune. In 1812 he purchased a seat in parliament for Weymouth and voted as a Tory. When upon the dissolution of parliament the patron refused to return him he brought an action and recovered part of his money.

Six years elapsed before Hume again entered the house, and during that interval he adopted the doctrines of James Mill and the philosophical reformers of the school of Jeremy Bentham. He joined Francis Place (*q.v.*) and others in seeking to establish schools for them on the Lancastrian system, and promoting the formation of savings banks.

In 1818, soon after his marriage with Miss Burnley, the daughter of an East India director, Hume was returned to parliament as member for the Border burghs. He was afterward successively elected for Middlesex (1830), Kilkenny (1837) and for the Montrose burghs (1842).

Hume became the self-elected guardian of the public purse, by challenging and bringing to a direct vote every single item of public expenditure. It was he who caused the word "retrenchment" to be added to the Radical program "peace and reform." He fought the old combination laws that hampered workmen and favoured masters; he brought about the repeal of the laws prohibiting the export of machinery and of the act preventing workmen from going abroad.

Hume constantly protested against flogging in the army, the impressment of sailors and imprisonment for debt. He took up the question of lighthouses and harbours; in the former he secured greater efficiency, in the latter he prevented useless expenditure. He died on Feb. 20, 1855.

HUMIDITY, ATMOSPHERIC. The atmosphere is made up of a number of gases, of which water vapour is in many respects the most important. This importance arises from the fact

that water vapour is the only constituent of air whose state changes at the temperatures encountered in the atmosphere. Water substance occurs as a vapour (invisible), as a liquid (fog, cloud and rain droplets) and as a solid (ice crystals, hail and snowflakes). The subject of atmospheric humidity deals only with water in its vapour state.

There is an upper limit to the amount of water vapour which a given space can contain, this upper limit depending oniy on the temperature of the vapour. At low temperatures the amount is small; at high temperatures it is large. The presence of other gases does not appreciably affect this relationship. When a given space contains the maximum amount of water vapour, the vapour is said to be saturated; air containing saturated vapour is also loosely but commonly referred to as saturated. From the foregoing, it follows that the amount of water vapour present near the earth's surface is nearly always greater than that in the cooler upper air; similarly, near the surface, the amount is greater in equatorial than in polar regions. The propoftion of water vapour in air is small but variable; it ranges from a very small fraction of 1% to nearly 3%. The processes by which water substance changes from one state to another, and the influence of the variability of the concentration of water vapour in the atmosphere, form the subject matter of many studies of weather phenomena.

There are several ways of expressing the water vapour content of air:

1. The relative humidity gives the amount of water vapour present in a volume of air as a percentage of the maximum possible amount in that volume at the same temperature. For example, a relative humidity of 25% means that one-quarter of the maximum amount is present; one of 100% indicates that the air is saturated. The relative humidity depends on the temperature as well as on the vapour content, falling as the former rises, and vice versa.

2. The absolute humidity specifies the mass of water vapour in unit volume of air. It also changes mith the temperature.

3. The humidity mixing ratio is the mass of water vapour per unit mass of the dry components of the air.

4. The specific humidity is the mass of water vapour per unit mass of air.

The difference between the numerical values of the humidity mixing ratio and the specific humidity of any mass of air is slight, and for most purposes the two are used interchangeably. These two quantities are especially useful in weather analysis, for they do not change with temperature but only when water vapour is added to or removed from the air, as by evaporation or condensation. or by mixing with moister or drier air.

Related to these measures of moisture content are the dew point and the wet-bulb temperature. The dew point is the temperature at which condensation commences when air is cooled at constant pressure and constant vapour content. The met-bulb temperature may he defined as the lowest temperature to which air can be cooled by evaporating water into it, the air itself supplying the heat necessary for the process. The former quantity is useful because it remains constant as long as water vapour is neither added to nor removed from the air, and the latter because it does not change when evaporation or condensation occurs in the air. The dew point is always lower than the met-bulb temperature except uhen the air is saturated, in which case the two coincide with the existing air temperature.

Both of these quantities find numerous applications in aeronautical meteorology. especially in cloud and fog forecasting. The dew point is useful for forecasting the height of the base of certain types of clouds. For example, the height of the base of the cumulus (woolpack) clouds which often develop during a summer afternoon may be predicted approximately from the formula

$$\text{height of base (in feet)} = 225\ (T\text{-}T_d)$$

where T is the temperature and T_d the dew point of the air near the surface, both in degrees Fahrenheit. For example, if it is expected that the spread between the tuo temperatures will be 10° F. during the afternoon, a cloud base height of 2,250ft. would be forecast. The heights of the bases of some other types of low clouds may be predicted in the same way. The wet-bulb temperature aloft is especially useful for studying the vertical stability of the atmosphere, which governs the formation and vertical extent of a number of types of clouds.

The determination of the humidity of the atmosphere is known as hygrometry. The first hygrometer! invented by Leonardo da Vinci about 1500, was based on the principle that certain substances, known as hygroscopic, have an affinity for water vapour and absorb it readily. With Leonardo's hygrometer the humidity was measured by weighing a ball of wool, which absorbed varying amounts of water vapour, large when the atmospheric humidity was high and small when it was low. Other instruments were later devised, depending on various principles. Horace Benedict de Saussure, in 1783, described a hygrometer which utilized a human hair, freed from grease. The hair lengthened with increasing humidity and shortened with decreasing humidity. In 1802, C. W. Boeckmann made measurements of humidity by comparing the readings of two thermometers, one with its bulb dry and the other wet. The lower the humidity relative to that for saturation, the greater was the spread between the two temperatures. Improving on a technique suggested earlier (1822) by Johann Wolfgang Dobereiner, Henri Victor Regnault in 1845 measured the dew point. A highly polished silver cylinder was cooled until dew formed on it and the temperature of the cylinder noted when this happened, thus giving the dew point. Refinements of these basic methods were made later.

Hygrometers may be divided into five types, according to the basic principles employed:

1. The evaporation method. The wet- and dry-bulb instrument, known as a psychrometer. is essentially the same as Boeckmann's hygrometer, described above. In one type the wet bulb is covered with muslin, which is kept moist by a wick extending to a vessel containing water. A steady flow of air past the wet bulb is necessary for accurate measurements. The sling psychrometer consists of two thermometers in a frame, with muslin covering the bulb of one. The latter is dipped in water and the assembly then whirled vigorously. The relative humidity corresponding to the wet- and dry-bulb temperatures is found from tables.

2. The condensation method. The dew-point hygrometer is based on Regnault's instrument. A thermometer is set up with its bulb in the polished silver cylinder, which contains ether. Air is bubbled through the ether. which cools by evaporation. The temperature at which water vapour starts to condense on the outside of the cylinder. as read by the thermometer, is the dew point. Comparison with the air temperature from another thermometer gives, mith the aid of tables. the relative humidity. Through the use of a photoelectric cell sensitive to dew formed on the reflecting surface, it is possible to balance the temperature at the dew point through direct or induction heating, and thus provide a recording dew-point hygrometer.

3. The hygroscopic method. The dimensions of certain substances. known as hygroscopic, vary with the relative humidity. Human hair has this property, increasing in length by about 2½% as the relative humidity rises from 0% to 100%. In the hair hygrometer, the relative humidity is obtained directly as a function of the length of the hair. Many household hygrometers are of this type. Sometimes goldbeater's skin is found more satisfactory than a hair. The chief disadvantage of hygrometers of this type is the slowness of their response in changing humidity at very low temperatures.

4. The chemical method. With the chemical hygrometer, a given quantity of air is exposed to a drying agent which absorbs the water vapour present; the humidity of the air is obtained by comparing the weight of the drier after absorption has occurred with that before, or by a similar means. The weighing method is the most accurate known but is not suitable for routine meteorological observations.

5. The electrical method. The electrical resistance of certain substances varies with the amount of moisture absorbed by them; lithium chloride is one of these. In one type of electrical hygrometer, measurement of the resistance of a film of lithium chloride permits the evaluation of the relative humidity. This instrument is used mainly for studies of the upper air.

An instrument which records the humidity is called a hygrograph. Most hygrographs depend on the hygroscopic principle, for the variations in the length of a hair are readily magnified and recorded on a revolving drum.

One of the factors governing human comfort is the relative humidity of the air, for it, in part, determines the rate at which perspiration evaporates, with its resultant cooling effect. No single optimum humidity can be given, for the moisture content of the air must be considered in conjunction with its temperature and movement. It is possible, with air conditioning of buildings, to control indoor conditions for maximum health and efficiency. Estimates of the best conditions vary for different countries. Thus in Great Britain an indoor temperature of 65° F. with a relative humidity of 50% to 60% is considered ideal, whereas in the United States and Canada a temperature of 72° F. with a relative humidity from 40% to 60% is preferred. Air conditioning is also of great importance in many industrial plants. To take one example only, printing establishments find humidity control in pressrooms and paper storage rooms helpful, for the properties and dimensions of paper vary with the relative humidity of the air. Most papers are handled with a minimum of trouble when the relative humidity is between 40% and 50%.

HUMILIATI, the name of an Italian monastic order created in the 12th century. Its origin is obscure. A group of Lombards came to Rome with the intention of obtaining the pope's approval of the rule of life which they had spontaneously chosen; while continuing to live in their houses in the midst of their families, they wished to lead a more pious existence than of old, to abandon oaths and litigation, to content themselves with a modest dress, and all in a spirit of Catholic piety. The pope approved their resolve to live in humility and purity, but forbade them to hold assemblies and to preach in public; the chronicler adding that they infringed the pope's wish and thus drew upon themselves his excommunication. Their name Humiliati ("Humiles" would have been more appropriate) arose from the fact that the clothes they wore were very simple and of one colour. This lay fraternity spread rapidly and soon put forth two new branches, a second order composed of women, and a third composed of priests. to which Innocent III granted a rule. His object was to reconcile the order with the Waldenses (*q.v.*), and, indeed. the rule reproduces several of the Waldensian propositions, ingeniously modified in the orthodox sense, but still very easily recognizable. It forbade useless oaths and the taking of God's name in vain; allowed voluntary poverty and marriage; regulated pious exercises; and approved the solidarity which already existed among the members of the association. Finally, by a singular concession, it authorized them to meet on Sunday to listen to the words of a brother "of proved faith and prudent piety," on condition that the hearers should not discuss among themselves either the articles of faith or the sacraments of the church. The bishops were forbidden to oppose any of the utterances of the Humiliati brethren, "for the spirit must not be stifled." So broad a discipline must of necessity have led back some waverers into the pale of the church, but the tradition of the independent Humiliati is confused with the history of the Waldenses throughout the later 12th century. Pius V suppressed the entire congregation in 1570–71. (P. AL.; X.)

HUMITE, a group of four related minerals consisting of basic magnesium fluosilicates: chondrodite, clinohumite, humite and norbergite. The four minerals are strikingly similar in appearance and are best distinguished by their optics and X-ray powder diffraction patterns. They are honey-yellow to brown or red in colour and have a vitreous to resinous lustre; hardness 6–6.5; specific gravity 3.1–3.2. The name humite, after Sir Abraham Hume (1749–1839), was given in 1813 to the small and brilliant honey-yellow crystals found in the blocks of crystalline limestone ejected from Monte Somma, Vesuvius; all but norbergite have since been recognized at this locality. Chondrodite (from the Greek word for a grain) was a name early in use for granular forms of these minerals found embedded in crystalline limestones in Sweden, Finland and at several places in New York and New Jersey. Large hyacinth-red crystals of all four species are associated with magnetite in the Tilly Foster iron mine at Brewster, N.Y.

The minerals have the formulas: norbergite, $Mg(F,OH)_2.Mg_2SiO_4$; chondrodite, $Mg(F,OH)_2.2Mg_2SiO_4$; humite, $Mg(F,OH)_2.3Mg_2SiO_4$; and clinohumite, $Mg(F,OH)_2.4Mg_2SiO_4$. Norbergite and humite are orthorhombic, the others monoclinic in crystallization. The lengths of the vertical axes are in the ratio 3:5:7:9, and this is also the ratio of the number of magnesium atoms present in each of the four minerals. Such a relation between the crystallographic constants and the chemical composition is known as a morphotropic relation. Structurally, the minerals consist of interleaved layers of the olivine (Mg_2SiO_4) structure and of brucite, $Mg(OH)_2$. The stacking sequence of these layers determines the compositional and crystallographic relations observed. (CL. F.)

HUMMEL, JOHANN NEPOMUK (1778–1837), German composer and pianist, was born on Nov. 14, 1778, at Pressburg, in Hungary. In 1785 his father became conductor at Schikaneder's theatre in Vienna. Schikaneder was a friend of Mozart and the librettist of the Magic *Flute*, .and introduced Hummel to Mozart who gave the boy instruction for two years. At nine years of age Hummel toured Europe with his father as a "Wunderkind"; when he was 11 he began to compose. After his return to Vienna he completed his studies under Albrechtsberger and Haydn; and at a later period he learned song writing from Salieri. From 1804 to 1811 he was Kapellmeister to Prince Eszterhazy. Beethoven's Mass in C was performed in 1810, and a remark passed by Hummel caused an estrangement between the two which was only healed just before Beethoven's death. The years 1811 to 1815 were spent in Vienna, and after the peace Hummel began to tour Europe as pianist and conductor, having enormous success everywhere. He died in 1837 at Weimar, where for a long time he had been the musical conductor of the court theatre. Hummel wrote, among other things, several operas, both tragic and comic, and two grand masses (Opus 80 and Opus 111). More important are his compositions for the pianoforte (his two concertos in A minor and B minor, and the sonata in F sharp minor), and his chamber music (the celebrated septet, and several trios, etc.). His experience as a player and teacher of the pianoforte was embodied in his Great Pianoforte School (Vienna), and the excellence of his method was attested by his pupils, Henselt and Ferdinand Hiller. Hummel continued the traditions of the earlier Viennese school of Mozart and Haydn; his style alike as pianist and composer was marked by purity and correctness rather than by passion and imagination.

HUMMINGBIRD, any of numerous small birds confined to the Americas and constituting the family Trochilidae, placed with the swifts (*q.v.*) in the order Apodiformes. They include the smallest of all birds, famous for the rainbow colours and delicate intermediate shades of the brilliant iridescent plumage of the males, which may also have striking crests, neck tufts and remarkably elongate tail feathers. Like the swifts they have short legs and small feet, narrow wings and long primaries. The extreme development of breastbone and keel is associated with rapid wingbeat, so fast as to appear a blur in smaller species. The bill is slender, usually straight, from two-fifths inches to five inches long, or curved in a third of a circle in the sicklebilled hummingbird (Eutoxeras aquila) of Costa Rica to Ecuador. The unusually developed tongue probes tube flowers for tiny insects and nectar as the bird balances in mid-air. The bird must move backward in flight to remove its bill from the flower and dart away in humming flight. The voice is weak, the song chippering, unmusical. The nest is a solidly built little cup of vegetable down, plant fibres and spider webs, in some species decorated with bits of lichens; usually less than an inch across the cavity, it contains two tiny elliptical white eggs. Parents are pugnacious in protecting eggs or young.

The smallest bird in the world is the fairy or Princess Helen's hummingbird (Calypte *helenae*) of Cuba, body two inches long and

bill two-fifths inches, its nest cavity three-fourths inches across and eggs three-tenths inches long. The vervain or verbena hummingbird (Mellisuga minima) of Jamaica and Hispaniola, also weighing less than 2 g.. has a slightly longer wing. The largest hummingbird is Patagona *gigas,* eight and one-half inches long in the Andes from Ecuador to Chile. About 325 hummingbirds are grouped in 123 genera, of which 72 have only 1 and 21 have 2 species each. The largest genus is *Amazilia,* with about 28 species from Brazil to Mexico. two (*A.* tzacatl and *A.* yucatanensis) reaching the lower Rio Grande valley of Texas. The plain-coloured hermits (Phaethornis), 22 species, range from Mexico through Brazil.

Hummingbirds range from Alaska to Tierra del Fuego, from lowlands to snowline at 16,000 ft, in Ecuador. Centre of abundance of species and numbers is in Colombia. The ruby-throat (*Archilochus colubris*) is the only one in eastern North America, the black-chinned species (*A.* alexandri) ranging the southwest to Texas and British Columbia. Six species live in California and western mountains, calliope (*Stellula* calliope) to British Columbia. rufous (Selasphorus *rufus*) to Alaska; six cross the Mexican border into Arizona and trans-Pecos Texas. (G. F. Ss.)

HUMOUR began its interesting career as a Latin word humor, meaning "moisture." In a more specialized sense "humour" meant the fluids of the body; this sense survives in part in medical usage. In the ancient physiology still current in the middle ages and later the four cardinal humours of the body were blood. phlegm, choler (yellow bile) and melancholy (black bile); the variant mixtures of these humours in different men determined their "complexions" or "temperaments." their physical and mental qualities, their dispositions: the ideal man had the ideally proportioned mixture of the four; a predominance of one produced a man who was sanguine (Latin sanguis, "blood"), phlegmatic, choleric or melancholic. Each of these complexions had specific characteristics so that the words carried much weight that they have since lost: the choleric man, for example, was not only quick to anger but yellow-faced, lean, hairy, proud. ambitious. revengeful and shrewd. Some knowledge of the four humours is helpful in reading Chaucer and Shakespeare and their contemporaries.

Renaissance Theory.— By further extension and specialization, humour in the 16th century came to denote usually an unbalanced mental condition, a mood, or unreasonable caprice, or a fixed folly or vice. As such, humour was a fit subject for the writer of comedy, whose traditional function, in Renaissance theory, was the correction of irrational or immoral conduct. The great exponent of the comedy of humours was Ben Jonson, who took for his own a word already popular and. as Jonson saw it, absurdly abused: all sorts of fools and knaves proudly insisted upon their personal humours. Jonson, at the beginning of Every Man *Out* of His *Humour,* distinguished two kinds of humour, in the sense in which the word is applied to disposition. One is true humour, in which one peculiar quality actually possesses a man, body and soul. But there is also an adopted humour, in which a man goes out of his way to appear singular by affecting certain modes of clothing, speech and social habits. This ridiculous pride in singularity Jonson scourges without mercy. Affected humours change with the years, with the fashions; they are manners, so that Jonson comes to speak of "recent humours . . . or manners of men that [go] along aith the times"; his 17th-century successors continued to find new humours, new kinds of offensive conduct, that offered material for the satiric comedy of manners.

18th and 19th Centuries.— By the end of the 17th century the English had come to be rather proud of the excellence of their comedy. claiming that it was superior to that of the ancients and of the modern French because of its humour; that is, its greater copiousness in comic characters. Moreover, they began to claim that this richness of the comic stage derived from the richness of their national life, which abounded in men of varied humours. England had long been known as the home of individualists, peculiar men, even madmen, so that when young Hamlet put his antic disposition on he was packed off to England where it would not be noticed. In that sense England had always had its "humorists" (its odd types, men with a humour). It was, however, Sir William Temple in "Of Poetry" (1690) who was the first to try to account for English eminence in humour—he claimed that the word itself was peculiar to the English language—by finding its causes: the native plenty of the soil, the ease of government and the uncertainty of the climate. These forces, he said, produce a nation of extremists and this has disadvantages, but wealth, liberty and varied weather produce a brilliant crop: health, courage, beauty, genius, goodness of nature and, among all these. humour "because every Man follows his own, and takes a Pleasure, perhaps a Pride, to shew it." When humour was seen in this light, not as an affected manner but as a natural, national expression, a distinct compliment to a race of rich and free men. its future was assured. William Congreve in "Concerning Humour in Comedy" (1695) confirmed Temple's observations on the English and analyzed closely the distinction between affectation and true humour. Temple's account was widely popular and the English variety of humours became one of the great commonplaces of the English heritage. The entire matter was regarded with much complacency. As one writer in 1725 said, "The pleasing Medley of Characters and Humours particular to Old England, make up together a very fine Scene; and the general Face of Peace and Prosperity that covers all, will well enough excuse a warm Englishman in thinking it the finest Country in the World." Another writer of 1777 summarized the history of "true humour" in a few words: "At length Commerce, and her companion Freedom, ushered into the world their genuine offspring, True Humour. To these she owed her birth; and when they expire, it will require no great sagacity to prophesy that she will follow her parents to the same grave." This was the humour of a national tradition complex in origin and expression, but one that may be described in outline as empirical, liberal and expansive, scientific, democratic and commercial, one that emphasized variety and the individual rather than conformity and the class. It was the Whig tradition of the Glorious Revolution of 1688, which made Englishmen proudly self-conscious of their liberties and wealth: and it was a legacy inherited and then independently cultivated by Americans. The continuing vitality of the tradition from which "True Humour" sprang can be seen in the 19th century, at its best, in John Stuart Mill's insistence that free scope should be given to varieties of character, that eccentricity in a society is proportional to genius, originality, mental vigour and moral courage. The major critic of its defects was Matthew Arnold, who saw its degeneration into the mere rawness of "Doing as One Likes." It drew its inspiration neither from the witty aristocracy nor the baseborn knaves and fools; it was distinctly "middle class": "the Courtier crys out for ***Wit,"*** according to George Farquhar's analysis of the public taste (1702), "the Citizen for *Humour.*"

Humour and Wit.—Wit was a form of intellectual quickness, raillery and repartee, likely to be an upper-class manner of discourse, likely to be dangerous, as are all sharp weapons that can cut good and bad alike; wit was associated with the aggressive, sexual Restoration rakes, who, in the eyes of good citizens, had used ridicule against religion and marriage and all moral and social decency. Wit was inferior, furthermore, as a literary form because it was primarily cleverness and thus without passion or heart; in comedy, therefore, it offered no cause for the action of characters; on the contrary, it was regarded as too often obliterating the distinctions between characters because some authors in their overflowing desire to display their wit tended to put their witticisms into the mouths of inappropriate characters. Congreve became the standard example of the excessively witty writer. But Congreve himself had declared that the manner of the wit should be adapted to the humour; that is. humour as a manner peculiar to one man was bound up necessarily in individual character and feeling and thus determined action and speech (including such wit as might be appropriate). Humour, then, unlike wit, was not the flash of an isolated sentence whose force was largely independent of the speaker or the time or place, but gathered its strength from a wide context, the previous life of the character, the relationships among a number of human beings in a complex specific dramatic situation. Humour was therefore more "natural," a growth of time, a freer and less restrained expression of character than wit.

Wit, like any impersonal mental skill, required books, learning, art; humour was a more universal gift. Wit surprised the mind, but humour was more delightful and appealed to the heart as well. To the more "polite" critics of the 18th century, where wit was more designed, concerted, regular and artificial, humour was more wild. loose, extravagant and fantastical, not consistent with true politeness; if humour was more diverting than wit it was only as a buffoon is more diverting than a gentleman: this was the account given by Adam Smith in 1755. Humour was therefore considered by some to be "low," but the prevalent tendency was to vindicate it. if humour is not found in the well-bred it is because they have learned to repress their feelings and adapt their manners to a rigid mold of decorum; among the lower orders, by passions and humour, nature appears in all its charming, unsophisticated diversities.

The development of the concept of humour was thus closely linked to the development of the concept of nature; humour flourished not in a nature that was a set of ideal or general norms or types in which individual variants were aberrations, but in a nature in which luxuriant variation and plenitude of forms were necessary and desirable, a "picturesque" nature in which irregularity and roughness of outline, the unusual and unexpected, even the grotesque, were admired and treasured.

By the mid-18th century humour was no longer an abnormality and a fit subject for the satirist but rather a whimsical oddity or foible, amusing and innocent. But more than that, unlike wit, which was often severe, bitter and satirical, humour very frequently exhibited generous, benevolent sentiments of heart which, though exerted in an odd manner, it was said, justly commanded our fondness and love. Benevolence, in one of its forms, giving free rein to inner impulse and trusting that spontaneous expression of personal feeling was good for both the individual and society, even if it seemed excessive or foolish or ludicrous by cool-headed standards. had a near relationship with humour. Certain free. jocund and liberal oddities and foibles might result from a generous flow of spirits and warm uncalculating benevolence, but these were amiable, even estimable failings. Humour might even be a guise to hide tender feelings.

18th-Century Humorists. — The 18th century was prolific in the creation of kindhearted "humorists," most notably Joseph Addison and Sir Richard Steele's Sir Roger de Coverley, Henry Fielding's Parson Adams, Oliver Goldsmith's Vicar of Wakefield and Laurence Sterne's Uncle Toby. The history of comic writing was reshaped so that though it may seem obvious to us that amiable humour has always existed, that Shakespeare and Cervantes and the humorous characters they created, for example, were greater than anything produced by later ages, if such is the case it is because we have inherited the 18th-century interpretations of those earlier authors. Falstaff and Don Quixote, though always highly admired as comic creations, were regarded as butts of ridicule, the one an amorous, lying, gluttonous buffoon, the other a lunatic designed to satirize chivalric romances, until well along into the 18th century; then Falstaif became a lovable, harmless rogue; Don Quixote became an enthusiastic philanthropist: even when his too ardent feelings betray him into ridiculous excesses and we are tempted to laugh at him, it is impossible to withhold our love and pity.

Thus humour, by the end of the 18th century and the beginning of the 19th, in its most exquisite moments was found to have an intimacy with sympathy and pathos. The inevitable distresses of a high-minded innocent like Don Quixote brought a tear to the eye even as the smile was upon the lip. Humour was the expression of a human nature that was, within itself and in its social and cosmic relations, a strange mixture, at once sublime and ridiculous. Humour was an essential resource of the sensitive and melancholy, a relief from and defense against the sadness of life that always weighs most heavily on those of keenest sensibilities. Sterne, with his unpredictable mingling of mirth and sentiment, laughter and tears, writing, as he claimed, against the "spleen," was tremendously popular and influential. The spleen was a nervous, depressive disorder that affected especially the finest tempers; it made men "humorists" and it made humour a necessary therapeutic. The English as a nation were notable for their spleen and their humour; the two were inseparable.

19th-Century **German** Humour. — Though the English had declared their monopoly of humour, other nations were not always prepared to acknowledge the claim. In the 19th century the Germans in particular became determined and solemn philosophers about humour. Jean Paul Richter, who was much influenced by English humour, especially Sterne's, and whose ideas on humour, in turn, were influential on Samuel Coleridge, Thomas De Quincey and Thomas Carlyle, developed in his *Vorschule der Asthetik* (1804) a theory of humour as the romantic form of the comic; in his highly complex exposition, the observer of a humorous situation must subjectively identify himself with the object of his laughter and thereby the object of his laughter is himself as well, indeed all humanity, of which both he and the object are a part. Humour destroys not the individual but the finite in its contrast with the infinite. In this universality humour finds no individual fools but only foolishness in a foolish world and is therefore tenderly tolerant. But when humour measures and connects with this little world the infinite one, there arises a laughter wherein there is still a pain of greatness, Richter says. Nor is it difficult to find later theories of humour with loftier pyramids of complexity.

Modern Humour. — In the 19th century humour was established as the highest and richest form of the comic. As such the word came also to be employed as a general term, as it usually is today, to denote anything comic, or anything that makes us laugh. By obvious extension of meaning a "humorist" is now someone consciously skilled in comic artistry, not, as the word was normally used until the 19th century, an unconscious subject of comedy himself. "Humour" is applied also to the ability to perceive or appreciate the comic. When qualified, of course, the word is used of a large variety of special areas of the comic. The word, therefore, now has little specific meaning except what it still may retain from its history in the 18th and 19th centuries, when it reached its apotheosis.

At its worst the idea of humour that developed in that period is a pudding of meaningless grotesquerie and gratuitous emotionalism. At its best it preserved a fine and difficult balance and a comprehensive conception of man and nature. It caught the enthusiasm of man's aspiring goodness and checked it with an eye for the incongruities of his concomitant weaknesses. At its best it did not identify innocence with the whole of nature or the complete virtue of man; innocence is also ludicrously short of fulfilling human capabilities. It measured reality, not as the satirist tends, by an ideal against which reality is terribly wanting, nor did it, in the manner of the sentimentalist, deny the gap of the real and the ideal. It accepted the difference with a liberal tolerance, or, unlike both satirist and sentimentalist, it found the ideal in the varied fullness of the real in all its imperfections. Its strength can be seen in the manner in which it prepared an enormous audience for the early Dickens; its weakness can be seen in the unwillingness of that audience to let Dickens get beyond *Pickwick Papers*.

In the 20th century humour no longer enjoys an unquestioned pre-eminence in the hierarchy of the comic. For one thing, increased historical study of the comic has led to the rejection of 18th- and 19th-century interpretations of earlier authors and to the understanding of modes of the comic that antedate the later idea of humour. The interest of many critics has turned also to questions of formal structural analysis, in which the emotions of the audience, essential in humour, are subordinated. And it is certainly true that one characteristic of the 20th century is an astringency (cynicism to those who do not like it, tough-mindedness to those who do) that questions sharply the liberal assumptions on which the 18th- and 19th-century idea of humour was based, regarding them as undisciplined both in intellect and emotion. It is note orthy that those critics who tend to regard the 18th and 19th centuries as unfortunate errors in the history of literature have revived "wit," using it once again, after its long eclipse by humour, in a 17th-century sense to denote the hard, bright quality of that fine fusion of intelligence and feeling found in the greatest poetry.

HUMPERDINCK, ENGELBERT (1854–1921), German composer known for his children's opera Hansel und Gretel. Born at Sieburg. Sept. 1, 1854, he studied under Ferdinand Hiller at Cologne and Franz Lachner and Joseph Rheinberger at Munich. In 1879 a Mendelssohn scholarship enabled him to go to Italy, where he met Wagner who invited him to assist in the production of Parsifal at Bayreuth. He taught at the Barcelona conservatory (1885–87) and at Frankfurt (1890–96) where he was also music critic of the *Frankfurter Zeitung.* Early works were the choral ballads, Die Wallfahrt nach Kevelaar (1878), Das *Glück* von *Eden*hall (1879) and the *Humoreske* (1880) for orchestra. Hansel und Gretel, conducted by Richard Strauss, was produced at Weimar on Dec. 23, 1893. The libretto, by the composer's sister Adelheid Wette, was based on the folk tale made familiar by the brothers Grimm. In this work Humperdinck showed an understanding of a child's mind and a subtle sense of poetry, notably in the atmosphere of the uoodland scene at twilight and in the realistic effects in the episode of the broken milk jug. The Wagnerian harmonies, often of simple tunes, and the resourceful orchestration maintain the musical interest on a high level.

Between 1895 and 1919 Humperdinck produced six further operas, including Dornroschen (Frankfurt, 1902) and Konigskinder (New York, 1910) but none of them, nor the pantomime The Miracle (London, 1911), achieved much success. He also wrote incidental music for plays by Aristophanes, Shakespeare and Maeterlinck, a *Moorish* Rhapsody for orchestra (1898), a string quartet, piano works and songs.

Humperdinck died at Neustrelitz, Sept. 27, 1921.

HUMPHREY (or HUMFREY), **LAWRENCE** (1527?–1590), president of Magdalen college, Oxford, and dean successively of Gloucester and Winchester, was born at Newport Pagnel. He was elected demy of Magdalen college in 1546 and fellow in 1548 He mas one of the most promising pupils of Peter Martyr, and on Mary's accession obtained leave from his college to travel abroad. He lived at Basel, Zürich, Frankfurt and Geneva, making the acquaintance of the leading Swiss ministers, whose ecclesiastical views he adopted. He returned to England at Elizabeth I's accession, was appointed regius professor of divinity at Oxford in 1560, and was recommended by Archbishop Parker and others for election as president of Magdalen. The fellows refused at first to elect so pronounced a reformer, but they yielded in 1561, and Humphrey gradually converted the college into a stronghold of Puritanism. In 1564 he and his friend Thomas Sampson, dean of Christ Church. mere called before Parker for refusing to wear the prescribed ecclesiastical vestments; and a prolonged controversy broke out, in which Bullinger and other foreign theologians took part as well as most of the leading churchmen in England. In spite of Bullinger's advice. Humphrey refused to conform; and Parker wished to deprive him as well as Sampson. But the presidency of Magdalen was elective and the visitor of the college was not Parker but the bishop of Winchester; and Humphrey escaped with temporary retirement. Parker, in fact, was not supported by the council; in 1566 Humphrey was selected to preach at St. Paul's Cross. and mas allowed to do so without the vestments. In that year, on the occasion of Elizabeth's visit to Oxford he wore his doctor's gown and habit, which the queen told him "became him very well": and his resistance now began to weaken. He yielded on the point before 1571 when he was made dean of Gloucester. In 1578 he was among those selected to attend the diet at Schmalkalden, and in 1580 he was made dean of Winchester. In 1585 he was persuaded by his bishop, Cooper. to restore the use of surplices in Magdalen College chapel. He died on Feb. 1, 1590, and was buried in the college chapel.

HUMPHREYS, ANDREW ATKINSON (1810–1883), U.S. soldier and engineer, was born at Philadelphia, on Nov. 2, 1810. Graduating at West Point in 1831, he served in the Civil War as a topographical engineer. He commanded a division, at the battle of Fredericksburg. He took part in the battles of Chancellorsville and Gettysburg and the Wilderness campaign. Toward the end of the war he commanded the famous 2nd corps. After the mar, now brevet major general, he returned to duty as chief engineer of the U.S. army and retired in 1879. He died at Washington, D.C., on Dec. 28, 1883.

HUMPHRY, OZIAS (1742–1810), English miniature painter, was born at Honiton and educated at the grammar school of that town. Attracted by the gallery of casts opened by the duke of Richmond, Humphry came to London and studied at Shipley's school; and later he left for Bath, where he lodged with Linley and became a great friend of his beautiful daughter, afterward Mrs. Sheridan. In 1766 he was in London warmly encouraged by Sir Joshua Reynolds, who was always interested in Devonshire painters. He was a great friend of the painter George Romney, with whom in 1773 he went to Italy, staying. on his way to Dover, at Knole, where the duke of Dorset gave him many commissions. In 1785 he went to India, visiting the native courts, painting a large number of miniatures and making many beautiful sketches. His sight failed him in 1797, and he died in Hampstead in 1810. (G. C. W.)

HUMUS is organic matter that has undergone extensive decomposition. It is brown to black in colour and imparts these colours to peat bogs and to many surface soils. Complex chemically, its compounds are known only in part. In addition to the nonliving organic material. to which the term "humus" is usually applied, soils contain great numbers of bacteria and other microorganisms that form humus from added organic materials and gradually decompose humus itself. Humus contains some of the phosphorus and sulfur and almost all the nitrogen of soils. It is important principally because during decomposition the nitrogen is gradually changed to simple forms that can be used by plants. Humus is valuable also because it increases the water absorption and improves the workability of soils (see also SOIL).

See C. A. Black, Soil-Plant Relationships (1957). (C. .4. BK.)

HUNALD, DUKE OF AQUITAINE, succeeded his father Odo, or Eudes, in 735 He refused to recognize the high authority of the Frankish mayor of the palace, Charles Martel, whereupon Charles marched south of the Loire, seized Bordeaux and Blaye, but eventually allowed Hunald to retain Aquitaine on promise of fidelity. At Charles's death in 741 Hunald declared war against the Franks, crossed the Loire and burned Chartres. Menaced by Pippin and Carloman, Hunald begged for peace in 745 and retired to a monastery, probably on the Isle of Ré. We find him later in Italy. where he allied himself with the Lombards and was stoned to death. He had left the duchy of Aquitaine to Waifer, who was probably his son. and who struggled for eight years in defending his independence against King Pippin. At the death of Pippin and at the beginning of the reign of Charlemagne, there was a last rising of the Aquitanians. This revolt was directed by a certain Hunald, who seems to have been a different person from the old duke of Aquitaine. (C. PF.)

HUNAN (HU-NAN SHENG), an important rice-producing province of China south of the central part of the Yangtze river (*q.v.*), bounded in the south by the Nan Ling mountains. Area 79,062 sq.mi., pop. (1953) 33,226,954. The province mostly comprises the drainage area of Tungting lake (Tung-t'ing Hu; *q.v.*). Except for the plain around the lake in the northeast and strips of river alluviums which narrow as the land rises in the south and west, much of the province consists of rough uplands of sandstone, limestone and granite. The largest river is the Hsiang Chiang (Siang Kiang) whose course is followed by the railroad from Hankow to Canton. At Heng-yang this railroad continues alongside a tributary stream almost due south, while a branch rail line runs over the Nan Ling mountains to Kuei-lin in Kwangsi province. River steamboats up to 500 tons can reach Ch'ang-sha on the

Hsiang Chiang and during flood periods may reach Heng-yang. Rainfall ranges from join. in the north to 58 in. in the south.

Rice is the leading field crop and, in the south. a growing season of up to 330 days permits two plantings on the same field each year. In the Tung-t'ing basin to the north the growing season is limited to about 300 days. Other field crops cultivated are rapeseed, broad beans, wheat, peas, barley and glutinous rice. Industrial crops include cotton, ramie, tung oil nut; tea (especially the Anhwa variety grown principally on the uplands), silk and tobacco. Oranges, tangerines, pomelo and pears are important fruits. Large quantities of sweet potatoes are grown. It was claimed in the late 1950s that the production of field crops had been raised to around 23,000,000,000 catties (one catty averages 1⅓ lb.) on 8,600,000 ac. of crop land. There is some lumber activities (pine, bamboo, fir) in the uplands.

Hunan is one of the leading mineral reservoirs of China, particularly in nonferrous metals. There are widespread coal deposits but only a few are economically significant. Hunan produces about 90% of China's antimony supplies. The province also accounts for about 10% of China's tungsten, 65% of its mercury, 90% of its manganese and much of the lead, zinc, gold, silver and sulfur. Although Hunan's population is overwhelmingly rural, a large number of industries have developed, including metals refining, dyes and fertilizer, glass, electric light bulbs, paper, silk gauze, matches, soap and cigarettes. A hydroelectric plant was started on the Tzu Shui (river) in the late 1950s. Ch'ang-sha, the provincial capital (pop. 650,600), is a market for rice, tea, lumber, ramie and metals as well as the major industrial centre and the site of Hunan university. Hsiang-t'an (*q.v.*) is an important industrial centre 20 mi. S.S.W. of Ch'ang-sha.

In the 1950s non-Chinese tribespeople in the western hill lands numbered about 400,000, of which about 320,000 were Miao and 51,000 were Yi (formerly Lolo) the rest comprised smaller ethnic groups. In the 1950s these tribespeoples were organized into national autonomous regions or districts.

The name Hu-nan means "south of the lake," referring to Tung-t'ing Hu. Before the Chinese migrated southward, this region mas inhabited by the ancestors of the Miao and Thai (T'ai) tribes. In the time of Confucius (6th century B.C.) it was part of the Ch'u kingdom. At the beginning of the Han dynasty (206 B.C.) it was in the Ch'ang-sha kingdom. During the T'ang dynasty (618–906) it formed a division of the Chiang-nan provinces; during the Sung dynasty (960–1279) part of the Ch'ing-hu provinces. The Mongols formed part of Hu-Kuang from it and this name was continued during the Ming dynasty (1368–1644). In 1665 under the Manchus. Hu-kuang was split, and one of the sections eventually became Hunan province. Strategically. the Hsiang Chiang valley has been important since the early Chinese moved south through Hunan to settle the Hsi Chiang (*q.v.*) drainage across the Nan Ling. The revolutionary Nationalist armies drove through Hunan northward from their Canton base to defeat the war lords in 1926–27. It was in this area that the Japanese were stopped in three campaigns during the Chinese-Japanese war (1894–95). In World War II the province was invaded by the Japanese who captured Ch'ang-sha in June 1944. Communist chief Mao Tse-tung started his peasants' associations in Hunan, Jan. 1927, and together with Chu Teh led various uprisings in 1928. However, the Nationalist forces drove Mao and his supporters into the Nan Ling hills from which they made their Long March to the west and north, finally ending at Yenan (Fu-shih) in Shensi province, not to return until 1949. (H. J. Ws.)

HUNDRED. In England the term "hundred" is particularly applied to an ancient territorial division intermediate between the villa and the county (*q.v.*). Such districts were also known in different parts of the country as wapentakes, wards or shires. In some parts of England a further intermediate division is to be found between the hundred and the county. Thus there is the trithing or riding (*q.v.*) in Yorkshire, the lathe in Kent, and the rape in Sussex. In Lincolnshire the whole county was divided into the three subcounties of Lindsey, Kesteven and Holland. The significance of the name hundred is a matter of some difficulty. The old theory is that the hundred denoted first a group of a hundred families, and then the district which these families occupied. According to another view the hundred was originally a term of measurement denoting a hundred hides of land, for there is good reason for considering that the hide was originally as much land as supported one family. It is important to notice that in the document compiled before the Norman Conquest, and now known as the *County Hidage,* the numbers of hides in all the counties are multiples of a hundred. and that in many cases the multiples agree with the number of hundreds ascribed to a county in Domesday Book. The hundreds of Devon, however, seem never to have contained a hundred hides; but various multiples of five, such as 20, 40 and 60. There, and in some of the other western counties, the hundreds are geographical divisions, to which a varying number of hides was attributed for fiscal purposes.

In the middle ages the hundred was chiefly important for its court of justice; and the word *hundredum* was as often applied to the court as to the district over which the court had jurisdiction. According to the compilation known as *Leges Henrici,* written shortly before 1118, it mas held 12 times a year, but an ordinance of 1234, after stating that it had been held fortnightly in the reign of Henry II, declares that its ordinary sessions were henceforth to take place every three weeks *(Dunstable Annals,* 139). Existing court rolls show that from the 13th to the 15th centuries it usually sat 17 times a year, in some hundreds in a fixed place, in others in various places, but in no regular course of rotation. Twice a year a specially full court was held, to which various names such as *hundredum legale* or *hundredum magnum* were applied. This was the sheriffs' turn held after Easter and Michaelmas in accordance with the Magna Carta of 121j. The chief object of these sessions was to see that all who ought to be were in the frankpledge, and that the articles of the view of frankpledge (*q.v.*) had been properly observed during the preceding half-year. Each township of the hundred was represented by a varying number of suitors who were bound to attend at these half-yearly sessions without individual summons. If the proper number failed to appear the whole township was amerced, the entry on the rolls being frequently of the form *"Villata de A. est in misericordia quia non venit plenarie."* All the 17 courts, including the two full courts, had jurisdiction in trespass covenant and debt of less than 40 shillings, and in these civil cases such of the freeholders of the county as were present were judges. But the sheriff or the lord of the hundred was the sole judge in the criminal business transacted at the full courts.

Because of the great fall in the value of money the hundred court began to decay rapidly under the Tudor sovereigns. They were for the most part extinguished by the County Courts act, 1867, which enacts that no action which can be brought in a county court shall thenceforth be brought in a hundred or other inferior court not being a court of record.

Until the Riot act. 1886. the most important of the surviving duties of the hundred was its liability to make good damages occasioned by rioters. (G. J. T.)

HUNDRED DAYS, the name commonly given to the period between March 20 1815, the date on which Napoleon arrived in Paris after his return from Elba, and June 28 181j, the date of the restoration of Louis XVIII. The phrase *Cent Jours* was first used by the prefect of Paris, the comte de Chabrol, in his speech welcoming the king.

See NAPOLEON, and FRANCE: *History.*

HUNDRED YEARS' WAR, THE. This name has been given by historians, not quite accurately, to the long struggle between England and France which, interrupted by two treaties and numerous truces. went on in an intermittent fashion from 1337 to 1453. Its fundamental cause was the anomaly by which the Plantagenet kings of England held an immense fief in southern France, the remains of the heritage of their ancestress Eleanor of Aquitaine. It mas natural that successive kings of France should endeavour to reunite to their crown-lands all the broad counties along the Garonne which had slipped out of the direct control of the Carolingian monarchs during the dark ages. It was equally natural that the kings of England should endeavour to cling to their ancient inheritance. Their task was made possible by the

fact that so late as the 14th century French national consciousness was still undeveloped, and most of the towns and many of the nobles of the South preferred the rule of an absentee duke of Aquitaine at London — who left them to manage for themselves for the most part — to that of the king at Paris with his grasping lawyers and tax-gatherers always on the spot.

The real character of the Hundred Years' War was disguised to a certain extent by the absurd claim of Edward III. and his successors to the crown of France — a claim adopted without sincere conviction from purely political reasons. Indeed Edward did not assume the title of King of France till the war had been running for several years (1338–40), and he sold his pretensions for solid consideration in land at the treaty of Brétigny (1360). That Henry V. almost succeeded in turning the shadow into substance for a few years in the 15th century had nothing to do with King Edward's original claim. Henry conquered half France as the head of a French political faction rather than as an English dynastic claimant, and his son was only recognized as king at Paris so long as French party-spirit was stronger than French national spirit, whose resurrection was displayed in the career of Joan of Arc. The real character of the struggle is well shown by the fact that after Paris had been recovered by the enemy in 1436, Bordeaux still held out for its English "Duke of Aquitaine" for 15 years more, and after having been once subdued, rose again in the name of King Henry VI., and fought for another year in the cause of southern particularism.

The dynastic side of the Hundred Years' War is a depressing story. Of its widespread economic and commercial effects this is not the place to speak, though they had much to do with the making of modern England. Its military aspect is most important, not only in the history of England and France, but in that of the general development of the art of war in Europe. Its opening years saw the end of the supremacy of feudal cavalry as the dominating power in battle: its last years witnessed the first instances of general actions decided by artillery.

PERIOD I. 1338–45

Friction between the king of England as duke of Aquitaine and the duke's overlord at Paris had been intermittent for the last century. In 1338 it had reached one of its not infrequent crises, but the main cause of rupture was the help given by Philip of Valois to Edward's Scottish enemies. In retaliation Edward stirred up the Flemings and other Netherland neighbours of France, and bought the help of the Emperor Lewis of Bavaria. His first attempts, however, to invade northern France with an army composed for the most part of the emperor's vassals in the Low Countries were complete failures. And no profit was got by Edward's proclamation of himself as rightful king of France — a step which he took in order that the Flemings might be able to say that they were not engaged in a treasonable attack on their suzerain. For Flanders, unlike the rest of the Netherlands, owed homage to France (1340). The only profit which Edward got out of the first period of the contest was the complete destruction of the French fleet at the battle of Sluys (June 25, 1340), which gave him the command of the sea for 30 years, — no small boon, for in the early days of the war French squadrons had raided and sacked Southampton, Portsmouth, Hastings and other seaports. But on land there was no decisive fighting — though Edward was eager to try against the French the tactics which the English had learned in their Welsh and Scottish wars, and of which he himself had given a victorious example at Halidon Hill (1333). But Philip of Valois accepted no general action, and Edward was unlucky in his sieges of Tournai and other places on the northern border of France. The Flemish campaigns were a complete failure, nor did Edward meet with much success in an attempt to attack France on another flank — the duchy of Brittany — where he supported the claimant in a contested succession who had not the approval of King Philip. With his exchequer drained dry and his parliament growing discontented, Edward consented to a two-year truce, which covered the years March 1343–March 1345.

PERIOD II. 1346–60 CRECY AND POITIERS

Very different was the course of military affairs when the two years of fitful truce ran out, and Edward invaded Normandy (July 1346) apparently with the object of drawing off the French from a dangerous attack on Guienne then in progress — but strategical objects are sometimes attributed to mediaeval generals on insufficient evidence. After wasting the whole duchy and capturing the rich town of Caen, Edward marched to the very gates of Paris; but when the whole power of France had been gathered against him, he judged that he had better not fight save under the most favourable tactical conditions. He swerved north, forced the passage of the Somme near its mouth, and then stood at bay, under the forest of Crécy, on a very cleverly chosen position, along a ridge of chalk downs, with a long easy slope like a glacis in front of him, and his flanks covered by the houses and enclosures of the villages of Crécy and Wadicourt. Edward had deliberately adopted the formation which had served the English well in their Scottish wars — central blocks of dismounted men-at-arms, with long wings of archers thrown out on each side. After a preliminary skirmish, in which Philip's advanced line of Genoese crossbowmen was shot to pieces by the English archery — who could give them six missiles for one — the cavalry charges began (Aug. 26, 1346). The fight of Crécy (*q.v.*) consisted in a dreadful slaughter by concentrated archery-shot of successive squadrons of the French knighthood; each feudal contingent pushed to the front as it came on the field, and charged up the long slope, to be riddled and finally brought to a stop by the thick flights of cloth-yard arrows which poured in from the flanks as well as the front. The futility of cavalry charges against trained archery in a favourable position was completely demonstrated, and Edward III. did not even need to put his reserves into action. Night only brought the battle to an end — and saw the wrecks of King Philip's chivalry disperse, leaving in front of the English line the bodies of John, king of Bohemia, the blind adventurer — the duke of Lorraine, ten counts and 1,500 gentlemen of coat armour — not to speak of thousands of mercenaries and retainers.

This frightful disaster to the cavalry arm shook to pieces the old theory of feudal war, which rested on the assumption that mailed knights charging in mass could ride over infantry of any sort. The English had taken to heart the results of Bannockburn, where cavalry had a severe lesson, and had gone over to the new tactics. Converging archery volleys, by highly trained professional bowmen, could prevent horsemen from closing, if the ground was favourable and steady supports of dismounted men-at-arms were in the line to give the archers confidence and flank-protection.

King Edward only utilized his victory at Crécy to carry out the siege of Calais, whose surrender after a long and obstinate defence gave him a permanent bridge-head across the Channel for further invasions of France (Aug. 4, 1347). Next summer both England and France were smitten by the awful plague of the Black Death, which swept away a fifth or a third of the population of both countries and upset all social conditions. It was no wonder that truces were concluded, which lasted for over two years; and were renewed — despite some local bickerings and raids by both sides — till 1354. Negotiation with John of France, who succeeded his father Philip of Valois, in 1350, for a permanent peace, coming to nothing, Edward resumed his policy of invasions of France, but apparently was aiming at breaking the enemy's spirit by destructive raids rather than at the reduction of provinces, for the armies made broad trails of devastation across the land, but did not linger to besiege large towns. In this spirit he wasted northern France in 1355, while his son Edward the Black Prince harried Languedoc almost as far as the shore of the Mediterranean. The French refused battle and shut themselves up in fortified places. Next year the king's second son, John of Lancaster, ravaged Normandy, while the Prince of Wales made a second great sweep through central France as far as the gates of Bourges and Tours. While returning laden with plunder, towards Bordeaux, he found himself in contact near Poitiers (*q.v.*) with John of France and an army thrice as great as his own. The king had abandoned his passive defensive policy of the last two years, and had resolved to risk a general action, despite the English archery. Twice in recent combats on a small scale, at

Saintes (1351) and Mauron (1352), the French, when facing English archery, had dismounted the main body of their men-at-arms, and kept on horseback only small detachments of picked horsemen, who tried to turn the line, or to slip in by rapid movement without meeting the full effect of the volley. John tried these same tactics, judging, truly enough, that the fully armoured knight was much less vulnerable on foot than when mounted, and might hope to close with his enemy, if the latter was distracted by preliminary manoeuvres of lightly moving horsemen.

Unfortunately for King John, the Prince of Wales had got into a position which was absolutely unassailable by cavalry, the front line being covered by a long hedge along the brow of the hill of Maupertuis, with but a single gap in it. But the dismounted knights did reach the hedge, though much thinned by the arrow-flight, and very bitter and prolonged fighting took place all along it. But the first French line was beaten back at last, the second flinched and turned away, and only the third, under King John himself, fought out the battle to the end. It finally broke up and retired, leaving King John and his younger son Philip prisoners. This was not so entirely an archery battle as Crécy, but could not have been won without the archers.

Poitiers might have been as indecisive a victory as Crécy, so far as the ending of the war was concerned, if it had not been that the French king had been captured, and naturally desired to ransom himself. It cured his subjects of any wish for general actions, and for the next four years they allowed the armies of King Edward to range about the land doing mischief to the open country, and shut themselves up in walled towns and castles, till the enemy had eaten up the countryside and was forced to move on for want of food. This destructive but inconclusive system of raids might apparently have gone on for an indefinite time, if King John had not made up his mind that captivity was intolerable, and offered to sign almost any terms of peace that King Edward chose to inflict upon him. He assented in the Treaty of London (March 1359) to conditions so humiliating that the French States General refused to ratify them. But in the following winter King Edward conducted a raiding tour all through Picardy, Champagne and the Isle de France with such ferocity that the spirit of the enemy was broken, and the regent of France and the States General assented to the terms which King John had already accepted, and preliminaries of peace were signed at the village of Brétigny, near Chartres, on May 8, 1360.

By this instrument Edward resigned his claim to the French crown in return for receiving back the whole duchy of Aquitaine, as it had been held by his ancestress, Queen Eleanor, free of vassalage to the king of France. He most unwisely reclaimed many counties which had been for a century and a half in French hands, and had quite lost all remembrance of their Plantagenet dukes—Poitou, the Limousin, Quercy, Rouergue, Marche, the Angoumois—a vast holding peopled by unwilling subjects. In addition Edward kept his conquest of Calais, and received back the county of Ponthieu by the mouth of the Somme, which had belonged to his grandmother, Eleanor of Castile, the queen of Edward I. But humiliating as were these renunciations, the French felt even more bitterly the charge of 4,000,000 gold crowns imposed as the ransom of their king. John, though a well meaning man enough, was an incapable sovereign, and, as everyone said, was not worth the money. Moreover he died only a few years after the treaty had been drawn up. Naturally only the early instalments of the ransom money were ever paid. Odd as it may seem, the complete ratification of the treaty was never put on paper, though Edward duly dropped his French title and received all the lands that he had been promised. He handed over Aquitaine to be ruled by his son, the Black Prince, as a fief of England.

PERIOD III. FROM THE TREATY OF BRÉTIGNY (1360) TO THE PEACE OF 1396

For nine years after the Treaty of Brétigny there was nominal peace between England and France, though it did not prevent English and French auxiliaries taking part against each other in the civil war of the duchy of Brittany and the kingdom of Castile. It was, in great measure, the unwisdom of the Black Prince's invasion of Spain—where he won, by force of archery, a great victory at Navarrete in 1367, but spent all his treasure and wrecked his own health—that led to the renewal of the French War. He had raised heavy sums in taxation from his unwilling subjects of the newly annexed regions, and in 1369 they rebelled, called for the aid of Charles V. as their rightful lord, and received it. There followed 11 years of unlucky war, in which the English gradually lost all the lands which had been ceded at Brétigny, and were reduced to their original holding in Guienne. The enemy, captained by the great Constable of France, Bertrand du Guesclin, always refused open battle—the terror of archery was still ever present. But while permitting the English to march unopposed in devastating raids through France, and observing a strict defensive behind walls when the invaders were in the field, the Constable worked on a deliberate plan of picking up by sudden surprises, often helped by treachery from within, outlying castles and cities where the enemy had no adequate garrisons, and from which his raiding army was far distant. The Black Prince, who might have made a good defence of his duchy, had collapsed under his Spanish fevers during the first campaign of the renewed war, and after taking the field once in a litter, and sacking the rebellious town of Limoges (1370), returned to England a broken invalid. The conduct of the war fell into the hands of John of Gaunt, duke of Lancaster, the Black Prince's younger brother. John was a convinced exponent of his father's old policy of bringing France to terms by continued circular raids and devastations. It failed completely, though the invasions themselves were sometimes of the most sweeping sort; in 1373 he marched, unfought, from Calais to Bordeaux, right past the gates of Paris. But he brought to Guienne only the wreck of an army; thousands had perished by the way from privation or in petty ambushes. Lancaster persisted in the same policy, and he and his younger brother, Thomas of Woodstock, led several more raids—almost as lengthy as the adventure of 1373 and quite as fruitless. Meanwhile region after region in the south was falling away to the French, and the command of the sea, won at Sluys in 1340, ceased to be certain after a naval defeat off La Rochelle in 1372.

Edward III. died in senile decay in 1377—his enemy Charles V. and Du Guesclin, the great Constable of France, both in 1380. After this the war slackened down. In England, and in France also, the Crown had fallen to a boy-king, oppressed with several ambitious and unscrupulous uncles, and in each country domestic politics took precedence of military adventure. It will be remembered that 1381 saw Wat Tyler's rebellion and all its wild scenes of massacre and reaction. But though there was no serious fighting after 1386, when there was much fear of a French invasion, and though the French encroachment in Aquitaine had nearly ceased, and a series of truces started in 1392, the war went on in theory till 1396. Then Richard II. having got the better of his uncles, concluded the peace of Paris with Charles VI. In form this odd document was only a truce for 30 years, on the territorial status *quo*, by which Richard kept Bordeaux and Bayonne and the Gascon lands between them, but tacitly abandoned all the other lost French dominions of his grandfather. As the agreement was technically only a truce, he was not forced to the humiliation of renouncing his vain title of King of France. But his marriage with Isabella, the young daughter of Charles VI., sufficiently showed that the 30 years' truce was really a permanent settlement of peace.

PERIOD IV. FROM 1396 TO 1414

When, three years only after the treaty of Paris, Richard II. was overthrown, imprisoned and finally murdered by his cousin Henry of Bolingbroke, it appeared at first quite likely that the fate of the French king's son-in-law would lead to war. But no open war followed—partly because Charles VI. relapsed into one of his intermittent fits of insanity, but much more because civil strife broke out in France between the Orleanist and the Burgundian parties, who were too much interested in each other's affairs to spare much attention for those of England. The Orleanist party, however, intermittently indulged in acts of hostility—sending auxiliaries to help the enemies of Henry IV.—the Scots

and the Welsh rebel Owen Glendower; and in 1403 the Constable and Admiral of France—both Orleanists—raided Plymouth and several Channel ports. In 1406, Orleanists and Burgundians, uniting for once, made attempts, the one on Guienne, the other on Calais—but both were foiled, and when in 1408, Burgundy murdered Orleans, the fight between their factions grew so much more bitter that molestations of the English coasts ceased, and civil! war became permanent in France. Henry IV. was then able to revenge himself in much the same surreptitious ways that the French had been using in his earlier years. He played a most unscrupulous game—lending troops to Burgundy in 1411 and to the Orleanists in 1412, on the general principle that it was profitable to England that the French should have plenty of trouble at home.

PERIOD V. FROM 1414 TO 1422

Henry IV., long broken in health, died on March 20, 1413, leaving his usurped crown to the most capable and ambitious of all the Plantagenets, his son, Henry of Monmouth, the conqueror of France—a model of formal piety from the moment that he came to the throne, a great soldier and a very unscrupulous politician. He very deliberately resolved to attack France, with the idea that a successful foreign war was the best means of keeping his own unruly subjects in good temper. After making a secret pact with John of Burgundy, he sent ambassadors to Paris to renew all the old claims of Edward III.; not only was all Aquitaine to be returned to him, but he was to be given the hand of one of the king's daughters with a competent dowry, and to receive the long-forgotten arrears of the ransom-money of King John, the prisoner of Poitiers. The French were in the throes of civil war, and to stave off invasion made liberal offers of restoration of lands in Aquitaine, and even prepared to discuss the marriage question. Henry professed himself shocked at their meanness and declared war (April 1415).

On Aug. 10, 1415, Henry V. set sail for Normandy with a well equipped army of 12,000 men, of whom two-thirds were archers. He was a strategist of a very different sort from Edward III. and John of Gaunt, and set before himself the splendid if tedious task of conquering France castle by castle and county by county, not that of indulging in futile raids of devastation. On landing he sat down before Harfleur, the town which commanded the mouth of the Seine (Le Wavre did not yet exist), and captured it by force of artillery and mining after a month's siege. This gave him a bridge-head in Normandy, whose conquest was his first aim. As autumn was now drawing on, he had to choose between going into winter quarters in Normandy or marching to Calais. He chose the latter course, probably with the idea that the French would try to stop him and risk a battle, which he desired most of all things. He was not wrong; after he had crossed the Somme with difficulty, he found the whole levy of the Orleanist faction in front of the village of Agincourt (*q.v.*) blocking the road to Calais (Oct. 25). Here was fought the last and most decisive of the great battles of the English archery. D'Albret, Constable of France and the duke of Orleans, used the tactics of Poitiers—an attack by a picked body of horse against the English front, followed by the advance of three solid lines of dismounted men-at-arms. And the result was the same as at Poitiers—the horsemen being shot down with ease. Henry found the French—weighed down by their heavy armour, on a front of ploughed fields sodden with October rain—lurching at a snail's pace towards him. After the archery had played upon them with good effect, he saw them flinch, and charged in upon them, knights and archers all together. They were rolled over in heaps and slaughtered miserably. The Constable was slain, the young Charles of Orleans—head of his faction—and the duke of Bourbon, taken prisoners. The Orleanist faction was for the moment almost annihilated, but finally made head under new leaders—the apathetic dauphin Charles becoming its nominal head, but the new Constable, Bernard of Armagnac, the real leader. And all such resistance as Henry was to meet was from this weakened party. The duke of Burgundy, under a secret agreement with the national enemy, held aloof from the war. Hence the renewed English invasion of France went on with steady progress—Normandy was conquered in three campaigns, 1417–1418–19, with many sieges but no open battle in the field. Henry continued to make offers similar to those which he had formulated in 1414—he must have back all the old lands of Edward III. and the hand and dowry of the mad king's daughter, Catharine.

The whole aspect of affairs then suddenly changed owing to a murder. The Dauphin lured John of Burgundy to a conference on the Bridge of Montereau, and there the duke was assassinated under circumstances of calculated treachery (Sept. 1, 1419). Wildly indignant and left without a leader, the Burgundian faction suddenly threw itself into the arms of the English, and offered to accept Henry as ruler of France; their only desire was to avenge the murder of Montereau. The young Philip of Burgundy put himself at the head of the movement. Hence the Treaty of Troyes (May 21, 1420), by which Henry, on marrying the Princess Catharine, was to be acknowledged as "heir of France," whose crown was to be entailed on their issue, the insane Charles VI. being allowed to retain the royal title till his death. The dauphin was to be completely disinherited "on account of his enormous crimes." The marriage being consummated (June 2), Henry found himself in possession of all those parts of France where the Burgundian faction was predominant—including Paris and a great part of the east and north. But everywhere towns and regions which adhered to the other faction lay in patches among the Burgundian lands. The dauphin was recognized as regent and representative of his incapable father, everywhere south of the Loire.

As head of the Burgundian party, and leading armies half of which consisted of his French supporters, Henry started on the tedious task of conquering in detail all the provinces where his title was denied. In 1420–21–22 he had taken Sens, Montereau, Melun, Dreux, Compiègne and Meaux, and was pushing ever southward, when he succumbed (Aug. 31, 1422) to an attack of fever and dysentery contracted in the trenches during the siege of Meaux. His insane father-in-law died only two months later, so that the infant Henry of Windsor, his only child by the Princess Catharine, was hailed as king of France, no less than of England, in his cradle.

PERIOD VI. 1423–53. EXPULSION OF THE ENGLISH

The next 20 years saw the slow destruction of the work of Henry V. which had been from the first a triumph of misdirected military genius, assisted by the perverse spirit of French faction. Even if he had driven Charles across the Pyrenees or the Alps, it is incredible that his two realms could have held together after his death.

There was little to rouse sympathy or loyalty in the hearts of the French when a king in his second year and an English regent replaced the formidable Henry of Monmouth. The marvel is that the struggle went on so long after his death. But John, duke of Bedford, the little king's uncle, was a soldier of merit and the dauphin's favourites were not. Hence Bedford's victories of Cravant (Aug. 1, 1423) and Verneuil (Aug. 17, 1424), won with armies which were half French in composition, kept the unnatural fabric of the Anglo-French union together, and in 1428 Bedford's advance reached the Loire and laid siege to Orleans. The high-water mark of progress had been attained. But the force before Orleans was but a few thousands strong, and northern France was sick of the English domination. The Burgundians, after ten years, were beginning to forget the murder of Montereau and to remember that they were Frenchmen.

Only on these considerations can the astounding career of Joan of Arc become comprehensible. When the prophetess, or the witch as the English called her, presented herself before the puzzled dauphin and preached her crusade to his doubting ear, she represented the spirit of outraged and indignant France. He resolved to give her mission a trial. Obeying the "voices" which bade her march straight for Orleans under her white banner, she and her company entered the city (April 29, 1429), and she directed a series of sorties which broke the English lines, and finally caused the siege to be raised. This sudden display of spirit produced surprise and then panic among the enemy. "Before that day 200 English would drive 500 French before them—

but now 200 French would beat and chase 400 English." A series of disasters followed, ending in the battle of Patay (June 19, 1429), where, at Joan's orders, the French charged in "before the archers could fix their stakes," and destroyed a third or more of the army of Lord Talbot. She then conducted the dauphin to Reims, where, as she had promised him, he was duly crowned king: every town where there was not a large English garrison threw open its gates as she passed.

Probably the insurrection wquld have spread over the whole of northern France if Joan had been properly backed by her master's ministers and captains. But they secretly derided her inspiration in which the soldiers and peasantry believed, gave her grudging support, and when she failed in a surprise attack on Paris, removed her from her position as adviser and inspirer of the army. The revolt continued, however, to spread, though Joan herself, conducting a raid for the relief of Compiègne, fell by ill-chance into the hands of the Burgundians, who sold her to the regent Bedford. He handed her over to a spiritual court composed of French clergy of the opposite faction, and after many months of captivity she was condemned as a sorceress and heretic, and burned at Rouen on May 29, 1431.

But though Joan suffered the death of a martyr, the movement which she had set going never ceased, though its progress was slow when it was no longer conducted by an enthusiast, but by politicians and captains of mercenary bands. But the basic fact in the situation was that the Burgundians were gradually dropping away from the English alliance: Duke Philip himself finally consented to make terms with his father's murderer at the Peace of Arras (1435) and in the following year Paris fell into the hands of the French—the burgher militia having refused to man their walls, and allowing the enemy to enter, while the small English garrison took refuge in the Bastille, and were starved out in a few days (April 1436). The regent Bedford was spared the humiliation of seeing his life's work undone—he had died in the previous autumn at Rouen.

The most astounding thing in the last weary period of the Hundred Years' War is that the fall of Paris was not immediately followed by the expulsion of the English from the whole of France. The struggle went on for no less than 17 years longer: The English Government in stupid national pride refused to make peace, as they might, by surrendering their boy king's French title; and contenting themselves with retaining the ever-loyal Guienne, Calais, and perhaps Normandy, where they had fortified themselves very strongly. Charles of France was apathetic and his resources ran low, on account of the general exhaustion.ot his realm; nevertheless it is surprising that those hard-fighting veterans, the earls of Warwick and Shrewsbury and the young duke Richard of York, kept Normandy practically intact, considering that the parliament at home grudged both men and money for the war, and that every French town revolted when revolt was possible. There was a long episode of truce in 1444–48, when—a peace party having at last appeared in England, led by the earl of Suffolk—an accommodation was almost secured, the young king was married to a French princess, Margaret of Anjou, and the English claims dwindled down to the retention of Normandy and Guienne. But the negotiations failed, and war broke out again in 1449.

This time the end had come; the duke of Somerset, commanding in Normandy, was an incapable general, but a much better man might have failed when the enemy came against him with overwhelming numbers and a great train of artillery which blew castle after castle to pieces. By 1450 most of the towns of Normandy had fallen, and the duke was being beleaguered in Caen. To relieve him there came over from England a small army, the last but one that crossed the sea during the Hundred Years' War. It was led by two veteran soldiers, Sir Matthew Gough and Sir Thomas Kyriel, but only numbered 3,500 men. On its way towards Caen it was encountered and annihilated by French forces under the Constable Richemont and the count of Clermont at Formigny (April 15, 1450). This was a battle on a small scale, but of high tactical import: the English had formed themselves in their usual order in a position covered by orchards and houses-dismounted men-at-arms in the centre, archers in long flanking wings. The French, instead of charging, brought up light field-guns opposite the archers and, keeping out of arrow range, played on the English line with roundshot till their opponents were goaded into advancing into the open to capture the guns. They were then charged in flank; a general hand to hand mêlée followed, and the French were completely victorious. Of all Kyriel's army only a few hundred got away. This was the end of the English in Normandy—Somerset surrendered Caen on June 24. Nothing now remained to King Henry VI. in the north save Calais.

The next year saw the French army directed against Guienne; no succour came from England; Jack Cade's rebellion was recently over and a bitter parliamentary contest between the dukes of York and Somerset was raging. The outworks of Bordeaux fell in May 1451, the city itself most unwillingly opened its gates on June 30. Bayonne, the last stronghold of Aquitanian loyalism, fell on Aug. 20. It looked as if the war had come to an end. But particularism was still strong: within six months of the fall of Bordeaux, Gascon nobles and burghers were visiting London to implore the aid of an English army and pledging themselves for revolt. The duke of York, as head of the English war party, prevailed on the king's council to make a final effort, and in Oct. 1452 the veteran Talbot, earl of Shrewsbury, the last surviving general of Henry V., came ashore in the Gironde with 3,000 men. On his arrival Bordeaux and all the minor towns rose in insurrection and expelled their French garrisons. But in the following summer the whole force of France was turned southward, and the fate of the duchy was settled. The French army, besieging the loyalist town of Castillon, had strengthened itself with trenches, palisades and guns of position against any relieving force. Talbot came against it with every man that he could raise, English or Gascon, but finding the enemy resolved not to leave his lines and fight in the open, risked an assault. Archery was of no use against entrenchments, and the relieving army tried to break through by main force in a great column. Its head was torn to pieces by a concentrated fire of artillery, and Talbot himself, overthrown by a roundshot, went down outside the trench. The assault having failed, the enemy sallied out from all sides and overwhelmed his leaderless troops. The last levy of Guienne and its English auxiliaries perished wholesale (July 17, 1453).

Yet so great was the hatred of the Bordelais for the French that they held out in despair for nearly three months after Castillon, and only surrendered when it became certain that no more help from England could be expected (Oct. 19, 1453). King Henry had just been struck with the first sudden access of the insanity uhich he inherited from his grandfather, Charles VI of France, and the Wars of the Roses were about to begin. For 20 years no English ruler had the power or the leisure to think of sending troops to continue the long war overseas. This mas the reason why secret emissaries from Guienne found no encouragement in London. It was a marvel that Calais did not share the fate of Bordeaux, and was still destined to remain English for a century, though in the stress of the Wars of the Roses, Queen Margaret of Anjou meditated selling it in exchange for a French mercenary army If Charles VII had been a man of energy, and not *"le bien servi,"* he might have mastered the last English foothold in France. But though war continued for a few years more, and the Senéchal of Normandy sacked Sandwich so late as 1457, the struggle petered out obscurely, and ended in a truce made by the Lancastrian party with Louis XI, whom they secured as their ally in English civil strife. (C. W. C. O)

HUNEKER, JAMES GIBBONS (1860–1921), **U.S.** critic, whose perceptive comments and brilliant style uon him a wide audience both in Europe and the United States, was born in Philadelphia, Jan. 31, 1860, and studied the piano in Philadelphia. Paris and New York. He taught piano at the National Conservatory of Music, New York city, 1886–98, and was musical and dramatic critic for the New *York Recorder* and *Morning Advertiser.*

He joined the *New York Sun* in 1900, the *Times* in 1918 and the *World* in 1919. *A* man of great versatility, he frequently wrote on art and literature as well as music and drama. His pub-

lished works include: *Chopin: the Man and His Music* (1900); *Overtones: a Book of Temperaments* (1904); *Iconoclasts:* a *Book of Dramatists* (1905); *Franz Liszt: a Study* (1911); *Egoists: a Book of Supermen* (1909); and *Ivory Apes and Peacocks* (1915). He died in Brooklyn, N.Y., Feb. 9, 1921.

HUNGARIAN LANGUAGE. Hungarian (self-designation MAGYAR) is spoken by about 12,000,000 persons. mainly in the central Danube valley, in Hungary. in Czechoslovakia, in Rumania and in Yugoslavia, and by scattered groups elsewhere (close to 500,000 in the United States).

History. — Hungarian belongs to the Uralic language family which includes the Finno-Ugrian and the Samoyed branches. Closest kin to Hungarian are the two other Ugric languages. Vogul and Ostyak. now spoken in western Siberia. From Cralic. Hungarian inherited about 250 basic words. and the Uralic portion still makes up more than three-fourths of the morphemes in a running text. Up to the conquest of present-day Hungary at the end of the 9th century A.D.. the vocabulary of Hungarian was greatly affected by old Iranian (metallurgical expressions), by Turkic (cattle breeding and agriculture) and to a minor extent by Ossetian and Caucasian. After the conquest the major influences came from Slavonic. Latin and German. The earliest occurrence of Hungarian words is in Arabic (8th-century), Greek (10th-century) and Latin (10th-century) texts; the first connected text. a funeral sermon. dates from the end of the 12th century. A major development of Hungarian took place around the turn of the 18th and 19th centuries, when in a quarter of a century 10,000 new words were introduced through neologistic formations, all in accordance with existing patterns which left the structure of the language unchanged. Dialectal differentiation is not very great.

Script. — During the 1st millennium after Christ, while they inhabited the steppes, the Hungarians acquired a script, related to the Old Turkic runes which, though not extensively used, survived until after the middle ages. The current Hungarian script was introduced in the 11th century by western Christianity and its orthography stabilized by the 16th century with the introduction of printing. The alphabet inciudes single letters and digraphs. The spelling is consistently phonetic. except that minor variations at morphological boundaries are not indicated and that remnants of historical spelling occur in family names. Of the vowels, the accentuated letters are pronounced long, the others short; thus *e* as in "bed." *á* as in "father." Of the consonants. *p, t* and *k* are unaspirated, *b*, d and *g* voiced; *y* (except at the end of family names where it stands for i) indicates palatal articulation, *ny* as in French *champagne; s* is pronounced as in "she," *sz* as in "six," *z* as in "zero," *zs* as in "rouge," *cs* as in "arch." *c* as in German *zehn*. Long consonants are written double (the first component only in case of the digraphs, in hyphenation both components: *össze* ["together"] but *osz-sze).*

Phonology. — The vowels include back vowels: *a d o ó u ú,* front rounded vowels: *o ő u ű,* and front unrounded vowels: *e é i í* (with many speakers differentiating two *e* phonemes). The consonants comprehend: stops; nasals; fricatives; affricates; and liquids: 1 (clear) and *r* (trilled). The occurrence of vowels in words is governed by vowel harmony: back vowels do not occur together with front rounded vowels. Consonant clusters are simple; initially in general no clusters occur. Stress is always on the first vowel of the word.

There is a distinction between falling intonation indicating assertion, and interrogative intonation which is rising if the utterance is not longer than two syllables and rising to the prefinal syllable and then falling if the utterance is longer.

Grammar. — The grammatical structure is transparent, and the categories clearly marked. The main morphological process is suffixation, by which words of considerable length can be produced; *e.g., verethetnélek* "I might cause thee to be beaten" *(ver* "beat," *-et* "cause," *-het* "may," *-né* [conditional], *-lek* "I thee"); *tanítványaimtól* "from my pupils" (*tanít* "teach," *-vány* [nominal derivative]: *-ai* [plural], *-m* "my," *-tól* "from"). Prefixes are rare, *legszebb* "most beautiful" from *szebb* "more beautiful." Suffixes often have two alternants, one with a front and one with a back vowel, which are added to stems with corresponding vowels *(cf.* vowel harmony), *Berlinben* "in Berlin." *Stockholmban* "in Stockholm." (This difference is sometimes employed for lexical purposes. *kever* "stir lightly," *kawar* "stir heavily," or in demonstratives, *ez* "this," *az* "that," *ide* "hither," *oda* "thither.")

Noun inflection indicates number, possessivity (reference to person and number, *emberem* "my man"), and case (there are about 25 cases, most of them indicating locality and direction, such as inessive "within"; other nonspatial relations, such as causal "for the sake of"). The cases are supplemented by postpositional constructions which do not show accommodation to the vowels of the head word, *emberben* "in man," *hdzbnn* "in the house," but *ember mellett* "besides the man," *hdz mellett* "besides the house." Adjectives have three degrees: *nagy* "big." *nagyobb* "bigger," *legnagyobb* "biggest"; there is also a degree expressing exaggeration, *legeslegnagyobb* "the very biggest." Personal pronouns have only two cases, nominative and accusative, the rest of the paradigm is supplemented by suffixed forms; *e.g., tn* "I," *engem* "me,!' but *bennem* "in me." *mellettem* "next to me."

There are two slightly different conjugational types: the so-called -ik verbs having the suffix *-ik,* and non-ik; *e.g., es-ik* "he, she, it falls," *üt* "he, she, it beats." The categories are: mood (indicative; conjunctive, indicating condition or wish; and imperative); tense (present and perfect); number and person; and definiteness: there is a reference in each verbal form to the definiteness of a third person object, or the lack of it. *lát* "he, she, it sees" (in general, something indefinite or unknown), but *ldtja* "he, she, it sees" (something definite, like the house, my house, a known person, etc.); in the first person singular there is also an inclusive form indicating an object in the second person, *látlak* "I see thee or you."

Both nominal and verbal derivation plays a great role, as a device partly for augmenting the vocabulary, as in *kot* "bind." *kottl* "rope," *kotelez* "oblige," *kotelezvkny* "I.O.U.," and partly for expressing nuances of reference, *csepeg* "drop," *csepereg* "drizzle," *cseppen* "drop (once)" from *csepp* "drop."

Syntax. — In attributive phrases adjectives are uninflected, *nagy ház* "big house." *nagy házakban* "in big houses." The article is the first element in phrases, *a* (preconsonantal) *nagy ház* "the big house," *az* (prevocalicj *ember* "the man." After numerals the "singular" form stands, *ezer ember* "a thousand men." Predicates are either verbal or nominal. and agree in number with the subject, *az ember lát* "the man sees," *az emberek látnak* "the men see," *az ember jó* "the man is good." *az emberek jdk* "the men are good." The order of phrases in a sentence is relatively free, but the stressed element which includes contrastive stress, question and negation must stand immediately before the predicate, 6 *otthon van* "he, she is at home." *ki van otthon* "who is at home?"

Országh, *Magyar-angol szótár* ("Hungarian-English Dictionary") (Budapest, 1953); G. Bárczi, *Magyar szófejtő szótár* ("Hungarian Etymological Dictionary") (Budapest, 1941). *Grammar:* J. Lotz, *Das ungarische Sprachsystem* (Stockholm, 1939). (*J. Lz.*)

HUNGARIAN LITERATURE. Nothing remains **of** the earliest Hungarian literature. Its existence can, however. be established with certainty. Through Hungarian folk tales and songs, elements have survived that can be traced back to pagan times. We also possess, unfortunately only in Latin and dating from between the 11th and 14th centuries, shortened versions of some Hungarian legends relating the origins of the Hungarian people; and episodes from the conquest of Hungary and from the Hungarian campaigns of the 10th century.

Earliest Works in Latin. — The establishment in 1001 of a Christian kingdom created the conditions for a new type of literature. Christian in content and Latin in language, which gradually ousted the older, unwritten. traditional preliterature, national in content and Hungarian in language. Up to the 13th century to write meant to write in Latin.

The first Hungarian writers in Latin appeared toward the middle

of the 11th century. They were the bishops Maur (Mór) and Nicholas (Miklós), the first the author of the first Hungarian saint's life. the second probably the author of the first Hungarian chronicle. This kind of literature centred around the royal court, the bishoprics and a Benedictine convent founded in 997 at Pannonhalma. In the second half of the 12th century the court of King Béla III (1172–96) became a centre of literati in which, besides Hungarian writers and scholars who had been studying at French or Italian universities, there were also representatives of the *Minnesang* and troubadour schools of poetry.

In the first four centuries of the new Hungarian kingdom, chronicles. lives of the saints and hymns were the principal literary products in Latin. Some of the chronicles stand out for the excellence of their form and originality of their conceptions. A notary of Ring BCla III—known as the Anonymus—wrote a *Gesta Ungarorum* in which lack of historical accuracy is counterbalanced by literary merit. Simon of Kéza. working under King Ladislas [Ladislaus) IV (1272–90), originated a theory which gained immense popularity in Hungary: that of the identity of Huns and Hungarians, which, though not warranted by historical fact, has haunted even modern research. In the 14th century Marc Kálti compiled a history of Hungary which was to serve as a basis for all later Hungarian histories.

The earliest saint's legend, dealing with the lives of St. Zoard and St. Benedict. was written *c.* 1060 by Bishop Maur. About 1100 were written the three legends of St. Stephen (the first Christian king of Hungary), the two legends of the bishop St. Gerard and the legend of St. Emeric, son of King Stephen. They were followed at the end of the 12th century by a legend of St. Ladislas. These legends are works of some individuality, and their heroes emerge as richly characterized human beings.

Hymns were mainly written in the 13th and 14th centuries for feasts of Hungarian saints. Mention should be made of a *Planctus destructionis regni Hungariac,* which gives a heart-rending picture of the destruction wrought by the Mongol invasion of 1241–42.

Earliest Works in Hungarian. — The first written traces of the Hungarian language consist of Hungarian words. mostly proper names, embedded in the Latin text of legal or ecclesiastical documents. The first connected example of the language is a short funeral oration written *c.* 1200, original and moving in its simplicity. The 13th century saw many translations from Latin, only one of nhich has come down, a free version of a poem by Godefroy de Breteuil; a complaint of the Virgin over her Son's body. This is the first poem written in Hungarian to survive. The 14th century also produced translations of the legends of St. Margaret and of St. Francis of Assisi. The so-called *Jdkai codex,* written *c.* 1440, which contains St. Francis' legend, is the oldest extant Hungarian codex.

The 1 jth century saw the first translations from the Bible. Two Hussite preachers. Thomas and Valentine. were responsible for this work. of which the prophetic Books, the Psalms and the Gospels have survived. A great part of the vocabulary, created for the purpose, is still in use. The Latin sermons of the Franciscan Pelbárt Temesvári constitute perhaps the greatest single achievement of Hungarian literature in that epoch. Though written in Latin they were intended for a Hungarian public, and became very popular in other European countries. A number of Temesvári's sermons have come down in Hungarian translations. Other translations include the first Hungarian drama. On *Three Christian Virgins,* a translation of the legend of St. Catherine of Alexandria and the beautiful translation of the Song of Solomon. There is also a Hungarian version of a Latin hymn in honour of St. Ladislas, and a hymn to the Virgin Mary by András Vásárhelyi.

Hungarian literature mas not entirely religious. The existence of a history of the Trojan war and of a Hungarian version of the Alexander romance can be inferred from their south Slavonic translations. In the 14th century, with laymen going in ever greater numbers to school, conditions for the development of secular literature greatly improved. Much of this literature mas simply occasional verse, of which very little has survived. We are fortunate enough to possess a song written in 1476 after the capture of Szabács by King Matthias Corvinus. From the 14th century onward more laymen went to study at universities abroad, and on their return tried to introduce the literary forms they had learned.

Renaissance **and** Reformation. — Even in the 1 jth century and at the beginning of the 16th Latin remained the language of serious literature. This perpetuation of Latin was a result partly of humanist influences in Hungary. In the second half of the 14th century Italian influence became predominant in Hungary through King Louis I of Anjou, a member of the royal house of Naples. In 136; the first Hungarian university was founded. In the middle of the 15th century, with the accession of King Matthias I, the court became a centre of humanism. Matthias' famous library, the Corvina. became widely known; he later founded a university in Pozsony and established in Buda the first Hungarian press. While vernacular literature was making its first hesitating steps, Latin literature reached its peak in Janus Pannonius, the greatest humanist of Hungary. Nephew of the archbishop of Esztergom, Janus Pannonius was educated in Italy. He achieved greatness only after his return to his own country, when, abandoning an earlier witty vein, he wrote a great number of elegies. The troubles of a responsible statesman, difficulties in combating the Turks, love of country, sorrow at his mother's death, his own illness, were all sources of inspiration. He also found it difficult to adapt himself to the iron discipline of Matthias' court.

The 16th century brought changes in the political, spiritual and literary life of Hungary. Politically the Turkish wars were the dominating factor. After the battle of Mohács (1526) the country was split into three parts, and the centres of humanist and literary thought were destroyed. Many distinguished humanists had to emigrate, among them Miklós Oláh (1493–1568). who belonged to the circle of Erasmus and who spent much time in the Netherlands; János Zsamboki, better known under his latinized name, Sambucus (1531–84), who worked in Vienna; and András Dudich (1533–89), who spent long periods in Poland and Silesia. The 16th century brought the dawn of a new era. The new impulse that transformed Hungarian literature was the Reformation.

In the 16th century not only Hungary but its literature was a battleground, and the aims of the writers of this period were above all practical. They wrote not for posterity but for their contemporaries. It was an age not of contemplation but of action, and it is small wonder that in such circumstances no major works of art were produced. This element of actuality had, however, an important consequence. In order to be understood by as wide a circle as possible, the writers had to write in Hungarian. Hungarian national literature really begins with the Reformation. Mention must here be made of three forerunners of this new era: Benedek Komjbthy, Gábor Pesti and Jbnos Sylvester. All three were of humble origin, were disciples of Erasmus and were active in translating parts of the Bible. With methods infinitely superior to those employed 100 years earlier by the Hussite teachers, they translated with a philological accuracy worthy of Erasmus himself. Pesti made also a very readable translation of Aesop's *Fables,* and in 1538 published a Latin-Hungarian dictionary. In 1539 Sylvester published the first Hungarian grammar and, to show the adaptability of his mother tongue to classical verse forms, wrote the first Hungarian poem in distichs. In 1541 he published a translation of the whole New Testament.

With the spread of the new religion the need for hymns in Hungarian became acute. Most of these were translations of the hymns of Luther or other German Protestant authors, or of the Psalms. Among translators must be mentioned András Batizi. also author of a world history and of several stories based on the Bible. Mihály Sztárai, who played an important role in the Hungarian Reformation, translated some of the Psalms into Hungarian verse. The most original in this group was András Szkhárosi Horvát, author of didactic poems, versified sermons and versified paraphrases of biblical stories, perhaps the greatest Hungarian satirist.

The second half of the 16th century saw the beginnings of Hungarian drama. Sztárai gave dramatic form to fictitious religious disputations: *Papok házassága* ("The Marriage of Priests") and *Az igaz papság tüköre* ("The Mirror of True Priesthood"). As plays these are primitive and have little to commend them. An-

other similar drama with an anti-Trinitarian tendency, *Debreceni Disputa* ("The Dispute of Debrecen"), is much better. *Balassi Menyhárt árulásáról irott komédia* ("Comedy on the Betrayal of Menyhbrt Balassi"), by an unknown author, is perhaps the most interesting literary achievement of the Reformation. This satirical comedy centres round a Hungarian aristocrat well known for his intrigues.

Gáspár Heltai (d. 1574) made a good adaptation of Aesop's *Fables*. A huge collection of sermons is the main product of Péter Bornemisza's (1535–84) literary activity. He gives an entrancing view of Hungarian life in the 16th century, teeming with fresh observations, vivid descriptions and original psychological comments. His volume "On the Temptations of the Devil" gives an interesting picture of sexual problems in the 16th century. A poem of farewell, written on leaving the country, is one of the gems of early Hungarian poetry.

Perhaps the greatest single literary achievement of the Hungarian Reformation was the translation of the Bible by Gáspár Károlyi (1590). This played a role similar to that played by the Authorized Version in the development of the English language.

Though contemplation and interest in religious and philosophical problems are by no means characteristic of the Hungarian mind, up to the 18th century religious literature seems to have fared better than secular literature. This was due partly, as has already been mentioned, to the fact that secular literature was not written down. The existence of secular literature is, however, well attested. The late 16th-century minstrels were men more learned than their predecessors, often driven to such a profession by the difficult economic conditions of the age. Many of their works were circulated in manuscript; many were printed. Perhaps the most important of these minstrels was Sebestyén Tinódi (d. 1556). By temperament he was more of a historian than a poet. He described the wars against the Turks with remarkable accuracy, but his verse is monotonous and shows little imaginative power. Tinódi also wrote music which assures him a place in the history of Hungarian music. Péter Ilosvai Selymes was the author of a romance, *Miklds Toldi* (1574), of little poetic merit, which achieved, however, great popularity in Hungary and served as a basis for János Arany's masterpiece in the 19th century. The hero, a man of immense strength who lived in the 14th century, is one of the most popular figures in Hungarian literature. This romance is the one piece of original conception in the steady flow of secondhand matter which characterizes the literature of the 15th century, a literature intended merely to entertain. Its principal genre is the so-called *széphistória* ("beautiful story") called after the Italian *bella istoria*. Perhaps the best is the "History of Argirus" by the otherwise unknown Albert Gergei. Though based on an Italian original, the story—written in verse—is interwoven with elements of Hungarian folklore and has a naïve charm. Most of the other *széphistória* are more or less free adaptations of western European originals.

The balance sheet of Hungarian literature in the 16th century would be depressing were it not for the figure of Bálint Balassi (1554–94). Balassi's life was a harassed one, spent in endless pursuit of lost rights, in fighting against the Turks, in wars, in adventures. He created a poetry highly original, reminiscent in many respects of that of the Cavalier poets of English literature. But if he has the dash and the frivolity of these writers, he has also a depth which they lack. Balassi calls to mind François Villon, enjoying fights, love, the good things in life, but with sudden and deeply sincere religious impulses. Unlike Villon, however, he shows a knowledge of nature. Balassi was not only a great poet, he was also a versifier of great dexterity. Technically, his verses are unmatched in early Hungarian literature.

Balassi had many imitators and followers. Perhaps the most important was János Rimay (1573–1631), a personal friend of Balassi and the editor of many of his verses.

The 17th Century.— The political situation of 17th-century Hungary makes it difficult to give a clear outline of the literature. The country was still divided into three parts. The first, under Turkish rule, played no part in the development of Hungarian literature. The second, under Habsburg rule, was open to western and Catholic influence; whereas the third part, Transylvania, was isolated from the main current of European thought. Though Transylvania had no university like that founded in 1635 in Nagyszombat by Péter Cardinal Pázmány, the Protestant college of Gyulafehérvár, patronized by the prince of Transylvania, Gibor Bethlen, played a similar role. Transylvanian intellectuals turned toward Protestant Germany, Holland and England. The most important was Albert Szenczi Molnár (1574–1634). He translated the *Institutes* of Calvin and the Geneva Psalms (1607). He also compiled a Latin-Hungarian and Hungarian-Latin dictionary, a Hungarian grammar, and wrote many sermons.

From the beginning of the second decade of the 17th century many Hungarian Protestant theologians went to Dutch universities. Some even visited England and translated the works of such puritan theologians as William Perkins and William Ames. From this epoch dates the first Hungarian travel book (*Europica Varietas*, 1620) by Márton Szepsi Csombor (1594–1623). The greatest Protestant scholar and writer of the 17th century was the puritan János Apáczai Csere (1625–59). His chief work, a Hungarian encyclopaedia in which he endeavoured to sum up the knowledge of his time, marks an important step in the development of a technical vocabulary. Protestant writers seem to have been interested more in learning than in letters. An interesting figure is that of the printer and pamphleteer Miklos Totfalusi Kis (1650–1702) who modernized Hungarian orthography.

By the end of the 16th century the Counter Reformation was gaining momentum in the western parts of Hungary. Among its representatives the vigorous personality of the Jesuit Péter Cardinal Pázmány (1570–1637) stands out. A master of Hungarian prose, he was an orator and essayist of the first order. A vigour of style, always clear though far irom simple, a use of popular expressions and a solidity of argument are the chief qualities of his work. As is to be expected, all his work is controversial, and his *Isteni igazságra vezérlő kalauz* ("Guide Leading to the Divine Truth," 1613) is a refutation of non-Catholic religious doctrines. Another Jesuit, Gyorgy Káldi, produced in 1626 the first Catholic translation of the Bible.

Under the influence of the Jesuits, many Hungarian aristocrats returned to the Catholic faith, and sent their sons to the Austrian Catholic universities and to Rome. There they became acquainted with the baroque style and introduced it into Hungarian literature Baroque influence can be seen in the work oi Miklós Zrinyi (1620–64). He belonged to a family with great traditions, and became one of the greatest Hungarian statesmen and generals of his time. Most of his prose work is an exposition of his political and strategic ideas. His greatest literary achievement is his epic *Szigeti Veszedelem* in 15 cantos. The subject is the siege in 1566 of Szigetvbr, defended against the Turks by Zrinyi's great-grandfather. Though the influence of the epics of Homer, Virgil, Ariosto and Tasso is clear, the work remains in concept and character profoundly original and Hungarian. Zrinyi succeeds in imbuing the historical facts, to which he closely adheres, with a symbolic value, which conveys his own political ideas.

Another epic poet of this time, István Gyöngyösi (1629–1704), was concerned with lesser subjects. He composed many epithalamia, was inventive and handled rhyme with great ease. His poems were much read during the 17th and 18th centuries

The works of aristocratic poets like Zrinyi and Gyongyosi form but a fraction of the poetic harvest of the 17th century, when writing poetry seems to have become the fashion among all classes. The so-called *Kuruc* songs stand out by their high artistic merit. The *Kurucs* were Hungarian partisans fighting against the Germans and the Habsburgs. Their poems—largely anonymous—give gripping descriptions of their poverty and misery, but also of their joys. Many celebrate the deeds of the great figures of the insurrection, particularly those of Francis Rákóczi, prince of Transylvania and leader of the last great rising (1703–11). Many Hungarian poets have sought inspiration in these *Kuruc* songs

Decadence.—The period between 1711 and about 1770 was a time of decadence in Hungarian literature Memoirs form what is best in the prose literature of this period. The autobiography of Miklós Bethlen (1642–1716), a leading Transylvanian politician, and the *Confessions* and *Mémoires* of Rákóczi, written respectively in Latin and French, make absorbing reading. The *Letters* of Kelemen Mikes (1690–1761), a companion in exile of Rákóczi, were addressed to an imaginary aunt. In choosing this genre Mikes was inspired by French influence, and his work stands out for its excellent style. The *Metamorphosis Transylvaniae* of Péter Apor (1676–1752) is a nostalgic reminiscence of the "good old days" in Transylvania before German customs had penetrated it.

Poetry of this epoch has little to offer. The poems of László Amadé (1703–64) are both in form and in content rococo. Amadé creates a Hungarian version of the *poésie galante*. He is matched by Ferenc Faludi (1704–79) who, however, takes his expressions from popular

language.

The middle of the 18th century saw the beginning of the "school dramas," so called because they were the Hungarian versions, prepared in schools, of foreign dramas.

This period of literary decadence produced notable works only in the fields of history and history of literature, Some of these were written in Latin. Among historians Mátyás Bél, Gyorgy Pray and István Katona are most important. The first historian of Hungarian literature, Dávid Czwittinger (1676–1743), wrote the biographies of about 300 Hungarian writers. His work was continued and improved by Péter Bod, whose *Magyar Athenás* ("Hungarian Athenaeum," 1766) deals with more than 500 Hungarian men of letters.

The Period of the Enlightenment. — The period between about 1772 and 1825 is often called that of the Enlightenment. Though immensely important in the development of the Hungarian spirit, it produced few writers of the first rank. However, this period prepared the ground for the splendid harvest of the 19th century, when Hungarian literature reached its greatest height. The Hungarian Enlightenment was more receptive of foreign (French and English) ideas than productive of original developments, and the main task of its exponents was to adapt the new ideas to the particularities of the Hungarian scene.

The first interpreter in Hungary of the ideas of the Enlightenment, György Bessenyei (1746–1811), decisively influenced Hungarian literature. It is with the publication, in 1772, of his first literary work, a translation (from the French) of Pope's *An Essay on Man,* that the new era begins. Bessenyei's aim was knowledge rather than pure art, and all his works serve a didactic purpose. From 1765 to 1782 he lived in Vienna, where he came to realize the backwardness of his own country. His best drama, *Agis tragédiája* ("The Tragedy of Agis," 1772), serves as a somewhat creaking vehicle for his antidespotic ideas. The problems touched upon in Greek guise remain recognizably Hungarian. His best work, *Tarimenes utazása* ("Tarimenes' Journey," 1802–04), the first real novel in Hungarian, remained unpublished for over a century. It is a bitter attack on everything that conflicts with the views of Enlightenment. With destructive irony, reminiscent of that of Swift, Bessenyei examines the shortcomings of human society.

The purely literary merit of Bessenyei's work is slight, but by writing in Hungarian, by trying his hand at various literary genres such as the drama and novel, hitherto practically unknown in Hungary, and by knocking at the closed door of Hungarian civilization with the new ideas of the Enlightenment he started a movement which put an end to the literary stagnation of the early part of the century. His personal influence induced several of his fellow officers—*e.g.,* Sándor Barotzi (1735–1809) and Abraham Barcsay (1742–1806)—to try to convey the ideas of the Enlightenment in Hungarian to a Hungarian public. This public was, as yet, virtually nonexistent, and works like those produced by Bessenyei were unlikely to create much desire to read.

Spurred on by new ideas, but basically traditionalists, the general of the cavalry, Jbzsef Gvadányi (1725–1801), and András Dugonics (1740–1810) achieved works of some literary merit and amusing enough to become popular. Gvadanyi's best work *Egy falusi nótárius budai utazasa* ("The Journey to Buda of a Village Notary," 1790) is a long narrative poem describing with humour and irony the adventures of a somewhat pretentious but basically sane notary who, on reaching the capital, is deeply shocked by the ioreign fashions prevailing there. The whole work is an apology for national and traditional values against encroaching foreign ideas. The novel *Etelka* (1788) by Dugonics, a sentimental love story in a historical setting, was the first Hungarian "best seller." It is a bad work by any standards, unoriginal, full of deplorable anachronisms, but its praise of the golden days of the Hungarian past and of popular tradition had a general appeal. Both Gvadanyi and Dugonics used a popular language, free from foreign influence, and this is perhaps their greatest merit. Ádám Pálóczi Horváth (1760–1820) belonged to the same group of writers representing national resistance to foreign ideas. His epic poem *Hunnias* (1787) on John Hunyadi would not justify the presence of his name in this survey. He left, however, in manuscript a collection of 450 poems (*Ötödjélszáz dnekek,* publ. Budapest, 1953), which is a treasure house of popular poetry and music and incorporates a number of poems of his own making. Those in the popular vein are still enjoyable, and his religious, psalmlike, poems are moving by their vigour and sincerity.

This period at the end of the 18th century is a period of discovery, and of experiments with language. Minor attempts at changing the traditional Hungarian verse form had been made by Bessenyei, Lorine Orczy and others, but other men were to explore the road on which János Sylvester had taken the first steps: the use of classical metre for Hungarian verse. The pioneers, Dávid Baróti Szabo (1739–1818), József Rajnis (1741–1812), Miklos Révai (1750–1807) were followed by Benedek Virág (1754–1830) who, influenced by Horace, imbued with poetic inspiration verse forms which for his predecessors were merely formal exercises. It fell to Dániel Berzsenyi (1776–1836) to show what use a really great poet could make of classical metre.

Berzsenyi is a giant of expression. What he has to say is neither particularly original in itself nor in its forms. It is the terseness and vigour of the expression, the power of conviction, that make his lines memorable. His ode to *Magyarokhoz* ("The Hungarians"), his *Fohasz* ("Prayer"), his elegy *A közelitő tél* ("On the Nearing Winter"), belong to a category beyond criticism. Berzsenyi could perceive, as few others could, the transitoriness of power, glory, friendship, of everything but God "whose existence shines like the burning sun but cannot be looked upon." He had taken irom his beloved Horace the acute perception of the ephemeral, but his *carpe diem* ("seize the day") is a mild, melancholy echo, almost a renunciation. Only the destinies of his country can really move him, "moral rectitude is every country's mainstay and foundation." He exults at the sight of groups of men abiding by their loyalties; and, looking into Hungary's past, he finds solace in the thought that "eagles engender but eagles, and the leopard of Nubia will not bear timid rabbits."

The ideas of the Enlightenment were not universally welcomed in Hungary. The traditionalist elements looked, as we have seen, with distrust on any imported ideas, and the government was increasingly distrustful of a spiritual trend which had led to the French Revolution and, in Hungary, to the conspiracy of Martinovics. László Szentjobi Szabo (1776–95), Ferenc Verseghy (1757–1822), János Batsanyi (1763–1845) went to prison—where Szentjóbi Szabó .died—for the crime of sympathy with these ideas. The most talented among them, Batsanyi, secured his place in the history of Hungarian literature by his poem *A franciaorszdgi változásokra* ("At the Changes in France"), a vigorous warning to all tyrants "to cast their watchful eyes on Paris."

Sentimentalism found its interpreters in Jbzsef Kármán (1769–9j) and Gabriel Dayka (1769–96). Kármán's only work of importance, *Fanni hagyomdnyai* ("The Papers of Fanny"), is a sentimental novel, written in the form of letters and diary entries. Very much on the lines of Goethe's *Werther,* the work nevertheless marks an important step in the history of the Hungarian novel. Dayka, a poet, died too young for the full measure of his talent to be realized.

The first really important lyric poet since Balassi was Mihály Csokonai Vitéz (1773–1805). A widely read, intelligent man, Csokonai continued the purely Hungarian poetical tradition, and his many songs to "Lilla" are a happy blend of rococo grace and thoughts less superficial than they appear. The influence of Rousseau is very noticeable in some of his longer philosophical poems which make a curious contrast to his popular drinking songs. He is an absolute master of form, and his poems, filled with subtle grace, show no trace of the acute sufferings of his life.

Pope's *The Rape of the Lock* served as a source of inspiration for Csokonai's comic epic *Dorottya* ("Dorothy"), but Csokonai's poem is original and very much Hungarian. The heroine, an old spinster, leads a revolt against men reluctant to marry. The language of the poem, not exempt from some slight vulgarity, is vigorous, the comic situations somewhat coarse but amusing. Mihaly Fazekas (1766–1828), a friend of Csokonai, won fame by his *Ludas Matyi,* a humorous narrative poem relating the clever vengeance of a serf on his cruel lord.

The place of Sándor Kisfaludy (1772–1844) in Hungarian literature is secured by his first work *Kesergő szerelem* ("Plaintive Love"), a song cycle depending on a very thin narrative thread: the hero Himfy finds no response to his love for Liza; in despair he goes to the wars, and returns to find that Liza still refuses to become his wife. Writing in a very elaborate verse form of 12 lines, devised by Kisfaludy and called the Himfy verse, the poet displays an astounding ingenuity in finding new variations on the theme of unhappy love. Though no one reading the whole cycle could escape a sense of monotony, the individual songs are often beautiful. "Plaintive Love" had an immense success, which prompted Kisfaludy to publish a second song cycle *Boldog szerelem* ("Happy Love," 1807), in which, with similar skill but less verve, he tried to find varied expressions to convey the apparently undisturbed bliss of his marriage. Among his better works must also be reckoned three tales, *Csobanc, Tdtika, Somló,* written in the romantic mood of *Rittergeschichten* ("stories of chivalry").

Few, if any, of the names mentioned in this account of the period following Bessenyei's appearance on the literary scene can be dissociated from Ferenc Kazinczy (1759–1831), a mediocre poet but an influential man of letters: for about 40 years he was the pivot of literary life. Aristocratic, cool, formal, efficient, his political conceptions were progressive, a luxury for which he paid with six years' imprisonment His aim was to purify Hungarian literature irom all vulgarity. He wanted a literature refined and limpid, neither baroque nor popular. What he hated above all was bad taste. His interest was focused on style, on presentation, on construction; the thoughts expressed were for him secondary To satisfy his desire for a more refined literature he became the head of the *neologi* who, opposed by the *orthologi,* tried to renew and enrich the Hungarian language to make it suitable to express the most elaborate thoughts. This language reform, which lasted through much of the 19th century, enriched Hungarian and made of it the most versatile instrument a poet can hope for. Kazinczy's activity. his correspondence and memoirs, his biting, satirical epigrams, his extensive translations of works, sometimes ill-chosen, but of varied nature so as to serve as stylistic exercises, and, above all, his great personal prestige and influence, leit an indelible mark on Hungarian letters.

The Early 19th Century. — The literary revival caused by Kazinczy's activity continued after his death, and even in the last years of his life the literary leadership of the country was assumed by Károly Kisfaludy (1788–1830), brother of Sándor In 1822 he iounded the literary magazine *Aurora,* the first of its kind, which achieved real popularity and to which all the important writers of the period contributed. Károly Kisfaludy's other important contribution to Hungarian literature was in the field of drama, where he was the first representative of romanticism and the first playwright to achieve con-

siclerable popular success. Among his many historical tragedies, *Iréne,* set in 15th-century Constantinople, and the Voivode Stibor are the best, though they fall short of the requirements of a really good play. His comedies are still enjoyable, and portray well a number of characters of the contemporary Hungarian society. He also tried his hand at short stories, and his satirical descriptions, still amusing and instructive, had at the time a political message which, with its mildly progressive ideas, was not unwelcome in a society basically conservative but more and more convinced of the necessity of social and political reforms.

While Kisfaludy's tragedies, often very shallow, were applauded all over the country, one of the best tragedies in Hungarian, published in 1820, remained entirely unknown. Its author, József Katona (1791–1830), a lawyer who in his student days had been attracted by the stage, translated from German a great number of dramas and wrote several original plays, all insignificant. In 1815 he wrote his masterpiece: Bank *bán* (the bdn was a high Hungarian dignitary). Set in the 13th century the play is a masterful combination of national and individual conflicts culminating in the murder of the queen by Bánk, the highest dignitary of the country, who wrongfully accuses her of having helped his brother Otto to violate Bank's wife. The queen, though responsible for many wrongful acts, had been innocent of this specific crime, and Bank realizes too late his fatal mistake. Particularly effective is the role of Tiborc, a poor peasant, whose figure has remained ever since the symbol of the oppressed. The tragedy, written in a vigorous prose, is a real work of art in content as well as in form.

Though it would be difficult to overestimate Kazinczy's contribution to the development of Hungarian letters, he himself, like his circle, produced no outstanding works of art. All the good, and many of the bad, poets were indebted to him; but the really strong talents had to break away and find, indeed create, their own forms of expression. This was the case with Berzsenyi, Csokonai, Károly Kisfaludy and another poet who had been in closer touch with Kazinczy than any of these: Ferenc Kolcsey (1790–1838). Kolcsey's poetical production was comparatively small, and his first poems belong to the somewhat anemic type which could cause no offense to Kazinczy. Later Kolcsey produced a number of striking poems, vigorous in thought and expression, grave, even sombre when they deal, as so often, with the problems of his country's situation. The most impressive manifestation of this mood, the *Hymnus* (1823) is a passionate plea to God to have pity on a people which through the bitter sufferings of the past "has already expiated the past as well as the future." The poem, set to music by Ferenc Erkel, is the Hungarian national anthem. Kolcsey was a politician of great standing, a brilliant orator; and his literary criticisms are also of very high standard, though unduly severe.

Mihaly Vorosmarty (1800–55) resembles Kölcsey in his general pessimism and his patriotic preoccupations. But unlike Kolcsey, whose manifold interests, as it were, softened his impact in any one field of his activity, Vorosmarty's whole genius was focused on literature. After Kazinczy and Károly Kisfaludy died, Vorosmarty became the central figure in literary life, but with much better claims to this role, as far as pure literary achievement is concerned, than either of his predecessors. He tried his hand at every literary genre, and in each produced works of abiding value. His first appearance on the literary scene, with a long epic poem written in hexameters, *Zalán futása* ("The Flight of Zalan," 1825), was a great success and was followed by many other historical tales, written in a romantic vein but not without an eye to contemporary political and social problems. These appear also in many of his best lyric poems, and his *Szózat* ("Appeal") is a worthy pendant to Kolcsey's *Hymnus.* Much interested in drama (he translated Julius Caesar and King *Lear*), he had little sense of the requirements of the stage. His best work, a charming and symbolic fairy tale, *Csongor és Tünde,* contrasts, in a fashion reminiscent of *A* Midsummer Night's *Dream,* the airy lightness of fable and poetry with the grotesque earthiness of men.

In Hungarian literature poetry was far ahead of drama, and the novel seemed slow in taking root. The first successful novelist, Miklós Jósika (1794–1865), a disciple of Walter Scott, made his appearance in 1836 with the historical novel *Abafi,* which marks a turning point in the history of the Hungarian novel. It remained his best work. Once the novel was well established as a literary medium, others tried it with increasing success.

József Eotvos (1813–71), who after the 1848 revolution was to become an important political theorist and at the end of his life was minister of public instruction, produced in his early years a few novels of which two, *A* falu *jegyzője* ("The Village Notary") and *Magyarország 1514-ben* ("Hungary in 1514"), published respectively in 1845 and 1847, figure among the best Hungarian novels. The first gives a depressing but not melodramatically exaggerated picture of feudal life in Eötvös' time, the second deals with Gyorgy Dózsa's peasants' revolt. Though the novels are lengthy and difficult to read, they have extraordinary qualities of characterization, both of individuals and of periods. Eotvos' vigorous realism had great evocative power; his heroes are set with a firm and knowledgeable hand against the background'of violent social clashes. His novels are political manifestos in support of the oppressed, and against the appalling injustices which lead to revolutions —of which the writer disapproves as a political means.

From the mid-1830s literature had become sufficiently appreciated to make writing attractive. Literature and politics were closely connected and their association was to become instrumental in the explosion of 1848. In the proliferation of writers and poets—if we except those already mentioned—few showed real talent. The novelists Ignác Nagy (1810–54) and Lajos Kuthy (1813–64), the playwrights Jdzsef Gaal (1811–64), Károly Obernyik (1815–55) and Zsigmond Czakó (1820–47) deserve mention.

Poetry was on an altogether higher level. Gergely Czuczor (1800–66) produced a few epic poems of a fairly high standard, but his best poems were in the style of folk songs. Many returned to the people and became a part of popular poetry. János Garay (1812–53) owes his fame, in Hungary, to his amusing tale in verse *Az* obsitos which relates the story of the mendacious braggart János Háry, immortalized in Zoltán Kodály's opera, Hdry *János.* Jdzsef Bajza (1804–58), popular in his time, lacks originality and his poems are too diffuse to be really effective. Bajza's significance lies in his activities as a literary critic. He played an important role in the organization of theatre life and became the first "administrator" of literature. His scrupulous honesty and his uncompromising rejection of complacency had a salutary influence His friend Ferenc Toldy (1805–75), a critic himself, made important contributions to the previously almost uncultivated field of the history of literature.

The folk song and folk ballad collections of János Erdélyi (1814–68) and János Kriza (1811–75) exerted great influence on the further development of Hungarian poetry.

"Popular poetry is the only real poetry" was a firmly held opinion of Sándor Petőfi (1823–49), one of the greatest Hungarian poets. The quality of Petőfi's production is uneven, but his best poems must rank among the masterpieces of world literature. He was an innovator, a revolutionary, by nature as well as by conviction. He hated convention and—not without a desire to *épater le* bourgeois—made a break with conventional subjects and with so-called poetic language. His descriptive poems are striking in the immediacy of the perception, in the directness of the language and in Petőfi's extraordinary capacity to infuse poetry into almost any subject The revolutionary violence of his patriotic poems, which are often frankly political, has a counterpart in the exquisite melancholy and tenderness of his love poems. Petőfi's thought lacks the depth of, say, Berzsenyi, Vorosmarty or Arany, but the sincerity and force of his expression brings it home to the heart of the reader, hence his great influence during the revolution in 1848. Petőfi's many songs are enchanting in their simplicity: in this genre he remains unsurpassed. In him the great popular song tradition, from the Kuruc songs and Balassi through Csokonai and Kisfaludy, reached its peak. Petőfi's epic poetry is of less value, though his naive popular epic poem Jdnos *vitéz* (1845) and his comic epic A *helység kalapácsa* ("The Hammer of the Village," 1844) are enjoyable. Petőfi's early death—he disappeared on July 31, 1849, in a battle with the Russians —was a tragic loss to Hungarian literature

The torch falling from Petőfi's hand was picked up by his friend, and in some ways his follower, Janos Arany (1817–82). Though older than Petőfi he became known only when Petőfi was already famous. They shared the same conviction of the value of popular poetry, but their approach to it was different. The difference between them is largely that between an extrovert and an introvert. Petőfi proclaims his feelings, almost carelessly, and only his genius saves him from writing bad verse. Arany, modest and retiring, is reluctant to unveil his inner self. (He never wrote a love poem.) He chooses his subject with great care, very often from history, and treats it with deep understanding of the human mind, and with impeccable artistry. His language is exquisitely chosen. He does not try to be popular but has the assurance of one who knows that what he writes is the language of the people, lifted to a degree rarely attained and never surpassed in Hungarian. His ballads, often romantic, have virile vigour, conciseness and uncommon evocative power. His great narrative poems, such as his *Toldi* trilogy and *Buda halála* ("Death of Buda"), while firmly rooted in Hungarian tradition, reflect eternal human problems. It is Arany's great merit that he is never boring to read, his philosophy appears through his characters and not in lengthy digressions, and a subtle humour brings welcome relief to mounting tensions.

The Late 19th Century.— The peaks of poetry reached by PetBfi and Arany remained inaccessible during the rest of the 19th century. The second half of the century produced a host of imitators. Even the more gifted found it difficult to get out of the rut. This does not apply to Mihály Tompa (1817–68), a contemporary and friend of Petofi and Arany, an original but mediocre poet whose popularity is today difficult to understand.

Hungary,, prostrated by the unsuccessful revolution of 1848–49, remained until 1867 under Austrian rule. The "epoch of compromise" which then followed was hardly more favourable to literature. The defeat was followed by half-hearted acceptance of the compromise and by a self-deceiving optimism which produced complacency and uninspired traditionalism. The strongest talent in this period of decadence, Janos Vajda (1827–97) trod a lonely path beset with devouring passions, gloomy visions. Solitary in his life as well as in his poetry, little recognized by his contemporaries, his influence on coming generations was great. Gyula Vargha (1853–1929), Sándor Endrődy (1850–1920), József Kiss (1843–1921), Gyula Reviczky (1855–89) and Mihály Szabolcska (1862–1921) all produced one or two poems of real beauty.

The theatre, steadily growing in popularity, could, even less than poetry, produce works of lasting value. In 1837 a national theatre was formed to produce works of merit, but the level of the plays was low.

The inexhaustible Ede Szigligeti (1814–78) wrote more than 100 plays. His tragedies are weak, but his comedies are amusing and he created a special genre, the so-called *népszinmű,* plays giving an idealized picture of village life. Szigligeti had a good sense of the stage and catered for a public delighted to watch plays presenting no problems.

Problems, social, political, religious, constituted the principal preoccupation of Imre Madach (1823–64), whose *Az* ember *tragédiája* ("The Tragedy of Man") is one of the glories of Hungarian literature. This dramatic poem, which follows man's destiny from his creation, through different stages of history into the future of a phalanstery (see FOURIER, FRANÇOIS MARIE CHARLES) and the ultimate extinction of life, shares some of the characteristics of such philosophical poems as Goethe's Faust. But it not only displays original thought incisively expressed, it is also remarkably effective on the stage. It is a play to be seen rather than to be read, and, well-produced, will hold its audience spellbound.

Gergely Csiky (1842–91), after Szigligeti the most popular and most prolific playwright of this epoch (35 plays), was a pseudo realist. The social conflicts which appear in his plays for the first time on the Hungarian stage are, to a large extent, artificial, secondhand and second-rate adaptations.

Only among the novelists can we find really outstanding achievements. Zsigmond Kemeny (1814–75) is, in many respects, a disciple of Balzac. Whether he sets the scene of his novels in the past as in Zord *idő* ("Grim Times," 1862), Rajongdk ("The Fanatics," 1858) or in his own time as in *Férj és nő* (("Husband and Wife," 1852), he displays a masterly skill in minute psychological analysis. His novels breathe tragedy; his characters are pushed toward their gloomy fate by a host of circumstances, never fortuitous but determined by their own deeds. Analysis often takes the place of action in Kemény's work and because of the effort needed to read them his novels have never known wide popularity.

The opposite is true of Mór Jdkai (1825–1904), undoubtedly the most popular Hungarian novelist. Jokai is a born storyteller, endowed with an exceptional imagination, which, although able to evoke any epoch, any milieu, remains firmly rooted in Hungarian soil. His characters are idealized, his descriptions inaccurate, but they carry the reader into a dream world, so realistic that he is tempted to forget that it is but the projection of Jókai's mind. In his works (more than 100 volumes), historical novels alternate with others centred on the problems of contemporary society, of which almost all the strata interested him. In following the hero—and a hero he is--we make acquaintance with a variety of worlds, strangely reminiscent of each other, for all owe their existence to Jokai.

Kálmán Mikszath (1847–1910) is entertaining in a different way: he observes with a keen eye his contemporaries, politicians, civil servants and their contacts with the people, and relates their doings with sly humour. The shortcomings of the society in which he lives are obvious to Mikszáth but, though a politician, he is little concerned with improvement. Mikszath is only less popular than Jókai.

Though his principal works were published early in the 20th century, Géza Gárdonyi (1863–1922) is a spiritual child of the 19th. His historical novels, well-constructed. easily read, are well meaning and harmless; *e.g., Az* egri csillagok ("The Stars of Eger," 1901), *A* ldthatatlan ember ("The Invisible Man," 1902).

During the 19th century, literary life in Hungary became, to some extent, organized, and literary societies played an important part. The Kisfaludy and Petofi societies, founded in 1836 and 1876 respectively, were particularly influential, though the authority of the Hungarian Academy, founded in 1825 by István Széchenyi, remained unchallenged. The principal literary critic of the second half of the century was Pál Gyulai (1826–1909), himself a poet and writer. Literary criticism, the history of Hungarian literature, attracted some of the best brains. Gusztav Heinrich (1845–1922) and Zsolt Beothy (1848–1922) were among the leading figures in this field.

The 20th Century.— As we have seen, with a few exceptions, such as Madách, the second half of the 19th century was an era of decline in which writers imitated Petofi or Arany, and based their work on social and political ideals which were becoming sterile. The great majority of Hungarian writers had been recruited from the ranks of the nobility which, in fact, constituted in Hungary the middle class. Only at the end of the century did some writers of lower middle-class origin come to the fore. The first important manifestation of the new era was the periodical *A Hét* ("The Week"), founded in 1890 by József Kiss, which without any definite program became the organ of a number of more or less gifted writers who brought some fresh air into a stifling fin de *siècle* atmosphere. Zoltán Ambrus (1861–1932), a disciple of Maupassant, and an outstanding theatrical expert, was the most important among them. Sándor Bródy (1863–1924) and Gyula Krudy (1878–1933) did not belong to any school and, perhaps because of that, wrote original short stories and novels.

The year 1906, when Endre Ady (1877–1919) burst into Hungarian life "with the new songs of a new epoch," marks a turning point. Ady's revolutionary political ideas, which provoked violent storms, made it difficult for some sections of society to accept that he was a poet of unusual genius. In form and content Ady is a lyrical poet of such originality that he defies comparison. He rejuvenated Hungarian language and poetical thought, and his rich production is of uniformly high quality. His poetry is infinitely varied; perhaps humour is the only note missing. Love, friendship, hatred and war, social and political problems, death, a desperate search for God, are among the chief sources of his inspiration His method of expression is symbolic. An external event—we are rarely told what it is—inspires a dream which defies any other description but that given in the poem itself.

In 1908 was founded the literary periodical Nyugat ("The West") with Hugo Ignotus (1869–1950) and Ern6 Osváth (1877–1929) as editors. The influence of this left-wing periodical, without any definite political program but strongly biased against the political fool's paradise of Hungarian life, cannot be overestimated. It brought together vigorous talents, who lifted Hungarian letters to a level remarkable by any standards.

Mihály Babits (1883–1941), an intellectual poet, master of form and a deep original thinker, was from 1929 editor of Nyugat. He was also a translator of exceptional ability; his *Divina* Comedia is probably the best existing translation of Dante Dezső Kosztolanyi (1885–1936), the greatest impressionist in Hungarian poetry, was a sensitive poet and an accomplished short-story writer On a slightly lower level Arpad Tóth (1886–1928), reminiscent of Keats, and Gyula Juhász (1883–1937) were masters in voicing the distress of the solitary and the oppressed. The delicate, reticent poetry of Lajos Áprily and Aladár Komjáthy, the deliberately childish verse of Ernő Szép, the light, chanson-like poems of Jeno Heltai (1871–1957) must also be mentioned.

Zsigmond Móricz (1879–1942) was undoubtedly one of the greatest novelists in Hungarian literature. His descriptions of provincial life are outstanding for their masterly portrayal of peasants and gentry, of the terrible conflicts between man and man, man and woman, man and misery Móricz was a realist in the true sense of the word, down to earth but perceptive, robust but capable of extraordinary tenderness. Margit Kaffka (1880–1918) was another important novelist (the first great woman writer in Hungary). Frigyes Karinthy (1888–1938), without producing "major works," exerted a considerable influence on his generation His splendid pastiches are studied in schools; his queer, inquiring mind had an uncanny ability to discover the absurd and the preposterous in human behaviour

It is always dangerous to give schematic pictures of anything as complex as literature, but for the sake of convenience it can be said that from 1908 there were three main streams discernible in Hungarian literature: the Nyugat group already mentioned which included the greatest talents; an official literature written by conservative-nationalist writers; and, lastly, a superficial boulevard literature with hardly any aim but entertainment. The principal writer of the second group was Ferenc Herczeg (1863–1954), author of many novels and some plays showing considerable theatrical skill. Cecily Tormay's historical novels gained more official recognition than their value would warrant. Of the third type, entitled, nevertheless, to literary recognition, must be mentioned playwrights The impressionist Dezső Szomory, with definite literary ambitions; Menyhért Lengyel whose Typhoon (1909) has known success all over the world; and the exceptionally gifted Ferenc Molnár (1878–1952), whose plays, imperfectly adapted to the tastes of international theatre audiences, do little justice to a talent which shows itself best in some little-known short stories on Budapest life.

The real importance of the Nyugat as the organ of a literary movement diminished considerably after World War I, the great writers and poets of the group gained official recognition and the conflict which opposed them to the traditionalist men of letters became less violent. The literary cake was in any case large enough to feed both groups. Solitary writers found it more difficult to obtain recognition. Lajos Nagy (1883–1954), a socialist short-story writer, and Jenő J. Tersbnszky, with his descriptions of vagabond life, deserve mention.

The solitary giant Dezső Szabó (1879–1945) an unsurpassed master of Hungarian prose, author of some powerful and bewildering novels and stories, alienated sympathy with his venomous. though often pertinent, attacks on almost everything. Lajos Kassbk (1887–) was the first worker to secure a place in Hungarian literature. A painful search for poetical form led him to an expressive, often pathetic, blank verse. His novels and particularly his moving autobiography (Egy ember *élete,* 1927) give a true picture of working-class life.

The period between World Wars I and II is one of extraordinary flowering in Hungarian letters. Most of the new writers of the prewar period were still active, and many new names appeared.

In poetry the greatest figure is that of Attila József (1905–37). His subjects, similar to those of Kassák, are treated with tender lyricism, changing sometimes into violent outbursts against the existing social order. Lőrincz Szabó (1900–57) was a master of fine observation, and a gifted translator of foreign poets. The Catholic priests Ladislas Mécs and Sándor Sík brought new life to religious poetry. Oszkár Gellért and Milbn Füst belong to the most talented poets reared by the Nyugat. The poetry of Miklós Radnoti (1909–44) reaches a tragic climax in his splendid poems written in a German camp and during a death-march in which he himself was to perish.

Gyula Illyés (1902–), considered by many as the greatest Hungarian poet of the mid-20th century, found inspiration in the life of the peasantry, also the subject of his many essays and semidocumentary descriptions, which exerted some influence on Hungarian opinion. Among postwar poets, Sándor Weores, Gyorgy Faludy, Ferenc Juhász, László Benjamin and László Nagy were probably the most talented.

In Hungary, as elsewhere, the novel became the principal form of

literary expression. To the writers already mentioned, who had been active before World War I, other names must be added. Between the wars Lajos Zilahy (1891–) and Sándor Marai produced good descriptions of the Hungarian bourgeoisie; Aron Tamasi and Jozsef Nyirő wrote on various aspects of Transylvanian life. The realistic novels of Pal Szabh, Janos Kodolanyi, Jozsef Darvas, the firsthand accounts of peasant life by Peter Veres, are probably among the best representatives of literature laden with a social "message." Problems of socialism had influenced some of the writers (*e.g.,* Attila Jozsef, Veres) even before World War II; later social and political considerations became overwhelming and, ior some years, they alone constituted the materials of literature. Much of this is negligible, but the novels of Tibor Déry are of literary value. Almost all the important novelists and poets (*e.g.,* Móricz, Heltai, Kodolanyi, Zilahy, Illyés) tried writing drama, but the greatest achievements in this field are the historical plays of László Németh (1901–). Centred on powerful personalities of the past (*e.g.,* Galileo, Pope Gregory VII) they excel in the evocation of historic settings and in the picturing of eternal conflicts which oppose the honest man, bent on improvements, to the incomprehension and hostility of his contemporaries.

During the 20th century literary criticism and the history of literature kept pace with growing production and an increased interest in letters. Of the older generation Aladár Schopflin (1872–1950), for many years chief critic of the *Nyugat;* of the generation between the wars, Antal Szerb (1901–45) are among the most outstanding figures. It is impossible not to mention Gyorgy Lukács (1885–), the great Marxist literary theorist, though Hungarian literature has formed but a small part of his studies. Jeno Pinter produced a number of manuals, lacking imagination, but useful compendia of facts. In János Horvath (1878–), a dignified and scholarly personality, Hungarian literary research reached a level which it would be difficult to surpass.

HUNGARY, a country of central Europe, is bounded on the west by Austria, on the north by Czechoslovakia, on the northeast by an outlying portion of the Ukrainian Soviet Republic, on the east by Rumania and on the south by Yugoslavia, with a post-World War II area of 35,919 sq.mi.

Physical Features. — From 1920 Hungary occupied only the central portion of the middle Danube basin, all of which had previously belonged to the historic kingdom of Hungary. The Danube actually forms its northern frontier from a point just below Pozsony (Bratislava or Pressburg) to Szob, where it turns southward; it has Hungarian territory on both its banks until it passes into Yugoslavia just south of Mohács. It is a main artery of communications for the country and a dividing line of historical, economic and cultural importance between its western and eastern portions.

Western Hungary forms a rough square, bounded on the north and on the east by the Danube, on the west by the last outliers of the Austrian Alps and on the south by the Mur and the Drave rivers. The southwestern corner of this square (the Gocsej) consists of low, tangled hills, among which deposits of oil were discovered in the 1930s.

Above these hills the river Rába (Raab), issuing from the Styrian Alps, turns northwest to run into the Danube at Gyor. Its lower basin, comprising an area of about 3,861 sq.mi., is flat, open and often marshy; in its northwestern corner lies the extensive but shallow Lake Ferto (Neusiedlersee). Halfway down its course it runs under the southwestern outliers of the Hungarian central range, limestone hills of varied formations ranging from Permian to Recent and associated with basalt, andesite and other volcanic rocks. This range, beginning with the isolated volcanic hills of Badacsony and Somló, broadens into the forested Bakony area, this being continued to the northeast by the detached ranges of Vértes (1,572 ft.), Pilis (2,484 ft.) and the group of hills on one of which Buda is situated. Some lignite is found here, and important deposits of bauxite have been discovered.

Under the southwestern slopes of these hills lies Lake Balaton (*q.v.*), south and southeast of which is a rolling downland, intersected by parallel streams whose water reaches the Danube directly or via the Sió or the Drave. Vast deposits of loess and loam make this area suitable for intensive agriculture. Rising as a mountainous island from its centre is the massif of the Mecsek hills, containing outcrops of numerous post-Carboniferous formations, Triassic and Jurassic limestones, granites, diorites and other igneous rocks, together with a considerable coal field.

Beyond the Danube the line of the central range is continued northeastward in a series of hills. The chief of these are the Borzsony (3.081 ft.) and the Cserhát (2,130 ft.) and then, between the Zagyva and the Hernád rivers, the Mátra (3,315 ft., mainly trachytes) and the Bükk (a complex of carboniferous shales, Jurassic limestones and volcanics); while beyond the Hernád to the frontier stretches part of the Eperjes-Tokaj volcanic range, renowned for the fertility of its soil and the quality of its vineyards. Below these hills is the Great Plain (Nagy-Alfold) of Hungary, an open, very flat expanse through which the Tisza (Tisa or Theiss) runs to join the Danube at a point below the frontier. Portions of this plain, especially in the south, consist of black-earth regions of great fertility. In other areas the soil is sandy and alkaline; there are also many marshy areas and lagoons. The Tisza itself was regulated only in the 19th century, and the plain is still liable to devastating floods when the snows melt in the mountains (annexed to the U.S.S.R.) in which the headwaters of the Tisza are situated. Irrigation and afforestation have only gradually reclaimed for agriculture the wilder parts of the plain, which formerly were used chiefly to maintain vast herds of horses and cattle, pastured under wild and picturesque conditions.

The climate of Hungary is transitional between oceanic and continental. The three great climatic regions of Europe, the west European, the east European and the Mediterranean, here struggle for supremacy. Mean annual temperatures range from 48° F. in the north to 52° F. in the south, and in general the country shows a positive isanomalous temperature. Temperatures may vary between 40° and 47° F. in the course of the year (in exposed districts of the Nagy-Alfold the upper limit is much higher). The distribution of precipitation over the land shows a decrease in amount eastward: the greatest quantity is received on the western slopes of the Bakony forest, where 30–35 in. fall per annum; the driest region is the middle Tisza, with less than 15 in. in dry years, though sheitered regions such as the southeastern slopes of the Hegyalja are very dry. Most rain falls in May and June (June has 13% of the year's total) with a tendency toward a secondary maximum, caused by Mediterranean influences, in late autumn (October, 10% of year's total), particularly in the Drave-Danube angle. On the Nagy-Alfold the rainfall occurs mainly during occasional storms but elsewhere it is more evenly distributed. The high summer temperatures, while excellent for wheat and maize, are dangerous when rainfall is below the average; and when this is associated with heavy winds disastrous sandstorms and crop destruction follow. One of the characteristics of the climate of most value to the people is the long autumn whereby the ripening of delicate crops (*e.g.,* grapes and other fruits) is assured. The critical feature of the climate from the agricultural point of view is the uncertainty of sufficient rainfall.

The response of natural vegetation to these climatic conditions is clear where original examples unaltered by man are found. The characteristic covering of the trans-Danubian lands is deciduous woodland, oak, beech, lime and chestnut, but these disappear rapidly toward the Nagy-Alfold, where steppe conditions prevail.

Natural Resources. — Most of the area of Hungary is mainly suitable for and devoted to agriculture. Large parts of western Hungary and the more sheltered portions of the Alfold consist of fertile land well adapted for intensive farming, including the cultivation of the main cereal and fodder crops, potatoes add sugar beet. The slopes of the hills along Lake Balaton and the Hegyalja or southern slopes of the hills running east from above Pest to Tokaj are ideally suited for viticulture. Many parts of the Alfold grow excellent fruit. The counties of Tolna and Somogy and parts of the Alfold can support a large cattle population. The treaty of Trianon left Hungary with little of its former resources in timber: only 12.7% of its acreage (chiefly in the Bakony and north of the Hegyalja) is forest, much of it of little commercial value. There is one small iron-ore field near Miskolcz, but no other minerals except a very small amount of manganese and the important bauxite deposits. These are situated in the

Vértes mountains, in the Bakony and near Villány, in southern Hungary., and reserves have been estimated at 500,000,000 tons. The best estimates of coal and lignite reserves vary from 700,000,000 to 1,000,000,000 tons. Hard coal is mined near Pécs. The lignite deposits lie in a belt extending from the Vértes mountains northeastward to the Borsod mountains. Neither coal nor lignite exists in sufficient quantity or quality to meet the needs of a highly developed industry. Oil is found near Lispe, on the southwestern frontier. There is practically no water power. (X.)

HISTORY

The history of the countries which were later to constitute the kingdom of Hungary, up to the close of the Roman period, will be found under PANNONIA and DACIA. The Romans were succeeded by Germanic tribes, and these in turn by the Huns (*q.v.*). After the death of Attila (453) his kingdom declined, and Germanic (Gothic) tribes again entered Pannonia and Dacia. The 6th century A.D. found the Lombards established in Pannonia, the Gepidae in Dacia. In 567 the Avars (*q.v.*), allying themselves with the Lombards, crushed the Gepidae, and in the following year they occupied Pannonia, the Lombards migrating to Italy. As the Avar kingdom declined, the western and northern portions of Hungary recovered independence under Slavonic rulers. In 791–797 Charlemagne crushed the Avars and established the first Ostmarks (*see* AUSTRIA), which probably occupied all the land between the Danube and the Save. North of the Danube, the important Slavonic kingdom of Moravia (*q.v.*) was founded about 828, while the heritage of the Avars east of the Danube is believed, on slight authority but with great probability, to have been under the suzerainty of the Bulgars.

THE KINGDOM, TO 1526

The Arpáds.—The Magyars, the founders of the Hungarian state, were by origin a Finno-Ugrian people from beyond the Urals; but they were driven into the steppes about the beginning of the Christian era, and there mingled with Turki peoples. From the 5th to the 9th century A.D. they lived round and behind the mouth of the Don in a federation known as the On-Ogur (Ten Arrows), from the Slav pronunciation of which the name "Hungarian" is derived. In the early 9th century they were vassals of the Khazars (*q.v.*). They were then organized in seven hordes or tribes. under hereditary chieftains. The chiefs of the most powerful single horde were also hereditary overlords of the entire nation. Under pressure from their eastern neighbours, the Petchenegs (*q.v.*), the nation migrated westward. accompanied by three dissident hordes of Khazars, known as the Kavars or Kabars, and some other minor Turki tribes. Some of them arrived at the mouth of the Danube in A.D. 889 and took service with the Greek emperor against the Bulgars, who, however, allied themselves with the pursuing Petchenegs. Meanwhile the emperor Arnulf had enlisted the help of other contingents in his war against Sviatopluk of Moravia; and, seeing in the middle Danube basin a place of refuge from its pursuers, the entire nation, under its leader Árpád, migrated across the Carpathians (896). They easily subjected the scattered populations of the central plain, destroyed the empire of Great Moravia in 906 and, in 907, defeated German forces gathered to meet them. They were then firmly established in what was now Hungary; but its mountainous and trackless periphery was only gradually brought under effective control, and in these areas the earlier, non-Magyar populations, although subjugated. lived on.

The Magyars proper settled chiefly in western Hungary; the Kavars on and east of the Tisza. During the early part of the 10th century the invaders repeatedly raided Germany, Italy, the Balkans and even France in search of booty and slaves. The turning point in their history was the crushing defeat inflicted on them by the emperor Otto I on the Lechfeld, outside Augsburg (Aug. 10, 955). Forced onto the defensive, they began to consider the necessity of entering the European political and religious community. Some of their chieftains had already adopted Byzantine Christianity; but Árpád's great-grandson, Géza, who succeeded to the chief leadership in 972 and was able to reestablish its authority after a period of near anarchy, turned to the west. An embassy was sent to Otto II at Quedlinburg in 973, and in 975 Géza and his family were baptized into the western church.

Stephen *I.*—Géza made little headway against the popular opposition, which resented particularly stubbornly the pope's insistence—which would, indeed, have undermined the whole national economic system—that no Christians might be kept in slavery. But he married his son Stephen to Gisela, daughter of Henry II of Bavaria and sister of the future emperor Henry II, in 996; and Stephen, when he succeeded his father in 997, crushed the leading representatives of the old regime with the help of armoured Bavarian knights. In A.D. 1000 (or 1001) Pope Silvester II bestowed on Stephen a kingly crown, Silvester's relations with his former pupil Otto III enabling Hungary to enter the western religious community without admitting the political suzerainty of the empire. Stephen now crushed the last ruler of the Kavars, who had hitherto remained independent, and reorganized his state as a political and religious unit on a system which remained for many centuries the essentially unaltered basis of Hungary's entire social and political structure.

The subdivision into tribes disappeared, as did the separate status of the Kavars and other associated elements, although the social subunit of the clan remained. The freemen, descended from the old Magyar and Turki warriors, retained their personal freedom, which was inalienable except on conviction for proved crime. They were entitled to meet in general assembly, and their lands (which, since the economy was still mainly pastoral, were largely held by each clan as common property) were inalienable and free of any obligation except that of military service. All land not occupied by the freemen (a substantial proportion of the whole) became crown property and its occupants tenants of the crown. Adopting the Frankish model, Stephen divided Hungary into 46 (later, when the effective frontiers were pushed forward, 72) counties (*vármegyek*), each under a count (comes), who was a nonhereditary official of the crown. The comes exercised jurisdiction over the inhabitants of the county, free or unfree. He collected rents and dues from the unfree tenants. two-thirds of this he transmitted to the royal treasury, keeping one third for administrative purposes. In war he led the freemen of his county. An impoverished freeman who took service with the comes paid dues for any crown land cultivated by him, and an unfree tenant cultivating a freeman's land paid dues to the owner.

The unfree population could not acquire technical membership of the Hungarian "nation" (*i.e.*, the status enjoyed by the descendants of the old conquerors) except by royal grant; but it was no longer enslaved. The immigrants, who now entered the country in large numbers, could often make advantageous terms for themselves amounting to personal freedom. They were often governed, in minor matters, by their own personal law, and no effort was made to magyarize them.

The frontier zone (gyepii) was under a special dispensation, its inhabitants usually forming free communities subject to no liability except that of defending the marches. As the effective frontiers were advanced, these areas were absorbed in the county systems. Large parts of Transylvania retained the *gyepü* organization for many centuries.

The king's representative and head of the whole administrative system was the palatine.

Ecclesiastically, Stephen divided Hungary into 10 (later 12) dioceses, of which that of Esztergom and later also that of Kalocsa, were archiepiscopal. The church was entitled to tithes from all taxable land, and Stephen bestowed large estates on the sees and on the monastic orders, among which the Benedictines were prominent. This order was the main civilizing and Christianizing agent in Hungary. Its foundation of Pannonhalma (1001) was an "archabbey," exempt from episcopal jurisdiction.

The *11th* Century.—Stephen (who was to be canonized in 1073) enjoyed immense personal prestige. His rule at home, once established, was unquestioned. He fought few foreign wars and his long reign was thus a period of consolidation and growing

prosperity during which, incidentally, the national economy moved over a long way toward agriculture from stockbreeding. But when Stephen died, in 1038, the country refused to accept his designated successor Peter (his half-Italian nephew by marriage) and in 1041 put up a rival king, Aba. With the help of his kinsman the emperor Henry III, Peter drove out Aba (1044), then doing homage to Henry for Hungary and introducing foreign officials and clerics. The Hungarians brought back from Poland three brothers. Stephen's cousins. One of these, Andrew (1046–60), expelled and slew Peter but then married his own infant son Salomon to Henry III's daughter Judith and had him crowned king in his own lifetime. The accepted law of succession entitled the eldest male member of the ruling family to succeed, and this act inaugurated a long struggle. Andrew's brother Béla I (1060–63) evicted Andrew with Polish help, but on his death the emperor installed Salomon. Béla's sons Géza and Ladislaus, representing the national party, revolted in 1074 and expelled Salomon, defeating a German army sent to his aid. It was the moment of the investiture conflict and Géza I (1074–77) appealed to Pope Gregory VII for help, accepting his kingdom from him as a fief of the Holy See. The emperor now abandoned his attempts to subjugate Hungary. On Géza's death Ladislaus I (1077–95), a heroic and beloved figure who was to be canonized in 1192, re-established internal order and reaffirmed the position of Christianity, which had been shaken by two great pagan revolts in 1046 and 1061 respectively. By intervening in the affairs of Croatia, he established a claim to the crown of that country. His nephew and successor Koloman (Kálmán; 1095–1116) made the claim effective; in 1102 Croatia (later part of Dalmatia) was united with the lands of the Hungarian crown, while retaining its own diet and laws. It was ruled, for the crown, by a viceroy or ban.

The 12th Century.—Koloman revised and modernized Hungary's laws but, although an enlightened and capable man, he was cruel and treacherous. To make the throne secure for his son Stephen, he blinded his own brother Almus and the latter's infant son Béla. Stephen II (1116–31), Hungary's worst king, died childless, and the blinded Béla II ruled (1131–41). His son Géza II (1141–62), a capable ruler, completed the organization of Transylvania by settling German immigrants, the "Saxons," behind its southern passes; the eastern passes were already guarded by the Szeklers (*q.v.*), a magyarized race of Turki origin. Both Saxons and Szeklers were privileged communities, self-governing under the crown, and all Transylvania was governed as a unit under a voivode. Hungary was now little molested from the west, where neither the Austrian nor the Bohemian dukes could threaten its independence, but was involved throughout the 12th century in an intermittent struggle with the rejuvenated Eastern Roman empire, which disputed its position in Dalmatia, contested its claims in the Balkans and supported rival claimants to the crown: thus the reign of Stephen III (1162–72) was disputed by his two uncles Ladislaus II and Stephen IV, acting as clients of Constantinople. Béla III (1172–96) had himself been brought up in Constantinople and designated to marry the emperor's heiress, when Hungary would have become a vassal of the Eastern Roman empire, but on his accession he married a French princess and reconstituted Hungary's position. Under him the country achieved great wealth and power, extending its influence far and wide in eastern Europe: Galicia was made a feudatory of Hungary and Serbia a satellite. At home the royal authority was re-established. Urban life developed and western cultural influences penetrated the national life.

The Golden *Bull.*—Béla's good work was mostly undone by his younger son Andrew, who disputed the succession of his elder brother Imre or Emeric (1196–1204), expelling the latter's infant son Ladislaus III (1205). Both Imre and Andrew bought adherents by lavish grants of crown land. The recipients exercised feudal rule over the crown tenants and even over the local freemen. When Andrew became king as Andrew II (1205–35) he continued this and other abusive practices in order to pay for an extravagant court and a foreign policy of personal ambition and adventure including the crusade on which he set out in 1217. In 1222 the freemen or "nobles" reacted and forced Andrew to promulgate the famous "Golden Bull," to which every Hungarian king had thereafter to swear. as the basic charter of the national liberties. It was, in fact, essentially a reaffirmation of earlier rights—for the nobles, of those agreed between their forefathers and St. Stephen; for other communities, such as the Saxons, of their charters, fortified by safeguards against abuse on the part either of the king and his officials or of individuals. But the nobles also modernized their rights: thus, as war was no longer a co-operative profit-earning enterprise, they were not to be forced to serve abroad, except for pay. They took the control of the counties into their own hands. The famous *jus resistendi* gave them the right to resist infringements of the bull.

The Later *Árpáds.*—Hardly had Andrew's son Béla IV (1235–70) succeeded his father when the Mongols (*q.v.*) invaded Hungary (1241–42), frightfully ravaging and depopulating the country. To reconstruct and defend it, Béla had to invite many new colonists and—out of undesired necessity—to build fortresses and to confer extensive near-feudal rights on their seneschals, thus, after all, promoting the power of a new oligarchy. Some of these great "barons" achieved semi-independent status during the troubled times that followed.

Much disorder was caused also by the wild, pagan Cumans (*q.v.*) who had fled to Hungary in great numbers before the Mongols and molested the country. To bind these unruly elements closer to his dynasty, Béla married his son Stephen V to a Cumanian princess. After a short reign (1270–72) Stephen was succeeded by his son Ladislaus IV "the Cumanian" (1272–90), a wild youth who cared only for his Cumanian companions, refused to beget lawful issue and so favoured his pagan friends that Pope Nicholas IV preached a crusade against him. He died without issue, leaving Hungary in turmoil. Local magnates ruled as de *facto* sovereign princes, and rival European dynasties claimed succession to the throne. His partisans succeeded in putting on the throne the last of the Árpáds, Andrew III (1290–1301), the Italian-born son of Andrew II's posthumous son by his third wife; but Andrew too died young, leaving no issue.

With him the house of Árpád became extinct. Some of its members had been weak and foolish, but they had enabled the Magyar nation to blend its ancient traditions with the newer ones of western civilization in a synthesis which was at once European and national. Their foreign policy had never been purely individual or dynastic, or at least never foreign-based; so that Hungary was still essentially a national state and subject of its own policy. Although it had good kings thereafter, few of them wholly identified their own interests with those of Hungary.

The Angevins and **Sigismund.**—The crown was now claimed by Wenceslaus II of Bohemia for his son Wenceslaus III, by Otto III of Bavaria and by the papal candidate, Charles Robert of Anjou, of the house of Naples, then still a child. After a confused struggle, Charles Robert was left in possession as Charles I of Hungary (1308–42). After growing to manhood, he gradually established his authority, and peace and prosperity returned. Under his reign and that of his son Louis I the Great (1342–82), who in virtue of a compact with his father-in-law Casimir III the Great of Poland, also ruled over Poland after 1370, Hungary enjoyed great power and prosperity. The newly born Rumanian principalities of Moldavia and Walachia were at first under Hungarian suzerainty. **A** chain of banats was organized in the northern Balkans, and Bosnia and Serbia made vassals.

It is true that during the latter years of Louis' reign Hungary was increasingly threatened by the advance of the Turks, before which threat Louis had to acknowledge the independence of the king of Bosnia. But Hungary itself was hardly yet directly menaced so long as Serbia stood. In Italy the Angevins followed an ambitious dynastic policy that for a time brought their house splendid successes, although it cost the nation a disproportionate price in blood and wealth. However, the exploitation of the gold and silver mines of the Szepes area (the yield of which fell to the royal treasury) brought the Angevin kings immense resources. Their domestic rule was rather despotic. as they seldom convoked the diet, but they respected the acquired rights of the various

classes of the population. Imbued as they were with the ideas of western feudalism. they did not seek to abolish the "magnate" class, only replacing the turbulent oligarchs who had disputed their rule with new men loyal to themselves: in this era, indeed, the "prelates, barons and notables" appear as a constitutional factor distinct from that of the "common nobles," but membership of it was ex-officio, not hereditary. As, however, the great landowners were now made to supply contingents (*banderia*) of their own tenants for war, to supplement the noble *levée* en *masse,* the structure of Hungary became partially feudal.

When Louis died his daughter Mary was crowned. A rival, Charles of Naples, was crowned in 1385 but assassinated next year. Mary survived to marry Sigismund of Luxembourg (1387) who ruled with her until her death in 1395, then alone until 1437. His first years were greatly disturbed by his struggles with the partisans of the Neapolitan dynasty and by the Turkish danger, which had become pressing after the annihilation of the Serbian power at Kossovo (1389). Sigismund led a crusaders' army into the Balkans but was heavily defeated at Nikopoli (1396) and barely escaped with his life. After this he followed a defensive policy in the south, converting Belgrade into a large fortress. But Serbia was lost to the Turks, and elsewhere also Sigismund was unfortunate. Bosnia, Walachia and Moldavia renounced their allegiance; Dalmatia was lost to Venice; the Szepes mining towns were pledged to Poland.

Sigismund's frequent and prolonged absences from Hungary after he became Roman emperor and king of Bohemia were unfortunate for the country. The oligarchy recovered its power. There was much social unrest, partly occasioned by the spread of Hussite doctrines from Bohemia. The nation felt itself sacrificed to foreign interests.

John **Hunyadi.**—Consequently, although the estates accepted Sigismund's son-in-law Albert V of Austria (1437–39) as his successor when he died. they did so only with the stipulation that he should not accept the imperial title or reside outside Hungary without their consent: in his absence he was to be represented by the palatine, who was to be elected jointly by the king and the estates. Crowned king of Hungary on Jan. 1, 1438, Albert was in fact elected German king as Albert II in March 1438 but died in Oct. 1439, leaving his widow Elizabeth with child.

To avoid an interregnum, the estates elected Wladyslaw III of Poland king (Ulászló I) but when he fell in the disastrous battle of Varna (1444) they accepted Albert's posthumous son as Ladislaus V, appointing as his guardian and governor of Hungary the great hero John (János) Hunyadi (*q.v.*), who had been successfully defending Hungary and, in particular, Transylvania against the now constantly repeated attacks of the Turks. He kept up the defense under increasing difficulties, being constantly thwarted by the jealous magnates and harassed by the Czech mercenary Jan Jiskra, while the emperor Frederick III encroached on the western provinces. Ladislaus himself had been brought up in Austria; his supporters were identified in the national eyes with the Austrian-based and feudal Habsburg rule. Hunyadi died in 1456, immediately after winning a last great victory over the Turks at Belgrade. Ladislaus' partisans, led by Ulrich of Cilli, instigated tbe murder of Hunyadi's elder son Ladislaus: but soon afterward the young king himself died, whereupon the common nobles, asserting their ancient claim—never yet formally abandoned—that the monarchy had been elective since the extinction of the male line of the Árpáds, proclaimed as king Hunyadi's surviving son Matthias Corvinus (see MATTHIAS I).

Matthias Corvinus.—The only national king to reign in Hungary after the Árpáds, Matthias Corvinus (1458–90) has been much lauded by the historians of Hungary. He was in truth a brilliant figure, an enlightened despot in advance of his age: a strong ruler, an efficient administrator, a patron of the cities and of the arts and letters. He reformed the administration, reorganized justice, founded a new university, curbed the oligarchy, protected the peasants. But although he began by buying off the emperor (whom a party of nobles had elected antiking), cultivating friendship with George of Bohemia and carrying on his father's work in the Balkans, he soon dropped or at least postponed the idea of serious offensive operations against the Turks (although conducting further successful but limited campaigns in 1463 and 1475) and engaged in ambitious schemes in the west. He dreamed of uniting central Europe under his own rule and of acquiring the imperial crown. He attacked Bohemia in 1468 and was crowned king by the Catholic party there; under the peace of Olomouc (Dec. 7, 1478) he had to allow George's successor Vladislav (Wladyslaw, son of Casimir IV of Poland) to share the royal title and rule over Bohemia, but kept Moravia, Lusatia and Silesia under his own rule. In 1477 and again in 1485 he besieged Vienna, taking it in the latter year, whereupon he annexed Austria, Styria and Carinthia. To help him achieve his ambitions, he organized a standing mercenary force, known as the "Black army," largely drawn from Silesia and Moravia, for the upkeep of which he forced even the Hungarian nobles to pay. He retained his popularity to the last among the small nobles and was deeply beloved by the peasants, but earned the bitter hatred of the privileged classes: when he died suddenly in 1490, not only did his Czech and Austrian possessions at once break away from Hungary (which had benefited little by his conquests) but a strong internal reaction set in.

The Jagiello Kings, **1490–1526.**—The throne was now claimed by two Jagiello brothers—Vladislav, king of Bohemia since 1471, and his younger brother John Albert—and by Maximilian of Habsburg, while the lesser nobles favoured the succession, which Matthias himself had been trying to secure, of his illegitimate son John Corvinus. The magnates favoured Vladislav, precisely because he was notoriously weak. Hiring the Black army for the coup, they got Vladislav crowned (he reigned as Ulászló II, 1490–1516). John Albert stood down in favour of his brother, and John Corvinus did not press his own claim. Maximilian, by the treaty of Pressburg (Nov. 7, 1491) agreed to recognize Vladislav in return for the restoration of the Austrian provinces, an indemnity and a promise of the succession for himself or his issue if Vladislav died without male heirs. The Habsburg connection was very unpopular in Hungary, and the diet refused to ratify the treaty; but Vladislav considered it binding on himself and soon slipped into the position of Maximilian's friend and client. He had got himself into a complicated matrimonial tangle which long prevented him from begetting lawful issue. At last he succeeded in marrying lawfully the French princess Anne de Candale, but her first child was a daughter. Anne. The national party, led by John (*q.v.*) Zápolya, voivode of Transylvania, extracted from the diet of 1505 a resolution never again to accept a foreign king. But now a son, Louis, was born (1506). Zápolya's Polish ally, King Sigismund I, changed his anti-Habsburg policy in return for renunciation by the Habsburgs of their claims on Poland, and agreement was reached in Vienna (1515) whereby Louis married Maximilian's granddaughter Anne, while his sister was betrothed to Maximilian's grandson Ferdinand. A double link now joined the Hungarian crown with the Habsburg dynasty.

Meanwhile the magnates, having used the Black army to achieve their purposes, had stipulated that it should be disbanded and Matthias' other "innovations" cancelled. Vladislav was a powerless puppet. He had to consent to strict limitation of the royal prerogatives: thus in 1507 the principle was established that no royal decree was valid unless confirmed by the council of state. His resources were so diminished by the extravagance and peculations of his entourage that at times he was literally dependent on charity for his personal upkeep. With the king out of the ring, the magnates and the small nobles fought bitterly for control. The latter strengthened their constitutional rights, on paper, considerably. They secured the passage of many laws safeguarding their position both in the central and in the local government and also the great codification of Hungarian customary law produced in 1514, under the name of the Tripartitum, by the jurist István Verboczi (himself a member of the lesser nobility). This work, although it never received legal sanction. was universally taken. up to 1848. as the authoritative handbook to the Hungarian constitution, reaffirming all the cardinal liberties of the Hungarian nobility and laying down the principle of the equality in law

of all nobles. In practice, however, the magnates could take advantage of the near anarchy to direct the affairs of state and to acquire enormous individual fortunes.

As everywhere in central Europe at the time, the position of both the towns and the peasants declined rapidly. Many oppressive decrees were passed against the peasants. Then in 1514 the cardinal Tamás Bakócz collected about 100,000 of them for a crusade against the Turks. Their commander, Gyorgy Dózsa, instead turned them against the lords. They were put down after atrocious fighting, and Dozsa was tortured to death in horrible fashion. The diet of 1514 condemned them to "real and perpetual servitude" and greatly increased their burdens.

When Vladislav died on March 13, 1516, his son was proclaimed king as Louis II, being then only ten years old. Rival cliques squabbled for control, and the nation's interests were ignored. Defense, in particular, had been totally neglected since Matthias' death.

The Turks had been quiet for 30 years, but in 1521 the sultan Soliman the Magnificent suddenly sent Louis a demand for tribute. It was refused, whereupon Soliman assaulted and reduced the fortresses of Sabac and Belgrade. Granted a respite by the sultan's decision to proceed first with the conquest of Rhodes, the Hungarian nation, now suddenly alive to its danger, voted the reestablishment of a standing army; but little was done to raise the force, as each party tried to put the burden of its upkeep on the other. Appeals for help from abroad met with only a small response.

In the summer of 1526 Soliman renewed his advance. Péterváraḍ (Peterwardein) fell at the end of July. The general *levée* had been proclaimed and Louis, having gathered a few thousand men round him, moved slowly down the right bank of the Danube, to give time for the local contingents to join him. But there was disorganization, delay and contradictory orders. The most important forces—Zápolya's from Transylvania and Frangepan's from Croatia—failed to appear. On Aug. 28 Louis made contact with the Turkish army in front of Mohács and, although his force consisted only of about 16,000 Hungarians and 2,000 mercenaries, decided, on the advice of Archbishop Paul Tomori of Kalócsa, to give battle. On Aug. 29 the Hungarians attacked; the king and his whole government led the centre of the line. The little army was utterly routed; Louis, one of the few survivors of the fighting, was drowned on his flight. The sultan could not believe that this pitiful array which he had so easily overcome could be the national army of Hungary. Advancing with extreme caution, he occupied Buda on Sept. 10, but speedily returned across the Danube, taking with him 105,000 captives. By the end of October the last Turkish regular had left Hungary; but where the armies had been it was as utterly destroyed as if a flood had passed over it. (C. A. M.)

PARTITION

The Turks having retired, one party elected as king John Zápolya, voivode of Transylvania (Oct. 14, 1526). A second diet in 1527 elected Louis' brother-in-law, Ferdinand I, archduke of Austria (emperor 1556–64). Soliman supported Zápolya, and an internecine struggle went on till 1538, when by the secret treaty of Nagyvárad, Hungary was divided: Ferdinand took Croatia, Slavonia and the western counties, Zápolya the remaining two-thirds, with the royal title and Buda as his capital; Ferdinand was to succeed on Zápolya's death. However, when Zapolya died (1540) his adherents elected his infant son John Sigismund (1540–71). Ferdinand then asserted his right and laid siege to Buda in spite of the remonstrances of George Martinuzzi (*q.v.*), Zápolya's able adviser, who knew that Soliman would not allow the emperor to reign at Buda.

This brought a new Turkish invasion that lasted till 1547, when the exigencies of a war with Persia induced Soliman to grant a truce. -Hungary was partitioned: Ferdinand kept his former share, subject to payment of an annual tribute; Transylvania and some adjacent counties were assigned to John Sigismund, with the title of prince; southern and central Hungary was annexed to the Turkish empire. This settlement lasted with some changes for 150 years. Throughout this time the history of Turkish Hungary is almost a blank. It was rendered practically uninhabited and uninhabitable: its population was reduced by plague and starvation or carried into slavery. The surviving Magyars clustered into the great village-towns of the plain, which afforded them a partial protection, while in the open country seminomadic Serbs or Vlachs (Rumanians) took their places. The national sentiment and what remained of national liberties found their best expression in Transylvania, where Turk and Habsburg were equally hated. The efforts of the Habsburgs to conquer Transylvania led to fresh Turkish invasions in 1552 and 1556, the latter being Soliman's last descent on Hungary, and memorable for the heroic defense of Szigetvár by Miklós Zrinyi. The truce of Adrianople suspended hostilities from 1568 to 1593, but frontier warfare was incessant and Habsburg relations with Transylvania were almost always bad. The Habsburgs, ruling over other states and regarding Royal Hungary (*i.e.*, their own portion of that country) as an unimportant border province, were constantly wounding Magyar sentiment. The office of palatine was suspended; and the country was governed from Vienna.

Before long the political conflict was reinforced and embittered by a religious one. Even before Mohacs the tenets of Protestantism had conquered nearly all Hungary, its Calvinist form ultimately prevailing among most of the Magyars (the Transylvanian Germans and some Slovaks remained Lutheran). The Turks tolerated all creeds, although least favourable to the Catholics; in Transylvania, religious equality between Catholics and Protestants was proclaimed in 1557. During the "Long War" (1593–1606), a confused, triangular struggle, Sigismund Báthory (*q.v.*) was victorious over the Turks, but the imperial armies under Georges Basta occupied Transylvania and initiated a violent persecution of the Protestants until Istvan Bocskay (*q.v.*), calling the Turks to his aid, expelled them and, by the peace of Vienna (June 23, 1606), obtained for all Hungary a promise of religious liberty and political federation and for himself recognition as sovereign prince of an enlarged Transylvania. He strengthened his position further under the truce of Zsitvatörök (Nov. 1606).

For the next 50 years a series of very able princes of Transylvania ruled as independent Transylvanian sovereigns and protectors of Hungary. Gabriel Bethlen (*q.v.*; 1613–29) was three times at war with the emperor Ferdinand II and twice crowned king of Hungary. George Rákóczy I (1630–48) forced Ferdinand III to grant full autonomy and religious liberty to Catholics and Protestants in Hungary and further enlarged and strengthened Transylvania, which during this period enjoyed something of a golden age, politically, culturally and economically. In Royal Hungary, meanwhile, the Counter-Reformation gained strength. Péter Pázmány, primate from 1616 to 1637, reconverted most of the nobles to Catholicism and founded a great Catholic university at Nagyszombat in the Slovak north (1635). Under Leopold I (1657–1705) religious persecution, led by the Hungarians George Szelepesényi and Leopold Kollonić, became intense. A rebellion led by Nicholas Zrinyi was crushed in 1671. Many Hungarian nobles were executed, and recalcitrant Protestant ministers were condemned to slavery in the Neapolitan galleys.

The Turkish power, after decline, revived when Mohammed Kuprili (*q.v.*) became grand vizier in 1656. After defeating George Rákóczy II he re-established Turkish suzerainty over Transylvania. The imperial general Raimondo Montecucculi, by the victory of Széntgothard (Aug. 1, 1664) repelled the Turks from the frontiers of Austria; but a new Hungarian rebellion, led by Imre Thököly, broke out in 1678. The imperial forces were driven back, and the grand vizier Kara Mustapha saw an opportunity: he invaded Royal Hungary and laid siege to Vienna (1683). Now, however, the tide turned. Vienna was saved by the intervention of John III Sobieski of Poland. The Turks were driven slowly back. Buda was recaptured in 1686. The last big battle of the war was the great victory won by Prince Eugene of Savoy at Zenta in 1697. The peace of Karlowitz (1699) left the emperor in possession of the whole of historic Hungary, except the banat of Temesvar.

THE HABSBURG MONARCHY, 1699-1918

Leopold's objective was finally to crush Hungarian separatism and Protestant heresy. He forced a diet, convoked in 1687, to accept the hereditary title of the Habsburg dynasty, in the male line, to the Hungarian crown; the possibility of modification of the national rights and liberties, by agreement between the king and the estates; and the abolition of the *jus resistendi*. Transylvania, while remaining a part of the lands of the Hungarian crown, was to be governed separately, as was the Military Frontier, a defense belt along the southern frontier of Hungary. Other areas left desolate by the Turks or rendered so during the wars of liberation were declared "neoacquistica," or at the disposal of the crown. The former owners, if they had taken the wrong side, were declared to have forfeited their estates, which were bestowed on imperial adherents, Hungarian or foreign, or kept as crown property. In the latter case many were largely colonized with immigrants. A particularly important element among these were the Serbs, of whom (besides others) 36,000 families had entered Hungary en bloc, led on by their patriarch in 1691–92. They were to have returned to their homes when liberated, but as the liberation did not ensue they remained in Hungary and at the disposal of the emperor. There was also a large further immigration of Rumanians, already the most numerous nationality of Transylvania.

The country was seething with discontent. Its opportunity to break out came when the emperor, involved in the War of the Spanish Succession, withdrew almost all his troops from Hungary. There was an immediate rebellion, which found a leader in Francis Rákóczy II (*q.v.*; 1704–11), elected prince by the diet on July 6, 1704. The armies he raised were numerous but ill-equipped, and without artillery. Louis XIV aided him with money, but the defeat of the French at Blenheim enabled the emperor to send an army into Hungary, and in 1705 Rákóczy was badly defeated. In 1707 two Rákóczian diets deposed the Habsburgs and formed an interim government with Rákóczy at its head, till a national king could be elected; but Joseph I (1705–11), who succeeded Leopold as emperor, refused to come to terms with his subjects, though pressed to do so by his allies.

In 1708 Rákóczy was again defeated at Trenčin, this time decisively, though a guerrilla war still went on. But in 1711 Joseph died and was succeeded by his brother Charles VI (1711–40), a man of different stamp. A congress met at Szatmár (April 27, 1711), and peace was restored on the basis of a general amnesty, full religious liberty and the inviolability of Magyar rights and privileges. This general understanding was elaborated in the following years in detailed agreements which formed the basis of Hungary's relations with the house of Habsburg up to 1918. Charles promised in 1715 and again in 1723 to respect the rights of the estates and of the Hungarian nobility; to rule Hungary through its diet, which was to be convoked regularly and only in accordance with its own laws, existing or to be legally enacted and not "after the pattern of other provinces"; to defend its integrity; and not to incorporate any part of it in his other dominions. In return the diet of 1723, following the initiative of the Croat delegates, accepted the Pragmatic Sanction providing for the female succession of the Habsburgs: so long as this lasted, Hungary would regard itself as united "indivisibly and inseparably" with the king-emperor's other dominions, this union being valid "for all events and also against external enemies."

At the same time, it accepted, and even begged for, the institution of a standing army for the national defense, quartered in Hungary but to be composed up to two-thirds of "foreigners"; it consented to pay for the upkeep of this force (by taxation levied from the socage peasants), provided only that the money and contingents must be voted by itself. This was a move necessitated by Hungary's exhaustion and depopulation, but it proved very detrimental to the national cause: a separate Hungarian war council should have been set up, but this was never done, so that a mainly non-Hungarian force, controlled from Vienna, became a powerful instrument of centralist rule.

In many other respects Charles interpreted his undertakings somewhat loosely. The diet was seldom convoked; Transylvania was kept separate, as was the Military Frontier. When the banat of Temesvár was recovered under the peace of Passarowitz (July 21, 1722), which concluded another war with the Turks, it also was kept as a "neoacquistica" under military administration and colonized with non-Hungarians, mainly Germans. The promised independence of the Hungarian chancellery and other central organs was only nominal; and a religious settlement imposed by Charles in 1731, after the diet itself had failed to agree, left the Hungarian Protestants in a position hardly better than that of their Austrian co-religionists. Considerable improvements were, however, introduced into the administration and the judiciary.

Maria Theresa.—When Charles was succeeded by Maria Theresa (1740–80), the famous agreement between the young queen and the diet was in fact reached only with difficulty and after hard bargaining. Yet the Hungarian nobles undoubtedly saved Maria Theresa's throne, and she was grateful to them. Although seldom convoking the diet she respected the nation's privileges and made no attempt to impose her new centralism on Hungary. She won the higher aristocracy to her side by favours, creating, especially in these quarters, some real attachment to Habsburg rule; she also did much to improve the condition of the peasantry. The country benefited above all by the long peace which it now enjoyed: prosperity increased and civilization returned.

This was partly due to the great increase of population which took place in the 18th century. The accepted calculations (which may be too low) put the total figure for the whole country, including Transylvania, at only about 2,500,000 in 1715. By the end of the century this figure had been trebled. The increase was due largely to colonization by non-Magyars, while it was also the Magyar areas that had suffered most severely under the Turkish occupation. Thus, whereas in the 15th century the Magyar-speaking population of Hungary had been at least 75% of the whole, by 1790 it was less than 40%. Slovaks, Ruthenians and Rumanians formed a majority in the mountainous areas of the north and east and even encroached into the plain. The south was largely Serb or German. Magyars were in a safe majority only in the centre of the country, and even here there were many German and other colonists. Among the non-Magyars the Serbs, in particular, formed an alien and hostile element. Another shadow on the picture was that, so long as the Magyar nobles clung to their privilege of exemption from taxation, Hungary was left out of the industrialization being promoted in Austria and was kept as the agricultural complement to Austrian industry. Thus the great and growing wealth of the country remained almost entirely agricultural. Industry hardly rose above the handwork level. The towns were no more than little market centres, themselves half agricultural: the small burgher class was, incidentally, mainly German-speaking. The gold and silver mines were no longer worked. But even agriculture could not be commercially profitable, except under exceptional conditions. Since a noble's land was inalienable, he could not raise mortgages on it. Communications were so bad that only estates near the frontier or near a waterway could export bulk objects such as wheat. And although the country was still half-empty, so that the centre and south lay fallow for lack of labour, the northern districts were already becoming congested; yet the landlords, fearing that all their labour would desert if free migration were once allowed, clung obstinately to the restrictions binding the villeins to the soil.

Joseph II and Leopold II.—Joseph II (1780–90) thought the moment proper to weld all his dominions into a unitary state. Postponing coronation (so that he need not swear to the Hungarian constitution), he attempted to enforce numerous measures, some salutary in themselves, in furtherance of his ideas. He enacted religious toleration and improved the condition of the peasants. But he also abolished the self-governing institutions of Hungary and introduced a bureaucratic rule with German as the official language. The national resistance grew so threatening that he had to revoke many of his measures on his deathbed, and Leopold II (1790–92) was forced to restore the status quo and recon-

firm the fundamental compacts made between the crown and the nation after the peace of Szatmár.

The National Revival.—The opening half of the reign of Francis II (Roman emperor 1792–1806; emperor of Austria as Francis I 1804–35) was quiet; the "Jacobin conspiracy" of Ignaz Martinovics was the work of a few men. But it made Francis distrust any political movement; the crown—the great reforming factor of the 18th century—was now the chief prop of reaction. The great landlords, who were making big fortunes out of the continental blockade during the Napoleonic wars, at first acquiesced readily enough, but Joseph II's attempted germanization had aroused a new nationalism. This at first took the shape of a linguistic, literary and romantic revival, but when the wartime prosperity was followed by a slump, aggravated by monetary depreciation, the movement widened into one for political, economic and social reform, largely directed against the "dead hand" of Austria. When in 1823 Francis tried to raise money and recruits by unconstitutional means the resistance was such that the diet had to be convoked in 1825 and regularly thereafter. It thus took the lead in the entire monarchy; and within it the reformers steadily pressed back the conservative elements.

The chief figures in the new movement were Count István Széchenyi, Francis (Ferencz) Deik, Baron József Eotvos and Louis (Lajos) Kossuth (*qq.v.*). They differed on many points. Széchenyi, who was entirely loyal to the crown, thought that social and economic reform should come first and should be worked out by the Magyars themselves: he himself set the example by personal sacrifices and was in fact responsible for many reforms. He strongly urged the emancipation of the serfs and the abolition of the old socage system, which had ceased to be profitable even to the landlord, but solemnly warned the nation against tampering with the link with Austria or alienating the non-Magyars. The fiery demagogue Kossuth, while agreeing with Széchenyi on many points, including the need to liberate the serfs and to encourage industrialization, argued (with some reason) that it was the political control of Vienna that was holding up reform. His agitation turned more and more against the foreign connection. He and the other enthusiasts were anxious to assert the claims of the Magyar language. The first legal concessions which Hungary extracted in this field were few indeed and concerned with the use of Magyar in the relations between Hungary and the central authorities; but the enthusiasts soon passed to preaching the doctrine that the cause of the Magyar race was identical with that of freedom and progress and that the duty of Hungary's non-Magyar inhabitants was to magyarize. Some of the "nationalities," especially the German burghers and the Jews (who since Joseph II's edict of toleration had begun entering the country in large numbers from Galicia), accepted this doctrine wholeheartedly enough; but similar national revivals were taking place among the Slovaks, Rumanians and Southern Slavs, and with these it clashed. These peoples looked to Vienna for protection. An acute conflict broke out with the Croats when the diet decreed that its own official language was henceforward to be Magyar instead of the neutral Latin. Ljudevit Gaj was now preaching the doctrine of "Illyrianism" (*i.e.*, the unification of all Southern Slavs, at first under the Habsburg sceptre), and this presented a real danger to the integrity of Hungary.

The diets of 1830 and the following years enacted certain reforms In the social field, but the progress was slow. Francis had taken the precaution of having his son Ferdinand (1835–48) crowned in his own lifetime, so that there was no bargaining on Ferdinand's succession; but his advisers took alarm and had Kossuth imprisoned (1837). Released in 1840, Kossuth intensified his agitation in the Pesti *Hirlap*, the first Hungarian political journal. New concessions were won from the government: mixed marriages were legalized and the nobles lost their monopoly of official positions. There was then some disintegration in the reformers' ranks, the moderates being frightened by Kossuth's radicalism. The moderates formed a Centre party, and Széchenyi even joined the government. However, just before the election of 1847, Deák succeeded in reuniting all liberals on the common platform of the "ten points," afterward known as the March laws: responsible government; popular representation; the incorporation of Transylvania; right of public meeting; absolute religious liberty; universal equality before the law; universal taxation; the abolition of serfdom with compensation to the landlords; abolition of the aviticum—an obsolete land tenure. The elections gave the Progressives a complete victory, all efforts to bring about a compromise with the government were fruitless and it was proposed to dissolve the diet.

The Revolution of 1848.—But in Feb. 1848 tidings reached Pressburg (Pozsony; now Bratislava) of the revolution at Paris and its repercussions throughout Germany, where every government was threatened with overthrow. Kossuth's motion for the appointment of an independent responsible ministry was accepted by the lower house. The emperor hesitated, but on March 13 the Vienna revolution broke out and Prince Metternich fled to England; yielding to pressure or panic, the harassed monarch appointed Count Louis Batthyány premier of the first responsible Hungarian ministry, which included Kossuth as minister of finance and Széchenyi as minister of home affairs. The March laws were enacted at Pressburg and received the royal assent (April 10), and Hungary became a virtually independent state.

Ferdinand's Slavophile minister Franz Anton Kolowrat-Liebsteinsky had, however, before his forced retirement, secured the appointment of Josef Jellačić (*q.v.*) as ban of Croatia. Jellačić now repudiated the authority of the Hungarian diet, declaring that he accepted that of Vienna only, replaced Magyar officials by Croat ones and proclaimed martial law. The Hungarian Serbs demanded complete autonomy (May 13) and, when Kossuth refused this, made contact with the Croats; analogous, although less far-reaching demands came from the Slovaks and Rumanians. At first Count Batthyány, who was even prepared to send Hungarian troops to Italy, secured the emperor's support; Jellačić was disavowed and dismissed. But the Hungarians lost the support of the crown by setting up their own national army (a measure necessitated, they said, by the threat from the Southern Slavs) and refusing to vote supplies for the Italian campaign. Meanwhile the revolutionary stirrings in Galicia had been crushed; the Czechs were seeking alliance with the crown; and, although the Germans of Vienna remained semirevolutionary and sought to make common cause with the Hungarians against the Slav danger, the provinces had reverted to conservatism and the danger presented to the monarchy by Pan-German liberalism was dwindling. When Josef Radetzky's victory at Custozza (July 25) set free the imperial armies in Italy, the court reinstated Jellačić in all his honours, and he invaded Hungary on Sept. 11. Further efforts at mediation having failed equally (the mob of Buda lynching the intermediary, the Austrian minister of war), the court placed Hungary under martial law and appointed Jellačić commander in chief (Oct. 3). The Hungarian ministry resigned, leaving Kossuth in charge at the head of a committee of national defense.

Repression and Reaction.—At first the Hungarians, helped by a further revolutionary outbreak in Vienna, defended themselves successfully, but Alfred Prince von Windischgratz reduced Vienna. The court camarilla replaced Ferdinand by his young nephew, Francis Joseph (Dec. 2), who issued a proclamation declaring his intention of "uniting all lands and peoples of the monarchy in one great state." Kossuth declared the change illegal and called on the nation to resist it. Windischgratz' armies entered Hungary; those of Jellačić re-entered it; Buda fell (Jan. 5, 1849); the Hungarian government retired to Debrecen. On March 4 the new Austrian constitution was issued; while paying lip service to Hungary's separate institutions, it abrogated all of those which were contrary to its own provision; it also treated Transylvania and Croatia as separate "crown lands" and promised a separate status to the Hungarian Serbs. The Hungarian diet retorted by declaring Hungary an independent state and the Habsburgs forfeit of the throne. Kossuth was made "governor" (April).

Meanwhile the Hungarian armies, under Arthur Gorgei (*q.v.*), Moricz Perczel, Henryk Dembin'ski, Gyorgy Klapka and Josef Bem, were winning considerable successes; the capital was reoccupied on May 25. Nicholas I of Russia now offered Francis

Joseph his help, in the spirit of the Holy Alliance. A Russian army under Gen. I. F. Paskevich invaded Hungary from the north; an Austrian, under J. J. Haynau, from the west. Dissension broke out among the Hungarians: between Kossuth and Görgei and between the moderates and the extremists. The government retired to Szeged, then to Arad. Kossuth fled to Turkey. After the main Hungarian army had been heavily defeated by overwhelming forces at Temesvár (Aug. 9), Gorgei surrendered to the Russians at Vilagos (Aug. 13).

Haynau began by having Batthyány executed in Budapest and 13 senior officers, thereafter known as the "martyrs of Arad," executed at Arad (Oct. 6). Many other persons were executed or imprisoned. On Oct. 17 a provisional administration was introduced, which cut off from Hungary Transylvania, an enlarged Croatia-Slavonia (with Fiume), the Military Frontier and a "Serb Voivodina" in the south; the rest of the country was divided into five districts. The old autonomy of the counties and municipalities was suspended, and the whole country ruled through a mainly non-Hungarian bureaucracy (popularly known as the "Bach Hussars"), assisted by a newly created gendarmerie. The various nationalities inhabiting Hungary were declared equal, and their languages equal also; but in practice German was the sole language of administration and education on all except the lowest levels.

In all this, the military were gradually replaced by civilians, but the "provisorium" became a "definitivum" in Jan. 1852, a year after the Austrian constitution had been suspended.

The principles on which Alexander, Freiherr von Bach (the *spiritus rector* of all this) worked were in many respects enlightened, but the oppressive and absolutist character of his regime united the nation against him; even the non-Magyars and the peasants declined to regard it as a change for the better. At first the nation pinned its hopes, fostered by Kossuth and the other *émigrés*, on foreign intervention. Meanwhile, Deik, leader of the moderate party, counselled passive resistance, in particular the nonpayment of taxes. This policy proved very successful, and the burden of keeping so many administrators, as well as soldiers to guard against a possible rising, with so little return grew almost intolerable to the Austrian exchequer. When its difficulties were brought to a head by the Italian war of 1859, Francis Joseph dismissed Bach and introduced various constitutional experiments; but in spite of the attempted mediation of the "Old Conservative" party, the nation refused to collaborate, and a series of concessions — including the abolition of the quinquepartite division (1859) and the restoration of the court chancellery and of Magyar as central official language (1860) — had no effect. When elections were allowed again (1860 also) they only brought a flamboyantly nationalist majority.

Dualism. — After the armistice of Villafranca (1859) it was, however, clear that the monarchy was not about to disintegrate. Both the crown and the nation came increasingly to wish for compromise. Negotiations, in which Deik and Julius (Gyula) Andrássy (*q.v.*) took the lead on the Hungarian side, were initiated. They dovetailed in with the parallel negotiations in the Austrian half of the monarchy, and an unwritten alliance, similar to that of 1848, emerged between the Hungarians and the liberal German centralists at the expense of the Slavs in each half of the monarchy. In June 1861 the centralist constitution of 1861 was suspended and a provisional government formed in Hungary. A committee was set up to work out a constitution based on the Pragmatic Sanction. The March laws were recognized as valid, but to be modified in practice where this seemed desirable; the Hungarians consented to treat with representatives of the Austrian lands on matters recognized under the Pragmatic Sanction as concerning other of the monarch's dominions, besides Hungary. The Seven Weeks' War of 1866 caused another interruption, but Deák did not raise his demands after Austria's defeat. In Feb. 1867 a responsible independent Hungarian ministry was formed under Andrássy, and in March the new constitution was adopted by 200 votes to 89. On June 8 Francis Joseph was crowned king of Hungary.

Hungary recovered her full independence and her integrity: the Voivodina had already been dissolved and Transylvania was now incorporated, the Military Frontier following. Fiume and the Murakoz returned to Hungary, but the Slavonian counties remained with Croatia, with which, in 1868, a separate agreement was concluded, doing full justice to Croatia's historic rights. For the "nationalities," under law 44 of 1868, the equality of languages was stipulated insofar as was consistent with the practical needs of administration. Non-Magyars were to be allowed the use of their language in private life, in the press, etc., in the courts and in administration and in county and municipal diets, in which records could be kept also in such languages when desired by one-fifth of those concerned. The government was obliged to provide facilities for any person to receive secondary education in his own language, and communities, churches and individuals were free to found and maintain schools which enjoyed equality of status with state schools. The army and foreign affairs remained common to Hungary and Austria, each under a joint minister (alternately from Austria and Hungary); a third joint minister was in charge of the finance for these portfolios. Delegations from the Austrian and Hungarian parliaments discussed the subjects. The respective quotas which each half of the monarchy was to pay were rediscussed every ten years, as were the Austro-Hungarian customs tariffs, Austria and Hungary forming a customs union.

In Hungary itself many elements were hostile to dualism and to any community of existence with Austria. They listened to the voice of Kossuth, the leader of 1848, now living in voluntary exile. Shortly before Francis Joseph's coronation, Kossuth, in his open "Cassandra letter," had accused Deák of treachery to the rights of the nation. The pure Magyars of the Alfold supported Kossuth and elected a parliamentary opposition that took its stand on the so-called "1848 constitutional basis" and called for revision or revocation of dualism and a pure personal union with Austria. The 1848 politicians adopted a negative attitude toward all demands of the state throughout the period of dualism, voted against the budgets and military estimates and attempted to discredit the dualist governments as traitors to the nation.

Threatened at once in Vienna and in Hungary and supported solely by the emperor-king, who throughout his life remained strictly loyal to his coronation oath and upheld the law 12 of 1867, the Hungarian minister-presidents, from Andrássy on, were often forced to employ subterfuges to secure the majorities necessary for the conduct of affairs. As the 1848 ideas were most prevalent in the poorer classes, the franchise was from the first so restricted as to confine all political influence to educated circles. The maintenance of dualism was secured, first and foremost, by enlisting the "gentry," who had lost the greater part of their estates through the agrarian reform decreed under art. 9 of the law of 1848 and executed during the period of absolutism of 1852–53 with the deliberate purpose of breaking the Hungarian aristocracy. As state officials and deputies, this class now became the chief supporters of the dualist governments. After Andrássy had become common minister for foreign affairs in 1871, his successors in the premiership of Hungary ruled with the help of the gentry and the new Jewish capitalists.

The rich natural resources of Hungary had begun to be exploited, railways had been built, mines and factories started, and the profits increased the solidity of the '67 governmental party, while the '48 party was, where possible, excluded from it. It was, however, only after the death of Deak, a puritan who refused to take any office, that this was developed into a regular system by Kálmán Tisza. whose prolonged period of office (1875–90) made the government party resting on the landed gentry and capital (the "Liberal" party or "Free Principle" party) into a permanent institution. He introduced strict discipline into his party, which was most necessary, since the government was forced year by year, in the interests of dualism, to pass unpopular laws, such as the military estimates for the "common" army, with its headquarters in Vienna and German word of command. The German-speaking army in Hungary was the occasion of continual conflicts; there were repeated students' riots and patriotic demonstrations against army decrees, these flames being vigorously

fanned by old Kossuth from Turin. Kálmán Tisza fell over a bill affecting Kossuth's rights of Hungarian citizenship.

His successors, Count Julius Szápáry (1890–92), Sándor Wekerle (1892–95), Baron Dezso Bánffy (1896–99) and Koloman Széll (1899–1903), had still greater difficulties to face. Resistance was increasing, both in Austria and in Hungary. In the decennial revision of the Austro-Hungarian customs tariff parliamentary discussions were stormy, and the differences between agrarian Hungary and industrial Austria grew acute: the Hungarians complained that their country was treated as a colonial market for the Austrian factories, and they increasingly demanded an independent customs territory. Similar difficulties arose over the commercial treaties with foreign states, which had also to be concluded in common with Austria, and over army questions, in the latter case mainly because of the preference shown to German and Slav officers for high positions. Thus dislike of dualism grew more acute in Hungary; not only the Kossuth party worked against it, but also other politicians who, while remaining loyal to the compromise, yet looked on it as elastic and aimed at altering its provisions by constitutional methods: creating an independent customs territory, giving the Hungarian element in the army its due and creating an autonomous national bank. Among these were Count Albert Apponyi and, later, the younger Count Julius Andrássy (*q.v.*). The number of malcontents increased after the Wekerle government introduced a reform of the marriage law on liberal lines in 1894; a new opposition party, the Catholic Peoples' party, came into being, led by Count Ferdinand Zichy (1829–1911) and supported by wide circles of Hungarian, German and Slovak peasantry. The minister-president, Bánffy, was only able to break the power of this party in the elections of 1896 by the most extreme means, forcible intervention by the gendarmerie. In the same year the nation and its king celebrated together its jubilee, the millenary of the occupation of Hungary by the Magyars. Yet events were shaping toward a rupture with the sovereign and the compromise. When Count Istvin Tisza, as minister-president, attempted to make parliamentary discussion possible in the interests of the army estimates by changing the standing orders and was defeated at the elections (1905), Francis Joseph first tried the expedient, attempted in Austria, of reforming the franchise, to put the nationalist gentry and middle classes in a minority against the workmen and national minorities. When this attempt (Baron Géza Fejerváry's ministry, 1905–06) broke down on the resistance of the counties, he entrusted the power to the united parties of the opposition (Wekerle's ministry, 1906–10), who promised to respect the compromise. This coalition ministry included Apponyi, Andrássy and Francis Kossuth, son of the old revolutionary, now dead. Public opinion, however, failing to receive from this ministry the anticipated changes in the compromise, soon abandoned it. At the next elections the old '67 party returned in triumph; it remained in power till World War I after being reorganized by István Tisza, who was minister-president for the second time, 1913–17.

It was only with great difficulty, however, that Tisza succeeded in carrying the army estimates in the last years preceding World War I. In the '48 party the influence of the leaders compromised in the Wekerle ministry was now superseded by that of Count Mihály Károlyi (*q.v.*), who introduced extreme tendencies into the Party of Independence. At the same time, symptoms of social unrest appeared. The Socialist party, which was Marxist in creed, made several unsuccessful efforts to find new followers among the agricultural labourers; but in the first decade of the 20th century it found an ally in the Radical party, composed of semi-Socialistic bourgeoisie, doctors, lawyers and merchants, mainly Jewish in origin, which aimed at a complete remodelling of social conditions with the assistance of general suffrage.

At the same time the question of the national minorities also became acute. The law of 1868 allowed considerable scope for educational development, unhampered by the state, to those nationalities which controlled churches: the Greek Orthodox Rumanians and Serbs and the Saxon Lutherans. The Roman Catholic, Calvinist and state schools were overwhelmingly Magyar; the state, however, fostered them in non-Magyar districts with the hope of magyarizing the pupils--sometimes with success but in other cases with the opposite effect. For some time after the compromise the leaders of the nationalities retired into passivity, but about the turn of the century the new generation became actively oppositional. Many of the Rumanians and some of the Serbs were already almost openly irredentist: others sought the support of the heir to the throne, the archduke Francis Ferdinand (*q.v.*), whose interest in the unity of the army also led him to wish to break the supremacy of the Magyars. He advocated replacing dualism by trialism, creating a third Slavonic state out of the southern Serbo-Croat parts of Austria and Hungary, with Bosnia, and thus putting Hungary in a minority of one to two. The situation was further complicated by the irredentist agitation conducted by the fellow countrymen beyond the frontier of the various nationalities. Even Count Tisza, who in his second term of office made several attempts to reach an understanding with the nationalities, especially the Rumanians, was obliged to the last to oppose general suffrage, because he feared that it would have meant the supremacy of the nationalities, assisted by the Hungarian Socialists (the Magyars numbered 54.5% of the total population), and therewith a federalization of the state. To prevent this, the abortive Andrássy draft of 1908 had attempted to combine general franchise with plural voting for the educated classes.

World War I.—World War I found Hungary in the throes of a parliamentary struggle conducted by all shades of the opposition, from Albert Apponyi to Mihály Károlyi, against Tisza's attempt, supported by the crown, to maintain the compromise intact. Tisza's voice was the only one raised in the crown councils of July 7 and 19, 1914, after the murder of the heir to the throne, against war and for giving the ultimatum to Serbia such a form as to make the avoidance of war possible. When, on the death of Francis Joseph (Nov. 21, 1916), the archduke Charles succeeded him as Charles I of Austria and Charles IV of Hungary, Tisza's obstinate fidelity to the prosecution of the war at Germany's side displeased the new sovereign. At the outbreak of the war, the parties of the opposition had sworn a Truce of God; but by 1917 they had forgotten it. Losses, privations and increasing food shortage, together with the absence of any prospect of final victory held out by the Austrian and German generals, kept the population in continuous unrest. On April 25, 1917, the Socialists, Károlyi's patty and Oszkar Jászi's Radicals founded the democratic electoral bloc. Charles called on Tisza to submit a draft for an extension of the suffrage, whereupon Tisza resigned. The cabinets of Count Moricz Esterházy (June 15–Aug. 20, 1917) and Sándor Wekerle (Aug. 20, 1917–Oct. 31, 1918) attempted, without real success, to meet the increasing desire for a division of the common institutions of 1867, especially of the army, which was still under Austrian leadership. The nationalist discontent was accompanied by agitation for general suffrage, largely the result of propaganda by Jászi's Radicals which, after Tisza's fall, was subject to no restraint. In the last two years of World War I the masses, especially in the capital, moved further to the left than they had in the preceding 50 years. (C. A. M.; X.)

THE REPUBLIC, 1919-20

When, in Oct. 1918, it became clear that the war was lost, the opposition took the offensive. On Oct. 25 a "national council" was formed under the presidency of Mihály Károlyi, with the program of dissolving parliament, introducing general suffrage and concluding immediate peace. Popular demonstrations demanded the appointment of Károlyi to carry through this program. After hesitation the king allowed the appointment and Károlyi took office with a Radical-Socialist government (Oct. 31). The Slovaks, Rumanians and Serbs were threatening to secede, and in the hope of saving the integrity of Hungary Károlyi travelled to Belgrade to meet the French commander, L. F. M. F. Franchet d'Esperey, but had to accept from him (Nov. 8) an armistice under which the Hungarian troops evacuated all southeastern Hungary. Serbian troops entered the southern areas; subsequently a Rumanian army entered Transylvania and Czech troops Slovakia. The king having renounced "participation in the con-

duct of state affairs" (Nov. 13), the national council proclaimed a republic and dissolved parliament (Nov. 16).

The government prepared to introduce a democratic political system and social reforms, including land reform, but hesitated and procrastinated. Having disarmed the returning soldiers in an attempt to document its pacifist nature, it had no force with which either to keep internal order or to resist the continued encroachments of the Rumanians, Czechs and Serbs, who were consolidating their positions in the peripheral areas. Within the government coalition the bourgeois elements had to retreat continuously before the Social Democrats; but the latter were now themselves threatened by Communist propaganda spread by Béla Kun (*q.v.*), a soviet agent of Hungarian-Jewish origin. When the entente's representative in Budapest, Colonel Vyx, sent a note ordering the Hungarian troops and authorities to withdraw still farther west, far into purely Magyar territory, and indicating that the new military demarcation line would form the future political frontier, the government, now headed by Dénes Berinkey since Károlyi had become president of the republic, resigned (March 21, 1919). The Social Democrats had already agreed to fuse with the Communists and to establish a dictatorship of the proletariat in alliance with Soviet Russia, who, Kun promised, would help against the Rumanians. Many bourgeois and professional soldiers at first supported Kun in this hope, but the help never materialized. Kun attacked the Czechs with some success, but was forced by the Allies to withdraw. At home his methods, which began by being doctrinaire and ended by being terroristic, alienated the bourgeoisie, the leading members of whom fled abroad and formed *émigré* committees in Vienna and Szeged (now under French occupation), the peasants and even the industrial workers. In an attempt to restore his position Kun attacked the Rumanians, but was defeated. He and his chief lieutenants fled to Vienna (Aug. 1).

The Rumanians occupied Budapest (Aug. 4), in which various nondescript governments failed successively to maintain themselves. On Nov. 14 the Rumanians, who meanwhile had looted the capital very thoroughly, were induced to retire. The *émigrés* had by now formed a counterrevolutionary government with a national army, the latter commanded by Admiral Horthy (Nicholas Horthy de Nagybanya, *q.v.*). This force entered Budapest. The Allies attempted to bring into being a broad, democratic coalition government, recognized (Nov. 25) the appointment as minister-president of Károly Huszár and insisted on the holding of elections under a secret suffrage (Jan. 25, 1920). Already, however, counterrevolutionary detachments had taken violent and indiscriminate reprisals against the workers' leaders and the Jews. The Social Democrats abstained in protest from the elections, which returned two almost equal parties: Christian Nationals and Smallholders. Only a fraction of the latter, however, represented the peasants. The government now restored the legal continuity by cancelling Károlyi's and Kun's changes and formally dissolved the link with Austria. Hungary remained a kingdom and, pending the future settlement of the constitutional issue, Admiral Horthy was elected regent (March 1, 1920).

THE REGENCY

The Treaty of Trianon.—On June 4 Hungary had to sign the treaty of Trianon, which gave to its neighbours 192,000 sq.km. of its area of 283,000 (Croatia-Slavonia excluded) and 10,649,416 of its population of 18,264,533. Almost all its non-Magyar-speaking populations were separated from it, and more than 3,000,000 Magyars, many of them living in immediate juxtaposition to the frontier. Its armed forces were limited to 35,000 men, lightly armed, and it was required to pay a sum, to be determined subsequently, in reparations. The treaty incidentally disrupted its entire economic structure. Hungary's determination to secure revision of it thereafter governed its whole foreign policy and in particular its relations with the three main beneficiaries of the treaty, Czechoslovakia, Rumania and Yugoslavia. Its relations with Austria were also at first disturbed by that state's claim to the German-speaking areas of western Hungary. Part of these were in fact ceded, but the protocol of Venice (Oct. 12, 1921) provided for a plebiscite in the city of Sopron (Oedenburg), which remained with Hungary after the vote.

Reconstruction.— The ministries of Huszár (Nov. 24, 1919–March 15, 1920), of A. Simonyi-Semadam (March 1j–July 19, 1920) and of Count Pál Teleki (July 19, 1920–April 14, 1921) had to face many difficulties. There was much economic and financial disorganization, in the course of which wild inflation set in. The workers' leaders who had fled abroad conducted a vigorous agitation against the excesses of the "white terror" that had followed Kun's "red terror." The peasants demanded land reform. The middle classes were embittered and impoverished by the inflation. The distress of the large numbers of officials and other middle-class elements who had been expelled by the successful states and had now arrived with their families in Budapest, completely destitute, was particularly acute. These elements, which were strongly nationalistic, formed the backbone of a radical undercurrent which was at once revolutionary against the Habsburgs and the feudal system associated with them and counterrevolutionary against the ideas of 1919. It was by playing these various discontents off against each other that Count Stephen (István) Bethlen (*q.v.*), while remaining in the background, was able to negotiate a general internal settlement. The Socialist leaders signed a regular treaty agreeing to give up agitation abroad or in the country districts and to support the government's foreign policy, in return for an amnesty, the secret ballot in the towns and certain other concessions. The Smallholders were pacified by a land reform which took 1,300,000 hold from the largest estates (a further distribution was to follow later) and by the promise of partnership in the government. They agreed that the open franchise should be reintroduced in the rural districts as a safeguard against Socialist agitation and in the faith that the government would not favour a Habsburg restoration. King Charles in fact attempted to return to Hungary on March 7, 1921, but was forced by domestic and foreign opposition to leave. After this Bethlen succeeded Teleki (April 14). The king made a second attempt to recover his throne on Oct. 29. This time government troops actually fired on him. He was removed, and under pressure from the powers the Hungarian parliament enacted a law declaring the Habsburgs forfeit of the throne. Next spring, having passed through his new franchise bill by emergency legislation (against strong obstruction from the Legitimists) Bethlen dissolved parliament and held new elections. These and all subsequent elections of the period between World Wars I and II, gave a safe majority to what was always popularly known thereafter as the "government party," against relatively weak minorities of Socialists and Liberals on the one side and Legitimists on the other. The Legitimists became a declining force after the death of the king in exile.

Bethlen now completed the liquidation (begun by Teleki) of the right-wing extremists, who were quite impotent during his regime, which they declared bitterly to be one of subordination to the forces of feudalism and big capital. In 1924 Bethlen succeeded, after prolonged negotiations, in raising a reconstruction loan, with the help of which the inflation was stopped and the pengö, a new stable currency based on gold (1 pengö = 0.263 g. of fine gold), introduced. In connection with this, a new, independent Hungarian bank of issue was set up on June 24, 1924. Under the new and more peaceable conditions, money, somewhat recklessly lent, poured into the country. The national economy was readapted and reconstructed: much industrialization carried through—sufficient to counteract, though not perceptibly to diminish, the rural overpopulation that was Hungary's biggest internal problem (and that although U.S. legislation had now closed the outlet of emigration). Industrial employment was good. The middle-class refugees were supplied with posts in an elastic state service, or pensioned off. Abroad, Hungary's relations with the west were good. There were a few not explicitly official escapades, such as an attempt made in 1925 to finance propaganda by forged French francs, but revisionist agitation was damped down, although Hungary's relations with its chief neighbours—now firmly linked in the little entente—could not seriously improve. Bethlen did, however, draw Hungary out of its isolation, partly by winning sympathy for her in the west and notably by concluding a treaty

of friendship with Italy (April 1927).

The weak point of the structure was that the balance of payments was invariably passive. The gap was closed by further borrowing, but the continued success of the operation depended entirely on the maintenance of satisfactory prices for Hungary's main exports, especially wheat. When the world economic crisis broke out in 1929, Hungary was not immediately involved. In April 1930 Bethlen secured the settlement of the reparations question and the lifting of the League of Nations' financial control. In May-June 1931 he held new elections which returned him to parliament at the head of another large majority. Immediately after, however, the full force of the financial crisis hit Hungary. Payments had to be suspended, and revelations of the real financial position caused a bitter outbreak of popular feeling against the government. Bethlen resigned (Aug. 19, 1931) in favour of the puritan Count Gyula Károlyi who, strictly pressed by Hungary's creditors, set himself to carry through a policy of retrenchment and budgetary reform. He initiated settlements with Hungary's foreign creditors, but the internal agitation against the "system," led on the one hand by the indebted farmers (who now founded a new Smallholders' party) and on the other by the middle-class elements in the state services and professions was too strong for him. On Sept. 21, 1932, he resigned.

The Gombos **Ministries 1932–36.**—The new minister-president was Gyula Gombos, former minister of defense, the leader of the "Right Radicals", notorious for his fascist, anti-Semitic and militarist views and, in foreign policy, the prophetic adherent of an "axis" to consist of Hungary (within its historic frontiers), Italy and Germany. By an immediate visit to Italy, Gombos committed Hungary to a "dynamic" foreign policy, thereby also consolidating his position at home against either "democratic" or "feudal" forces. The axis, however, could not be formed, as Italy and Germany were at loggerheads over Austria. Moreover, on a visit to Berlin (June 1933) Gombos learned that Adolf Hitler, while willing to let Hungary share in the partition of Czechoslovakia, was opposed to its aspirations in Rumania and Yugoslavia. All Hungary could do was to link itself with Italy and Austria under the Rome protocols (March 17, 1934), which relieved it from the economic pressure of the little entente but also committed it to an anti-German line over Austria. At home Gombos was largely under the tutelage of a parliament "made" by Bethlen (which the regent refused to allow him to dissolve) and in the continued grip of the financial crisis, international, domestic and personal. Perforce he postponed all the revolutionary measures promised by him, even declaring publicly that he had "revised his views on the Jewish question," and settled down to a sober program of technical and orthodox reconstruction. In March 1935 he forced the regent's hand and carried through elections which gave him a parliamentary majority of his own followers, but internal opposition was still holding him in check when he fell fatally ill in June 1936. He died on Oct. 6, and the regent appointed the more conciliatory Kálmán Darinyi to succeed him.

Darányi, Imrédy and **Teleki.**—Meanwhile renewed intimacy with Italy had brought Hungary into further conflict with the little entente over the murder (Oct. 1934) of King Alexander of Yugoslavia, for which it was partly responsible and openly blamed. After the Franco-Italian negotiations of 1935 for a Danubian settlement had borne no fruit, and Hitler had occupied the Rhineland and concluded the agreement of July 11, 1936, with Austria, Hungary felt itself directly threatened by Germany. Hitler now began to exercise pressure on Hungary's internal affairs; but Hungary did not dare seek agreement with the little entente even if concessions had been offered in return, which they were not. Hungary negotiated with its neighbours in the hope of securing from them consent to its rearmament, now a question of extreme urgency in view of the patent imminence of war; but tried while so doing to detach Yugoslavia, with which it was now willing to bury the hatchet, by a separate agreement.

Darányi at first made considerable concessions to anti-German opinion; during his term of office, also, a new franchise was enacted which, while restricting the number of voters, restored the secret ballot in the rural districts. But he was hard pressed by the right wing of his own party and by extremist groups even further to the right. He and his foreign minister, K. Kánya, visited Berlin in Nov. 1937 and there acquired the conviction that Hitler meant soon to incorporate Austria and attack Czechoslovakia. These reports strengthened the hand of the military party, which urged the necessity for uncompromising rearmament and, in connection therewith, for a more active policy against the Jews. In March 1938 Darinyi announced a rearmament program and a law limiting the participation of Jews in certain walks of life. He also offered concessions to Ferenc Szálasi, the leader of the principal extremist movement, the Arrow Cross. For this he was dismissed by Horthy in favour of Béla Imrédy, formerly Gombos' minister of finance (May 1938). Imrédy had Szálasi imprisoned, took other measures against the extreme right and made several last-hour attempts to win support from the western powers—which, in the view of himself, Horthy, Bethlen and Teleki (who had returned to office as minister of education) were certain to win the coming war. When Horthy, Imrédy and Kánya paid a state visit to Kiel in Aug. 1938 they, pleading Hungary's unarmed condition, rejected overtures made to them by the Germans to co-operate against Czechoslovakia; and when the Munich crisis broke out they limited Hungary's demands to the ethnically Magyar area and made every effort to get them satisfied by the general consent. It was not by their wish that—Britain and France having shown them little sympathy—they had to fall back on Italy's support. Eventually an arbitral decision, rendered by Germany and Italy on Nov. 2, 1938, awarded Hungary an area of 12,012 sq.km. with a population of 1,048,537, preponderantly Magyar but containing also Slovak minorities.

The hostility that Hungary had encountered from Germany during the negotiations, together with the impression of the feebleness and indifference of the west, had convinced the government that it must follow a more definitely pro-axis policy. In Dec. 1938 Kánya, who had personally offended both Hitler and Joachim von Ribbentrop, was dropped for István Csiky. The latter visited Hitler (Jan. 11, 1939) and promised full co-operation, to be documented by Hungary's signing the Anti-Comintern pact (which it did on Feb. 2, 1939) and leaving the League of Nations. Imrédy announced his intention of introducing authoritarian methods and further anti-Jewish legislation. A revolt of the conservative elements in his party put him in a minority. Horthy refused to accept his resignation, but his enemies discovered a Jewish strain in his ancestry and he resigned (Feb. 16, 1939). Teleki, a man fundamentally opposed to the Germans, took office and put up what resistance he could to Germany at home and abroad. Seeing the breakup of Czechoslovakia imminent, he planned to annex Ruthenia without Germany's consent, although a last-moment invitation to act came from Germany before Hungary could move. Hungarian troops then occupied this area (12,061 sq.km., pop. 664,226, mainly Ruthenian), thus securing a long-desired common frontier with Poland. When, however, Teleki visited Berlin with Csáky in April he did not dare go back on Hungary's previous promises to follow an "axis policy," only stipulating that Hungary would not participate, directly or indirectly, in an attack on Poland. In May Teleki held elections, under the secret franchise, but with the disconcerting result that the Arrow Cross and similar parties secured 42 mandates out of 281 and the right wing of the government party was as strong as ever.

World War II.—When Hitler attacked Poland, Hungary refused a request to allow German troops transit across its territory. Both groups of belligerents wished southeastern Europe to remain out of the war, and this suited Teleki well enough as he wished to realize his further claims by general consent when the war should be over. Hungary proclaimed itself nonbelligerent. Meanwhile, while maintaining its claims against Rumania, it sought the friendship of Yugoslavia more pressingly than ever. At first this patient policy was very popular in the country, but after Hitler's successes in the spring of 1940 Teleki was strongly attacked by the right for having backed the wrong horse; when, therefore, on June 26, the U.S.S.R. sent its ultimatum to Rumania, he decided that he could wait no longer. Against the wishes of Germany and Italy he raised Hungary's claims on Transylvania. Before his threatening

insistence the axis powers agreed to mediate and finally, Rumania having asked for their arbitration, rendered an award (Aug. 30). This took the Hungarian claim as basis but scaled it down and gave Hungary 43,104 sq.km. (about two-fifths of the total) with a population of 2,577,260, including about 1,000,000 Rumanians. After this Hungary made some further concessions to the right and adhered to the Tripartite pact (Nov. 20) but, in an attempt to counteract the effect of this and to strengthen its rear against Germany, signed a "Pact of Eternal Friendship" with Yugoslavia (Dec. 12). Since September, however, it had been allowing German troops to cross its territory into Rumania. Germany now prepared to use these troops to attack Greece. Then, in March 1941, a coup d'état in Yugoslavia overthrew the government that had signed the Tripartite pact, and Hitler prepared to attack Yugoslavia. The Hungarian government was thus caught on the horns of a dilemma: it refused to join in the attack, but did not attempt to deny Germany the use of its territory and decided to move into the vacuum of the Voivodina if Croatia declared its independence. Great Britain having shown strong disapproval of this plan, Teleki committed suicide (April 2-3). His successor, László Bárdossy, carried out the program. The reannexed area comprised 10,619 sq.km. and the population 1,030,027. Great Britain now broke off diplomatic relations.

Originally Hitler had not meant Hungary to participate in the war against the U.S.S.R.; but a party in the country, fearing to be left behind by Rumania in the race for Germany's favour, was anxious that it should do so. After aircraft had dropped bombs on Košice (Kassa) (June 26, 1941; an incident not wholly explained) Bárdossy, accepting the version that the aircraft were Russian, declared a state of war to exist between Hungary and the U.S.S.R. Only a small expeditionary force was sent out at first, and it was recalled in the autumn. It was then still thought that the war would be short and easy and not involve Hungary in complications with the west. But on Dec. 6 Great Britain declared war on Hungary, and on Dec. 12 Hungary itself, under strong German pressure, declared war on the United States. In Jan. 1942 Germany demanded a serious military effort of Hungary and extracted a promise to send out about 200,000 men, some of whom Germany undertook to equip., Just at this time a lamentable incident occurred in Novi Sad (Ujvidék), the largest town in the reoccupied Yugoslav territory. There had been partisan activity, and the officer sent to restore order rounded up and massacred several hundred persons, some Serbs, others Jews, others even Magyars who had been taken as hostages. Horthy was further irritated by Bárdossy's handling of a bill to make his son István Horthy deputy regent (in reality, successor presumptive to the regency) and replaced him on March 9, 1942, by Miklos Kállay, a politician of the so-called "Conservative-Liberal" school.

Like Horthy, but unlike Bárdossy, Kállay believed not only in an Allied victory but also in the possibility of splitting the east from the west. He allowed the troops to go out, although insisting that Hungary's struggle was purely defensive, but avoided any hostile acts of even words toward the west. He and the veteran minister of the interior, F. Keresztes-Fischer, gave the Jews a measure of real protection almost unparalleled on the continent and allowed the press and parties of the left much freedom. Under their protection an independence front began to take shape. Its members were the Social Democracts (with the crypto-Communists in the background); the Smallholders' party, now professing strongly democratic ideals; "progressive intellectuals," who either remained unorganized or (since the leader of the Liberal party, K. Rassay, refused his co-operation) attached themselves to the Smallholders' party; and a small group of intellectuals who formed a National Peasant party.

In Jan. 1943 the ill-equipped and spiritless Hungarian army suffered a grave defeat at Voronezh, losing a large part of its effective and nearly all its equipment. The survivors of the fighting units were now brought home, but some second-line divisions left as occupation troops. Kállay now sent several emissaries to make secret contact with the Allies in August; one of these actually signed with the British ambassador at Ankara, Turk., an instrument of unconditional surrender, to take effect when the Allied troops reached Hungary. But no such agreement could have immediate effect. Pending developments, the Allies persisted in demanding from Kallay "deeds," notably sabotage of war production and withdrawal of the remaining troops from Russia. Kállay protested that sabotage would involve the immediate occupation of Hungary by Germany, which was growing openly suspicious and hostile, while the troops were almost literally prisoners in German hands. He made, however, repeated requests for their withdrawal, which in fact exacerbated the Germans to a high degree. On March 17, 1944, Hitler called Horthy to Bavaria and presented him with an ultimatum: either to co-operate fully or to submit to the occupation of Hungary by German, Slovak, Croat and Rumanian troops. Horthy accepted the former alternative, but before his train had returned, German forces had entered Hungary and gestapo units, armed with long-prepared lists, were arresting prominent liberal and left-wing politicians, legitimists and Jews.

A collaborationist government under Dome Sztojay sent another army to the front and promised co-operation at home. The Germans took advantage of the occasion to round up and deport, for slave labour or the gas chambers, the Jews of Hungary. Although nearly all the Jews of the country districts, about 400,000 in number, suffered this fate, the government seems really not to have been aware of the exterminations until June, when this was reported to Horthy. He ordered the deportations to stop and, although two more country districts were "cleared" after the order, the Jewish population of Budapest was saved. It had to submit to the full rigour of the Nuremberg laws. however.

When Rumania surrendered (Aug. 23, 1944) Horthy decided to extricate Hungary from the war. It was no easy operation, for its only properly armed forces were now at the front, whereas Hungary was full of German troops. To make things worse. Horthy insisted, as a point of honour, on giving Germany notice of his intention. Finally, he still hoped to keep the Russians at bay and to open the frontiers to Anglo-American troops: only after some weeks, when the Russians were long across the Carpathians, did he send a mission to Moscow, which on Oct. 11 concluded a preliminary armistice. The whole affair was shot through with mutual misunderstandings. On Oct. 15 Horthy issued a proclamation of intention to surrender; but the few officers prepared to obey him failed to get back to Budapest, or their troops refused to follow them. German troops occupied Buda and removed Horthy as a prisoner. Szálasi assumed nominal power but in fact authority was in the hands of the German and Hungarian military in western Hungary, of the Russians in eastern.

The German-Hungarian armies left Buda — heroically defended by Gen. I. Hindy — as a "hedgehog" and retreated slowly, taking with them the ministries, skilled workers and equipment from the factories and supplies of all kinds. More than 1,000,000 persons left Hungary, with much of its portable wealth. Fighting on Hungarian soil went on until April 4, 1945.

Meanwhile a new provisional government had been formed at Debrecen on Dec. 23, 1944. This consisted nominally of a coalition of the parties of the independence front (Communists, Social Democrats, Smallholders, National Peasants and, for a while, Bourgeois Radicals) with some individuals who had been in Moscow (the members of the mission that had concluded the preliminary armistice) and, as minister-president, Béla Miklos, the general commanding the 1st army. This government had to sign an armistice with the Allies (Jan. 20, 1945) which *inter alia* imposed on Hungary the obligation to pay in reparations to the U.S.S.R., Yugoslavia and Czechoslovakia a sum equivalent to $300,000,000, to reduce its armed forces to eight divisions and to withdraw its military and civilian authorities to within the Trianon frontiers. The definitive peace treaty. signed in Paris on Feb. 10, 1947, restored the Trianon frontiers, with the further aggravation that Czechoslovakia obtained an extended bridgehead opposite Bratislava that cut the main direct line between Budapest and Vienna

The government had to face a situation of extraordinary difficulty. The country had been ravaged by war and stripped by the retreating Germans; it was subsequently denuded still more effectively by the huge Soviet occupying forces, whose conduct aroused bitter resentment Economically, financially and politically there was disorganization. The history of the subsequent years is that of partial recovery; but at the same time Hungary was being gradually but remorselessly transformed into a powerless satellite of the U.S.S.R. (C. A. M.)

THE PEOPLE'S REPUBLIC

The deliberations and the program agreed upon at the provisional assembly oi Debrecen were not iree from Communist pressure. This program contained, however, some of the genuine aims of the parties represented, a radical land reform among them. This was started immediately but it met with the distrust of the peasantry who would have preferred a transfer of agrarian property rights in conditions of undoubted legality and backed by state credit in solid currency and not in inflated money. Unqualified socialization was not envisaged at Debrecen, and a coalition government was taken for granted.

The general elections of Nov. 4, 1945, were conducted by secret ballot and without apparent compulsion, but considerable sections of Hungarian opinion went unorganized to the polls; already the adjectives "antifascist" and "democratic" were used with great elasticity, and opinion called "undemocratic" was excluded. Out of 409 seats 245 went to the Smallholder party. Zoltan Tildy formed a coalition government. Upon the proclamation of the republic (Feb. 1, 1946) he became president and handed over the premiership to Ferenc Nagy, a deputy of the same party. The Smallholder leaders were increasingly coerced to sever links with their firmer and more outspoken followers and colleagues who were grouping themselves round Dezso Sulyok and later formed the Freedom party. At the beginning of 1947 large-scale arrests took place under the pretext of a conspiracy led by Gen. Lajos Veress. Numerous Smallholder politicians were implicated, among them Béla Kovacs, secretary-general oi the party, imprisoned in February. Ferenc Kagy was persuaded by a ruse to leave the country. He signed his resignation under protest in Switzerland, in order to liberate his son, aged four, who was retained as a hostage in Hungary (May 31, 1947). A nominal Smallholder, Lajos Dinnyes, took his place.

New elections were held on a revised iranchise (Aug. 31, 1947), this time under pressure. The Communists increased irom 17.1% to 21.6% of the votes cast, the Social Democrats decreasrd from 16.9% to 15.1%; the Smallholders were down irom 57% to 14.6%; there was a considerable (39.7%) opposition vote of the right. These latter parties, however, were successively reduced to silence and their leaders imprisoned or driven into exile. Meanwhile, the new government again consisted of a nominal coalition of "progressive parties," in which the Communists were in fact the only important figures. All but its crypto-Communist members had now left the Kational Peasant party, which was kept in being only in order to mislead the Hungarian peasants. The Social Democrats now suffered the same fate as the Smallholders. Their leaders were denounced as fascists, and the survivors fused with the Communists in June 1948 into a Hungarian Workers' party. Tildy was disgraced and forced to resign on July 30, 1948, and was succeeded as president of the republic by Árpad Szakasits, a vacillating Socialist, later arrested and tried in a "people's court."

Further elections, this time farcical, were held on May 15. 1949. Again a nominal coalition took office, but Communist dictatorship was now undisguised. The subsequent struggles between politicians were of Communists against each other. Among others the minister of the interior, Laszlo Rajk, who was accused of "Titoism," was hanged on Oct. 15, 1949. The chief centre of resistance to the regime was now the Roman Catholic Church, which, unlike the other denominations, had refused to come to terms with it. The cardinal primate, Archbishop Joseph Mindszenty, was tried for "espionage" on Feb. 8, 1949, and sentenced to life imprisonment.

In an unexpectedly candid speech made on Feb. 29, 1952, Matyas (Roth) Rákosi (1892–), deputy premier from Nov. 1945 and first secretary of the Workers' party, described how the Hungarian Communists entered into coalitions in order to dispose of their partners. Summarizing the history of seven years, he referred to the gradual slicing off of his allies and potential victims as "salami tactics," declaring that these necessary tactics nevertheless succeeded only because the presence in the country of the Soviet army. On Aug. 14, 1952, Istvan Dobi, a Peasant figurehead, resigned as premier and was promoted chairman of the presidential council of the national assembly (head of state), while Rákosi became chairman of the council of ministers.

On May 17, 1953, there was another election, in which the government list received 96.2% of a poll that was 98% of those on the electoral register. But, as an effect of the changes in the U.S.S.R., where after Stalin's death a "collective leadership" was proclaimed, Rakosi on July 4 resigned as premier. His successor, Imre Nagy, announced a "new course" in the government's economic policy. Admitting that the industrial development plan had placed too heavy a burden on the country's resources, Nagy declared that the government's aim in economic policy should be to cut its coat according to its cloth. The "new course" was abandoned in the spring of 1955, and in Xpril Nagy had to resign and was dismissed from the party central committee.

In May 1954, at the time of its third congress, the Hungarian Workers' Communist party (Magyar Dolgozók Partja) had 810,227 members and 54,380 "candidates" grouped in 21,551 cells or basic organizations. The Youth league (D.I.Sz.) totalled 577,000 members.

Under Communist leadership Hungary's part in foreign affairs was integrated with that of the U.S.S.R. and its satellites under the general policy laid down in Moscow.

The rehabilitation of Béla Kun and Rajk (spring 1956) merely exposed Communism to ridicule. The "new line" of de-Stalinization only hastened the moral bankruptcy and disintegration of the Communist party. Liberalizing measures were accepted but were felt to be insincere and inconsistent, especially as in April 1956 Imre Nagy, the only Communist leader who had achieved some national standing since 1945, was expelled from the party. Moreover, the collective treaty of mutual assistance signed in Warsaw on May 14, 1955, was felt to be an indication that the Soviet Union was strengthening its grip.

Rákosi's resignation (July 18, 1956) brought some relief but made Hungarians no more amenable to a new "national" form of communism. The public reappearance of discredited politicians of the old parties (Tildy, Szakasits) did not lessen the tension. Writers were in open revolt by September; university students rejected the Youth league as their organization. On Oct. 23 street demonstrations by students began. The movement spread spontaneously, within hours, and eventually led to a unanimous and firm national resistance. Events quickly outstripped simple plans for reform or for a peaceful transition; it seemed that dismay, hatred and bitterness had broken through, after years of repression.

Imre Nagy was called back to power on Oct. 24. This did not stop the movement. Despite his promises of Soviet withdrawal, iree elections, the restoration of agrarian property rights and impartial justice, the insurgents, joined by the majority of the Hungarian army, went on to occupy public buildings and centres of production. None of the four governments announced between Oct. 27 and Nov. 4 had a chance of consolidation or actual administration. Béla Kovacs, announced as a minister, was believed to have reiused every office in a coalition with the Communists; the other names — with the possible exception of Anna Kethly, released from prison shortly before these events — seemed to reassure no one. Students, workers, peasants and soldiers shared in the fighting in the teeth of violent repression by Soviet units. Cardinal Mindszenty was liberated. Imre Nagy repudiated the Warsaw treaty and asked for an immediate international recognition of Hungary's status of neutrality (Oct. 31–Nov. 1).

The insurgent army commanded by Maj. Gen. Pal Maleter came nearest to an established authority in a confused situation. The Soviet command began negotiations with him which were alleged to hasten the withdrawal of Soviet troops. On Nov. 4, however, the Russians counterattacked. For about a week fighting was again intense, especially in industrial and mining centres. Subsequently the resistance was mainly passive and took the form of a general strike. Deportations to the U.S.S.R., food shortage and destruction compelled more than 150,000 Hungarians to leave the country.

After Nov. 4 an administration was formed by the Soviet command, under the nominal premiership of the dissident Communist Janos Kadar. He visited Moscow in March 1957. Henceforth, "the traitor Nagy" was denounced and a neu enemy, named "revisionism" (*i.e.*, of Marxism-Leninism), began to be pursued. On May 27 an agreement was signed in Budapest legalizing the prescnce oi Soviet armed forces in Hungary. From June 28 to 30 the reorganized Hungarian Socialist Workers' (Communist) party held its congress: its membership was given as 345,733. In Sept. 1957 the UN general assembly endorsed the report of its committee of five (Austria, Ceylon, Denmark. Tunisia and Uruguay) which stated that the Kadar government "came into being solely as the result of military intervention." Kadar resigned in Jan. 1958 and was succeeded by Ferenc Münnich. (B. Mr.)

POPULATION

Before World War I Hungary or Magyarorszag (the state of the Magyars) covered, as part of the Xustro-Hungarian empire, a total area of 125.631 sq.mi. The blood of the original invaders must soon have become heavily diluted with Slavonic, Rumanian. Turkish. German and other strains, but in 1910 about half the total population of 20,886,500 was listed as Magyar-speaking.

The treaty of Trianon. cutting off the provinces with Slovak, Ruthenian, Rumanian and Serbo-Croat majorities, reduced Hungary to an area of 35,935 sq.mi. The population of the new state was 7,990,202 in 1920 and 8,688,319 at the 1930 census, and it was estimated at 9,082,400 in 1939, within the Trianon frontiers. The 1941 census revealed a population of 9,314,323 within the same frontiers. After the reannexation of territories awarded to Hungary on four successive occasions (see above). the country's area increased by April 1941 to 66,271 sq.mi. with an estimated population of 14,669,000. In 1945 Hungary found itself reduced to its Trianon size. By the Paris peace treaty of Feb. 10. 1947, a bridgehead facing Bratislava, on the right hank of the Danube. was ceded to Czechoslovakia, reducing Hungary's area to 35,911 sq.mi. The Jan. 1, 1949, census showed that the area was 35,905 sq.mi. and the population was 9,204,799. The 1960 census reflected a population of 9,976,530 in an area of 35,919 sq.mi.

Both before 1938 and after 1945 Hungary was predominantly Magyar-speaking and, as a result of World War II. the Magyar-speaking proportion of the population rose from 92.1% to 96.6%.

The German minority was in fact larger than the Hungarian sources admitted, and by 1939 it was estimated at 530,000. Many Germans left the country early in 1945 with the retreating German armies, and others were transferred according to the Potsdam

three-power agreement of Aug. 2, 1945.

The Jewish minority also was larger than the 1930 census according to religion suggested (see Table I), for many Jews mere converts to Catholicism or to Calvinism. It was estimated that the Jews who remained in Hungary after R'orld War II represented about one-third their prewar number and that more than 300.000 were exterminated during the war.

TABLE I.—Population According to *Religion*

Religion	1920		1930		1949*	
	Number	Per cent	Number	Per cent	Number	Per cent

The tonns were relatively numerous but small, having mostly originated as market centres. Budapest, originally two cities (the fortress Buda and the market Pest opposite it, on the left bank of the Danube), is a case by itself, having concentrated within its boundaries not only the administrative services required by the capital of a state (of a state, moreover, much larger than post-1920 Hungary) but also much of its industry. In Dec. 1949 Budapest's boundaries were extended to bring in the industrial satellite towns of Pestszenterzsebet, Cjpest and Kispest, raising its population to 1,589,065. (See Table II.)

TABLE 11.—Population *of Major* Towns

Tonn	1920	1930	1941	1949	1960
Budapest	929,690	1,006,184	1,164,963	1,589,065	1,807,299

Education.— All education was state conducted and given on a basis of dialectical materialism, two hours a week, however, being allowed for optional religious education. In 1954–5j there were 6,185 primary schools with 1,208,000 pupils and 46,100 teachers. and 405 secondary schools with 162,500 pupils and 7,500 teachers.

There were also 21 institutions of higher education, including four universities (Budapest, Debrecen, Pecs and Szeged) and four colleges of engineering (one old. Budapest, and three new, Szeged, Miskolc and Veszprem), with a total of 47,500 students and a teaching staff of 7,200.

GOVERNMENT AND ADMINISTRATION

Constitution.—Hungary was declared a republic on Feb. 1, 1946. A new constitution was adopted on Aug. 20, 1949. This was an almost exact copy of the constitution of the U.S.S.R., except that provisions safeguarding the rights of the national minorities replaced the federal provisions in the original. The highest organ of state authority is (in theory) the national assembly, elected by universal, direct, equal and secret adult suffrage.

Under the electoral law of 1953 the qualifying age for franchise was lowered from 20 years to 18 years, and the number of deputies was reduced from 395 to 298 elected in 20 constituencies from single lists presented by the Communist-controlled Patriotic People's front. The front was composed of the three parties which nominally governed the country in coalition (the Workers' party, the Smallholders' party and the National Peasant party) and of mass organizations of which the Trade Union federation was the largest.

The national assembly enacts legislation and appoints or dismisses ministries and ministers. Between its meetings its work is carried out by a presidential council, which consists of a chairman, two vice-presidents, a secretary and 17 members and can initiate legislation and issue orders in council having legislative force; it also performs the functions of the head of the state. Current administration is under a council of ministers who are appointed by and responsible to the parliament and may not be members of the presidential council. In practice it is this latter body that (under Moscow) controls Hungarian affairs; it consists of active Communists, whereas the presidential council consists of figureheads.

The arms of Hungary consist of a crossed hammer and sickle bordered with wheat ears and surmounted by a Soviet star.

The main geographical unit of local administration remains the old county (megye), of which, after a rationalization carried through in 1950, there remained 19. The municipal cities, 11 in number, enjoy a status roughly equivalent to that of the counties. Budapest has a special position and organization. The counties are divided into jmnsok, or rural districts (two to four to each county). which are in turn divided into communes (kozsegek), as the larger towns are divided into *keruletek* (boroughs or wards).

The judiciary is elected and responsible to its electors. Its functions would appear to be largely political. The various legal codes are those of the U.S.S.R.

Defense.— The peace treaty of 1947 limited Hungary's defense forces to a land army of 65,000 and an air force of 5.000 with 70 combat aircraft. By 1948 Hungary had only four poorly equipped divisions.

It was in that year, however, that the government under Soviet direction decided to reorganize the armed forces. Military service was made universal and compulsory between the ages of 20 and 50; active service was two years in the army, three years in the air force and 27 months in the forces of the interior, comprising security troops and frontier guards.

It was estimated that by April 1957 there were 205,000 men in the armed forces; there were nine infantry and three armoured divisions. There were also five air divisions with a total of 550 aircraft. Hungary was a member of the mutual defense treaty signed in Warsaw on May 14, 195j, by the U.S.S.R. and its six other satellite states.

ECONOMY

Agriculture.— By the mid-20th century agriculture was still the largest single industry of Hungary. In 1945 about 78% of the country's area (i e., 12,603,400 *hold* or 17 896.800 ac.) was listed as agricultural land (arable land. pastures. gardens and vineyards) Before World War II 1,382.800 smallholders owned 24.6% of agricultural land, uhile 3,870 large estates together covered 32.2% of agricultural land (5,748,100 ac.). By a decree of March 15, 1945, the government decided to parcel out the large estates. When the reform was carried out. about 6,752.000 ac., 30% of the country's area, changed hands (see Table III). The number of smallholders increased to 1,790,824 and by 1948 they owned betneen them 9,072,444 ac.; that is. 49% of all agricultural land. The Hungarian Smallholders' party, like every Peasant party in eastern Europe. stood for a democratic political system and land reform. It rejected Socialism or Communism because the system meant nationalization of land; it stressed, however, the necessity for setting up co-operatives for specific purposes or for

TABLE III.—*Hungarian* Land Reform of *1945*

Holdings by size	Number	Per cent	Total area (in *hold*)	Per cent
Before land reform

More than 200 *hold*				...

*One *hold*=1.42 ac. or 0.575 **ha.**

embracing the whole life of a village community. Immediately after World War II the Hungarian Communist party was too weak and too insecure in the saddle to challenge openly the peasants' way of life. But on March 5, 1949, in a speech in Budapest. Jozsef Revai, a prominent Hungarian Communist, confirmed that the Communist parties had allowed the eastern European nations to believe that a people's democracy was to be merely a plebeian and popular form of bourgeois democracy and that the land reforms of 1945 were made in defense of small landowners, and he justified subsequent political developments by recalling that both Lenin and Stalin had insisted that all power had to be in the hands of the proletariat and that it could not be shared with peasants or any other class of the population.

At first the number of agricultural small holdings had been allowed to multiply, but, when these were shown to be uneconomic, they were made to give place to planned agricultural production along lines of collectivization. By 1949 collectivization was still in its initial stage, but by Jan. 1953 the country had 5,315 producers' co-operatives grouping 413,000 small holdings and covering 3,425,890 ac. or 19.1% of all agricultural land. State farms occupied another 1,753,700 ac. of the agricultural land, or 10%. The so-called "new course" introduced by mid-1953 represented some concession to private farming and halted the progress of large-scale collectivization. Rakosi revealed in May 1954 that more than half fhe total collectivized peasants had seized the opportunity of leaving the producers' co-operatives and that many co-operatives had been dissolved. Nevertheless, by Oct. 1956 there were 5,191 producers' co-operatives comprising 25% of the agricultural land. By Jan. 1957, after the October revolution, the number of co-operatives fell to 2.700 covering about 12% of all agricultural land.

No increase of agricultural production followed the Communist land reform and the attempt at collectivization. Table IV shows

TABLE *IV.— Agricultural Production*
(in ooo metric tons)

Crop	1920–25	1926–30	1934–38	1948–50	1955

that the average wheat crop in 1948–50 was 17.4% less than that of 1934–38. It also shows the tendency to concentrate upon crops of value to the export market, such as sugar or bacon and ham (therefore an increase in production of maize used to feed pigs). While pigs increased in numbers, other achievements in the domain of animal husbandry fell below the standards fixed *(see* Table V).

TABLE V.—*Livestock*

*1948.

Industry. — The 1941 census revealed that while 48.7% of the population was engaged in agriculture, 25.4% derived their living from industry, including mining. These figures reflected the continuous increase in industrialization which had been proceeding from 1867, The process had been accelerated after 1920 when Hungary was forced to develop new industries in order to replace those lost under the treaty of Trianon and to absorb the surplus rural population.

After World War II, when the country became a part of a centrally planned Soviet system, the pace of industrialization was greatly increased with emphasis on heavy industry. In this connection, all private industry and banking and practically all private trade were nationalized. In 1947 a three-year plan was initiated with the aim of raising industrial production by 27% as compared with 1938.

On May 17, 1950, the national assembly passed a revised five-year plan under which far greater importance was assigned to industry than had been originally intended. Hungary was to be "a country of steel and machines." The total capital investment was increased from 50,900,000,000 forints to 85,000,000,000 forints. The volume of all industrial production by 1954 was to represent 310% of that of 1949, instead of 186%.

Table VI shows that up to 1955 industrialization made steady and considerable progress. Industrial production in 1956 fell somewhat as a result of the October revolution. In 1954 the first blast furnace and two open-hearth furnaces at Sztalinvaros (formerly Dunapentele), a new centre of iron and steel production, were inaugurated. Under the 1950–54 five-year plan the iron and steel works of Diosgyor were modernized. A big hydroelectric power station was being built at Tiszalok. on the Tisza river. Between 1937 and 1956 the installed capacity in power stations rose from 854,000 kw. to 1,269,000 kw.

On Nov. 6, 1954, in Moscow, was signed an agreement transferring to Hungary the Soviet shares of all Magyar-Soviet mixed companies formed in 1945, namely those concerned with exploitation of crude petroleum, bauxite, aluminum, Danube navigation, civil aviation and the Soviet Bank for Trade and Industry in Budapest. The number of industrial workers rose between 1949 and Sept. 1956 from 520,000 to 939,000.

Currency and Finance.— To finance long-term development plans it was necessary to restrict consumer purchasing power and reinvest an ever-growing share of the national income in industrial production.

Civilian consumption was reduced by various techniques previously adopted in the U.S.S.R. First, by raising production "norms" and at the same time stabilizing wages, the worker was made to produce more without an increase in wages. Second, the pay packet was further reduced through taxation, compulsory savings and forced contributions. generally equal to a month's pay, to the yearly state loans. Third, because production had been concentrated on heavy industry and because consumer products were scarce, the regime brought buying power in line with the available supply of goods by manipulating prices. This aim was achieved in a variety of ways, by rationing with controlled and "free market" prices, by derationing with one set of prices always nearer the previously "free" one, by insufficient wage increases and by monetary reforms which greatly reduced both consumer savings and consumer purchasing power.

On July 31, 1946, the forint superseded the pengo, victim of the postwar hyperinflation. The official exchange rate of the new currency was 11.74 forints to the U.S. dollar, as compared with 115.5 octillion (+ 26 zeros!) pengo, probably the highest exchange ratio in the history of money.

On March 1, 1950, when the rouble had been put on a gold basis and its external value raised from 5.30 to 4 roubles to the dollar, the exchange rate of the forint to the rouble was proportionately reduced; thus the prices of Hungarian imports from the U.S.S.R (22.7% of the total in 1950) rose, while the prices of Hungarian exports to the U.S.S.R. (22.7% of the total in 1950) fell correspondingly

The Hungarian budget is of a Soviet type, and so includes invest-

ments in the nationalized economy. (See Table VII.)

Foreign Trade.—In 1957, after nine years of almost complete secrecy, Hungary published a comprehensive picture of its foreign trade. (See Table VIII.)

TABLE VIII.—*Foreign Trade*
(in 000,000 forints)

Item		1952	1953	1954	1955	1956
Total trade . . .	Imports	5,207.8	5,331.1	6,018.9	6,274.0	5,359.8
	Exports	5,197.8	5,904.2	6,163.6	7,147.9	5,785.4
Trade with the Socialist camp	Imports	3,769.6	4,050.1	4,094.2	3,444.8	3,331.2
	Exports	3,814.6	4,644.9	4,538.1	4,753.5	3,598.8
Trade with the U.S.S.R.	Imports	1,386 6	1,663.5	1,718.7	1,163.7	1,238.4
	Exports	1,740.6	2,198.2	2.018.0	1,794.9	1,413.7

Source: *Statisztikai Havi Kozlemenyek* (Budapest, 1957)

Table VIII shows that while in 1952 the so-called Socialist countries supplied 72.5% of Hungarian imports and took 73% of Hungarian exports, in 1956 the respective proportions were 63% and 62%. The U.S.S.R. was the most important single source of imports: it supplied 26.6% in 1952 and 23% in 1956. It also was the most important destination of exports as it took 33.5% in 1952 and 24.4% in 1956.

Communications — In 1956 there were 7,100 mi. of railways and 39.569 mi. of roads. All the seven bridges over the Danube at Budapest were rebuilt, and in May 1955 a new railroad bridge at Ujpest was opened to traffic. By the end of 1954 the restored road and railway bridge at Komarno, linking Hungary to Slovakia, was inaugurated.

It was estimated that in 1953 Hungary had 120,000 telephones. In 1954 it had 1,236,000 radio sets.

HUNGERFORD, WALTER HUNGERFORD, BARON (d. 1449), English soldier. belonged to a Wiltshire family. His father, Sir Thomas Hungerford (d. 1398), became speaker of the house of commons in 1377, through the influence of John of Gaunt, and is the first person formally mentioned in the rolls of parliament as holding the office. Walter Hungerford also served as speaker. He fought at Agincourt and was an envoy at the council of Constance and the congress of Arras. An executor of Henry V's will and a member of the council under Henry VI, Hungerford became a baron in 1426, and he was lord treasurer from 1426 to 1431.

HUNGERFORD, a town of Berkshire, Eng., near the Wiltshire border 8 mi. W. of Newbury. Pop. (1951) 3.020. It is an agricultural and market town lying on the Dun where it joins the Kennet (trout and crayfish streams). in a valley in the Berkshire Douns; the Kennet and Avon canal also passes through it. John of Gaunt gave to the citizens manorial rights, including common pasture and fishing, in memory of which a red rose of Lancaster is still presented to a reigning sovereign first passing through the town. On Tuttiday or Hockney day. the second Tuesday after Easter. the burgesses, summoned by a horn blown from the town hall, attend their Hocktide court to elect the constable and other officials for the year. The two tuttimen with garlanded poles collect the "head penny" from each house enjoying common rights.

At Lambourn. to the north, are well-known racing stables.

HUNINGUE, a town of France, department of Haut-Rhin (Alsace), on the left bank of the Rhine and a branch of the Rhine-Rhône canal. 3 mi. N. of Basle by rail. Pop. (1954) 4,162. The town grew round a fortress at a Rhine crossing. The duke of Lauenburg took it from the imperialists in 1634 and Louis XIV of France later bought it. Sébastien le Prestre de Vauban fortified it (1679–81), and a Rhine bridge was then built. The fortress was dismantled after 181j. The town makes chemicals, molasses, watches and cigars.

HUNKERS AND BARNBURNERS, in U.S. political history. the popular names of two factions into which the Democratic party in New York state split during the 1840s. Both groups played an important part in the presidential election of 1844. The Hunkers, said to be named after the Dutch hunkerer, referring to a person who seeks office for himself, and led by William L. Marcy (*q.v.*) and Daniel S. Dickinson, were the conservative urban group. The Barnburners, whose name was supposedly derived from the act of a farmer who set his barn afire to rid it of rats. were the radicals, led by Martin van Buren (*q.v.*) and his supporters.

The factions had their origin in canal politics. The Hunkers advocated the use of canal revenues to complete the canals, whereas the Barnburners insisted they should be used to pay the state debt. Later, when the Hunkers supported and accepted the annexation of Texas and the Barnburners supported the Wilmot proviso, the split became irrevocable.

The Hunkers, advocates of the chartering of state banks, opposed the Barnburners on that issue, and the factions also disagreed on the distribution of patronage. The Hunkers supported James K. Polk and were violently opposed to antislavery agitation, The Barnburners opposed slavery in the territories, or, more precisely, opposed the extension of slavery into newly opened territories. In 1848 they left the Democratic national convention, nominated Van Buren for president, and joined the Free Soil party (*q.v.*), which also nominated him. The coalition won no electoral votes. however. Later some of the Barnburners returned to the Democratic party. but when the Republican party was organized the younger Barnburners joined it.

HUNNERIC (d. 484), king of the Vandals, was a son of King Gaiseric, and was sent to Italy as a hostage in 435 when his father made a treaty with the emperor Valentinian III. After his return to the Vandal court at Carthage, he married a daughter of Theodoric I, king of the Visigoths; but when this princess was suspected of attempting to poison her father-in-law, she was mutilated and was sent back to Europe.

Hunneric became king of the Vandals on his father's death in 477. Like Gaiseric he was an Arian, and his reign is memorable for his cruel persecution of members of the Orthodox Christian Church in his dominions. His second wife was Eudocia, a daughter of Valentinian III and his wife Eudocia. (See VANDALS.)

HUNNIS, WILLIAM (d. 1597), English musician and poet, was as early as 1549 in the service of William Herbert, afterward earl of Pembroke. In 1550 he published *Certayne Psalms . . . in Englishe Metre,* and shortly afterward was made a gentleman of the chapel royal.

During the reign of Mary he was implicated in plots against the queen, and was imprisoned for some time. In 1566 he was made master of the children of the chapel royal. No complete piece of his is extant, perhaps because of the rule that the plays acted by the children should not have been previously printed. In his later years he purchased land at Barking.

Hunnis's extant works include *Certayne Psalms* (1549), *A Hive Full of Hunnye* (1578), *Seven Sobbes of a Sorrowful Soule for Sinne* (1583), *Hunnies Recreations* (1588), 16 poems in the *Paradzse of Dainty Devices* (1576) and two in *England's Helicon* (1600). See Mrs C. Carmichael Stopes's tract on William Hunnis, reprinted (1892)

from the *Jahrbuch der deutschen Shakespeare Gesellschaft.*

HUNS, a name given to at least four peoples, whose identity remains obscure. (1) The Huns, who invaded the East Roman empire from about A.D. 372 to 453 and were most formidable under the leadership of Attila. (2) The Hungarians or Magyars who crossed the Carpathians into Hungary in A.D. 898 and mingled with the races they found there. (3) The White Huns (Ephthalites), who troubled the Persian empire from about 420 to 557 and were known to the Byzantines (see HEPHTHALITES). (4) The Hûnas, who invaded India during the same period. It is most probable that the last two are identical and although it cannot be proved that the Magyars are descended from the horde which sent forth the Huns in the 4th century, it is possible that they were originally Ephthalites. Our present knowledge of the history and distribution of the Huns tends to support this view. In the 1st century A.D. the Chinese drove the Hiung-nu westward, and while one division of the Huns remained in Transoxiana and Afghanistan, another pushed further west and rested near the southern Urals. From this point the Huns invaded Europe, and when their power collapsed, after the death of Attila, many of them may have returned to their original haunts. Possibly the Bulgarians and Khazars were offshoots of the same horde. The Magyars may very well have gradually spread first to the Don and then beyond it, until in the 9th century they entered Hungary. Authorities are not even agreed as to the branch of the Turanians to which the Huns should be referred; the physical characteristics of these nomad armies were very variable and there is no certain ethnic or linguistic identification. Hiung-nu seems not to be a particular but a general term for warlike nomads. The warlike and vigorous temper of the Huns has led many writers to regard them as Turks. The Turks were perhaps not distinguished by name or institutions from other tribes before the 5th century, but the Huns may have been an earlier offshoot of the same stock. Apart from this the Hungarians may have received an infusion of Turkish blood not only from the Osmanlis but from the Kumans and other tribes who settled in the country.

History. — The authentic history of the Huns in Europe practically begins about the year A.D. 372, when under a leader named Balamir (or, according to some mss. Balamber) they began a westward movement from their settlements in the steppes lying to the north of the Caspian. After crushing, or compelling the alliance of various nations unknown to fame (Alpilzuri, Alcidzuri, Himari, Tuncarsi, Boisci), they at length reached the Alani, a powerful nation which had its seat between the Volga and the Don; these also, after a struggle, they defeated and finally enlisted in their service. They then proceeded, in 374, to invade the empire of the Ostrogoths (Greutungi), ruled over by the aged Ermanaric, or Hermanric, who died (perhaps by his own hand) while the critical attack was still impending. Under his son Hunimund a section of his subjects promptly made a humiliating peace; under Withemir (Winithar), however, who succeeded him in the larger part of his dominions, an armed resistance was organized; but it resulted only in repeated defeat, and finally in the death of the king. The representatives of his son Witheric put an end to the conflict by accepting the condition of vassalage. Balamir now directed his victorious arms still farther westward against that portion of the Visigothic nation (or Tervingi) which acknowledged the authority of Athanaric. The latter entrenched himself on the frontier which had separated him from the Ostrogoths, behind the "Greutung-rampart" and the Dniester; but he was surprised by the enemy, who forded the river in the night, fell suddenly upon his camp, and compelled him to abandon his position. Athanaric next attempted to establish himself in the territory between the Pruth and the Danube, and with this object set about heightening the old Roman wall which Trajan had erected in the north-eastern Dacia; before his fortifications, however, were complete, the Huns were again upon him, and without a battle he was forced to retreat to the Danube. The remainder of the Visigoths, under Alavivus and Fritigern, now began to seek, and ultimately were successful in obtaining (376), the permission of the emperor Valens to settle in Thrace; Athanaric meanwhile took refuge in Transylvania, thus abandoning the field without any serious struggle to the irresistible Huns. For more than fifty years the Roman world was undisturbed by any aggressive act on the part of the new invaders, who contented themselves with over-powering various tribes which lived to the north of the Danube. In some instances, in fact, the Huns lent their aid to the Romans against third parties; thus in 404–405 certain Hunnic tribes, under a chief or king named Uldin, assisted Honorius in the struggle with Radagaisus (Ratigar) and his Ostrogoths, and took a prominent part in the decisive battle fought in the neighbourhood of Florence. Once indeed, in 409, they are said to have crossed the Danube and invaded Bulgaria under perhaps the same chief (Uldin), but extensive desertions soon compelled a retreat.

About the year 432 a Hunnic king, Ruas or Rugulas, made himself of such importance that he received from Theodosius II. an annual stipend or tribute of 350 pounds of gold (£14,000), along with the rank of Roman general. Quarrels soon arose, partly out of the circumstance that the Romans had sought to make alliances with certain Danubian tribes which Ruas chose to regard as properly subject to himself, partly also because some of the undoubted subjects of the Hun had found refuge on Roman territory; and Theodosius, in reply to an indignant and insulting message which he had received about this cause of dispute, was preparing to send off a special embassy when tidings arrived that Ruas was dead and that he had been succeeded in his kingdom by Attila and Bleda, the two sons of his brother Mundzuk (433). Shortly afterwards the treaty of Margus (not far from the modern Belgrade) was ratified; this treaty provided for Roman tribute to Attila, the surrender of fugitives, the institution of free markets and regulations as to alliances with other powers. The Romans held to the treaty and during the ensuing eight years the Huns made their extensive conquests in Scythia, Media and Persia.

In 445 Bleda died, and two years afterwards Attila, now sole ruler, undertook one of his most important expeditions against the Eastern empire; on this occasion he pushed southwards as far as Thermopylae, Gallipoli and the walls of Constantinople; peace was cheaply purchased by tripling the yearly tribute (which accordingly now stood at 2,100 pounds of gold, or £84,000 sterling) and by the payment of a heavy indemnity. In 448 again occurred various diplomatic negotiations, and especially the embassy of Maximinus, of which many curious details have been recorded by Priscus his companion. Then followed, in 451, that westward movement across the Rhine which was only arrested at last, with terrible slaughter, on the Catalaunian plains (according to common belief, in the neighbourhood of the modern Chblons, but more probably at a point some 50m. to the south-east, near Mery-sur-Seine). The following year (452) that of the Italian campaign, was marked by such events as the sack of Aquileia, the destruction of the cities of Venetia, and that historical interview with Pope Leo I. which resulted in the return of Attila to Pannonia, where in 453 he died (see ATTILA). Almost immediately afterwards the empire he had amassed rather than consolidated fell to pieces. His too numerous sons began to quarrel about their inheritance, while Ardaric, the king of the Gepidae, was placing himself at the head of a general revolt of the dependent nations. The inevitable struggle came to a crisis near the river Netad in Pannonia, in a battle in which 30,000 of the Huns and their confederates, including Ellak, Attila's eldest son, were slain. The nation, thus broken, rapidly dispersed, exactly as the White Huns did after a similar defeat about a hundred years later. One horde settled under Roman protection in Little Scythia (the Dobruja), and others in Dacia Ripensis (on the confines of Serbia and Bulgaria) or on the southern borders of Pannonia. Many, however, appear to have returned to what is now South Russia, and may perhaps have taken part in the ethnical combinations which produced the Bulgarians.

The chief original authorities are Ammianus Marcellinus, Priscus, Jordanes, Procopius, Sidonius Apollinaris and Menander Protector.

(C. El; A. N. J. W.)

HUNSDON, HENRY CAREY, 1ST BARON (*c.* 1524–1596), English soldier and courtier, was a son of William Carey (d. 1529): his mother was Mary (d. 1543), a sister of Anne Boleyn, and he was consequently cousin to Queen Elizabeth. Member of parliament for Buckingham under Edward VI. and Mary, he was knighted in 1558, was created Baron Hunsdon in 1559, and in 1561 became a privy councillor and a knight of the Garter. In 1568 he became governor of Berwick and warden of the east Marches, and he gained a decisive victory over the northern rebels under Leonard Dacre near Carlisle in February 1570. In 1583 he became lord chamberlain, but he did not relinquish his post at Berwick. Hunsdon was one of the commissioners appointed to try Mary queen of Scots; after Mary's execution he went on a mission to James VI. of Scotland, and when the Spanish Armada was expected he commanded the queen's bodyguard. He died in London, at Somerset House, on July 23, 1596.

HUNSTANTON, a seaside town and urban district in the King's Lynn parliamentary division of Norfolk, Eng., on the east shore of the Wash, 47 mi. N.W. of Norwich by road. Pop. (1951) 3,419. Area 1.7 sq.mi. Behind the sands is a promenade ($1\frac{1}{4}$ mi.) rising up on to the cliffs to the north, and behind this is the "Green." Sailing is one of the many summer activities. The royal residence of Sandringham is 8 mi. S.

HUNT, ALFRED WILLIAM (1830–1896), English painter, son of Andrew Hunt, a landscape painter, was born at Liverpool on Nov. 15, 1830. Most of his pictures are in private ownership; but, his "Windsor Castle" is in the Tate gallery, "Working Late" in the Walker art gallery, Liverpool, and others at South Kensington. He died in London on May 3, 1896.

See *Exhibition of Drawings in Water Colour by Alfred William Hunt,* Burlington Fine Arts Club (1897); H. C. Marillier, *The Liverpool School of Painters* (1904).

HUNT, HENRY (1773–1835), English reformer, was born at Upavon, Wilts., on Nov. 6. He was for many years the most prominent among the more extreme English reformers under the oppression of Sidmouth and Castlereagh: indeed, after the defection of Burdett he had a position which was almost that of recognized leader. In person. training and character, he much resembled William Cobbett (*q.v.*). He was tall, florid and bulky; a typical English farmer both in occupation and appearance; he was as pugnacious, as unreasonable, as devoted and as vain as his more famous rival; he was possibly more courageous. But *littera scripta manet:* Cobbett wrote magnificent English which has preserved him a growing fame; Hunt is forgotten because we can no longer hear the voice and eloquence which gave him the name of Orator Hunt. He first adopted radical principles in 1806 and continued his agitation at a persistent series of public meetings and dinners until Aug. 1819 when he presided at the great meeting at St. Peter's fields, Manchester, which was attacked by the yeomanry (*see* PETERLOO). The white hat, which he wore on that occasion and which was stated to have been stove in by a sword cut, became the badge of reform, and for several years to wear a white hat was as symbolical as later it was to wear a red tie. He was sentenced to imprisonment for two and a half years; from his prison he sent out *A peep into a jail,* an exposure of Ilchester gaol which had its share in promoting prison reform. He took a great share in causing the *crescendo* of indignation which eventually overturned the oligarchy in 1832. In 1830 he was himself elected M.P. for Preston, a borough which, by virtue of a scot-and-lot franchise, was one of the very few with a working class electorate. In Parliament he presented a petition for women's rights, and moved (despite his farming connection) against the Corn Laws. But the Reform Act of 1832, in granting the vote to the middle class and standardizing the franchise, necessarily disfranchised the mass of the electors at Preston. Hunt lost his seat in the election of 1833 and died on Feb. 15, 1835.

See *Memoirs of Henry Hunt Esq.,* by himself (1820–22); R. Huish, *Life of Hunt (1836).* (R. W. P.)

HUNT, HENRY JACKSON (1819–1889), American soldier, was born in Detroit, Mich., on Sept. 14, 1819, and graduated at the U.S. Military Academy in 1839. He served with great gallantry in the Mexican War, became captain in 1852, and major in 1861. His professional attainments were great, and in 1856 he was a member of a board entrusted with the revision of light artillery drill and tactics. He took part in the first battle of Bull Run in 1861, and soon afterwards became chief of artillery in the Washington defences. As a colonel on the staff of General M'Clellan he organized and trained the artillery reserve of the Army of the Potomac. Throughout the Civil War he contributed more than any officer to the effective employment of the artillery arm. With the artillery reserve he rendered the greatest assistance at the battle of Malvern hill, and soon afterwards he became chief of artillery in the Army of the Potomac. On the day after the battle of South Mountain he was made brigadier-general of volunteers. At the Antietam, Fredericksburg and Chancellorsville, he rendered further good service, and at Gettysburg his handling of the artillery was conspicuous. When the U.S. army was reorganized in 1866 he became colonel of artillery and president of the permanent artillery board. In 1883 he retired to become governor of the Soldiers' Home, Washington, D.C. He died on Feb. 11, 1889. He was the author of *Instructions for Field Artillery* (1860).

HUNT, JAMES HENRY LEIGH (1784–1859), English essayist and poet, was born at Southgate, Middlesex. His father had been a lawyer in Philadelphia, and had left the United States because of his loyalist sympathies. The son, who was educated at Christ's Hospital, began writing verse as soon as he left school, and soon became a constant contributor to the newspapers. In 1808 he became editor of the *Examiner,* a clever journal owned by his brother John. The brothers were sent to prison for an attack in the *Examiner* on the prince regent. The offensive phrase was "a fat Adonis of 50." Leigh Hunt's imprisonment had compensations, for it brought Byron, Moore, Brougham and other friends of liberty to see him in prison. Another joint enterprise of the Hunt brothers was a quarterly, the *Reflector.* The essays published as *The Round Table* (2 vols., 1816–17), conjointly with William Hazlitt, appeared in the *Examiner.*

In 'S~' Leigh Hunt wrote his *Story of Rimini,* which established his fame as a poet. Though few read it now, the poem is important in the history of English poetry because in it Hunt went back to the rhythms of Chaucer and Spenser and thus became one of the pioneers of the new romantic school. In 1818 appeared a collection of poems entitled *Foliage,* followed in 1819 by *Hero and Leander,* and *Bacchus and Ariadne.* In the same year he reprinted these two works with *The Story of Rimini* and *The Descent of Liberty* with the title of *Poetical Works,* and started the *Indicator,* in which some of his best work appeared. Both Keats and Shelley belonged to the circle gathered around him at Hampstead, which also included William Hazlitt, Charles Lamb, Bryan Procter, Benjamin Haydon, Cowden Clarke, C. W. Dilke, Walter Coulson, John Hamilton Reynolds and other men of liberal sympathies. After Shelley's departure for Italy Leigh Hunt's financial situation became desperate. Marianne Hunt (*née* Kent), his rather unattractive wife, wrote to Mrs. Shelley, with the result that Leigh Hunt was invited to go out to meet Shelley and Byron at Pisa. Byron provided the Hunts and their family (there were seven children) with a lodging in the Villa Lanfranchi, and Leigh Hunt was to publish a liberal paper. But Byron was annoyed when he learned that Leigh Hunt had no longer a share in the *Examiner,* and the connection proved an unhappy one. Nevertheless, though Byron was not always gracious, he made substantial payments to Hunt, and before he left for Greece made over to John Hunt exceedingly valuable copyrights. The ill-starred *Liberal* existed through four quarterly numbers. The Hunts remained in Italy until 1825. After his return to England Hunt revenged himself for the slights he had received from Byron in the ill-judged *Lord Byron and some of his Contemporaries* (1828), which brought down on him the scorn of Moore.

From that time onwards Leigh Hunt's life was a constant

struggle with sickness and poverty. He edited various papers, and published many admirable volumes of criticism, but was often dependent on Mrs. Shelley's kindness until in 1847 he received a Civil List pension. Hunt was a generous critic, and had a fresh open mind which recognized genius before it was acknowledged elsewhere, He had been one of the first to recognize a great poet in Keats, and he lived to welcome the early poems of Tennyson. He died at Putney on Aug. 28, 1859. His most important later works were two excellent selections (1844 and 1846) from the English poets, A Book for *a* Corner (2 vols., 1849), Autobiography (3 vols., 1850), Table Talk (1851). His narrative poems, original and translated, many of the shorter of which are minor classics, were collected as Stories in *Verse* (1855). Leigh Hunt excelled especially in narrative poetry, of which "Abou ben Adhem" and "Solomon's Ring" are excellent examples on a small scale.

Leigh Hunt's other works include: *Amyntas,* A *Tale* of *the Woods* (1820), translated from Tasso; The Seer, or *Common*-Places *refreshed* (2 pts., 1840–41); three of the Canterbury Tales in *The Poems* of *Geoffrey Chaucer,* modernized (1841); Stories *from the Italian* Poets (1846): *Men, Women and* Books (2 vols., 1847); *The* Old Court *Suburb* (2 vols., 1855; ed. A. Dobson. 1902): selections from Beaumont and Fletcher (1855); and, mith S. Adams Lee. *The* Book of the Sonnet (Boston, 1867). His Po*etical Works* (2 vols.), revised by himself and edited by Lee, were printed at Boston. U.S.A., in 1857, and an edition (London and New York) by his son, Thornton Hunt, appeared in 1860. Among volumes of selections are: Essays (1887), ed. A. Symons; Leigh *Hunt* as *Poet and* Essayist (1889), ed. C. Kent; Essays and *Poems* (1891), ed. R. B. Johnson for the "Temple Library"; Prefaces by Leigh Hunt-, *Mainly to his* Periodicals, ea. R. Brimley Johnson (1928).

His *Autobiography* was revised by himself shortly before his death, and edited (1859) by his son Thornton Hunt, who also arranged his Correspondence (2 vols.. 1862). Additional letters were printed by the Cowden Clarkes in their Recollections of *Writers* (1878). The *Autobiography* was edited (2 vols., 1903) with full bibliographical note by R. Ingpen.

See bibliography of his works compiled by Alexander Ireland *(List of the Writings of William Hazlitt and Leigh Hunt,* 1868) ; short lives of Hunt by Cosmo Monkhouse ("Great Writers," 1893) and by R. B. Johnson (1896).

HUNT, SIR (HENRY CECIL) JOHN (1910–), British soldier, mountaineer and explorer, was the leader of the expedition which made the first ascent of Everest (29,028 ft.). Born on June 22, 1910, and educated at Marlborough and the Royal Military college, Sandhurst, he was commissioned to the 60th Rifles and served in India and Burma. partly on police work. From there he made acquaintance mith the Karakoram (1935) and the Sikkim Himalaya (1937, 1939). He served with his regiment during World War II. and took part with distinction in the north African and Italian campaigns. For his command of the 11th Indian brigade during the Greek rebellion (1944–46) he was awarded the commander of the order of the British empire.

In 1952 he was recalled from an army post in Germany to lead the 1953 British Everest expedition. His leadership was characterized by thorough planning and by the personal part he took in every job. On the mountain, he finally went up with one Sherpa in support of the first summit pair, leaving loads at 27,300 ft. on the southeastern ridge. The success of the expedition was in great measure the success of its planning and esprit de corps. He wrote The Ascent of *Everest* (1953) and in 1956 left the army to become the first secretary of the Duke of Edinburgh's award, a scheme to foster the idea of adventure and service among boys.

(C. W. F. N.)

HUNT, RICHARD MORRIS (1828–1895), U.S. architect, who introduced 19th-century French traditions into American architecture. was born in Brattleboro, Vt., on Oct. 31, 1828. He studied in Europe (1843–54), mainly in the École des Beaux Arts at Paris, and in 1854 was appointed inspector of works on the buildings connecting the Tuileries with the Louvre. Under Hector Lefuel he designed the Paviilon de la Bibliothèque, opposite the Palais Royal.

In 18jj he returned to New York, and was employed on the extension of the Capitol at Washington. He designed the Lenox library (now torn down) and the Tribune buildings in New Tork; the Theological librsry, and Marquand chapel at Princeton; the Divinity college and the Scroll and Key building at Yale; the Vanderbilt mausoleum on Staten island, and the Yorktown monument. For the administration building at the World's Columbian exposition at Chicago in 1893 Hunt received the gold medal of the Institute of British Architects. Among the most noteworthy of his domestic buildings were the residences of W. K. Vanderbilt and Henry G. Marquand in New York city; George W. Yanderbilt's country house at Biltmore, and several of the large "cottages" at Newport (R.I.), including "Marble House" and "The Breakers."

Hunt was the leader of a school that established in the United States the manner and the traditions of the Beaux Arts. He took a prominent part in the founding of the American Institute of Architects, and from 1888 was its president. His talent was eminently practical; and he was almost equally successful in the ornate style of the early Renaissance in France, in the picturesque style of his comfortable villas, and the monumental style of the Lenox library.

He died on July 31. 189j.

HUNT, THOMAS STERRY (1826–1892), U.S. geologist and chemist. was born at Norwich, Conn., on Sept. 5, 1826. He became interested in natural science, and in 1845 he was elected a member of the Association of American Geologists and Naturalists at Yale (1849). In 1848 he read a paper in Philadelphia On Acid Springs and Gypsum Deposits of the Onondaga Salt Group. At Yale he became assistant to Prof. B. Silliman, Jr., and in 1846 was appointed a chemist to the geological survey of Vermont. In 1847 he was appointed to similar duties on the Canadian geological survey at Montreal under Sir William Logan, and this post he held until 1872. In 1859 he was elected F.R.S., and he was one of the original members and president of the Royal Society of Canada. He died in New York city on Feb. 12, 1892.

His publications include *Chemical* and *Geological Essays* (1875, ed. 2, 1879); *Mineral Physiology and Physiography* (1886) ; *A New Basis for Chemistry* (1887, ed. 3. 1891) ; *Systematic Mineralogy* (1891). *See* an obituary notice by Persiior Frazer, *Amer. Geologist* (xi. Jan. 1893), with portrait. A complete bibliography of his work is given in *Bulletin* of *the Geol. Soc. of America,* vol. 4, p. 379.

HUNT, WILLIAM HENRY (1790–1864), English water-colour painter. was born in London, on March 28, 1790. He was apprenticed about 1805 to John Varley, the landscape painter, with whom he remained five or six years, exhibiting three oil pictures at the Royal Academy in 1807. He exhibited regularly at the Society of Painters in Water-colour, of which he became a full member in 1827. He died on Feb. 10, 1864.

Hunt was one of the creators of the English school of water-colour painting. His subjects, especially those of his later life, are extremeiy simple; but, by the delicacy, humour and fine power of their treatment, they rank second to works of the highest art only.

HUNT, WILLIAM HOLMAN (1827–1910), English artist and principal member of the Pre-Raphaelite Brotherhood, to whose tenets he remained faithful throughout his career. He was born in London on April 2, 1827, the son of a city warehouse manager. At first discouraged in his artistic ambitions, he worked as a clerk to an estate agent, but in 1843 began studying in the National gallery and British museum. The following year he entered the Royal Academy schools where he met his lifelong friend John Everett Millais, two years his junior. His first Academy picture) "Hark!" was exhibited in 1846, followed by a subject from Walter Scott, "Dr. Rochecliffe Performing Divine Service in the Cottage of Joceline Joliffe at Woodstock" (1847), and another from Keats's "Eve of St. Agnes," "The Flight of Madeline and Porphyro," in 1848. In August of that year D. G. Rossetti began working with Hunt. To the Academy exhibition of 1849 Hunt sent his picture "Rienzi" (Mrs. M. E. Clarke collection) on which appeared the initials "P.R.B." after his surname. The works of

these three men, Hunt, Millais and Rossetti, with their clear hard colour, brilliant lighting and careful delineation of detail heralded the new movement (*see* PAINTING: *Great Britain*). Also in that year, Hunt accompanied Rossetti on a visit to Paris and Belgium.

Public opinion, at first unreceptive, became actively hostile toward the Brotherhood when in 1850 Hunt showed his "Christians Escaping From the Druids" (Ashmolean museum, Oxford). John Ruskin praised "Valentine Protecting Sylvia From Proteus" (1851) and it gained a prize at Liverpool, while in 1852 "Strayed Sheep" (Tate gallery, London) was similarly honoured at Birmingham. Religious subjects, foreshadowed by "The Hireling Shepherd" (1853; later version in Manchester), henceforth dominated Hunt's attention, and in 1854 "The Light of the World" (Keble college, Oxford), an allegory of Christ knocking at the door of the human soul, was championed by Ruskin and brought the artist his first public success.

In Jan. 1854 Hunt began a two-year visit to Syria and Palestine to glean firsthand knowledge of the Holy Land. After considerable difficulties and adventures he completed in July 1855 "The Scapegoat" (Lady Lever Art gallery, Port Sunlight), a solitary outcast animal on the shores of the Dead sea, the subject being inspired by Isa. liii, 4–6, and Lev. xvi, 20–22. Painted in part at Usdum on the Dead sea, and in Jerusalem, the work was rightly criticized by Ruskin for atmospheric inconsistencies and inadequate anatomical verisimilitude. Artistic qualities suffered at the expense of religious symbolism, and this defect recurred in the elaborate "The Finding of the Saviour in the Temple" (1854–60; Birmingham), sold to Gambart for a record sum of 5,500 guineas. Hunt paid two more visits to Jerusalem, in 1869 and 1875, and "The Shadow of Death" (1870; Manchester) contains a view of Nazareth seen through the windows of the carpenter's shop. Among the most important of his later paintings are "The Triumph of the Innocents" (two versions: 1884; Tate gallery, London; 1885; Liverpool), "May Morning on Magdalen Tower" (1889; Lady Lever Art gallery) and "The Miracle of the Sacred Fire" (1898)—finished just before his sight began to fail.

In 1905 Hunt succeeded G. F. Watts to the Order of Merit and received a doctorate of civil law from Oxford university. He died in London on Sept. 7, 1910, and was buried in St. Paul's.

HUNT, WILLIAM MORRIS (1824–1879), U.S. painter, most important for the French influence he brought to America, was born at Brattleboro, Vt., on March 31, 1824. He attended Harvard, but his real education began when he studied with Couture in Paris and then came under the influence of Jean François Millet. The companionship of Millet had a lasting influence on Hunt's character and style, and his work grew in strength, beauty, and seriousness. Through the Boston society circles in which he moved, he introduced the works of Millet, Rousseau, Corot and others of the French Barbizon school, and he more than any other turned the rising generation of American painters toward Paris. On his return in 1855 he painted some of his best pictures, reminiscent of his life in France and of Millet's influence. Such are "The Belated Kid," "Girl at the Fountain," "Hurdy-Gurdy Boy," etc. But the public called for portraits, and it became the fashion to sit for him.

Among his best paintings of this kind are those of William M. Evarts, Mrs. Charles Francis Adams, the Rev. James Freeman Clarke, William H. Gardner, Chief Justice Shaw, and Judge Horace Gray. Unfortunately many of his paintings and sketches together with five large Millets and other art treasures collected by him in Europe, were destroyed in the great Boston fire of 1872.

Among his later works American landscapes predominated. They also include the "Bathers" (twice painted) and the allegories for the senate chamber of the State capitol at Albany (N.Y.), now lost by the disintegration of the stone panels on which they were painted. Hunt was drowned at the Isles of Shoals on Sept. 8, 1879. He wrote *Talks about Art* (London, 1878).

HUNTER, ROBERT (d. 1734), colonial governor of New York, New Jersey and Jamaica, was the son of James and Margaret (Spalding) Hunter of Hunterston, Ayrshire, Scotland. Forsaking his apprenticeship as an apothecary, Hunter joined the British army and fought at Blenheim (1704) under Marlborough, with whom he seems to have been personally acquainted. In 1707 Hunter was chosen lieutenant-governor of Virginia, but on the way to America he was captured by the French, remaining as their prisoner until exchanged for the bishop of Quebec. Hunter was commissioned as governor of New York and the Jerseys in 1709. Accompanying the new executive to America in 1710 were 3,000 Palatine refugees who were ordered to undertake the production of naval stores. This Hudson river venture proved to be a failure despite the governor's intense interest and expense in the project. Hunter's career in America was characterized by a series of political and religious entanglements, but he was one of the best loved administrators ever selected by England. He played an important rôle both at the New London congress (1711) and at New York in preparing the colonial contingents for the last campaign of Queen Anne's War. In 1719 Hunter returned to England, and for several years was consulted as an authority on colonial affairs by the board of trade. His last commission was the governorship of Jamaica which office he held until his death on March 31, 1734. (R. L. BE.)

HUNTER, SIR ROBERT (1844–1913), English lawyer and philanthropist, who devoted much of his time to safeguarding the rights of the public in regard to open spaces and the preservation of rights of way, was born on Oct. 27, 1844. In 1882 he became solicitor to the general post office. One of the principal promoters of the Commons Preservation society, founded in 1865, he became in 1868 its solicitor and successfully conducted suits for preserving Wimbledon and Wandsworth commons and for recovering a portion, wrongfully enclosed, of Epping forest. Ashdown forest, Hampstead heath, Hindhead and the New forest also were safeguarded by him. He was made a knight commander of the Order of the Bath in 1911, and died at Haslemere on Nov. 6, 1913.

HUNTER, ROBERT MERCER TALIAFERRO (1809–1887), American statesman, was born in Essex county, Va., on April 21, 1809. He entered the University of Virginia in his 17th year and was one of its first graduates; he then studied law at the Winchester (Va.) law school, and in 1830 was admitted to the bar. From 1837 to 1843 and from 1845 to 1847 he was a member of the National House of Representatives, being speaker from 1839 to 1841; and from 1847 to 1861 he was in the Senate, where he was chairman of the finance committee (1850–61). He is credited with having brought about a reduction of the quantity of silver in the smaller coins; he was the author of the Tariff Act of 1857 and of the bonded-warehouse system, and was one of the first to advocate civil service reform. In 1853 he declined President Fillmore's offer to make him secretary of State. At the national Democratic convention at Charleston, S.C., in 1860 he was the Virginia delegation's choice as candidate for the presidency of the United States, but was defeated for the nomination by Stephen A. Douglas. Hunter did not regard Lincoln's election as being of itself a sufficient cause for secession, and in Jan. 1861 he proposed an elaborate but impracticable scheme for the adjustment of differences between the North and the South, but when this and several other efforts to the same end had failed he quietly urged his own State to pass the ordinance of secession. In 1861–62 he was secretary of State in the Southern Confederacy; and in 1862–65 was a member of the Confederate senate, in which he was, at times, a caustic critic of the Davis administration. He was one of the commissioners to treat at the Hampton Roads conference in 1865, and after the surrender of General Lee was summoned by President Lincoln to Richmond to confer regarding the restoration of Virginia in the Union. From 1874 to 1880 he was treasurer of Virginia, and from 1885 until his death near Lloyds, Virginia, on July 18, 1887, was collector of the port of Tappahannock, Virginia.

See Martha T. Hunter, *A Memoir of Robert M. T. Hunter* (1903) for his private life, and D. R. Anderson, *Robert Mercer Taliaferro Hunter,* in the John P. Branch Historical Papers of Randolph Macon College (vol. ii. No. 2, 1906), for his public career. *See* also "Correspondence of Robt. M. T. Hunter, 1826–1876," ed. by Charles Henry Ambler, *Amer. Hist. Assoc. Ann. Report, 1916,* vol. ii.

HUNTER, WILLIAM AND JOHN, brothers, were among the most distinguished and influential of British medical teachers and practitioners. Both brothers excelled particularly. although in different ways, in the teaching of anatomy. William was preeminent in the practice of obstetrics and John was outstanding as a surgeon. John, in addition, carried out many highly original and important studies and experiments in many areas of comparative biology, anatomy, physiology and pathology.

William and John Hunter were both born at Long Calderwood, in East Kilbride, Lanarkshire, William on May 23, 1718, and John on Feb. 13, 1728. They were the seventh and tenth children, respectively, of John and Agnes Hunter, and were descended on their father's side from the Ayrshire family of Hunter of Hunterston. Their brother James, the fifth child, showed great promise of success in medicine before his early death at the age of 30. Their sister, Dorothea, the eighth child, married James Baillie and became the mother of the distinguished pathologist Matthew Baillie and of the dramatist Joanna Baillie (*qq.v.*).

William's education and training were considerably more formal than were John's. William matriculated in 1731 at the university in Glasgow. then began his medical study late in 1736 or early in 1737 by taking up residence with William Cullen in Hamilton. After having attended medical lectures in Edinburgh in 1739 and 1740, he went to London in 1740 residing first with William Smellie and later with James Douglas. He became a surgical pupil at St. George's hospital in 1741 under James Wilkie, and was admitted to the Corporation of Surgeons in 1747. He received the degree of doctor of medicine from Glasgow in 1750, and, becoming disfranchised from the Corporation of Surgeons, was admitted a licentiate of the College of Physicians in London in 1756. William became surgeon-man-midwife to the Middlesex hospital in 1748 and to the British Lying-in hospital in 1749, but presumably, since he abandoned surgery by 1756, the tenure of neither of these positions was of long duration.

William first began to teach in 1746. It is often claimed that his first lectures were delivered to a society of navy surgeons, but this is incorrect, since the society was not founded until after Hunter had begun to teach. He continued to lecture throughout his life. His lectures dealt principally with surgery or anatomy; they were erudite. extremely polished and always well attended. His most distinguished pupil was his brother John. Through his teaching he revivified the teaching of anatomy in Great Britain, which was badly in need of reform. He had traveled in France in 1743–44 and also in 1748 and introduced to Great Britain the Paris method of providing each student with a cadaver to dissect for himself. In 1766 he purchased a house in Great Windmill street, began to teach in it in 1767 and later took up residence there, having had it rebuilt to contain an amphitheatre, dissecting rooms and a fine museum. He amassed a splendid collection of anatomical and pathological preparations for use in his teaching; he was an avid collector also of ancient coins and medals, of minerals. shells and corals, and especially of books. His library mas outstanding for any age. Ultimately after his death these collections became the property of the University of Glasgow. When the Royal Academy was founded in 1768 Hunter was appointed professor of anatomy and lectured on anatomy to artists.

William Hunter's practice, after 1756, was devoted principally to obstetrics, and he was the most successful specialist in this field in Great Britain during his day. Among his many distinguished patients the most distinguished of all was Queen Charlotte. She first consulted him during her first pregnancy in 1762, and he was named physician extraordinary to her majesty the same year. He attended her also during two subsequent pregnancies. He was influential, in the history of British obstetrics, through his opposition to the use of the forceps. But further than this, by virtue of his high standards of teaching and practice, obstetrics was removed from the hands of the midwives to become an accepted branch of medicine itself.

William Hunter published three books. One, *Two Introductory Lectures,* published posthumously (1784). illuminates the character of his teaching Another. *Medical Commentaries* (1762; *Supplement,* 1764) is of principal interest in that it contains details of his controversies with the Monros over priority for the injections of the testicular tubules and for the discovery of the absorptive functions of the lymphatics. and with Percivall Pott over credit for the elucidation of the nature of congenital hernia. But he was really a man of one book, and his great masterpiece was the *Anatomy of the Human Gravid Uterus, Exhibited in Figures,* an elephant folio published in 1774 as the only medical publication to be issued by the famous Baskerville press. William spent 30 years in its preparation. Jan van Riemsdyck made many of the drawings for the 34 plates, Robert (later Sir Robert) Strange prepared some of the engravings. and the book has rarely been excelled as an anatomical monograph. William published in addition to his books a small number of scattered essays or case histories, dealing principally with the circulatory. the skeletal or the reproductive organs. Other subjects covered were emphysema. the cellular membrane, the pupillary membrane, signs of murder, the lacrymal ducts, a description of an animal from India, and so forth.

John Hunter, in contrast to his brother, never completed a course of studies in any university, and, as was often customary for surgeons during the 18th century, he never attempted to become a doctor of medicine. He first went to London in 1748 to assist in the preparation of dissections for the course of anatomy which William had begun to teach two years before, and for 11 minters he continued to learn anatomy in his brother's dissecting rooms. In the summers of 1749 and 1750 he learned surgery from William Cheselden at Chelsea hospital, and when Cheselden became ill may have become a pupil at St. Bartholomew's in 1751. He is said to have become a surgeon's pupil at St. George's in 1754. In the spring of 1755 he entered as a gentleman commoner at St. Mary's hall. Oxford, but apparently remained for less than two months; his interest was in nature, not books. He seems to have become house surgeon at St. George's in 1756, and nas admitted a member of the Corporation of Surgeons in 1768.

Like William, John devoted great energy to teaching. During his second year in London he is said to have superintended some of his brother's pupils in practical anatomy, and he is reputed to have assisted him in lecturing after 1754. In 1753 he was elected a master of anatomy at Surgeon's hall, with the duties of reading lectures. He started his own private lectures on the principles and practice of surgery in the early 1770s and continued them until 1790. In addition, he had teaching duties from 1768 at St. George's (to which he had been elected surgeon in 1758), and these included taking house pupils. His various students included many who were later to become famous in their own right: Edward Jenner, John Abernethy, Anthony Carlisle, Henry Cline, Astley Cooper and William Blizard were among the British, and Philip Syng Physick, John Morgan and John Shippen among the Americans, who profited from his teaching. As a lecturer, he mas far less fluent than William. His ideas spilled from his mind faster than the nords from his tongue or his pen, and his use of language was far less elegant than his brother's. Yet the range of his interest and knowledge in widely various aspects of medicine and natural history, his lively curiosity and his penetration of thought were such that he could not fail, no matter what the manner of his style or delivery, to be highly stimulating to his students. Like William, he became a collector, and amassed a collection of well over 10,000 anatomical pathological and biological specimens. By his will, his collection was after his death offered for sale to the government. The government purchased it in 1799; the Corporation of Surgeons became its custodian, and when the corporation was constituted as the Royal College of Surgeons in 1800 the Hunterian collection was among its most important assets. The specimens were unfortunately mostly destroyed by enemy bombing during World War II.

From the time of his appointment in 1756 as house surgeon to St. George's. John excelled in surgery. In 1760, after an illness,

he accepted a commission as surgeon on the staff of the army, and accompanied the expedition against Belle-Île-En-Mer in 1761. He returned to London in 1763 and practised surgery there until he died. He was the leading surgeon in London and, like William, had many distinguished patients. In 1776 he was named surgeon extraordinary to George III; he was appointed deputy surgeon general to the army in 1786, and surgeon general and inspector general of hospitals in 1790. His services to surgery were to some degree similar to those of Williams's to obstetrics. He not only made specific contributions of great importance, as for instance by the introduction of the high operation for aneurism of the popliteal artery; he attained for surgery the dignity of a scientific profession, basing its practice on a vast body of general biological principles.

The range of John's accomplishments was very different from that of his brother. He published three books before he died: *The Natural History of the Human Teetlz, A Treatise on the Venereal Disease,* and *Observations on Certain Parts of tlze Animal Oeconony; the Animal Oeconomy,* like William's *Medical Commentaries,* was not a unified book but represented a collection of separate articles. These had either been previously published in periodicals or would have been appropriate for such publication. In addition. a fourth book, *A Treatise on the Blood, Inflammation and Gun-shot Wounds* was published posthumously in 1794, the year after he died. The books on the teeth, the venereal disease and on the blood would each of them alone have sufficed to bring him fame as an investigator and thinker. illustrating, as each did, his faculties of searching deep into principles to the benefit of practice.

In addition, John published a number of shorter communications describing some of his other discoveries. dealing with such topics as post-mortem digestion of the stomach (1772). air sacs in birds (1774), production of heat by animals and vegetables (1775), apparent transmission of smallpox from mother to fetus (1780), organs of hearing in fishes (1782), descent of the testis (1786), structure of the placenta (1786), secretion by the crop of the breeding pigeon (1786), extirpation of one ovary (1787), structure and economy of whales (1787), introsusception (1789), horny excrescences of the human body (1791), bees (1792), fossil bones presented to the Royal society (1794, posthumous) and so forth.

These reflect only a fraction of the diversity of John Hunter's interests. He expended apparently boundless energies on anatomical, pathological, biological and even geological investigations. His first anatomical studies were made when he was still in William's school. When he was on the military expedition to Portugal he acquired considerable knowledge of gunshot wounds and inflammation, but also studied digestion during hibernation in reptiles. After 1772, when he moved to a house at Earl's Court, he kept a small menagerie at his residence for the purposes of study and experimentation: hedgehogs, bees, leopards, blackbirds, to name only a few of his varied animals. He did not confine his experimental studies to lower animals; in an attempt to demonstrate that gonorrhea and syphilis are manifestations of a single disease he inoculated himself and contracted syphilis, and there are some who believe that this caused much of the illness that he sufferedduring his later years.

He enjoyed due recognition for his discoveries. He was elected a fellow of the Royal society in Feb. 1767, three months before William. He was Croonian lecturer at the Royal society from 1776 to 1782; he received the Copley medal, the highest honour in the Royal society's anard. in 1787. and was elected to membership in the American Philosophical society in 1787.

The full diversity and depth of John Hunter's investigations will never be known. Only a small proportion of his work was published during his lifetime, and after his death the major part of his manuscripts was destroyed by his brother-in-law, one of his executors. Everard {later Sir Everard) Home, who claimed that he destroyed the papers on Hunter's directions. They were not burned. however. until 1823, and there are many who believe that Home plagiarized their contents before destroying them.

The accusation of plagiarism was first made by William Clift, Hunter's amanuensis at the time of his death. Clift copied a number of the original notes between 1793 and 1800, and his copies are published in John's *Essays and Observations on Natural History, Anatomy, Physiology, Psychology and Geology,* which appeared in 1861 under the editorship of Richard Owen, Clift's son-in-law.

There are fine portraits of both brothers, including one of William by Johann Zoffany,and one of John by Sir Joshua Reynolds of which an equally fine engraving was made by William Sharp.

William remained a bachelor, his fiancée, Jane Douglas, having died in 1744. John in 1771 married Anne Home, a poetess of no mean merit, who published her poems and wrote words for some of Haydn's English Canzonets.

Four children were born to Anne and John Hunter. Two died young; the other two, Agnes Margaretta and John Banks, survived, but both died without issue.

The various differences already alluded to in the lives and accomplishments of the two brothers reflected very real differences in their personalities. William was in many ways a restrained person, scholarly in outlook, frugal and very nearly ascetic in his habits and probably somewhat vain in regard to his social and professional position. John, in contrast, was unconstrained, unbookish, sometimes crude though often vivid in his expression, and honest, unself-conscious and generous perhaps even to a fault. His warmth and vitality found little counterpart in his brother.

While the association between William and John was close during their early years in London, the brothers later, perhaps in part because of their differences in temperament, drifted apart. William was not invited to John's wedding in 1771, and relations between the brothers were finally completely ruptured during 1780 as a result of a public controversy between them over priorities for the discovery of the nature of the utero-placental circulation. They never again met except once when John gave surgical attention to William during the latter's final illness. John did not attend his brother's funeral and was not mentioned in William's will.

Yet for all their differences, they shared in common what was probably the key characteristic for their total accomplishment, their complete and utter devotion to their work. They both died at work, William! on March 30, 1783, having ten days before arisen from his sickbed to lecture, John, on Oct. 16, 1793, during a board meeting at St. George's. William was buried in the vaults of St. James's, Piccadilly, and John in those of St. Martin-in-the-Fields. In 1859, through the efforts of F. T. Buckland. John's remains were reinterred in Westminster abbey on the north side of the nave. William had reformed and refined the teaching of anatomy in Great Britain, and had raised obstetrics to the rank of a respected medical discipline. John had not only established the principles of surgery soundly on a broad biological basis, but had also enriched many fields of natural history through his indefatigable study and experimentation. The legacy of both brothers remained not only in their museums and their writings, but also in their vitalizing influence on anatomy, obstetrics and surgery, which is still felt.

BIBLIOGRAPHY.—S. F. Simmons, *An Account of tlze Life and Writings of the late William Hunter* (1783), is the only biography of William by a contemporary. D. Ottley, *The Life of John Hunter,* in *The Works of John Hunter,* ed. by J. F. Palmer, 1 vol. (1835–37), is the most useful near-contemporary biography of John. G. C. Peachey, *A Memoir of William and Jolzn Hunter* (1924), contains the fullest and most reliable information concerning both brothers.

W. R. LeFanu, "The Writings of William Hunter F. R. S.," *The Bibliotheck* 1:3–14, (1958), presents a bibliography of William's writings. LeFanu, in *John Hunter, A List of his Books* (1946) presents a bibliography of those of John's works which were printed in book form. No such accurate bibliography has been compiled for John's articles, but LeFanu in the *List of Books* gives references to the available lists of them. (J. M. O.)

HUNTER RIVER, a river of New South Wales, Austr. It is 340 mi. long, rising in the Liverpool range behind the main crest of the eastern highlands. A longitudinal stream to near Denman, it there joins and continues to the sea the transverse course of its main tributary. the Goulburn. This transverse valley leads inland to the Cassilis gap. the lowest crossing point of the highlands between southern Queensland and western Victoria. Below the junction the valley widens and at Branxton gap near Singleton enters

the coastal lowland, there much wider than elsewhere in New South Wales. Through this breach in the highlands, Pacific influences penetrate westward and vegetation types from the inland slopes approach the coast. The climate of the valley is both warmer and more humid than that of neighbouring territories. With generally good soils, the valley naturally favoured farming and especially fruit growing; vineyards were formerly more widespread but today specialize in the production of fine light wines. The rough country of the upper valleys is mainly devoted to the grazing of cattle, sheep and horses, and there is much timber cutting on the forested slopes. The scattered sawmills along the streams provide hardwood timber for furniture making and for constructional work. Dairying is the main agricultural pursuit in the middle and lower valley; wheat growing has given way to the cultivation of forage crops—maize, hay and lucerne.

The Hunter has eroded its valley in a structural basin of coal measures of Permocarboniferous age! and rich coal seams outcrop in many places. When John Shortland discovered the river in 1797 he reported an exposure of coal near where Newcastle (*q.v.*) now stands. Working of these upper or Newcastle seams began as early as 1800, and coal export was well established by 1850. The richer lower or Greta seams were discovered in 1856 and have long provided the greater part of the output. The most important mines lie along the eastern outcrop of the Greta coals; south of the lower river between Maitland and Cessnock. Open-cast working is carried on to the northwest near Muswellbrook on the upper Hunter. The seams are generally thick and relatively easily worked and the coal is of good quality, though often with a rather high sulphur content. Proximity to a good harbour (Newcastle) at the river mouth made coal shipment easy to oversea and Xustralian coastal markets. Labour troubles frequently checked development. but output increased steadily after World War II. Greater internal consumption. in industry and on the railways, and the growing use of oil fuel in ships caused a considerable falling off in exports overseas and in the supply of bunkers. Though the Hunter is navigable for 35 mi. upstream it is little used for transport because of erratic changes of level. (T. HER.)

See J. H. Abbott, *The Newcastle Packets and the Hunter Valley* (Sydney, 1943); F. R. Mauldon, *A Study in Social Economics: The Hunter River Valley* (Melbourne, 1927).

HUNTING is the seeking. pursuing and taking of game and wild animals for subsistence, profit or sport. Hunting for sport is defined in Great Britain and western Europe as the taking of any wild animal by the aid of hounds that hunt by nose. In the United States and elsewhere, hunting refers also to the field sport of shooting small and large game. For bow and arrow hunting *see* ARCHERY. *See* also FALCONRY. For zoological information on various animals see articles under their common names, as ANTELOPE; DEER; for occurrences *see* articles on continents, countries and states and provinces.

The present article deals with the sport of hunting in its various aspects throughout the world, and is arranged as follows:

I. INTRODUCTION

1. History. — To early man, hunting was a necessity. It was not only a means of obtaining food, but provided many of the other necessities of life such as clothing and tools (*see* HUNTING AND FISHING, PRIMITIVE). As a civilization advanced, certain animals were domesticated and new breeds developed to serve the needs of man. Hunting then became a privileged sport, primarily indulged in by the landed aristocracy of Asia and Europe

As new areas were opened up in America and Africa, hunting again became a principal means of survival, and has remained so in remote parts of the world. In the new areas. such as those in North America from the end of the 16th century until into the 20th, there seemed to be an unlimited game supply and there was much unnecessary waste. As populations increased so did the amount of hunting, and wild animal populations were reduced at a correspondingly quicker rate. When hunting was no longer necessary people turned to it as a sport, hunting some species to extinction; the quagga, for example, once plentiful on the African plains. is extinct. The bison, once innumerable in America, exists only because a fen survivors nere formed into a breeding herd and carefully preserved. Among birds the passenger pigeon. also an American species and once common. has entirely ceased to exist. The process is continuing, notably in Africa.

2. Controls. — Because game was being slaughtered indiscriminately by market hunters and sportsmen. Ians were passed in nearly every country to protect wild game. Limits were put on the number of animals mhich each hunter was entitled to kill, and licences. which bring in a substantial revenue. became part of modern game management. In the United States, for example, the federal government controls migratory game birds within the U.S. borders since these migrate not only from state to state, but between Canada and Mexico. Other game comes under the jurisdiction of the individual states, all of which have highly developed programs and trained staffs to enforce regulations covering hunting seasons and game-in-season bag and possession limits. Game again became relatively plentiful and even abundant in many areas where it had formerly become scarce. Similar game conservation schemes began to be implemented in India in 1860, in Africa at the end of the 19th century and in eastern Europe in the years after World War II. In Britain, Scandinavia and the rest of western Europe the right to hunt is generally attached to the ownership of land, and the preservation of wild life is a function exercised or delegated by landowners.

See also WILDLIFE CONSERVATION. (E. P. B.; W. S.)

II. BIG GAME HUNTING

The pursuit of large game (often at great risk to the hunter) and the search for gold probably share the credit for drawing the majority of explorers into the unknown. and there can be no doubt that big game hunting has always exercised great fascination for mankind.

1. Planning. — The sportsman should ascertain the best time of pear for hunting. Quite apart from the question of health, should he visit the country at an unfavourable season he may stand small

chance of sport because of some peculiar local condition, for example, high grass nhich may prevent him from seeing anything. Another factor is water: as a rule this is fairly plentiful in any district nhere game is abundant, but at some seasons remains only in certain localities round ahich the game concentrates. Information on these points will be given by the game department of the country concerned, and the following information should also be obtained: (1) what stores and equipment can be obtained locally; (2) what means of transport is generally used between the proposed base and the actual shooting grounds; (3) whether this transport is easily obtained, and how; and (4) whether trackers are available Good maps of the country are another essential item.

The question of the mast suitable firearms is largely a matter of personal preference built upon experience, but generally speaking the best weapon for stalking (see *Method*, below) is a rifle of the "magnum" small calibre type which develops a very high muzzle velocity and so gives a flat trajectory. thus eliminating the difficulties of judging distance. It is always a mistake, however. to select a rifle which does not fire a fairly heavy bullet. as very light bullets are liable merely to wound without killing, and 150 grains is a fairly safe minimum weight. For dangerous game which is shot at close quarters the inexperienced hunter will be well advised to use a heavy double-barreled rifle of a calibre of about .470. Many experienced hunters use nothing but small calibre but the beginner can adopt such methods when he has gained experience for himself. Nearly all big-game territories possess, in addition to their conservation departments, private firms of safari organizers. Their services. and advice on local conditions and technical matters. are generally relied upon by visitors.

2. Methods.—The methods of hunting depend on the type of country in nhich the game is found, and on the size and habits of the creatures themselves. In open country free from trees, game can be viewed from afar; in these conditions a slow and stealthy approach is necessary, use being made of every tuft of grass. rock or hollow as a means of concealment and attention being paid to the direction of the wind. This is known as "stalking."

In dense bush or scrub it is impossible to see more than a few yards Game in these conditions is come upon suddenly and the best chance of getting a shot is to walk slowly and cautiously. ever on the alert. This form of hunting has been described by different names but none is so graphic or realistic as the North American "still hunting."

Some animals cannot be stalked or still-hunted. for instance big beasts mhich herd together, as do elephants. They leave well-defined tracks, or spoor, in soft ground and a skilful hunter can follow their trail even on hard ground. This method is called "tracking."

Other animals inhabit, or retire to, patches of dense jungle so thick that it is impossible for a man to advance silently within shooting distance. Tracking and still hunting are out of the question and there the best chance of success is to drive the animal out into the open or along some path where the sportsman is waiting. This is done with the help of a number of men or dogs. or, in certain parts of India, with a line of elephants—methods universally known as "driving" or "beating." If, however. no form of help is available in circumstances such as these. the only course for the sportsman is to wait in hiding over some spot where the animal will probably pass or return. Such a place may be a water hole, game trail, crossing point or a salt lick; in the case of beasts of prey. it may be a half-eaten kill. This waiting method is known as "sitting up," or "sitting." It should, however, be noted that sitting up over water or a salt lick is not generally considered a sportsmanlike procedure and it is prohibited by law in some localities.

Another form of hunting which is commonly practised in pursuit of deer is known as "calling." It consists of waiting in hiding and making noises in imitation of the call of a female during the rutting season or else of the challenge of a male. In either case a male will answer and will gradually come right up to the sportsman believing him to be a possible mate or a probable antagonist. Calling deer is one of the oldest European hunting techniques, dating back long before the introduction of firearms. It is much used by hunters of roebuck in Germany and Austria, and has been successfully adopted by moose hunters in North America.

(G. Bu.; X.)

A. North America

North America offers many opportunities for hunting, and the sport is popular. There are many types of hunting there, depending on the type of game, the terrain, the climate, and the preferences of the hunter. He may depend solely on his own devices and pursue his game on foot, and without the aid of dogs. He may travel by horseback, jeep or other motor vehicle; in some of the vast and remote hunting areas of North America a horse or jeep is practically a necessity. Airplanes are increasingly used to reach nilderness areas. Most hunting, however, is done within a mile or so of roads because of the difficulty of getting game out of remote country. This is unfortunate in a way because in a number of inaccessible areas game. such as deer, for example, becomes too plentiful for the food supply and the animals grow poor or die of starvation.

1. Deer.—Deer are the most widely hunted big game animal, since they are widely distributed and thrive in areas close to civilization. The term is usually used to cover three species, white tail, mule and black tail. Moose, elk (wapiti) and caribou are also members of the deer family (Cervidae); they are discussed below under their popular names.

The white tail deer are distinguished by their antlers; the main beams first grow upward and then project forward horizontally and the spines grow off them at the vertical; the mule deer and black tail deer have much in common and there is disagreement as to nhether they represent one or tno separate species They are distinguished by the fact that the mule deer has a white rump and a black tip on the tail which is held down when running. The black tail deer raises its tail nhen running but the tail appears all black nhen it is down. Both have forked antlers, and the ears of the mule deer are particularly large.

White tail deer are generally considered an eastern deer. while mule deer or black tail deer inhabit the far nest, but the ranges overlap in most of the western United States and northern Mexico Mule deer are called black tail deer along the west coast nhere they are found from California northnard through British Columbia.

In the east, deer are usually found in thick pine growth, brush or dense forest undergrowth "Jumping" a deer and placing a telling shot in this kind of country is difficult even for an experienced hunter. Still hunting is one of the most successful methods employed. but "sitting" (see Methods, above) offers other good opportunities—the saddle between two mountains. for instance, makes a natural crossing point for deer as well as other game. The successful hunter must always be conscious of the wind direction, for a deer may come aithin range if it does not scent the hunter and if it sees no movement. Hunters sometimes form themselves into groups, one group taking stands near known crossing points, while the other drives toward them. In a few areas in the east where there are swamps, or where hunting is for other reasons difficult, the law permits driving deer with dogs, though this is generally illegal.

The same methods are used for hunting mule deer in the west, but there is more open country where the hunter can observe a great area with the aid of a telescope or binoculars, and there are greater opportunities for long-range shooting. When disturbed, deer seldom run straight and are inclined to circle. It is not uncommon for a hunter, who has put up a deer in front of him, to find it later behind him.

2. American Elk (Wapiti).—The American elk, a member of the deer family, at one time roamed most of the United States and southern Canada. Elk are now found primarily in the Rocky mountain region of the western United States, where in the fall they come down from the high mountains for wintering. A few have been reintroduced in the east. as in Virginia, but the numbers are small and there is no open season for them. Elk are hunted much in the same way as deer. A large bull elk may stand 60 in. at the shoulder and weigh from 800 to 1,000 lb. Any of the high-

powered medium calibre rifles (.25 cal. or above) are adequate for taking elk

3. Moose.—The moose is the largest of the deer family; an unusually large bull will weigh from 1.100 to 1.600 lb . stand about 75 in. at the shoulder and have an antler spread of up to 75 in. Moose are now found in a few of the western states of the United States and in Canada and Alaska. The Alaskan moose are the largest and darkest in colour, and one of the popular hunting grounds for these animals is the Kenai peninsula. Moose are not easily found, they travel fast and over long distances. Many are taken with medium-powered cartridges.

4. Pronghorn Antelope.— The pronghorn antelope (*Antilocapra americana,* a group distinct from that to which the African antelope belongs) are plains animals which at one time inhabited much of the plains area of the United States and parts of Mexico They became very nearly extinct and were reintroduced in many areas. where they remained fully protected until the herds increased to the point where hunting could be permitted. They multiply rapidly and are a popular game animal in the far western United States and north-central Mexico.

The male antelope averages about 100 to 120 Ib. and stands about 24 to 36 in. at the shoulder. They are exceedingly swift and offer a difficult target when running. At 100 yd. range a hunter will have to lead a crossing antelope by 10–12 ft. A good stalk will permit a standing shot at reasonable range, but without one a hunter needs an accurate, long-range rifle.

5. Caribou.— In the 1850s the caribou (the name by which the North American species of the reindeer genus is known) were found not only in Canada, Alaska and Greenland but also in the northern part of the United States, including New England. Since then the southern limit of their range has moved northward and their numbers have decreased. There are several subspecies of caribou. depending largely upon geographical location.

The caribou and the reindeer differ from other genera of deer in that the female bears antlers. They are also the most gregarious, roaming in herds as large as 1,000 or more. A large mountain caribou may weigh 600 or 700 Ib., the woodland caribou a little less and the barren ground caribou of the far north only about 300 lb. Caribou are hunted in Canada and Alaska, the woodland and mountain caribou being the most interesting to hunt and providing the best trophies.

6. Bear.—North America has the two largest carnivorous animals—Alaskan brown bears and polar bears. As the name might imply. the range of the Alaskan brown bear is limited to the Pacific slope in Alaska and the offshore islands. Brown bears are not only the most impressive of the Xorth American big game animals but they are also the most dangerous, particularly when wounded. They may attack without provocation, and have great powers of recovery, so the hunter should be equipped with a powerful rifle. Alaskan brown bears come out of hibernation in May and the spring is generally the best time to hunt them. Kodiak Island is famed for its particularly large brown bears. A brown bear may stand 10–12 ft. tall on his hind legs and weigh in the neighbourhood of 1,500 lb. The claws may be four inches long.

The only rival of the brown bear in size is the Arctic polar bear. An average male weighs nearly 1,000 lb.. but individuals may be as heavy as 1.600 Ib. In the 20th century hunting polar bears in Arctic America has become an increasingly popular sport, although it is an expensive one.

During recent years, big game experts have come to the conclusion that the only difference between the brown bear and the grizzly bear is geographic. What is known as the brown bear lives near the coastal regions where a more bountiful food supply, and possibly other conditions, result in larger growth.

The bears that are found inland in Alaska (75 mi. from the coast) have been classified as grizzly bears for purposes of Boone and Crockett measurements. These bears are smaller: and a very large one would weigh not over 1000 lb. and measure not over 8½ ft. in length.

The grizzly hear has sometimes been referred to as the "silver tip" because some of them have grayish tips on the long hair of the upper parts. Like the brown bear, however, the grizzly varies greatly in colour. Some are almost black while others are light tan. In most of the United States they have become almost extinct, but a few are left in the Rocky mountain region and on the western coast of Canada. British Columbia is one of the favourite areas for sportsmen in search of these animals.

The most common and most widely distributed bear on the North American continent is the American black bear, which is not as aggressive as its larger cousins Its weight varies from 200 to 500 lb In spite of its size and the fact that it sometimes lives close to civilization, the black bear is not easy to find, for it has a good nose and sensitive ear. The best time of the year to hunt the black bear is in the spring, during the early berry season. Because of the difficulty in finding them, hounds are frequently used for tracking

7. Sheep.—Mountain sheep, of which the Rocky Mountain bighorn is probably the most nidely distributed, are found in the western North America mountain regions from blexico to the Arctic circle The white Dall sheep is found primarily in Alaska, and the dark-coloured Stone sheep ranges from British Columbia northward into the Yukon.

8. Predators.— Common predators include coyotes, foxes and bobcats. Dogs are sometimes used to hunt them, but calling is also employed; in the latter case, a sound akin to that of a wounded or snared rabbit is made.

On rare occasions jaguar and mountain lion (also known as cougar, panther, catamount and puma; *q.v.*) have been called. but the surest way of hunting these large cats is with well-trained hounds. The animals customarily take to a tree when the hounds track them down. They are both formidable enemies of dogs, however, and a too aggressive dog is apt to be hurt if he closes in on one of these animals. The jaguar, one of the highly prized trophies in America, is occasionally found in the southwestern region of the United States but more often in Mexico where it is known as el *tigre.* It is hunted successfully on the west coast of Mexico and on the eastern gulf coast in the region of Tampico and is also found in southern Mexico in the states of Campeche, Tabasco and Chiapas The jaguar is also hunted in South America. Good hunting is to be found in Colombia. Brazil, Peru and Bolivia. The Lest time to hunt jaguar is during the winter months.

At one time mountain lions were found in many parts of North America but they are now extinct throughout much of their former range. They are found in greatest numbers in the Rocky mountain region, from the southern part of the continent up into Canada. Vancouver Island seems to have a particularly high concentration and it is there that they have been known occasionally to attack humans, although they are generally considered to be somewhat cowardly When one is cornered, or treed, it is advisable for the hunter to maintain a safe distance.

9. Wild Boar.—Although the European boar, sometimes called the Russian boar, is not native to America, there are some in the United States since they were imported for hunting on large private estates and later escaped to the wild; they can be hunted in the area of Newport, N H.. in Monterey county, Calif , and in Graham county. N.C., and Monroe county, the adjoining area in Tennessee. There are closed seasons in Tennessee and North Carolina, where hunts are closely regulated, but none in California and New Hampshire. Locating a wild boar is difficult without the aid of dogs or of a guide who knows the country. Wild boars are largely nocturnal, and during the day retreat into cover. At dawn they are sometimes found feeding in the open. In California they are hunted from horses or jeeps, or on foot. A hunter sometimes walks or rides along the ridges in the early morning looking into canyons on either side. If he sees nothing before 9 A.M. the hunt is finished for the day, for by that time the boars have sought cover. An unusually large boar may weigh as much as 500 lb. Boars are formidable beasts and can be dangerous at close quarters.

10. Peccary.— The peccary, known also as the javelina, wild pig or musk-hog, is not a member of the swine family although it resembles a pig in many ways, roots with a piglike snout and grunts like a pig. It is small in comparison with the wild European boar, and is native to America. There are two subspecies, the

collared peccary of the southwestern United States and Mexico, and the white-lipped peccary of the Central and South American jungle regions. A good-sized collared peccary will weigh about 50 lb., while the white-lipped peccary may weigh closer to 75 lb. Collared peccaries have been considered primarily a desert animal and they thrive under desert conditions. However, they have been noted ranging up into the pine region of Arizona.

Peccaries live primarily in caves and are gregarious creatures. With their sensitive noses and ears they are difficult for the hunter to find. The collared peccary travels in herds of about ten, but the white-lipped peccaries are customarily found in great numbers and it is not unusual to find 50 or more in one group. If the wind is right the hunter may smell or hear them before sighting them, and can then stalk them.

11. Musk-Ox.—The musk-ox is a shaggy wild ox of Arctic America. The Eskimos have hunted it intensively for food and clothing and it is feared that the herds face extinction, although rigid protective measures have been instituted. (E. P. B.)

B. Europe

1. Great Britain.—Great Britain's only true big game animal is the red deer. The hunting of stag with hounds by mounted hunters (see *Hunting with Hounds,* below) was formerly called "hunting at force." and in the 20th century it continues in parts of England. On the open mountains of the Scottish highlands red deer are stalked with the rifle. The stalking season begins at the end of September and lasts three weeks, ending when the rut (mating season) begins, since it is not customary in Great Britain to take game at any season of the year when mating or breeding occurs. In woodland areas of the British Isles fallow deer and roebuck are stalked with the rifle. The method generally used is similar to American "still hunting," but since World War II some British sportsmen have adopted the German *hochstand* technique. in which the hunter waits on a platform erected in a tree to ambush animals passing below.

2. Northern Europe.—In Scandinavia the game to be found includes reindeer, red deer, roe deer. European elk and bear. Of these the elk is probably the most important and, in Norway, it is more widely distributed than any other species of big game. Its habitat includes all the larger areas of coniferous forest, but it is a great wanderer-and will on occasions invade districts where it has been previously unknown. Elk are hunted either by still hunting or with special hounds which run them to bay.

The European reindeer is of the barren-ground type, being smaller in the body than the woodland types of Canada and Alaska and carrying long, slender horns which show less palmation than those of the North American caribou. In former times reindeer were very widely distributed throughout the whole of Scandinavia, but after mid-20th century it was found only on the mountain plateaus above timberline; in summer it prefers those mountains where there are plenty of snowfields.

Red deer are not very widely distributed in Scandinavia, existing only along the western coast of Norway from Bokn fjord in the south to Namdal in the north, and in a few other scattered areas. The only localities where they are found in any numbers are the two islands of Tustna and Hitra. Bears still exist, but in such small number that they are negligible from a sporting point of view. Polar bears, however, are hunted on the Arctic icefields of northern Norway.

Much of the big game of central and southern Russia has been exterminated. but some of the best hunting grounds of the future may lie in northern Russia in Europe and Siberia in Asia. From Scandinavia to the eastern coast of Siberia, elk and reindeer are to be found. Farther north reindeer exist everywhere on the tundra and they are particularly common on the Kola peninsula and the island of Novaya Zemlya.

Other species of game to be found in Russia are lynx and hear, both of which are plentiful, while big grey timber wolves are ubiquitous and follow the elk. Polar bears are fairly common in the northern parts of the island of Novaya Zemlya and walrus may sometimes be encountered on the ice floes.

3. Central an a Southern Europe.—The magnificent red deer, brown bear and roebuck that formerly inhabited the reserved forests of central Europe have been sadly depleted. In the Carpathians game still exists in considerable numbers. Chamois, red and roe deer run large in these mountains and it is probable that better heads are to be found there than anywhere else in Europe. Similarly Tirol has been less affected than the lower lands. Chamois are to be found in the Alps in fair numbers, although all the best districts are preserved.

In Spain the big game are brown bear, red deer, chamois and Spanish ibex. the latter a magnificent creature very strictly preserved. Red deer are found in the forests of the Sierra Morena and Andalusia. Bear are very scarce and are confined almost entirely to the Pyrenees and Cantabrian mountains in the north, as are the chamois or izards. These are somewhat. smaller than the chamois of Tirol. both in size of bodies and heads.

In the Balkans game has been carefully preserved. Yugoslav red deer are probably the finest in the world, and possibly the most expensive to shoot. The country also supports fallow and roe deer, ibex and bear.

The Sardinian mouflon offers the sportsman of moderate means an opportunity to hunt big game. It inhabits the higher mountains. especially the Gennargentu mountains. and good heads may still be obtained although they are becoming more scarce every year. This handsome wild sheep is also found in Corsica.

In the Federal Republic of Germany hunting is strictly controlled both by statute and custom. The chief big game animals are red, fallow and roe deer and wild boar in the forests, and ibex above the snow line. The regard in which such animals are held, and the ceremony which attends all hunting in Germany. ensures that sport of a high order is maintained, although it is necessarily limited. Similar comments apply to the Belgian Ardennes and the undulating woodlands of Maastricht., Neth. France and Italy possess the same types of game as Germany but have failed to conserve it. In Italy progress is being made on a code of conduct designed to eliminate undesirable competition among sportsmen for the necessarily restricted game stock. (G. Bu.; W. S.)

C. Asia

Asia contains greater variations both in climate and physical features than any other continent and, although its big game may not be quite so numerous either in species or actual numbers as those of Africa, it offers unique attractions to the big game hunter.

1. Western **Asia.**—Mouflon, similar to the Sardinian species but larger, are to be found in the mountains of Asia Minor, while the Russian Caucasus provides some of the most difficult yet splendid sport in the world. In the higher ranges lives a fine wild goat, the West Caucasian tahr (tur), which in the east gives way to the East Caucasian tahr, an animal which carries horns very similar to those of the Himalayan bharal, or wild blue sheep, but which has a short beard and is a true goat. In the wooded valleys may be found the maral, a magnificent specimen of the red deer species almost as large as the American wapiti. The pasan, or Persian wild goat, inhabits the Caucasus, the ranges of northern Iran down to Baluchistan, and the hills on the Indian frontier in Sind. where it is known as the Sind ibex.

In Iran, tigers live in the low-lying forests to the south of the Caspian sea and probably farther east as well, while the maral of the Caucasus extends well into Iran. The mountain ranges hold at least one variety of wild sheep, which is very similar to the Indian urial but slightly larger in body and with a much finer head, and the plains carry several varieties of gazelle. Leopards are common in many parts. Mesopotamia offers little hunting, although gazelle are found in the desert. A species of ibex inhabits the mountains of the Sinai peninsula, and possibly extends farther inland, while specimens of the Arabian oryx can be obtained from Aden. The Arabian tahr inhabits the mountains of Oman and gazelle are found in the desert.

2. Central Asia.—The whole of this vast area is a good hunting ground. In the higher ranges are wild sheep with widely sweeping horns. Of these the *Ovis poli* (Marco Polo's sheep) of the Pamirs is probably the best known and certainly carries the longest horns, although they are not so massive as those of the ***Ovis*** *Karelini* of

the Tien Shan, or of the *Ovis ammon* of the Altai, which has the most massive horns of all. The range of these central Asiatic wild sheep is large, extending right through Manchuria to Kamchatka, and different species and subspecies exist throughout the mountains and hills of Manchuria and northern China. Southward, on the plateau of Tibet, they are represented by the *Ovis ammon hodgsoni* (Tibetan argali), the ammon of the Indian sportsman and the nyan of the Tibetans. Ibex range from the northern bank of the Sutlej river through the Himalayas, Karakorum and Pamirs, to the Tien Shan, the biggest heads being found in the north.

3. China. — In the mountains of northern China wild sheep are found, and tigers extend throughout the forests of eastern China from Manchuria to the extreme south. There are strong grounds for belief that Manchuria is the original home of the tiger and that it later extended its range southward. At birth tiger cubs are woolly, indicating a natural protection against cold, and although tigers are found in the hottest jungles of India they dislike heat and their pads will blister when they are forced to cross open ground in the hot weather. The tiger is found in China, Thailand, Burma, India: Malaya and Indonesia. In southern China the forests and cultivation give way to uncultivated higher lands which culminate finally in mountains where game typical of southern Tibet, the bharal and the takin, are to be found.

4. Southeast Asia. — Indochina holds, in addition to tiger, leopard and is probably the eastern outpost of the Indian elephant, gaur and rhinoceros. These animals all also exist in Thailand and there, too, may he found the curious Schomburgh's deer with its widely spreading and many-pointed antlers, as well as a small representative of the Indian sambar. This grand deer probably originated in India, for it is in that country that it attains the greatest size of both body and horn. but it has a very wide habitat, being found throughout the Malay peninsula, Indonesia and Borneo as well as in Ceylon.

5. Tibet and the Himalayas. — South of the Kunlun mountains lies the Tibetan plateau, the highest and most extensive in the world. Only one animal seems to be almost ubiquitous throughout Tibet and that is the bharal, or wild blue sheep of the Himalayas, regarded by some naturalists as the connecting link between sheep and goats. Tibetan antelope roam the Chang Thang, the desert of northern Tibet which has an average altitude of 15,000 ft., and there, too, are to be found herds of wild yak. Farther south the Tibetan argali and Tibetan gazelle may be obtained: while in the lower districts to the east of Lhasa there are forests which hold Thorold's deer, a large deer very few specimens of which have ever been obtained by European sportsmen. Also in Tibet are small bluish bears and numerous wolves while in the west, bordering on the Himalayas, the snow leopard (ounce) and Tibetan lynx exist but are rarely encountered.

The Himalayas provide magnificent stalking, the quarry being, in addition to those Tibetan animals already mentioned, ibex, tahr, markhor and urial, while other game animals are goral, serow and two species of bear, one black and one brown. The latter exists only in the higher ranges near the snow line and is a variety of the brown bear of Europe. In the western Himalayas are to be found specimens of the Kashmir stag, a deer very similar to, but larger than, the red deer of Scotland, while in the east there is an isolated pocket of territory in the Chumbi valley which is the home of a still larger stag, the shou.

6. India, Ceylon and Burma. — India contains the oldest and best-known hunting grounds of all. Sportsmen had been accustomed to shooting tigers there long before any big game hunter had set foot in Africa. The principal game fields are the Terai, a narrow belt of tropical jungle which runs along-the foot of the Himalayas from the Jumna river to Assam and which holds tiger, elephant, rhinoceros, sloth (or honey) bear, black Himalayan bear, sambar. or Ceylon elk, cheetah, swamp deer and other smaller varieties; the jungles of central India in which tiger, gaur (commonly called the bison), sambar and sloth bear are the most important big game; the damp and intensely thick jungles of southern India and the Mysore plateau where elephant. gaur and tiger are found; and the Nilgiri hills where there is a species of wild goat locally known as the "ibex" which is really a variety of tahr. Assam and Sundarbands, the semiflooded delta of the Ganges, are the home of the buffalo, which was also common at one time in Madhya Pradesh. but which has become almost extinct in that district. In India there are some firms and government agencies which make a business of conducting visiting sportsmen on hunting tours.

Burma is the best ground for elephant, gaur and tsine (banteng; *q.v.*), a wild ox akin to the gaur. Leopard abound in all the areas mentioned while the Indian antelope. or black buck, and gazelle exist in large numbers on the plains, especially in the deserts of Bikaner and the Punjab. The big game of Ceylon is very similar to that of India except that tigers do not exist on the island and all the horned or antlered game carry much smaller heads. while the elephants are almost invariably tuskless. (G. Bu.; **S.**)

D. Africa

1. General Considerations. — Although the game fields of the African continent were the last to be discovered they have suffered from the attacks of hunters more than those of any other part of the world, except some parts of North America. Such attacks. however, have not been delivered by the man who shot for sport, and if sport alone had been the object of pursuit it is doubtful whether the number of game would have decreased very materially. The settlers shot for the sake of meat and hides, and wherever commercialism entered into the question the fate of wild game was sealed. The Dutch settlers must be held responsible for the complete extinction of the quagga (a kind of zebra) and the general extermination of game from the greater part of the country which lies to the south of the Limpopo river. Similarly the early elephant hunters had much for which to answer. However, shooting alone has not been responsible for the elimination of big game from huge areas of Africa. Colonization by European settlers drove the wild animals into country that was unsuitable for them, and this advance of civilization has been the most serious menace to the African fauna. The spread of industry and agriculture, accelerated by modern methods of forest clearance, have opened up Africa at unexpected speed. and a further element is the presence of a native population newly possessed of opportunities to destroy wild animals on a large scale. and in places eager to do so for motives of profit. .There are. however, gigantic tracts of country quite unsuitable for colonization and in these areas the game should flourish for many years if the game lams existing in most parts of the continent can be efficiently administered.

The real wealth of Africa as far as big game is concerned lies in its wonderful variety of antelopes and gazelles. There are more than 60 different species, but no specimen of the deer tribe seems to be indigenous to the continent. A few red deer exist in northern Africa in the neighbourhood of Tunis, but it is probable that these were either imported or else are the descendants of some that migrated from Spain before the formation of the Strait of Gibraltar. Africa shares with Asia the rhinoceros and the elephant, but both African varieties of rhinoceros (black and white) are different from any variety of Asiatic rhinoceros. The giraffe and okapi are quite distinctive and peculiar to Africa, while the African buffalo, with all its varieties, is as distinctive as is the African elephant. The leopard is distributed throughout,the continent and is similar to the Asiatic species, although an experienced sportsman can usually detect the difference in the skins. The lion reigns supreme among the wild creatures throughout the whole of Africa.

Legal codes have been drawn up for the protection of wild life, but these are more easily devised than enforced. Several factors. apart from the vast distances common to most African countries, combine to make enforcement difficult. There are, for instance, different game codes in different territories and, except in those instances where major rivers or mountain ranges separate one national territory from another, migrating game herds crossing the frontier may be in double peril because of conflicting regulations on either side of it. These regulations define hunting areas. closed seasons and numbers which sportsmen are permitted to kill, hut they necessarily vary from year to year.

The lion, the leopard, the buffalo, the rhinoceros and the elephant have long dominated the imagination of hunters. They are

raised to a class by themselves by the fact that to shoot them the hunter must risk his life. All of these animals are aggressive when threatened: and well able to take care of themselves. The lion, which traditionally has been the hunter's most desired quarry, exists in diminishing numbers. Some ecologists believe that in the Africa of the future the lion may be in danger of extinction as a wild animal. The spread of farming communities has meant that lions, though they seldom become man-eating, have nevertheless become regarded as a menace to human life, and they are hunted down over ever-widening areas. Elsewhere, tribesmen have freely employed their newly acquired means of destruction. Simultaneously, the general contraction of game areas has reduced the number of beasts on which lions prey, also restricting their habitat. The consequence is that few heavy-maned lions remain outside the Masai tribal areas (where, it is worth noting, the spearing of lions is a tribal custom and test of manhood). Lions remaining elsewhere are generally of inferior type, and of less interest to the sporting hunter. Licences to shoot lion have been issued on a reduced scale by several African administrations.

Much the same is true, and for similar reasons! of rhinoceros, except that the situation has been even more serious and for some years the decline in rhinoceros numbers has accelerated to a serious and even grave degree. Two further causes were the susceptibility of the rhinoceros to drought, which in the 1950s repeatedly affected rhinoceros-inhabited areas, and the market in powdered rhinoceros horn as an aphrodisiac for which high prices continued to be offered.

Leopards are now unevenly distributed over Africa but remain a much-sought quarry of big game hunters eager to pit their skill against the most cunning, and perhaps the most resolute, of the major cats. In European and native farming areas where leopards have become extinct the local populations of baboons have increased to a point at which they constitute a constant hazard to agriculture. Cheetah are nearly extinct. Elephants maintain their number where their habitat remains undisturbed, though such areas are decreasing. With the same reservations, buffalo also maintain their strength and being most formidable. do not invite much attention from poachers. The remaining African animals which by tradition rank as game were in the past sought for the trophies provided by their heads, rather than the hazards which their taking involved. Of the trophy game which inhabited the forests, both the greater and the lesser kudu seem safe from the danger of drastic reduction. The hunt for the greater kudu continues to be perhaps the most challenging of all safari enterprises. Sable antelope are rarer since they can be captured or killed more easily and their meat is valuable, especially that of the bulls. Roan antelope have suffered greatly through efforts to combat the tsetse fly by destroying game over wide areas, and have also suffered from poaching. The ecological position of the wary, forest-dwelling antelope, the bongo (*q.v.*), remains obscure.

Of .the plains game, common giraffe have remained plentiful though some varieties have been reported to be growing rare. Populations of eland rise and fall periodically because the species is subject to rinderpest, but where their habitat remains their numbers are expected to be maintained too. Hartebeeste and wildeheeste (gnu) remain in great numbers. So do impala and Thomson's gazelle, though there are fewer Grant's gazelle. Zebra are much poached but the herds remain large. Fewer wart hogs were reported by the 1960s. Other animal life, such as apes and the lesser buck (bushbuck, reedbuck, steinbock and klipspringer) are not of interest to hunters who are principally interested in seeking trophies.

The trophy motive has been much reduced since in modern households large rooms are seldom available for the display of heads, and in recent decades there has been a tendency for the big game hunter to use a camera instead of a gun. However, this in itself cannot be expected to have much effect on animal populations. since it is not the sportsman but the poacher and the spread of civilization that are reducing the wildlife population in most African territories. (W. S.)

2. Principal Hunting **Grounds.**—*Northeast* and East Africa. —Most northerly of the major game territories is the Sudan which has a great variety of hunting grounds. On the east the hills hold ibex. while gazelles and oryx are found in the deserts of Kordofan and Dongola and Barbary sheep in the barren hills. But the chief hunting grounds of the Sudan lie in the south, up the Blue and White Niles. There may be obtained specimens of the giant eland (Lord Derby's) and the white rhinoceros, an animal which was once common in South Africa but is now unknown except in southern Sudan, northern Congo and Uganda. Elephants and buffalo are both common but the tusks of the former and horns of the latter are not big in the Sudan.

In Kenya, the most popular of the African big game fields, game may be seen in numbers to be encountered nowhere else in Africa in spite of the fact that the herds are not nearly so large or numerous as they once were. Every kind of country and climate is encountered in Kenya and each has its own fauna. Starting from the Indian ocean the first district is the coast belt, where game is plentiful but not so easily obtained as in other parts. The bag, however, may include elephant, buffalo, rhinoceros, eland. lion, bushbuck and some of the smaller antelopes. The next, and by far the most popular district, is the highlands which consist of great rolling plains interspersed with patches of bush and situated at an elevation of from 5,400 to 7,000 ft., in places reaching 9.000 ft. A great part of this area has been settled by Europeans but nearly 11,000,000 ac, are permanently reserved for the Masai tribe. The eastern half of this area is a game reserve but the western half is the most popular hunting ground, and specimens of almost every variety of East African game may be obtained there. A very large portion of Kenya is taken up by desert, to the north of the highlands. where the game is confined to oryx, Grévy's zebra, dikdik and Grant's gazelle. which gives place to Sömmerring's gazelle in the Jubaland region of the Somali Republic.

Southeast Africa.—The real tropical African country is not found much in Kenya but covers an extensive part of Tanganyika, where there is nearly as much possibility of varied sport as in Kenya. Here is the land of the sable antelope, which extends right down through Nyasaland. Northern and Southern Rhodesia to the frontiers of the Kalahari desert, but for really big sable antelope Angola is the best district. Rhodesia, both north and south, formerly was a fine hunting ground and still offers a chance of big kudu and roan antelope. Mozambique is heavily poached, but in the big swamps around the mouth of the Zambesi buffalo roam in great herds. South Africa now has little to show in the way of big game, although the region of Zululand probably still offers the best chance for nyala and the Kalahari is the only place where gemsbok exists (see ANTELOPE).

Western, West *Central* and *North* Africa.—The west coast holds plenty of game but not nearly in such profusion as the east, and this fact combined with the doubtful climate prevent its attracting sportsmen in numbers. Further, the heads of animals run smaller as a rule than they do in the east, while elephants carry lighter tusks. The West African buffalo, or bush cow, is, however, a distinctive type which is found nowhere else. The immense tracts of Gabon and the Republic of Congo, the Central African Republic and the Republic of the (former Belgian) Congo are seldom visited by sportsmen other than professional elephant hunters. but bordering on the eastern boundary of the Republic of the Congo lies Uganda which is the district par excellence for elephant and buffalo, as well as that shy and retiring water antelope, the sitatunga (see ANTELOPE). To the north the great Sahara desert is the home of gazelles, and in the hills of Morocco and near Algiers the sportsman who does not have time for a long journey has a chance of finding Barbary sheep. (G. BU.)

3. Safaris.—Reliable safari organizations can be employed to make all arrangements for a safari into east or west Africa. Some short duration safaris (about ten days' hunting) into equatorial Africa have also been established. Costs, on an all-expense basis out of New York. for example, range from about $2,000. Safaris into east Africa are generally set up for a minimum of about 30 days of hunting. If the customer wants an all-around take of game or desires to go into the more remote areas, the safari organization will probably ask that he allow more hunting time. Hunting time may run to 60 or 90 days depending on the territory to be hunted

and the game desired. There are no standard rates. but a safari into east Africa may cost the individual about $100 per day if there is one client per white hunter, less if there are two.

With the exception of all-expense safaris, licences are an extra expense. The cost of both general and special licences varies, and regulations change from time to time. The safari organizations furnish information about the costs and the white hunters serving as individual guides assist in procuring licences and gun permits. The organization will also recommend, and often supply, guns of the special large calibre used for large and dangerous game. Camping equipment, cooks, gun bearers, trackers, skinners and other services are generally covered by the fee. (E. P. B.)

E. Other Game Fields

South America has little in the way of attractions to the big game hunter, the jaguar being the only animal worthy of pursuit. In Australia the only indigenous large animal is the kangaroo which is scarcely big game for the sportsman's rifle; but in the Northern Territory there are herds of buffalo, the descendants of domesticated animals which escaped into the bush and have been wild for many generations. Some of the bulls carry quite good heads.

New Zealand is very different and is a country of peculiar interest in that all its game has been imported. These experiments in importation have been most successful with the result that magnificent red deer heads have been obtained, and the following animals seem to have become acclimatized: red deer (to such an extent that it has become a pest); North American moose and wapiti; chamois; Indian sambar, cheetah, tahr and bharal: and mule deer. (G. Bu.; X.)

III. SHOOTING SMALL GAME

The field sport of hunting small game and game birds with a gun is known as "hunting" in the United States and Canada and as "shooting" in Great Britain. It is practised in most countries of the world, although what is regarded as game map vary from country to country. Sometimes game is defined as a product of the wild that is killed for meat; sometimes as an animal or bird that is hunted for sport or that state or other law specifies as legitimate quarry.

1. North America.— In North America game usually is classified as those animals and birds that can be hunted for sport, but which are protected with a closed season for part of the year and on which there is a definite bag limit. In some places certain fur-bearing animals are similarly protected but hunting or trapping these animals for commercial use technically removes them from the small game category. Animals or birds that may legally be hunted for sport but are not classified either as game or as fur bearers are usually known as predators or vermin.

Rabbits and hares probably are the most popular small game animals in North America and the cottontail, the common U.S. name for several species of rabbit (*q.v.*), is the most popular of these, in part because many hunters value its meat and in part because it is relatively plentiful. Some states in the United States do not even class the rabbit as a game animal, and those that do allow relatively long open seasons. Dogs often are used to hunt rabbits and shotguns usually are the preferred weapon. Hunters should be aware that rabbits are the most important source of human infection with tularemia (*q.v.*).

In some parts of North America the brush rabbit and the swamp or marsh rabbit are popular game. Among the hares are included the snowshoe rabbit (varying hare), several jack rabbits and the large arctic hare.

In many areas of North America gray and red squirrel rank second to the cottontail in popularity among hunters. A shy and elusive target, the squirrel tests the sportsman's marksmanship and woodcraft. A .22 calibre rifle is preferred but shotguns also are commonly used.

Other North American small game include the prairie dog of the western plains, opossum, raccoon and woodchuck. Dogs are used to tree opossom and raccoon. both of which are hunted at night. In some states of the United States the raccoon is considered a predator and is unprotected. Both animals also have been trapped and hunted as fur bearers.

The woodchuck, groundhog or whistler (French-Canadian *siffleur*), the North American representatives of the European marmots, and the somewhat similar but smaller prairie dog require superior stalking and shooting skill. Many are bagged with .22 cal. rifles but often longer range guns are used; high-velocity cartridges are preferred and telescopic sights recommended.

North American small fur-bearing animals include badger, beaver, fisher, marten! mink, muskrat, otter and weasel; all have beer? trapped commercially for their fur and all have been hunted as small game or as predators.

Common predators include bobcat or North American bay lynx, sometimes called wildcat, Canadian lynx, coyote, gray and red fox, skunk. wolf and wolverine. They are not classed as game but both the wolf and wolverine are protected in certain parts of Alaska. R?inged predators include crow: owls and hawks, although many owls and hawks are protected. The great horned owl. the goshawk (largest of the hawks), the Cooper's hawk and the sharp-shinned hawk are not protected in all states because of their destruction of poultry.

Upland Game Birds.—Upland game birds provide some of the most popular sport for hunters (U.S.) or shooters (British). The ruffed grouse is a favourite, as are prairie chickens (sharp-tailed grouse and sage hen), spruce grouse and blue grouse (sooty grouse). Other popular game birds include chukar and Hungarian (European gray) partridge, pigeons and doves, ptarmigan and American woodcock. Quail, including bobwhite quail. mountain quail. valley quail and others, are widespread and attract many sportsmen. The ring neck pheasant. successfully introduced to North America, ranks high as a sporting bird. It is especially popular in the grain-belt area of the north central United States and Canada west of the Great Lakes into British Columbia. Perhaps the most highly regarded game bird in North America is the native wild turkey. which conservation measures have preserved in sufficient numbers for restricted shooting in most of the southern United States.

See also *Game Shooting* With *Dogs*, below. (E. P. B.)

Migratory Waterfowl Shooting.—The population of ducks and geese frequenting the U.S. flyways has varied greatly in the 20th century. yet. with the exception of rabbit shooting, more persons in the U.S. hunt wild ducks and geese than any other species of game.

Curtailment of legal limits and shortening of gunning seasons did not diminish the numbers of duck hunters, and there continued to be great pressures on the waterfowl populations. As in hunting upland game birds, however, the size of the bag should not be the gauge by which shooting success is measured; to the sportsman the number of birds secured is secondary to the pleasure of taking game in a sporting manner.

Wild ducks were formerly sold in the commercial market, and spring shooting (when waterfowl were on the return flight from the south to breeding grounds) was legal. Widespread slaughter of ducks to supply the market, especially in the spring when it prevented natural reproduction that might maintain flocks, threatened to bring about their extermination. The imposition of protective measures, however, was complicated by the fact that migration extended across international borders. The great bulk of the wild ducks and geese nest north of the 40th parallel. The population of these birds, therefore, depends to a great extent on conditions found in the northern United States and also in Canada during the breeding, hatching and rearing seasons, and on the protection of the ducks during these seasons.

On March 14, 1913, the U.S. government passed a law forbidding return-flight or spring shooting of waterfowl. and on Dec. 8. 1916, a treaty was entered into with Great Britain providing for similar protection of the birds in Canada. A law mas enacted on July 3, 1918, to put the treaty into effect. From that date both spring shooting and the sale of wild ducks and geese were illegal. The act of 1918 was declared constitutional by the United States supreme court on April 19, 1920. A similar convention with Mexico was concluded in 1937.

Responsibility for carrying out provisions of the Migratory Bird treaty in the U.S. was vested in the fish and wildlife service of

the department of the interior. This agency checks waterfowl populations to determine length of seasons and bag limits. Ducks Unlimited. an organization of sportsmen, and other groups also promoted measures devoted to the conservation of waterfowl.

Wildfowl travel over well-defined flyways, and four such routes in the U.S. are designated as the Atlantic flyway, Mississippi valley flyway, Central flyway and Pacific coast flyway. Certain shooting seasons are assigned each of the states on these flyways. Bag, possession limits and dates of open seasons, as well as hours of shooting, all of which may vary, are fixed by the U.S. department of the interior. State game administrators have some options in the application of regulatory measures, such as acceptance of split seasons. Wildfowl hunting regulations for each flyway have been announced annually since 1948.

Wildlife refuges established by the federal government in every section of the U.S. proved effective minter resting places for the wildfowl population. These sanctuaries, where no shooting is permitted. aid greatly in the conservation of wild ducks and geese, and provide future hunting opportunities.

Different ways of hunting wild ducks are pass shooting, jump shooting. timber shooting and shooting from a blind, a boat or a pit. with or without decoys. On the Canadian prairies, in the grain provinces, there is shooting in the stooks (stubble fields). The most popular form of duck hunting is over decoys from a blind. The shooter is concealed in a blind which may be in a lake or pond, along a shoreline or in shallow water. Before the blind are placed decoys of wood, rubber, canvas or other material. Wild birds, passing over, notice the flock of "feeding ducks" and swing in to alight. When the decoyed birds come within range, the hunters fire. Some wildfowlers are extraordinarily skilful in using a duck call to entice the wild birds into gun range. It is recommended that a retriever be in the blind with the gunners. There are various types of blinds. all of which are made to appear as natural as possible so as to lull the suspicions of the ducks. Boats may be disguised with rushes or otherwise camouflaged. Tidal water duck hunters use a battery or sink box. Movement frightens waterfowl. and experienced duck shooters are more careful about remaining perfectly still and having their companions and dogs do so than in having their apparel and cover blend with the surroundings. Some claim a sedge or golden coloured dog is not so noticeable as a black dog; most experienced hunters. however, agree that stillness, rather than coat colour. is of greatest importance.

Wild geese are more wary than ducks. They are hunted most successlully from pits or blinds with decoys. Along the Mississippi valley flyway, the pit blind is used almost exclusively, and is required in some localities. Some of the finest goose shooting on the American continent is available in the wheat fields in the Horseshoe lake area of Illinois. (W. F. Bn.)

2. British Isles.—Grouse Shooting.—The best-known branch of the sport in Britain is undoubtedly grouse shooting. Red grouse inhabit the high heather-covered hills of Scotland. northern England. Wales and Northern Ireland. Their presence made sporting rights over the moors an important commercial asset, and large sums are paid for shooting tenancies by sportsmen from many parts of the world. By systematically burning off old heather to encourage younger and more vigorous growth, the birds' chief food supply can be greatly increased and the stock correspondingly multiplied. Large bags have been made as a result. Two examples are 2.929 grouse to eight guns in a day in Lancashire in 1915 and 1.070 in a day by Lord Walsingham alone in Yorkshire in 1888. Such performances are unlikely to be repeated. or indeed attempted, again.

There are two main methods of shooting grouse: driving and "dogging." In driving, teams of beaters maneuver the birds over shooters u-ho wait in camouflaged butts. or shooting stands. In dogging. the shooters walk across the moor in line, preceded by dogs which mark the birds. Driving is considered to give the more difficult shooting and also has an advantage in that the older birds. which tend to become sterile after their first breeding season, are normally killed first and "birds of the year," being less strong on the wing and therefore slower over the guns, are left to form a rigorous parent stock for the following season. Dogging remains, however, the accepted method of shooting grouse in many districts in which beaters are not readily available.

Partridge *Shooting*.—The same two methods are used in the shooting of partridges, but this bird mainly inhabits the grain-growing areas and sport takes place over farmland instead of moor. After World War II the mechanization of farming reduced the land labour force, and therefore the supply of beaters, with the result that more shooting has been done over dogs. As in the United States and Canada, many changes in farming practice proved to be to the disadvantage of partridge and other game, especially the early plowing-in of stubbles, which removes winter food supply. The partridge population was thus much reduced in many areas. It seemed likely that gamekeepers. who hitherto did no more than protect partridges from attack by natural enemies and poachers, would need to rear some birds artificially. This was long believed impossible. but it was successfully accomplished in Denmark. By the 1960s a remarkable recovery had been achieved in the numbers of British partridges.

Pheasant Shooting.—In Great Britain, some sportsmen have felt that pheasants can supply sporting chances of shooting only under more or less artificial conditions. Preservation and artificial rearing are necessary to provide a concentration of birds. and. since gun dogs are not used in the same manner as they are in North America, the services of beaters are employed to put the birds over the guns at a height and pace to test the shooter's skill. Pheasants were introduced to Britain by the Romans, and the British, in their turn, took them to North America. The pheasant is the one bird which is now common to all countries where shooting is a recognized sport.

Black *Grouse, Ptarmigan* and *Capercaillie*.—Most of the shooting of other game in Great Britain is corollary to the sport to be had with grouse, partridges and pheasants. Black grouse, or blackcock (*q.v.*), for example, are to be found in most places where there are grouse. and the methods of shooting the two species are identical. Ptarmigan. on the other hand, belong only to the higher ranges of grouse country or to deer forests. They provide uninteresting shooting because of their tameness. Capercaillie. or capercailzie. may be found only in the neighbourhood of trees; the name is derived from the Gaelic "cabhar coille," or cock of the wood, and it is in the heart of pine and fir woods that this grouse makes its home. The birds are driven in winter, and give opportunities for remarkably high and fast shooting.

Snipe Shooting.—Snipe are to be found on most grouse moors, but snipe shooting is a sport by itself, enjoyed wherever there is suitable bogland. The bird rises from the ground like a flash. twisting this way and that, and to hit so elusive a mark needs a quick eye and hand. Snipe shooting is a sport of the winter months in Great Britain, for the home-bred birds are joined by the migrations from the continent in November. The largest bags of snipe have been made in the Hebrides, but Ireland and Wales, especially the former. provide some of the best snipe ground, and in England there are possibilities of good shooting in Norfolk.

Woodcock.—Woodcock shooting belongs principally to certain iocalities on the line of the birds' migration. As with snipe. large numbers of woodcock from the continent pass through the British Isles every autumn in a general direction from northeast to southwest. The shooting at Ballykine and its neighbourliood on the shores of Lough Mask in the Republic of Ireland is possibly the best in the world. Large bags are obtained in Cornwall. the limit of the line of flight in England. and in the west of Scotland, particularly the Isle of Islay. The difficulty of the shooting arises from the erratic movement of the bird when flying among trees. A woodcock in the open is a comparatively simple mark.

Hares and Rabbits.—Ground game provides shooting which is variously regarded as sport according to the standards of the shooter. Hares, which are destructive to crops, have to he shot down but hare driving produces few opportunities for interesting work with a gun. (See *Hunting With Hounds:* Have *Hunting*, below.) Rabbit shooting. however, may afford considerable tests of hand, eye and brain. for a rabbit gets to its top speed in an amazingly small space of ground. and takes every advantage of cover and obstacle. The European rabbit, unlike the North American

cottontail which normally nests above ground, lives in burrows and the main British methods of shooting rabbits are ferreting and laying out. In the former, ferrets are put to ground in the rabbits' burrows or "buries," and the animals are shot as they bolt from the holes. If the second method, that of laying out, is adopted. a day or two before the shoot, the gamekeeper goes the round of the buries nith some sort of evil-smelling mixture, such as paraffin (kerosene) and tar, which he sprinkles into each hole. The rabbits leave their holes at night to feed but do not return to them, objecting to the smell. On the day of the shoot the rabbits are found lying out in the undergrowth from which they are dislodged by beaters with sticks. or by spaniels.

Wildfowl.—Sport with wildfowl (ducks and geese) must always be of an uncertain nature, depending largely on the weather. The worse the weather the better, so far as the wildfowler is concerned; gales bring the fowl in from the sea to shelter, and frost confines the spaces of water where they can feed by night and rest by day. The shooter waits at dawn and dusk at certain points over which he knows the ducks will pass when flighting to and from their feeding grounds. A retriever is used to pick the birds in the dark or from the water into which they may fall. Duck hunters may use a "hide" or blind. Before World War II punt-gunning on the sea or in river estuaries was practised by a few amateurs and by professional hunters supplying birds for market. A flat-bottomed boat carrying a heavy swivel gun was used. The fowl were shot sitting, or just at the rise from the water.

Because little individual expenditure is involved in the conservation of the stock. wildfowl shooting is widely followed on both sides of the Atlantic ocean. (W. S.)

3. Game Shooting With Dogs.—Sporting dogs have been used to find, point and retrieve game for centuries. The development of gun dogs to suit the needs of hunters, however. has covered a wide range of breeds and divergent hunting activities, embracing fox. deer. bear and rabbit hounds, the pointing breeds, spaniel varieties and the recognized retrievers. (See also Dog.)

Only the Chesapeake bay retriever and the American water spaniel are distinctively U.S. breeds: the various other gun dog types have emanated from the British Isles or other countries. chiefly in Europe. Through selective breeding, adaptation and training, the dogs have been developed for. and have become proficient in, hunting. (*See* also *Hunting with Hounds*, below.)

Gun dogs are generally classified according to the specialty of the breeds. The group of pointing dogs includes the pointer and English setter. the most popular of these breeds; also the Brittany spaniel, German short-haired pointer. Gordon and Irish setters, the wire-haired pointing griffon, Weimaraner, Vizsla and Spinoni. The sporting spaniels are headed by the English springer. the cocker (both English and American breeds), clumber, field. Sussex and Welsh springer spaniels. The retriever breeds include the Labrador. Chesapeake bay, Irish water spaniel. curly-coated, flat-coated and golden retriever and American water spaniel.

In the United States gun dog in the main implies one of the breeds adapted to finding. pointing and retrieving game from upland and marsh. Pointers and setters unquestionably are most prominent. but all of the pedigreed sporting breeds have their advocates. Thousands of dogs are bred and registered each year to supply demands as more and more hunters realize the effectiveness of a good dog. Under modern hunting conditions a dog is essential to find game and to avoid tiresome tramping in fruitless quests.

Choice of a Gun Do,?.—Breeds are developed especially for certain work. Though such labels as "all-purpose" or "every-use" are applied to some hreeds. these do not compare in performance with the specialized pointing dogs, the hunting spaniels and the recognized retrievers.

If a hunter concentrates on upland game bird shooting—quail, ruffed grouse, pheasant. woodcock, prairie chicken. Hungarian partridge and valley quail—a pointer or setter is his best choice, followed by such less popular but warmly admired breeds as the Brittany spaniel (the only pointing spaniel breed), the German short-haired and the Weimaraner. If ducks are hunted in addition to pheasants and rabbits, a spaniel may best serve the purpose, preferably an English springer or a cocker. If waterfowl shooting is preferred, with perhaps an occasional foray for ring-necked pheasants, the retriever breeds. expert in water work and able to do a satisfactory job on land as well, should serve effectively. The Labrador, Chesapeake and golden retrievers are the most popular of there varieties.

The excellence of U.S. gun dog breeds may be attributed to the field trial sport—competitions for sporting dogs held under actual or simulated hunting conditions. Field trials enable breeders to evaluate the natural qualifications and refinements of a performer and select for breeding purposes individuals that can contribute to breed improvement. Accurate ancestries are on record in public stud books. and authentic information on a dog's winning and producing record in field trials is readily available.

The ultimate purpose of field trials is breed improvement, or development of improved gun dog performance in the shooting field. The best shooting dogs, those which work in a manner highly satisfactory to the average hunter, are bred from the finest field trial stock.

While the type of gun dog preferred for various kinds of hunting may differ. the important natural qualities to look for. whatever the breed. are instinct to hunt. good nose, intelligence, good constitution, nervous energy. good eyesight and hearing. tractable disposition, courage, and good conformation, style and appearance. In the case of the pointing breeds, the instinct to point is an important qualification.

The hunting dog must possess bird sense and hunt to the course chosen. should search upwind for hody scent of game, locate quickly and accurately. be well-mannered and steady to wing and shot. A pointing dog is expected to be staunch and to back a brace mate on sight or at command. He should not false point, potter (waste time) on foot-scent. blink birds (point but leave before the flush) or trail another dog with which he may he hunting.

Pointing dogs are versatile performers. They are efficient in hunting bobwhite quail in its native habitat; pheasants in meadowland. cornfield or swale; prairie chickens or Hungarian partridges in stubble; even ruffed grouse. characteristically found in woodlands or brush country; and, in Great Britain. red grouse. The accepted standards of performance for these various game birds differ. but this does not preclude a smart gun dog's being able to handle each satisfactorily. For example, the experienced quail dog can select objectives that are the most promising concealments, knows the habits of the game quested. and searches likely places depending on the time of day, character oi cover and weather conditions.

The various pointing hreeds differ in their methods. Pointers and setters hunt at greater speed and wider range than the close-working types like the German short-haired. Brittany, Weimaraner and kindred types. Retrieving is an acquired art with these breeds, although predisposed, and for short-haireds and Weimaraners adeptness at water work is a desirable attribute.

Individuals in the different hunting breeds naturally vary in ability. It has been said the setter is relatively slow in learning but improves steadily with experience, whereas the pointer learns more readily and is usually more easily trained. Such generalizations, however. are refuted by many individuals of both breeds. It is true that the setter can take the cold and wet and punishing briars more unflinchingly than the pointer, thanks to his long-haired coat, but in burr-laden areas the same coat picks up the stickers.

Most upland game bird hunting is done on foot. Consequently extreme range is impracticable and dogs are required to be subservient to the gun. In the U.S. south, however, quail hunting from horseback continues to be popular. though the number of places where it may be enjoyed has dwindled. For quail, the wide-ranging dog is referred to as a covey clog; the close-searching, keen nosed. adjustable single-bird dog is preferred in some situations.

The use of spaniels in U.S. game coverts became popular in the late 1920s. The rise to popularity of the springer and cocker was coincident with the flourishing of the pheasant. for the methods of the spaniels proved particularly suited to hunting these birds. The pheasant's trick of fleeing afoot. running off from the point of a setter or pointer, is circumvented by the spaniel's method of

quartering the ground ahead of the gun, covering all territory within ordinary shooting range at a fast. snappy pace. The spaniel springs his quarry and after flushing should immediately stop, assuming a sitting position. He is expected to retrieve only on command. It is essential that the spaniel be under control at all times. Most spaniels take to water readily and are what may be termed natural retrievers.

The retrievers are specialists. The Labrador, golden, Chesapeake and other retriever breeds have been bred, developed and trained to function in an important phase of bird shooting—the recovery of dead and crippled game. Although the retriever can be used in spaniel fashion ahead of the gun, his proper work is always after the shot. When hunting feather or fur, the retriever walks at heel, sits upon order and, when game is flushed, goes to retrieve when ordered to fetch. The dog is expected to mark the donned game. and should seek the fall in a brisk, quiet manner, thoroughly quartering the immediate area around the fall without unnecessary disturbance off the line. He should have a tender mouth and retrieve readily to hand.

When working on waterfowl, the retriever's place is in the blind or boat until actually ordered to go out. The fall of ducks should be noted and retained. for a requirement is the ability to mark several dead or wounded ducks. then deliver each in turn.

(W. F. BN.)

IV. HUNTING WITH HOUNDS

In the British Isles, some parts of the United States and elsewhere. hunting with hounds is a communal pastime which arouses much local enthusiasm.

1. Stag Hunting.— In Great Britain the sport of stag hunting, formerly called "hunting at force," entails the chase of deer by horsemen with a pack of hounds. It has been practised in this manner for more than 700 years. That it had its inception as a recreation of royalty seems obvious. and once orthodox rules were put into effect. stag hunting became the most fashionable of noble sports, although fox hunting superseded it early in the 19th century. It may be presumed that the first pursuit of the stag with "running" hounds was initiated in France. As a sport of the chase. it was brought to England by the Normans. who had adopted the French tongue and manners. The monks and clergy had a passion for the chase, hunting in great style with large retinues of servants. Because of the extent of their hunting proclivities, they were severely criticized and rebuked by moralists for neglecting their teachings. They were later prohibited from owning hounds under penalty of imprisonment. William Twici, huntsman to King Edward II, wrote about stag hunting in *Art de venerie (c.* 1314), as did Count Gaston de Foix in *Le Livre de Chasse* in 1387. Edward III, while engaged in a war with France, maintained 60 couples of staghounds, which he took with him to the battlefields. The modern method of chasing the stag. buck and hind was developed in the reign of Queen Elizabeth I. The queen's privy buckhounds were kept by Lord Leicester at Kenilworth (1575), and. under the supervision of Ranger Pollard, the royal Devonshire staghounds were kennelled at Simonsbath in 1598 and continued to hunt until 1825. Of the 20th-century packs, their successors, the Devon and Somerset staghounds have the most distinguished continuous history. including the period of World War II. When hunting returned to normal after that war, there were five packs of English staghounds and one of buckhounds (the distinction being that staghounds hunt red deer while buckhounds hunt fallow), two of staghounds in Ireland and five in France. French conditions differ from those in Great Britain in that most of the hunting there takes place inside the forest, whereas in Great Britain pursuit involves galloping across open moorland. Some British packs hunt carted stag, which is never caught but returns in a horsebox to the hunt's headquarters at the end of the day. This is in contrast with British fox-hunting tradition, which insists that the fox shall be genuinely wild and on its own familiar ground.

When World War II began, the British government encouraged the stalking and shooting of deer for food. This method. however. could not be followed in the well-populated west country, and hunting with staghounds was resorted to in order to save farm crops from depredation by deer. The stag-hunting season opens on Aug. 10 and continues until Oct. 10, at which time the rut is due to begin and hinds (female red deer) are hunted instead of stags. Stags are again hunted for six weeks from the beginning of April. when they have regained their full strength. Only warrantable stags, judged from the evidence of their antlers to be five years old or more, are considered fair quarry. The method of hunting, unchanged for four centuries, begins when the harbourer (a hunt servant) locates a warrantable stag in covert. A few hounds with special scenting pcwers, known as tufters, then hunt the stag into the open. where the main body of the pack joins in and the chase commences.

2. Hare Hunting.—-Hare hunting, in which hounds track by scent; is not to be confused with coursing (*q.v.*), in which pursuit is by sight. With mounted followers and hounds known as harriers, hare hunting ranked second only to stag hunting in Great Britain until fox hunting displaced both; until World War II it still took precedence in the hilly west of England. James I (1566–1625) followed the sport keenly, if unethically by modern standards, "live hares in baskets being carried unto the Heath." In a letter to his son Henry, prince of Wales, he had this to say about hare hunting:

> I cannot omit heere the hunting. namely, with running houndes, which is the most honourable and noblest sort thereof; for it is a thievish forme of hunting to shoote with gunnes and bowes; and greyhound hunting [coursing] is not so martial a game.

William Somervile (1675–1742), poet of the chase, referred to the joys of hunting hare, and keynoted its fascination in describing the tactics of the quarry—"a thousand shifts she tries." Somervile was an early advocate for "a diff'rent hound for ev'ry diff'rent chase." In the France of the Bourbons. the grandeur of the chase was unparalleled. An example of lavishness is cited by records of sport in the preserves at Chantilly, the residence of Prince Louis Henry de Bourbon. There, between 1748 and 1779. registered game accounted for in the chase totaled 77,750 hares, 3.363 stags and hinds and one fox. The prince maintained 240 horses and many packs of hounds.

Because of the multitudinous maneuvers of the hare, ali followers of this sport are able to see a large proportion of what goes on. Whether a man rides hard or little, "or not at all." hare hunting is considered a fascinating sport and an excellent school of horsemanship for its followers. In addition, this sport is much cheaper to conduct than other chasing sports and requires smaller areas over which to hunt.

3. Beagling.—The chase of the hare with hounds by foot followers is the oldest form of scent hunting organized as a sport. Xenophon wrote of it in Greece in 400 B.C. almost exactly as it is practised in Great Britain, where the word "beagle" is thought to derive from the Gaelic *beag* meaning "small"—the beagle being only about 14 in. tall. In the 20th century beagling increased rapidly in popularity both in Great Britain and the United States. Mechanization, resulting in the partial disappearance of horses, is doubtless an underlying cause. A contributory factor is its relative cheapness. Since the hare is capable of much greater speed than the hounds, and is the wiliest of quarries, its successful foot hunting is the art of venery at its highest. In Great Britain when hare is the object of the chase, whether by harriers or beagles, hunt uniforms are green, not scarlet as for the fox.

4. Otter Hunting.— Otter hunting is a sport particularly followed by enthusiastic fanciers of hounds who, when the fox-hunting and hare seasons are over, can enjoy the tracking of otter up and down the many streams in the British Isles. The season begins in mid-April and extends until about the middle of September. Because of the wandering propensities of the otter, the greatest difficulty encountered by the otter hunter lies in locating it. The otter starts its travels about midnight, and the earlier the hunter is afoot the more certain he is of being able to mark his quarry. It is necessary to strike his drag, or scent, and put hounds in the direction of his couch. a hole at the riverbank into which he may dive upon hearing the hounds. The scent is usually several hours old. and once hounds strike, there is the danger of their taking a line heel way, that is, going in the opposite direction to that

which the otter was traveling when it made its trail. Terriers are used to bolt (uncover) the otter if it is marked in a holt (temporary refuge). Otter hunting is an arduous sport. and in spite of the otter's strong scent it often escapes hounds. The otter's scent seems to be an unwanted one for unentered (young) hounds. and there is often difficulty in getting them to take it. Otter hunting, as an organized sport with packs of hounds, is more than 800 years old.

5. Fox Hunting in Great Britain. — England is the home of fox hunting as a sport. and a lasting tradition has been established. Opinion varies as to when fox hunting first became a recognized sport. In its inception, it was tried as an adjunct to stag and hare hunting. with the same hounds used to chase each quarry. The fox mas looked upon as a lowly creature and hardly an object of high sport. But once fox hunting took hold. the fox had few enemies except hounds and became a cherished object of the chase. Authentic and complete hunting diaries depicting the true situation prior to the 18th century are nonexistent. Honours for maintaining the first pack of hounds used exclusively for hunting the fox seem to be divided between Viscount Lowther. Lord Arundel and Thomas Boothby, with respective dates 1660, 1690 and 1698. In 1726 Squire William Draper devoted much of his time to fox hunting. with the express purpose of reducing the number of "lamb killing" foxes in Yorkshire. The form of modern fox hunting took shape in the 19th century shortly after Hugo Meynell—"the father of the modern English chase[x] — started hunting; and it soon developed into a national pastime. Whether in England or elsewhere, the traditional procedure is still observed and the proper kit worn. A fox hunt is conducted by the master. and, in theory. all who take part in it do so at his invitation even when they pay for the privilege. The hounds. generally 15–20 couple. are controlled by the huntsman, who may be the master himself but who is generally the senior paid servant of the hunt. He has two or three whippers-in to assist him in reconnaissance and in keeping the hounds together as a pack. Master, huntsman and whippers-in take precedence over all other riders to hounds. The huntsinan controls hounds by voice: his calls being known as cheers, and by his horn — a copper tube about eight inches long. the two notes of which, though not loud, have a peculiar carrying and penetrating quality. A day's hunting begins with a meet, at which the followers join the hounds, acknowledge the master and are frequently offered hospitality by one of their number who acts as host for the occasion. On the command of the master, hounds move off to draw (search) the covert, which may be woodland, patch of gorse or field in which it is suspected that a fox may he. When the fox is found, the fact being signalled by the cry of hounds and notes of the horn, the hunt begins and ordinarily proceeds to the stage where the fox is viewed. a moment which is signalled by a holloa, a high-pitched cry. If a kill follows. the brush (tail). mask (head) and pads (feet) of the fox may be given as trophies by the master to any followers whom he considers to have acquitted themselves so as to deserve the honour. The body of the fox is then thrown to the hounds.

Fox-hunting uniform is usually a scarlet coat with white stock (cravat) and black velvet cap for the master, huntsman and whippers-in. Followers of sufficient prestige are invited to wear scarlet. with the individual buttons of the hunt, and top hat (the velvet cap being strictly the prerogative of those actively engaged in the control of hounds, though by modern usage women also wear it). Other followers wear black coats. with top hats or bowlers. In the case of some ancestral hunts run by noble families the uniform may be green. yellow or gray instead of scarlet.

The entourage of a hunt includes among its lesser functionaries grooms, second horsemen (who ride relief horses for the master. his staff and leading followers), terrier men and earth stoppers. Of the last two, the former convey, either on horseback or foot. terriers which are sent down to bolt the fox should it escape into an earth (a fox's underground den) or drain; the duty of the latter is to ensure that the earths are temporarily closed on a hunting day to give the hounds the best chance of a kill. The most fashionable hunts operate in the midland counties lying around Leicester, but hunting takes place all over England, Wales, Ireland and parts of Scotland from November, when the harvest is gathered, until April, when new crops begin to grow. Cub hunting. when the young entries (hounds new to the sport) are taught to hunt with the pack, is carried on in September and October.

Just prior to World War I. fox hunting reached a zenith of popularity as an English field sport. Horse and hound breeding had arrived at a highly developed state, and hunting itself was well organized and regulated by the Master of Foxhounds association. While the sport undoubtedly lacked the golden flavour of hunting as it was enjoyed during the Victorian era, it nonetheless attained certain other compensating attributes. When the country was mobilized for war in 1914, many nonsympathizers felt that the death knell of this amusement had been tolled. but by judicious and drastic measures. which included reduction in the number of hounds, hunting weathered the storm.

An upsurge in interest following the war did not put an end to hunting difficulties. The changes in patterns of ownership and use conditions of rural England. begun prior to 1914, were accentuated. Great landowners and their tenant farmers began to be replaced by numerous small holders, and barbed wire became a menace. These threats to the sport were handled by the Master of Foxhounds association, whose members promoted the benefits of hunting to both the countryside and the community.

The experiences of World War I helped fox hunters to combat some of the problems of World War II. In spite of the scarcity of feed and other hardships. the government took the position that hunting on a vastly reduced scale served a useful purpose. Consequently, with the assistance of the many sporting farmers, with hunt staffs consisting of men ineligible for service, and also with the aid of women, establishments able to do so continued on a skeleton basis.

With the end of the war a section of the urban population of Great Britain initiated a campaign to prohibit fox hunting. Their efforts encountered vehement opposition in the countryside. and this was strongly reinforced with the return from military service of the more active hunters. It soon became evident that feeling on the subject was running high, but the anti-fox-hunting party promoted a bill to secure the abolition of the sport. When the measure was debated in the house of commons in 1949 the bill was defeated. Thereafter fox hunting rapidly re-established itself after its wartime difficulties. By the 1960s there were about 230 recognized packs of foxhounds in Great Britain and Ireland, approximately the same number there had been in 1939 on the eve of World War II; in 1885 there had been 191. (W. S.)

6. Fox Hunting in the United States. — Early *History.*— Contrary to general belief, fox hunting began awakening in North America at about the same time it did in England. A number of early settlers brought hounds. horses and hunt servants from England to Xmerica to carry on the type of sport in vogue at the time they left home. Authentic information as to when the first pack of hounds was devoted exclusively to fox is not more available in the U.S. than it is in England. There is evidence, however, that fox hunting of sorts was carried on in the colonies as early as 1650, following the arrival in Maryland of Robert Brooke. This man came from England in his own private ship with a pack of hounds, accompanied by his family and 28 servants. On the record, Brooke can be designated as the first known master of a pack of hounds in colonial America. His most important contribution to fox hunting was the Brooke hound. which has remained an entity and formed the basic breeding stock for such famous American hound strains as the Trigg and Walker. Whereas England developed fox hunting as a sport — its style, finesse and science — American fox hunters were the first to ride straight cross country while following hounds. In England, hunting at the outset was the pastime of royalty and the landed aristocracy, who considered the sport a personal hobby requiring the finest of clothes, good hunters, well-bred hound.: and skilfully trained servants. Also, because the dictates of etiquette required a certain amount of dignity and restraint. all hunting procedure was conducted according to rule. In America, while all was unsettled. untamed and unrestricted. the country and its customs not as yet having been defined, almost everything was done in individual and uninhibited fashion.

HUNTING AND FISHING FOR BIG GAME

1. African natives spearing a hyena
2. Setting up a trap for big game in the Malay Peninsula
3. Papuans of New Guinea hunting fish in the native manner
4. Wiama Indians of northern Brazil trapping the peccary (wild hog)
5. Chinese fishermen of Hang-chow-fu fishing with cormorants; a cord around the bird's neck prevents its swallowing the fish
6. Eskimos harpooning walruses from an "umiak" or skin-boat
7. Siamese fishermen fishing with nets on poles, in a "kiong" or canal

When the sport spread from one locality to another. only the most casual notice was taken of how anyone else went about it. Wad this not been the case, it would undoubtedly have taken many more generations for fox hunting to make real headway in North America.

While fox hunting in England started as an exclusively upper-class pastime, it worked down democratically, eventually becoming a national sport. In America, on the other hand, there came a period when attempts were made by certain groups to make of it a privileged sport, limited to a few select club members. Finally, in order to make of hunting all that it should be, attitudes were recast on a broader and more democratic basis.

In 1742 Thomas Walker of Virginia imported a pack of foxhounds from England and established himself as the master of the Castle Hill hounds. the only pre-Revolutionary pack to span the vears into the 20th century without losing its specific identity. Fox hunting became the favourite pastime of several presidents of the United States. cabinet members, justices of the supreme court. senators, congressmen and high-ranking army and navy officers. George Washington devoted practically all his spare time to the chase. having learned the sport from his friend Lord Thomas Fairfax. who came to Virginia in 1746. Martha Washington also hunted occasionally. Thomas Jefferson was a "keen hunter, as eager after a fox as Washington himself."

In 1766 the Gloccester Foxhunting club was organized in Philadelphia by 27 prominent sportsmen and is important as the first recorded fox-hunting club established in America. Although it was disbanded in 1518. hunting continued in the neighbourhood of Philadelphia with increasing spirit. being conducted by many offshoot groups of the Gloucester. In New York city. fox hunting was extremely popular before and after the Revolution. Many early newspapers carried accounts of hunting on Manhattan Island as well as Long Island, North Riding and Westchester county. Col. Jaines de Lancey and Gen. Statts Long Morris maintained well-known packs of foxhounds.

In 1783 the St. George Hunt club was organized in New York city with John Evers its first master. Evers had brought a pack from England in 1768. Members of the club included George Washington, Alexander Hamilton, Charles Lee and John Jay. When Evers died in 1807 Cadwallader D. Colden (mayor of New York city. 1818) became master. About this same period in New York there existed a Colonial hunt. Little is known of its make-up. During the period of the War of 1812. the Belvidere hunt was established on Manhattan Island by Edward and Rufus Prime. n-ho lived at 1 Broadway. The Belvidere scheduled most of its fixtures at Cato's Inn. 67th street and Third avenue. Fox hunting continued on Manhattan Island until about 1821. The population of the city at that time was 123.706.

Other prominent organizations established in the 1800s included the Baltimore and Washington hunts. Among the Washingtonians who followed hounds in those days were Andrew Jackson. John Marshall and Roger B. Taney. In 1856 the Brooklyn Foxhunt club was organized by T. C. Carpendale. Henry W. Herbert. who gained fame as a writer under the pseudonym "Frank Forester." was a member of this hunt. as mas William T. Porter. who established the Spirit *of* tile *Times* (1831), early American sporting newspaper. The Brooklyn Foxhunt club was disbanded in 1861.

In Canada the Montreal hunt, founded in 1826, continued through the years to become the oldest organized hunt on the North American continent. The Toronto hunt was established in 1843. By the second half of the 20th century Canada had more than 100 recognized hunts associated with the Master of Foxhounds association of Sorth America.

Growth of For *Hunting* in *the United* States.—Before the American Revolution, fox hunting. as indicated above. was a hit-or-miss affair. most packs being trencher-fed (hounds being owned individually and brought together only when hunting). Though the Revolution interrupted the sport, some informal activity in it continued. George Washington, for example. mentioned above as an enthusiast. often managed to enjoy a few hours of hunting between battles, according to his diary. Between the Revolutionary and Civil wars fox hunting was followed seriously by Americans, particularly the landed gentry of Virginia, Maryland and Pennsylvania. Hounds and hunt servants were imported from England, and much more attention was paid to formality than had been previously. The Civil War halted this. however, only four hunts surviving, two in Canada and two in the United States. But immediately following that war enthusiasm returned, and the importation of hounds and hunt staffs increased steadily.

The formation of the Masters of Foxhounds association in 1907 did much to stabilize hunting and improve it through organization. Territories were allotted to recognized hunts, hunt colours were registered. and type of country and preferred type of horse were listed. The period directly after World War I saw the establishment of many new packs. and the depression of the 1930s did not affect the sport seriously. Interest continued through World War II. But what wars and depressions could not destroy, prosperity seemed to threaten. The postwar increase in building meant the conversion of many large farms and estates to building developments. Thus land through which the hunt had been accustomed to gallop. especially around the big cities. was lost to the sport and hunting was curtailed. On the other hand. there developed a newly born interest in parts of the west. midwest and southwest. in territories formerly given over to ranching. By the 1960s there were 90 recognized fox hunts in the United States.

Differences Between *Hunting* in the *U.S.* and in *England.*—U.S. fox hunting. though it follows the etiquette and general rules of English fox hunting. has had to adjust itself to somewhat dissimilar conditions. In England the fox is protected. and the earths. drains, etc.. are stopped (see abovej during the night before a meet while the fox is out foraging. Furthermore England has fewer large. dense woodlands and swamps through which a horse and rider cannot penetrate. In the U.S. earths are not stopped. so the fox goes to ground more frequently than not. and most U.S. masters do not consider it sporting to dig out a fox except at the beginning of a run. Much of the territory is not negotiable by a horse. Consequently the method of hunting is different; in many parts of the country a more rugged type of horse is preferred and hounds must be trained to be more independent and to hunt much more on their own than are the English hounds, which are far better disciplined and leis independent.

Country.—To a fox hunter the term "country" means topography of terrain and type of obstacle. There is the stone-wall country of New England and upper New York state. for example, where the fields are small and the walls rough and often unjumpable except where they have been panelled with telephone poles called riders. Long gallops are few and checks frequent. A rugged, half-bred horse is preferred, one whose tendons mill not suffer in heavy. muddy going. As a contrast, along the eastern seaboard and in Pennsylvania is the post-and-rail country. with great rolling fields enclosed in the familiar split chestnut rail fencing. These run from 4 to 4½ ft. in height. so many are panelled with "chicken coops." a solid board construction, wider at the bottom than at the top and shaped like a peaked roof. In this country the thoroughbred horse is usually preferred. as the going is much faster and not so rough as it is farther north. American fox hunters like timber jumps and find the hedges. ditches and banks of the British Isles terrifying. whereas the average British or Irish rider prefers a ten-foot bank to a three-foot barway. The modern wire fence bedevils the sport of both British and American enthusiasts, whereas the Australians train their horses to jump wire with complete aplomb.

But though hounds and countries may differ, in the 20th century as in the 18th. fox hunting is still a question of pitting animal intelligence against animal intelligence. Modern weapons have not been introduced. As in the days when the sport was the prerogative of kings and nobles, it is the hounds that do the hunting, the field following along as best it may.

"One-Gallus" Fox *Hunters.*—Another form of fox hunting which is strictly indigenous to the Sorth American continent is that enjoyed by a very large number of individual, informal hunters. Often called night fox hunting, this sport. game or pastime might be described as a passive. "hill-topping" type of fox hunting—a fox race in which the only active participants are the fox and

hounds with people sitting around a fire on top a hill in the moonlight and listening to hound music. Those who enjoy this pastime do so without ritual, equipment or style; all that is required is a foxhound. The respective owners of the individual hounds. who group them so as to make up a pack, possess a devotion to this form of recreation which cannot be claimed by many hard-riding foxhunters; viz., a knowledge and love of hounds. They know about hound breeding, hound development, what they do, how they run and how they speak to the line. Field trials include a U.S. open.

During the fox race, an owner by listening carefully can single out. his own hound and its position in the race by the manner in which the hound throws its tongue. The Sox-race type of American hound has been bred for nearly 300 years, and many individualized hound strains have become famous. The most popular are the Walkers, Triggs, Julys and Goodmans.

HUNTING AND FISHING, PRIMITIVE. Both archaeological evidence from the past and observations on the simpler societies of the present day show an appreciation of animal food and considerable ingenuity in methods of capturing it. The earliest fossil teeth suggest that man was omnivorous, eating flesh as well as vegetable products; primitive hearths contain animal bones intentionally smashed with stones for the extraction of marrow; and stone weapons have been found embedded in vertebra and skull of Paleolithic reindeer (Dordogne) and Neolithic ox (Cambridge). The cave paintings of western Europe are thought to represent the efforts of hunters to obtain success in their hunting by magic.

Before the invention of agriculture primitive man everywhere depended on hunting and fishing for his supply of animal food. Later, hunting became accessory to agriculture. providing variety in the vegetable diet and surviving as sport or recreation; or was required to protect flocks and herds, against predatory beasts. Primitive agriculture often is the work of women, while men are hunters. But where nature is sufficiently lavish in vegetable food. or where land mammals are comparatively few and small, hunting is of secondary importance to fishing, and fishing to agriculture; which then usually becomes men's work or the work of the entire family.

In modern times few tribes survive who support themselves entirely by hunting. Civilization and political control have encroached upon outlying less desirable lands into which hunting tribes had retreated. The development of aviation brought most regions of wilderness under routine observation, and the depletion of game makes it impossible for all but a few hunting bands to maintain themselves by hunting alone. In a few subarctic areas, as in Canada and Serbia, the seasonal trapping of fur-hearing animals can be followed on a scale sufficient to enable a small number of individuals to support their families on a bare subsistence level, depending upon the trader to supply trapping equipment, firearms. clothing and staple foods in exchange for furs. Nevertheless, these hunters are intermittently dependent upon government aid. The result is that surviving primitive hunters in most parts of the world have adjusted their living economy to that of the nations in control of their original territory, though they still preserve the traditions of recent times when they were self-supporting. By collecting and integrating these traditions and surviving folkways the anthropological field researcher often is able to reconstruct the mode of life of a given tribe when the people did live as independent hunters.

This article is limited to the consideration of people who were gatherers of wild food as distinguished from those who produced at least a sizable fraction of their food by the domestication of plants and animals. For ages all human beings lived entirely by what nature provided but eventually some groups here and there began to supplement the available supply of wild food by the cultivation of plants and the taming of birds and animals. In historical perspective by gradual extension of these practices agriculture and animal husbandry became the primary form of economy. Peoples may be characterized as pure hunters and food gatherers, primary hunters, secondary agriculturists, primary agriculturists, secondary herders. primary herders. and finally populations whose entire support is by farming and stock raising. Thus in 1492 the Indian tribes of North America east of meridian 100° west and south of parallel 45° north were for the most part secondary agriculturists. In a relatively small area comprising what are now New Mexico and Arizona; with a fringe in border states, the Indians were primarily agricultural. resorting to hunting for skins and a supplementary food supply only. But much of what is now the United States and Canada was occupied by pure hunters and gatherers. The aboriginal inhabitants of Mexico. middle America and the Andean highlands north of latitude 35° were primarily agricultural. For the most part the lowlands of the corresponding parts of South America were secondarily agricultural. Below parallel 35° south. the aboriginal tribes were almost entirely hunters and gatherers of wild foods. In the old world of corresponding date (1492) pure

hunters and gatherers dominated Australia, a few isolated areas in Siberia, Africa and southeastern Asia. Most of the Pacific islands approached a primary agricultural economy, supplemented by the gathering of wild foods.

The term civilization implies (among other features) dense populations dependent on a well-organized integration of agriculture and animal husbandry. a form of living which had appeared in the valleys of the Tigris and Euphrates, the Sile and the Indus rivers by about 4000 B.C.

Density of human population depends upon the group's mode of life. Under a pure hunting and food-gathering economy population must of necessity be sparse. It has been estimated that for people depending entirely upon food gathering and hunting there must be available from 7 to joo sq.mi. per capita according to climatic conditions. Since a hunting and food-gathering form of existence seems to have prevailed until about 10000 or 8000 B.C. and, if the minimum space required for such a mode of life be taken as 7 sq.mi. per capita and the earth's surface as 50,000,000 sq.mi., it can be hypothesized that the total world population at that time could not have exceeded 7,000,000 persons. At any rate, great populations pertain to modern times. Hunters and even fishing peoples could not have maintained cities in the modern sense without engaging in extensive farming and stock raising. In fact permanent towns were rarely possible, the family group being forced to move whenever the supply of food began to decline. The existence of large populations is fundamentally dependent upon farming and animal husbandry.

The recognition of definite rights over hunting grounds or fishing waters is usually clearly established and poaching vigorously resented by the rightful owners! who are sometimes, however, placated by a share of the spoil. The Eskimo may form an exception to this rule! for it appears that they have no strict division of hunting territory. The rights of the individual or the hunting group over the game killed were sometimes definitely fixed in primitive societies. Usually the man whose arrow first struck the animal, or first struck it in a vital part, had first claim. In the Xndaman Islands a pig belonged to the man whose arrow first struck it. but a bachelor had to be content to see it distributed by one of the older men, all the best parts going to his seniors, while he and his contemporaries received the inferior parts.

Magic plays a very important part in primitive hunting and fishing. and a man relies for his success on supernatural as well as natural means. while ill-success is ascribed less to lack of skill and inadequate weapons, than to failure in some preliminary ritual, or to the stronger magic of some rival force.

See AGRICULTURE, PRIMITIVE.

PRIMITIVE INVENTIVENESS IN FOOD GETTING

HUNTING

Methods of hunting vary with the nature of the country and of the animal hunted, the ingenuity and inventiveness of the hunters and the materials at their disposal. The Australians had few and plain weapons before European contact: their traps and snares were for the most part, simple and obvious. They depended on their stone or bone-tipped spears. wooden clubs and missile club or boomerang. They stalked both emus and kangaroos. used pituri plant decoctions to stupefy emus at nater holes, and exploited the curiosity of the bird by luring it on to a pitfall in nhich it was speared. The Bushmen of the Kalahari desert, south Africa, run an unnounded springbok to a standstill in the hottest part of the day, keeping the animal constantly on the move. preventing it from lying down, until. by reason of the hot sand getting between its hoofs. it sinks exhausted to the ground. The Eskimos pursue sea birds in kayaks, folloning them by the bubbles when they rise, and by tiring them out. catch them by hand. They also run down fanns in the spring, driving them into deep snow, a method formerly used by the Plains Indians for killing the floundering bison in winter.

Disguise, Traps, Snares, etc.—Patience and cunning of a higher order are seen in the devices by which the hunter conceals his approach and in the various nooses. snares, nets, traps, game pits and decoys found almost universally among primitive hunters. The Australian covers his head with waterweeds as he swims after waterfowl, or approaches the emu carrying a leafy branch to prevent the bird from noticing him. The African Bushman scatters a handful of dust over his head to make himself the same colour as the dry grass, or plaits a kind of saddle of grass, sticks some ostrich feathers in it and places it on his shoulders, holding up a long stick with the head curved to look like an ostrich. He imitates the actions of the bird, feeding, running, preening its feathers, and, always moving up wind, contrives to get as near as possible to the flock before discharging his poisoned arrow. Sometimes the imitation is too realistic, and the cock bird, resenting the advances of a rival, attacks the hunter. The North American Indians stalked deer disguised in deerskin, and put on a bison skin when stalking bison. Nooses, snares, traps and pitfalls are quite varied, and the peculiarities of the animal to be lured are carefully studied, human ingenuity being pitted against animal cunning. Firing the bush or prairie was a method of startling game, which could easily be trapped or knocked over in terrified flight. Fire forinerly was used by African natives for elephant hunting. When a herd was discovered a large circle surrounding it was fired and the entrapped animals, crowded together, bewildered by the flames and blinded by the smoke, would be unable to escape. In North America the Plains Indians used fire in killing bison.

Weapons.—Any stick or stone can be picked up at random to knock over birds and small game, but specially shaped clubs or throwing sticks are common, such as the African knobkerry and the Australian waddy, which developed into the more specialized trombash of the Upper Nile or the Australian boomerang (*q.v.*). The Australian spear is often only a stick, with its end hardened in the fire, though barbs may be added, or stone heads fixed in with "gum." The knife is a sharpened stone or is made of the leg bone of the emu. In Australia! as in arctic America, the spear is propelled by the spear thrower to give greater range. Except in Australia bows and arrows are universal among primitive hunters, varying according to the skill of the maker, the materials at his disposal and the prospective victims. The blowpipe or blowgun is more silent than bow and arrow and, with its poisoned darts. is one of the deadliest weapons in the hands of the primitive hunter.

See BOW AND ARROW; WEAPONS, PRIMITIVE.

Poisons.—Poisons are both animal and vegetable, and consist of many ingredients which are mixed with secrecy and magic. The central Australians catch emu by pounding up pituri (*Duboisia hopwoodi*) leaves with water as a bait; the bird becomes stupefied and is easily speared. In parts of the Amazon region the poison is assaca sap. The Macusi of British Guiana make their famous *curare* (*q.v.*) poison from the climbing *Strychnos toxifera,* mixed with other plants, adding black and red ants, and the poison fangs of snakes. The Punan poison in Borneo is the dried juice of the upas tree. The Bushmen of south Africa have a wide range of vegetable poisons, including *Strychnos, Euphorbia, Digitalis, Strophanthus* and the "Bushman poison bush," *Acokanthera venenata.* They add snake poison glands, poisonous spiders and scorpions, and in particular the little and specially deadly caterpillar called *"ngwa."*

Dogs.—Dogs have long been used to track and kill game, and their remains are found in deposits of Neolithic and earlier ages. The hunting dogs of the Lilloet of British Columbia were carefully trained and treated: one good dog was worth a large dressed elk skin. Among the Eskimo seal hunting would be scarcely possible without the help of dogs to smell out the breathing holes under the snow. Dogs help the Labrador Eskimo in hunting the polar bear.

Among the Gilyaks of the Amur river region, Siberia, the dog is held in high esteem, for at death the soul of the hunter is believed to pass into his favourite dog, which is fed with choice food and finally sacrificed on his master's grave.

The Nagas of northeastern India hunt in large numbers while the dogs drive out the game. Custom provides for the dogs (or their owners) a share of the quarry, known as the "dog's share."

The "dog's share" also is a recognized part of the spoil in Africa and in Melanesia.

Fishing

Fishing is commonly accessory to hunting and as widely distributed but more restricted in its range, since purely fishing peoples are found only on the banks of large rivers or lakes or on sea coasts. There: however, if the fish are abundant, fishers are able to maintain a more settled life than hunters on land, supporting themselves entirely on their catch, for food and trade. They are also less isolated than hunting peoples. Fish are not easily exterminated, and large groups can live in fishing villages, while the water provides a means of intercommunication.

There are tribes among whom fish forms the staple food the year round. The Indians on the banks of the great rivers of northwest America. where sturgeon grow to an extraordinary size, could catch and dry enough fish to last from one season to the next, and if not. there was scarcely a month in which some species of salmon could not be caught. The Eskimo are great fishermen and in the winter live mainly on sea or river produce. In the summer the women fish while the men hunt, and dried or frozen fish and seal meat form the winter provisions. At the extremity of the South American continent the coast-dwelling Fuegians fish from their frail boats made of bark and train their dogs to assist them by plunging into the water and driving the fish. Fishing is important on all the great rivers of Siberia. The Gilyaks and Golds of the Amur river live entirely on fish and on the bears which crowd down to join in the fishing; when the salmon run. Transparent fish skin supplies the windows for their semi-subterranean houses, and, in former days, the clothing was of salmon skin! ornamented with carp skin, a fashion later abandoned, although fish skin shoes are worn in the summer.

In Africa many people living on the banks of the great rivers or on the shores of the great lakes are mainly if not entirely dependent on fishing. Throughout the islands of the Pacific, fish, dugong and turtle are especially welcome as a change in the ordinary vegetable diet. In some islands anything connected with fishing is considered sacred; the type of fish-eaten by pregnant women, priests and other special groups may be circumscribed. In southeastern Asia! in the Malay archipelago and on the Chinese coast. are families and groups of families who seldom land on shore and never settle there for any length of time. Their homes are their boats, and fishing is their livelihood, supplemented by trade, or, in former times, by piracy.

Simplest Methods. — The most primitive fishing methods consist merely in the collecting; the fish are caught by hand. speared or shot with bow and arrow. The .Australians catch catfish with their feet, or, stirring up the water, hit or spear the fish coming to the surface. The African Bushmen spread grass on the surface of a pool, then, wading in, push the grass and fish into the shallows where they are easily caught. Farther north, near Stanley pool (Belgian Congo). as the river shrinks in the dry season, fish are scooped out of pockets in the rocks with gourds. a pint or more at a dip. And when the *sukai*, the "fish of fishes" (Onchorynchus), swam up the Fraser river (British Columbia) to spawn or the oolichan (*Thaleichthys pacificus*) choked the river in a plentiful run. the Salish Indians speared them in hundreds or scooped them up in buckets.

Weapons and Nets. — Spears, bows and arrows are the principal weapons for fishing as for hunting, to which may be added harpoons for larger fish and sea mammals. Nets are fairly general from the small hand nets, mainly used by women and children in shallow water and at low tide, to enormous seine or drag nets stretching right across reaches of the rivers or shallows of the sea; but the use of hook and line, though found among many primitive fishers, is not universal. The Andamanese. most skillful fishermen: used no hook or line; the central Australians had no hooks before the coming of the white man, and neither nets nor hook and line were known to the Tasmanians. The Bushmen have barbed harpoons for fishing, but rely on baskets instead of nets. In Torres straits the Murray islanders wade into the sea with conical baskets to scoop up the sardinelike shoals of *tup*. In central Australia nets made of rushes, without floats or sinkers, are stretched from tree to tree or stakes. and left there. If a man wants some fish: he swims out and helps himself.

Fire and Poison. — In fishing fire is man's ally, as in hunting, and fish are everywhere lured to destruction by the light of a torch. Poison is also commonly used. In Africa circles of *Euphorbia* stakes are planted in a river, and the fish become entangled and stupefied; or bruised stems of poisonous plants are thrown in. and the helpless fish float to the surface. The Polynesians mix *Tephrosia piscatoris* or *Barringtonia speciosa* with taro as a poison bait and catch the fish by hand.

Dogs and Suckerfish. — The dog is occasionally used to drive fish (*e.g.*, by the Fuegians, by the Ainu of Japan and in some places in England and Ireland) as otters are trained on the Yangtze; while in Chinese lakes and canals cormorants dive for fish: with a cord round their necks to prevent the catch from being swallowed. In Australia and Torres straits, as in Central America: suckerfish (*Echeneis naucrates* or *remora)* are used for catching small turtle. The fish is thrown out of a canoe with a line attached to the tail and attaches itself to the turtle. The line may then be drawn in, together with the turtle, or may serve as a guide to a man who swims down and gives the turtle a finishing blow.

HUNTINGDON, EARLS OF. GEORGE HASTINGS, first earl of Huntingdon[1] (*c.* 1488–1545). was the son and successor of Edward. second Baron Hastings (d. 1500), and the grandson of William. Baron Hastings. who was put to death by Richard III in 1483 He mas created earl of Huntingdon in 1529, and he was one of the royalist leaders during the suppression of the rising known as the Pilgrimage of Grace in 1536.

His eldest son FRANCIS, the second earl (c. 1514–1561), was a close friend and political ally of John Dudley, duke of Northumberland. sharing the duke's fall and imprisonment after the death of Edward VI in 1553; but he was quickly released, and was employed on public business by Mary.

His brother Edward (*c.* 1520–1j72) was one of Mary's most valuable servants; a stout Roman Catholic. he was master of the horse and then lord chamberlain to the queen, and was created Baron Hastings of Loughborough in 1558, this title becoming extinct when he died.

The second earl's eldest son HENRY, the third earl (*c.* 1535–1595), married Korthumberland's daughter Catherine. His mother was Catherine Pole (d. 1576), a descendant of George, Duke of Clarence; and, asserting that he was thus entitled to succeed Elizabeth on the English throne, Huntingdon won a certain amount of support, especially from the Protestants and the enemies of Rlary, queen of Scots. In 1572 he was appointed president of the council of the north and during the period between the flight of Mary to England in 1568 and the defeat of the Spanish armada, twenty years later, he was frequently employed in the north of England. He was for a short time in 1569 one of the custodians of Mary. Lady Elizabeth Hastings (1682–1739), daughter of Theophilus, the seventh earl, was famous for her charities and her piety. Her beauty drew encomiums from Congreve and from Steele in the pages of the *Tatler,* and her other qualities were praised by William Law. She was a benefactor to Queen's college, Oxford. THEOPHILUS (1696–1746), the ninth earl, was the husband of the famous Selina, countess of Huntingdon (*q.v.*). The earldom became dormant in 1789, and was not revived until 1818.

See H. N. Bell, The *Huntingdon Peerage* (1820).

HUNTINGDON, SELINA HASTINGS, COUNTESS OF (1707–1791), English religious leader and founder of a sect of Calvinistic Methodists, known as the Countess of Huntingdon's

[1]The title of earl of Huntingdon had previously been held in other families (see HUNTINGDONSHIRE). The famous Robin Hood (*q.v.*) is said to have had a claim to the earldom.

Connection, was the daughter of Washington Shirley, 2nd Earl Ferrers. She was born at Stanton Harold, near Ashby-de-la-Zouch, Leicestershire, on Aug. 24, 1707, and in 1727 married Theophilus Hastings, 9th earl of Huntingdon. In 1739 she joined the first Methodist society in Fetter Lane, London. On the death of her husband in 1746 she threw in her lot with Wesley and Whitefield in the work of the great revival. Isaac Watts, Philip Doddridge and A. M Toplady were among her friends. In 1748 she gave Whitefield a scarf as her chaplain, and he frequently preached in her London house in Park Street to audiences that included Chesterfield, Walpole and Bolingbroke. In her chapel at Bath there was a curtained recess dubbed "Nicodemus's corner," where some of the bishops sat incognito to hear him Lady Huntingdon spent her ample means in building chapels in different parts of England, *e.g.*, at Brighton (1761), London and Bath (1765), Tunbridge Wells (1769), and appointed ministers to officiate in them. under the impression that as a peeress she had a right to employ as many chaplains as she pleased In 1j68 she converted the old mansion of Trevecca, near Talgarth, in South Wales, into a theological seminary for young ministers for the connection.

Up to 1779 Lady Huntingdon and her chaplains continued members of the Church of England, but in that year the prohibition of her chaplains by the consistorial court from preaching in the Pantheon, a large building in London rented for the purpose by the countess, compelled her, in order to evade the injunction, to take shelter under the Toleration Act. This step placed her legally among dissenters. Till her death in London on June 17, 1791, Lady Huntingdon continued to exercise an active, and even autocratic, superintendence over her chapels and chaplains. She successfully petitioned George III. in regard to the gaiety of Archbishop Corn\\-allis's establishment, and made a vigorous protest against the anti-Calvinistic minutes of the Wesleyan Conference of 1770, and against relaxing the terms of subscription in 1772. Her 64 chapels and the college were bequeathed to four trustees. In 1792 the college was removed to Cheshunt, Hertfordshire. where it remained till 1905, when it was transferred to Cambridge.

See The Life of the Countess of Huntingdon (2 vols., *1844)*; A. H. New, *The Coronet and the Cross, or Memorials of Selina, Counters of Huntingdon* (1857); **Sarah** Tyler, *The Countess of Huntingdon and her Circle* (1907).

HUNTINGDON, a municipal borough and county town in the Huntingdon parliamentary division of Huntingdonshire. Eng.. on the Ouse. 60 mi. N. of London by road. Pop. (1951) 5,282. Area **3.3** sq.mi. Huntingdon (*Huntandun* in 921) was recovered from the Danes about 921 by Edward the Elder. who raised a fortress there. probably on the site of the Danish defenses. but in 1010 the Danes again destroyed it. A castle was built by order of William the Conqueror to guard the river crossing but it was among those destroyed by order of Henry II in 1174. At the time of Domesday Book Huntingdon n-as a royal borough. Three monasteries and three hospitals were founded and 16 parish churches built in mediaeval times. but by 1j50 only 3 churches and one hospital remained. The borough was incorporated by Richard III in 1484. and in 1630 Charles I granted a new charter. which remained in operation until 1835 The burgesses were represented in parliament by two members from 1295 to 1867 and by one until 188j when representation ceased. Huntingdon owed its prosperity to its situation on the Roman Ermine street which made it a coaching centre. It is now the centre of an agricultural area with other industries making beer. soft drinks, hosiery. foodstuffs and electrical equipment.. Ornamental plants are grown. During the Civil War it was several times occupied by the royalists though they sacked it in 1645. It forms a twin ton-n with Godmanchester (*q.v.*) with which it is linked by an old bridge (*c.* 1300).

The ton-n is mainly Georgian and consists basically of one street. in the centre of nhich is the market place where are All Saints' church, the mother church of the borough. which was rebuilt between 1475 and 1520, the town hall (1745) and the 17th-century Walden's house. now the County Council offices. The parish church of St. Mary is on the site of the Augustinian priory in which David Bruce. Scottish earl of Huntingdon. was buried. Some Norman remains of the 1ath-century hospice of St. John the Baptist were incorporated in the buildings of Huntingdon grammar school. once attended by Oliver Cromwell. who was born in the town. and by Samuel Pepys. Hinchingbrooke house. chiefly of the 16th century and the seat of the Cromwell family. occupies the site and preserves the plan of a Benedictine nunnery.

HUNTINGDONSHIRE (abbr. Hunts). an east midland county of England, bounded north and west by Northamptonshire, southwest by Bedfordshire and east by Cambridgeshire.

Physical Features.——All the stratified rocks are of Jurassic age, except a small area of Lower Greensand north of Potton. The Greensands form low, rounded hills. A narrow strip of Inferior Oolite reaches from Thrapston by Oundle to Wansford near Peterborough. It is represented about Wansford by the Northampton Sands and by a slight development of the Lincolnshire Limestone. The Great Oolite Series has at the base the Upper Estuarine Clays; in the middle. the Great Oolite Limestone. which forms the escarpment of Alwalton Lynch; and at the top, the Great Oolite Clay. The Cornbrash is exposed along part of the Billing brook and near Yaxley. Over the remainder of the county the lower rocks are covered by Oxford Clay, about 600-ft. thick. All the strata have a general dip southeast. Much glacial drift clay with stones covers the older rocks; it is a bluish clay, often containing masses of chalk. The fens on the eastern side of the county are underlain by Oxford Clay. which here and there projects through the prevailing newer deposit of silt and loam. There are usually two beds of peat or peaty soil separated by a bed of marine deposits. Black loamy alluvium and valley gravels, the most recent deposits, occur in the valleys of the Ouse and Nene. Calcareous tufa is formed by the springs near Alwalton. Oxford Clay is dug for brickmaking at Fletton and Warboys.

The Bedford Levels occupy about 50,000 ac. in the northeast. The Ouse skirts the borders of the county near St. Neots. and after flowing north to Huntingdon runs eastward past St. Ives into Cambridgeshire on its way to the Wash. The Kym. from Northamptonshire. joins the Ouse at St. Neots. while the Alconbury brook falls into it at Huntingdon. The Nene forms for 1j mi. the northwestern border of the county and quitting it near Peterborough. enters the Wash below Wisbech. in Cambridgeshire. The course of the old Sene river flows eastward midway between Huntingdon and Peterborough, and about 1½ mi. N.E. of Ramsey it is intersected by the Forty Foot. or Yermuyden's drain, a navigable cut connecting it with the old Bedford river in Cambridgeshire.

History and Antiquities.— Flint implements of the Lower Palaeolithic Age, together with contemporary mammalian bones, are found in most of the gravel workings of the Nene and Ouse valleys. By the latter 1950s, however, no remains of the Upper Palaeolithic or Mesolithic ages had been identified. It is along these same areas of gravel and alluvial soil that there is most evidence of prehistoric settlement. Surface finds of chipped flint tools and flakes are common and can be attributed to the Neolithic and succeeding Bronze ages. During the Bronze Age the fen areas became drier and there, too. tools and weapons ha e frequently been found.

Population was scarce in the immediate pre-Roman Iron Age but after the Roman Conquest most of the clay uplands were occupied in addition to the valleys and there is evidence of trade along the waterways. Small towns were built along the Roman Ermine street at Godmanchester and Chesterton and at the latter pottery making became an important industry.

There is no evidence of early Saxon settlement except in the extreme north and south, the area between the Ouse and Nene being almost devoid of pagan cemeteries. The county was probably divided tribally betn-een the Sweodora (west) and the South Gyrwas (east).

After their conquest of East Anglia in the latter half of the 9th century. Huntingdon became an important seat of the Danes. About 921 Edward the Elder wrested the fen country from the Danes and a few years later the district was included in the earldom of East Xnglia. Religious foundations were established at Ramsey and St. Neots by the Benedictines in the 10th century and a cell at St. Ives before the Conquest. In 1011 Huntingdonshire

was again overrun by the Danes and in 1016 was attacked by Canute. A few years later the shire was included in the earldom of Thored (of the Middle Angles), but in 1051 it was detached from Mercia and formed part of Harold's East Anglian earldom. Shortly before the Conquest. however. it was bestowed on Siward, and became an outlying portion of the earldom of Northumberland passing to David of Scotland. After the separation of the earldom from the crown of Scotland in the Bruce and Balliol disputes. it was conferred on various persons and finally in 1529, on George, Baron Hastings, whose descendants now hold it.

The Norman Conquest was followed by a general confiscation of estates. only four or five thanes retaining lands. In the Domesday survey it is recorded that the abbot of Ramsey held 26 manors while most of the other holdings were divided between the crown and the sheriff, Count Eustace of Boulogne. This shrievalty was united with that of Cambridgeshire by 11jj and remained united except from 1636 to 1643. when they were independent of each other. The boundaries of the county have scarcely changed since the time of the Domesday survey: except that parts of the Bedfordshire parishes of Everton. Pertenhall and Keysoe and the Northamptonshire parish of Hargrave were then assessed under this county. At Huntingdon the castle remains as an earthwork, and the castle at Kimbolton is a mansion. restored by Sir John Vanbrugh and later acquired by Kimbolton grammar school. Both Hinchingbrooke,house (16th century), once occupied by the Cromwells and later by the earls of Sandwich, and Elton hall (1664) are mansions with art collections.

At the end of the 11th century Huntingdonshire was constituted an archdeaconry, comprising the deaneries of Huntingdon, St. Ives, Yaxley, St. Neots and Leightonstone. and the divisions remained unchanged until the creation of the deanery of Kimbolton in 1879. The county was transferred from the diocese of Lincoln to that of Ely in 1837. During the reign of William the Conqueror the Benedictines established a nunnery at Winchingbrooke. while in 1147 the Cistercian abbev was founded at Sawtry. In the same century the Austin canons established a priory at Huntingdon, while another at Stonely is first mentioned in 12 74. Toward the end of the 13th century the Austin friars had a house at Huntingdon.

Fine bridges span the Ouse at Huntingdon (*c.* 1300), St. Ives (c. 1400) and St. Neots (c. 1600). Great Paxton church dates from the 11th century. Outstanding 12th-century churches are at Alwalton, Bury. Eynesbury. Fletton. Haddon. Ramsey and Southoe and 13th-century churches at Alconbury Kimbolton and Yaxley. St Neots is a beautiful example of the late 1jth century

In 1174 Henry II captured and destroyed Huntingdon castle and during the Wars of the Roses the tonn was sacked by the Lancastrians Huntingdon although the birthplace of Oliver Cromwell. had royalist sympathies in the Civil War. St. Neots market square was the scene of a battle in 1648 when a royalist force was routed and the earl of Holland. captured. In the reign of Charles I Nicholas Ferrar founded the famous religious community at Little Gidding.

Industries. — Although Huntingdonshire has always been mainly an agricultural county. there was, even during mediaeval times, a considerable volume of trade and industry based on navigation between the Wash and the riverside towns of St. Neots, Huntingdon. Godmanchester and St. Ives. At the latter was held in the 13th century an annual cloth fair of international importance. This trade was intensified when locks on the Ouse were completed as far upstream as St. Neots in the early 17th century.

These towns still support a variety of light industries and in the north at Fletton is one of the principal brickmaking centres of the country. . Other chief industries, in order of persons employed in the late 1950s, were electrical engineering. plastics. canning, woodworking. building, motor engineering, agricultural engineering, hosiery manufacture. milling, paper manufacture and printing.

Agriculture. — In 1954 the total acreage under crops and grass was 198,214. Of this figure arable and temporary grass accounted for 154.414 ac.. the remainder being permanent grass. The agricultural depression of the 1930s was the cause of a large increase in the acreage of rough grass and derelict land in the county. During World War II. large drainage and reclamation schemes were carried out; thereafter a high standard of husbandry was maintained. The farm land of most of the county is a heavy clay soil. and the chief crops gronn are wheat. barley. potatoes, sugar beets and clover. In the northeast there is an area of rich fenland, the town of Rarnsey being the centre of this district. The main crops grown there are potatoes, sugar beets and some vegetable crops such as carrots. Although three-quarters of the county was arable in the late 19jos, livestock returns showed increases in everything, except sheep. over 1939 figures. Milk and beef were produced in about equal proportions.

Gravels of the Ouse valley form the chief source of water, but supplies also come from Northamptonshire and Cambridgeshire.

Woodwalton fen (514 ac.), first endowed as a nature reserve in 1919, has a rich fen flora and is the place where the large copper butterfly was reintroduced into England from the Netherlands about 1929. Holme fen and Monk's wood are also nature reserves.

Communications. — The middle of the county is traversed from south to north by the main line of the eastern region of British railways, which enters it at St. Neots and passing by Huntingdon leaves it at Peterborough. From St. Ives lines run northeast to Ely (Cambridgeshire) and north to Wisbech (Cambridgeshire!. The northwestern border is served by lines between Peterborough and Wansford. There were about 648 mi. of highways in the late 1950s.

Population and Administration. — The area of the administrative county is 365.7 sq.mi. with a population (1961) of 79.579. The county contains four hundreds. The municipal boroughs are Godmanchester (pop. 1951. 2.502), Huntingdon (5,282), the county town! and St. Ives (3,078); the urban districts are Old Fletton, Ramsey and St. Neots; there are four rural districts. The county is in the southeastern circuit and assizes are held at Huntingdon. It has one court of quarter sessions and is divided into six petty sessional divisions. The county returns one member to parliament.

HUNTINGTON, a U.S. family whose fortune was established in the development of western railroads.

COLLIS POTTER HUNTINGTON (1821-d goo), U.S railroad builder. was born at Harminton. Conn.. Oct. 22, 1821. He went to work uhen he was 14 and at the age of 28 he set out for the California gold fields. An early advocate of an overland railway. Huntington, mith Mark Hopkins, Leland Stanford and the Crocker brothers. incorporated the Central Pacific Railroad of California in 1861. Huntington secured government land grants and financial aid to construct a line from the Pacific coast to a meeting with the Union Pacific. Later he turned his attention to the building of the Southern Pacific and completed the 9.600-mi. line. He also made the Chesapeake and Ohio a profitable line by extending its eastern terminus and operating it in connection with the Southern Pacific. Huntington died Xug. 13, 1900, near Raquette Lake, N.Y.

His nephew, HENRY EDWARDS HUNTINGTON (1850–1927), was born at Oneonta, N.Y, Feb. 27, 1850. After working in hardware firms, in 1871 he supervised one of his father's sawmills, and ultimately held important executive positions with several railroads and promoted electric railway and utility development in California, particularly in Los Angeles. After 1910 he devoted considerable time to assembling a choice art collection and library. especially rich in rare editions of early English literature and in Americana. The library and mansion housing it were deeded to the U.S. public in perpetuity, and a trust fund of $8,000,000 was established for further additions, research and publications. He died in Philadelphia. hlay 23. 1927.

ARCHER MILTON HUNTINGTON (1870–1955), the adopted son of C. P. Huntington, American Hispanic scholar, was born in New York city. March 10, 1870. While studying in Spain. he specialized in Spanish archaeology. In 1904 he founded the Hispanic Society of America, to which he gave a home, endowment and collections

He died Dec. 11, 1955, in Bethel, Conn. (W. H. D.)

HUNTINGTON, DANIEL (1816–1906), U.S. painter of the romantic school. was born in New York on Oct. 14, 1816. In 1835 he studied with S. F. B. Morse, and produced "A Bar-Room Politician" and "A Toper Asleep." Subsequently he painted some landscapes on the Hudson river and in 1839 went to Rome. On his return to America he painted portraits and began the illustration of *Pilgrim's Progress*, but his eyesight failed and in 1844 he went back to Rome. Returning to New York in 1846 he devoted his time chiefly to portrait painting, although he had painted many genre, religious and historical subjects. He was president of the National academy, 1862–70, and again 1877–90. He died on April 19, 1906, in New York city.

HUNTINGTON, ELLSWORTH (1876–1947), U.S. geographer well known for his doctrines with regard to the influence of climate on civilization. was born at Galesburg, Ill., on Sept. 16, 1876, and educated at Beloit college, Wis. (A.B., 1897), Harvard (A.M., 1902) and Yale (Ph D.. 1909). From 1897 to 1901 he was an instructor in Euphrates college, Harput (Turkey) and in 1901 he carried out an exploration of the canyons of the Euphrates river for which he was awarded the Gill memorial of the Royal Geographical society. In 1903–06 he traveled widely with expeditions in central Asia, recorded in his books *Explorations in Turkistan* (1905) and *The Pulse of Asia* (1907), the latter one of his best. He then taught for some years at Yale. as instructor and later as assistant professor of geography; in 1917 was appointed research associate. In 1909 he headed the Yale expedition to Palestine and Asia and in 1911 published *Palestine and Its Transformation.* From 1910 to 1913 he was research associate of the Carnegie Institution of Washington and made climatic investigations in the United States. Mexico and Central America. His work was notably concerned with climate and its relation to land forms. geological and historical changes, and to human activities and the distribution of civilizations. His researches bore fruit in *The Climatic Factor* (1914), *Civilization and Climate* (1915; rev. ed., 1924) and *World Power and Evolution* (1 919). These interests led him to investigate the causes of climatic variation, in *Climatic Changes*, with S. S. Yisher (1922), and *Earth and Sun* (1923). In addition to a number of textbooks, several in collaboration, other important works are *The Character of Races* (1924); *The Pulse of Progress* (1926); *The Human Habztat* (1927). In later years he wrote extensively on heredity and eugenics. A vigorous and prolific writer nho as a geographer gained a world-wide reputation, his last book, *Mainsprings of Civilization* (194j) provides an epitome of much of his wide-ranging earlier work. He died on Oct. 17, 1947, at New Haven, Conn.

See *Geographical* ***Review,*** pp. 153–55 (1948). (*G.* My)

HUNTINGTON, SAMUEL (1731–1796), U.S. jurist and public official, was born at Windham. Conn.. on July 3, 1731. He received only a common school education, but read widely and in 1753 began to study law. In 1760 he settled at Norwich, Conn., nhere he achieved rapid and extensive success in his practice. He was elected to the assembly of the Colony from Norwich in 1764 and served until he was appointed associate justice of the supreme court in 1774. The following year he was made a member of the governor's council. Despite these royal appointments he sided with the Colonies in the impending struggle with the mother country, and in 1775 became a member of the Connecticut council of safety. Later in that year he nas elected a delegate to the Continental Congress, and as such in 1776 voted for and signed the Declaration of Independence. He nas a member of the congress until 1783. and served from Sept. 1779, to July 1781, as its president, succeeding John Jay in that office He returned to Connecticut in 1783 to be made chief justice of the supreme court in 1784, lieutenant-governor in 178j and governor in 1786. The latter office he retained by successive annual re-elections until his death at Norwich on Jan. 5, 1796.

HUNTINGTON, a city of West Yirginia, U.S., and seat of Cabell county, lies on the Ohio river just below the mouth of the Guyandot river near the point where Ohio, Kentucky and West Virginia meet. It is an important railway, trading and manufacturing centre about 50 mi. W. of Charleston.

Huntington was founded and incorporated in 1871 as the western terminus of the Chesapeake and Ohio railroad, on the site of Molderby's Landing, a stretch of farm land that extended along the Ohio river from the west bank of the Guyandot It was named for Collis P. Huntington, president of the railroad, who delegated his brother-in-law Col. Delos A. Emmons to purchase 21 farms embracing 5.000 ac. of level land along the river bank. He then employed Rufus Cook, a Boston engineer, to lay out a city of broad streets and boulevards. In a spirited election in 1887, the seat of Cabell county was moved from Barboursville to Huntington.

The yards, division point, general locomotive and car shops of the Chesapeake and Ohio railway were established there and the city grew rapidly.

Apart from the railway shops and offices there are foundries. nickel and nickel alloy plants, and factories producing electrical equipment, glass, cement, furniture and food products. There are a number of wholesale houses, and oil and gas interests. The Ohio river furnishes facilities for shipment of coal and for gasoline from Louisiana and Texas.

Huntington is the seat of a state mental hospital and six private hospitals. The oldest house of the city is preserved in Ritter park, where there is also an art gallery.

Marshall college (state supported) with an enrollment of about 3,500 was founded as Marshall academy in 1837 and named for Chief Justice John Marshall.

Huntington suffered from floods in 1884, 1913, 1936 and 1937; the 1937 flood was particularly disastrous. An 11-mi. wall was constructed with locks and dams giving maximum flood protection. and making Huntington one of the few walled cities of North America.

Pop. (1960) 83,627. (For comparative population figures *see* table in WEST VIRGINIA: *Population.*) The Huntington-Ashland standard metropolitan statistical area had a population of 254.780 in 1960. (K. K. McC.)

HUNTINGTON PARK, a commercial, industrial and residential city in south-central Los Angeles county, Calif., U.S. It is sometimes called the "shopkeeper of southern Los Angeles," and is located 7 mi. S. of the Los Angeles civic centre.

Throughout much of the 19th century, Huntington Park was a portion of the Rancho San Antonio. It remained a possession of the Lugo family from 1810 until 1865. After passing through a succession of hands without development, it was acquired by real estate subdividers after 1900. These men advertised the area as La Park, but in 1904 the name was changed to Huntington Park, after Henry E. Huntington's Pacific Electric railroad was completed through the proposed city. In 1906 Huntington Park was incorporated as a California General Laws city. It adopted a city-manager form of local government in 1957.

It became a major centre for retail sales, supplying a populous area of about 350,000, and its manufactures include oil-well equipment, automobiles and parts, rubber goods. paints, steel, iron and heavy hardware. For comparative population figures *see* table in CALIFORNIA: *Population.* (J. M. Wo.)

HUNTINGTOWER, a village in the parish of Tibbermore, Perthshire. Scot.. on the Almond. 3 mi. N.W. of Perth. Huntingtower (originally Ruthven) castle was the scene of the Raid of Ruthven, when the Protestants under William, earl of Gowrie, kidnapped the boy king James VI, in 1582. The earl's sons were killed in the Gowrie conspiracy (1600), after which the Scots parliamenr ordered the barony to be known in future as Huntingtower. The castle has been restored. (G. S. P.)

HUNTLY, EARLS AND MARQUESSES OF. This Scottish title. in the Gordon family, dates as to the earldom from 1449, and as to the marquessate (the premier marquessate in Scotland) irom 1599. The first earl (d. 1470) was Alexander de Seton, lord of Gordon—a title known before 1408; and his son George (d. 1502), by his marriage with Princess Annabella (afterward divorced), daughter of James I of Scotland, had several children, including. besides his successor the 3rd earl (Alexander), a second son Adam (who became earl of Sutherland), a third son William (irom whom the mother of the poet Byron was descended) and a daughter Katherine. who first married Perkin

Warbeck and afterward Sir Matthew Cradock (from whom the earls of Pembroke descended). Alexander, the 3rd earl (d 1524), consolidated the position of his house as supreme in the north; he led the Scottish vanguard at Flodden. and was a supporter of Albany against Angus. His grandson George. 4th earl (1514–62), who in 1548 was granted the earldom of Moray, played a leading part in the troubles of his time in Scotland, and in 1562 revolted against Queen Mary and was killed in fight at Corrichie, near Xberdeen. His son George (d. 1576) was restored to the forfeited earldom in 1565; he became Bothwell's close associate —he helped Bothwell. who had married his sister, to obtain a divorce from her; and he was a powerful supporter of Mary till he seceded from her cause in 1572.

GEORGE GORDON, 1st marquess of Huntly (1562–1636), son of the 5th earl of Huntly. and of Anne. daughter of James Hamilton. earl of Arran and duke of Chatelherault. was born in 1562, and educated in France as a Roman Catholic. He took part in the plot which led to the execution of blorton in 1581 and in the conspiracy which delivered King James VI from the Kuthven raiders in 1583. In 1588 he signed the Presbyterian confession of faith. but continued to engage in plots for the Spanish invasion of Scotland. On Nov. 28 he was appointed captain of the guard, and while carrying out his duties at Holyrood his treasonable correspondence was discovered. James. however, pardoned him. In April 1589 he raised a rebellion in the north. but was obliged to submit. and after a short imprisonment in Borthwick castle was again set at liberty. He next involved himself in a private war with the Grants and the Mackintoshes, who were assisted by the earls of Atholl and Murray; and on Feb. 8. 1592, he set fire to Murray's castle of Donibristle in Fife. and stabbed the earl to death with his own hand. This outrage. which originated the ballad "The Bonnie Earl of Moray," brought down upon Huntly his enemies. who ravaged his lands. In December the "Spanish Blanks" were intercepted (see ERROLL, FRANCIS HAY. 9TH EARL OF). two of which bore Huntly's signature, and a charge of treason was again preferred against him. On Nov. 26. he and the other rebel lords were freed from the charge of treason. heing ordered at the same time. however, to renounce Komanism or leave the kingdom. On their refusal they were attainted. Subsequently Huntly joined Erroll and Bothwell in a conspiracy to imprison the king. Huntly and Erroll gained a victory over the king's troops at Glenlivat. but his castle of Strathbogie was blown up by James, and he left Scotland about March 1595. He returned secretly. submitted to the Kirk and was restored to his estates. In 1599 he was created a marquess and. with Lennox. appointed lieutenant of the north. He was treated with great favour by the king. and was reconciled with Murray and Argyll. Doubts. however. as to the genuineness of his abjuration again troubled the Kirk. On March 19. 1607, he was summoned before the privy council. Huntly thereupon went to England and appealed to James himself. He was excommunicated in 1608, and imprisoned in Stirling Castle until Dec. 10, 1610, when he signed again the confession of faith. He was again imprisoned in 1616. At the accession of Charles I Huntly lost much of his influence at court. For the private war waged against the Crichtons from 1630 onward, he was again summoned before the privy council in 1635, and was imprisoned in Edinburgh castle. He died at Dundee on June 13, 1636, after declaring himself a Roman Catholic.

GEORGE GORDON, 2nd marquess of Huntly (d. 1649), his eldest son by Lady Henrietta, daughter of the duke of Lennox, was brought up in England as a Protestant, and created earl of Enzie by James I. His influence in Scotland was employed by the king to balance that of Argyll in the dealings with the Covenanters. In the Civil War he took the king's side, and in 1647 was excepted from the general pardon; in March 1649, he was beheaded by order of the Scots parliament at Edinburgh. The attainder was reversed by parliament in 1661.

HUNTLY, a small burgh of Aberdeenshire, Scot., at the confluence of the Deveron and Bogie, salmon and trout rivers, 39 mi. N.W. of Aberdeen by road. Pop. (1961) 3,952. It is a market, angling and holiday town and the centre of a large agricultural area with industries that include the weaving of woolen cloth and the making of agricultural machinery. Huntly is built on a rectangular plan, and in the market square are the "Stan'in stanes" of Strathbogie, probably prehistoric, and the Brander library, above which is the MacDonald museum. George MacDonald (*q.v.*) mas born in Huntly. The Gordon schools were founded in 1839. Huntly (Strathhogie until 1506) castle, ½ mi. N. and now in ruins, was owned in the 14th century by the Gordons, who rebuilt it. It was blown up in 1594, restored in 1602 and in 1752 Huntly lodge (later a hotel) was built from its stones.

HUNTSVILLE, a city of northeastern Alabama, U.S., and the seat of Madison county, is about 85 mi. N. of Birmingham. It was founded in 1805 by John Hunt of Virginia, a Revolutionary War veteran, and was originally called Twickenham by Leroy Pope, a kinsman of Alexander Pope who had settled in the area, in memory of the English poet's home. In 1811 the settlement was incorporated as Huntsville by the territorial government, the first in Alabama to receive a city charter. It was the meeting place of the convention that framed the first state constitution (1819). During the Civil War, the town was occupied by Federal troops (1862). After the war, its former position as a commercial centre for hay, cotton, corn and tobacco was restored.

By mid-20th century the development of the U.S. Redstone arsenal as a centre for rocket and guided missile research had resulted in considerable growth of the city in area and population. The city's manufactures include textiles, sheet metal products, cottonseed oil, stoves, wire staples and farm implements. It is also known for its watercress nurseries. Monte Sano state park is nearby.

Huntsville has two Negro colleges, the Alabama Agricultural and Mechanical college (1875) and Oakwood college (1896).

The population of Huntsville in 1960 was 72,365. The standard metropolitan statistical area of Huntsville (Madison county) had 117,348 inhabitants in 1960. For comparative population figures see table in ALABAMA: Population. (B. CR.)

HUNYADI, JOHN (JANOS) (c. 1387–1456), Hungarian statesman and warrior, was the son of Vojk, a Magyarized Vlach who married Elizabeth Morzsinay. He derived his family name from the small family estate of Hunyad, in Transylvania. The epithet Corvinus, adopted by his son Matthias, was derived from another property, Piatra da Corvo. While a youth, he entered the service of King Sigismunc!, accompanied him to Frankfort in 1410; took part in the Hussite War in 1420, and in 1437 drove the Turks from Semendria. For these services he received numerous estates and a seat in the royal council. In 1438 King Albert II. made him ban of Szoreny, a most dangerous dignity entailing constant warfare with the Turks. On the death of Albert in 1439, Hunyadi supported the candidature of the young Polish king Wladislaus III. (1440), against the partisans of the Austrian candidate Ladislaus V., took a prominent part in the ensuing civil war and was rewarded by Wladislaus III. with the captaincy of the fortress of Belgrade and the voivodeship of Transylvania, which latter dignity he shared with his rival Mihaly Ujlaki.

The burden of the Turkish War now rested entirely on his shoulders. He won brilliant victories at Semendria (1441), near Hermannstadt (1442) and near the Iron Gates (1442). In 1443 he advanced across the Balkans, captured Niš, defeated three Turkish pashas, and, after taking Sofia, united with king Wladislaus' army and defeated Murad II. at Snaim. When he returned home (Feb. 1444), he had broken the sultan's power in Bosnia, Herzegovina, Serbia, Bulgaria and Albania. The Pope, the despot of Serbia (George Branković) and the prince of Albania (George Castriota) urged him on his return to resume the war and drive the Turks from Europe. All preparations were made, when Turkish envoys arrived in Hungary to conclude a ten years' truce. The pact was concluded, but broken when news arrived that a Venetian fleet had started to prevent the Sultan (who had retired to Asia Minor) from recrossing into Europe. In July the Hungarian army recrossed the frontier and advanced towards the Euxine coast to join the galleys. Branković, however, privately informed Murad of the advance, and prevented Castriota from joining it. On reaching Varna, the Hungarians found that the Venetian galleys had failed to prevent the transit of the sultan, who now confronted them with fourfold odds, and in Nov. 1444

they were utterly routed, Wladislaus falling on the field and Hunyadi narrowly escaping.

At the diet which met in 1445 a provisional government of five Magyar captain-generals, was formed, Hunyadi receiving Transylvania and the ultra-Theissian counties as his district; but the resulting anarchy became unendurable, and in June 1446 Hunyadi was unanimously elected governor of Hungary in the name of Ladislaus V., with regal powers. His first act as governor was to proceed against the German king Frederick III., who refused to deliver up the young king. After ravaging Styria, Carinthia and Carniola and threatening Vienna, Hunyadi's difficulties elsewhere compelled him to make a truce with Frederick for two years. In 1448 he received a golden chain and the title of prince from Pope Nicholas V., and immediately afterwards resumed the war with the Turks. He lost the two days' battle of Kosovo owing to the treachery of Dan, hospodar of Wallachia, and of his old enemy Branković, who imprisoned him at Semendria; but he was ransomed by the Magyars, and, after composing his differences with his enemies in Hungary, led a punitive expedition against the Serbian prince. In 1450 Hunyadi went to Pressburg to negotiate with Frederick the terms of the surrender of Ladislaus V. To refute the accusation made by his enemies that he was aiming at the throne, he resigned all his dignities into the hands of the young king, on his return to Hungary in 1453, whereupon Ladislaus created him count of Bestercze and captain-general of the kingdom.

Meanwhile the Turkish danger had again become pressing. In 1455 Hunyadi provisioned and armed the fortress of Belgrade at his own expense, and leaving in it a garrison under his brother-in-law Mihály Szilágyi and his eldest son László, he proceeded to form a relief army and a fleet of zoo corvettes. To the eternal shame of the Magyar nobles, he was left entirely to his own resources. His one ally was the Franciscan friar, Giovanni da Capistrano (see JOHN, SAINT), thanks to whose preachings Hunyadi's small mercenary army was reinforced by a host of peasant volunteers. On July 14, 1456, Hunyadi with his flotilla destroyed the Turkish fleet; on the 21st and 22nd he routed the forces investing Belgrade. forcing Mohammed to raise the siege. return to Constantinople, and thus securing the independence of Hungary for another 70 years. On Aug. 11, however, Hunyadi died of plague in his camp.

Hunyadi was one of Christendom's most glorious champions, and also a great statesman. He recognized the insufficiency and the unreliability of the feudal levies, and was one of the first to employ a regular army on a large scale. A man of average education, he owed his influence partly to his natural genius and partly to the transparent integrity and nobility of his character.

Bain, "The Siege of Belgrade, 1456," *Eng. Hist. Rev.* (1892); A. Bonfini, *Rerum ungaricarum libri xlv., editio septima* (1771).

HUNZA (also known as KANJUT) and **NAGAR,** two states of Pakistan, on the northwest frontier of Kashmir (*q.v.*) under the administration of the Gilgit agency. The two states, which are divided by a river which runs in a bed 600 ft, wide between cliffs 300 ft. high, are inhabited generally by people of the same stock, speaking the same language and professing the same form of the Moslem religion. Hunza has an area of 3,900 sq.mi. Formerly Hunza was the more prominent of the two, because it held possession of the passes leading to the Pamirs, and could plunder the caravans on their way between Turkistan and India. But they are both shut up in a recess of the mountains, and were of no importance until about 1889, when the advance of Russia up to the frontiers of Afghanistan: and the great development of her military sources in Asia, increased the necessity for strengthening the British line of defense. This led to the establishment of the Gilgit agency, the occupation of Chitral, and the Hunza expedition of 1891, n-hich asserted British authority over Hunza and Nagar. The country is inhabited by a Dard race of the Yeshkun caste speaking Burishki. Pop. of Hunza (1951) 15,691; of Nagar (1951) 18,333. Sagar has an area of 1,600 sq.mi. (See GILGIT.) The Hunza-Nagar expedition of 1891, under Colonel A. Durand. was due to the defiant attitude of the Hunza and Nagar chiefs toward the British agent at Gilgit. The fort at Silt was stormed. and after a fortnight's delay the cliffs (1,000 ft. high) beyond it were also carried by assault. The chief of Nagar was reinstated and the half brother of the raja of Hunza was installed as chief. Pakistan acquired control of the states after 1948.

HUON OF BORDEAUX, hero of romance. The French *chanson de geste* of Huon de Bordeaux dates from the first half of the 13th century. Huon. son of Seguin of Bordeaux, kills Charlot, the emperor's son: who had laid an ambush for him, without recognizing his assailant. He is condemned by Charlemagne to be hanged, but reprieved on condition that he visits the court of Gaudisse, the amir of Babylon, and brings back a handful of hair from the amir's beard and four of his back teeth: after having slain the greatest of his knights and three times kissed his daughter Esclarmonde. By the help of the fairy dwarf Oberon, Huon succeeds in this errand. in the course of which he meets with further adventures. The Charlot of the story has been identified by A. Longnon (*Romania* viii. 1–11) with Charles l'Enfant, one of the sons of Charles the Bald and Irmintrude. The poem exists in a later version in alexandrines. and, with its continuations; was put into prose in 1454 and printed by Michel le Noir in 1516, since when it has appeared in many forms, notably in a beautifully printed and illustrated adaptation (1898) in modern French by Gaston Paris. The romance had a great vogue in England through the translation (*c.* 1540) of John Bourchier. Lord Berners, as *Huon of Burdeuxe.* The tale was dramatized and produced in Paris by the Confrérie de la Passion in 1557, and in Philip Henslowe's diary there is a note of a perlormance of a play, *Hewen of Burdoche,* on Dec. 28, 1593. For the literary fortune of the fairy part of the romance see OBERON.

The *Chanson de geste* of Huon de Bordeaux was edited by F. Guessard and C. Grandmaison for the *Anciens poètes de la France* in **1860;** Lord Berners's translation was edited for the E.E.T.S. by S. L. Lee in 1883–85. *See* also *Hist. litt. de la France* (vol. xxvi., 1873); L. Gautier, *Les Épopées françaises* (2nd ed. vol. iii. pp. 719–773); A. Grai, I *complementi della Chanson de Huon de Bordeaux* (1878); M. Schweigel, "Esclarmonde," etc. in *Ausg. u. Abhandl. . . . der roman. phil.* (1889); *C.* Voretzsch, *Epische Studien,* vol. i. (1900).

HUON PINE, botanical name *Dacrydium franklinii,* the most valuable timber tree of Tasmania, Austr., member of the order Coniferae. It is a fine tree of pyramidal outline, 80 to 100 ft high and 10 to 20 ft. in girth at the base with slender. pendulous much-divided branchlets. densely covered with the minute scalelike sharply keeled bright green leaves. It occurs in Tasmania's swampy localities from the upper Huon river to Port Davey and Macquarie harbour, but is less abundant than formerly because of the demand for its timber, especially for ship- and boatbuilding. The wood is close grained and easily worked. See CONIFERS; GYMNOSPERMS.

HUPA, the most advanced and best-known Indian tribe of the Pacific coast division of the Athabascan linguistic stock. At mid-20th century about 600 lived near the lower Trinity river in Hoopa valley. northwestern California. Their traditional culture, shared by the Turok (*q.v.*) and Karok, was characterized by an economy of deer and elk hunting. salmon fishing and food gathering; canoes, frame houses of planks bearing individual names: clanless villages, a wealth aristocracy owning debt slaves, fishing places and oak groves, shell and woodpecker scalp currency, treasures of albino deerskins! fine basketry, huge obsidian blades? furs, etc.; little political authority but an intricate law of property; wealth displaying. dancing to the recitation of narrative magical formulas. Theirs was the southernmost efflorescence of the native culture characteristic of the north Pacific coast, though lacking the potlatch festivals, secret societies and masks, totem poles and carving art of the northern tribes.

See J. Goddard, "Life and Culture of the Hupa," *Univ. Calif. Publ. Amer. Archaeol. Etlzn.,* vol. i (1904); A. L. Kroeber, Bureau of American Ethnology *Bull. 78* (1925).

HUPEH (HU-PEI SHENG), a province in the central Yangtze

(*q.v.*) river valley in the heart of agricultural China. Area 72,394 sq.mi. Pop. (1957 est.) 30,790,000. The eastern part of the province (about two-thirds) is lowland. The Yangtze and its chief tributary. the Han, meander in great loops past a maze of shallow lakes the chief of which. the Tung-t'ing Hu (*q.v.*), lies just south of the border of Hunan. The western part (about one-third) is upland and rises to 5,000–6.000 ft. in the mountains of the Wu Shan and Ta-pa Shan. In the north the low T'ung-pai Shan divides the Han valley from the north China plain. On the east and southeast the ranges of the Ta-pieh Shan and Mu-fou Shan constrict the plain through which the Yangtze leaves the province.

Summers are hot and humid, winters relatively mild. The 300-day growing season and 47-in. average annual rainfall favour agriculture. The region is transitional between the rice and winter wheat realms. with rice dominant. This also is one of the three most important cotton regions of China. Maize, kaoliang, tea and sweet potatoes are other food crops, while soybeans, silk, hemp and tobacco are other industrial crops. Tung-nut–oil production from the western hills ranks high. In the late 1950s it was claimed that the production of food grains for the province had reached 21,940,000,000 catties (one catty averages $1\frac{1}{3}$ lb.); ginned cotton, 4,300,000 piculs (one picul averages $133\frac{1}{3}$ lb.); and vegetable oils, 6.020.000 piculs.

Iron ore at Ta-yeh and coking coal nearby form the basis for one of the most significant iron and steel complexes in China. with a steel plant built in the late 1950s at Huang-shih on the Tangtze near the southeast border. Gypsum is important, especially at Ying-ch'eng in the northwest.

The population is mostly concentrated in the eastern lowlands where the Han river joins the Yangtze at the great tricity metropolis of Wu-han (*q.v.*). This major industrial 'and commercial centre had a population of 2.146.000 in 1957. with the heavier concentration in Hankow, the most important city in central China. The first bridge over the Yangtze, constructed there in 1956, permits through traffic from Peking to Canton. Commercially, Wu-han (Hankow, Wu-ch'ang and Han-yang) municipality commands the gateway to the Szechwan basin in the west and to Hunan and Kweichow in the south and southwest. Ocean-going steamships reach Wu-han and transport products to Shanghai and abroad. Across the Han river bridge from Hankow is the heavy-industry centre of Han-yang. From the latter runs the great bridge across the Tangtze joining Hankow and the provincial seat of Wu-ch'ang. I-ch'ang (*q.v.*) and Sha-shih farther up the Tangtze in south central Hupeh are important provincial and commercial centres. South of Sha-shih is the Ch'ing-chiang (Kingkiang) flood detention basin or reservoir covering about 350 sq.mi. In the middle reaches of the Han river is the twin city of Hsiang-fan (Siangfan), consisting of Fan-ch'eng on the north bank and Hsiang-yang (Siangyang) on the south bank, handling the products of the Han basin.

Under the Manchus, Hupeh n-as originally part of the ancient province of Hu-kuang. After Nanking fell to the Japanese in Dec. 1937 during the Chinese-Japanese War, Hupeh was host province to the National government of China: Hankow being the temporary capital until the government moved to Chungking in Szechn-an. (H. J. Ws.)

HURD, RICHARD (1720–1808), English bishop and writer, was born at Congreve. Penkridge. Staffordshire, on Jan. 13, 1720, and educated at Emmanuel college. Cambridge, of which he became a fellow. He was ordained in 1734, and in 1748 he published some *Remarks* on an *Enquiry into the Rejection of Christian Miracles by the Heathens* (1746), by William Weston, a fellow of St. John's college, Cambridge. He prepared editions, which won the praise of Gibbon. of the *Ars poetica* and *Epistola ad Pisones* (1749), and the *Epistola ad Augustum* (1751) of Horace. A compliment in the preface to the edition of 1749 led to a lasting friendship with William Warburton, through whose influence he was appointed one of the preachers at Whitehall in 17jo.

In 1765 Hurd became preacher at Lincoln's Inn. and in 1767 archdeacon of Gloucester. In 1768 he delivered at Lincoln's Inn the first Warburton lectures. which were published in 1772 as *An Introduction to the Study of the Prophecies concerning the Christian Church*. He became bishop of Lichfield and Coventry in 1774 and tno years later tutor to the prince of Wales and the duke of York. In 1781 he was translated to the see of Worcester. He built at Hartlebury Castle a fine library, to which he transferred Pope's and Warburton's books. purchased on the latter's death. In 1783 he declined the primacy.

Hurd's *Lettevs on Chivalry and Romance* (1762), written in continuation of a dialogue on the age of Queen Elizabeth which was included in his *Moral and Political Dialogues* (1759), had some influence in stimulating the romantic movement; two later dialogues On *the Uses of Foreign Travel* were printed in 1763.

Hurd edited the *Works* of William Warburton, the Select *Works* (1772) of Abraham Cowley, and left materials for an edition of Addison (6 vols., 1811). His own works were published in 8 vols. in 1811. *See* Francis Kilvert, *Memoirs* of . . . *Richard Huvd* (1860).

HURDES, LAS, or JURDES, a region of northwest Spain, south of Salamanca and the Sierra de Peña de Francia and east of the Sierra de Bejar. The Hurdanos are a peculiar people, probably originally a settlement of religious and political refugees; they number about 6,000 and inhabit primitive slate hamlets in the isolated mountainous region of the Sierra de Gata. The principal wealth consists in goats and bees. Much damage is done by boars and wolves. In the high-lying districts the Hurdanos suffer from goitre; along the rivers they are subject to malaria. After World War I rapid progress was made in the improvement of this region, until the outbreak of the civil war of 1936–39.

A good road was built from La Alberca to the lovely valley of Las Batuecas. which was previously almost inaccessible.

See M. Legendre. *Las Jurdes. Étude de géographie humaine* (192;).

HURDLING, running races over a series of obstacles. called hurdles. which are set a fixed distance apart. Indoors the race distances vary from 45 yd. to 70 yd.. over 42-in. or 30-in. hurdles, 1j yd. from the start to the first hurdle and usually with 10 yd. between hurdles. Outdoors the competitive distances are longer, and an additional competition over 36-in. hurdles is added. The standard hurdle heights and distances are often shortened for secondary-school competition, but collegiate and international outdoor competition is conducted at 120 yd., over ten 42-in. hurdles set 10 yd. apart with a 1j-yd. start and finish; at 220 yd. over ten 30-in. hurdles set 20 yd. apart with 20-yd. start and finish; at 440 yd. over ten 36-in. hurdles set $38\frac{1}{4}$ yd. apart with a $49\frac{1}{4}$-yd. start and a $46\frac{1}{2}$-yd. finish. Oxford, Cambridge and National Collegiate Athletic association distances are 120-yd. high hurdles and 220-yd. low hurdles. Amateur Athletic union championship races are conducted in all three hurdle races in either metres or yards. For indoor competition the standard A.A.C. distances are 50 yd. (4 hurdles), 60 yd. (5 hurdles) and 70 yd. (6 hurdles).

History. — Hurdling began in 19th-century England, and the first races were held at Eton college about 1837. In those days hurdlers merely ran and jumped over each hurdle in turn, landing on both feet and usually checking their forward momentum. In an effort to gain more efficient hurdle clearance and to prevent stopping after each hurdle was cleared, a new form came into use in England shortly after 1840. Hurdlers began to "sail" over the hurdle with the body upright, front leg curled under the body and the rear leg trailing. This provided more efficient clearance and allowed for a landing on one foot, thus helping to maintain forward momentum.

Experimentation with standard numbers of steps between hurdles soon followed: and the step pattern for hurdlers was the result. Hurdlers take 3 steps between each high hurdle. 7 steps between each low hurdle and usually 1j between each intermediate hurdle. Further refinements in hurdling were made by A. C. M. Croome of Oxford university about 1885. He showed more economical hurdle clearance by using a straight front leg with a forward lunge of the trunk. This "step-over" action is the basis of modern hurdling style.

Alvin Kraenzlein of the Cniversity of Pennsylvania illustrated in 1898 the advantage of sprinting action between the hurdles when he turned from sprinting to hurdling to set world records;

and Earl Thomson, later a U.S. navy coach. showed how more forward lean was advantageous with the introduction of his double-arm forward thrust as he cleared the barrier. Thomson's form made it possible for hurdlers to bring the trailing leg through nearly "flat." putting them in the best sprinting position for the next stride forward after the hurdle has been cleared. The pause or checking of forward momentum after the hurdle was cleared was virtually eliminated as a result.

Method of Hurdling. — In clearing a hurdle, the athlete takes off about 7 ft. from the hurdle by leaning forward, raising the "lead" leg and extending the opposite arm (or both arms) directly fonvard as he drives from the ground. The rear or trailing leg, bent at the knee, is brought forward over the hurdle at right angles to the body as the arm thrust pulls the trunk forward over the thigh of the lead leg. As the hurdle is cleared, the leading leg is cut down about 5 ft. beyond the hurdle; the body maintains its forward lean so the trailing leg can be pulled through almost parallel to the ground with the toe up. As the hurdler comes off the hurdle, he must continue to pull the trailing leg completely through and forward into the next step, while maintaining his forward lean so he is in sprinting position for the steps between hurdles. Hurdlers must vary body angle slightly when running the different hurdle races. The forward lean is extreme in the high hurdles, moderate in the intermediate hurdles and almost erect in the low hurdles as the hurdler steps over the 2 ft. 6 in. barriers.

Champions. — United States athletes have dominated international competition in the 20th century with some outstanding stars of modern times being Dick Attlesey, Fred Wolcott, Harrison Dillard, Jack Davis and Lee Calhoun in the high and low hurdles and Glenn Hardin, Charles Moore and Glenn Davis in the intermediate hurdles.

For records *see* OLYMPIC GAMES.

(D. B. CM.; S. J.R.; E. J.G.)

HURDY-GURDY, now loosely used as a synonym for any grinding organ. but strictly a medieval drone instrument with strings set in vibration by the friction of a wheel, being a development of the *organistrum* reduced in size so that it could be conveniently played by one person instead of two.

The hurdy-gurdy originated in France: and during the 13th and 14th centuries was known by the name of *Symphonia* or *Chyfonie,* and in Germany, *Lira* or *Leyer.* Its popularity remained undiminished in France until late in the 18th century, but in Germany it never obtained recognition among serious musicians. The idea embodied in the mechanism stimulated ingenuity, however, the result being such musical curiosities as the *Geigenwerk* or *Geigen-Clavicymbel* of Hans Hayden, of Nürnberg *(c.* 1600), a harpsichord in which the strings, instead of being plucked by quills: were set in vibration by small wheels.

HURGRONJE, CHRISTIAAN SNOUCK (1857–1936), Dutch orientalist noted for his studies of Arabic and of Islam, was born at Oosterhaut on Feb. 8, 1857. After completing his studies in theology and oriental languages he went to Arabia, where he stayed for several years, and to other parts of the near east. The result of these travels was his work *Mekka,* 2 vol. (1888–89). He refused a nomination as professor of Arabic at Cambridge university in succession to Robertson Smith and also nominations in Germany and at Leiden, preferring to continue his studies on Islam in the Netherlands Indies (1889–1906), where for several years he was counselor to the government in Islamic affairs. In 1893–94 he published *De Atjehers,* which was translated into English in 1900. He returned to the Netherlands in 1906, where he accepted the chair of Arabic at the University of Leiden; in 1907 he was nominated counselor for Indian and Arabian affairs to the Dutch and the Netherlands Indies government. Among his other works are *Nederland en* de *Islam* (1911) and *Verspreide Geschnifften* (1923 *et seq.).* He died on June 26, 1936.

HURLEY, PATRICK JAY (1883–), U.S. politician, soldier and diplomatist, was born on Jan. 8, 1883, in Indian territory. now Oklahoma. In 1908 he began the practice of law in Oklahoma. After serving as colonel in the American expeditionary force during World War I, Hurley was prominent in Republican party politics during the 1920s, serving as secretary of war in the Hoover administration (1929–33). On U.S. entrance into World War II, Hurley, promoted to brigadier general, went to the far east as Gen. George C. Marshall's personal representative to examine the possibility of relieving U.S. troops on Bataan. During the remainder of the war, Hurley served in various diplomatic capacities as President Roosevelt's personal representative. As U.S. ambassador to China in 1944–45, Hurley, in the interest of intensifying the Chinese war effort, attempted vainly to reconcile the Kuomintang government and the Communist faction; his mission was a failure and he resigned his post in Nov. 1945 after some controversy with the administration. (1%'.R. E.)

HURLING. An outdoor stick and ball game somewhat akin to hockey (*q.v.*) and long recognized as the national pastime of Ireland. There is considerable reference to hurling (*iomáin* in Gaelicj in the oldest Irish manuscripts; the heroes of the ancient tales were all expert hurlers. The stick used is called a hurley, *camán* in Gaelic, and *camáns* in relief decorate some monuments to 15th-century chieftains.

Hurling was for long a communal game played between rival parishes with unlimited numbers of players on either side. Boughs of stripped wood bent to the form of a bow were used as goal posts. Games were often played for heavy money stakes.

An association to revive and standardize hurling, the Gaelic Athletic association, was founded in Thurles, County Tipperary, in 1884, and by mid-20th century there were more than 2,000 clubs in Ireland. County, provincial and all-Ireland championships are played.

Method of Play. — The stick, resembling a hockey stick, is made of young pliable ash, 3 ft. long and $3\frac{1}{2}$ in. wide in the striking part. The width of the striking part enables the ball to be hit overhead from man to man as well as along the ground. Each team consists of 15 players. The average pitch is 150 yd. long and 90 yd. wide. The goals at each end have posts 16 ft. high and 21 ft. apart with a crossbar 8 ft. above the ground. One point is scored by hitting the ball over the opposing crossbar, at any height between the posts. A goal, scored by driving the ball under the crossbar, is equal to three points. The ball, or *slitter,* is of cork. wound with wool and leather covered. It may be caught in the hand before hitting but not thrown or lifted; it may also be hit from left or right. (P. D. M.)

HURON. This French epithet, meaning "bristle head" or "ruffian," was applied to a group of Indian tribes calling themselves Wendat, whence Wyandot. At the time of their discovery by Jacques Cartier in 1534 they were settled in agricultural villages near the St. Lawrence river. The family, the matrilineal clan, the larger clan groupings called phratries and the tribal confederacy were the main social and political units. Political leaders were selected by the matrons. The Hurons belonged to the Iroquoian linguistic family but were bitter enemies of the Iroquois, with whom they competed in the fur trade. Before the arrival of Samuel de Champlain in 1603 the Iroquois had driven part of the Hurons from the St. Lawrence river westward into Ontario, where kindred tribes seem to have been already resident.

About 1590 four of these groups, the Bear, Cord, Rock and Deer people, established a confederacy which included also a number of smaller or dependent tribes. The confederacy numbered perhaps 20,000 persons. The Hurons received the French as friends and the Jesuit missionaries made many converts; but in 1648–50 Iroquois invasions destroyed the confederacy, thousands of Hurons being killed, others taken captive or forced to settle among their conquerors and the remnants driven west. These fragments drifted back and forth between Michigan, Wisconsin, Ontario, Ohio and Quebec, in alliance or conflict with many tribes, some of them also victims of the Iroquois.

At mid-20th century there remained about joo Huron at Lorette in Quebec and 900 Wyandot in northeastern Oklahoma.

See also CANADA: *Native Peoples;* IROQUOIS; and MANA: *Ambivalence* (on Huron religion).

HURON, LAKE, named by the French from the Huron Indians, the second largest of the Great Lakes of North America, is bordered on the west by the state of Michigan, U.S., and on the north and east by the province of Ontario, Can. The lake roughly has the form of a wide crescent convex to the northeast, with Georgian bay lying outside the crescent in that direction. The lake is 247 mi. long from northwest to southeast, and its maximum width is 101 mi. The surface area of the lake, including Georgian bay, is 23,010 sq.mi., and the area of its drainage basin, excluding lake surface, is 49.610 sq.mi. The mean annual precipitation in the area is 31 in. The mean height of the lake above sea level is 581 ft., the same-as that of Lake Michigan, with which it is joined at its northwestern extremity by the Straits of Mackinac. The deepest point in the lake, 750 ft., is 169 ft. below sea level. Currents in the lake generally are slight and variable, the most consistent movement of water being a slow drift from the northwest toward the outlet at the south end. (For comparisons with the other Great Lakes, a discussion of their origins, connections, utilizations, etc., *see* GREAT LAKES, THE.)

History. — Huron was the first of the Great Lakes to be discovered by Europeans. Samuel de Champlain and Étienne Brulé, traveling up the Ottawa and Mattawa rivers, reached Georgian bay in 161j. Brule traversed the North channel to the St. Marys river in 1618. A Jesuit mission, named Ste. Marie, was established among the Huron Indians at the Wye river (southeastern corner of Georgian bay) in 1638. Iroquois Indians destroyed the mission and wiped out most of the Huron nation in 1649. After that the centre of French activities was shifted northwestward to the settlement at Sault Ste. Marie on the river connecting Lakes Superior and Huron. Father Jacques Marquette established a mission at St. Ignace on the Straits of Mackinac in 1671.

Meanwhile Louis Jolliet, returning eastward from the Sault in 1669, had traveled by canoe down Lake Huron: through St. Clair river and lake and the Detroit river, and discovered Lake Erie. Robert Cavelier de la Salle's ship the "Griffin," sailing westward from Niagara, traversed Lake Huron in 1679. A fort was built on the St. Clair river in 1686 by Daniel Greysolon, Sieur Dulhut. British penetration of the lower lakes developed strongly in the mid-I700s. Major Robert Rogers with zoo rangers captured Detroit for the British in 1760 and took Michilimackinac on the Straits of Mackinac in 1761. At the close of the Revolutionary War the boundary between the United States and Canada was drawn through Lake Huron from its south end to the St. Marys river. The fort on Mackinac Island, overlooking the Straits of Mackinac. was captured by the British in the War of 1812 and reoccupied by U.S. troops at the close of the war.

Physiography. — Inflow into Lake Huron is received from Lake Superior via the St. Marys river (73,700 cu.ft. per second), from Lake Michigan and from numerous streams draining the adjacent lands. The discharge of the lake, through the St. Clair river at its south end, averages 177,500 cu.ft. per second. When strong winds blow from the east or northeast, over the expanse of Georgian bay and eastern Lake Huron, they develop high seas which run athwart the main course of traffic through the lake.

Resistant Niagaran Dolomite rock forms the north shore of the lake for 40 mi. eastward from the Straits of Mackinac. and also forms the southern and western shores of the chain of islands and of Saugeen peninsula, nhich separate the main body of the lake from Georgian bay. Dundee and other limestones underlie the south shore of Lake Huron from the straits southeastnard to Thunder bay, and an unusually pure phase of the limestone. quarried at Calcite and Rogers City, Mich., is the principal source of flux material for the steel industry of the loner lakes.

There is evidence that the surface of Lake Huron was approximately 400 ft. below its present level when the margin of the last continental glacier retreated and permitted the lake to drain from the northeastern corner of Georgian bay to the Mattawa and Ottawa river valleys of Ontario. Uplift of the land has since raised that outlet area and caused the lake to rise and discharge down the St. Clair river.

The principal mineral resources of the region are the widely distributed sand and gravel; petroleum, limestone and salt in the lower peninsula of Michigan; nickel ores. mined near Sudbury, Ont., and uranium, found mainly near Blind River, Ont.

Harbours **and** Commerce. — The average season of navigation on Lake Huron is from mid-April to mid-December in the north and from early April to late December in the south. The most important traffic on the lake is the through commerce betneen Lake Erie and Lakes Superior and Michigan, but large tonnages of limestone are loaded at Rockport and Rogers City, Mich., along the west coast of Lake Huron. Other harbours, important in local trade, include: in Michigan, Cheboygan, near the Straits of Mackinac; Alpena, on the southwestern shore of Thunder bay; Bay City, at the head of Saginaw bay; and Harbor Beach. 60 mi. N. of the head of the St. Clair river; and. in Ontario on Georgian bay, Collingwood, Midland, Tiffin, Port McNicoll and Depot Harbor. *See* GEORGIAN BAY; MACKINAC, STRAITS OF.

HURONIAN: *see* PRE-CAMBRIAN TIME.

HURRIANS, a people who played an important role in the history and culture of the near east during the 2nd millennium B.C. Little was known of them to modern scholars until. in the course of the first half of the 20th century! archaeological research and a gradually increased understanding of the Hurrian language helped to trace the zone of their expansion. Even so, many aspects of their early history and provenance remained uncertain, constituting some of the most arduous problems of the historiography of the area.

The earliest recorded presence of demonstrably Hurrian onomastic elements (personal and place names) goes back to Mesopotamian records of the late 3rd millennium, notably those of the 3rd dynasty of Ur; these point uniformly to the area east of the Tigris and the mountain region of Zagros as the Hurrian habitat and to gradual penetration of hlesopotamia proper. From then on, and especially during the early 2nd millennium, there is scattered evidence of a westward spread of Hurrians. An inscribed Hurrian tablet of northern Mesopotamian provenance, apparently dating from the Old Akkadian period, was published in 1948; some religious poems in Hurrian from Mari (Tell el Hariri) on the middle Euphrates belong to Hammurabi's time; and Xlalakh (Tell Atchanaj in northern Syria was considerably hurrianized in the 18th century B.C. An even greater westward migration must have taken place after 1700 B.C., probably issuing from the area between Lake Van and the Zagros. When the records become abundant, c. 1 joo B.C., there is evidence of Hurrian dominance or presence over a wide area. This Hurrian wave was probably set in motion by the intrusion of Indo-Iranians from the north into the region of the later Iran and is connected with the approximately contemporary incursions of Kassites into Babylonia and perhaps of Hyksos into Egypt. There is every indication that Hurrians overthrew the Assyrian dynasty of Shamshi-Adad I and Ishme-Dagan I and subsequently dominated Xssyria. East of the Tigris the flourishing commercial centre of Nuzi was a basically Hurrian community, as is shown by the proper names of its inhabitants and various other Hurrian linguistic elements in its records. Hurrian influence prevailed in many communities of Syria. Hurrian names predominate at Alalakh; and Ugarit has yielded. besides its Canaanite records, Hurrian religious texts in alphabetic cuneiform, a conventional syllabic Sumero-Hurrian vocabulary and a short Hurrian-Akkadian bilingual document. Hurrians likewise occupied large sections of eastern Asia Minor, thereby becoming eastern neighbours and later partly dependents of the Hittites.

Yet the Hurrian heartland during this period of maximum expansion was northern blesopotamia, the country then known as Hurri, where the political units were dominated by dynasts of Indo-Iranian origin. In the 15th century B.C. these principalities and their dependencies ranging from the Iranian mountains to Syria were united into a state called Mitanni or (in Mesopotamian records) Hanigalbat, under the leadership of an Indo-Iranian warrior caste natned *maryannu,* which, like the royal names (*e.g.,* Artatama, Shaushshatar), has a clearly Indo-European etymology. Mitanni, with its capital Washshukanni, warred especially with

Thutmose III of Egypt for the possession of Syria. During the reign of Xmenhotep III of Egypt friendly relations prevailed, an extensive letter from the Hurrian king Tushratta to this Pharaoh is the longest extant Hurrian text. In the middle years of the 14th century B C, after the political decline of Egypt under the Pharaoh Ikhnaton the resurgent Hittite empire under Suppiluliumas I defeated Mitanni and reduced Tushratta's son Mattiwaza to vassaldom, while Assyria under Ashur-uballit I seized the opportunity to reassert its independence. In spite of political subjection, the continued Hurrian ethnic and cultural presence in Syria and in the Cilician region (Kizzuwatna) exerted a strong influence on the Hittite empire.

The carvings at Yazilikaya suggest that the official pantheon of the empire was thoroughly hurrianized through the inclusion and syncretization of Hurrian deities, especially Teshub and Hebat; Hurrian cultic texts nere found at the capital site of Hattusas (Bogazkoy); Hittite queens had Hurrian names: and Hurrian mythology appears in Hittite epic poems. Moreover. the Indo-Iranian overlords of Mitanni had introduced horse breeding and chariot warfare into the near east, and Mitannian specialists in this line were employed by the Hittites at Hattusas.

The principality of Hayasha in the Armenian mountains was another Hittite dependency; Suppiluliumas, in a famous treaty with its ruler Huqqanas, warns him against certain incestuous family relations which seem to have been originally current among the Hurrians under a fratriarchal system, also attested in traces at Nuzi. This hinterland region provided the last stronghold for Hurrian ethnic identity. The people of the Haldian (Khaldian) kingdom of Urartu during the 9th–7th centuries B.C. spoke a language definitely akin to Hurrian. Everywhere else Hurrians appear to have spent themselves in the latter part of the 2nd millennium B.C.; before modern discoveries only such meagre traces as the brief mentions of "Horites" in the Pentateuch remained as uninstructive witnesses of their forgotten greatness. Yet the typically Hurrian "Armenoid" physical type had left its lingering imprint on the racial features of the near east.

Language. — The Hurrian language, once called improperly Mitannian or Subarian (after Subartu, an old cuneiform name for regions north of Sumer and Akkad), is attested chiefly in four varieties of cuneiform: Old Akkadian; Babylonian; specifically Hurrian; and consonantal Ugaritic. Continuous texts, mostly from Mari, from the Amarna archives in Egypt (Tushratta's letter), from Bogazköy and from Ugarit, are supplemented by onomastic materials, glosses and loan words from many sites, notably Nuzi and Alalakh Combinatory analysis, especially of the long continuous text of the Tushratta letter, has permitted considerable penetration into the language, which is neither Indo-European nor Semitic. The grammatical structure is dominated by a profusion of suffixes, and the verbal system is particularly complicated. There is a basic distinction of transitive and intransitive forms and constructions; the full transitive expression is conceived in a passive sense. nith the object of the action in a "subject case," while the doer takes on the form of the "agent case," so that "and my brother requested a wife" is expressed as *šeniwwuš-an ašti šaruša* "by my brother and" (Sena "brother," *-iwwu-* "my," *-š* agent suffix, an "and") "a wife" (*ašti* subject case without suffix) "was requested" (*šaruša*). These characteristics suggest that Hurrian may have an affinity not only with Urartaean but with modern Georgian and related languages of the Caucasus.

HURRICANE, a tropical storm, originally in the West Indies only, but a term now applied to this type of storm in other parts of the world. The name is derived from the word huracan of the Arawak-speaking Indians of the West Indies. It is also used to designate a wind of force 12 on the Beaufort scale (*q.v.*), that is, a wind of more than 75 m.p.h.

The hurricane season lasts roughly from June to October. In midseason, Aug. and Sept.. hurricanes develop mainly near or to the east of the Lesser Antilles. Early and late in the season, in June and from the latter part of September onward, the area with most frequent formation is the western Caribbean. The Gulf of Mexico also is a breeding ground for hurricanes, as is the Pacific just off the Central American coast. In the Atlantic-Gulf region the mean hurricane frequency is seven per year; it is reasonable to assume that about the same number form in the eastern Pacific, but the information is quite uncertain in that area. In individual years the frequency has ranged irregularly from 2 to 21 in the Atlantic. However, when considering frequency in terms of decades, a definite cycle is apparent. Hurricane frequency was high from 1890 (roughly the start of the record) to 1910, low from 1910 to 1930 and high from 1930 to the late 1950s.

After formation. most hurricanes move northwest, gradually turning more directly north as they move out of the tropics. The United States intercepts all hurricanes moving northward in the Gulf, and since the land mass extends farther east with increasing latitude. it also intercepts many hurricanes moving northward on the ocean side of Florida. Some of the most extensive damage suffered from hurricanes has been sustained in New England. This damage has resulted partly from the nind, especially the effect of wind upon the sea near coasts, but also from floods following heavy rains in the mountainous sections of New England.

See TROPICAL STORM. (H. RL.)

HURRY (URRY), **SIR JOHN** (d. 1650), Scottish soldier of fortune, was born in Aberdeenshire and saw much service as a young man in Germany. In 1641 he was involved in the plot known as the "Incident" (see HAMILTON, JAMES HAMILTON. *1st* Duke of). At the outbreak of the Civil War Hurry joined the army of the earl of Essex, but early in 1643 he deserted to the royalists, bringing with him information on which Rupert acted at once. Thus was brought about the action of Chalgrove field, where Hurry again showed conspicuous valour; he was knighted on the same evening. In 1644 he was with Rupert at Marston Moor. where with Lucas he led the victorious left wing of horse. But a little later, thinking the king's cause lost, he again deserted, and eventually was sent with Baillie against Montrose in the Highlands. His detached operations were conducted with great skill, but his attempt to surprise Montrose' camp at Auldearn ended in complete disaster. He once more joined Charles's party, and he was taken prisoner in the campaign of Preston (1648). Sir John Hurry was Montrose' major general in the last desperate attempt of the Scottish royalists. Taken at Carbisdale, he was beheaded at Edinburgh. May 29, 1650.

HURST, JOHN FLETCHER (1834–1903), U.S. Methodist Episcopal bishop and educator, was born in Salem. Md., on Aug. 17, 1834. He graduated at Dickinson college, Carlisle. Pa.. in 1854, taught for tno years and then went to Germany to study at Halle. On his return to the U.S. he was engaged in pastoral work. and from 1867 to 1871 taught Methodist mission institutes in Germany. In 1871 he became professor of historical theology at Drew Theological seminary, Madison, N.J., of which he was president from 1873 till 1880, when he was made a bishop. He died at Bethesda, Md., on May 4, 1903.

Bishop Hurst. by his devotion, recovered the endowment of Drew Theological seminary, lost by the failure in 1876 of Daniel Drew, its founder. The American university (Methodist Episcopal) at Washington, D.C.. for postgraduate work, of which he was chancellor from 1891 till 1902, was the outcome of his labours to improve the quality of Methodist scholarship. Besides translating and revising many important works he published *A* History of *Rationalism* (1865; rev. ed., 1901); Life and *Literature in* the *Fatherland* (18jj), brilliant sketches of Germany: *Indika:* the *Country* and People *of* India and Ceylon (1891); *History* of the Christian Church (1897–1900); and edited the History of *Methodism* (1902–04), a co-operative work.

HURSTMONCEUX or HERSTMONCEUX, a village in the Hailsham rural district of East Sussex. Eng., on the Brighton-Hastings road 12 mi. N. of Eastbourne. Pop. (1951) 1,856. It takes its name from Waleran de Hcrst Monceux, lord of the manor in 1216.

The castle. built in 1440 by Sir Roper de Fienes as a fortified manor surrounded by a moat. is one of the earliest brick buildings in England. Towers flank the corners and there is a beautiful turreted entrance gate, but the interior was destroyed in 1777 when Canon Robert Hare-Naylor (father of Augustus and Tulius Hare) used the material to build Hurstinonceux place. In 1948 the castle became the home of the Royal observatory which had been at Greenwich since 1675. All Saints church dates from the 11th century.

HUSAIN IBN ALI (*c.* 1854–1931), amir of Mecca from 1908 to 1916 and king of Hejaz from 1916 to 1924, was the second son of Mohammed ibn Xun oi the Abadila clan of Ashraf. He was brought up in Bedouin surroundings but spent a great part of his liie at Constantinople. Reputed to harbour Anglophil tendencies, he was deeply versed in the byways of Ottoman politics. His best trait was a profound knowledge of the desert, for n'hich he always maintained a genuine affection. At the beginning of his amirate he won golden opinions by his sagacity and modesty and set himself vigorously to forward Turkish interests in Arabia. In 1910 he subdued a rebellion in Asir and subsequently invaded Qasim without result, but in 1913 he began to show his true colours by opposing the extension of the Hejaz railway to Mecca.

When World War I broke out he entered into negotiations with the British, which culminated in the Arab revolt in June 1916. In October he proclaimed himself "king of the Arab countries" though he was formally recognized only as king of Hejaz. At the Versailles peace conference (1919) he was represented by his third son, Faisal, but refused to ratify the treaty as a protest against the mandatory regimes imposed on Syria, Palestine and Iraq. Subsequently his domestic policy was marked by ever-increasing avarice and reaction, while he sowed the seeds of iuture trouble by deliberately courting the enmity of Ibn Sa'ud. In March 1924, while on a visit to Trans-Jordan. he proclaimed himseli caliph; but war with Ibn Sa'ud was imminent, and the Wahhabi attack on Ta'if in September found him unprepared. On Oct. 5 he abdicated and proceeded to Aqaba. In July 1925 the British conveyed him to Cyprus, where he lived till 1930. He died at Amman in 1931.

By his first marriage Husain had three sons: Ali, Abdullah. amir of Trans-Jordan, and Faisal. The first of these, Ali ibn Husain, who was born about 1880, took no conspicuous part in affairs during his father's amirate. Aiter World War I he became amir of Medina and in that capacity did much useful work in connection with the reconstruction of the Hejaz railway. In 1924 he was pressed to accept the amirate of Trans-Jordan but declined in favour of returning to Medina. He succeeded his iather as second king of Hejaz on Oct. 3, 1924, but abdicated on Dec. 10 of the following year (*see* HEJAZ) and returned to Baghdad to live as the guest of his brother Faisal.

HUSBAND AND WIFE. For the methods by which the relation of husband and wife may be constituted and dissolved see MARRIAGE and DIVORCE: *see* also ROMAN LAW. The present article deals only with the effect of marriage on the legal position of the spouses.

The person chiefly affected by the contract is the wife, who under most early systems oi law became subject In consequence of the marriage to some kind of disability. though the husband by virtue of his marriage accepted a number of liabilities. The most iavourable system scarcely left the wife as iree as an unmarried woman and the most uniavourable subjected her absolutely to the authority of her husband. In modern times in English law the trend has been to lessen or remove the disabilities of the wife and to reduce the obligations of the husband; and the effect of marriage on property is perhaps the most important of the consequences arising irom the relationship, and on this point the laws of different countries show wide diversity of principles.

English Law.— The contract of marriage, which is by law regarded as a civil contract only, is in its essence a consent on the part of a man and woman to cohabit with each other and with each other only. This contract differs irom all other civil contracts in that it is indissoluble at the will of the parties. The English common law relating to marriage is indigenous to the country, the rules relating alike to the ceremony itself and to the legal results oi the ceremony being entirely insular in their origin and deducible irom no foreign source. There is, however, considerable analogy between the later development of the civil law oi Rome and the modern law of England—in that both, starting from an extreme theory of the possessory right oi the husband over the person and property of the wife, have subsequently tended toward practical equality between the sexes. The original concept in English law mas an absolute merger of the personality of husband and wife by virtue of the marriage ceremony. Hence a man could not grant or give anything to his wife. because she was himself, and if there n-ere any compacts between them beiore marriage they were dissolved by the union of persons. A husband, moreover, during his lifetime, had an absolute power of disposing of the personal property and chattels real (leasehold interests) of the wife, no act of hers being of any iorce to affect or transier that which by the intermarriane she had assigned to him. In the wiie's freeholds the husband's ownership was not absolute, he having no power to dispose of them without her consent, although as master and governor of the family he was entitled to receive the profits during the life of his wife

Courts oi equity, however, in process ot time considerably modified the stringency of the common law by the introduction of the doctrine of separate estate, *i.e.*, property settled to the wife for her separate use. In such case a married woman was entitled to deal with her property as it she were unmarried. Connected with the doctrine of separate use mas the equitable contrivance of restraint on anticipation whereby property might be so settled to the separate use of a married woman that she could not, during coverture, alienate it or anticipate the income; this, originally a device ior the protection of married women, in the society of the 20th century became a restriction upon women's enjoyment of their property, and the Married Women (Restraint Upon Anticipation) act. 1949, provides that no restraint upon anticipation or alienation attached to enjoyment of property by a woman which could not have been attached to enjoyment of property by a man was to have any effect after the passing of the act. This measure was made retrospective so that it was to have effect irrespective of the date of the act or instrument containing the provision which attached the restriction. In yet another way the court of chancery interiered to protect the interests of married women. When a husband applied to the court to get possession of his wife's choses in action (*i.e.*, a legal right not in possession), he was required to make provision for her and her chiidren out of the fund sought to be recovered. This provision was called the wife's equity to a settlement.

The corresponding interests of the wife in the property oi the husband were much less satisfactory. Besides a general right to maintenance at her husband's expense she had at common law a right to don-er in her husband's lands and, ii he died intestate. to a third of his personal estate. Both of these rights were abolished by the Administration of Estates act, 1925, which substituted thereior the provisions following. If an intestate leaves surviving a husband or wife (with or without issue) the survivor takes the personal chattels of the deceased absolutely with a sum of £1,000 irom the residuary estate. and in addition (should the intestate leave no issue) a life interest in the residuary estate. If the intestate leaves issue, then a life estate of one-hali of the residuary estate goes to the surviving spouse, and the other half on statutory trusts for the issue of the intestate. The act further provided for the ultimate distribution of the residuary estate. Under the older law the regulation of the respective rights of husband, wife and children by marriage settlements tended largely to obviate the hardships and injustices imposed upon women by the common lam.

In close relation to the above provisions oi the Administration of Estates act are those of the Inheritance (Family Provisions) act, 1938, which empower the court to award payments to a widow or widower or, in certain circumstances. a child oi a deceased person where, in its opinion, reasonable provision has not already been made.

A necessary sequence to the theory of the unity of person in the marriage relation was that neither husband nor wife could give evidence against the other in any legal proceeding whether civil or criminal. Survivals of this old law still exist in the fact that the combination oi husband and wife, without a third party. for an unlawful purpose does not constitute an indictable misdemeanour so as to support a charge oi conspiracy; and (apart irom treason and murder) it is still a good defense for a wife to prove that the crime with which she is charged was committed in the presence of and under the coercion of her husband (15 and 16 G.5. c. 86 s. 47). A third survival of the old law was to be found in the fact that a husband continued liable for the pure torts of his wife, *i.e.*, ior any tort not directly connected with a contract (*Edwards* v. *Porter*, 1925, X.C. 1) but this rule was abolished by the Law Reiorm (Married Women and Tortieasors) act, 1935, which provides, among other thinrs, that a husband is no longer liable ior a tort committed by his wife whether before or after marriage merely because of his marriage.

The iundamental changes introduced by the Married Women's Property acts, 1882, 1893, 1907, have enormously improved the position of a woman unprotected by settlements, practically placing her in the position of a feme sole.

The chief provisions of the act of 1882 are, shortly, that a married woman is capable of acquiring, holding and disposing of, by will or otherwise, any real and personal property: in the same manner as if she were a single woman, without the intervention of any trustee. The property of a woman married after the commencement oi the act, whether belonging to her at the time of marriage or acquired aiter marriage, is held by her as a feme sole. After marriage a woman remains liable for antenuptial debts and liabilities, and as between her and her husband, in the absence of contract to the contrary, her separate property is deemed primarily liable, the husband being liable only to the extent of property acquired irom or through his wife.

The Married Women's Property act of 1893 provided specifically that every contract thereinafter entered into by a married woman, otherwise than as an agent, should be deemed to be a contract entered into by her with respect to and be binding upon her separate property, whether she was or was not in fact possessed of or entitled to any separate property at the time when she entered into such contract, that

it should bind all separate property which she might at that time or thereaiter be possessed of or entitled to, and that it should be enforceable by process oi law against all property which she might thereaiter, while discovert, be possessed of or entitled to. The act of 1907 provided that a settlement or agreement ior a settlement whether before or aiter marriage, respecting the property of the woman, should not be valid unless executed by her if she was of iull age or confirmed by her aiter she attained full age. The act of 1908 provided that married women possessing separate property should be liable for the maintenance of their parents. The Guardianship of Infants act, 1925, gave the mother of an infant equal right with the father to apply to a court of guardianship of a child. The act of 1926 provided ior the legitimation of children *(see* LEGITIMACY AND LEGITIMATION) by the subsequent marriage of their parents. The Law of Property act, 1925, enabled a married woman, without her husband, to dispose of or join in disposing of real or personai propcrty held by her solely or jointly as trustee or personal representative in like manner as if she mere a ieme sole. It further enabled her to disclaim any estate or interest in land without the concurrence of her husband and to acquire as well irom her husband as irom any other person any interest in real or personal property, and to hold the same either solely or jointly with third parties as a trustee or personal reprrsentative as if she mere a ieme sole.

The broad effect of modern legislation, starting with the Married Women's Property act, 1882, and culminating in the Law Reform (Married Women and Tortieasors) act, 1935, has been to provide that a married woman can acquire, hold and dispose of property as if she 1%-erea single woman. "She has iull capacity to enter into contracts, is subject to the bankruptcy law, and her husband is no longer liable on her ante-nuptial contracts." At the same time the husband remains liable ior the maintenance of his wife, who continues to have the right to pledge his credit ior necessaries according to his standards oi life; and in certain respects, notably by the Law Reform (Miscellaneous Provisions) act, 1949, and the Married Women's (Maintenance) act, 1949, the machinery for enforcing payment where the husband has failed adequately to maintain has been improved. The parties to a marriage are still one in law, so that they cannot sue one another in tort. The change is neatly illustrated in *Rees* v. Hughes (1946. K.B.D. 517) where it was decided that, when a woman leaves sufficient estate to pay funeral expenses, her husband is no longer liable for them, a married woman now being in the same position as a man in her capacity to own and dispose of property. *Drinkwater* v. *Kimber* (1952.2 Q.B.D. 281) and *Baylis* v. *Blackwell* (1952.1 K.B.D. 154) exemplify the continued unity in lam created by the marriage relation. In the former, where the plaintiffs were man and wife, and the male plaintiff mas held partly responsihie for the collision, the defendant was unable to recover irom the husband any contribution in respect of the damage to the wife, since the latter herself could not have recovered damages from her husband; in the latter, a husband was held not to be entitled to sue his wife for an antenuptial tort.

Law of Scotland. — For the law oi Scotland, which differs less from English lam than the use of a very different terminology mould lead us to suppose, see SCOTS LAW. (W. W.-P.; W. T. Ws.)

Continental Law. — On the continent of Europe and especially among the Latin nations (after age-long vicissitudes of varying custom and procedure possibly derived from an infiltration of Teutonic law and principle into the civil code) the main ideas of Roman jurisprudence became established as the bases of the law governing the marriage relation. The leading ieature in modern continental marriage law is the community of goods between husband and wife. Of this system it is said "the community is not regarded in French law as a legal entity except for the purposes of taking an account. It is somewhat like a private partnership." It generally extends to all property of the husband and wife and to the income or other proceeds derived therefrom. It extends also to all immovable property of the husband and n-iie acquired during the marriage. By a law dated Sept. 22, 1942, it 7%-asestehded to salary or business profits earned by the wife as well as those of the husband. The property thus acquired is liable to the debts of the spouses existing at the time of the marriage, to the debts contracted by the husband or the wife during the community, mith the husband's consent, and to debts contracted ior the maintenance of the iamily.

By two laws dated Feb. 18, 1938, and Sept. 22, 1942, the property oi the community was made liable to debts contracted during the community by the wife as representing her husband. This requires the civil court's permission, when the husband is not in a condition to give his consent, but not when the wife contracts as a manageress of affairs for the community. That property is also liable to the debts contracted during the community by the wife in her own name, in the interest of the family with civil court's sanction, and by the mife in the interest of her individual business, without civil court's sanction. When the community is dissolved an account is taken to ascertain what each partner owes to the partnership and what the partnership owes them: and the partnership property is divided equally between husband and wife. Certain modifications of this general principle have, however, been introduced in French legislation by a series of enactments dating from 1881 which sonleu-hat assimilates the Gallic law to that of England in matters relating to personal savings or profits derived by a married woman irom her individual exertions. A law dated July 13, 1907, confirmed by the law of 1942, accorded to a married woman an absolute right to deal as she pleases with salary or business profits earned by her or with any property she may have purchased therewith; an enactment of 1924 gave protection (subject to certain saieguards against fraud) to the goods and property of a married woman from seizure by her husband's creditors, whether such property was owned by her before marriage. has since been inherited by her or has been acquired by her personal exertions. Should she, however, squander her separate estate her husband may apply to the court to restrict her freedom of disposal.

In Denmarl;, Finland, Iceland, Norway and Sweden the legal effects resulting irom the contract of marriage are practically identical, the result of the adoption by these countries of the Marriage act of 1925 and the Inheritance act of 1926 being to confer on husband and wife legal equality during lifetime and equal rights of inheritance upon the death of either oi the parties. In these countries the principle of community of property between husband and wife is preserved concurrently with right to the possession of separate estate. The communal property can only be encumbered or disposed of with the joint consent oi the spouses, but the separate estate may be disposed of by either without reference to the other. Separate estate may consist of antenuptial property, not brought into the community upon the marriage, or such earnings of either spouse as are not required for the iamily maintenance. In case of desertion, bankruptcy or mismanagement of the joint estate by husband or wife the lam permits of an equitable resettlement by the court. In Germany the civil code came into operation in 1900 (art. 1367) provided that the wife's wages or earnings shall form part of her *Vorbehaltsgut* or separate estate, which a previous article (1365) placed outside her husband's control. In Italy a law of July 17, 1919, abolished the last contractual incapacity of married women. Henceiorth the husband has no legal right either to veto or control the acts of his wife or to interfere with her separate estate. In 1906 Switzerland enacted a statute conferring on married women contractual emancipation. (W. W.-P.; J. M.-M. L.)

United States Law.—As in England, the most remarkable changes in the law of husband and wife in the United States occurred with respect to the wife's control over property, although other innovations are of considerable importance. In the United States, Married Women's Property acts had become common by the end of the 19th century. This legislation, conferring on the wife the right to deal mith her property as a single woman, was closely followed by acts permitting her to control her own earnings, to sue and be sued and to enter into contracts. The practical eifect oi the legislation placed the mife on an equal plane with her husband in property control.

Notwithstanding this general achievement, specific provisions of state law differ greatly. The Married Women's Property acts have had pronounced but varied effects on the types of permissible common holdings by the husband and mife. Dower, a widow's life interest in certain lands of her husband. and curtesy, a somewhat similar interest oi the husband's where there have been legitimate children born of the marriage, are still recognized in many states. Where they have been abolished they have generally been replaced by giving the surviving spouse rights in a designated portion of intestate propcrty, both real and personal. In addition to these protections to the spouse, most jurisdictions also have provided for the existence of certain property free from creditors' claims by passage of homestead and exempt property and allowance legislation.

In some instances efforts to remove the wife's common-lam disabilities have progressed, it is thought, to a point where her position is more advantageous than her husband's. The so-called disabilities under which she sufiers, such as the disability of contracting as a surety, are, however, not only to be regarded as favouring the wife but as affording protection to the family as well.

Neither husband nor wife is ordinarily liable for the other's obligations However, where the wife incurs debts ior household purchases or for the education of children, she is rebuttably presumed to be acting as her husband's agent. In those states with family expense statutes, she is regarded as a codebtor for such expenditures. Such statutes have, in fact, gone far toward effectuating a joint responsibility for support. There is also an incipient trend to impose on the mifc a positive duty to support her husband.

In the community-property states, in addition to the separate funds oi husband and wife, a third fund comprising property acquired during the marriage by efforts of the spouses is recognized. Persons in these states at one time possessed a significant income-tax advantage over the residenrs of noncommunity-property jurisdictions. This was virtually eliminated by provision of the Internal Revenue act of 1948 for income-tax returns filed jointly by husband and wife and allowing them to split the income for taxation in the bracket applicable to 50% of the total.

Certain rules, which were derived irom the uniqueness of the marriage relationship, remained in effect. In nearly all jurisdictions the privilege of one spouse not to testify against the other was still in force. Rights to contract *inter* se are restricted in an ever-smaller number of jurisdictions, while in a majority husband and wife continued to be barred from suing one another in tort for personal injuries. Even the presumption that a wife's crime committed in the husband's presence was committed under his coercion was retained, or proof of coercion was available to the wife as a defense, in 40 states.

The direction of modern law is, nonetheless, clear. It seeks to

equalize the rights and, increasingly, the obligations of husband and wife and to recognize them, in their actions and responsibilities, as individuals (M. K. R.)

HÜSEYIN RAHMI GURPINAR (1864–1944), Turkish novelist, was a prolific writer who skilfully depicted Istanbul middle and loner-middle class society. Born in Istanbul in 1864. the son of a general, he was educated privately and at the School of Political Science. He retired from the civil service in 1908 and thereafter, apart from a short spell as a member of parliament. lived a solitary life on Heybeli Island in the Sea of Marmara. He was a disciple of Ahmed Midhat rather than of the French-inspired school of writers but soon developed an independent style. He wrote over 30 novels, a number of short stories and a few unsuccessful plays, and translated several French novels. He is at his best in reproducing dialogue and his work is valuable to the student of Istanbul life and language at the turn of the century.

See O. Spies, *Die turkische Prosaliteratur der Gegenwart* (1943). (F. I.)

HU SHIH (1891–1962), Chinese historian, philosopher and diplomat, called the father of China's literary renaissance, was born in Shanghai in 1891, the son of a magistrate in Formosa who died in 1895. His ancestral home was in Hui-chou, Anhui province. Precocious as a child, Hu Shih began early to study the classics, mainly through the sacrifice and encouragement of his widowed mother. In 1904–10 he attended school in Shanghai, where he displayed independence of judgment by publishing. at the age of 15, articles in the living tongue of the people instead of the ancient classical style, in which, however, he was fully competent. In 1910 he passed the examinations held in Peking for study in the United States under the newly established Boxer Indemnity fund. He entered Cornell university and in 1914 received his A.B. degree. At the 25th reunion of his class he was named its most distinguished member. In 1917 he received his doctorate at Columbia university, where he was much influenced by the pragmatism of John Dewey. While yet a student in the university he published suggestions for language reform that were echoed by like-minded scholars in China. In 1916, for example, he resolved never to write poetry except in the spoken language. The year 1917, when he returned to China to teach philosophy in the Peking National university, marks the beginning of the literary renaissance that flourished until the Japanese invasion in 1937 *(see* CHINESE LITERATURE). The movement was hailed by younger writers, teachers and students in all parts of the country, and hundreds of periodicals arose to establish the spoken language as a suitable literary medium. Though the work of Hu Shih has been compared to that of Wycliffe and Dante in creating for England and Italy their respective national languages, he himself has described it as the culmination of a long evolutionary process in which Chinese novels and dramas had earlier set the pattern. The movement did not stop, however, with language reform; it went on to the revaluation and reorganization of China's entire cultural and social heritage. Hu Shih led the way by championing, in the new medium, neglected figures in Chinese history. and by applying the most rigorous historical methods to the study of ancient texts and to the authorship and development of China's great novels. His numerous articles in Chinese, written mith kindliness and great clarity, have been brought together in several collections. Two English works may be mentioned: *The Development* of *the Logical Method in Ancient China* (1928) and *The Chinese Renaissance* (1934). Among his books in Chinese are: "A History of Chinese Philosophy" (ancient period), "The Philosophy of Tai Tung-yuan" and "My Liie to the Age of Forty." Except for an interval (1928–30) when he taught in Shanghai, he continued at the Peking National university, where he later became dean of the college of arts. For nearly four pears he was China's ambassador to the United States, returning to his university in 1946 to be chancellor. After the establishment of the Communist regime he lived in New York city, continuing his researches in history and philosophy. In 1957 he was appointed one of China's representatives in the United Nations.

In 1958 he returned to Taiwan (Formosa) to engage in writing and to direct China's leading scholarly organization, the Academia Sinica. He died there on Feb. 24, 1962. (A. W. H.)

HUSKISSON, WILLIAM (1770–1830), English statesman and financier, was descended from an old Staffordshire family of moderate iortune, and was born at Birch Moreton, Worcestershire, on March 11, 1770. He went to Paris at 14 to the care of his uncle, Doctor Gem, physician to the British embassy in Paris, and witnessed the French Revolution. In Jan. 1793 he was employed by Dundas in the carrying out of the Aliens act; and in 1795 he was appointed undersecretary for war. Huskisson sat in parliament for Morpeth (1796–1802), Liskeard (1804–07), Harwich (1807–12), Chichester (1812–23) and Liverpool (1823–30). He was secretary to the treasury under Pitt (1804–05) and Portland (1807–09). He took a prominent part in the Corn law debates of 1814 and 1815; and in 1819 he presented a memorandum to Lord Liverpool advocating a large reduction in the unfunded debt and explaining a method for the resumption of cash payments which was embodied in the act passed the same year. In 1821 he was a member of the committee appointed to inquire into the causes of the agricultural distress then prevailing, and the proposed relaxation of the Corn laws embodied in the report was understood to have been chiefly due to his strenuous advocacy. In 1823 he was appointed president of the board of trade and-treasurer of the navy, and shortly afterward he received a seat in the cabinet. In the same year he was returned for Liverpool as successor to Canning, and as the only man who could reconcile the Tory merchants to a free trade policy. Among the more important legislative changes with which he was principally connected were a reform of the navigation acts, admitting other nations to a full equality and reciprocity of shipping duties; the repeal of the labour laws; the introduction of a new sinking fund; the reduction of the duties on manufactures and on the importation of foreign goods; and the repeal of the quarantine duties. In accordance mith his suggestion Canning in 1827 introduced a measure on the Corn laws proposing the adoption of a sliding scale to regulate the amount of duty. A misapprehension between Huskisson and the duke oi Wellington led to the duke proposing an amendment, the success of which caused the abandonment of the measure by the government. After the death of Canning in the same year Huskisson accepted the secretaryship oi the colonies under Lord Goderich, an office which he continued to hold in the new cabinet formed by the duke of Wellington in the following year. After succeeding with great difficulty in inducing the cabinet to agree to a compromise on the Corn laws, Huskisson resigned office in May 1828 on account of a difference with his colleagues in regard to the disfranchisement of East Retford. On Sept. 15, 1830, he was accidentally killed by a locomotive engine while present at the opening of the Liverpool and Manchester railway.

HUSS or Hus, **JOHN** (1369–1415), Bohemian reformer, was born of peasant parents at Husinec (Husinetz), near the Bavarian frontier. He was educated at the University of Prague where he began to lecture in 1398. He was made dean of the philosophical faculty in Oct. 1401, and was rector (Oct. 1402–April 1403) of the university. His appointment in 1302 as rector of the Bethlehem chapel. which had been erected in 1391 by zealous citizens of Prague to provide good popular preaching in the Bohemian tongue, influenced his religious life, and led him to an appreciation of the philosophical and theological writings of Wycliffe, whose *Trialogus* he had translated into Czech in 1403.

In 1405, while still unconscious of any opposition to Catholicism, Huss published his *De omni sanguine Christi glorificato*, in which he declaimed against forged miracles and ecclesiastical greed, and urged Christians to desist irom looking for sensible signs of Christ's presence, but rather to seek Him in His enduring word. More than once, also. Huss was appointed to be synod preacher, and in this capacity he delivered at the provincial councils of Bohemia many admonitions. In 1408, however, the clergy laid before the archbishop a formal complaint against the strong expressions used by Huss with regard to clerical abuses. He was deprived of his appointment as synodal preacher, and forbidden the exercise of priestly functions. Simultaneously with these proceedings, negotiations had been going on for the removal of the long-continued papal schism. King Wenceslaus of Bohemia had requested that the clergy and the university observe a strict neutrality toward both popes. Hut the clergy remained supporters of Gregory XII, and of the university only the Bohemian "nation" under Huss avowed neutrality. There followed an expression of nationalist feeling, with the result that a royal edict (Jan. 18, 1409) was issued, by which the Bohemian "nation" received three votes, while only one was allotted to the Bavarians, Saxons and Poles combined; whereupon all the foreigners, to the number oi several thousands, immediately withdrew from Prague.

His Teaching. — It was a dangerous triumph ior Huss; for his popularity at court and in the general community had been secured only at the price of clerical antipathy. Among the first results of the changed ortler of things were on the one hand the election of Huss (Oct. 1409) to be again rector of the university, but on the other hand the appoint-

ment by the archbishop of an inquisitor to inquire into charges of heretical teaching and inflammatory preaching brought against him. He had spoken disrespectfully of the church, it was said, had even hinted that Antichrist might be found to be in Rome, had fomented in his preaching the quarrel between Bohemians and Germans, and had, notwithstanding all that had passed, continued to speak of Wycliffe as both a pious man and an orthodox teacher. The direct result of this investigation is not known, but it is probably connected with the promulgation by Pope Alexander V, in 1409, of a bull which ordered the abjuration of all Wycliffite heresies and the surrender of all his books, while at the same time—a measure specially leveled at the pulpit of Bethlehem chapel—all preaching was prohibited except in localities by long usage set apart for that use. The archbishop publicly burned about 200 volumes of the writings of Wycliffe, and excommunicated Huss and certain of his friends, who had in the meantime protested and appealed to the new pope (John XXIII). Again the populace rose on behalf of their hero, who continued to preach in the Bethlehem chapel, and in the university began publicly to defend the so-called heretical treatises of Wycliffe, while from king and queen, nobles and burghers, a petition was sent to Rome praying that the condemnation and prohibition in the bull of Alexander V might be quashed. In March 1411 the ban was anew pronounced upon Huss, and ultimatelv the whole city was laid under interdict; yet he went on

The struggle entered on a new phase with the proclamation of the papal bulls by which a religious war was decreed againdt the excommunicated King Ladislaus of Naples, and indulgence was promised to all who should take part in it. By his bold opposition to this procedure against Ladislaus. and still more by his doctrine that indulgence could never be sold without simony, and could not be lawfully granted except by genuine contrition and repentance. Huss at last isolated himself, not only irom the archiepiscopal party but also from the theological faculty of the university. The excommunication against Huss was renewed, and the interdict again laid on all places which should give him shelter. In December Huss had to yield to the king's wish by temporarily withdrawing from Prague to Kozihradek, and to Krakowitz. There he carried on a copious correspondence, and composed the *De ecclesia,* which subsequently furnished most of the material for the charges against him. This work mas largely based on the doctrines of Wycliffe.

Trial and Death.—In 1413 his presence was requested at the council of Constance, and, arriving there on Nov. 3, 1414, he received the famous imperial "safe conduct," the promise of which had been one of his inducements to quit the comparative security he had enjoyed in Bohemia. This safe conduct stated that, whatever judgment might be passed on him, Huss should be allowed to return freely to Bohemia. This by no means provided for his immunity from punishment. If faith to him had not been broken he would have been sent back to Bohemia to be punished by his sovereign, the king of Bohemia. The treachery of King Sigismund is undeniable and was indeed admitted by the king himself. The saie conduct was probably indeed given by him to entice Huss to Constance. On Dec. 4 the pope appointed a commission of three bishops to investigate the case against the heretic, and to procure witnesses; but the flight of Pope John XXIII in the following March furnished a pretext for the removal of Huss from the Dominican convent to a more secure place oi confinement under the charge of the bishop of Constance at Gottlieben on the Rhine. On May 4 the temper of the council was revealed in its unanimous condemnation of Wycliffe, especially of the so-called "forty-five articles," as erroneous, heretical. revolutionary. On June 5, when the case of Huss came up for hearing, he was unable to make his defense by reason of the violent outcries. The sitting of June 7, at which King Sigismund was present, was better disciplined. Propositions extracted from the *De ecclesia* were brought up, and the relations between Wycliffe and Huss were discussed. The accused repudiated the charge of having abandoned the doctrine of transubstantiation. while expressing admiration ior Wycliffe. On June 8 he declared that among the propositions he could abjure was that relating to transubstantiation; among those he felt constrained to maintain mas that which denied that Peter mas the head of the church. The council finally demanded that Huss should declare that he had erred in all the articles cited against him; second, that he should promise on oath neither to hold nor teach them in the future; third, that he should publicly recant them. He declined, and sentence of death was pronounced on July 6, in the presence of Sigismund and a full sitting of the council. Once again he attempted to remonstrate, but in vain, and finally he betook himself to silent prayer. He was handed over to the secular arm: and on the same day the fire was kindled, and his voice as it audibly prayed in the words of the "Kyrie Eleison" was soon stifled in the smoke, When the flames had done their office, the ashes that were left and even the soil on which they lay were carefully removed and thrown into the Rhine.

Not many words are needed to convey a tolerably adequate estimate of the character and work of the "pale thin man in mean attire," who in sickness and poverty thus ended at the stake the 46th year of a busy life. The value of Huss as a scholar was iormerly underrated. The publication of his *Super IV sententiarum* has proved that he was a man of real learning. Yet his principal glory will always be iounded on his spiritual teaching. It is not easy to formulate precisely the beliefs for which he died, and certainly some of them, *e.g.,* that regarding the church, were such as many Protestants would regard as unguarded and difficult to harmonize with the maintenance of external church order. By propagating the reiormatory doctrines of Wycliffe, Huss may be said to have handed on to Luther the torch which kindled the Reformation. His popularity in his own country was due both to his oratorical powers and to his pastoral activity.

BIBLIOGRAPHY.—The works of Huss were published at Nuremberg in 1558 (reprinted with new matter at Frankfort in 1715); by K. J. Erben at Prague (1865–68); and by W. Flojšhaus at Prague (1904 fol.). In 1869 F. Palacky edited *Documenta J. Hus vitam, doctrinam, causam in Constantiensi conrilio. See* also the *Letters,* trans. into Eng. by H. B. Workman (1904); J. Loserth, *Hus und Wiclif* (1884; 2nd ed., 1925; Eng. trans., 1884); G. von Lechler, *Johannes Hus* (1889); Count Lützow, *The Life and Times of John Hus* (1909; 2nd ed., 1921); W. N. Schwarze, *John Huss* (1915); D. S. Schaff, *John Huss* (1915).

HUSSAR, originally the name of a soldier belonging to a corps of light horse raised by Matthias Corvinus, king of Hungary, in 1458, to fight against the Turks. The hussar was the typical Hungarian cavalry soldier, and, in the absence of good light cavalry in the regular armies of central and western Europe, the name and character of the hussars gradually spread into Prussia, France, etc. Frederick the Great sent Maj. H. J. von Zieten to study the work of this type of cavalry in the Austrian service. and Zicten so far improved on the Austrian model that he defeated his old teacher, General Baranyai. in an encounter between the Prussian and Austrian hussars at Rothschloss in 1741. The typical uniform oi the Hungarian hussar was followed, with modifications, in other European armies. It consisted of a busbq or a high cylindrical cloth cap. jacket with heavy braiding and a dolman or pelisse, a loose coat worn hanging from the left shoulder. Several hussar regiments of the British army were converted irom light dragoons in the 19th century. The name survived into the Korean war when the 29th British Commonwealth brigade group, embarking irom England in Oct. 1950, included the 8th Royal Irish hussars as the tank unit. (Ls. Ms.)

HUSSERL, EDMUND (1859–1938). philosopher. the father of phenomenology, was born of Jewish parents at Prossnitz (Prostejov) in Moravia on April 8. 1859. To complete the mathematical studies that he had begun in German universities, he went to Vienna in 1834. where. under the influence of Franz Brentano. he discovered that his real bent was for philosophy. In 188; he joined the Lutheran Church. He taught philosophy as *Privatdozent* (unpaid but ofticial lecturer) at Halle from 1887, then as proiessor at Göttingen from 1901 and at Freiburg im Breisgau from 1916 to his retirement in 1928. He died at Freiburg on April 27, 1938.

The phenomenological method, discovered by Husserl about 1896 as a new philosophical approach to describe and define the genuine essence (*eidos*) of conscious data, was presented ior the first time in his *Logische Untersuchungen,* 2 vol. (Halle, 1900–01). In that work he applies this method primarily to the more formal meanings oi logic and mathematics. Intentionality of the consciousness (*i.e.,* the necessary relation of every conscious act to a meaningiul object) is emphasized as being the universal law of awareness; as the source and root of the content and value of all knowledge, he maintains the absolute priority of the intuition.

In *Ideen zu einer reinen Phanomenologie,* hook i (Halle, 1913), phenomenological description is presented as the necessary propaedeutic method to begin authentic philosophical inquiry about every intentional meaning whatsoever. To grasp the meaning of the "intentionally given" in its purity, phenomenological "reduction" is necessary; reduced to meaning as such. the world to be explained in philosophy is not the existing world supposed by the natural attitude, but an infinite multitude of meaningful data, unified by the universal structures by which these data belong to the world. Phenomenology has to describe the basic meanings and structures by "intentional analysis" oi them; *i.e.,* an analysis of their meaning as such. Such an analysis has to respect the necessary relation act-object of all consciousness; consequently the "noetical" (act) and "noematical" (object) aspects of every intentional datum must be analyzed correlatively. Transcendental phenomenology. the theory of the universal constitution of all meaning by the transcendental ego, is nothing else than the metaphysical background required by the intentional analysis. Phenomenology at this stage claims to be a universal and transcendental philosophy, as in the *Cartesianische Meditationen* (Fr. trans., *Méditations cartésiennes,* Paris, 1931) and in "Die Krisis der europäischen Wissenschaften und die transcendentale Phanomenologie," *Philosophia,* i (Belgrade, 1936).

Husserl's descriptive method and his theories about intentionality and intuition exercised wide influence on philosophy, especially in Germany (Max Scheler, Martin Heidegger) and in France (Jean-Paul Sartre, Maurice Merleau-Ponty), and also on psychology (Ludwig Binswanger, F. Buytendijk). In 1939 his manuscripts (about 40,000 pages) were brought together to form the *Archives-Husserl* at Louvain. Much of this material has been published in thr collection *Husserliana,* directed by *H.* L. van Breda (The Hague, 1950 ff.).

HUSSITES, the name given to the followers of John Huss (1369–1415), the Bohemian reformer. They were at first often called Wycliffites, as the theological theories of Huss were largely founded on the teachings of Wycliffe. Huss indeed laid more stress on Church reform than on theological controversy. On such matters he always writes as a disciple of Wycliffe. The Hussite movement may be said to have sprung from three main sources. Bohemia was long but very loosely connected with the Church of Rome. The connection became closer at the time when the papacy was discredited by the great schism. The rapacity of its representatives in Bohemia, and the immorality of the clergy caused general indignation. The Hussite movement was also a democratic one, an uprising of the peasantry against the landowners at a period when a third of the soil belonged to the clergy. F'inaliy, national enthusiasm for the Slavic race contributed largely to its importance. The towns were mainly German; and by the regulations of the University of Prague Germans also held almost all the more important ecclesiastical offices —a condition of things greatly resented by the natives of Bohemia, which at this period had reached a high degree of intellectual development. (*See* BOHEMIA.)

Utraquism.—The Hussite movement assumed a revolutionary character as soon as the news of the death of Huss reached Prague. The knights and nobles of Bohemia and Moravia, who were in favour of Church reform, sent to the council at Constance (Sept. 2, 141j) a protest which condemned the execution of Huss in the strongest language. The uncompromising attitude of Sigismund, king of the Romans, caused trouble in various parts of Bohemia. and many Romanist priests were driven from their parishes. Almost from the first the Hussites were divided into two principal sections. Shortly befcre his death Huss had accepted a doctrine preached during his absence by his adherents at Prague, namely, that of "utraquism," *i.e.,* the obligation of the faithful to receive communion in both kinds. This doctrine became the watchword of the moderate Hussites, known as the Utraquists, while the more advanced Hussites known as the Taborites from the name of their stronghold, recognized only two sacraments, Baptism and Communion, and rejected most of the ceremonial of the Roman Church.

Anti-Hussite Movements.— Under the influence of his brother Sigismund, Ring Wenzel endeavoured to stem the Hussite movement. A certain number of Hussites left Prague. They held meetings in various parts of Bohemia, particularly at Usti, near the spot where the town of Tabor was founded soon after ards. At these meetings Sigismund was violently denounced, and the people everywhere prepared for war. The troubles at Prague continued, and on July 30, 1419, when a Hussite procession marched through the streets, stones were thrown at the Hussites from the windows of the town hall of the "new town." The people, headed by John Žižka (1376–1424), threw the burgomaster and several town councillors from the windows and they were immediately killed by the crowd. On hearing this news King Wenzel was seized with an apoplectic fit and died a few days afterwards. The death of the king resulted in renewed troubles in Prague and in almost all parts of Bohemia. Many Romanists. most of them Germans, were expelled from the Bohemian cities. In Prague, in Nov. 1419, severe fighting took place between the Hussites and the mercenaries whom Queen Sophia (widow of Wenzel) had hurriedly collected. After a considerable part of the city had been destroyed a truce was concluded on Nov. 13. The nobles, who, though favourable to the Hussite cause, yet supported Sophia, promised to act as mediators with Sigismund; while the citizens of Prague consented to restore to the royal forces the castle of Vyšehrad, which had fallen into their hands. Žižka, who disapproved of this compromise, left Prague and retired to Plzeň (Pilsen), then into southern Bohemia, and after defeating the Romanists at Sudomeř—the first pitched battle of the Hussite wars—he arrived at Usti, one of the earliest meeting-places of the Hussites. Not considering its situation sufficiently strong, he moved to the neighbouring new settlement of the Hussites, to which the biblical name of Tabor was given. The ecclesiastical organization of Tabor had a somewhat puritanic character, and the Government was established on a thoroughly democratic basis. Four captains of the people were elected, one of whom was Žižka; and a strictly military discipline was instituted.

The Articles **of** Prague.—On March 17, 1420, Martin V proclaimed a crusade "for the destruction of the Wycliffites, Hussites and all other heretics in Bohemia." **A** vast army of crusaders arrived before Prague on June 30 (see ŽIŽKA, JOHN). Negotiations took place for a settlement of the religious differences. The united Hussites formulated their demands in a statement known as the "Articles of Prague." This document, the most important of the Hussite period, runs thus:

"I. The word of God shall be preached and made known in the kingdom of Bohemia freely and in an orderly manner by the priests of the Lord. . . .

"II. The sacrament of the most Holy Eucharist shall be freely administered in the two kinds, that is bread and wine, to all the faithful in Christ who are not precluded by mortal sin—according to the word and disposition of Our Saviour.

"III. The secular power over riches and worldly goods which the clergy possesses in contradiction to Christ's precept, to the prejudice of its office and to the detriment of the secular arm, shall be taken and withdrawn from it, and the clergy itself shall be brought back to the evangelical rule and an apostolic life such as that which Christ and his apostles led. . . .

"IV. All mortal sins, and in particular all public and other disorders, which are contrary to God's law, shall in every rank of life be duly and judiciously prohibited and destroyed by those whose office it is."

These articles, which contain the essence of the Hussite doctrine, were rejected by Sigismund. Hostilities therefore continued, and nearly all Bohemia fell into the hands of the Hussites. Internal troubles prevented them from availing themselves completely of their victory. At Prague a demagogue, the priest John of Želivo, for a time obtained almost unlimited authority over the lower classes of the townsmen; and at Tabor a communistic movement (that of the so-called Adamites) was sternly suppressed by Žižka. Sigismund only arrived in Bohemia at the end of 1421. He took possession of the town of Kutnar Hora (Kuttenberg), but was decisively defeated by Žižka at Německy Brod (Deutschbrod) on Jan. 6, 1422. Bohemia was now again for a time free from foreign intervention, but internal discord again broke out caused partly by theological strife, partly by the ambition of agitators. There were troubles at Tabor itself, where a more advanced party opposed Žižka's authority. Bohemia obtained a temporary respite when, in 1422, Prince Sigismund Korybutovii: of Poland became for a short time ruler of the country. His authority was recognized by the Utraquist nobles, the citizens of Prague, and the more moderate Taborites, including Žižka. Korybutovič, however, remained but a short time in Bohemia; after his departure civil war broke out, the Taborites opposing in arms the more moderate Utraquists, whose principal stronghold was Prague. On April 27, 1423, Žižka now again leading, the Tahorites defeated at Horic the Utraquist army under Čenek of Wartemberg; shortly afterward an armistice was concluded at Konopoišt.

Further Anti-Hussite Attacks.— Papal influence had meanwhile succeeded in calling forth a new crusade against Bohemia, but it resulted in complete failure. In spite of the endeavours of their rulers, the Slavs of Poland and Lithuania did not wish to attack the kindred Bohemians; the Germans were prevented by internal discord from taking joint action against the Hussites; and the king of Denmark, who had landed in Germany with a large force, soon returned to his own country. Free for a time from foreign aggression, the Hussites invaded Moravia, where a large part of the population favoured their creed; but, again paralyzed by dissensions, soon returned to Bohemia. The city of Königgrätz (Králové Hradec), which had been under Utra-

quist rule, espoused the doctrine of Tabor, and called Žižka to its aid. After several military successes gained by Žižka (*q.v.*) in 1423 and 1424, a treaty of peace between the Hussites was concluded on Sept. 13, 1424, at Liben, now part of Prague.

In 1426 the Hussites were again attacked by foreign enemies. In June their forces, led by Prokop the Great—who took the command of the Taborites shortly after Žižka's death in Oct. 1424—and Sigismund Korybutovič, who had returned to Bohemia, signally defeated the Germans at Aussig (Usti nad Labem). After this great victory, and another at Tachau in 1427, the Hussites repeatedly invaded Germany.

The almost uninterrupted victories of the Hussites now rendered vain all hope of subduing them by force of arms. Moreover, the conspicuously democratic character of the Hussite movement caused the German princes, who were afraid that such views might extend to their own countries, to desire peace. Many Hussites, particularly the Utraquist clergy, were also in favour of peace. Negotiations for this purpose were to take place at the council which had been summoned to meet at Basel on March 3, 1431. The Roman see reluctantly consented to the presence of heretics at this council, but indignantly rejected the suggestion of the Hussites that members of the Greek Church and representatives of all Christian creeds should also be present. Before definitely giving its consent to peace negotiations, the Roman Church determined on making a last effort to reduce the Hussites to subjection. On Aug. 1, 1431, a large army of crusaders, under Frederick, margrave of Brandenburg, crossed the Bohemian frontier; but on the arrival of the Hussite army under Prokop the crusaders immediately took to flight, almost without offering resistance.

Settlement: **of** Disputes.--On Oct. 15, the members of the council, who had already assembled at Basel, issued a formal invitation to the Hussites to take part in its deliberations. Prolonged negotiations ensued; but finally a Hussite embassy arrived at Basel on Jan. 4, 1433. It was found impossible to arrive at an agreement. Negotiations were not, however, broken off; and a change in the political situation of Bohemia finally resulted in a settlement. In 1434 war again broke out between the Utraquists and the Taborites. On May 30 the Taborite army, led by Prokop the Great and Prokop the Less, who both fell in the battle, was totally defeated and almost annihilated at Lipan. The moderate party thus obtained the upper hand; and it formulated its demands in a document known as the *Compactata,* which incorporated the principles laid down in the Articles of Prague.

On July 5, 1436, the compacts were formally accepted at Iglau, in Moravia, by King Sigismund, by the Hussite delegates, and by the representatives of the Roman Church. The Utraquist creed, frequently varying in its details, continued to be that of the established Church of Bohemia till all non-Roman religious services were prohibited shortly after the battle of the White Mountain in 1620. The Taborite party never recovered from its defeat at Lipan, and after the town of Tabor had been captured by George of Poděbrad in 1452 Utraquist religious worship was established there. The Bohemian brethren, whose intellectual originator was Peter Chelčicky, to a certain extent continued the Taborite traditions, and in the 15th and 16th centuries included most of the strongest opponents of Rome in Bohemia. After the beginning of the German Reformation many Utraquists adopted to a large extent the doctrines of Luther and Calvin; and in 1567 obtained the repeal of the compacts, which no longer seemed sufficiently far-reaching.

See E. Denis, *Huss et la guerre des Hussites* (1878); Count Lützow, *Bohemia; an Historical Sketch* (1896); *H.* Toman, *Husitské Válečnictvi* (1898). (Lz.)

HUTCHESON, FRANCIS (1694–1747), British philosopher, the exponent of the moral-sense theory in ethics, was born on Aug. 8. 1694, at Drumalig in County Down, the son of a Presbyterian minister. From 1710 to 1716, he studied philosophy, classics and theology at Glasgow university. He then opened a private academy in Dublin, where he made many friends among the clergy of the Established Church. In 1729, he returned to Glasgow as professor of moral philosophy. In spite of being accused in 1738 before the Glasgow presbytery for holding that the standard of moral goodness was the promotion of the happiness of others and that we could have a knowledge of good and evil without and prior to a knowledge of God, Hutcheson enjoyed a well-deserved popularity. He died in Glasgow in 1747.

Ethics.—Hutcheson wrote on all the major branches of philosophy, but is important chiefly for his ethical writings. His theory was propounded in his *Inquiry Into the Original of Our Ideas of Beauty and Virtue,* in two treatises (London, 1725; rev. ed., *Inquiry Concerning Beauty, Order, Harmony and Design* and *Inquiry Concerning Moral Good and Evil,* 1726); and in *An Essay on the Nature and Conduct of the Passions and Affections, With Illustrations Upon the Moral Sense* (London, 1728). Later works were *Philosophiae moralis institutio compendiaria, ethices et jurisprudentiae naturalis elementa continens* (Glasgow, 1742) and the posthumous *System of Moral Philosophy,* 2 vol. (Glasgow, London, 1755). Opposing Hobbes and Bernard de Mandeville, he closely followed the 3rd earl of Shaftesbury, especially as regards the analogy between beauty and virtue, the functions assigned to the moral sense, the position that the benevolent feelings form an original and irreducible part of our nature and the unhesitating adoption of the principle that the test of virtuous action is its tendency to promote the general welfare. According to Hutcheson, man has a variety of senses, internal as well as external, reflex as well as direct, the definition of a sense being "any determination of our minds to receive ideas independently on our will, and to have perceptions of pleasure and pain" *(Essay on the Nature and Conduct of the Passions,* §1). Without exhaustively enumerating these "senses," he specifies, besides the five external senses (1) consciousness, by which each man has a perception of his own mind; (2) the sense of beauty; (3) a public sense, or *sensus communis,* "a determination to be pleased with the happiness of others and to be uneasy at their misery"; (4) the moral sense, or "moral sense of beauty in actions and affections, by which we perceive virtue or vice, in ourselves or others"; (5) a sense of honour or praise and blame; (6) a sense of the ridiculous. Of these "senses" the "moral sense" is the most important. It is implanted in man and pronounces immediately on the character of actions and affections, approving those which are virtuous and disapproving those which are vicious, because the Author of Nature "has made virtue a lovely form to excite our pursuit of it, and has given us strong affections to be the springs of each virtuous action." Hutcheson's use of the term "moral sense" and his failure to couple it invariably with the term "moral judgment" tends to obscure the part played by deliberation.

But though Hutcheson usually describes the moral faculty as acting instinctively and immediately, he does not confound the moral faculty with the moral standard. The criterion of right action is for him, as for Shaftesbury, its tendency to promote the general welfare of mankind. He thus anticipates the utilitarianism of Jeremy Bentham even in the use of the phrase "the greatest happiness for the greatest number" *(Inquiry Concerning Moral Good and Evil,* §3). But since intuition has no possible connection with an empirical calculation of results, Hutcheson in adopting such a criterion practically denies his fundamental assumption. His most distinctive ethical doctrine is the "benevolent theory" of morals by which he opposes Hobbes. He maintains not only that benevolence is the direct source of many of our actions, but also that it is the only source of those actions of which, on reflection, we approve. Actions which flow from self-love only are morally indifferent,, though in so far as a man may justly regard himself as a part of the rational system and may thus "be, in part, an object of his own benevolence," the "personal virtues" may be regarded as fitting objects of moral approbation. Hutcheson inconsistently declares that while self-love merits neither approbation nor condemnation, the satisfaction of the dictates of self-love is one of the very conditions of the preservation of society. In the *Synopsis metaphysicae (see* below), he holds that will is determined by motives in conjunction with our character and habit of mind, and that the only true liberty is the liberty of acting as we will. not the liberty of willing as we will.

The prominence given by Hume and Adam Smith to the analysis of moral action and moral approbation, with the attempt to distinguish between the respective province of the reason and that of the emotions in these processes, is undoubtedly due to the influence of Hutcheson. To a study of Shaftesbury and Hutcheson we might probably attribute Hume's unequivocal adoption of the utilitarian standard. Objections to Hutcheson's system were made by John Balguy in *The Foundation of Moral Goodness* (1727–28); by the dissenter John Taylor (1694–1761) in *An Examination of the Scheme of Morality Advanced by Dr. Hutcheson* (1759); and, most notably, by Richard Price (*q.v.*) in his *Review of the Principal Questions and Difficulties in Morals* (1758). (*See* ETHICS, HISTORY OF.)

Epistemology and Logic. — Hutcheson's most important work apart from the ethical writings was the *Metnphysicae synopsis ontologiam et pneumatologiam complectens* (Glasgow, 1742; and ed., *Synopsis metaphysicae,* etc., 1744). Both his epistemology and his logic are interesting mainly as a link between Locke and the Scottish school. With Locke he rejects the doctrine of innate ideas (*see,* for instance, *Inquiry Concerning Moral Good and Evil,* 1 *ad fin.,* and $4; *cf. Synopsis,* pars i. cap. 2); but he modifies Locke's doctrine and anticipates Thomas Reid when he states that the ideas of extension. figure, motion and rest "are more properly ideas accompanying the sensations of sight and touch than the sensations of either of these senses"; that the idea of self accompanies every thought; and that the ideas of number, duration and existence accompany every other idea whatsoever (see *Essay,* art. 1; *Synopsis,* pars i. cap. 1, pars ii. cap. 1). Like Locke, Hutcheson also depreciates the importance of the so-called laws of thought, distinguishes between the primary and secondary qualities of bodies, asserts that we cannot know the inmost essences of things though they excite various ideas in us and assumes that external things are known only through the medium of ideas (*Synopsis,* pars i. cap. 1). He accounts for our assurance of the reality of externals by referring it to a natural instinct (*Synopsis,* pars i. cap. 1). Of the correspondence between our ideas of the primary qualities of things and the things themselves God alone is the cause, having effected it through a law of nature.

Hutcheson diverges from Locke in his account of the idea of personal identity, which he appears to have regarded as made known to us directly by consciousness. Generally, he speaks as if we had a direct consciousness of mind as distinct from body (*see,* for instance. *Synopsis,* pars ii. cap. 3), though in the posthumous *System of Moral Philosophy* he expressly states that we know mind as we know body "by qualities immediately perceived though the substance of both be unknown" (bk. i, ch. 1). Other points in which he supplemented or departed from Locke are: the distinction between perception proper and sensation proper. which is not explicitly worked out; the imperfection of the ordinary division of the external senses into five; the limitation of consciousness to a special mental faculty; and the disposition to refer on disputed questions of philosophy not so much to formal arguments as to the testimony of consciousness and our natural instincts. The last point suggests the "common-sense philosophy" of Reid.

The short *Logicae compendium* contains a large proportion of psychological matter. The author distinguishes between the mental result and its verbal expression (idea as distinct from term; judgment as distinct from proposition). constantly employs the word "idea" and defines logical truth as *convenientia signorum cum rebus significatis* ("a concord of the signs with the things signified"), thus implicitly repudiating a merely formal view of logic.

Aesthetics. — Hutcheson is one of the earliest modern writers on aesthetics. He maintains that the special sense by which we perceive beauty. harmony and proportion is a *reflex* sense. presupposing sight and hearing. Beauty is also perceived in universal truths, in the operations of general causes and in moral principles and actions. Thus, the analogy between beauty and virtue, a favourite topic with Shaftesbury, is prominent in Hutcheson also. (*See* AESTHETICS.)

HUTCHINS, ROBERT MAYNARD (1899–), U.S. educator and critic of overspecialization and lack of balance in the college curriculum and the failure of colleges and universities to maintain and enlarge the intellectual tradition of the western world. He was born in Brooklyn, N.Y., on Jan. 17, 1899. After two years at Oberlin college, Oberlin, O., he served in the ambulance service of the U.S. army, 1917–19, and the Italian army. 1918–19. He received the degrees of A.B. (1921) and LL.B. (1925) from Yale where he later became dean of the law school. In 1929, at the age of 30, he was elected president of The University of Chicago, becoming chancellor in 1945 and remaining there until his appointment as a foundation executive in 1951. He became a centre of controversy by insisting that the problems of higher education in the United States following World War I have been confusion about the purposes of higher education, with consequent overemphasis upon athletics, social life and specific vocational training, and use of hours spent in class as a measure of a student's education. His criticisms and proposals have been vigorously debated and widely accepted. His interests in educational reform are part of his broader concern with the improvement of American society. His vigorous defense of nonconformity and protest as having been essential to the growth of that society and his analysis of education in the United States as drifting toward specialization and pragmatism are presented in his published lectures, including *The Higher Learning in America* (1936), *Education for Freedom* (1943), *The Conflict in Education* (1953), *University of Utopia* (1953) and *Sonze Observations on American Education* (1956). His other publications include books and articles on education and *Freedom, Education, and the Fund: Essays and Addresses, 1946–1956* (1956). He became editor in chief of *Great Books of the Western World* (1952) and chairman of the board of editors of *Encyclopedia Britannica.*

(R. W. TR.)

HUTCHINSON, ANNE (*c.* 1600–1643), American religious enthusiast and one of the founders of Rhode Island, was born in Lincolnshire, Eng., the daughter of a clergyman, Francis Marbury, and according to tradition, a cousin of John Dryden. She married William Hutchinson, and in 1634 emigrated to Boston, Mass. Although her orthodoxy was suspected and for a time she was not admitted to the church, she soon organized meetings among the Boston women, among whom her exceptional ability and her services as a nurse had given her great influence. At these meetings, which were soon attended even by some of the ministers and magistrates, she discussed and commented upon recent sermons and gave expression to her own theological views. She asserted that she; John Cotton (*q.v.*) and her brother-in-law, the Rev. John Wheelwright, were under a "covenant of grace," that they had a special inspiration, a "peculiar indwelling of the Holy Ghost," whereas the other ministers of the colony were under a "covenant of works." Anne Hutchinson, according to Winthrop a woman "of a ready wit and bold spirit," was, in fact, voicing a protest against the legalism of the Massachusetts Puritans, and was also striking at the authority of the clergy in an intensely theocratic community. As a result the entire colony was divided into factions. Mrs. Hutchinson was supported by Gov. Sir Henry Vane. Cotton, Wheelwright and the great majority of the Boston church; opposed to her were Deputy Gov. John Winthrop, the Rev. John Wilson of the Boston church and all of the country magistrates and churches. The strength of the parties was tested at the general court of election of May 1637, when Winthrop defeated Vane for the governorship. Cotton recanted, Vane returned to England in disgust, Wheelwright was tried and banished. Mrs. Hutchinson was tried by the general court chiefly for "traducing the ministers," and was sentenced to banishment; later she was

tried before the Boston church and formally excommunicated. With William Coddington and others she established a settlement on the island of Aquidneck (now Rhode Island) in **1638.** Four years later, after the death of her husband, she settled on Long Island sound near what is now New Rochelle, N.Y., and was killed by the Indians in Aug. **1643,** an event regarded in Massachusetts as a manifestation of divine providence. Anne Hutchinson and her followers were called "Antinomians," rather as a term of reproach than with any reference to her doctrinal theories, and the controversy in which she was involved is known as the "Antinomian controversy."

Ellis, *The Puritan Age and Rule in the Colony of Massachusetts, 1629–1685* (1888); Helen Augur, *An American Jezebel: the Life of Anne Hutchinson* (1930); Edith Curtis, *Anne Hutchinson: a Biography* (1930). (RT. P. B.)

HUTCHINSON, JOHN (1615–1664), English Puritan, son of Sir Thomas Hutchinson of Owthorpe, Nottinghamshire, was baptized on Sept. **18, 1615.** On the outbreak of the Civil War he took parliament's side and was made in **1643** governor of Nottingham castle, which he defended till the triumph of the parliamentary cause. He became a member of parliament for Nottinghamshire in March **1646,** took the side of the Independents, opposed the offers of the king at Newport and signed the death warrant. Though a member at first of the council of state, he disapproved of Oliver Cromwell's policy and took no further part in politics during the lifetime of the protector.

He resumed his seat in the recalled Long parliament in May **1659,** and followed George Monk in opposing John Lambert, believing that Monk intended to maintain the Commonwealth. He was returned to the Convention parliament for Nottingham but expelled on June **9, 1660.**

In Oct. **1663** he was arrested upon suspicion of being concerned in the Yorkshire plot, imprisoned in the Tower of London and in Sandown castle, Kent, where he died on Sept. **11, 1664.**

HUTCHINSON, JOHN (1674–1737), English theological writer, was born at Spennithorne, Yorkshire, in 1674. He served as stenard in several families of position, latterly in that of the duke of Somerset, nho ultimately obtained for him the post of riding purveyor to the master of the horse, a sinecure worth about £200.

He taught that the Bible contained the elements not only of true religion but also of all rational philosophy. He held that the Hebrew must be read without points, and his interpretation rested largely on fanciful symbolism. His followers were called Hutchinsonians.

His *Works* were edited by Robert Spearman and Julius Bate 12 vol. (1748). A *Supplement,* with *Life* by Spearman prefixed, appeared in 1765.

HUTCHINSON. SIR JONATHAN (1828–1913), English surgeon and pathologist. whose principal nork was in the study of syphilis, was born on July **23, 1828,** at Selby. Yorkshire, his parents belonging to the Society of Friends. He entered St. Bartholomew's hospital and gained a reputation as a skillful operator and a scientific inquirer. He was Hunterian professor at the Royal College of Surgeons, 1879–83, and in **1889** nas president of the college. His lectures on neuropathogenesis, gout, leprosy, diseases of the tongue. etc., as well as his studies in syphilis, were full of original observations. He was the founder of the London Polyclinic or Post-graduate School of Medicine and the promoter of the New Sydenham society for the publication of translations of important foreign medical treatises. He published several volumes on his own subjects and was editor of the quarterly *Archives* of *Surgery.* Hutchinson received a knighthood in 1908 and died at Haslemere on June 26, 1913.

HUTCHINSON, THOMAS (1711–1780), the last royal governor of the province of Massachusetts, son of a wealthy merchant of Boston, Mass., mas born there on Sept. **9,** 1711. He graduated at Harvard in 1727 and for several years thereafter devoted himself to business. In 1737 he began his public career as a member of the Boston board of selectmen, and a few weeks later he was elected to the general court of Massachusetts Bay, of which he was a member until 1740 and again from 1742 to 1749, serving as speaker in **1747,** 1748 and 1749. He consistently contended for a sound financial system and vigorously opposed the operations of the "land bank" and the issue of pernicious bills of credit. His first trip to England was in 1740 when he represented his colony in a boundary dispute with New Hampshire. He was a member of the Massachusetts council from **1749** to **17j6,** was chief justice of the superior court of the province from **1761** to **1769,** was lieutenant governor from 1758 to 1771, acting as governor in the latter two years. and from 1771 to **1774** was governor. In 1754 he was a delegate from Massachusetts to the Albany convention and, with Franklin, was a member of the committee appointed to draw up a plan of union. Though he recognized the legality of the Stamp act of 1765, he considered the measure inexpedient and impolitic and urged its repeal, but his attitude was misunderstood; he was considered by many to have instigated the passage of the act, and in Aug. 1765 a mob sacked his Boston residence and destroyed many valuable manuscripts and documents. He was acting governor at the time of the "Boston massacre" in 1770, and it was his orders that removed the British troops from the town. Throughout the prerevolutionary disturbances in Massachusetts he was the representative of the British ministry, and though he disapproved of some of the ministerial measures he felt impelled to enforce them and necessarily incurred the hostility of the Whig or patriot element. In 1774, upon the appointment of Gen. Thomas Gage as military governor, he went to England, and acted as an adviser to George III and the British ministry on American affairs, uniformly counseling moderation. He died at Brompton, now part of London, on June **3, 1780.**

He wrote *A Brief Statement of the Claim of the Colonies (1764);* a *Collection of Original Papers Relative to the History of Massachusetts Bay* (1769), reprinted as *The Hutchinson Papers* by the Prince Society in 1865; and a judicious, accurate and very valuable *History of the Province of Massachusetts Bay* (vol i, 1764, vol. ii, 1767, and vol iii, 1828). His *Dzary and Letters, With an Account of Hzs Administtation,* was published at Boston in 1884–86.

See J. K. Hosmer, *Lzfe of Thomas Hutchinson* (1896); and a biographical chapter in John Fiske, *Essays Historical and Literary* (1902) For an estimate of Hutchinson as an historian, *see* M. C. Tyler, *Literary History of the American Revolution* (1897).

HUTCHINSON, a city of south-central Kansas, US., and seat of Reno county, **40** mi. N.W. of Wichita Established on the north bank of the Arkansas river in **1871** by C. C. Hutchinson. who was originally sent to Kansas as an Indian agent for the federal government, Hutchinson began developing with the arrival of the Santa Fe railroad in **1872,** the year of the city's incorporation.

In Sept. **1887** thick beds of salt were discovered there, which led to the development of a major industry. The city sits atop what are reputedly some of the world's richest salt deposits, which are mined, processed and shipped to markets in all parts of the U.S. Hutchinson is also a principal primary hard wheat market, aith a grain storage capacity of approximately 35,000,000 bu. It is centred in one of the middle west's richest oil fields, and its petroleum production, banking, transportation, flour milling, building products, farm machinery manufacturing and wholesale grocery business are important factors in the economy of the area.

Hutchinson is the site of the annual Kansas State fair, several important athletic tournaments and the State Industrial reformatory. Hutchinson junior college. founded in **1928** as a senior high school, is operated as a part of the public-school system. For comparative population figures *see* table in KANSAS: *Population.*

(R. W. RI.)

HUTTEN, PHILIPP VON (*c.* 1511–1546), German knight, a relative of Ulrich von Hutten, joined the band of adventurers which under Georg Hohermuth, or George of Spires, sailed to Venezuela, or Venosala as Hutten calls it, with the object of conquering and exploiting this land in the interests of the Augsburg family of Welser. The party landed at Coro in February 1535 and Hutten accompanied Hohermuth on his toilsome expedition into the interior in search of treasure. After the death of Hohermuth in December 1540 he became captain-general of Venezuela. Soon after this event he vanished into the interior,

returning after five years of wandering to find that a Spaniard, Juan de Caravazil, or Caravajil, had been appointed governor in his absence. With his travelling companion, Bartholomew Welser the younger, he was seized by Caravazil in April 1546 and the two were afterwards put to death.

Hutten left some letters, and also a narrative of the earlier part of his adventures, this *Zeitung aus India Junkher Philipps von Hutten* being published in 1785.

HUTTEN, ULRICH VON (1488–1523), German humanist and soldier, was born on April 21, 1488, at the castle of Steckelberg, near Fulda, in Hesse. His life may be divided into four parts:—his youth and cloister-life (1488–1504); his wanderings in pursuit of knowledge (1504–1515); his strife with Ulrich of Wurttemberg (1515–1519); and his connection with the Reformation (1519–1523). He was the eldest son of a poor but not undistinguished knightly family.

Wanderings. — As he was mean of stature and sickly his father sent him to the Benedictine house at Fulda; the thirst for learning there seized on him, and in 1505 he fled from the monastic life. He went first to Cologne, next to Erfurt, and then to Frankfort-on-Oder on the opening in 1506 of the new university of that town. For a time he was in Leipzig, and in 1508 we find him a shipwrecked beggar on the Pomeranian coast. In 1509 the university of Greifswald welcomed him, but the sensitive ill-regulated youth, who took the liberties of genius, wearied his burgher patrons. He left Greifswald and was robbed of clothes and books, his only baggage, by the servants of his late friends; in the dead of winter, half starved, frozen, penniless, he reached Rostock.

Here under the protection of the Humanists he wrote against his Greifswald patrons, thus beginning the long list of his satires and fierce attacks on personal or public foes. From Rostock he wandered on to Wittenberg and Leipzig, to Vienna and on to Pavia, where he spent the year 1511 and part of 1512. In the siege of Pavia (1512) by papal troops and Swiss, he was plundered by both sides, and escaped, sick and penniless, to Bologna; on his recovery he took service as a private soldier in the emperor's army.

In 1514 he was again in Germany, under the patronage of the elector of Mainz, Archbishop Albert of Brandenburg. But the murder in 1515 of his relative Hans von Hutten by Ulrich, duke of Wiirttemberg, changed the whole course of his life; satire, chief refuge of the weak, became Hutten's weapon; with one hand he took his part in the famous *Epistolae obscurorum virorum*, and with the other launched scathing letters, eloquent Ciceronian orations, or biting satires against the duke. The emperor took Hutten under his protection and gave him a laureate crown in 1517. The poet, who had meanwhile revisited Italy, again attached himself to the electoral court at Mainz. In 1518 his friend Pirckheimer urged him to abandon the court and dedicate himself to letters, but he insisted on his mission as a knight of the empire.

The Knightly Satirist. — In 1519 he issued in one volume his five attacks on Duke Ulrich, and then took part in the private war against him; in this affair he became intimate with Franz von Sickingen, the champion of the knightly order (Ritterstand). Hutten now espoused the Lutheran cause, but he was at the same time mixed up in the attempt of the "Ritterstand" to assert itself as the militia of the empire against the independence of the German princes. Soon after this time he discovered at Fulda a copy of the manifesto of the emperor Henry IV. against Hildebrand, and published it with comments as an attack on the papal claims over Germany. He hoped thereby to interest the new emperor Charles V., and the higher orders in the empire, in behalf of German liberties; but the appeal failed. Luther had succeeded by speaking to cities and common folk in homely phrase, because he touched heart and conscience; Hutten tried to touch the more cultivated sympathies and dormant patriotism of princes and bishops, nobles and knights. And so he at once gained an undying name in the republic of letters and ruined his own career. He showed that the artificial verse-making of the Humanists could be connected with the new outburst of genuine German poetry. The Minnesinger was gone; the new national singer, a Luther or a Hans Sachs, was heralded by the stirring lines of Hutten's pen. These have in them a splendid natural swing and ring, strong and patriotic.

The attack on the papacy, and Luther's vast and sudden popularity, frightened Elector Albert, who dismissed Hutten from his court. Hoping for imperial favour, he betook himself to Charles V., but was rebuffed. He now attached himself more closely to Franz von Sickingen. He fled to Basel, where Erasmus refused to see him, both for fear of his loathsome diseases, and also because the beggared knight was sure to borrow money from him. A paper war consequently broke out between the two Humanists, which embittered Hutten's last days, and stained the memory of Erasmus. From Basel Ulrich went to Miilhausen; and then to Zurich.

There Zwingli helped him with money, and found him a refuge on the little isle of Ufenau on the Zurich lake. There the frail and worn-out poet, writing swift satire to the end, died on Aug. 29, 1523 at the age of thirty-five. He left behind him some debts due to compassionate friends; he did not even own a single book, and all his goods amounted to the clothes on his back, a bundle of letters, and that valiant pen which had fought so many a sharp battle, and had won for the poor knight-errant a sure place in the annals of literature.

Ulrich von Hutten is one of those men of genius at whom propriety is shocked, and whom the mean-spirited avoid. Yet through his short and buffeted life he was befriended, with wonderful charity and patience, by the chief leaders of the Humanist movement. For, in spite of his irritable vanity, his immoral life and habits, his odious diseases, his painful restlessness, Hutten had much in him that strong men could admire, for he passionately loved truth for its own sake. His patriotism is beyond dispute, though the cause with which he associated himself was particularist and doomed to failure. There was no salvation for Germany in the Ritterstand. It is as humanist and poet, and for his frank and noble nature that his claims to honour lie. A swarm of writings issued from his pen; at first the smooth elegance of his Latin prose and verse seemed strangely to miss his real character; he was the Cicero and Ovid of Germany before he became its Lucian.

His chief works were his *Ars versificandi* (1511); the *Nemo* (1518); a worh on the *Morbus Gallicus* (1519); the volume of Steckelberg complaints against Duke Ulrich (including his four *Ciceronian Orations*, his *Letters* and the *Phalarismus)* also in 1519; the *Vadismus* (1520); and the controversy with Erasmus at the end of his life. Besides these were many admirable poems in Latin and German. He was one of the most distinguished contributors to, though not the originator of the *Epistolae obscurorum virorum*, that famous satire on the theoiogians of Cologne with which the friends of Reuchlin defended him. In 1909 the Latin text of the *Epistolae* with an English translation was published by F. G. Stokes. D. F. Strauss concludes that he had no share in the first part, but that his hand is clearly visible in the second part, which he attributes in the main to him. To him is due the more serious and severe tone of that bitter portion of the satire. *See* W. Brecht, **Die** *Verfasser der Epistolae obscurorum virorum* (1904).

For a complete catalogue of the writings of Hutten, *see* E. Bocking, *Index Bibliographicus Huttenianus* (1858). Bocking also edited the complete works (7 vol., 1859–62). **A** selection of Hutten's German writings, edited by G. Balke, appeared in 1891.

BIBLIOGRAPHY.—The best biography (though it is also somewhat of a political pamphlet) is that of D. F. Strauss *(Ulrich von Hutten,* 1857; new ed. by O. Clemen, 1914; Eng. trans. by G Sturge, 1874), with which may be compared P. Kalkoff, *Ulrich oon Hutten und die Reformation* (1920), and Huttens, *Vaganten zeit und Untergang* (1925), in which a less favourable view of Hutten's political and religious activity is taken.

HUTTER, LEBNHARD (1563–1616), German Lutheran theologian, born at Nellingen, near Ulm, began to lecture at Jena in 1594, and in 1596 became professor of theology at Wittenberg. where he died on Oct. 23, 1616. Hutter was a champion of Lutheran orthodoxy, as set down in the confessions and embodied in his own *Compendium locorum theologicorum* (1610; reprinted 1863). He was called "Luther redonatus."

In reply to Rudolf Hospinian's *Concordia discors* (1607), he wrote *Concordia concors* (1614), defending the formula of Con-

cord, which he regarded as inspired. His *Irenicum vere christianum* is directed against David Pareus (1548–1622), of Heidelberg, aho had pleaded for a reconciliation of Lutheranism and Calvinism; his *Calvinista aulopoliticus* (1610) nas written against the "damnable Calvinism" which was becoming prevalent in Holstein and Brandenburg. Another work, based on the formula of Concord, was entitled *Loci communes theologici*. Karl von Hase used his name as the symbol of orthodoxy in his *Hutterus redivivus* (1827).

HUTTON, ARTHUR WOLLASTQN (1848–1912), English clergyman and author, was born at Spridlington, Lincolnshire, on Sept. 5, 1848. A scholar of Exeter college, Oxford, he took orders in the Church of England in 1872, but under Newman's influence became a Roman Catholic and from 1876 to 1883 was a member of the Edgbaston Oratorian community. Later he renounced Roman Catholicism and became known as an agnostic and freethinker. For several years he was librarian at the National Liberal club in London. In 1898 he mas readmitted to the Church of England, and from 1903 until his death was rector of Bow church, London.

Hutton died at Blackheath on March 25, 1912. He wrote a *Life of Manning* (1892).

HUTTON, JAMES (1726–1797), Scottish geologist who formulated the basic theory that geologic phenomena can be explained in terms of observable geologic processes, was born in Edinburgh on June 3, 1726. He qualified as a doctor of medicine, studying in Edinburgh and Paris, but turned to practical agriculture, in which he made many improvements. In 1768 he retired, and from then until his death (in Edinburgh on March 26, 1797) he devoted himself to scientific pursuits.

Hutton conceived larger ideas than were entertained by the mineralogists of his day. He desired to trace the origin of the various minerals and rocks and thus to arrive at some clear understanding of the history of the earth. In 1785 he communicated his views to the recently established Royal Society of Edinburgh in a paper entitled "Theory of the Earth, or an Investigation of the Laws Observable in the Composition, Dissolution, and Restoration of Land Upon the Globe," published in the society's *Transactions*. Hutton's work was little recognized until the publication of John Playfair's *Illustrations of the Huttonian Theory* (1802; facsimile reprint with introduction by G. W. White, 1956), a lucid exposition of the postulate that the processes that have been at work on the earth in the past are the same as those now in operation.

The same volume of the *Transactions* in which his "Theory of the Earth" appeared contained also a "Theory of Rain," which was read to the Royal society in 1784 His other works include: *Dissertations on DifferentSubjects in Natural Philosophy* (1792), in which he discussed the nature of matter, fluidity, cohesion, light, heat and electricity, and *Arc Investigation of the Principles of Knowledge, and of the Progress of Reason From Sense to Science and Philosophy*. His closing years were devoted to the extension and republication of his *Theory of the Earth*, of which two volumes appeared in 1795. A portion of the manuscript of a third volume was edited by A. Geikie in 1899.

For an evaluation of Hutton's contributions to geologic theory *see* GEOLOGY: *Development of the Science: 18th-Century Advances*. (A. GEI.; *X.*)

HUTTON, RICHARD HOLT (1826–1897), English writer and theologian, son of Joseph Hutton, Unitarian minister at Leeds, was born at Leeds on June 2, 1826. From 1855 to 1895 Hutton and Walter Bagehot were joint editors of the *National Review*, a new monthly, and conducted it for ten years. In 1861 Hutton became joint editor and part proprietor of the *Spectator*, then a \yell-known Liberal weekly. Hutton's own articles became and remained up to the last one of the best-known features of serious and thoughtful English journalism. He was an original member of the Metaphysical society (1869), an antivivisectionist and a member of the royal commission (1875) on that subject. Hutton died on Sept. 9, 1897. Selections from his *Spectator* articles were published in 1899 under the title of *Aspects of Religious and Scientific Thought*.

HUXLEY, SIR JULIAN SORELL (1887–), English biologist, philosopher, educator and author who had a great influence in the modern development of embryology, systematics, behaviour and evolution. The son of Leonard Huxley and the grandson of Thomas Henry Huxley, he was born June 32, 1887, at London. He was educated at Eton and at Balliol college: Oxford. Some of his most important positions were those of assistant professor at Rice institute, Houston, Tex. (1913–16); fellow, New college, Oxford (1919–25); professor, King's college, University of London (1925–27); secretary of the Zoological Society of London (1935–42): and director general of the United Nations Educational, Scientific and Cultural organization (1946–48). He was an officer of many scientific societies, several of which he organized. He mas elected a fellow of the Royal society in 1938. Huxley was author, co-author or editor of many important books, including *The Individual in the Animal Kingdom* (1912); *Religion Without Revelation* (1927); *The Science of Life* (1931); *Problenzs of Relative Growth* (1932); *The Captive Shrew and Other Poems of a Biologist* (1932); *The Elements of Experimental Embryology* (1934); *The New Systematics* (1940); *The Uniqueness of Man* (1941); *Evolution, the Modern Synthesis* (1942); *Touchstone for Ethics, 1893–1943* (1947); *Soviet Genetics and World Science* (1949); *Evolution as a Process* (1954); and *Toward a New Humanism* (1957).

Huxley was a leader in relating science to human social life and to religion. His versatility of interests, combined with scientific scholarship, philosophical penetration and communication with the public, constitute his noteworthy contributions to modern culture. (A. E. E.)

HUXLEY, THOMAS HENRY (1825–1895), English biologist whose speculations on philosophy and religion led him to a powerful advocacy of the principle of agnosticism: was born on May 4, 1825, at Ealing, the seventh child of George Huxley, a schoolmaster. "Physically. . . I am the son of my mother so completely . . . that I can hardly find any trace of my father in myself, except an inborn faculty for drawing, . . . a hot temper, and that amount of tenacity of purpose which unfriendly observers sometimes call obstinacy." (*Life*, i, 3.) When his father moved to Coventry about 1835, young Henry was left to his own devices. His great desire to be a mechanical engineer ended in his devotion to "the mechanical engineering of living machines." At the age of 17, with his elder brother James, he commenced regular medical studies at Charing Cross hospital, and on graduating in 1845 published his first paper on the hitherto unrecognized layer in the inner sheath of hairs, subsequently known as Huxley's layer.

Having obtained the qualification of the Royal College of Surgeons, Huxley sought and received an appointment in the Royal Navy; according to books kept on board Nelson's old ship "Victory," he was posted for duty to Haslar hospital. Huxley's chief at Haslar, Sir John Richardson, a well-known arctic explorer and naturalist, recognized his ability and procured for him the post of surgeon in H.M.S. "Rattlesnake," which was about to set out for surveying work in Torres strait, between north Australia and Papua. By the time the ship was paid off at Chatham in Nov. 1850, Huxley had made a profound study of the surface life of the tropical seas. His important paper "On the Anatomy and the Affinities of the Family of Medusae" was printed by the Royal society in its *Philosophical Transactions* (1849). Huxley united the hydroid polyps with the Medusae to form a class, the Hydrozoa, in which the body consisted of two layers comparable with the ectoderm and endoderm formed during the development of higher animals.

Huxlcy was elected a fellow of the Royal ,society in 1851, and in the following year received the society's royal medal and was elected to the council.

In anatomical studies, his views differed sharply from the accepted notions of Richard Owen, the leading comparative anatomist in Great Britain. Owen was a disciple of Georges Cuvier, and adopted largely from him the deductive explanation from idealistic conceptions of anatomical facts, to which he added the transcendental "archetypal" theory of Lorenz Oken. Huxley would have none of either view, for his methods were purely inductive. He would not hazard any statement beyond what the facts revealed?

and Herbert Spencer, whose acquaintance he made in *1852*, was unable to convert him to belief in evolution in its widest sense *(Life*, i, *168)*. At about the same time, in his first interview with Charles Darwin, Huxley expressed his belief "in the sharpness of the line of demarcation between natural groups" and was received with a humorous smile *(Life*, i, *169)*.

In July *1854*, after leaving naval service earlier that year, Huxley became lecturer in natural history at the School of Mines, and in *1855* naturalist to the geological survey. His most important published work at this period was the Croonian lecture of 1858 on "The Theory of the Vertebrate Skull," in which, by his inductive method, he completely demolished the idealistic views of the origin of the skull held by Richard Owen. This finally disposed of the "archetype," and may be said to have liberated the English anatomical school from the deductive method.

In *1859* Darwin's *The Origin of Species* was published. This was a momentous event in the history of science, and not least for Huxley, who found in Darwin's theory an intelligible hypothesis on which to base a study of evolution. At the Oxford meeting of the British Association for the Advancement of Science in *1860*, Huxley's defense of evolution against the attacks of Bishop Samuel Wilberforce *(q.v.)* resulted in a victory for science over obscurantism. *(See* also DARWIN, CHARLES ROBERT; DARWINISM.) Owen, who could not break with orthodoxy, asserted that man was clearly marked off from other animals by the anatomical structure of his brain. This statement was inconsistent with known facts, and was effectually refuted by Huxley in various papers and lectures, summed up in *1863* in *Man's Place in Nature*. In 1881 he asserted that if the hypothesis of evolution "had not existed, the palaeontologist would have had to invent it" *(Essays*, iv, *44)*. In *1892* he wrote: "The doctrine of evolution is no speculation, but a generalization of certain facts . . . classed by biologists under the heads of Embryology and of Palaeontology" *(Essays*, v, 42).

Meanwhile, Huxley had been drawn into paleontological research. His numerous memoirs on fossil fishes established many far-reaching morphological facts. The study of fossil reptiles led to his demonstration of the fundamental affinity of reptiles with birds as one group, under the title of Sauropsida. His *Lessons in Elementary Physiology (1866)* and *Anatomy of Vertebrated Animals (1871)* were masterpieces of exposition in these subjects. He also proposed a rearrangement of the zoological regions into the primary divisions — Arctogaea, to include the land areas of the northern hemisphere, and Notogaea for the remainder.

From *1870* onward Huxley was more and more drawn away from scientific research by the claims of public duty. Between *1862* and *1884* he served on no less than ten royal commissions. From *1871* to 1880 he was a secretary of the Royal society, and from 1883 to *1885* its president; while from 1870 to *1872* he served as a member of the newly constituted London school board. During his brief period of activity in this last position, he probably made a deeper impress on the foundations of national elementary education than any other man. He made war on the scholastic methods which wearied the mind in merely taxing the memory; the children were to be prepared to take their place worthily in the community. Physical training was to be the basis of the curriculum; domestic economy, at any rate for girls, was insisted upon, and for all some development of the aesthetic sense by means of drawing and singing. Reading, writing and arithmetic were the indispensable tools for acquiring knowledge, and intellectual discipline was to be gained through studying the rudiments of physical science. He insisted on the teaching of the Bible, partly for its standing as a great literary heritage, partly because he was "seriously perplexed to know by what practical measure the religious feeling, which is the essential basis of conduct, was to be kept up, in the present utterly chaotic state of opinion in these matters, without its use" *(Essays*, iii, 397), and also because it was "the most democratic book in the world."

In *1872* the School of Mines was moved to South Kensington, and Huxley had, for the first time, appliances for teaching beyond the lecture room. Up to this time he had been able to bring his influence to bear upon his pupils by oral teaching only; but now he was able to design a laboratory course enabling the student to examine for himself the things described in lectures. His system of instruction, for classes of elementary teachers, in the general principles of biology indirectly affected the teaching of the subject throughout the country. In *1892* he was made a privy councilor.

The later years of Huxley's life were mainly occupied with contributions to periodical literature on subjects connected with philosophy and theology. The only approach to certainty which he admitted lay in the order of nature. "If there is anything in the world which I do firmly believe in, it is the universal validity of the law of causation, but that universality cannot be proved by any amount of experience." *(Essays*, ix, 121.) The assertion that "There is only one method by which intellectual truth can be reached, whether the subject-matter of investigation belongs to the world of physics or to the world of consciousness" *(Essays*, ix, 126) laid him open to the charge of materialism, which he vigorously repelled.

From 1880 onward Huxley was occupied in a campaign against orthodox beliefs. In 1885 he formulated "the perfect ideal of religion" in a passage which has become famous: "In the 8th century B.C. in the heart of a world of idolatrous polytheists, the Hebrew prophets put forth a conception of religion which appears to be as wonderful an inspiration of genius as the art of Pheidias or the science of Aristotle. 'And what doth the Lord require of thee, but to do justly, and to love mercy, and to walk humbly with God' " *(Essays*, iv, 161). Two years later he was writing: "That there is no evidence of the existence of such a being as the God of the theologians is true enough" *(Life*, ii, *162)*. He never really advanced beyond the recognition of "the passionless impersonality of the unknown and unknowable which science shows everywhere underlying the thin veil of phenomena" *(Life*, i, 239), though he insisted that "atheism is on purely philosophical grounds untenable" *(Life*, ii, *162)*. In its place he put forward the principle of agnosticism *(q.v.)* which involved the subordination of belief to evidence and reason *(Life*, ii, *221)*.

Huxley's personal creed was a kind of scientific Calvinism. He finally defines that which, "since the second century, has assumed to itself the title of orthodox Christianity" as a "varying compound of some of the best and some of the worst elements of Paganism and Judaism, moulded in practice by the innate character of certain people of the Western world" *(Essays*, v, 142). He did not omit, however, to do justice to "the bright side of Christianity," and was deeply impressed with the life of St. Catherine of Siena. He contrasted the moral with the aesthetic sense, which he declared to be intuitive, and, in the Romanes lecture for *1893* (Oxfordj, defined "law and morals" to be "restraints upon the struggle for existence between men in society." Apparently he thought that the moral sense in its origin was institutional and in its development utilitarian. "The cosmic process has no sort of relation to moral ends" *(Essays*, ix, *83)*; "of moral purpose I see no trace in nature. That is an article of exclusive human manufacture" *(Life*, ii, *268)*. The cosmic process gives rise to what is evil in man's moral life, and in the long run will get the best of the contest, and "resume its sway" when evolution enters on its downward course *(Essays*, ix, *45)*. Huxley's health broke down completely in 1885. In 1890 he moved from London to Eastbourne, where, after a painful illness, he died on June 29, 1895.

In 1855 Huxley had married Henrietta Anne Heathorn, whom he had met during one of the visits of the "Rattlesnake" to Sydney, Austr. Their eldest son, Leonard (1860–1933), was a classical scholar and writer on scientific, educational and literary subjects. Leonard Huxley's eldest son, Julian *(1887–*), achieved fame as a biologist and writer on science and philosophy and was knighted in 1958; another son, Aldous *(1894–*), also became a well-known writer.

BIBLIOGRAPHY.—Huxley's own works include: *Scientific Memoirs*, 5 vol. (1898–1903); *Collected Essays*, 9 vol. **(1898)**; *Diary of the Voyage of H.M.S. "Rattlesnake," ed.* by Julian Huxley (1935). *See* also L. Huxley, *Life and Letters* of *Thomas Henry Huxley*, 2 vol., 1st ed. (1900), 3 vol., 2nd ed. (1903); T. **H.** and Julian Huxley, *Evolution and bthics* (1947); P. Chalmcrs Mitchell, *Thomas Henry Huxley, a Sketch of His Life and Work* (1900); E. Clodd, *Thomas Henry Huxley* (1902); J. **R.** Ainsworth Davis, *Thonzas Henry Huxley* (1907); W. Irvine, *Apes, Angels, and Victorians* (1955). *(G.* DE B.)

HUY, a town of Belgium (Lat. *Hoium,* and Flem. *Hoei),* on the two banks of the Meuse, at the point where it is joined by the Hoyoux. Pop. (1955 est.) 13,112. It is 19 mi. E. of Namur and a trifle less west of Liège. Huy certainly dates from the 9th century. Its citadel crowns a grey rock between which and the Meuse is the fine collegiate church of Notre Dame (14th century with 13th century gateway). The citadel is partly a military depot and partly a prison. The ruins are still shown of the abbey of Neufmoustier founded by Peter the Hermit on his return from the first crusade. He was buried there in 111j. Neufmoustier was one of ten abbeys in this town alone dependent on the bishopric-of Liege. Huy is surrounded by vineyards, and the bridge which crosses the Meuse at this point connects the fertile Hesbaye north of the river with the rocky Condroz south of it.

HUYGENS (latinized HUGENIUS), **CHRISTIAAN** (1629–1695), Dutch mathematician, astronomer and physicist. was the founder of the wave theory of light. He was born at The Hague on April 14, 1629. In 1655, Huygens, working with his brother Constantijn on the improvement of the telescope, hit upon a new method of grinding and polishing lenses. The immediate results of the clearer definition obtained were the detection of a satellite of Saturn and the resolution of Saturn's rings into their true form. Huygens was also in 1656 the first effective observer of the Orion nebula; he delineated the bright region still known by his name and detected the multiple character of its nuclear star. His application of the pendulum to regulate the movement of clocks sprang from his experience of the need for an exact measure of time in observing the heavens. The invention dates from 1656. On June 16, 1657, Huygens presented his first "pendulum-clock" to the states-general; and the *Horologium,* containing a description of the requisite mechanism, was published in 1658.

In 1663 he was elected a fellow of the Royal Society, and delivered before that body in Jan. 1669 a clear and concise statement of the laws governing the collision of elastic bodies.

Huygens had before this time taken up residence in France. In 1665 Jean Colbert. on behalf of Louis XIV. made him an offer too tempting to be refused, and from 1666 to 1681 his stay at the Bibliothbque du Roi was only interrupted by two short visits to his native country. His *magnum opus* dates from this period. The *Horologium oscillatorium* (1673) contained many original discoveries, as well as the first successful attempt to deal with the dynamics of a system. This remarkable treatise also included the determination of the true relation between the length of a pendulum and the time of its oscillation; the invention of the theory of evolutes; the discovery that the cycloid is its own evolute; the ingenious although practically inoperative idea of correcting the "circular error" of the pendulum by applying cycloidal cheeks to clocks. The theorems on centrifugal force in circular motion with which it concluded helped Sir Isaac Newton to formulate his law of gravitation.

In 1681 he returned to Holland. He then spent six years on the production of lenses of enormous focal distance, which, mounted on high poles and connected with the eyepiece by means of a cord, formed what were called aerial telescopes. Three of his object glasses, of respectively 122, 170 and 210 ft. focal length, are in the possession of the Royal Society. He also succeeded in constructing an almost perfectly achromatic eyepiece, still known by his name. But his researches in physical optics constitute his chief title deed to immortality. He developed the nave theory of light which had already been adopted by Robert Hooke in 1665; he assumed that all the points of a wave front originate secondary waves, the aggregate effect of which is to reconstitute the primary disturbance at the subsequent stages of its advance, thus accomplishing its propagation;'so that each primary wave front is the envelope of an indefinite number of secondary undulations. This resolution of the original wave is the well-known principle of Huygens, and by its means he was able to prove the fundamental laws of optics and to assign the correct construction for the direction of the extraordinary ray in uniaxial crystals. These investigations, together with his experiments on polarization, are recorded in his *Traité de la lumière,* composed in 1678 and published at Leyden in 1690.

Huygens died at The Hague on June 8, 1695, bequeathing his manuscripts to the University of Leyden.

HUYGENS, SIR CONSTANTIJN (1596–1687), Dutch poet and diplomatist, was born at The Hague on Sept. 4, 1596. His father, Christiaan Huygens, was secretary to the state council. Constantijn received a liberal education, became a master of Latin verse, a great gymnast, a good musician and an accomplished artist. After a year's further study at Leyden, he went, in 1618, to London with the English ambassador Dudley Carleton. He remained in London for several months, and then went to Oxford, where he studied for some time in the Bodleian library, and to Woodstock, Windsor and Cambridge. He was introduced at the English court, and played the lute before James I. An intimacy sprang up between the young Dutch poet and John Donne, for whose genius Huygens preserved through life an unbounded admiration. He returned to Holland in company with the English contingent of the synod of Dort, and in 1619 he received a diplomatic mission at Venice; on his return he nearly lost his life in scaling the topmost spire of Strasbourg cathedral. In 1621 he published his *Batava Tempe,* and in the same year he went again to London, as secretary to the ambassador, Wijngaerdan, but returned in three months. During his third diplomatic visit (1621–23) his volume of satires, *'t Costelick Mal,* dedicated to Jacob Cats, appeared at The Hague. In the autumn of 1622 he was knighted by James I. In 1625 he was appointed private secretary to the stadholder, and in 1630 a member of the privy council. In 1634 he is supposed to have completed his long-talked-of version of the poems of Donne, fragments of which exist. In 1637 his wife, Susanna van Baerle, died. Their married life is celebrated in the didactic poem, *Dagwerck. Hofwijck* (1653) describes the splendid house and garden which Huygens built for himself at The Hague In 1647 he wrote his poem *Oogentroost,* to gratify his blind friend Lucretia van Trello. Huygens wrote only one play, *Trijntje Cornelis,* which deals with the adventures of the wife of a ship's captain at Zaandam. In 1658 he rearranged his poems. and issued them with many additions, under the title of *Corn Flowers.* He proposed to the government that the present highway from The Hague to the sea at Scheveningen should be constructed. and during his absence on a diplomatic mission to the French court in 1666 the road was made as a compliment to the venerable statesman. who expressed his gratitude in a descriptive poem entitled *Zeestraet.* Huygens edited his poems for the last time in 1672, and died in his 91st year, on March 28, 1687. He was buried, with the pomp of a national funeral, in the church of St. Jacob, on April 4. His second son, Christiaan, the eminent astronomer. is noticed separately.

Constantijn Huygens is the most brilliant figure in Dutch literary history. Other statesmen surpassed him in political influence, and at least two other poets surpassed him in the value and originality of their writings. But his figure was more dignified and splendid, his talents were more varied and his general accomplishments more remarkable than those of any other person of his age, the greatest age in the history of the Netherlands. Huygens is the *grand seigneur* of the republic. the type of aristocratic oligarchy, the jewel and ornament of Dutch liberty. As a poet Huygens shows a finer sense of form than any other early Dutch writer; the language, in his hands, becomes as flexible as Italian. His epistles and lighter pieces, in particular. display his metrical ease and facility to perfection.

See the complete edition by T. A. Worp of his works, 8 vol. (1892–99) and of his correspondence, 6 vol. (1913–17); also G. Kalff, *Constantin Huygens* (1900). (E. G.; X.)

HUYSMANS, the name of three Flemish painters, who matriculated in the Antwerp gild in the 17th century.

JACOB HUYSMANS (1633?–1696), was born at Antwerp. He went to England toward the close of the reign of Charles II. and competed with Peter Lely as a fashionable portrait painter. Among the portraits executed by him are those of Queen Catherine of Braganza and Izaak Walton. He died in London in 1696

JAN BAPTIST HUYSMANS (1654–1716), was born and died in Antwerp. There are several of his paintings in the museums of Antwerp, Brussels and Munich, representing southern landscapes

with hgures and cattle.

His elder brother, CORNELIUS HUYSMANS (1648–1727), was born at Antwerp and educated by Gaspar de Wit and Jacob van Artois. Cornelius is the only master of the name of Huysmans whose talent was largely acknowledged. He received lessons from two artists, one of whom was familiar with the Roman art of Nicolas Poussin. while the other inherited the scenic style of the school of Rubens. He combined the two in a rich. highly coloured style, seldom attempting anything but woodside views with fancy backgrounds, half Italian: half Flemish. He first practised at Malines, where he married in 1682. From 1706 to 1717 he lived at Antwerp, and then returned to Malines, where he died on June 1, 1727. According to Walpole, he also visited England. Though most of his pictures were composed for cabinets rather than for churches, he sometimes emulated van Artois in the production of large sacred pieces, and for many years his "Christ on the Road to Emmaus" adorned the choir of Notre Dame of Malines.

HUYSMANS, CAMILLE (1871–), Belgian statesman. was born at Bilsen in Belgian Limbourg on May 26, 1871. After graduating in Germanic philology at Liège, he became a professor. first at the College Libéral at Ypres, and then at the Université Nouvelle, Brussels. He wrote in the *Peuple* and other Socialist papers, and, after World War I, started the Flemish *Volksgazet* in Antwerp. He entered the chamber in 1910, first as deputy for Brussels and then for Antwerp, where he became an alderman of public instruction. From 1905 until 1922 he was secretary of the Socialist international bureau. After the war he became the chief organizer of the Socialist party in Antwerp. In June 1925 he became minister of science and arts, in 1936 president of the chamber of deputies and from Aug, 1946 to March 1947 he was prime minister. His works include: *Limburghsch Jaarboek* (1891–95); *Toponymische Studie* (in conjunction with J. Cuvelier. 1897); *Stockholm* (1919); *De Coster's Stephanie* (1926); *Don Juan,* a Flemish dramatic work of the 18th century (1928); *The Works* of *De Swaen,* 4 vol. (1928); *Letters to* a *Young Socialist* (1945).

HUYSMANS, JORIS KARL (1848–1907), French novelist, was born in Paris on Feb. 5, 1848. He belonged to a family of artists of Dutch extraction; he entered the ministry of the interior and was pensioned after 30 years' service. He thus led a thoroughly bourgeois existence in striking enough contrast to the character of his novels. His earliest venture in literature, *Le Drageoir à épices* (1874), contained stories and short prose poems showing the influence of Baudelaire. *Marthe* (1876), the life of a courtesan, was published in Brussels, and Huysmans contributed a story, "Sac au dos," to *Les Soirkes de Médan,* the collection of stories of the Franco-German war published by Zola. He then wrote a series of novels of everyday life, including *Les Sœurs Vatard* (1879), *En Ménage* (1881), and *A vau-l'eau* (1882), in which he outdid Zola in minute and uncompromising realism. Of these the most important is *En Ménage,* which describes the complete disillusion of two friends, Adrien and Cyprien. the one by means of marriage, the other by a vulgar liaison: "The book," says Lalou, "oozes with misanthropy, with hatred of a society incurably common, ugly and stupid." But there is more in Huysmans' work than the presentment in realistic detail of the more disagreeable side of life. He was, in fact, influenced more directly by Flaubert and the brothers de Goncourt than by Zola.

In *L' Art moderne* (1883) Huysmans gave a careful study of impressionism and in *Certains* (1889) a series of studies of contemporary artists. He went on to glorify art at the expense of nature, and the real importance of his work is to be found in his later works, in which the excesses of the aesthetic revolt find a serious and quite humourless exponent. *À Rebours* (1884), the history of the morbid tastes of a decadent aristocrat, des Esseintes, provides a caricature of literary and artistic symbolism which nevertheless contained much of the real beliefs of the aesthetes. In *Là-Bas* Huysmans' most characteristic hero, Durtal, makes his appearance. Durtal is occupied in writing the life of Gilles de Rais; the insight he gains into Satanism is supplemented by modern Parisian students of the black art; but already there are signs of a leaning to religion in the sympathetic figures of the religious bell ringer of Saint Sulpice and his wife. *En Route* (1895) relates the conversion of Durtal to mysticism and catholicism in his retreat to La Trappe.

In *La Cathkdrale* (1898). Huysmans gives a symbolist interpretation of the architecture of the cathedral of Chartres which is a magnificent evocation of the spirit of the place. The life of *Sainte Lydwine de Schiedam* (1901), an exposition of the value of suffering, gives further proof of his conversion; and *L'Oblat* (1903) describes Durtal's retreat to the Val des Saints, where he is attached as an oblate to a Benedictine monastery. Huysmans was nominated by Edmond de Goncourt as a member of the Académie des Goncourt. He died as a devout Catholic, after a long illness of cancer in the palate on May 13, 1907. Before his death he destroyed his unpublished manuscripts. His last book was *Les Foules de Lourdes* (1906).

See Arthur Symons, *Studies in Two Literatures* (1897), *The Symbolist Movement in Literature* (1899); Jean Lionnet in *L'Évolution des idées* (1903); Eugène Gilbert in *France et Belgique* (1905); J. Sargeret in *Les Grands convertis* (1906).

HUYSUM, JAN VAN (1682–1749), Dutch painter of still life and landscapes. was born at Amsterdam on April 15, 1682, and died in his native city on Feb. 8, 1749. He was the son and pupil of Justus van Huysum, who is said to have been expeditious in decorating doorways, screens and vases. His pictures of flowers and fruit, in oil and water colours, were finished in every detail and highly prized during his lifetime. He also painted landscapes with Arcadian scenery. His work may be seen in many European galleries.

HUYTON-WITH-ROBY, an urban district (1895) in the Huyton parliamentary division of Lancashire. Eng.. 6 mi. E. of Liverpool. Pop. (1951) 55,796. Area 4.8 sq.mi. Though Hitune and Rabil were mentioned in Domesday, the town was not of much importance until its rapid growth as a dormitory area for Liverpool. Pre-eminently residential, it has industries making cables, hosiery-knitting machines, foodstuffs. vacuum flasks and metal goods. George Stephenson's Liverpool-Manchester railway, which was laid down in 1830 and is probably the second oldest in England, runs through the town.

HVAR, a Dalmatian island in the Adriatic sea (Ital. Lesina), in Croatia, Yugos. Pop. (1953) 12,721. It is 43 mi. long and from 2 mi. to 5 mi. broad. Area 112 sq.mi. The warm and equable climate lends itself to the successful growth of grapes, olives, figs. dates and the locust bean. Other industries of the islanders are the making of rosemary essence and liqueurs, beekeeping, boatbuilding, fishing and marble quarrying. There are many villages but Hvar (Lesina), the capital, and Stari Grad (Cittavecchia) are the chief towns and seaports. The former possesses, among other beautiful Venetian buildings. the finest loggia in Dalmatia, and has also an arsenal and an observatory. It is a Roman Catholic bishopric and nearby there is a Franciscan monastery, which was burned by the Turks in 1471 but rebuilt in 1571. Stari Grad is one of the busiest ports in the Dalmatian islands, and still possesses "Cyclopean" walls, possibly raised by the primitive Illyrians whose stone cists and bronze instruments have been found near the capital. The island is memorable as the home of two Slav poets. Lucic, a writer of exquisite lyrics, and the more famous Hektorovic (1487–1572), a democratic noble, several centuries ahead of his time, who devoted his genius to the writing of national songs.

About 390 B.C. a Greek colony from Paros built a city on the site of the present Hvar and called it Paros or Pharos. In 229 B.C. Demetrius, the lieutenant of the Illyrian queen Teuta, betrayed the island to the Romans. but as he proved false to them also, they razed his capital in 219 B.C. Neos Pharos, now Stari Grad, took its place and flourished till the 7th century, when the Slavs, fleeing from the Avars, settled upon the island. Throughout the middle ages, and on to modern times, it remained purely Slavonic. The island became a bishopric in 1145 and received a charter from Venice in 1331; was sacked by the Genoese in 1354 and 1358; ceded to Hungary in the same year; held by Dubrovnik (Ragusa) from 1413 to 1416 and incorporated in the Venetian dominions in 1420. During the 16th century Hvar had a considerable maritime trade

and though sacked and partly burned by the Turks in 1571, it remained the chief arsrnal of Venice in those waters until 1776. In 1797 it passed to Austria, was held by the French from 1805 until 1813, when it was surrendered to Austria, remaining in the possession of that country until the close of World War I. In 1918 it was forcibly occupied by the Italians, until it was formally annexed to Yugoslavia; but in 1941 the Italians reoccupied it.

HVIEZDOSLAV (pseudonym of PAVOL ORSZÁGH) (1849–1921), the most powerful and versatile of Slovak poets, was born at Vyšný Kubin, Slovakia, Feb. 2, 1849. In the 1860s, when he began to write in Slovak, the new literary language was still in its uncertain initial stage; by the time of his death the Slovaks already possessed an extensive poetic literature of a high order. Hviezdoslav's contribution to this development was of decisive importance. In his main epics—*Hájnikova* Qena("The Gamekeeper's Wife"; 1886) and *Ežo Vlkolinský* (1890)—he treated local themes in a style which combined realistic descriptive power with lyric echoes from folksong. In his voluminous lyric output he experimented with a variety of metrical forms and forged a characteristic style, interwoven with neologisms and dialect elements. Most memorable are his *Krvavé sonety* ("Blood-red sonnets"; 1919) which express a moving and unconventional attitude to World War I. He died in the village of his birth, June 8, 1921.

(R. AY.)

HWAI SENG, Chinese monk, traveled with Sung Yun to India in 518–521 to collect books.

HWANG-HO, the most northerly of China's great rivers, approximately 2,900 mi. in length. The name, literally the "Yellow river." is due to the loess (*hwang tu* or "yellow earth") which it carries in suspension and which it derives from the deposits stretching across the middle part of its basin. The Hwang-ho flows through a region having a much lower rainfall than the Yangtze basin and its discharge is in consequence very much smaller. It pursues a very composite course. It rises in a marshy trough just west of the Tsaring-nor within the parallel ranges of the Kuen-Lun whose central and northern ranges it eventually cuts across before entering on the Ordos, an extension of the Gobi desert. The northern limit of the Ordos is defined by the mountain arc of the Ala-shan Khara-narin-ula and Ta-tsing-shan, and the Hwang-ho, keeping on the inner side of this arc, occupies a much more open valley than in its upper course. Then the river which was heading eastward for the "grill of Peking" deserts this mature valley to turn abruptly southward and in a very rapid and obviously immature course rushes through a long trench cut into the very border of the loess-filled basin of North Shensi. At the south end of this north–south course, it receives first the Fen-ho on its left bank and then the Wei-ho on its right bank, which together gather up the drainage of a string of fertile loess basins in south Shansi and central Shensi. Their combined waters then flow due east. as though the Wei-ho were the master stream, through the Tungkwan gorge, where the river is restricted by the approach of the ridges of south Shansi toward the Tsin-ling. and enter on the funnel-shaped valley which leads across Honan to the north China plain. The Tungkwan gorge forms the historic gateway into the north China plain from the Wei-ho valley and beyond from Kansu and the Tarim basin. About Kaifeng the valley gives way to the plain and there the character of the river changes also. With the neighbourhood of Kaifeng as a pivot. the Hwang-ho, after breaking its dykes during flood, has several times shifted bodily the whole of its lower course through the plain. For over five centuries before 1852 the Yellow river entered the Yellow sea well to the south of the Shantung uplands, but since 1852 its mouth has lain to the north of them, involving a change of more than 250 mi. (*See* CHINA.)

The most irregular feature in this long course of the Hwang-ho is the entrenched torrent along the Shansi-Shensi border in the very middle of its course and between two mature valley stretches, that across the Ordos and that through Honan. This disposition suggests that the torrent stretch has comparatively recently joined two formerly independent drainage systems. In its course across the Ordos the Hwang-ho is heading for the ridge and trough country of the "grill of Peking." The troughs are broad enough to take the river and an enormous deltaic fan to the northwest of Peking, too big to be produced by any existing stream of the neighbourhood. may represent its outfall. In its valley course through Honan the Hwang-ho simply continues the line of the broad Wei-ho valley and these together, though broken by the Tungkwan gorge, may represent a second formerly independent river. The headstreams of the Wei-ho valley lie near to the point where the upper Huang-ho emerges from the Kuen-Lun ranges. The upper Hwang-ho may be related therefore to either the Ordos or the Wei-ho system. If the grill of Peking were tilted, up in the north and down in the south, which the decreasing elevation of its ridges to the south would indicate has actually taken place, then the Ordos river would be compelled to turn southward until it could escape to the east. This it could not do until it came across the great Ta-hwa fault along which the grill system is broken against the Tsin-ling. By this means it would encounter the southernmost of the once independent rivers that flow along the northern foot of the Tsin-ling ranges.

In its torrential stretches the current is too swift and in its course through the plain the channel is too wide and shallow for the Hwang-ho to be of much use for navigation. The Ordos loop is navigable from Chungwei to Hokow except during low water in winter and flood in summer. but the region through which it flows is unproductive. Further down, there is some local traffic along the trench between Hokow and Tungkwan, but it is nearly all downstream because of the swift current. In its lower course only the last 25 mi. are really suitable for navigation.

The economic significance of the Hwang-ho is not as an artery of commerce but as the source of many of the floods which from time to time devastate the north China plain and which have earned it the names of "China's Sorrow," "The Ungovernable," "The Scourge of the Sons of Han." The plain has only a very gentle slope toward the sea and is to some degree the deltaic accumulation of the Hwang-ho, the Hwai-ho and the Chihli rivers. In its course over it the channel of the Hwang-ho becomes exceedingly broad and shallow. With the agricultural reclamation of the plain this broad channel has become confined by dyke construction and the river silt formerly spread over a wide area has become concentrated on the river bed itself so that the river is now flowing on the top of the plain as much as within it. The river surface of the Hwang-ho is at low water 15 ft. above the general level of the plain, at high water as much as 30 ft. It is estimated that it is raising its bed, mainly when the current is slackening after the summer floods, at the rate of 1 ft. in every 100 years, but this represents only about 1% of the total amount of silt brought down within such a period. In this lower course the dykes are sufficiently far apart for the river to have considerable swing, which not only lengthens the river course but also facilitates the breaching of the dykes by an aggressive meander. The International Famine Relief commission in the 1920s proposed to control the river by straightening its channel which would increase the current and thereby the scour of the river bed and would prevent the breaching of dykes by meandering. By this means it was hoped not only to prevent flood but also to add to the land reclaimed for agriculture. Little, however, if anything was done about these proposals.

In 1955 the Chinese Communist regime published a long-range plan designed to transform "China's Sorrow" into an economically useful river. The plan called for the building of a series of hydroelectric stations and storage reservoirs along the Hwang-ho to contain the seasonal floods. Vast areas of the loess region were to be afforested to stem the heavy erosion. Large tracts were to be irrigated along the arid upper course and along the lower reaches of the north China plain. The first major project initiated under this long-term development plan was the construction of a 1,000,000-kw. hydroelectric station and dam on the Hwang-ho at San-men-hsia (Three-Gate gorge), on the Honan-Shansi border, 130 mi. W. of Cheng-hsien (Chengchow). Plans were announced for a second dam and 1,000,000-kw. hydroelectric station, to be constructed at the Liu-chia-hsia, on the Kansu-Tsinghai border, 50 mi. W.N.W. of Lan-chou (Lanchow).

HWICCE, one of the kingdoms of Anglo-Saxon Britain, coin-

ciding generally with the medieval diocese of Worcester, the early bishops of which bore the title "Episcopus Hwicciorum" It would therefore include Worcestershire, Gloucestershire except the forest of Dean, the southern half of Warwickshire and the neighbourhood of Bath. The name Hwicce survives in Wychwood forest in Oxfordshire. This district, or at all events the southern portion, was according to the *Anglo-Saxon Chronicle*, *s.a.* 577, originally conquered by the West Saxons under Ceawlin. In later times, however, the kingdom of the Hwicce appears to have been always subject to Mercian supremacy and possibly it was separated from Wessex in the time of Edwin. The first kings were two brothers, Eanhere and Eanfrith, probably contemporaries of Wulfhere. They were followed by Osric, a contemporary of Aethelred, and by Oshere. Oshere's three sons Aethelheard, Aethelweard and Aethelric succeeded him, the two last reigning in 706 At the beginning of Offa's reign the kingdom was ruled by three brothers named Eanbert, Uhtred and Aldred; the latter two lived until *c.* 780 After them the title of king seems to have been given up. Their successor Aethelmund, who was killed in a campaign against Wessex in 802, is described only as an earl. The district remained in possession of the rulers of Mercia until the fall of that kingdom. Together with the rest of English Mercia it submitted to Ring Alfred *c.* 877–883 under Earl Aethelred, who possibly himself belonged to the Hwicce. No list of kings has been preserved, and it is not known whether the dynasty was connected with that of Wessex or Mercia.

See Bede, *Historia Eccles.*, ed by Plummer, iv, 23 (1896); Birch, *Cartularium Saxonicum* (1885–89). (F. G. M. B.)

HYACINTH, also called JACINTH, one of the most popular of spring garden flowers (Liliaceae or lily family) It was in cultivation prior to 1597, at which date it is mentioned by John Gerard. 'By the middle of the 18th century about 50 single-flowered varieties and nearly 100 double-flowered ones were described as a selection of the best from the catalogues of two celebrated Dutch growers. One of the Dutch sorts, called La Reine de Femmes, a single white, is said to have produced from 34 to 38 flowers in a spike, and on its first appearance to have sold for 50 guilders a bulb; while one called Overwinnaar, or Conqueror, a double blue, sold at first for 100 guilders, Gloria Mundi for 500 guilders and Koning Saloman for 600 guilders. Several sorts are at that period mentioned as blooming well in water glasses.

ROCHE

COMMON HYACINTH (HYACINTHUS ORIENTALIS)

The original of the cultivated hyacinth, *Hyacinthus orientalis*, a native of Greece and Asia Minor, is by comparison with these an insignificant plant, bearing on a spike only a few small, narrow-lobed, washy blue flowers, resembling in form those of the common English bluebell. So great has been the improvement effected by the florists, and chiefly by the Dutch, that the modern hyacinth would scarcely be recognized as the descendant of the type above referred to. The spikes are long and dense, composed of a large number of flowers; spikes produced by strong bulbs not infrequently measure six to nine inches in length and from seven to nine inches in circumference, with the flowers closely set from bottom to top. Size of the individual flowers and the breadth of their recurving lobes have been much increased, and the colours have gained in brilliancy and depth.

The peculiarities of the soil and climate of the Netherlands are so favourable to hyacinth production that Dutch florists have made a specialty of the growth of those and other bulbous-rooted flowers. Hundreds of acres are devoted to the growth of hyacinths in the vicinity of Haarlem.

In the spring flower garden few plants make a more effective display than the hyacinth. Dotted in clumps in the flower borders and arranged in masses of well-contrasted colours in beds, there are no flowers which impart during their season—late spring—a gayer tone to the garden.

The cultivation of hyacinths is easy, for the purchased bulbs already contain a well-developed flower bud and sufficient nourishment to ensure flowering the following spring, even when grown in pebbles and water. The bulbs, which need a winter chilling, should be planted in late autumn for bloom the following spring. Any ordinary garden soil will do, but if it is enriched with well-rotted manure the results are improved. The manure should be put at the bottom of the hole and covered with an inch of soil for no manure should directly touch the bulb. Bulbs should be planted five or six inches deep and spaced eight to ten inches apart. In severe climates the beds should be covered with a winter mulch of straw or stray manure, which should be removed in early April in the U.S. (earlier in England).

Most of the older varieties of hyacinth were single flowered and among the most fragrant of all garden flowers. The fad for double-flowered sorts, of which many were developed, led to a coincident loss of fragrance. Most modern varieties are again single flowered and their fragrance is generally superb. The single-flowered sorts produce more regular and symmetrical spikes of blossom, the flowers being closely set and more or less horizontal, whereas in most of the double sorts the bells are distant and dependent, so that the spike is loose and by comparison an ineffective display.

Originally blue, the hyacinth can now be had in white, pink, mauve and various shades of blue from pale to porcelain. The Roman hyacinth *(H. orientalis albulus)* is less hardy than the common sort and has two or three flower stalks to each plant.

(N. TR.)

HYACINTH or JACINTH, in mineralogy, a variety of zircon (zirconium silicate) of yellonish-red colour, used as a gem stone. Hyacinth is not a common mineral. It occurs, with other zircons, in the gem gravels of Ceylon, and very fine stones have been found as pebbles at Mudgee, N.S.W. Most of the gems known in trade as hyacinth are only garnets, generally the deep orange-brown hessonite or cinnamon stone. The stones known as Compostella hyacinths are simply ferruginous quartz from Santiago de Compostella, Sp. For composition and characters *see* ZIRCON.

(L. J. S.; X.)

HYACINTHUS, in Greek legend, a young man (parentage variously given) of Amyclae in Laconia. According to the general story, which is probably late and composite, his great beauty attracted the love of Apollo, who killed him accidentally when teaching him to throw the discus (quoit); others say that Zephyrus (or Boreas) out of jealousy deflected the quoit so that it hit Hyacinthus on the head and killed him. According to the representation on the throne of Apollo at Amyclae he was translated into Heaven with his virgin sister Polyboea. Out of his blood there grew the flower called *hyacinthos* (perhaps a fritillary; not our hyacinth), the petals of which were marked with the mournful exclamation *AI, AI* ("alas"). It was also said to have sprung from the blood of Ajax, son of Telamon.

The death of Hyacinthus was celebrated at Amyclae by the second most important of Spartan festivals, the Hyacinthia, which took place in the Spartan month Hyacinthius. What month this was is not certain. Arguing from Xenophon *(Hellenica)* we get May; assuming that the Spartan Hyacinthius is the Attic Hecatombaion, we get July; or again it may be the Attic Scirophorion, June. At all events the Hyacinthia was an early summer festival. It lasted three days, and the rites gradually passed from mourning for Hyacinthus to rejoicings in the majesty of Apollo. This festival is clearly connected with vegetation, and marks the passage from the youthful verdure of spring to the dry heat of summer and the ripening of the grain.

There can be little doubt that Hyacinthus is a pre-Hellenic god. His name is not Greek. The precise relation that he bears to Apollo is obscure. The supposed "tomb of Hyacinthus," which forms the base of the monument of Apollo at Amyclae, described by Pausanias, may be taken as evidence of his subordination to the greater god. Into the "tomb" at Amyclae were put offerings for

the hero, before gifts were made to the god. This and the taboo on cereals during the first part of the Amyclean festival suggest an underworld vegetation deity whose death is mourned like that of Adonis. Sir James Frazer suggests that he may have been regarded as spending the winter months in the underworld and returning to earth in the spring when the "hyacinth" blooms. With the growth of the hyacinth from his blood should be compared the oriental stories of flowers springing from the blood of Attis (*q.v.*) and from that of Adonis (*q.v.*).

HYADES, "the rainy ones," a group of five stars in the head of the constellation Taurus. In mythology they were maidens (their number and parentage vary in different accounts) who nursed the infant Dionysus, and as a reward were translated to heaven and placed among the stars (Hyginus, *Poet. astron.).* According to another version they were sisters, whose brother Hyas was killed while hunting (Ovid, *Fasti;* Hyginus, *Fab.).* They lamented him so bitterly that Zeus, out of compassion, changed them into stars—five into the Hyades, the remainder into the Pleiades. Their name is derived from the fact that the rainy season commenced when they rose at the same time as the sun (May 7–21).

The Romans derived the name from *Hys* (pig), and translated it by *Suculae* (Cicero, *De nut. deor.).*

HYATT, ALPHEUS (1838–1902), U.S. zoologist and paleontologist achieved eminence in the study of invertebrate fossil records. He was born at Washington, D.C., on April 5, 1838. He studied at Harvard (1858–62) under Louis Agassiz and in 1863 served as a volunteer in the Civil War, attaining the rank of captain. In 1867 he was appointed curator of the Essex institute at Salem, Mass., and in 1870 became professor of zoology and paleontology at the Massachusetts Institute of Technology (resigned 1888) and custodian of the Boston Society of Natural History (curator in 1881). In 1886 he was appointed assistant for paleontology in the Cambridge museum of comparative anatomy, and in 1889 was attached to the United States geological survey as paleontologist. Hyatt rose to foremost rank among U.S. investigators in the field of invertebrate paleontology. He was the chief founder of the American Society of Naturalists, acting as first president in 1883. He also took a leading part in establishing the marine biological laboratories at Annisquam and Woods Hole, Mass.

Hyatt died at Cambridge on Jan. 15, 1902.

His works include *Observations on Polyzoa* (1866); *Fossil Cephalopods of the Museum of Comparative Zoology* (1867); *Revision of North American Porifera* (1875–77); *Genera of Fossil Cephalopoda* (1883); *Larval Theory of the Origin of Cellular Tissue* (1884); *Genesis of the Arietidae* (1889); and *Phylogeny of an Acquired Characteristic* (1894). He wrote the section on Cephalopoda in Karl von Zittel's *Palaontologie* (1900); and his valuable study on the fossil pond snails of Steinheim, "The Genesis of the Tertiary Species of Planorbis at Steinheim." appeared in the *Memoirs* of the Boston Natural History society in 1880.

Hyatt was a founder and editor (1867–71) of the *American Naturalist.*

HYBLA, the name of several cities in Sicily. The best known historically is Hybla Major. near modern Melilli, where numerous Sicel tombs have been found, about 4 mi. S.W of Megara Hyblaea (*q.v.*). It was this Hybla that was famous for its honey. Orsi *(Romische Mitteilungen,* 1909) identifies Hybla Major with Paternb; the view here given is that of Ziegler (Pauly-Wissowa, *Realencyklopädie, s.v.*). Another Hybla, known as Hybla Minor or Geleatis, is represented by the modern Paternb, with its conspicuous medieval castle. Various remains have been found, especially tombs of the Sicel period; and there are also numerous Roman remains, two arches of a bridge, remains of baths, cisterns, etc.

HYBRIDISM. A hybrid or mongrel is the offspring of a cross between dissimilar parents; *e.g.,* belonging to different species or to very distinct races, varieties or breeds. Such crosses used to be regarded as something base and evil, hence the word "hybrid" is derived from a Greek word meaning "insult" or "outrage." In genetics, any individual heterozygous for one or more genes or chromosome structures is, however, called a hybrid *(see* HEREDITY). In this wider sense, almost all individuals of sexually reproducing organisms, including man, are hybrids, because their parents usually differ in several genes. Hybridism is a corollary to sexual reproduction. Only where self-fertilization is the rule (as in wheat) can many individuals be homozygous or "pure" (*i.e.*, carrying like genes for any certain character) and, hence, nonhybrid.

Hybridism is biologically very important because it permits accumulation in natural populations of sexually reproducing organisms of hereditary variability. This variability may be compared to a store of raw materials from which evolutionary changes are built. Yet, hybridization of forms which possess genetic systems adapted to different environments or living conditions results in emergence of disharmonious and ill-adapted types. Hybridism is in general favourable on lower levels of evolution but unfavourable on higher levels.

Hybrid Vigour or **Heterosis.**—Customs and laws which forbade inbreeding (marriage of close relatives) have existed in many countries since antiquity. Their biological justification lies in the fact that the offspring of matings of close relatives are frequently inferior in vigour to crossbred individuals. The extent of the deterioration of the viability produced by inbreeding varies in different organisms. In maize, no inbred lines equal crossbred strains in vigour or yield. In man, inbreeding is generally deleterious, yet marriages of brothers and sisters practised in some royal families of Egypt and Peru allegedly led to no undesirable results. Many plant species reproduce mostly or exclusively by self-fertilization, which is the closest possible form of inbreeding. Crossing of inbred lines is followed in the immediate offspring by hybrid vigour or heterosis; *i.e.,* by restoration of the vigour lost during inbreeding. The extent of heterosis is, as expected, proportional to the degree of harmfulness of inbreeding in the same species or race *(see* INBREEDING).

To account for the observed effects of inbreeding and crossing, G. F. Shull (1908) and D. F. Jones (1917) postulated that normally crossbred strains carry unfavourable recessive genes in heterozygous condition, covered up by their more favourable dominant alleles. In different lines different unfavourable recessives become homozygous because of inbreeding. Intercrossing of the inbred lines results, therefore, in the deleterious recessives becoming again concealed by heterozygosis. hence the restored vigour in the hybrid. A proof of this hypothesis was obtained two to three decades after its formulation, chiefly through genetic analysis of natural populations of *Drosophila* flies (q *v.).* Almost every individual in such populations carries deleterious recessive genes, often recessive lethals, concealed in heterozygous condition. In the homozygous condition recessive lethals often cause the death of an organism in an early stage of development. There is no doubt that human populations are comparable in this respect to those of *Drosophila* flies; at any rate, numerous hereditary defects appear much more frequently in the offspring of consanguineous marriages than in marriages between persons not known to be related.

The surprising fact that deleterious recessive genes accumulate in natural populations of organisms is explained very simply. Mutations occur in all organisms, and most mutations are known to be unfavourable to their carriers. Unfavourable dominant and semidominant mutants are rapidly eliminated by natural selection. The fate of the unfavourable recessives depends upon the reproductive biology of the organism in question. Where self-fertilization or mating of close relatives is the rule (as in wheat and many other plants), the recessive defects become homozygous and are eliminated soon after their appearance by natural selection. In such organisms inbreeding is not deleterious and outbreeding is not accompanied by heterosis. Where consanguineous matings are rare, unfavourable recessive mutants are protected, or "sheltered," from natural selection by their dominant alleles, and, therefore, are allowed to accumulate in the populations. Here inbreeding is deleterious and heterosis clearly pronounced.

Heterosis is taken advantage of in plant and animal breeding. The development of hybrid corn in the United States is a striking application of the modern science of heredity to agriculture. Hybrid corn is the first generation hybrid between two inbred

lines of maize. The average increase in yield in hybrid corn, compared to the open-pollinated varieties (from which the inbred lines giving rise to the hybrid were obtained), is between 15% and 20%, and some increases up to 35% have been recorded. For example, in 1943 approximately 50,000,000 ac. of hybrid corn mere planted in the corn belt of the Cnited States, and it is estimated that the yields were increased thereby by over 600,000,000 bu.

G. Dahlberg (1938) surmised that the increase of the average stature of the human populations observed in many countries for more than a century may be due, in part, to heterosis. Inhabitants of sparsely populated country districts may be somewhat inbred. The development of communications and increasing population densities led to wide intercrossing of human strains, to increased hybridity and to heterosis.

Isolating Mechanisms.—Hybridization of species of sexually reproducing organisms is restricted or prevented by a variety of isolating mechanisms. The simplest of these is geographic isolation—related forms inhabit different territories and their meeting and mating are hindered or excluded by their separation. Geographic isolation prevents the interbreeding not only of distinct species but of races and colonies of the same species as well. Human races were geographically isolated before the advent of civilization and even now the fusion of races is hindered somewhat by separation.

Reproductive isolation is the common name for isolating mechanisms other than geographic isolation. Complete reproductive isolation indicates distinction of species, but its rudiments may occur even between races. The principal kinds of reproductive isolation are as follows.

Ecological Isolation.—Representatives of different species may lack the opportunity to hybridize because, though they share the same geographic area, they occupy different habitats and seldom or never come in contact. Thus, some pairs of related plant species in England differ in that one member occurs only on soils with high and the other with low lime content.

Seasonal *Isolation.*—Related species may have different and nonoverlapping breeding or flowering seasons.

Sexual or Psychologzcal Isolation.—When sexually mature representatives of related species occur in the same milieu, matings between individuals which belong to the same species occur more readily than those between different species. Absolute aversion from copulation with individuals of foreign species is very common; on the other hand, instances are known where distinct species which do not normally occur together intercross readily if artificially placed next to each other. Causes which make interspecific matings repugnant are diverse. Differences in specific scents are undoubtedly important in many insects. Differences in songs may play an important role among birds. The courtship techniques are more or less fixed within a species but different between species. In many spiders, insects, mollusks, fish and birds courtship develops into highly complex rituals which make species recognition secure. In some instances the psychological barriers to crossing can be overcome by conditioning and training.

Mechanical Isolation.—Differences in the structures of the genitalia or of other body parts which play a role in the sexual act may prevent normal coitus and sperm delivery. This is particularly true among insects and other arthropods with chitinous genitalia. Differences in the flower structures and scents among species of plants are analogues of the mechanical and sexual isolations on the animal level.

Incompatibility of *the* Sex Cells.—Failure of hybridization may be caused by spermatozoa of one species not being normally viable in the sexual ducts of another, or not being attracted to the foreign egg cells. Failure of the pollen of one species to develop pollen tubes on the stigma or in the style of another is a very important isolating mechanism in higher plants.

Hybrid Inviability.—The development of the organism produced by the union of sex cells of different species may be abnormal, and terminate in death at any stage of the life cycle. Yet, some species hybrids (*e.g.*, the mule) are not inferior in bodily vigour to the parental species, and may even exhibit the phenomenon of heterosis. The death of the hybrids is sometimes caused by relatively minor disturbances, the proper treatment of which may allow the hybrids to survive. Thus, some plant hybrids can be brought to maturity by excising the embryos from the seeds and cultivating them for a time on artificial media.

Hybrid Sterility.—Species hybrids often fail to produce mature sex cells (*e.g.*, the mule), or these sex cells give rise to poorly viable offspring in the next generation. Sterility of a hybrid is not necessarily an accompaniment of constitutional weakness—some weak hybrids are fertile and some vigorous ones sterile. Causes underlying hybrid sterility fall into at least two categories: chromosomal sterility (attributable to differences in the gene arrangements in the chromosomes of the parental species) and genic sterility (produced by the gene composition of the hybrid).

It should be understood that species are kept apart in nature by different isolating mechanisms or combinations of isolating mechanisms. Thus, sexual isolation is important in species of *Drosophila* flies but not among species of toads. Hybrid sterility is not necessarily a mark of species distinction; hybrids between some unquestionably good species are fertile (*e.g.*, between mallard and pintail ducks). Any reproductive isolating mechanism has, however, the same biological end effect: prevention of hybridization, and consequently of gene exchange, between species. *See* also ANIMAL BREEDING; PLANT BREEDING.

HYDANTOIN crystallizes from water in colourless needles, and melts at 208°–220° C. It is constitutionally glycolyl urea, or the ureide of glycollic acid, CO$\langle$NH.CH$_2$ / NH.CO$\rangle$, and is obtained by heating allantoin or alloxan with hydriodic acid, by heating bromoacetylurea with alcoholic ammonia or by the action of urea on dihydroxytartaric acid. When hydrolysed with baryta water, hydantoin yields hydantoic (glycoluric) acid,

$$H_2N.CO.NH.CH_2.CO_2H$$

colourless prisms, m.p. 153°–156°, which are readily soluble in hot water.

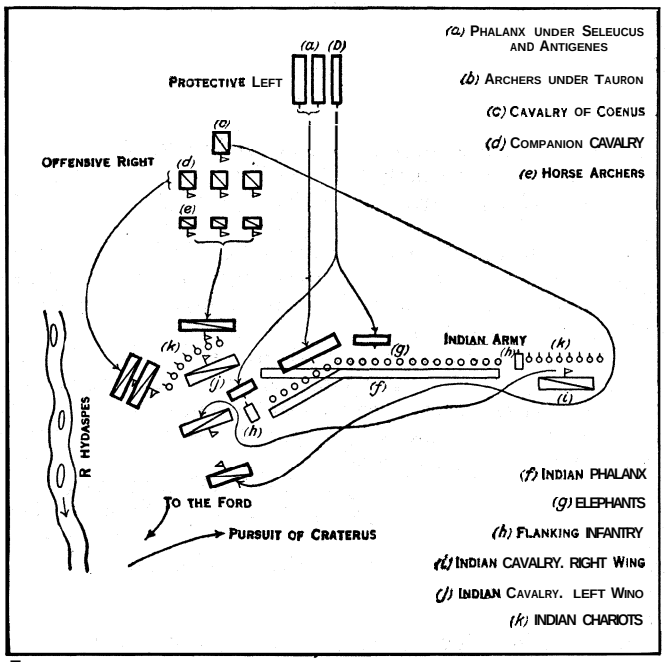
HYDASPES, BATTLE OF THE (326 B.C.). The battle of the Hydaspes (Jhelum) is the most interesting of the four great battles fought by Alexander. since he was not only faced by a well-organized enemy protected by a river in flood but by a force of war elephants against which his decisive arm—heavy cavalry—was useless. Porus, his adversary, occupied the left bank of the river; he was a man of courage and sense, the most efficient general Alexander ever met. According to Diodorus, his army consisted of 50,000 infantry, 3,000 cavalry, about 1.000 chariots and 130 elephants.

Alexander was encamped near modern Jalapur, the left bank of the river being picketed by the Indians. As he was not able to force a crossing, he divided his army into many parts and laid in a great store of corn in order to make Porus believe that he did not intend to cross until the winter had set in. In any case he could not cross in face of Porus, since the elephants drawn up on the far bank "by their aspect and trumpeting" would have caused his horse to take panic; he therefore resolved to steal a crossing under the cover of the following stratagem. He sent parties of cavalry up and down the river to make every kind of noise, Porus marching along the opposite bank where the clamour was heard.

After a time, nothing taking place, Porus "perceiving that his fear had been groundless" kept his position in his camp. Having thus stupefied his adversary, Alexander determined to make a night march and cross the river at a bend about 18 mi. N. of modern Jhelum. He left Craterus in camp with the bulk of the army, instructing him not to attempt to force a passage unless Porus moved away; then, at the head of 5,000 horse and about 9,000 foot, he set out northward to the point of crossing where skin rafts and pontoons had been secreted.

The river was successfully crossed and, once the army was marshalled. Alexander advanced at the head of the cavalry, ordering the infantry to follow at a slow pace in regular formation. His object was to fix his enemy before he could deploy or retire.

Preliminary Engagement. — Porus, still seeing a large force in Alexander's camp. on hearing that a crossing of the river had been



THE BATTLE OF THE HYDASPES. 326 B.C., BETWEEN PORUS AND ALEXANDER

Alexander executed his favourite manoeuvre of attacking with the right wing (d), first employing horse archers and then charging with the cavalry

effected by the enemy. sent forward his son at the head of 2.000 cavalry and 120 chariots to delay them. On seeing this force approach. Alexander at first thought that it was Porus himself, and sent out his horse archers to reconnoitre. Learning, however, that it was but a detachment, he charged home killing Porus' son and 400 of his men. Apprised of this defeat. Porus was in doubt what to do. Craterus was now attempting to cross the river, and Alexander was advancing on him at top speed. Leaving some elephants and a small force to watch the ford. he moved off the clayey ground, and deployed his elephants into line at intervals of about 100 ft. Behind these he drew up his infantry in phalangial order. On the flanks he posted forces of cavalry, infantry and his chariots.

Seeing the Indians drawn up in order of battle, Alexander halted his cavalry so that his infantry might come up, and then, after resting them, he determined to advance against the enemy's left wing, and so avoid the elephants. His plan was as follows: The horse archers were to move against the enemy's left to throw his cavalry into confusion. Under cover of this fire the Companion cavalry were to move against this same wing, and attack the Indian cavalry "while still in a state of disorder." By moving the bulk of his cavalry against the enemy's left wing he foresaw that Porus would probably withdraw his right wing cavalry to support his left wing, and so uncover his right wing. To take advantage of this probability he ordered Coenus and a force of horse, directly he saw Porus move his right wing cavalry, to gallop round the enemy's right wing and charge it in rear. The phalanx and the archers were ordered not to engage "until they observed the enemy's cavalry and phalanx of infantry thrown into disorder by the cavalry under his command."

The Battle. — To understand the battle as described by Arrian it must be presumed that Porus wheeled back the left of his army to meet the approaching attack. and that he drew his elephants more and more from his right toward his left. With his right wing cavalry he did exactly what Alexander had foreseen, whereupon Coenus galloped round the rear of the Indian infantry, and. as Arrian says. "threw the ranks as well as the decisions of the Indians into confusion." To counter this charge Porus wheeled round his cavalry to meet it, whereupon Alexander, seeing his opportunity, charged home at the head of his Companions and drove the enemy back onto their elephants "as to a friendly uall for refuge." The elephants, thrown into confusion, were nevertheless urged forward by their mahouts, whereupon the phalanx, covered by the archers, charged down on them, but itself became disorganized. The Indian cavalry, seeing this, wheeled round to charge, but Alexander had once again reorganized his cavalry, and, charging the Indian cavalry. cut them down in great numbers. One by one the mahouts were killed, and "when the beasts were tired out . . . they began to retire sloaly, facing the foe like ships backing water, merely uttering a shrill piping sound." Alexander now surrounded the whole of the enemy's line with his cavalry, and, giving the signal to the infantry to link shields, he charged his disorganized foe, and won the battle after eight hours fierce contest. The pursuit was at once taken up by Craterus. According to Diodorus the Indian losses were 12.000 and Alexander's 980.

Tactics. — The first paint which strikes the student is the preparatory moral attack made by Alexander on Porus by a series of feints which blind him by tiring out his vigilance. Directly this has been accomplished. he sets out at the head of a small force; he did not require a large one, because the whole idea of his attack was based on surprise. For surprise to prove successful, it was essential that Porus should not notice any serious reduction in the numbers opposed to him; consequently, when he learned of Alexander's advance. he did not realize what was happening. In brief, it was because Craterus was so strong that the surprise of the smaller force was so complete. Alexander's main problem was. seeing that he could not attack the Indian front, which of its two flanks should he select. His army was so small that he must maintain touch with Craterus, and if he could turn Porus' left flank he would facilitate the crossing of the river by Craterus. He decided to concentrate against the enemy's left flank, and to assist this concentration he detached Coenus, for by this economical distribution of force he added vastly to his main blow which was delivered under cover of demoralization due to surprise. Secured on his right flank by the river and his main army which threatened the Indian rear, he protected the left of his cavalry by the phalanx, and prepared his assault by the fire of his horse archers. Then in oblique order he converged on the enemy's left. As the enemy cavalry was scattered the phalanx approached and with it he delivered a left-hand punch under cover of which he withdrew his cavalry — his right-hand punch. No sooner was this done than he withdrew his phalanx, and charged home with his cavalry. Then with his phalanx, (his left) he knocked his antagonist out.

HYDATID, the bladder-worm stage (fluid-filled sac containing heads) of the tapeworm Echinococcus.

HYDE, the name of an English family distinguished in the 17th century. Robert Hyde of Norbury, Cheshire, had several sons, of whom the third was Lawrence Hyde of Gussage St. Michael, Dorsetshire. Lawrence's son Henry was father of Edward Hyde, 1st earl of Clarendon (*q.v.*), whose second son by his second wife was Lawrence, earl of Rochester (*q.v.*) and whose daughter Anne married James; duke of York. Another son of Lawrence was Sir Lawrence Hyde, attorney general to Anne of Denmark, James I's consort; and a third son was Sir Nicholas Hyde (d. 1631), chief justice of England. Sir Nicholas entered parliament in 1601 and soon became prominent as an opponent of the court, though he does not appear to have distinguished himself in the law.

Before long, however, he deserted the popular party, and in 1626 he was employed by the duke of Buckingham in his defense against impeachment by the commons; and in the following year he was appointed chief justice of the king's bench. In 1629 Hyde was one of the judges who condemned Sir John Eliot. Denzil Holles and Valentine for conspiracy in parliament to resist the king's orders; refusing to admit their plea that they could not be called upon to answer out of parliament for acts done in parliament. He died in Aug. 1631.

Robert (1595–1665), son of Lawrence, attorney general to Anne of Denmark, became recorder of Salisbury and represented that

borough in the Long Parliament. in which he professed royalist principles, voting against the attainder of the earl of Strafford. He gave refuge to Charles II on his flight from Worcester in **1651,** and on the Restoration was knighted, made a judge of the common pleas and in **1663** chief justice of the king's bench.

See Lord Clarendon, *The Life of Edward, Earl of Clarendon,* 3 vol. (1827); Edward Foss, *The Judges of England,* 9 vol. (1848–64).

HYDE, CHARLES CHENEY (1873–1952), U.S. authority on international law, was born in Chicago, Ill., on May 22, **1873.** He was educated at Yale (A.B., **1895;** A.M., **1898)** and Harvard law school (LL.B, **1898).** After engaging in private practice, and teaching at Northwestern university law school, Chicago, Hyde was appointed to the Hamilton Fish professorship of international law and diplomacy at Columbia university, New York city, which he occupied from **1925** to 1945.

He was a member of the panel known as the Permanent Court of Arbitration at The Hague, an editor of the *American Journal of International Law,* president of the American Society of International Law and a member of the Institut de Droit International.

As solicitor for the U.S. department of state, he was responsible for drafting, in 1923, what became a model treaty of commerce and navigation. His private practice included the representation of several governments.

Hyde's major treatise, *International Law Chiefly as Interpreted and Applied by the United States* (1922; rev. ed., 1945), was often cited by courts and international tribunals. Richly documented, it became the standard work mirroring the United States approach. For the future he concluded that the price of peace might prove to be the gradual and ultimate vesting of all military power in some international security organization. He died in New York city, Feb. **13, 1952.** (J. N. HE.)

HYDE, DOUGLAS (DUBHGLAS DE H-IDE, known in Ireland as "An Craoibhin Aoibhinn") (1860–1949), president of Eire 1938–45, Irish scholar and writer, was born at Frenchpark, County Roscommon, **1860,** and educated at Trinity college, Dublin. In 1891 he acted as interim professor of modern languages at the University of New Brunswick, Can. He formed in **1893** the Gaelic league, for the preservation and extension of the Irish language, and was president of that body until **1915.** In **1899** his production, before a vice-regal committee on education, of letters from leading Celtic scholars throughout Europe saved the Irish language on the intermediate board which regulated the curriculums for Irish schools.

During 1905 he toured America and raised £11,000 for the Gaelic league. On his return he was appointed a member of a royal commission on Irish university education. Hyde was professor of modern Irish at University college, Dublin, 1909–32. He became a senator in the Irish Free State in **1925,** and editor of *Lia Fáil.* The movement created by him resulted in the compulsory teaching of the language in Irish schools. In **1938** Hyde was elected president of Eire.

He died July 12, 1949.

Among Hyde's more important works are *A Literary History of Ireland* **(1899);** collections and translations of the *Love Songs of Connacht* **(1893);** *Raftery's Irish Songs* (1904, 1933); *The Religious Songs of Connacht* **(1906).** He also wrote several short plays in Irish.

HYDE, THOMAS (1636–1703), English philologist whose chief work was in the study of ancient Persian, was born at Billingsley, near Bridgnorth, in Shropshire on June **29, 1636.** At King's college, Cambridge, he studied languages under Abraham Wheelocke, and after only one year of residence was invited to London to assist Brian Walton in his edition of the Polyglot Bible.

Besides correcting the Arabic, Persian and Syriac texts for that work, Hyde transcribed into Persian characters the Persian translation of the Pentateuch, which had been printed in Hebrew letters at Constantinople in **1546.** To this work Hyde appended the Latin version which accompanies it in the Polyglot.

After holding various preferments, he was at length appointed, in **1691,** Laudian professor of Arabic; and in **1697,** on the deprivation of Roger Altham, regius professor of Hebrew and a canon of Christ .Church. Under Charles II, James II and William III, Hyde discharged the duties of eastern interpreter to the court. He died at Oxford on Feb. **18,** 1703. In his *Historia religionis veterum Persarum* (1700) he made the first attempt to correct from eastern sources the errors of the Greek and Roman historians who had described the religion of the ancient Persians.

With the exception of the *Historia religionis,* which was republished by Hunt and Costard in **1760,** the writings of Hyde, including some unpublished manuscripts, were collected and printed by Gregory Sharpe in **1767** under the title *Syntagma dzssertationum quas olim. . . Thomas Hyde separatim edidit,* with a life of the author. Hyde also published a catalogue of the Bodleian library in **1674.**

HYDE, a market town and municipal borough **(1881)** in the Stalybridge and Hyde parliamentary division of Cheshire, Eng., 7½ mi. E. of Manchester. Population **(1951)** 31,494. Area **6.5** sq.mi.

Standing on the Peak Forest canal and on the Tame, which divides it from Lancashire, it has grown up with the establishment of the cotton industry, though the Hyde family held the manor as early as the reign of John.

Besides the staple cotton trade there are heavy and light engineering and factories for making rubber, leather, leather cloth, hats, paper, ice cream, etc., and there are coal mines in the vicinity. Werneth Low, on the edge of the Pennines 1½ mi. S., was bought by the borough as a war memorial.

HYDE DE NEUVILLE, JEAN GUILLAUME, BARON (1776–1857), French politician, was born at La Charité-sur-Loire (Nièvre), on Jan. 24. 1776, of an English family which had emigrated with the Stuarts after the rebellion of 1745. From 1793 he was an active agent of the exiled Bourbon princes; he took part in the royalist rising in Berry in 1796, and after the coup d'état of **18** Brumaire (Nov. **9,** 1799) tried to persuade Bonaparte to recall the Bourbons. After an accusation of complicity in the infernal machine conspiracy (1800–01), subsequently retracted, Hyde de h'euville went to the United States, returning after the Restoration.

His mission from Louis XVIII to induce the British government to transfer Napoleon to a safer place of exile than Elba was cut short by the emperor's return to France in March 1815. Under the Restoration he was ambassador at Washington, D.C., and at Lisbon, where his action at the time of the coup d'état of Dom Miguel (April **30. 1824)** was disapproved in Paris. Hyde de Neuville was recalled. He then opposed the policy of Villele's cabinet in the chamber and in **1828** became minister of marine in Martignac's moderate administration. During the Polignac ministry (1829–30) he was again in opposition, being a firm upholder of the charter; but after the revolution of July 1830 he entered an all but solitary protest against the exclusion of the legitimate line of the Bourbons from the throne, and resigned his seat. He died in Paris on May **28, 18.5';.**

His *Mémoires et souvenirs,* 3 vol. (1888), compiled from his notes by his nieces, the vicomtesse de Bardonnet and the baronne Laurenceau, are of great interest for the Revolution and the Restoration An English edition translated and abridged by F. Jackson was published, 2 vol (1913).

HYDE PARK, a township and unincorporated village of Dutchess county, N.Y., U.S., is located on the east side of the Hudson river about 80 mi. N. of New York city and includes the land that formerly comprised the estate where Pres. Franklin Delano Roosevelt was born and is buried. Part of the estate, including the Roosevelt family home and the president's grave, is a National Historic site. Adjacent to this is the Franklin D. Roosevelt library, containing more than **30,000** books, a museum, the president's papers and the papers of many of his contemporaries and associates. It also houses collections of material on U.S. history and politics from 1910 to 1945, U.S. naval history and New York colonial history.

The township, established in **1821,** may have taken its name from an estate called after Edward Hyde, Viscount Cornbury, governor of New York (1702–08). The Frederick W. Vanderbilt mansion, constructed on this property in **1898,** and the Vanderbilt estate are now a National Historic site and arboretum. The village was originally named Stoutenburg's Landing after the first

white settler, who arrived in 1741. It is chiefly a residential village with a population of less than 7,000. (E. M. A.)

HYDERABAD, OSMAN ALI, NIZAM OF (1886–), was born in Hyderabad. April 6, 1886. and after a private education succeeded his father, Mahbub Ali. on Aug. 29, 1911. He achieved considerable learning; patronized the foundation of Osmania university, Hyderabad. in 1918; and despite enormous riches lived frugally. But, unlike some neighbouring princes. he maintained the feudal character of his state: showed little interest in the increasing voice of the Hindu majority among his people; and sponsored the formation of Majlis Ittehad al-hluslimin. or Movement for Moslem Unity, with its private army. the Razakars. After the partition of the subcontinent into Pakistan and India the nizam persisted for a year in his refusal to accede to the latter. He disputed India's claim to Great Britain's lapsed paramountcy; appealed to his special alliance with the British (in 1918 the king-emperor. George V, had conferred upon him the titles of "exalted highness" and ',faithful ally"); and placed his case before the United Nations. He rejected an Indian ultimatum and on Sept. 13, 1948, Indian troops entered his state. Four days later the nizam yielded. On Jan. 26. 1950, he was appointed constitutional head. or *rajpramukh,* of the state.

HYDERABAD, a former constituent state of India: was divided between the states of Andhra Pradesh, Mysore and Bombay on Nov. 1. 1956. Area 82,168 sq.mi.; pop. (1951) 18,655,108. The state occupied a large part of the plateau of the Deccan. It was bounded north and northeast by the Berar area of Madhya Pradesh, south and southeast by Mysore and Andhra and west by Bombay. Two tracts may be distinguished from one another geologically and ethnically, and are locally knoun from the languages spoken as Telingana (Telugu-speaking area) and Marathwara (Marathi-speaking). In some parts it is mountainous, wooded and picturesque. in others flat and undulating. The territory is well watered, with many rivers. tanks and artificial sheets of n-ater, especially in Telingana. The principal rivers are the Godavari. with its tributaries. the Dudna. Manjra and Pranhita; the Wardha, with its tributary the Penganga; and the Kistna. with its tributary the Tungabhadra. The climate is in general good; and as there are no arid bare deserts, hot winds are little felt.

The revenue of the state is largely derived from the land. and the development of irrigation and railways caused considerable expansion. More than half the population is dependent on agriculture. The soil is generally fertile, though in some parts it consists of *chilka,* a red and gritty mould little fitted for agriculture. The principal crops are millets, rice. wheat, oilseeds, cotton. tobacco and fruits and garden produce. Lac, gums and oils are found, and hides. raw and tanned, are of commercial importance. The principal exports are cotton, oilseeds. grain. timber, indigenous clothing and hides; the imports are salt. timber. European piece goods, sugar. cattle. metals, oil and yarn. Mineral resources include coal. copper. iron, diamonds and gold, but development was not very successful. The only coal mine worked in the later 1950s was a large one at Singareni.

The Bombay-Madras line (Central railway) runs through the southwest of the former state, and another line (the former nizam's railway) runs from Wadi junction on this line through Hyderabad to Bezwada. The Hyderabad-Godavari line traverses rich cotton country, and cotton presses have been erected along the line. There are also cotton-weaving and flour mills. The state formerly had its own currency. the osmani sikka (O.S. 116 = Indian Rs. 100), but this was replaced by the Indian rupee on April 1, 1955.

The nizam of Hyderabad was the principal Moslem ruler in India. The family was founded by Asaf Jah, a distinguished Turkoman soldier of the emperor Aurangzeb, who in 1713 mas appointed subahdar of the Deccan. but eventually threw off the control of the Delhi court. His death in 1748 was followed by internecine struggle among his descendants, in which the British and French took part. At one time the French nominee. Salabat Jang, established himself with the help of the marquis de Bussy. But when the British had secured their predominance throughout southern India. Nizam Xli took his place. He confirmed the grant of the Northern Circars in 1766, and joined in the two wars against Tipu Sultan in 1792 and 1799. The additions of territory which he acquired by these wars were afterward (1800) ceded to the British, as payment for the subsidiary force which he had undertaken to maintain. By a later treaty in 1853, the districts known as Berar were "assigned" to defray the cost of the Hyderabad contingent. In 1857 when the mutiny broke out, the nizam remained loyal to the British. In 1902 by a treaty made by Lord Curzon, Berar was leased in perpetuity to the British government, and the Hyderabad contingent was merged in the Indian army. The last nizam and first *rajpramukh,* Osman Ali, received the title of "faithful ally" of the British government. He received Rs. 25 lakhs (£167,000) a year for the rent of Berar, thus substituting a fixed for a fluctuating source of income. A British financial adviser was appointed and a resident, representing the government of India. had his headquarters at Hyderabad.

At the 1947 partition of the Indian subcontinent, difficulties at once arose over Hyderabad. Although more than 86% of its population is Hindu, government was in Moslem aristocratic hands. When India and Pakistan became independent, the nizam declined for the time being to accede to either, and signed with India, the country within which his was isolated, a "standstill" agreement to last one year from Nov. 29. 1947. Meanwhile, Indian troops were withdrawn. However. Hyderabad subsequently raised difficulties about contributions to defense; banned Indian currency; tried to obtain a loan from Pakistan; and failed to introduce representative government and Hindu participation in the administration. Most serious of all were Indian allegations of raids into dominion territory by the Razakars, a Hyderabad irregular army under Kazim Razvi, pledged to fight to the last man for Moslem supremacy in the Deccan. Further Indo-Hyderabad negotiations were abortive. India felt that Hyderabad was using the standstill arrangement to play for time, and now insisted upon accession as a prerequisite of all further progress; the nizam, adamantly jealous of his independence, appealed, as "faithful ally," to King George VI. Deadlock was now complete and on Sept. 13, 1948. Indian troops marched in. The Razakars were dispersed and the nizam capitulated. After a period of military and provisional civil government, a popular ministry and legislature were set up in March 1952. The nizam was installed as constitutional head of state (*rajpramukh*). Following partition Berar was definitely merged with the Central Provinces (Madhya Pradesh).

HYDERABAD, capital of the state of Andhra Prndesh and the former state of Hyderabad, India. with surrounding administrative district, on the right bank of the Musi. a tributary of the Kistna. with Golconda 5 mi. to the northwest and the city and cantonment of Secunderabad (British till 1945) 6½ mi. to the northeast. It is the fourth largest city in India; pop. (1961) 1,252,337, including suburbs and cantonment. It was,founded in 1589 by Mohammed Kuli. fifth of the Kutb Shahi kings. The Char Minar or Four hiinarets (1591) stand in the centre of the city. with four roads radiating from their base. The Xshur Khana (1594), a ceremonial building, the hospital. the Gosha Mahal palace and the Mecca mosque, a sombre building designed after a mosque at Mecca, were the other principal buildings of the Kutb Shahi period, though the mosque was only completed in the time of Aurangzeb. The city proper is surrounded by a stone wall with 13 gates, completed in the time of the first nizam, who made Hyderabad his capital. There are several fine palaces built by various nizams, and the former British residency is an imposing building in a large park on the left bank of the Musi, northeast of the city. The bazaars around it are picturesque. Four bridges crossed the Musi, the most notable of which was the Purana Pul, of 23 arches, built in 1593. In 1908, however, the river, swollen by torrential rain. swept them away. Enormous damage was done, and thousands of lives were lost. Osmania university (1918) is unique among Indian universities in that Urdu was the medium of instruction from its inception. English being taught as a compulsory second language. The university has a number of component colleges in or near the city. Hyderabad is an important centre of general trade. and there is a cotton mill in its vicinity.

HYDERABAD DISTRICT (1,957 sq.mi.) had a population in 1951 of

1,596,750. It was formed after the accession of Hyderabad to India, from parts of the nizam's *sars-i-khas illaka* or privy estate and other privilege areas.

HYDERABAD, a city and cantonment, district and division of West Pakistan; the city was the capital of the former Sind province. It stands on a hill about 3 mi. from the left bank of the Indus and 90 mi. E.N.E. of Karachi. Pop. (1951) 241.801. including 12.389 in the cantonment. On the site of the present fort is supposed to have stood the ancient town of Nirun, which in the 8th century A.D. submitted to the Arab general Mohammed bin Kasim. In 1768 the present city was founded by Ghulam Shah Kalhora; and it remained the capital of Sind until 1843. After the battle of Meeanee (Miani) it was surrendered to the British and the capital transferred to Karachi. After the separation of Karachi from Sind in 1948 it became the capital of the province. When separate provinces in West Pakistan were abolished in 1955 it became the headquarters of a division. The city is built on the most northerly hills of the Ganjo range, a site of great natural strength. In the fort, which covers an area of 36 ac., are the arsenal and the palaces of the former mirs of Sind. In addition to the manufacture of silk: gold and silver embroidery, lacquerware and pottery, a number of modern factories have been established including those for glass, cotton textiles, tanning, oilseed crushing and vegetable ghee refining, fruit cordials, jams and fruit canning. One of the four Sind industrial trading estates was established at Hyderabad in the mid-1950s. It is the seat of the University of Sind (1947).

HYDERABAD DISTRICT has an area of 5,084 sq.mi.; pop. (1951) 892,539. It consists of a vast alluvial plain on the left bank of the Indus, 210 mi. long and 48 mi. broad. A limestone range, the Ganjo hills, runs due south nearly parallel to the river for about 14 mi. Forests fringe the river and avenues of trees line the canals in an otherwise monotonous landscape. The principal crops are millets, rice: oilseeds, cotton and wheat, which are dependent on irrigation, mostly from government canals.

Three railways traverse the district: (1) one of the main lines of the North-Western railway, following the Indus valley and crossing the river near Hyderabad on its way to Karachi; (2) a broad-gauge branch running south to Badin; and (3) a metre-gauge line from Hyderabad to Khokarpar on the Indian border. Hala (9,481), 30 m i N. of Hyderabad, is famous for glazed pottery and tiles (made from Indus clay and powdered flint), lacquerware and susis, striped cotton cloth.

HYDERABAD DIVISION comprises Hyderabad, Tatta, Dadu, Mirpur Khas and Sanghar districts.

HYDER ALI or HAIDAR ALI (c. 1722–1782), Indian ruler and commander. This Mohammedan soldier-adventurer was the great-grandson of a fakir or wandering ascetic of Islam who came from the Punjab to Gulburga in the Deccan, and the second son of a naik or chief constable at Budikota, near Kolar in Mysore. His elder brother rose to command a brigade in the Mysore army, while Hyder acquired a useful familiarity with the tactics of the French under Joseph Dupleix. He is said to have induced his brother to employ a Parsee to purchase artillery and small arms from the Bombay government and to enrol about 30 sailors of different European nations as gunners and is thus credited with having been "the first Indian who formed a corps of sepoys armed with fire-locks and bayonets, and who had a train of artillery served by Europeans."

After the siege of Devanhalli (1749) Hyder received an independent command in Mysore; within the next 12 years his energy and ability had made him master of minister and rajah alike. In everything but in name he was ruler of the kingdom. In 1763 the conquest of Kanara gave him the treasures of Bednor, which he resolved to make the most splendid capital in India: under his own name, thenceforth changed from Hyder Naik into Hyder Ali Khan Bahadur; and in 1765 he retrieved previous defeat by the Marathas by destroying the Nairs or military caste of the Malabar coast and by conquering Calicut.

Hyder Ali now occupied the serious attention of the Madras government. which in 1766 agreed to furnish the nizam of the Deccan with troops to be used against the common foe. But a secret arrangement was agreed upon between the two Indian powers, the result of which was that Col. Joseph Smith's small force was met with a united army of 80,000 men and 100 guns. British dash and sepoy fidelity, however, prevailed, first in the battle of Chengam (Sept. 2. 1767) and again still more remarkably in that of Tiruvannamalai (Trinomalai).

On the loss of his recently made fleet and forts on the western coast, Hyder Ali offered peace overtures; on their rejection, bringing all his resources and strategy into play. he forced Colonel Smith to raise the siege of Bangalore and brought his army within five miles of Madras. The result was the treaty of April 1769, providing for the mutual restitution of all conquests and for mutual aid and alliance in defensive war; it was followed by a commercial treaty in 1770 with the authorities of Bombay. Under these arrangements Hyder Ali, when defeated by the Marathas in 1772, claimed British assistance, but in vain; this breach of faith aroused a desire for vengeance.

His time came when in 1778 the British, on the declaration of war with France, resolved to drive the French out of India. The capture of Mahé on the Malabar coast in 1779, followed by the annexation of lands belonging to a dependent of his own, gave him a pretext. Again master of all that the Marathas had taken from him, and with empire extended to the Kistna, he descended through the passes of the Ghats amid burning villages, reaching Conjeeveram, only 45 mi. from Madras, unopposed. Not till the smoke was seen from St. Thomas' Mount, where Sir Hector Munro commanded 5,200 troops, was any movement made; then, however, the British general sought to join a smaller body under Col. William Baillie recalled from Guntur. The incapacity of the officers resulted in the destruction of Baillie's force of 2,800 (Sept. 10, 1780). Warren Hastings sent from Bengal Sir Eyre Coote, who, though repulsed at Chidambaram, defeated Hyder thrice successively in the battles of Porto Novo, Pollilur and Sholingarh, while his son Tipu (see TIPU SAHIB) was forced to raise the siege of Wandiwash, and Vellore was provisioned. On the arrival of Lord hfacartney as governor of Madras, the British fleet captured Negapatam and forced Hyder Ali to confess that he could never ruin a power which had command of the sea. He had sent Tipu to the west coast, to seek the assistance of the French fleet, when his death took place at Chittur in Dec. 1782.

See L. B. Bowring, *Haidar Ali and* ***Tipu*** *Sultan* (Oxford, *1893).* For the personal character and administration of Hyder Ali *see* the *History of Hydur Naik,* written by Mir Hussein Ali Khan Kirmani, trans. from the Persian by Col. W. Miles and published by the Oriental Translation Fund (London, 1842), and the curious work written by Le Maître de la Tour, commandant of his artillery *(Histoire d'Hayder-Ali Khan,* Paris, 1783) For the whole life and times *see* Mark Wilks, *Historical Sketches of the South of India, 3* vol. (London, 1810–17); H. N. Pearson, *Menzoirs oj Schwartz* (London, 1834); *N.* K. Sinha, *Haidar Ali* (Calcutta, 1949).

HYDNOCARPUS, an Indo-Malayan genus of trees of the family Flacourtiaceae. The seeds of some species are a source of hydnocarpus or chaulmoogra oil, which has some therapeutic effectiveness in some forms of leprosy (*q.v.*) but is of questionable or no value in others. Chaulmoogra oil and its purified derivatives as chemotherapeutic agents have been largely replaced by antibiotics. (N. TR.)

HYDRA, an island of Greece (anc. HYDREA), lying about 4 mi. off the southeast coast of Argolis and forming with the neighbouring island of Dokos (Dhoko) the Bay of Hydra. The greatest length from southwest to northeast is about 11 mi., and the area is 20 sq.mi.; a rocky and treeless ridge with hardly a patch or two of arable soil. Hence the epigram of Antonios Kriezes to the queen of Greece: "The island produces prickly pears in abundance, splendid sea captains and excellent prime ministers." The highest point, Mt. Ere, so called (according to Miaoules) from the Albanian word for wind, is 1,936 ft. high. The next is known as the Prophet Elias, from the large convent on its summit. There the patriot Theodorus Kolokotrones was imprisoned, and a pine tree is still called after him. In former times the island was richly wooded as its Turkish name Tchamliza, "the place of pines," shows. It was once well watered (hence the designation Hydrea), but is now wholly dependent on the rain supply, and sometimes water

must be brought from the mainland. This change may be due in part to earthquakes, which are frequent; that of 1769 continued for six days.

Hydra, the chief town, population 2,563, near the middle of the northern coast, on a very irregular site. has uhite and handsome houses, and its streets, though narrow, are clean. There are three other ports on the north coast—Mandraki, Molo, Panagia, but none sufficiently sheltered. Almost all the population of the island is collected in the town, which has a bishop, a local court, numerous churches and a high school. Cotton and silk weaving, tanning and shipbuilding are carried on, and there is a fairly active trade.

Hydra was of no importance in ancient times. In 1580 it was the refuge of Albanians from Kokkinyas in Troezenia; and other emigrants followed in 1590, 1628. 1635, 1640 and subsequent pears. At the close of the 17th century the Hydriotes took part in the reviving commerce of the Peloponnesus. About 1716 they began to build *sakturia* (of from 10 to 15 tons' burden), and to visit the islands of the Aegean; not long after they introduced the *latinadzka* (40–50 tons). and sailed as far as Alexandria, Constantinople, Trieste and Venice; eventually to France and even America.

From the grain trade of south Russia they derived great uealth. In 1813 there were about 22.000 people on the island, and of these 10,000 were seafarers. At the time of the outbreak of the war of Greek independence the total population was 28.190, of whom 16.460 were natives and the rest foreigners. One of their chief families, the Konduriotti, was worth £2,000,000. Into the national struggle the Hydriotes flung themselves with rare enthusiasm and devotion and the final deliverance of Greece was mainly due to their fleets.

See Pouqueville, Voy. de la *Grèce,* vol. vi; Antonios Miaoules, Ὑπόμνημα περὶ τῆς νήσου Ὕδρας (Munich, 1834), Id., Συνοπτικὴ ἱστορία τῶν ναυμαχιῶν 61b τῶν πλοίων τῶν τρίων νήσων, Ὕδρας, Πέτσων καὶ Ψαρῶν (Nauplia, 1833); Id. Ἱστορία τῆς νήσου Ὕδρας (Athens, 1874); G. D. Kriezes, Ἱστορία τῆς νήσου Ὕδρας (Patras, 1860).

HYDRA, in Greek legend, the offspring of Typhon and Echidna, a gigantic monster with nine heads (the number is variously given), the centre one being immortal. Its haunt mas the marshes of Lerna by Argos. The destruction of this hydra was one of the 12 "labours" of Hercules. which he accomplished with the assistance of Iolaus. Finding that as soon as one head was cut off two grew in its place, they burned out the roots with firebrands, and at last severed the immortal head from the body, and buried it under a rock. The arrows dipped by Hercules in the poisonous blood or gall inflicted fatal wounds.

HYDRACRYLIC ACID is a sirupy liquid, which on distillation is resolved into water and acrylic acid, $CH_2:CH.CO_2H$. It is β-hydroxypropionic acid, $CH_2OH.CH_2.CO_2H$, and is prepared by acting with silver oxide and water on β-iodopropionic acid, or from ethylene by the addition of hypochlorous acid, the addition product being then treated with potassium cyanide and hydrolyzed by an acid. Hydracrylic aldehyde, $CH_2OH\,CH_2.CHO$, is obtained as a colourless oil by heating acrolein with water.

HYDRANGEA is a genus of shrubs of the saxifrage family embracing about 80 species. distributed in North and South America and Asia. The simple leaves are opposite, petioled and marginally toothed. Flowers, in corymbiform cymes or cymose panicles, are four-five-parted, perfect, marginally sterile, or all sterile. Sepals are enlarged. often dentate; petals are small; stamens. numbering eight-ten; two-celled capsule opening between the diverging styles. Its persistent flower clusters, erect or climbing, are effective ornamentals in borders and arbours.

Hydrangea flowers are white or coloured. The colours, pink or blue, depend upon the presence of aluminum in the floral buds before opening. In those plants growing in basic soil the flowers are pink; in acid soil they are clear blue. The blue colour may be maintained by adding a soluble aluminum sulfate to the soil. Conversely, the pink colour may be maintained by adding lime to the soil.

Hydrangea is propagated by suckers, parts of older plants or cuttings. Cuttings are obtained in summer from young stems of plants grown under glass. Rooted cuttings may be cultivated in pots or in beds of rich, well-drained, loamy soil, with frequent watering. Partial shade is desired for foliage; sunlight stimulates flowering. In the fall or in early spring, the stems are pruned back to a few pairs of buds. For winter protection the plants may be lifted from beds for storage in cool cellars; otherwise, the stems may be tied together within straw or burlap and the plants covered with boughs; or the beds may be boarded along sides and filled with light earth. Seeds. seldom if ever used, should be planted in the fall in boxes under a scant soil cover.

H. petiolaris, native to Japan, is a luxuriant vine, with pure white, fragrant flowers, climbing by roots. H. *arborescence,* var. *grandiflora* (hills of snow), an American species, is renowned for its mostly sterile white flower clusters up to 7 in. across. Its rhizomes and roots contain a diuretic principle. Frequently cultivated in northern gardens is H. *paniculata,* var. *grandiflora* (Peegee hydrangea), with panicles of flowers up to 12 in. long, changing to pink and russet in the autumn. *H. macrophylla* (largeleaf hydrangea) of greenhouses or gardens bears blue or pink flowers.

(O. LA.)

HYDRASTIS, a genus comprising two species of plants of the Ranunculaceae family, one species occurring in Japan and the other in eastern North America, known as golden seal or orangeroot.

The native species is a low perennial herb that sends up, in early spring, from a thick yellow rootstock a single radical leaf and a simple hairy stem that is two-leaved near the apex and terminated by a single greenish-white flower bearing many stamens and 12 or more pistils in a head, the two-ovuled pistils becoming crimson, fleshy, berrylike in fruit. The rootstocks are gathered in the wild and under cultivation for the alkaloid hydrastine used in medicine. (J. M. BL.)

HYDRATE, in chemistry, a liquid or solid compound containing combined water. In some cases the crystalline character of a solid hydrate depends on this water which is present. Common examples of hydrates are the well-known sodium compounds: Glauber's salt (*q.v.*), which is decahydrated sodium sulfate, $Na_2SO_4.10H_2O$; washing soda, which is decahydrated sodium carbonate. $Na_2CO_3.10H_2O$; and borax, uhich is sodium pyroborate, $Na_2B_4O_7$, with five or ten molecules of water. Blue vitriol, $CuSO_4.5H_2O$, the pentahydrated copper sulfate, is another common example.

The alums owe their characteristic crystalline form partly to the presence of combined water; for example, potash alum, $KAl(SO_4)_2.12H_2O$, crystallizes in will-defined octahedra, which crumble into powder on removing the water. Acids and bases also form hydrates. $Ba(OH)_2.8H_2O$, hydrated barium hydroxide, is a well-crystallized substance. Sulfuric acid and hydrochloric acid combine with water to form hydrates, and since certain of these are stable only at comparatively low temperatures they are termed cryohydrates.

A remarkably stable solid hydrate is chloral hydrate, $CCl_3.CH(OH)_2$, produced by adding water to liquid chloral (*q.v.*). In this substance the added water has probably become hydroxide of constitution. so that this hydrate may be regarded as a connecting link between the loosely knit hydrates and the true hydroxides (*q v.*). (G. T. M.; X.)

HYDRAULICS: *see* MECHANICS, FLUID.

HYDRAULICS, APPLIED. Applied hydraulics is that science of engineering utilizing the basic principles of fluid mechanics and hydraulics to applied problems of economically developing and utilizing an available supply of water. Although the applied problems associated with utilization of other liquids such as oils in hydraulically operating mechanisms are sometimes included in applied hydraulics, this article will deal with the subject in the narrower sense.

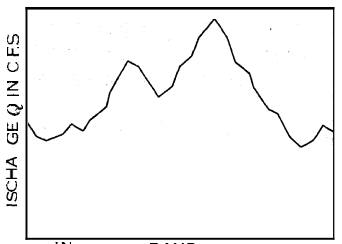
Some system of storage usually must be provided for a water supply, involving dams, diversion works, spillways and energy dissipaters (stilling basins). Water must be conveyed to its point of utilization and some system must be provided for drainage of used or excess water away from the point of utilization. Proper control of the water involves hydraulic machinery and measuring

devices throughout. Special hydraulics problems have to do with river engineering and coastal engineering. Frequently model studies can be used to advantage in the design and construction of hydraulic structures. Each of these subjects is treated briefly in the following article. Not considered in this article, however, is the fact that the usefulness of applied hydraulics is frequently conditioned or limited by social, economic and political considerations (see WATER RIGHTS).

WATER

Use.--When man diverts water from its natural location or course of movement, it is the job of the hydraulic engineer to design the system for diverting and using the water and also to care for the problems associated with such diversion. The various uses of water can be divided broadly into consumptive and temporary. Water which is temporarily used is diverted and then later returned to the natural drainage system (or to storage). This water can then be used repeatedly as it progresses down the natural drainage to the ocean. Consumptive use of water involves evaporation, transpiration and chemical combination of the water so that it cannot return to the natural drainage system. Among the more common uses of water are domestic, industrial, agricultural (including irrigation), power (both hydro power and condensing water for steam plants), sanitation, navigation, flood control, recreation and maintenance of marine life. One or more of these purposes may be the primary reason for using water at a specific location. Consideration, however, must also be given to each of these uses to ensure that one or more of them is not denied to some other hydraulic project.

Multipurpose projects are those that involve one or more of the foregoing purposes. Basically, multipurpose projects are designed and operated so that the combined use of the water provides maximum benefits for all concerned. Usually this requires a compromise for at least some of the interests, since the water must be handled in different ways for different purposes. In the operation of a reservoir, for example, a maximum available storage space is required for flood control, whereas for hydro power and irrigation projects the reservoir should be full.



BY COURTESY OF MAURICE L. ALBERTSON

FIG. 1.— TYPICALHYDROGRAPH

Examples of multipurpose projects include the St. Lawrence seaway the Tennessee Valley authority, the Damodar valley in India, the Columbia basin project in Washington, the Colorado-Big Thompson project in Colorado and the Missouri river project in the north central United States. In many projects, flood control is the primary purpose (see FLOOD). The U.S. army corps of engineers is charged with the primary responsibility of designing and building flood-control works along individual rivers and in metropolitan areas of the United States. The bureau of reclamation does similar work in the utilization of water on the arid lands of the western United States.

Supply.— The principal factors involved in the utilization of a water supply are its quantity, quality and location. The existing situation with respect to these factors must be related to the needs of the project. The quantity of the water is expressed in terms of discharge—the volume rate of flow—and in terms of total volume over a period of time. Knowledge of the minimum, maximum and average values are needed if the project is to operate successfully under varying conditions. The quality of water involves its chemical composition, for example, its hardness or mineral content; its bacterial content: materials such as sediment in suspension; temperature; and reliability. The location of the water involves both its placement on the surface of the earth and its elevation or depth.

Sometimes the needs of a particular project permit a wide variation in these characteristics. In other projects the characteristics must be controlled within narrow limits.

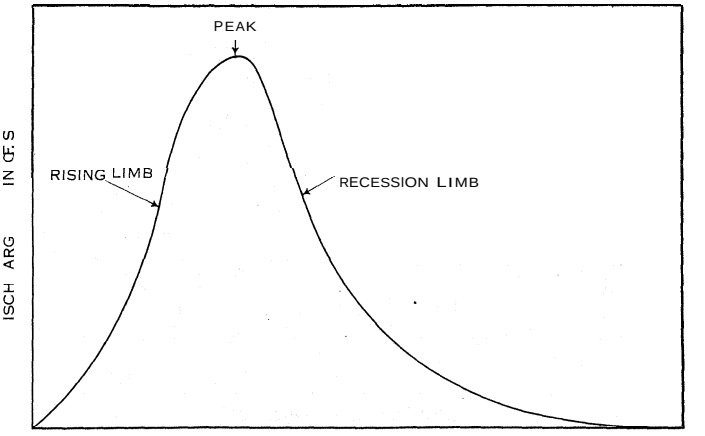
FIG. 2.—ISOHYETAL MAP

A study of the hydrologic cycle (*see* HYDROLOGY; WATER SUPPLY) reveals the source and disposition of water diverted and utilized in applied hydraulics. The principal source of a water supply is precipitation. Water is also obtained from deep underground sources and from the ocean. Rainfall may be available directly as surface runoff or indirectly as ground water (*q.v.*). Snowfall is not immediately available but is later released as melt from snowbanks or glaciers, and in turn may become either surface flow or ground water. The deep underground water is that which is not replaced by seepage from the surface of the earth but rather has been trapped during geologic processes.

Precipitation frequently must be analyzed in the hydraulic design of a project. Factors considered are the rate and total amount of rainfall over a period of time ranging from a few hours to several years. Both the maximum and minimum are significant. An isohyetal map (fig. 2) is used to show the amount of rainfall over a given area during a period of two days. (For maximum rates of rainfall, see RAINFALL.)

The hydrograph (fig. 1) is a chart that shows the variation, with respect to time, of the depth of flow or the discharge in a river or stream. It is used by the hydraulic engineer to indicate the variations in runoff with which he must contend. These may be



BY COURTESY OF MAURICE L. ALBERTSON

FIG. 3.— TYPICALHYDROGRAPH FOR SINGLE STORM

caused by daily fluctuations due to variations in barometric pressure, evapo-transpiration and temperature, which affects both snow melt and ground-water flow. The surface runoff from a single storm creates a hydrograph similar to the one in fig. 3. Other variations are seasonal and are related to evapo-transpiration, availability of ground water and precipitation, average daily temperature and seasonal movement of air masses. Long-range cycles of precipitation and runoff have been found to exist over a period of approximately 21 years. These long-range cycles are claimed by some scientists to be correlated with similar cycles in the activity of the sun. (For magnitudes of flow in rivers see RIVER AND RIVER ENGINEERING.)

In studying and obtaining a water supply, it is necessary to take measurements of the precipitation, the runoff, the ground-water level, the water level in lakes and reservoirs and the amount of water delivered for use. Such measurements require a wide array of instruments, some read and recorded by an observer and others which record automatically.

Storage. — Because of the irregular supply or the irregular demand for water, storage facilities are needed to provide water for future use or disposition. Storage may also be needed to allow sediment carried by the water in a stream to settle out. The storage may be for a short period of time to compensate for the variations in hourly consumption by a metropolitan area, or for as long as a period of several years to provide water during a possible drought. The storage in Lake Mead (32,000,000 ac.ft.), created by Hoover dam on the Colorado river, for example, is intended, if necessary, to last over a period of many years of less than average flow.

Water can be stored above or below ground. Above ground it may be stored in reservoirs. channels, valleys such as that of the Mississippi river, or in snow and glaciers. Underground storage may result from natural seepage of rain water or runoff as well as from artificial water spreading. Water spreading not only increases the quantity of ground water but in some cases is used to dissipate floods from small watersheds. Important factors to consider in the storage of water are losses due to seepage and evaporation as well as possible significant changes in quality. These include changes in chemical, bacteriological and sediment composition, as well as in temperature.

FIG. 4. — TYPICAL EARTH DAM

Surface reservoirs must be carefully planned as to location and operation. The storage capatity with respect to water-surface elevation in the reservoir must be determined together with a mass curve, the variation of accumulated runoff over a period of time. In the design and operation of a reservoir, plans also must be made for the disposition of sediment that is carried in with the water. This sediment can completely fill a reservoir in a few years if it is introduced in sufficient quantities. Coarse sediment settles out at the entrance to the reservoir where the water is slowed and its sediment-carrying capacity reduced. The finer materials, which may take many days to settle, are usually carried as a dense submerged current under the reservoir along the old channel, and deposited at the bottom of the reservoir. An example of the effect of sediment deposits is Elephant Butte reservoir in New Mexico the capacity of which was decreased by 16% during the period 1915–40 by sediment deposited from the upstream watershed at the rate of 1,600 tons per square mile per year.

Reservoirs may be operated singly or in combination. Furthermore, in multipurpose projects their use must be considered in connection with the various needs of possibly conflicting operations. Obtaining maximum efficiency of operation is a complicated procedure, so complicated in fact that electronic computers are used to integrate all the variables to be considered.

FIG. 5. — TYPICAL OVERFALL GRAVITY DAM

HYDRAULIC WORKS

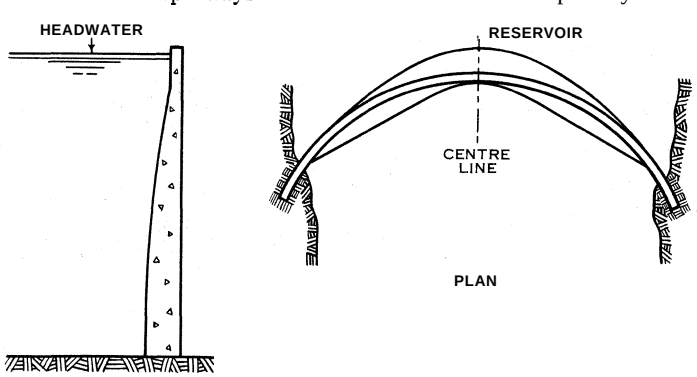
Dams. — The creation of a reservoir usually requires construction of a dam to impound and store water, either temporarily or for longer periods of time, for use while stored or for later release and use. Low dams are used to divert water from one conveyance system, such as a river, into another. The basic problems involved in the design and construction of a dam are the stability of the dam; the seepage of water around, through, or under the dam; the disposition of floodwaters; protection against waves and sudden drawdown; and foundation support for the dam. Stability of the dam involves its vertical weight, the pressure of the water upstream, the pressure of the silt upstream, the pressure of the ice upstream. uplift pressure under the dam, the foundation materials and seismic forces from vibrations such as explosions and earthquakes. Seepage takes place through all dams to a greater or lesser extent. It is only when the seepage is of such quantity as to waste the water or to endanger the safety of the dam that it becomes of major concern. The failure of most dams is due to flood flows for which there has not been provided adequate spillway capacity for passing the flood flow over, around or through the dam. (For a fuller discussion of the construction and operation of dams, see DAM.)

Spillways and Outlet Works. — Nearly all types of dams and control works that require release of water involve a spillway or outlet works of some kind. **A** spillway is a structure which permits the water to pass around, over, through or under a dam or other structure safely, in desired quantities and at the desired time. This water may be floodwater that cannot be stored in the reservoir or it may be water stored under normal conditions that is released for use downstream.

The crest of the overfall type of spillway is shaped like the underside of the jet of water that flows over a weir (*q.v.*). The water, after leaving the spillway, flows into a stilling basin downstream from the dam where its kinetic energy is dissipated.

The morning-glory or shaft spillway is usually located in the reservoir upstream from the dam. The water flows radially inward over a rounded crest down a shaft to a pipeline that passes through, under or around the dam.

Side-channel spillways accumulate the water over a spillway crest



BY COURTESY OF MAURICE L. ALBERTSON

FIG. 6. — TYPICAL ARCH DAM

upstream from the dam and carry it into a tunnel or chute around the end of the dam.

Spillways that siphon water over the top of a dam are advantageous for drops in elevation of 50 ft. or less. Because of the siphoning action it is possible to obtain a much greater discharge for a given size opening or passsgeway.

The flow (Q) over a spillway crest is represented by the equation $Q = KLH^{3/2}$ in which K is the coefficient of flow (approximately 4), L is the length of the spillway crest and H is the height of the water in the reservoir above the spillway crest.

Outlet works arc used to discharge water through a dam at a level lower than the crest of a spillway and are thus under greater pressure than an ordinary spillway, the head sometimes reaching hundreds of feet. The water, after passing through the outlet, is discharged into a stilling basin. Various types of gates and regulating valves control the rate of flow.

Energy-Dissipation Systems.—In order to protect the banks and beds of a stream or river against erosion and to reduce waves, surges and water spray, kinetic energy of the initial high-velocity flow in the spillway or outlet works must be dissipated. Kinetic energy can be dissipated by shear resistance and pressure resistance (fig. 7). A boundary along which water is flowing will create a resistance to the flow that results in a reduction in kinetic energy (fig. 7[A]), which is converted to turbulence and heat. Furthermore, energy can be dissipated in either the vertical or horizontal direction or in a combination of both. The hydraulic jump (fig. 7[B]) is based upon the momentum principle. Dissipation of energy in the direction vertically downward is shown in fig. 7(C), while the manifold stilling basin (fig. 7[D]) dissipates energy vertically upward.

Dissipating energy vertically results in radial spreading of the flow and very efficient dissipation with little energy remaining in the form of high-velocity jets or eddies or in the form of waves to erode the bed and banks of the downstream channel.

Conveyance and Diversion Systems.—Conveyance systems, in the form of natural or man-made waterways or conduits, are used to transport water from point of origin, diversion or storage to point of further storage, utilization or waste, while diversion works are for the purpose of diverting water from storage or from one conveyance system into another. Such diversion works can consist of a simple head gate that releases stored water into the conveyance system or of a complex combination of a diversion dam with control gates, sluice gates and head gates. The control gates on the diversion dam are intended to pass floodwaters and to control the elevation of the water upstream in order to divert the desired quantity into the conveyance system. Sluice gates are mounted at a much lower level in order to wash any sand or other sediment away from the head gates. This prevents sediment from entering the head gates of the conveyance system.

Immediately downstream from the head gates is usually a device for ejecting or removing any undesirable sediment that may have entered the conveyance system. This ejector usually flushes such sediment back into the main channel (fig. 8). Usually near the head gate is also located a device, such as a Parshall flume, for measuring the water diverted into the conveyance system.

FIG. 8.— TYPICAL LAYOUT OF DIVERSION DAM AND CANAL HEADWORKS

Closed conduits such as pipes and tunnels are often used for conveying water from one point to another. The pipes may consist of cast iron, steel, concrete, clay or wood stave. Penstocks are a special type of pipes that convey water into hydroelectric turbines. The design of an economic closed conduit depends in part upon the resistance to flow (see MECHANICS, FLUID). In some flow systems the boundary resistance is of major importance, whereas in others the energy losses due to fittings, bends, gates, valves, etc., called minor losses, are of primary importance.

Measurement of flow in closed conduits is usually accomplished by means of measuring flow pressures with a Pitot tube, Venturi meter, orifice meter, flow nozzle or other device and computing the rate and volume of flow from the pressure values thus obtained. (See MECHANICS, FLUID: Applications: *Fluid* Meters).

Water hammer, a pressure wave that travels through the water with the speed of sound, must be considered in any closed conduit where automatic and sudden stoppages of flow are apt to occur. If the pressure generated is of sufficient magnitude, it can burst the conduit. Although water hammer is frequently thought to be the noise associated with the sudden closure of a water faucet on a water line such as that in a home, the noise created in such cases is caused by the conduit or pipe, actuated by a water hammer, striking some other object such as a wall.

Some closed conduits operate partially full so that there is air above the liquid: This air may be at atmospheric pressure or at some modified pressure. Under these conditions the problems of analysis and design are the same as for flow in an open channel.

Examples of closed conduits include domestic water-supply systems, cross-country lines for natural gas and other petroleum products, industrial and agricultural water supplies and pipelines for chemical and industrial processes.

Open channels include flow of water in natural channels such as rivers and in artificial channels such as canals, flumes and aqueducts. The type of boundary may be rigid or it may be alluvial so that sand or gravel is moved along the bed. (For the method of analyzing flow in open channels, see MECHANICS, FLUID: *Applications: Flow* of *Liquids* in Open Channels.)

Associated with diversion and conveyance systems are regulating and control structures such as gates and valves to control the flow, measuring devices to measure the amount of water being diverted and delivered to the consumer, turnouts to deliver water, wasteways to dispose of excess water, checks to maintain the water in the canal at a higher level for delivery at small discharges, dividers to divide the flow into certain proportions regardless of the amount of the total flow and locks to permit vessels to go from one level to another.

Protective structures are also necessary on conveyance systems. These include automatic spillways to dispose of unexpected flows automatically without damage to the structures; overchutes to carry excessive drainage water such as storm runoff over canals;

culverts to carry excess water under canals; bridges and aqueducts to carry vehicular and pedestrian traffic as well as water over canals or natural drainage systems; drain inlets which permit a small amount of surface drainage to enter the canal; and sand traps and settling basins which collect excess sediment.

Drainage Systems. — Often a drainage system is employed in connection with hydraulic projects to transport waste or excess water safely and economically to a river or other point of disposition. This drainage water may be flowing over the surface of the ground or underground. Surface water usually consists of storm water or excess and waste water from irrigation, industrial and domestic sources. Surface water must be taken around, over, under or through the main conveyance system. This is usually done through overchutes and culverts or under bridges and aqueducts.

Subsurface drainage involves ground water and water that has leaked into the earth through porous media. Such drainage is usually accomplished by means of systems of tile piping laid underground or by open trenches, ditches and cuts that intercept the subsurface water and dispose of it. (See LAND RECLAMATION.)

Control structures for water-drainage systems are similar to those for water-conveyance systems.

HYDRAULIC MACHINERY

To serve its purposes a hydraulic project must have machinery. Machinery to control and regulate flow usually consists of gates or valves. Pumps are used to add energy to the flow while turbines subtract energy from the system by converting it into other forms such as mechanical or electric energy.

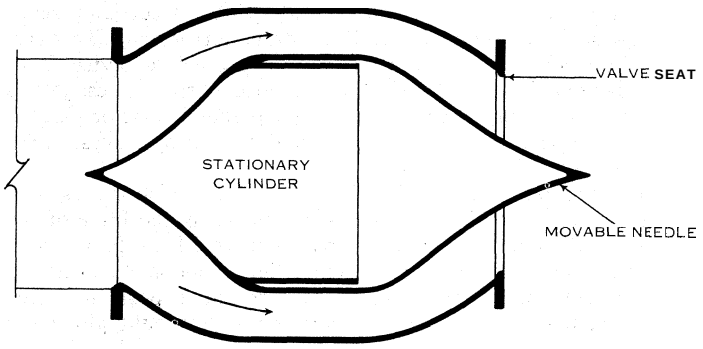
Gates. — Gates may be designed to operate under low heads of only a few feet or high heads of several hundred feet. They may be operated manually or automatically. Low-head gates are usually associated with spillways and canals while high-head gates are usually to be found with outlet works and penstocks for dams and hydroelectric plants.

A radial or Taintor gate is a segment of a cylinder at the centre of which is the pivot for the gate (fig. 5). One of the least expensive as well as one of the simplest to operate, it is used for control gates on dams, head gates, control gates and checks in canals. and for sluice gates.

The leaf gate consists of a sliding plane located in a conduit perpendicular to the direction of flow. Leaf gates that are hinged along one edge are for low head only, while the sliding or vertical-lift gates are designed for both low and high heads. For low heads the sliding or vertical-lift gate simply slides along a seat since the friction is not too great to be overcome by a hoisting mechanism. For high heads, however, it is necessary to have wheels on the gate or wheels fixed in the seat so that the sliding friction is reduced. Otherwise the friction would be so great that the gates could not be raised or lowered.

For the crests of dams and other types of diversion works flashboards and needles are sometimes used. Flashboards are horizontal boards and needles are vertical boards. Both are placed across the flow in order to increase the elevation of the water surface, usually for diversion purposes. Stop logs are usually planks or logs that slide into vertical grooves on the side of a canal or flume in order to close a flow passage either temporarily or permanently.

Valves. — Valves are associated with closed conduits and usually are designed for high-head conditions. Outlet works associated with discharge at a low level behind a dam or the discharge of water into a hydroelectric plant are usually controlled by valves. The most common type of valve is the needle valve (fig. 9). The interior part of the valve is composed of two streamlined sections, one of which is rigid and remains fixed, the other being movable so that it can move into the opening. A modification of this valve is the tube valve, which has the movable portion at the downstream end cut off in order to simplify its operation. A further simplification of the needle valve is the hollow-jet valve, which has the movable portion upstream and the casing, as well as the interior, cut off downstream. This valve discharges directly into the atmosphere rather than into a conduit downstream. Perhaps the simplest of valves for high-head installation is the Howell-Bunger



BY COURTESY OF MAURICE L. ALBERTSON

FIG. 9. — NEEDLE VALVE

valve, consisting of a cone facing upstream that moves into the cylindrical valve chamber to close off the flow. This type of valve discharges radially outward into the atmosphere and greatly aids energy dissipation but increases spray.

The cylinder gate is similar in some respects to the tube valve except that it operates in a vertical direction and is customarily used to release water from a reservoir.

Butterfly valves (fig. 10) are most commonly used to control the flow from a penstock into a hydroelectric turbine because of the very small energy loss through the valve. When the valve is open the butterfly leaf is simply a streamlined disk parallel to the flow. To close the valve, the butterfly leaf is turned 90° so that it is perpendicular to the flow, shutting it off.

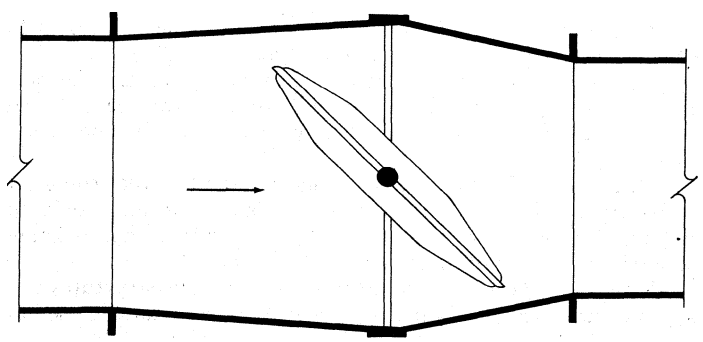
The discharge from gates and valves frequently has sufficient kinetic energy that stilling basins must be provided downstream.

Pumps **and** Turbines. — Pumps and turbines (see PUMP; TURBINE: WATER) are similar in design and operation except that the water flows in one direction for the pump and in the opposite direction for the turbine. The purpose of the pump is to increase the kinetic energy or the potential energy of the water in the system. Some of the largest pumps ever built were for Grand Coulee dam, Washington. These operate with 65,000 h.p. at 200 r.p.m. to deliver 1,350 cu.ft. per second (c.f.s.) of water against a head of 310 it. Centrifugal pumps can be combined in multiple stages in order to pump against extremely high heads. One of the highest-head pumps ever built was for 875 gal. per minute (g.p.m.) against a head of 8,600 ft.

The Francis-type turbine corresponds to the centrifugal pump and the Kaplan-type turbine to the propeller pump (see TURBINE: WATER). Some of the largest Francis-type turbines are the 115,000-h.p. turbines for Hoover dam, Arizona-Nevada, which operate at 180 r.p.m. with a head of 510 ft. At Grand Coulee dam there are 150,000-h.p. turbines operating at 120 r.p.m. with a head of 330 ft. At the Marne plant in Italy is a Kaplan turbine for 7,320 h.p. under 105 ft. of head. Francis turbines have been used for heads greater than 1,000 ft.

COASTAL ENGINEERING

Hydraulics problems associated with coastal engineering involve the design, operation and maintenance of docks, harbours, beaches, estuaries and navigation channels. Natural phenomena that com-



BY COURTESY OF MAURICE L. ALBERTSON

FIG. 10. — BUTTERFLY VALVE

plicate this work are waves, surges, tides, littoral currents. scour and deposition of sediment, and salt-water intrusions. To overcome these complications various types of protective devices have been developed, including breakwaters, groins, spur dikes, jetties and sea walls. Long dikes or walls built perpendicular or parallel to the shore protect it against waves and erosion by waves. (See BREAKWATER; JETTY.)

The reduction of the height of waves is accomplished most frequently by means of breakwaters which break up the force of the waves, allowing an inner harbour area to be used for safe mooring, operating, handling, loading and unloading of shipping. Littoral currents along the shore erode, transport and deposit sediment that frequently undermines or covers structures built along the shore. Consequently, special consideration and study of sediment control as well as wave control is required when designing and constructing coastal works.

Salt-nater intrusions into fresh-water bays and river estuaries frequently cause difficulty if this water is being used for industrial. agricultural or domestic consumption. Special procedures have been devised for control of the inflow of salt water.

Tides result in a fluctuation of water-surface elevation along a coast varying from a few inches to many feet, the highest tides reaching approximately 60 ft. in the Bay of Fundy in Canada and in the estuary of the Severn river in Great Britain. Although much discussion has taken place regarding the harnessing of the energy in tides, only a few small plants have been built and only in northern France has large-scale hydroelectric power been developed from this source.

MODELS

In hydraulic engineering great use is made of model systems by the operation of which the characteristics of similar but larger hydraulic systems can be predicted. There are three types of similarity — geometric, kinematic and dynamic. If two objects are geometrically similar their shape is similar, although they may not be the same size. Kinematic similarity requires that the pattern of flows about or through the object be the same in the model and in the prototype. Dynamic similarity requires that the ratio of forces acting at any point in the model be the same as the ratio of forces acting at the corresponding point in the prototype. For most hydraulic model studies these forces are associated with the Froude number, relating to gravitational forces, the Reynolds number, viscous forces; and the Weber number, surface energy forces. (See DIMENSIONAL ANALYSIS.) Each of these forces in the dimensionless number is related to the force of inertia. (For a discussion of similarity, see MECHANICS, FLUID.)

Models are built: (1) to study the general appearance and the relative proportions of the various features as they will be in the prototype structure; (2) to study the flow pattern (magnitude and direction of velocity and acceleration) over, through or around the object; (3) to study the pressure distribution and resulting forces on the object or its parts; (4) to determine flow capacities and calibrate the various flow passages; (5) to determine hydraulic efficiencies of hydraulic machinery; (6) to determine mechanical-energy loss due to shear drag and pressure drag; (7) to determine whether the prototype will operate as intended; (8) to determine ways of improving the design of the prototype so that it will operate more effectively; (9) to find ways of changing the design to reduce the eventual cost of the prototype.

The chief advantages of a model are that, by its use, the purposes and objectives of a hydraulic project can be attained more economically, quickly, simply, conveniently and completely.

The principal disadvantage of a model is the fact that complete similarity in the model is sometimes difficult or impossible to obtain. Consequently, in some cases only partial or approximate answers can be obtained by means of a model.

Models have been used for most of the hydraulic structures and systems discussed in this article. They are also commonly used to study naval vessels, aircraft and various types of hydroelectric machinery, as well as pipes, rivers, harbours and hydraulic structures such as dams, spillways and stilling basins.

HYDRAULIC TURBINE: see TURBINE: WATER.

HYDRAZINE is a colourless liquid which solidifies at 1.8° to 2.0° C. and boils at 114.5° C. Having the chemical formula of N_2H_4, it belongs to a group of hydrogen-nitrogen compounds known as the hydronitrogens and was first prepared by T. Curtius (1887).

Hydrazine is a powerful reducing agent and is used in the silvering of mirrors and the formation of metal films on glass and plastics. It is used as a corrosion inhibitor to remove dissolved oxygen from boiler waters. A mixture of hydrazine, water and methyl alcohol was used by the Germans in World War II as a rocket- and jet-propulsion fuel.

Anhydrous hydrazine is miscible in all proportions with water, methyl and ethyl alcohols. It forms a high boiling azeotrope with water containing 68.5% N_2H_4 and boiling at 120.5° C. (771 mm. pressure). Care must be taken in the storage of anhydrous hydrazine and its aqueous solutions, since these absorb moisture and carbon dioxide and react chemically with oxygen of the atmosphere. Hydrazine solutions and vapour are toxic. Hydrazine vapour mixed with air is inflammable. Aqueous solutions of hydrazine are more weakly basic than ammonia.

Preparation. — It may be obtained by the reduction of nitrosoamines, nitramines and the nitrosohydroxylamine sulfonates and by the thermal, photochemical or electrical decomposition of ammonia. It is produced technically from aqueous ammonia (or urea) by oxidation with hypochlorite in the presence of gelatin or glue (Raschig process). This process is operated at temperatures between 160° and 180" C. under pressure to yield continuously a dilute reaction liquor containing about 2% N_2H_4.

Concentration is effected by fractional distillation to give a product marketed as 85% or 100% hydrazine hydrate. $N_2H_4.H_2O$. Further concentration to anhydrous hydrazine must be accomplished by dehydration with barium oxide or caustic soda. The anhydrous material is also obtained by treating hydrazine sulfate with liquid ammonia (A. W. Browne).

Salts.—Hydrazine forms two series of salts, $N_2H_4.HX$ and $N_2H_4.2HX$, where HX represents a monobasic acid. Best-known salts are the sparingly soluble sulfate, $N_2H_4.H_2SO_4$, the mono- and dihydrochlorides, $N_2H_4.HCl$ and $N_2H_4.2HCl$ and the mononitrate, $N_2H_4.HNO_3$. The mononitrate has found application as a high explosive and as an ingredient of high-explosive compositions. The bromide $N_2H_4.HBr$ is used as a soldering flux. Double salts such as the chlorides, $N_2H_4.HCl.MCl_2$, and the sulfates, $(N_2H_4)_2.H_2SO_4.MSO_4$ are also known. The copper compound, $(N_2H_4)_2.H_2SO_4.CuSO_4$ has interesting algaecidal and fungicidal properties and has found application as an agricultural fungistatic material. Compounds containing co-ordinated hydrazine. *i.e.*, hydrazinates, have been prepared, for example, $ZnCl_2.2N_2H_4$ and $Co(N_2H_4)_3SO_4$.

Organic **Hydrazines.**—Derivatives of hydrazine have been prepared in which one, two, three and even four of the hydrogen atoms are replaced by alkyl, cycloaliphatic and/or aryl radicals. The simple alkyl hydrazines such as methylhydrazine, $CH_3N_2H_3$ and dimethylhydrazine $(CH_3)_2N_2H_2$ are prepared from the amines and chloramine by a modification of the Raschig process. Phenylhydrazine. $C_6H_5N_2H_3$, was discovered by E. Fischer in 1877 and was employed by him in his classical researches on sugar; it is used along with other organic derivatives of hydrazine to

detect organic substances containing carbonyl groups (see ALDEHYDES AND KETONES; CARBOHYDRATES) since it condenses with these to form hydrazones and azines with the elimination of water.

Acid hydrazides, $RCON_2H_3$, are obtainable by the action of hydrazine on acid chlorides or esters. Best known are the hydrazine derivatives of carbonic acid such as semicarbazide. $CO(NH_2)(N_2H_3)$, carbohydrazide, $CO(N_2H_3)_2$, bi-urea, $(-NHCONH_2)_2$, and aminoguanidine, $C(NH)(NH_2)(N_2H_3)$. The latter substance is obtained in the form of its salts by condensation of cyanamide with hydrazine.

Organic derivatives of hydrazine find application in analytical chemistry (dithizone), as biologically active substances (isonicotinic acid hydrazide in the treatment of tuberculosis) and as chemical intermediates, for example, in the production of specialty fuels, plastics and resinous substances, photographic chemicals and as blowing agents for the manufacture of foam rubber.

For additional information on the hydronitrogens see NITROGEN and AMMONIA.

BIBLIOGRAPHY.—H. Wieland, *Die Hydrazine* (1913); *L.* **F.** Audrieth and B. *A.* Ogg, *The Chemistry of Hydrazine* **(1951)**; *C.* **C.** Clark, *Hydrazine* (1953). (L. *F.* A.)

HYDRAZOIC ACID, sometimes called azoimide, is a compound of hydrogen and nitrogen. It is a colourless liquid, boiling at 37° C., and is sensitive to shock, exploding violently but with a limited radius of action. The acid has a characteristic odour, said to resemble that of a damp cellar, and the vapour causes headache and attacks the mucous membrane. Its salts, which are called azides, and its organic derivatives are also explosive but to a lesser extent. The acid (HN_3) and its derivatives present many points of theoretical interest, but the only derivative of commercial importance is lead azide. This is used as an initiating explosive in detonators and percussion caps and is in some ways superior to mercuric fulminate, especially in being less sensitive to moisture.

Organic derivatives of hydrazoic acid were the first to be known and resulted from the discovery of the aromatic diazo compounds by P. Griess. He found in 1866 that the perhalides of these are converted into azides by ammonia.

$$C_6H_5.N_2.Br_3 + NH_3 \rightarrow C_6H_5N_3 + 3HBr$$

The acid itself was first prepared by T. Curtius in 1890 by the alkaline hydrolysis of benzyl azide; he found that after acidification the acid could be separated by distilling in steam. The first preparation from inorganic materials was by J. Wislicenus in 1892; he used a reaction which remained at mid-20th century still the most important for obtaining the free acid and its salts, the action of nitrous oxide on sodamide at about zoo° C.

$$NaNH_2 + N_2O \rightarrow NaN_3 + 3H_2O$$

A number of other methods are known, mostly using hydrazine as starting material. This reacts with nitrous acid to give hydrazoic acid, but there are many side reactions so that a useful yield is obtained only under carefully regulated conditions. The anhydrous acid can be prepared from its aqueous solution, which is less explosive than the pure acid, by repeated fractional distillation, but the best method is to warm the pure sodium salt with stearic acid, condense the acid at −40° C., and distill it under reduced pressure between −50° and −80° C.

The chemical behaviour can be roughly summarized by saying that the radical N_3 behaves like a halogen, so that the salts resemble the chlorides and the free acid hydrogen chloride. In aqueous solution, however, it is only a weak acid and of approximately the same strength as acetic acid.

Structure.— The constitution of the azide group N_3 which is covalently linked to hydrogen in the acid and to carbon in the organic derivatives, and which exists as an anion in the salts, nas a matter of controversy for many years. The first formula proposed (I) was that of Emil Fischer in 1878 and this was accepted until J. Thiele and A. Angeli pointed out in 1911 that the straight chain formula (II) could be held to give a better explanation of certain reactions.

(I)  (II) $-N=N\equiv N$

A decision was impossible at that time. The demonstration that the cyclic formula (I) is incorrect could only be reached when methods became available whereby the actual positions of the atoms in a molecule could be determined. This was first done for the azide ion in sodium and potassium azides by S. B. Hendricks and L. Pauling in 1925, and the result was confirmed later by the Raman spectrum of the ion in solution. The three nitrogen atoms lie in a straight line and the ion is symmetrical about the central atom. The ion must be written $N\leftarrow\overline{N}\rightarrow N$, or with dots representing valency electrons as  . It resembles in structure the cyanate ion, $\overline{N}=C=O$ or  and the structure of the potassium cyanate crystal is almost identical with that of potassium azide.

For the covalently linked azide group a straight chain structure is established beyond doubt by the electron diffraction of methyl azide studied by L. O. Brockway and Pauling in 1933 and by the X-ray analysis of crystalline cyanuric azide carried out independently by Miss I. E. Knaggs and E. W. Hughes in 1935. The group is not. however, symmetrical about the central atom as in the ion; the molecule can be represented as below, the figures showing the distances in angstrom units:

$$H_3C\ 1.47\ N\ 1.24\ N\ 1.10\ N$$

Such a structure cannot be represented by a single formula based on the older views of valency. The original Thiele-Angeli formula (II above) must be rejected because it involves pentacovalent nitrogen, a state not known in any other compound of the element. The alternatives are $R-N=N\leftarrow N$ and $R-N\leftarrow N\equiv N$, which can be written

 and 

these must be excluded as they stand because they imply much higher molecular electric moments than those observed and because the bond lengths do not fit the experimental results. The structure must be taken to be a resonance hybrid (see RESONANCE. THEORY OF) of these two straight chain formulas, a view which is supported by the known heats of formation of phenyl azide and of ethyl azido-acetate. Such a conclusion can be reached only when the existence of resonance is realized and it is thus easy to see why in the earlier part of the century the controversy could not be settled. The azide group is one of the few where, using conventional formulas, no one formula can be written even as an approximation.

Derivatives.— The organic derivatives of hydrazoic acid can be divided into two classes, the alkyl and aryl azides in which the group is attached to a hydrocarbon radical. and the acyl azides which contain the group $-CO.N_3$. Apart from reactions which involve its breakdown, the behaviour of the azide group in all these recalls that of a halogen atom, a further justification for its description as a pseudohalogen. Thus methyl azide, a liquid boiling at 20° C. and somewhat less explosive than the acid, is hydrolyzed by alkalies to methyl alcohol and the alkali azide. while phenyl azide resists such hydrolysis. The aryl azides, which are considerably more stable, show a variety of addition reactions with compounds containing a reactive methylene group and with ethylenic and acetylenic unsaturated compounds. These have been much studied and lead to derivatives of 1,2,3-triazoline.

The acyl azides are derivatives of carboxylic acids and are best obtained by the action of the acid chloride on sodium azide. They resemble acid chlorides in many ways and, though the majority are reasonably stable, certain of them are among the most explosive compounds known; for example the diazide of carbonic acid detonates if gently rubbed with a glass rod. The important reaction of the acyl azides is the Curtius rearrangement which occurs when they decompose in solution. Nitrogen is lost and the resulting radical rearranges to an isocyanate by an intramolecular process (see MOLECULAR REARRANGEMENTS).

$$R.CO.N_3 \rightarrow N_2 + R.CO.N. \longrightarrow R.NCO$$

Since the isocyanate can be hydrolyzed to a primary amine, the reaction is useful for effecting the change $R.COOH \longrightarrow R.NH_2$.

(T. W. J. T.)

HYDRIDES. Chemical compounds in which one or more hydrogen atoms are attached to a metal or metalloid (metallike) atom are called hydrides. Compounds of this class have interesting applications because of their high hydrogen content; some are useful as rocket fuels and as hydrogen sources for filling balloons and others are of prime importance in nuclear fusion processes. The term hydride is also applicable to metallic phases whose composition may vary within narrow limits; *e.g.*, palladium hydride which has the approximate composition Pd_2H. It is used loosely to include solid solutions of hydrogen in metals and all compounds of hydrogen with single elements, including ammonia, NH_3, and even water, H_2O.

All metals are capable of dissolving small amounts of hydrogen, particularly at high temperatures or on melting. Those metals which form true hydrides are likewise capable of dissolving small amounts of hydrogen prior to hydride formation. These solutions of hydrogen in metal are quite different from hydrides and this term is not properly used to describe them.

It is well known that the hydrogen penetration of many metals causes a weakening or embrittling referred to as hydrogen embrittlement. Hydrogen diffuses with great rapidity through several heated metals such as palladium, iron and nickel; it reacts with palladium and about 40 metals to form compounds most of which are brittle. These compounds dissociate on stronger heating, giving back the metal and hydrogen gas. The volume of hydrogen which is taken up by some metals is quite remarkable. Thus titanium hydride, TiH_2, is a metallic-appearing compound which contains 1,620 times its volume of hydrogen. This hydrogen is released by heating to red heat or by reaction with strong acids. The hydrogen atoms in titanium hydride are more tightly packed together than in solidified pure hydrogen at its freezing point.

Hydrides of many of the metals capable of dissolving hydrogen in small amounts are known to exist even though they cannot be formed by reaction of the metal with hydrogen. Such hydrides must be made by indirect syntheses and decompose on heating.

Four types of hydrides have been recognized under a classification based on the type of chemical bond involved.

1. Saline or saltlike: hydrides in which hydrogen is present as an anion H^- similar in size to the fluoride ion F^-. In these compounds hydrogen displays its family resemblance to the halogens: fluorine, chlorine, etc. Saline hydrides are physically similar to corresponding fluorides except that they react vigorously with water giving off large volumes of hydrogen. This property renders them useful as light, portable sources of hydrogen. Examples of primary saline hydrides are sodium hydride, NaH, and calcium hydride, CaH_2. Examples of complex saline hydrides are lithium aluminum hydride, $LiAlH_4$, and sodium borohydride, $NaBH_4$, both of which are chemicals of commerce used as reducing agents.

2. Metallic (formerly termed interstitial): alloylike hydrides which possess some of the characteristics of metals such as lustre and strong electrical conductivity. They tend, however, to be more brittle and sometimes harder than the metals from which they are made. These compounds are regarded as intermediate in nature between salts and alloys. The hydrogen is probably closely associated with two electrons and therefore resembles the anionic form found in saline hydrides. The metal may be regarded as a cation of maximum charge which has given one of its electrons to hydrogen and shares one or more electrons with other metal ions such that the assemblage is immersed in a "sea" of such electrons. Metallic hydrides have also been regarded as made up of protons (positive hydrogen ions H^+), and metal atoms in an electron sea. The lustre and electrical conductivity are attributed to the relative freedom of electron movement in the hydride. Examples are titanium hydride, TiH_2; lanthanum dihydride, LaH_2; thorium dihydride, ThH_2, and a higher hydride, Th_4H_{15}; and uranium hydride, UH_3. Metallic hydrides are generally not reactive toward water unless the finely divided metals themselves are reactive. Thus palladium hydride does not react appreciably with water whereas uranium hydride does.

3. Dimeric or polymeric: hydrides in which hydrogen is presumed to have formed a connecting bridge between metal or metalloid atoms. Classical examples are furnished by the numerous hydrides of boron; *e.g.*, diborane, $H_2BH_2BH_2$ (whose formula is so written to indicate the two bridging hydrogen atoms); penta-

borane, B_5H_9; decaborane, $B_{10}H_{14}$; etc. Such hydrides burn with evolution of considerably more energy than provided by carbonsceous fuels and are of interest as high-energy fuels for rockets. Alurninum and possibly copper and beryllium hydrides belong in the polymeric category. All of these hydrides are nonconductors and may be solid, liquid or gaseous. All are thermally unstable and some explode on contact with air or moisture.

4. Covalent-volatile: hydrides in which the bonds are evidently normal covalent bonds without strong residual affinities. Examples are: silane, SiH_4; arsine, AsH_3; germane, GeH_4; aluminum borohydride, $Al(BH_4)_3$; and digermane, Ge_2H_6. These hydrides are volatile, thermally unstable and usually possess a strong odour. Some are exceptionally toxic, *e.g.*, AsH_3, and others may ignite on contact with air or moisture, *e.g.*, $Al(BH_4)_3$.

The above classification is not rigid and in some cases the distinctions made are a matter of degree, *e.g.*, $LiBH_4$ and $Al(BH_4)_3$, rather than of intrinsic differences. Many families of compounds, such as chlorides, for example, may be similarly differentiated. The reason for the existence of the four categories may be interpreted on the basis of three properties of the metal atom: ionization potential (a measure of the ease with which the atom may lose an electron), number of bonding electrons and number of unfilled energy levels. Two other factors are also involved: the cohesive energy (a measure of the cohesiveness of a metal) and the radius of the metal atom and ion.

Hydrides may also be classed as primary or binary, *i.e.*, one metal and hydrogen such as BaH_2, or as secondary, double or complex, *i.e.*, containing more than one metal or metalloid and hydrogen, such as $NaBH_4$. The term double hydride is best applied to compounds or solid solutions of hydrides in each other such as $ZrNiH_3$ or $CaH_2.xBaH_2$ where the hydrogen is not necessarily associated with only one of the metal atoms. Various atoms or groups may be substituted in part for hydrogen giving substituted hydrides such as dimethyl aluminum hydride, $(CH_3)_2AlH$; dichloroaluminum hydride, Cl_2AlH; sodium trimethoxyborohydride, $NaB(OCH_3)_3H$; etc.

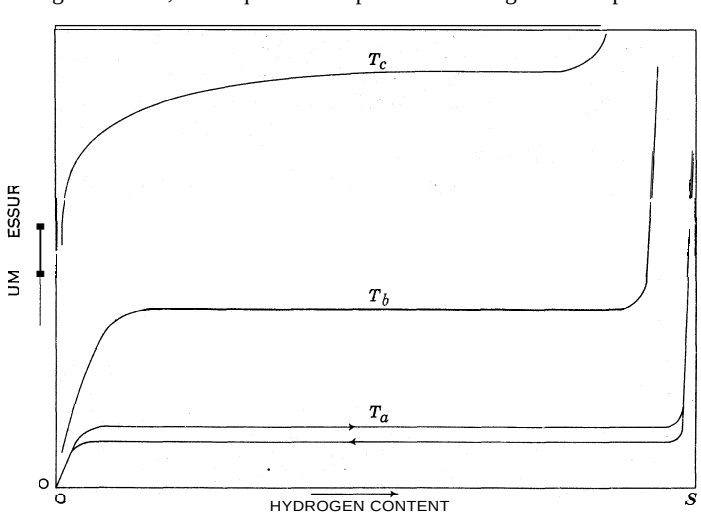
Hydrides.—Lithium borohydride reacts vigorously with water, yielding approximately 4 l. of hydrogen per gram of borohydride. (Half of this hydrogen comes from the water.) Advantage has been taken of this property of several hydrides in the design of portable hydrogen generators for military purposes or use in remote areas. All of the hydrides are reducing agents and several find widespread use for this reason. Thermal dissociation to the metal and hydrogen may be utilized, in the case of volatile hydrides, as a means of depositing metal films or preparing pure metals for use in transistors, etc.

Properties of a number of hydrides are summarized in Table I and Table II which have been compiled from many sources. The heats of formation (col. 6) are rounded off and for the most part are for compositions less than stoichiometric (whole-number ratio of atoms). Where these compositions are known they are indicated in parentheses. Note that in Table I heats of formation are given per molecule of hydrogen contained and in Table II per molecule of compound.

In most cases solid binary hydrides decompose before melting. An exception is lithium hydride which may be melted under hydrogen at 688° C. with a small change in dissociation pressure and electrical conductivity but a large increase in volume. The solid secondary hydrides usually melt at or slightly above the decomposition temperature; *e.g.*, $LiAlH_4$ about 150° C., $LiBH_4$ about 280° C. Some, such as $Be(BH_4)_2$ and $Al(BH_4)_3$, show less ionic and more covalent character and melt well below the temperature of rapid decomposition. The covalent hydrides show normal melting points for the most part. Metallic hydrides are all decomposed before melting, although at the melting point of the metal considerable hydrogen may be reabsorbed.

Saline binary hydrides are insoluble in conventional solvents, including liquid ammonia. They dissolve in fused halides, carbides and, in the case of the alkali hydrides (not LiH), in fused hydroxides. These hydridei are somewhat denser than the parent metals. The metallic hydrides, which are less dense than the parent metals, show typical metallic solubilities, the solvent metal either increasing or decreasing the hydrogen content. Metallic hydrides are wet by mercury and may disperse therein (F. H. Spedding, 1944; A. R. Ubbelohde, 1950). No general rules are formulated concerning solubility of other classes of hydrides.

Dissociation **of Hydrides.**—The thermal dissociation of binary saline and metallic hydrides is generally reversible, whereas polymeric, covalent and secondary hydrides usually decompose irreversibly on heating. Reversible dissociation implies a pressure- and temperature-dependent equilibrium between hydrogen and the solid phases (figure) whereas irreversible dissociation implies only a more or less characteristic decomposition temperature where evolution of hydrogen first becomes noticeable (Tables I and II). In the case of reversible dissociation, the relation of temperature, pressure and hydrogen content has been found somewhat complicated by the fact that at certain magnitudes of these three variables a phenomenon known as hysteresis occurs. This is illustrated by isotherm T_a in the figure where the arrows indicate direction of changing hydrogen content. Thus when hydrogen is being absorbed, the equilibrium pressure at a given temperature



RELATION BETWEEN EQUILIBRIUM PRESSURE AND HYDROGEN CONTENT AT VARIOUS TEMPERATURES

The isotherms are in order of increasing temperature T_a, T_b, T_c. The hydrogen content ranges from zero to S where S is the limiting hydrogen content, usually an integer. Note that horizontal portions (plateaus) become shorter as the temperature increases. They disappear at some higher temperature called the critical temperature (not shown)

may be higher than when the hydrogen is being desorbed during the measurement.

The reversible dissociation of hydrides is found to follow, over short temperature intervals, the relation: $\log P = -A/T + b$ where P is dissociation pressure, T absolute temperature and A and b are constants. A more general relation (C. E. Messer, 1953) is: $\log P = \log P_1 + 2\log\left(\frac{n}{c-n}\right) + W/T\left(\frac{2n}{S} - 1\right)$ where P_1 and W are constants, n is the hydrogen-to-metal ratio and S is a parameter which varies slightly with T. It mill be observed in curves T_a, T_b and T_c of the figure that over certain regions of composition the equilibrium pressure is independent of composition. Values of dissociation pressures in such plateau regions are more meaningful than in those regions near the limiting composition where the pressure changes rapidly with composition. A similar interpretation of the curves shown based on hydrogen-hydrogen-lattice site interaction rather than on phases has been suggested (R. M. Barrer, 1948; J. R. Lacher, 1937; A. Harasima et *al.*, 1947; G. Libowitz, 1957).

The dissociation pressure of saline deuterides is usually greater than that of corresponding hydrides at a given temperature (E. F. Sollers and J. L. Crenshaw, 1937).

Reactions and Uses.—In general the chemical behaviour of the saline primary hydrides is similar to that of the metal element. These hydrides all burn vigorously in air and react rapidly with water and less rapidly with alcohols, according to the equation: $MH + HOH \longrightarrow MOH + H_2$ or $MH_2 + 2H_2O \longrightarrow M(OH)_2 + 2H_2$

The hydrogen so evolved is not in as active a condition as that evolved by the parent metals (*e.g.*, sodium) with water, and primary saline hydrides are correspondingly less active reducing agents than the metals. At elevated temperatures where dissociation occurs, the binary saline hydrides show reducing properties. Potassium hydride reduces carbon dioxide to potassium formate at 225° C. (H. Moissan, 1902). Calcium hydride reduces refractory oxides to metals (titanium, zirconium, uranium, etc.) at about 600° C. (F. M. Perkin, 1907; P. P. Alexander, 1936) where it is slightly dissociated, and reduces sulfates to sulfides (W. E. Caldwell and F. C. Krauskopf, 1930). Sodium hydride is a condensing agent for Claisen and related condensations (V. L. Hansley, 1940). It has been used as a hydrogenation catalyst (A. M. Muckenfuss, 1935).

Sodium, calcium and lithium hydrides have been used for generation of hydrogen by reaction with water. Sodium hydride in molten sodium hydroxide has been used for removing oxide scale from iron and steel.

In general the saline secondary hydrides are powerful reducing agents. Lithium aluminum hydride (discovered by H. I. Schlesinger and A. E. Finholt, 1947) has been widely used for the reduction to alcohols of such compounds as organic acids, esters, anhydrides, amides, nitriles, aldehydes, ketones, etc. (W. G. Brown and R. F. Nystrom, 1947). Examples of such reactions are the following:

$$NaH + CH_2(COOC_2H_5)_2 \rightarrow H_2 + NaCH(COOC_2H_5)_2$$

$$NaBH_4 + 4(CH_3)_2CO \rightarrow [(CH_3)_2CHO]_4NaB \xrightarrow{2H_2O} 4(CH_3)_2CHOH + NaBO_2$$

$$2LiAlH_4 + CH_3CH_2COOCH_3 \rightarrow (CH_3CH_2CH_2O)_4LiAl +$$

$$(CH_3O)_4LiAl \xrightarrow[HCl]{aq.} LiCl + AlCl_3 + 4CH_3CH_2CH_2OH + 4CH_3OH$$

$$LiAlH_4 + 2CH_3CN \rightarrow (CH_3CH_2N)_2LiAl \xrightarrow[HCl]{aq.} 2CH_3CH_2NH_2 + LiCl + AlCl_3$$

$$LiAlH_4 + 4CH_2{=}CH - CH_2I \longrightarrow 4CH_2{=}CH - CH_3 + [LiAlI_4]$$

The solubility of lithium aluminum hydride in ethers or ether-benzene mixtures greatly increases its utility. Compounds such as quinones, Schiff bases, disulfides, acetylenes, aromatic condensed ring systems, nitrocompounds, alkyl halides, alkylhalosilanes, epoxides, sulfonic acids, sulfonylhalides, pyridine derivatives, etc., have been reduced. Carbon to carbon double bonds are unaffected unless conjugated with a carbonyl and phenyl group. Lithium borohydride is a similar but less powerful and versatile reducing agent. It is, however, soluble both in ethers and in primary amines which latter react with lithium aluminum hydride. Sodium borohydride (Schlesinger and H. C. Brown, 1945) has been used in aqueous solution for the reduction of aldehydes and ketones to alcohols (S. W. Chaikin and W. G. Brown, 1949). Sodium trimethoxyborohydride has also been used for the latter reductions (I. Sheft, 1944) and lithium tri-t-butoxyaluminum hydride for reduction of acid chlorides to aldehydes (H. C. Brown, 1956). Sodium borohydride in aqueous solution reduces many metal ions to free metals or borides. The reaction of this hydride with water is catalyzed by nickel or cobalt salts (presumably via the colloidal metals or borides) and by boric acid (H. R. Hoekstra, 1945). The latter combination has been used for hydrogen generation. Lithium borohydride reacts vigorously with water, often inflaming. If the reaction is adiabatic, nearly 14 l. of steam and hydrogen at 100° C. may be produced by 1 g. of the hydride.

Diborane and other dimeric and polymeric hydrides are, for the most part, active reducing agents. Diborane is exceptionally reactive and frequently yields substitution as well as reduction products. Aluminum hydride when freshly prepared acts in the same general fashion as lithium aluminum hydride. Both diborane and aluminum hydride have been decomposed thermally to produce coatings of boron and aluminum on heated objects. Aluminum has been electrodeposited from an ethereal solution of aluminum chloride containing aluminum hydride (D. E. Couch, 1951; A. Brenner, 1956).

The metallic hydrides react, in general, as expected from the independent properties of their components. The hydrogen obtained via aqueous attack is reactive at least in part and will effect reductions comparable to those obtained by dissolving metals in dilute acids. The hydrogen obtained by thermal dissociation is highly active as in the case of the saline hydrides. Several of the metallic hydrides are hydrogenation catalysts; *e.g.*, TiH_2, Pd_2H, ZrH_2. Metallic hydrides find uses in powder metallurgy and for the preparation of metal sponge.

Most of the covalent hydrides are relatively mild reducing agents. The instability of many members of this class makes their study difficult. Bismuth, lead and tin have been deposited in specular form by decomposition of the hydrides at or above room temperature (F. Paneth, 1925). Germanium hydrides have been studied in greater detail (C. A. Kraus, 1949).

Preparation. — The most general method for preparing binary hydrides was first described in 1811 (J. L. Gay-Lussac, L. J. Thénard). It consists of heating a metal in pure hydrogen until absorption occurs, then cooling slowly. All of the binary saline and metallic hydrides may be prepared in this way, although agitation of the reaction mixture is required in the case of sodium and potassium hydrides and hydrogen at high pressure is required for magnesium hydride. Beryllium hydride has not been prepared by this method. Nearly all of the binary hydrides may be made by the action of atomic hydrogen, generated in a glow discharge, upon the metals or metal alkyls, etc. (Paneth, 1922; Schlesinger, 1931; E. Pietsch, 1933). This method is claimed to yield hydrides of tin, lead, bismuth, polonium, gallium. beryllium, thorium, silver, gold, thallium, tantalum, copper and boron.

Reduction of metal oxides or halides at high temperature by calcium, calcium hydride, magnesium or aluminum in the presence of hydrogen has been used to prepare many hydrides; *e.g.*, LiH, CaH_2, ZrH_2, TiH_2 (Alexander, 1936). This method may be employed even for thermolabile volatile hydrides, *e.g.*, B_2H_6, if these are removed rapidly from the reaction zone by a stream of hydrogen (D. T. Hurd, 1949).

Hydrogen evolved at the cathode during electrolysis of aqueous solutions is also active and has been reported to combine with many cathode metals. This method is useful for the preparation of most metallic hydrides but is obviously unsuited to the preparation of water-reactive types. Many metals which do not form true hydrides may be supersaturated with hydrogen when used as cathode metals, mechanical disintegration sometimes occurring as a result. The plating of metals at potentials where hydrogen is also discharged usually leads to absorption of hydrogen. Thus freshly

deposited chromium contains many times its own volume of hydrogen.

Hydrolysis of borides, silicides, germanides by water, aqueous acids or nonaqueous acids, *e.g.,* ammonium bromide (liquid ammonia), has been used for the preparation of boranes, silanes and germanes (F. Jones, 1878; A. Stock, 1917; Hurd, 1947). Copper hydride has been made by reduction of aqueous copper sulfate solutions with hypophosphite (A. Wurtz, 1844).

One of the most elegant and versatile methods of preparing hydrides involves the use of alkali metal hydrides as starting reagents (Schlesinger, Finholt and H. C. Brown, 1946). Lithium aluminum hydride is prepared by reacting finely powdered lithium hydride with aluminum chloride in ethereal solution. Sodium borohydride is prepared without a solvent by reacting sodium hydride with methyl borate at 260° C. An excess of methyl borate yields sodium trimethoxyborohydride. In each case the product is leached away from the insoluble by-product:

$$4LiH + AlCl_3 \rightarrow 3LiCl + LiAlH_4$$
($NaAlH_4$, $LiGaH_4$, B_2H_6 similarly)

$$4NaH + B(OCH_3)_3 \rightarrow 3NaOCH_3 + NaBH_4$$

From these two hydrides many others may be prepared by metathetical reactions; *e.g.:*

$$NaBH_4 + LiCl \xrightarrow{\text{amine}} NaCl + LiBH_4$$

$$3NaBH_4 + AlCl_3 \xrightarrow{\text{heat}} 3NaCl + Al(BH_4)_3$$

$$NaBH_4 + 4BF_3 \xrightarrow{\text{ether}} 3NaBF_4 + 2B_2H_6$$

$$NaBH_4 + SnCl_4 \xrightarrow{\text{aq.}} [NaBCl_4] + SnH_4$$

$$LiBH_4 + (CH_3)_4NF \xrightarrow{\text{water}} LiF + (CH_3)_4NBH_4$$

$$LiAlH_4 + MX_n \xrightarrow{\text{ether}} LiAlX_4 + MH_n$$
(B_2H_6, AlH_3, SiH_4, GeH_4, SnH_4, AsH_3, SbH_3, etc., similarly)

$$LiAlH_4 + MR_n \rightarrow LiAlH_3R + MH_n$$
(BeH_2, MgH_2, ZnH_2, CdH_2, HgH_2 similarly)

The latter two equations are schematic, X represents halogen, R represents an alkyl group (*e.g.,* methyl) and M is a metal or metalloid atom. Borohydrides of titanium, thorium, etc., have been prepared from the halides and aluminum borohydride (Hoekstra and J. J. Katz, 1948). Aluminohydrides and galliohydrides have been prepared by reacting alkali metal hydrides with the respective alkyls, and several borohydrides may be prepared directly from diborane, *e.g.:*

$$NaH + B(C_2H_5)_3 \rightarrow NaBH(C_2H_5)_3$$

$$ZnH_2 + B_2H_6 \rightarrow Zn(BH_4)_2$$

$$2Ga(CH_3)_3 + 3B_2H_6 \xrightarrow{-45°} 2(CH_3)_2GaBH_4 + 2B_2H_5CH_3$$

The preparation and structure of many substituted boron hydrides, especially amino derivatives, have been studied (A. B. Burg, 1950), including such compounds as $Na_2HB(CH_3)_2$, $[(CH_3)_2PBH_2]_3$, $(CH_3)_3PBH_3$, etc. Borazole, $B_3N_3H_6$, is the parent substance of a number of related compounds (Schlesinger, 1950). See also ADSORPTION; BORON; HYDROGEN; SILICON.

HYDROCARBON, in chemistry, a compound of carbon and hydrogen. Many occur in nature. Petroleum is mainly composed of such compounds; they are present also in the volatile essential oils of plants and in some plant pigments. Familiar examples of the artificial production of hydrocarbons are: (1) the distillation of coal, which yields town gas and coal tar (*q.v.*), both largely composed of hydrocarbons; (2) the hydrogenation of coal under pressure; (3) the formation of petroleum spirit by high temperature and catalytic "cracking" of high-boiling petroleum distillates; and (4) the formation of acetylene by the action of water on calcium carbide. Acetylene is used, not only for welding, but also as an important raw material for the manufacture of solvents, plastics and artificial rubber. For details reference should be made to the articles wherein the above subjects are treated. From the chemical standpoint the hydrocarbons are of fundamental importance because of their variety of types and their great number, and still greater number of derivatives. *See* CHEMISTRY: *Organic;* CARCINOGENIC CHEMICALS. (J. W. CK.)

HYDROCELE, the medical term for any collection of fluid other than pus or blood in the neighbourhood of the testis or cord. The fluid is usually serous. Hydrocele may be congenital or arise in the middle-aged without apparent cause. The hydrocele appears as a rounded, fluctuating translucent swelling in the scrotum, and when greatly distended causes a dragging pain. It may be treated and cured by surgical procedures.

HYDROCEPHALUS is a condition, either developmental or acquired, in which there is an abnormal accumulation of the body fluids within the skull. The congenital form is often associated with other developmental anomalies of the spine and spinal cord. The acquired variety usually results from some inflammatory disease such as meningitis, but may occur also as a result of tumours and other obstructions. The immediate cause of hydrocephalus is some interference with the circulation of the fluids in and around the brain. Two varieties are often mentioned, internal and external. In the former the ventricles of the brain become more or less distended with cerebrospinal fluid, which compresses the brain and interferes with its function. In the latter fluid accumulates in the arachnoid spaces on the outer aspect of the brain; this also compresses the brain.

The two varieties are frequently combined. In most instances the condition is progressive, associated with enlargement of the head and separation of the sutures and fontanels of the skull; mental retardation also results. The shape of the face and head, sometimes referred to as Marshall Hall's facies. is characteristic.

When a fetus is afflicted with this disorder, the size of the head may cause serious complications of labour. The condition, however, can be recognized during the prenatal period by X-rays and other diagnostic means, and the situation handled satisfactorily so far as the mother is concerned.

No medical or radiologic treatment is of benefit. except in those cases in which the condition results from a radiosensitive tumour. Various methods of surgical treatment have been tried, with a certain amount of success. (F. L. A.; X.)

ELODEA DENSA: (A) STEM WITH WHORLS OF LANCEOLATE LEAVES, SHOWING THEIR MINUTELY SERRATE MARGINS, REDUCED TO $\frac{3}{5}$ NATURAL SIZE; (B) SPATHE AND THE FLOWERS, $\times\frac{3}{4}$; (C) HABIT, SHOWING LONG-PEDUNCLED STAMINATE FLOWERS. $\times\frac{1}{4}$; (D) STAMINATE FLOWER, NATURAL SIZE

HYDROCHARITACEAE, a family of chiefly aquatic plants belonging to the order Hydrales

(Butomales) and including such commonly cultivated aquarium plants as the water weed or water thyme (Elodea), eelgrass (*Vallisneria*), frogbit (*Hydrocharis* and *Limnobium*) and water soldier (Stmtioides). The plants are rooted in mud, sometimes becoming free-floating. The leaves are diverse; they are either basal and wholly submersed or with blades emersed, or bladeless and borne in whorls along the stem and wholly submerged.

The flowers are enclosed in a spathelike structure in the leaf axils. regular. usually unisexual with the sexes on different plants, rarely in the same flower. The male flowers number one to several in a spathe, the female ones are usually solitary. The perianth is in two or one series, the outer series three. rarely two. green, not overlapping, the inner three, two or none, overlapping in bud and petallike, often borne on an elongate tubelike extension of the receptacle (hypanthium). The number of stamens may range from three to many. The ovary is inferior (below the perianth and stamens) and is one-celled with several seeds on the ovary wall. The fruit is leathery.

This is a family of plants of diverse habit held together by the inferior ovary, spathelike involucre and elongate tubelike receptacle and parietal placentation.

HYDROCHLORIC ACID AND HYDROGEN CHLORIDE. Hydrogen chloride. a compound containing the elements hydrogen and chlorine, is a gas under ordinary conditions. The name hydrochloric acid was formerly applied to both the gas and its solution in water, but later practice favours the restriction of the term hydrochloric acid to the aqueous solution.

Hydrogen chloride and hydrochloric acid, like coal tar, were considered troublesome waste products before they became industrially important. In the 19th century manufacturers of soda ash, under attack because of the noxious fumes discharged from their chimneys. worked out a process for converting it into liquid form; the resultant hydrochloric acid was dumped at sea until a method was found for utilizing it in the manufacture of chlorine, which was much in demand for bleaching.

Hydrochloric acid is present in the digestive juices of the human stomach. Excessive secretion of the acid causes gastric ulcers; a marked deficiency of it impairs the digestive process and is sometimes the primary cause of deficiency anemias. (See GASTRIC AND DUODENAL ULCER; ANEMIA.)

The acid was first mentioned by Johann Rudolf Glauber in 1648, while the gas was first prepared by Joseph Priestley in 1772. The composition of hydrogen chloride was elucidated by Sir Humphry Davy in 1810. Having first shown that chlorine is an elementary substance, Davy demonstrated that hydrogen chloride contains only hydrogen and chlorine, for, on causing the gas to react with sodium and potassium. he obtained only hydrogen and the chloride of the metal. Previously the gas. then known as muriatic acid, was assumed by Claude Louis Berthollet and Antoine Lavoisier to contain oxygen.

Annual production of hydrochloric acid in the United States at mid-20th century was about 350.000 short tons (basis 100% HCI). By-product hydrochloric acid from chlorination of organic materials accounted for 55% of the total; 25% was produced from salt and 20% from chlorine. Principal uses of hydrochloric acid were as follows: activation of oil wells 30%; chemical production 23%; metal production 13%; food industries 12%; metal and general cleaning 10%; miscellaneous 12%.

Preparation — Hydrogenchloride may be formed by the combination of chlorine and hydrogen with no change in volume: $H_2 + Cl_2 = 2HCl$. The reaction is accompanied by the evolution of 22 kilocalories of heat per gram mol of HCl and the compound is stable. being only 0.2% decomposed at 1.j50° C. A mixture of hydrogen and chlorine may be kept at room temperature without apparent reaction. Exposure to sunlight causes an explosive reaction which also occurs when the gases are heated to 250° C. The reaction appears to be hastened by moisture. With well-dried gases it has been found that only 80% reacts in ten minutes at 450° C. A stream of burning hydrogen continues to burn with a steady flame in chlorine and vice versa. The reaction may be brought about also by igniting the two gases after they are brought together in a blow torch.

Hydrogen chloride is prepared both on a laboratory and on an industrial scale by the reaction of a chloride, generally that of sodium, with concentrated sulfuric acid. At moderate temperatures only half of the hydrogen from the sulfuric acid reacts, hydrogen chloride is evolved and a residue of sodium bisulfate remains: $NaCl+H_2SO_4=NaHSO_4+HCl$. At a temperature of 500° C., two molecules of hydrogen chloride per molecule of sulfuric acid may be obtained, the residue being sodium sulfate (salt cake) $2NaCl + H_2SO_4 = Na_2SO_4 + 2HCl$. This reaction, which mas employed in the Le Blanc process for the manufacture of sodium carbonate (see ALKALI MANUFACTURE), provided more hydrogen chloride than could be utilized as hydrochloric acid and much of it was consumed in producing chlorine. With the advent of cheaper chlorine (*q.v.*) the relative positions of chlorine and hydrochloric acid were reversed and considerable hydrochloric acid thereafter was made from chlorine.

Hydrogen chloride is produced by the hydrolysis (see SOLUTIONS) of some chlorides. Phosphorus trichloride hydrolyzes completely at room temperature ($PCl_3 + 3H_2O = H_3PO_3 + 3HCl$) to phosphorous acid and hydrogen chloride. At elevated temperatures magnesium chloride is hydrolyzed by steam ($MgCl_2 + H_2O = MgO + 2HCl$). A convenient way to prepare hydrogen chloride gas in the laboratory is to drop concentrated hydrochloric acid into concentrated sulfuric acid. Hydrogen chloride is also a by-product of the chlorination of many organic substances and this has become an important source.

Hydrochloric acid is prepared by dissolving gaseous hydrogen chloride in water. The solubility of the gas is less at higher temperatures and consequently provision must be made to remove the considerable amount of heat produced when the gas dissolves. Because of the corrosive nature of the acid, ceramic or glass apparatus is commonly used. Tantalum is the most resistant of the metals to corrosion in the presence of hydrochloric acid and, although expensive, is employed to some extent. Pure hydrochloric acid is colourless. The yellow colour of some commercial products is caused by iron and other impurities. Hydrochloric acid is usually marketed as a solution containing 28%–36% hydrogen chloride by weight (18–22 Baumé) commonly known as concentrated hydrochloric acid. The concentration of hydrochloric acid may be approximately calculated by subtracting 1.00 from its specific gravity and multiplying the remainder by 200. For example, hydrochloric acid of specific gravity 1.10 contains $200\times.10=20\%$ by weight of HCl. Anhydrous liquid hydrogen chloride in steel cylinders is available. but because the vapour pressure is about 50 atm. at ordinary temperatures, heavy and expensive containers are required and the use of hydrogen chloride in this form is limited.

Properties. — Hydrogen chloride has a molecular weight of 36.465. It is a colourless gas of strong odour; at 0° C. and 1 atm., weighing 1.639 gr. per litre. The boiling point is −85° C., the freezing point −114° C., the critical temperature is 52° C. and critical pressure 90 atm. Deuterium chloride (DCl) has similar properties but its boiling point is 3° lower and its freezing point 1° lower (*see* DEUTERIUM). The heat, capacity at constant pressure at T° Kelvin is $6.70-0.84\times10^{-3}T$ cal. per g. mol. At 25° C. the free energy is −22.690 cal./mol., the entropy 44.5 cal./mol./degree. The gas is very soluble in water, at 20° C. water will dissolve 477 times its own volume of hydrogen chloride. Because of its great solubility the gas fumes in moist air, forming a mist of hydrochloric acid. The solubility does not follow Henry's law. While at 20° C. hydrogen chloride at 760 mm. pressure is in equilibrium with a solution 42% HCl by weight, the pressure is less than 0.1 mm. over a 15% solution. The solution of one mole (36.465 g.) of gaseous hydrogen chloride in a large amount of water is accompanied by the evolution of 17.63 kilocalories of heat. At 1 atm. a solution 20.24% by weight HCl has the maximum boiling point 110° C., and boils without change in composition. On boiling acids of either greater or less strength than the constant boiling mixture, the composition of the liquid

approaches 20.24%. Since the composition of the constant boiling, or azeotropic, mixture depends upon the atmospheric pressure, it is not considered a chemical compound. However, at low temperatures solid hydrates of hydrogen chloride may be crystallized from the concentrated solution. While liquefied hydrogen chloride and solutions of the gas in nonpolar liquids are extremely poor conductors of electricity, the aqueous solution is a good conductor. At 25° C., the equivalent conductance of tenth normal hydrochloric acid is 389.8, and the limiting equivalent conductance 426.1 reciprocal ohms. Thus. hydrochloric acid is a strong electrolyte. The extensive dissociation in aqueous solution is attributed to the formation of a hydrated hydrogen (hydronium) ion, $HCl + H_2O = H_3O^+ + Cl^-$, this reaction being essentially complete in dilute solution.

Gaseous hydrogen chloride reacts with active metals and their oxides, hydroxides and carbonates to produce chlorides. With ammonia gas it forms fumes of ammonium chloride, $NH_3 + HCl = NH_4Cl$. These reactions occur readily only in the presence of moisture. Completely dry hydrogen chloride is very unreactive. The reactions of hydrochloric acid are those of the hydrogen and chloride ions: both probably hydrated in solution. Some of the reactions of hydrochloric acid which may be attributed to the hydrogen ion are: reactions with metals in which hydrogen gas is displaced; *e.g.,* with zinc ($Zn + 2H^+ + 2Cl^- = H_2 + Zn^{++} + 2Cl^-$); with oxides or hydroxides which are neutralized with the formation of water; *e.g.,* with calcium hydroxide ($Ca[OH]_2 + 2H^+ + 2Cl^- = Ca^{++} + 2Cl^- + 2H_2O$); with salts of weak acids in which the weak acid is displaced: *e.g.,* with iron sulfide ($FeS + 2H^+ + 2Cl^- = Fe^{++} + 2Cl^- + H_2S$). Some of the many uses of hydrochloric acid as a laboratory reagent, *e.g.,* the preparation of metallic chlorides, hydrogen sulfide, sulfur dioxide and carbon dioxide, and the use of a standardized solution of hydrochloric acid in the volumetric determination of alkalis. are suggested by the examples above.

Exposure to as little as 0.1% by volume hydrogen chloride gas in the atmosphere may cause death in a few minutes, but concentrations of 0.001% to 0.005% may be tolerated for several hours without injury. Concentrated hydrochloric acid causes burns and inflammation of the skin, but dilute acid is relatively harmless. Chloride ion is. of course, harmless. being normally present to the extent of 0.25% in human blood and 0.1% to 0.2% as hydrochloric acid in the gastric juices.

The chloride ion is colourless, extremely stable in solution and only oxidized to chlorine by very strong oxidizing agents such as manganese dioxide, dichromate ion and permanganate ion. With manganese dioxide the reaction is: $MnO_2 + 2Cl^- + 4H^+ = Mn^{++} + Cl_2 + 2H_2O$. This and similar reactions also consume hydrogen ions and hence take place more readily in strongly acid solution.

The limiting equivalent conductance of the chloride ion in water at 25° C. is 76.3 reciprocal ohms. In crystals the chloride ion has a radius of 1.81 Å. Chlorides of the alkalis and alkaline earths possess the ionic type of crystal. with high melting points and low volatility. Passing toward the less metallic elements, the chlorides become more volatile and the bonding tends toward the covalent type. Sodium chloride boils at 1,465° C.. magnesium chloride at 1.418" C., aluminum chloride at 180° C.. and silicon chloride at 57° C. Chlorides are, with the exception of silver, mercurous. lead, cuprous and palladous chlorides, soluble in water. The chlorides of nonmetallic elements are, however, generally completely hydrolyzed in water. and many metallic chlorides such as aluminum chloride cannot be recovered in anhydrous condition from solution. On removal of water, hydrogen chloride formed by partial hydrolysis is also lost, hydrolysis becomes complete and only the oxide or hydroxide is obtained. A few chlorides such as bismuth chloride hydrolyze to insoluble basic chlorides; *e.g.,* BiOCl.

The chloride ion enters into many complex ions (see COORDINATION COMPOUNDS); *e.g.,* chloroplatinare ($PtCl_6^=$) and chloraurate ($AuCl_4^-$). Chloroplatinic acid. H_2PtCl_6, finds application in analytical chemistry because its potassium salt is one of the least soluble salts of that metal. The solubility oi cuprous chloride in hydrochloric acid, of gold in aqua regia (*q.v.*), and a number of other reactions are attributed to the formation of stable complex chloride-containing ions. For the same reasons, oxides which dissolve with great difficulty in other acids of equal strength dissolve readily in strong hydrochloric acid. Iron rust (ferric oxide) is readily dissolved by hydrochloric but no: by sulfuric or nitric acid. This reaction accounts for a large industrial use of hydrochloric acid, the cleaning of the surface of iron or steel preparatory to tinning. In industry large amounts of hydrochloric acid are used in preparing both organic and inorganic chlorides. (For chlorides of industrial significance see CHLORINE.)

Analytical.— Hydrochloric acid may be quantitatively determined by titration with a standard base or by the measurement of the amount of chloride present. For dilute solutions the hydrogen-ion (*q.v.*) concentration is also an adequate measure of the total acid (HCI) present. The chloride ion is determined gravimetrically by precipitation as silver chloride which is dried and weighed. It may be determined volumetrically by titration with a standard silver nitrate solution using potassium chromate as indicator (Mohr method); or by the addition of an excess of standard silver nitrate solution and titration of the excess silver ion by standard thiosulfate solution with ferric ion as indicator (Volhard method). Qualitatively, chloride ion is distinguished from bromide and iodide ions by the white colour of silver chloride, silver bromide and silver iodide being yellow-, and silver chloride is soluble in dilute ammonium hydroxide while the other two are not. A chloride also forms volatile brownish-red chromyl dichloride (CrO_2Cl_2) when heated with a dichromate and concentrated sulfuric acid; neither bromides nor iodides react in this nay.

HYDRODYNAMICS, the branch of hydromechanics which deals with the motion of fluids (see MECHANICS, FLUID).

HYDROELECTRIC POWER GENERATION: see ELECTRIC POWER GENERATION: Hydroelectric *Generation.*

HYDROGEN is a gaseous element usually assigned to the first group of the periodic system. The hydrogen atom is the lightest of all atoms in weight; it consists of a nucleus with one unit of positive charge and one electron.

Hydrogen is present in almost all animal and vegetable matter, in compounds in which it is joined to carbon and other elements. In the form of hydrocarbons; it is a constituent of petroleum and coal and is contained in all acids. Some authorities believe that hydrogen compounds are more numerous than those of any other element, although until recently the precedence of carbon was generally accepted.

On the weight basis, hydrogen is the ninth most abundant element; the hydrogen content of the earth, including air and terrestrial waters as well as the earth's crust, is 0.9%. Hydrogen is found in the free state in gases irom volcanoes and fumaroles, and occluded in salt deposits, rocks and meteorites. It occurs in many stars, in comets and in the upper atmosphere. Spectroscopic examination indicates that hydrogen constitutes the bulk of the outer atmosphere of the sun; during total eclipse it is observed in the form of protuberances of incandescent gas reaching as far as 300,000 mi. into space.

The chemical atomic weight of hydrogen is 1.0080. Natural hydrogen as it occurs in combined form in water is a mixture of two isotopes (*q.v.*): hydrogen proper, also referred to as light hydrogen or protium (symbol H. ^1H or H^1) and deuterium (*q.v.*) or heavy hydrogen (symbol ^2H, H^2 or D). These two isotopes are present in the ratio of 5000:1 and have the chemical atomic weights of 1.0079 and 2.0142 respectively. Their nuclei are called proton and deuteron respectively. A third isotope of hydrogen. tritium (symbol ^3H, H^3 or T), occurs in nature only in minute amounts, but can be produced artificially. It is radioactive and has a half-life time of 12.5 years.

History. — It appears that Theophrastus Paracelsus in the 16th century had handled hydrogen, since he found that an inflammable gas was evolved when a metal was dissolved in an acid. However. hydrogen was then confused with other inflammable gases such as hydrocarbons and carbon monoxide. In 1766. Henry Cavendish showed that hydrogen, then called "inflammable air," phlogiston or the inflammable principle, was distinct from other combustible gases by measuring its density and the amount of gas evolved from a given amount of acid and metal. J. Warltire noticed in 1776 that water was formed when hydrogen was burned. In 1781 Cavendish confirmed this observation and Antoine L. Lavoisier coined the name hydrogen (Greek for "maker of water"). In 1929, on the basis of earlier theoretical work by P. M. Dennison. Karl F. Bonhoeffer and Paul Harteck showed that ordinary hydrogen is a mixture of two kinds of molecules, orthohydrogen and parahydrogen. In 1931, Harold C. Urey. Ferdinand G. Brickwedde and George M. Murphy discovered the heavy hydrogen isotope. Tritium was first 'prepared by Lord Rutherford, Marcus L. E. Oliphant and Harteck by the bombardment of deuterophosphoric acid with fast deuterons in 1935.

Uses of Hydrogen. — The first industrial use of hydrogen was the inflation of balloons by Jacques A. C. Charles in 1783. The barrage balloons used in England during World War II were filled with hydrogen. Hydrogen is used as fuel gas in the oxyhydrogen flame (see FLAME) in the production of synthetic gems. for melting and working of silica or quartz and of platinum, for lead burning and for autogeneous welding and cutting. However, in the latter application, hydrogen was being replaced by acetylene.

Hydrogen is the reducing agent in the manufacture of metallic tungsten and molybdenum and in the production of spongy iron for use in powder metallurgy. A hydrogen atmosphere is employed in the pouring of special castings, in the manufacture of magnesium, in the annealing of metals and for the cooling of large electric motors. Large quantities of hydrogen are used in the synthesis of ammonia, of methyl alcohol, in the Fischer-Tropsch synthesis (see below) and in the hydrogenation of various organic chemicals (*e.g.*, benzene, phenol, naphthalene) and of vegetable and animal oils and fats (in the production of margarine and vegetable shortening) and of coal (in the conversion to petroleumlike material). During World War II the major portion of Germany's petroleum requirement was produced by the latter process. Hydrogen is used to reduce aldehydes, fatty acids of esters to the corresponding alcohols and to manuiacture hydrogen chloride and bromide (see OXIDATION AND REDUCTION). A number oi petroleum refining processes are carried out in the presence of hydrogen, but usually in these processes, more hydrogen is formed than consumed. Liquid hydrogen is used in the laboratory to produce extremely low temperatures. Regarding the use oi hydrogen in the hydrogen bomb, see ATOMIC ENERGY.

Production of Hydrogen. — Hydrogen is prepared in the laboratory by the interaction of zinc and dilute acid, usually in Kipp's apparatus, according to the equation $Zn + 2H^+ = Zn^{++} + Hz$ or by the electrolysis of a dilute acid or alkali according to the equations: $2H^+ + 2e^- = Hz$, or $2Na^+ + 2e^- = 2Na$ and $2Na + 2H_2O = 2Na^+ + 2OH^- + Hz$. Hydrogen, used ior the first time industrially ior inflating a balloon, mas prepared by the reacting iron with sulfuric acid. With the military use of balloons a great many methods for producing hydrogen were devised that could be operated in the field and required relatively light raw material and equipment. After the advent of aircraft and the availability of helium as a balloon gas, these methods Iost their importance, although some of them (*e.g.,* the reaction between water and calcium hydride, the hydrolith process) were used during World War II to inflate weather balloons.

The steam-methanol process based on the decomposition reaction $CH_3OH + H_2O = 3H_2 + CO_2$ was also used by the armed forces for producing hydrogen in portable equipment. On an industrial scale, large amounts of hydrogen are produced by the reaction of steam and spongy iron at 650° C., $3Fe + 4H_2O = Fe_3O_4 + 4H_2$. The iron is recovered by reducing the iron oxide with water gas (*q.v.*), a mixture of hydrogen and carbon monoxide, $Fe_3O_4 + 2H_2 + 2C0 = 3Fe + 2H_2O + 2CO_2$. The cheapest source of hydrogen is water gas, from which carbon monoxide is removed by the water gas shift reaction $CO + H_2O \rightleftarrows CO_2 + H_2$ in the presence of a catalyst such as iron oxide containing some chromium oxide. In order to reduce the amount of carbon monoxide present at equilibrium, an excess of steam is used and the reaction is carried out at the lowest temperature, 400°–500° C., at which the reaction velocity is sufficiently high. The carbon dioxide thus formed is then washed out by water or another aqueous solution. The residual carbon monoxide is removed by scrubbing with a cuprous chloride solution or by repeating the water gas shift reaction or by reduction to methane.

By the interaction of methane (or other hydrocarbons) and steam ($CH_4 + 2H_2O \rightleftarrows CO_2 + 4H_2$ and $CH_4 + H_2O \rightleftarrows CO + 3H_2$) in the presence of a suitable catalyst (nickel) at 800°–900° C., a mixture of hydrogen, carbon monoxide and carbon dioxide is obtained. It is then treated as water gas. Hydrogen can also be recovered from water gas or coke oven gas by low temperature fractional distillation since its boiling point (−252° C.) is much lower than that of carbon monoxide (−191° C.) or of nitrogen (−195° C.). This method was extensively used in Germany prior to and during World War II. The thermal decomposition of hydrocarbons over heated brick checkerwork is a convenient method for producing hydrogen in cases when hydrocarbon gases are readily available (*e.g.,* refineries) and when the purity of hydrogen is of no great importance. The purest hydrogen (99.9%) is obtained by electrolysis oi alkaline water in cells specially built to permit separation of the hydrogen and oxygen, the yield being approximately 7 cu.ft. of hydrogen per kilowatt hour. Hydrogen is a by-product in the electrolytic manufacture of caustic alkali and chlorine (*q.v.*), in the butyl alcohol-acetone fermentation and in the refining of petroleum naphthas over platinum and similar catalysts to motor gasoline and to aromatic hydrocarbons. Industrial hydrogen must be specially purified for each particular use.

Orthohydrogen and Parahydrogen. — Hydrogen gas under normal conditions consists of molecules, each of which contains two atoms. The nuclear magnets (spins) of both protons are oriented in the same direction in orthohydrogen molecules. In parahydrogen molecules these magnets are oriented in opposite directions. The ortho molecules rotate with odd rotational quantum numbers while the para molecules rotate with even quantum numbers. Normally, conversions do not occur between ortho and para molecules and for this reason orthohydrogen and parahydrogen can be regarded as two distinct modifications of hydrogen. The equilibrium between orthohydrogen and parahydrogen can be readily established in the presence of catalysts (*e.g.,* charcoal at temperatures below −100° C. and platinized asbestos above −100° C.). The equilibrium concentration of parahydrogen depends on the temperature as shown by the following figures:

−253.1° C.....99.82%	−153.1° C.....32.87%
−223.1" C.....76.89%	0° C.. .....25.13%
−193.1° C.....48.39%	

Thus essentially pure parahydrogen can be produced by bringing hydrogen into contact with charcoal at the temperature of liquid hydrogen, while orthohydrogen cannot be prepared directly since the equilibrium concentration of parahydrogen does not fall below 25%, the amount present in normal hydrogen. Parahydrogen differs from normal hydrogen in its physical properties such as vapour pressure, boiling point, melting point, specific heat, heat conductivity and spectrum, but the two kinds of hydrogen are identical as far as chemical properties are concerned. Parahydrogen can be kept at room temperature without appreciable conversion for many months. At elevated temperatures, under the influence of electric discharges or in the presence of metals and paramagnetic substances, parahydrogen is converted to normal hydrogen. The interconversion of ortho- and parahydrogen is being used extensively for scientific investigations.

Atomic Hydrogen. — When hydrogen molecules are exposed to excessive heat, *e.g.,* contact with a white hot tungsten filament (Irving Langmuir, 1914), to an electric discharge (Robert W. Wood, 1921; Bonhoeffer, 1924), or to an electric arc, they dissociate into atoms. The atoms thus formed have a short lifetime that depends on the pressure (*e.g.,* 0.3 sec. at a pressure of 0.5 mm.Hg). Platinum, nickel and other metals destroy the activity of atomic or active hydrogen by catalyzing the recombination of the atoms. Atomic hydrogen reacts even at room temperature with hydrocarbons (except with methane) causing dehydrogenation, cracking and in the case of unsaturated hydrocarbons, hydrogenation.

It combines with sulfur, tellurium, phosphorus, arsenic, lithium, sodium, chlorine, bromine and other elements and reduces metallic oxides. Atomic hydrogen forms hydrogen peroxide with oxygen, a reaction which has found industrial application. The heat of recombination of the hydrogen atoms is utilized in the arc welding process of Langmuir.

Physical Properties. — Hydrogen is an odourless, colourless and tasteless gas. It is the lightest chemical element. For some physical properties of normal hydrogen and of parahydrogen see Table I.

Hydrogen has the highest heat conductivity and the highest coefficient of diffusion of all the gases. Hydrogen diffuses through porous substances such as clay and has the unique property of diffusing through rubber and, at elevated temperatures, through quartz and silica. It also diffuses through the metals of the nickel, palladium and platinum groups; diffusion is accompanied by the dissolution of hydrogen. Thus under certain conditions palladium can take up almost 900 vol. of hydrogen at 20° C. and atmospheric pressure. The diffusion of hydrogen through a palladium thimble is used in the laboratory to purify hydrogen. The standard electrode potential of hydrogen is zero according to a generally accepted convention.

Chemical Properties. — Hydrogen has chemical properties similar to those of the elements of Groups I and VII of the periodic systems. Combined with the electronegative halogens, hydrogen resembles the

TABLE I.—*Some Properties of Normal Hydrogen and Parahydrogen*

Density at 0° C., 760 mm. pressure	0.08987 g/l.
Buoyancy in air	1.203 g/l.
Melting point: normal hydrogen	−259.24° C.
parahydrogen	−259.28° C.
Boiling point: normal hydrogen	−252.78° C.
parahydrogen	−252.87° C.
Critical temperature	−239.91° C.
Critical pressure	12.8 atm.
Critical density	0.03102 g./ml.
Specific heat:	
gas at const. vol. 20°–100° C.	2.35 cal./g.
liquid at const. vol. −257.4° C.	1.77 cal./g.
solid at const. vol. −260.4° C.	0.536 cal./g.
Heat of evaporation	108 cal./g.
Heat of fusion	14.0 cal./g.
Heat conductivity at 0° C.	0.000413 cal./cm. sec. ° C.
Coefficient of expansion	0.00366
Pressure coefficient	0.0036627
Molecular diameter	2.5×10^{-8} cm.
Heat of dissociation	102.72 kg. cal./mol.
Heat of combustion, 20° C., 1 atm.	68.351 kg. cal./mol.
Ionization potential	13.527 v.

alkali metals since it forms positive ions on dissolution in water. In its compounds with the electropositive alkali metals (hydrides) hydrogen behaves as an electronegative element since it attracts an extra electron to form a negative ion. This ion is discharged at the positive anode on electrolyzing the molten hydride. In volatile hydrides hydrogen forms a nonionic covalent bond. The bond in all gaseous hydrogen halides is similar except in hydrogen fluoride. Hydrogen is univalent in all its compounds.

Under proper conditions, hydrogen combines directly with most of the lighter elements and many of the heavier elements. The reaction with fluorine to form hydrogen fluoride is very violent, even at −252° C. Mixtures of hydrogen and chlorine can react with explosive violence on irradiation or under the influence of a spark. Mixtures of hydrogen and oxygen react at a measurable rate only above 300° C. Such mixtures containing 4% to 94% hydrogen can ignite or explode when heated to 550°–600° C. or brought into contact with a catalyst, spark or flame. Especially violent is the explosion in detonating gas containing oxygen and hydrogen in the proportion 1:2. In air or oxygen, hydrogen burns with a nonluminous flame. With bromine, iodine, the alkali metals, alkaline earths, sulfur, etc., hydrogen reacts at elevated temperatures. Nitrogen and hydrogen form ammonia under pressure above 300° C. in the presence of a suitable catalyst. Carbon and hydrogen combine in the electric arc to form acetylene and they also form various other hydrocarbons in the presence of a catalyst at moderate temperatures. The dissolution of hydrogen by palladium and other metals is accompanied by the formation of hydrides. Hydrogen reduces the oxides of most metals, and some metallic salts, to the metals, especially at elevated temperatures and pressures. The reduction of an aqueous solution of a metallic salt (*e.g.*, palladium chloride) by hydrogen corresponds to the reverse reaction as it occurs in the dissolution of metals in acids. Which of these two reactions will occur depends on the standard electrode potential of the metals involved. All metals that have positive potentials measured on the hydrogen scale can displace hydrogen ions from a solution according to the general reaction $M+H^+=M^++\frac{1}{2}H_2$ while metals with negative potentials will be produced by reducing the corresponding metallic ions with gaseous hydrogen. In the presence of nickel or platinum catalysts, hydrogen combines with unsaturated organic compounds (*see* HYDROGENATION) and reduces certain oxygenated organic compounds to compounds containing less or no oxygen (*see* OXIDATION AND REDUCTION). Under high pressure and temperature, coal and similar material can be converted into petroleumlike products by catalytic hydrogenation.

With carbon monoxide, hydrogen forms a great variety of products depending on the pressure, temperature and catalyst used. Thus the product can be methane, methyl alcohol, a mixture of various alcohols or of hydrocarbons. The latter two processes were originated by Franz Fischer and Hans Tropsch in 1925. In a variation of these processes, in the oxo process, a mixture of hydrogen and carbon monoxide is reacted with olefins to form aldehydes.

Compounds.—Hydrogen ions (*q.v.*), H^+ are present in solutions of acids (*q.v.*) and are responsible for their characteristic properties such as sour taste, neutralization of bases, dissolution of base metals accompanied by evolution of hydrogen and colour changes with certain dyes (*e.g.*, blue litmus to red). In aqueous solutions of hydrogen ions, protons are not present as such but are associated with water molecules forming hydronium ions $(H_3O)^+$. Since water is dissociated to a certain extent into hydrogen and hydroxyl ions (*see* HYDROXIDE) according to $H_2O=H^++OH^-$ water is amphoteric; *i.e.*, it can either lose or take up a hydrogen ion and thus can act as an acid or a base. With other elements hydrogen forms three types of compounds (*see* HYDRIDES): saltlike compounds (*e.g.*, hydrides of alkali metals and alkaline earths); volatile compounds (*e.g.*, water H_2O, ammonia NH_3, phosphine PH_3, hydrocarbons, hydrogen halides); and metallike hydrides (*e.g.*, hydrides of palladium, titanium and zirconium). Besides the compounds already mentioned the following compounds of hydrogen are the most common: hydrogen peroxide (*q.v.*) H_2O_2, hydrazine (*q.v.*) N_2H_4, hydrazoic acid HN_3, hydrogen sulfide H_2S (*see* SULFUR), hydrogen fluoride H_2F_2 (*see* FLUORINE), hydrogen cyanide or prussic acid (*q.v.*) HCN and hydrogen chloride HCl (*see* HYDROCHLORIC ACID). With carbon, hydrogen forms a very large number of compounds, the hydrocarbons (*q.v.*). All these hydrogen compounds have important technical applications. Hydrogen is present in a great variety of compounds, formed by three or more elements, such as acids, bases (*see* HYDROXIDE), compounds containing combined water (*see* HYDRATE) and in almost all organic compounds.

Analysis.—The hydrogen content of a gas is often determined by admixing a known amount of oxygen and measuring the contraction that is caused by the formation of liquid water when the gas is brought into contact with a glowing filament or with a spark. In the presence of other combustible gases, the hydrogen is determined by reacting it with hot copper oxide according to $H_2+CuO=Cu+H_2O$. Other methods that are used for determining the purity of hydrogen and the amount of hydrogen present in other gases are based on measuring density, refractive index, the masses of the components (by the mass spectrograph) and the thermal conductivity.

(A. Fs.)

HYDROGENATION is the addition of molecular hydrogen to a multiple linkage in the presence of a catalyst. Hydrogenolysis is a special case of hydrogenation in which the addition of hydrogen results in cleavage of the bond.

Few reactions, if any, have served chemists in all branches of organic chemistry so extensively as have catalytic hydrogenation and hydrogenolysis. These processes have vastly enlarged the world's supply of edible fats and soap and have upgraded the quality of gasoline as well as opening a new source of supply.

The basic problem in the synthesis of edible fats is summed up (from Carleton Ellis, *Hydrogenation of Organic Substances* [p. 36], copyright 1930, D. Van Nostrand Co., Inc., Princeton, N.J.) as follows:

"For years the dream of the oil chemist was to find a solution to the problem of converting oleic acid into stearic acid, or olein into stearin, simply by the addition of hydrogen, so as to make valuable hard fats from relatively cheap raw material. Superficially the problem looked simple. Oleic acid is the next-door neighbor of stearic acid, apparently differing only in having a little less hydrogen than stearic acid has in its constitution. Only a trifling amount of hydrogen, less than 1 per cent, is required to transform oleic into stearic acid.

"But the problem was far from simple, as oleic acid stubbornly resisted the invasion of hydrogen into its structure to any material extent under the earlier methods of hydrogen addition, and not until later years, with the discovery of effective hydrogen carriers or catalyzers, has it become possible to bring about this conversion economically with large yields so as to warrant commercial exploitation in an extensive way."

Although the first synthetic edible fats were produced in France in the late 1860s, the industrial importance of the hydrogenation process dates from 1897, when Paul Sabatier discovered that the introduction of a trace of nickel as a catalyst facilitated the mixture of hydrogen with the molecules of carbon compounds.

The manufacture of gasoline by the hydrogenolysis of coal was originated in Germany during World War I by Friedrich Bergius.

Methods.—Several methods are used for carrying out hydrogenation reactions. In the presence of very active catalysts, such as platinum and palladium, and easily hydrogenated material, such as olefins, ketones, aldehydes, or nitro compounds, the reactions can be carried out at a pressure of 1 to 4 atmospheres and at a temperature up to 80° C. For other hydrogenations much higher pressures are used and the reactions are carried out in autoclaves which can withstand high pressures and temperatures.

Low-Pressure Hydrogenation.—This method can be effected in an apparatus consisting of a shielded reaction bottle and a shaker mechanism. The reaction bottle is attached to a hydrogen reservoir. The progress of the reaction is followed by noting the pressure drop.

High-Pressure Hydrogenation.—In the laboratory this process is usually carried out in a steel rocking autoclave which can withstand a pressure of 400 atm. at a temperature of 400° C. The autoclave, fitted with a pressure gauge, is mounted in an electrical heating jacket, the temperature of which is controlled by means

of a thermocouple and an electrical control system The compound, alone or in solution. is agitated with the catalyst and hydrogen at elevated pressure.

Catalysts. — The catalysts most commonly used for low-pressure hydrogenation are platinum oxide, supported palladium and Raney nickel. These catalysts are easily prepared and have high activity at low temperatures and pressures. They catalyze the hydrogenation of a variety of functional groups. For high-pressure hydrogenations copper chromite and nickel supported on kieselguhr are the catalysts most extensively used. The choice of a catalyst depends on the functional group to be hydrogenated and, in the case of polyfunctional groups, on the desired selectivity of hydrogenation.

Variables Affecting Hydrogenation.--One of the primary factors that determine the ease with which a catalytic hydrogenation can be effected is the nature of the functional group to be reduced. There are however, in addition, several external factors such as:

Temperature and Pressure. — In general an increase in temperature causes an increased rate of hydrogenation. For the hydrogenation of most functional groups there is an optimum temperature for the reaction. At temperatures much below this point, the reaction is usually too slow to be practical. Neither is it desirable to conduct the hydrogenation above the optimum temperature since then the rates of side reactions are increased.

An increase in pressure produces an increase in the rate of hydrogenation. The pressure selected for conducting a hydrogenation depends largely on the particular compound in question. For example. with phenol and benzene an increase of pressure from 30 to 300 atm. increases the rate of hydrogenation only by about 50% in the presence of nickel, whereas the rate of hydrogenation of aniline increases three- to fourfold.

Agitation.—In order to effect a hydrogenation smoothly, it is necessary to bring the acceptor, catalyst and hydrogen in intimate contact. This is usually accomplished by shaking the reaction mixture, thus keeping the catalyst well dispersed and affording continuous supply of reactants to the surface.' The rate of reaction increases steadily with agitation up to a certain point.

Solvent. — In many cases, it is desirable to conduct a hydrogenation in the presence of a suitable solvent, especially in the case of high-melting solids and compounds that react very vigorously with hydrogen. Solvents also often facilitate the suspension of the catalyst in the reaction mixture and prevent the separation of an immiscible liquid. The solvents that have been found most useful are ethyl alcohol, low-boiling alkanes, ether, dioxane and acetic acid; the latter can be used only with platinum and palladium type catalysts.

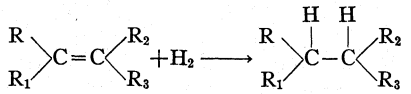
Catalyst Poisoning. — This can be either deliberate or unintentional. In certain types of selective hydrogenation, the catalyst is deliberately poisoned in order to deactivate it to the desired level. The partial poisoning of the nickel catalyst with sulfur makes it an efficient catalyst for the hydrogenation of butadiene to butene without causing the latter to be hydrogenated. The poisoning of palladium with sulfur permits the selective hydrogenation of an acyl chloride to an aldehyde.

Catalyst poisoning is usually unintentional. Deterioration of the catalysts on use can be attributed generally to the presence of sulfur in the reactants, to clogging of the catalyst pores with carbonaceous material and to a host of other causes. In general, Group Vb of the periodic table (phosphorous, arsenic, antimony, bismuth) and Group VIb (sulfur, selenium, tellurium) are poisons for the hydrogenating catalysts such as nickel, platinum and palladium. A poisoned catalyst can often be reactivated by oxidation with certain peracids in the presence of hydrogen peroxide. Oxidation converts the poison into a compound that does not retard catalyst efficiency.

Function of the Catalyst. — The detailed mechanism of hydrogenation, in spite of the significance of the reaction and the extensive studies carried out in various countries, is not too well understood. **A** good catalyst for hydrogenation must maintain its activity under reaction conditions and must (a) adsorb and activate hydrogen, (b) adsorb and activate the hydrogen acceptor, (c) maintain them in the proper space relationship and (d) desorb the hydrogenated compound.

EXAMPLES

Hydrogenation of Functional **Groups.**—*Olefins.*—The reaction can be presented by the general formula:



The saturation of olefinic double bonds occurs readily in the presence of any of the typical hydrogenation catalysts listed above. Platinum and palladium are active at low pressures and temperatures, nickel is active at higher pressures and at temperatures of 40°–60° C.. while copper chromite is active at 100° C. and zoo atm. pressure. The ease of hydrogenation depends on the number and nature of attached groups; an increase in substitution is accompanied by decreasing ease of hydrogenation.

The purpose of hydrogenation of vegetable or animal oils is to obtain a hard fat of greater viscosity than the original liquid oil and to remove certain undesirable impurities, thus rendering the oil edible and useful for industrial consumption. The process consists essentially in hydrogenation of the glycerides of unsaturated acids into glycerides of saturated or partially saturated acids. The reaction is carried out at 100°–200° C. and at pressures less than 15 atm. Nickel is the most commonly used catalyst. The quantity of nickel used is less than 1%. In the latter 1950s in the United States about 1,000,000 tons of glycerides, mainly cottonseed and soybean oil, were hydrogenated to make shortening.

The hydrogenation of diisobutylene to isooctane is of special industrial interest because of the high antiknock performance of the isooctane (2,2,4-trimethylpentane) in internal combustion engines.

Aromatics. — Aromatic rings are more difficult to hydrogenate than isolated olefinic double bonds. Nickel type catalysts are perhaps the most satisfactory catalysts; temperatures ranging from 125° to 175° C. and pressures of about 100 atm. are satisfactory. Platinum oxide is an effective catalyst for the hydrogenation only in the presence of acids, such as acetic acid. The hydrogenation of mononuclear aromatic hydrocarbons proceeds to completion to form cyclohexanes. The hydrogenation of benzene to cyclohexane and of phenol to cyclohexanol are of commercial importance, since these two compounds on oxidation form adipic acid which is the main intermediate in the production of nylon (synthetic fibre).

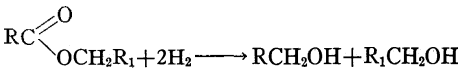
Naphthalene can be hydrogenated to tetrahydronaphthalene (tetraline) and decahydronaphthalene (decaline) depending on the experimental conditions. Both compounds are important industrial solvents.

Hydrogenolysis of Functional Groups. — Nitro Compounds. —The nitro group undergoes catalytic reduction with great ease and any of the common hydrogenation catalysts is effective:

$$RNO_2+3H_2\longrightarrow RNH_2+2H_2O$$

Reduction of the nitro group is highly exothermic and certain precautions must be taken to prevent dangerously high reaction temperatures. The hydrogenation of these compounds can be controlled by use of a low ratio of catalyst to acceptor and low temperatures. In order that the water produced during the hydrogenolysis does not destroy the homogeneity of the reaction medium it is advisable to use an alcohol as a solvent.

Esters. — Copper chromite is the catalyst most widely used for the reduction of esters to primary alcohols:



The reaction is generally conducted at 250° C. and 175 atm. pressure. Substituents containing a functional group have no marked effect on the yield of primary alcohol, provided they are located at sufficiently great distance from the ester function. When the ester is directly bound to an aromatic ring reaction (A)

takes place, if the aromatic ring is separated from the ester by one or more carbon atoms reaction (B) occurs:

(A) $C_6H_5C(=O)OC_2H_5 + 3H_2 \longrightarrow C_6H_5CH_3 + C_2H_5OH + H_2O$

(B) $C_6H_5CH_2C(=O)OC_2H_5 + 2H_2 \longrightarrow C_6H_5CH_2CH_2OH + C_2H_5OH$

Hydrogenolysis of esters is used extensively commercially for making higher molecular weight alcohols from the esters of fatty acids and from waxes. The alcohols thus produced are esterified with sulfuric acid and converted to synthetic detergents

Acid Chlorides.—Often it is necessary to convert an acid to the corresponding aldehyde. The most convenient method of accomplishing this involves the conversion of the acid to the acid chloride and hydrogenation of this derivative in the presence of a supported palladium catalyst, generally palladium on barium sulfate. This selective hydrogenation, known as the Rosenmund reduction, is applicable for the preparation of aliphatic, aromatic and heterocyclic aldehydes.

$$RC(=O)Cl + H_2 \longrightarrow RCHO + HCl$$

Experimental conditions must be chosen so that the aldehyde is not further reduced to the alcohol or hydrocarbon. This is often accomplished by the addition of a regulator, which is simply a selective poison that deactivates the catalyst with respect to reduction of aldehydes but not with respect to acid chlorides. A compound containing sulfur is usually used for this purpose; quinoline treated with sulfur is most commonly used. The reduction is accomplished by bubbling hydrogen through a solution of the acid chloride in which the catalyst and the regulator are suspended.

The Rosenmund reduction is used extensively in the synthesis of fine chemicals and pharmaceuticals.

Hydrogenolysis of Carbon-Carbon Bonds.—*Paraffins.*—Under conditions that are sufficiently drastic paraffinic hydrocarbons undergo extensive hydrogenolysis to yield principally methane. In the presence of nickel at 400° C.. hexane. for example, reacts with hydrogen to yield methane. By employing conditions that are less drastic it is possible to effect a more selective reaction by removing certain specific methyl groups (as methane) from branched-chain hydrocarbons to form hydrocarbons having one less carbon atom. In this reaction, referred as selective demethylation, methyl groups attached to secondary carbon atoms are removed more readily than those attached to tertiary carbon atoms. Methyl groups attached to quaternary carbon atoms are the most difficult of all to remove.

$$CH_3-C(CH_3)(CH_3)-CH(CH_3)-CH_2-CH_2+H_2 \longrightarrow CH_3-C(CH_3)(CH_3)-CH(CH_3)-CH_3+CH_4$$

The reaction is conducted at 200°–320° C. and 1–20 atm. pressure in a flow system with nickel or cobalt as catalyst Careful control of reaction conditions is necessary.

This reaction is of practical importance in that it can be used for the synthesis of branched-chain hydrocarbons that are difficult to obtain by conventional means.

Alkylaromatics.—The large demand for simple, relatively lox- molecular weight aromatic hydrocarbons, such as benzene, toluene and naphthalene. directed attention toward the utilization of kerosene extracts containing high concentrations of alkyl-substituted benzenes and naphthalenes. The hydrogenolysis of the alkylaromatics is usually carried out at high temperatures, 525°–625° C., 25–70 atm. pressures, a hydrogen to hydrocarbon ratio of 3:1 and an hourly liquid space velocity (volume of liquid charged per volume of catalyst per hour) of 1.0. The catalysts preferred are molybdena, chromia or vanadia deposited on alumina.

Primary Alcohols.—The hydrogenolysis of primary alcohols in the presence of catalysts, such as nickel, platinum or palladium, furnishes excellent yields of hydrocarbons having one less carbon atom than the original alcohol:

$$RCH_2OH + 2H_2 \longrightarrow RH + CH_4 + H_2O$$

In the presence of a nickel catalyst the reaction is conducted at 250° C. and 50–100 atm. pressure. The reaction has been applied to a variety of alcohols.

Hydrogenolysis of Coal.—Coal is a mixture of very high molecular weight compounds, containing sulfur, oxygen and nitrogen, in addition to carbon and hydrogen. Coal in a powdered form is first mixed with a small amount of catalyst and with a high-boiling recycle oil containing aromatics, hydroaromatics and phenols. This paste and about 2,000 cu.m. of hydrogen per ton of coal oil is pumped at 500 atm. through a preheater in which the mixture is heated to about 430° C. From the preheater the reactants pass through three pressure vessels in series, where the exothermic heat of reaction results in a temperature increase to 470° C. The contact time is of the order of two hours.

The products are: (1) heavy oil which is recycled to make coal oil paste, (2) middle oil, boiling in the range of 200°–310° C., which is submitted to vapour phase hydrogenolysis to form motor fuel. (3) a relatively small fraction of gasoline, (4) gaseous hydrocarbons, and (5) residue of unreacted coal ash, which is used for fuel.

Most heavy metals and their oxides and sulfides are active as catalysts in primary liquefaction of coal. Tin added as massive metal or as any reactive compound is the most active catalyst known for converting bituminous coal to a heavy oil by hydrogenolysis.

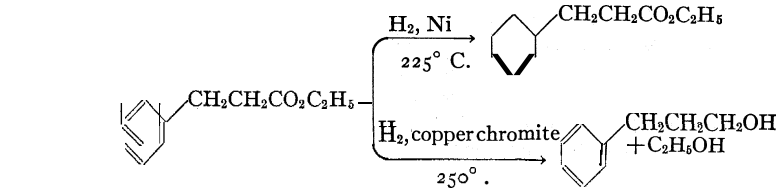
The coal hydrogenation method was used in Germany before and during World War II.

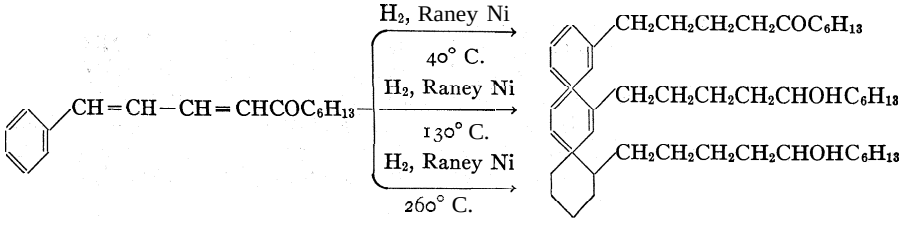
Selective Hydrogenation.— This is a valuable tool used by chemists for reducing one functional group in the presence of another functional group, which is also able to undergo hydrogenation.

This type of hydrogenation is made possible by the existence of a variety of catalysts, wide choice of temperature and pressure conditions, a choice of solvents and a reasonable knowledge of the relative reactivity toward hydrogenation of the various functional groups.

The choice of catalysts can be of great importance. Copper chromite, for example, is more active for the reduction of the carbon-oxygen bond than for that of the benzenoid ring. Nickel is more active toward a benzenoid ring than toward an ester group.

Some of the examples listed below show the effect of catalysts and the effect of temperatures upon the selective hydrogenation of certain compounds:





Hydrogenation of Carbon Monoxide. — A diversity of chemical reactions has involved the catalytic hydrogenation of carbon monoxide. Many of these reactions are of industrial importance.

Methane.—A complete hydrogenation to methane occurs when carbon monoxide and hydrogen are brought into contact in the presence of a nickel catalyst at a temperature above z50° C. This reaction is of industrial importance in the conversion of the carbon monoxide of manufactured gas to methane to increase the heating value and to provide a less toxic fuel gas.

Methanol.—The synthesis of methanol is an outstanding example of the practical importance of catalytic processes. The production of methyl alcohol in the United States in the latter 1950s was about 800.000 tons.

Carbon monoxide may react with hydrogen in many different ways. Methyl alcohol is formed only if certain selective catalysts are used. Only in 1923 was the means found to make methanol the main product of the hydrogenation of carbon monoxide. This was brought about through the use of certain mixed catalysts containing zinc oxide and chromium oxide and a reaction apparatus that did not contain iron or iron alloys.

The prevailing commercial catalysts are composed of the above two oxides, to which copper or copper oxide may or may not be added. The copper is a good conductor of heat, with the result that its addition promotes the distribution of the heat of reaction throughout the catalyst bed; furthermore, it can enhance the activity of the zinc–chromium catalyst. The ratios of the various constituents vary.

The lowest temperature at which the reaction has been found to proceed at an appreciable rate in the presence of a catalyst is 225° C. Most commercial syntheses operate between 300° and 375° C., and between 275 and 350 atm. The usual conversion of carbon monoxide to methanol is 12% to 15%. The ratios of hydrogen to carbon monoxide used vary from 2:1 to 6:1, and the gaseous space velocities (volume of gas per volume of catalyst per hour) from 20,000 to 50,000.

Fischer–Tropsch Synthesis. — Catalysts such as nickel and cobalt, which normally yield chiefly methane from a mixture of hydrogen and carbon monoxide at atmospheric pressure and 250°–400° C., may be modified by the addition of oxides of thorium, magnesium or aluminum and by special preparation procedures so as to produce mainly liquid hydrocarbons. If modified iron is used as a catalyst, alcohols and liquid hydrocarbons are produced. This discovery, made in 1925 by Franz Fischer and Hans Tropsch led to the rapid industrial development of synthetic gasoline in Germany during 1931–38.

Nickel catalysts were soon found to be less useful than cobalt or iron. Cobalt catalysts were used exclusively in all German plants during 1932–46, although later research on iron catalysts showed that with proper preparations and suitable experimental conditions they would equal the performance of the cobalt catalyst.

The standard catalyst in the commercial synthesis of gasoline in Germany during World War II was composed of:

$$Co:ThO_2:MgO:kieselguhr = 100:5:8:200$$

The best results were obtained when pressures of from j to 15 atm. and temperatures of about 250° C. were used and the ratio of $H_2:CO = 2:1$. The product of this synthesis contained about 14% methane, 1% ethane, 25% C_3 and C_4 hydrocarbons, 30% gasoline. 14% diesel oil, 14% paraffin wax and 1% to 2% aliphatic alcohols. The hydrocarbons obtained were mixtures of paraffins and olefins; no naphthenes or diolefins were formed.

Active iron catalysts for the synthesis can be prepared by impregnating precipitated ferric hydroxide with aqueous potassium carbonate so that the dried mixture will contain 0.25% potassium oxide. The activity and durability of the iron catalyst is enhanced by pretreatment with pure carbon monoxide at 325" C.

Synthesis conditions with the iron catalysts are 225°–235° c., zo atm. press.. using 1 vol. of H_2 per 1 vol. of CO and a space velocity of 100 to zoo vol. of the reactant gas per volume of catalyst per hour. The percentage composition of the product is 15% (C_1+C_2), 15% (C_3+Cu), 24% (C_5 to C_{10}), 12% (C_{11} to C_{18}), 22% hydrocarbons boiling above 320° C. and 12% oxygenated organic compounds.

Oxo Reaction. — The oxo reaction involves the addition of carbon monoxide and hydrogen to an olefin in the presence of a cobalt catalyst to produce an aldehyde containing one carbon atom more than the starting compound. The reaction can be presented by the following general equation:

$$RCH=CH_2+CO+H_2 \longrightarrow RCH_2CH_2CHO \text{ and } R\overset{\overset{CHO}{|}}{C}HCH_3$$

The reaction may be regarded as the addition of a hydrogen atom and a formyl group across the double bond. The reaction was first carried out (Roelen. 1938) with ethylene and the products of the reaction were diethyl ketone and propionaldehyde. Because both products contained a carbonyl or oxo group, the reaction was called the oxo reaction. Later it was found that the ketone formation was relatively unimportant; aldehydes being the principal products.

The effective catalyst in the oxo synthesis is cobalt hydrocarbonyl. which probably results from the intermediate formation of dicobalt octacarbonyl:

$$2Co+8CO \longrightarrow [(CoCO)_4]_2 \qquad \Delta H = -55 \text{ kg. cal./mole}$$
$$H_2+[(CoCO)_4]_2 \longrightarrow 2HCo(CO)_4$$

For a maximum yield of aldehydes the reaction should be operated at as low a temperature as possible, compatible with a reasonable rate. The temperature is usually 110°–140° C., and under these conditions the cobalt should be introduced as dicobalt octacarbonyl. As the temperature is raised, there is a tendency for the aldehydes to be reduced to the alcohols. The usual operating pressure of the oxo synthesis is 200 to 300 atm. of synthesis gas ($H_2:CO = 1:1$). It is possible to adjust conditions so that the aldehydes are produced even at 185° C.; this can be done by using sufficient gas to enable the oxo synthesis to proceed, but insufficient to permit the subsequent hydrogenation.

Most oxo reactions are performed with cobalt concentration of about 0.5 to j mole per cent.

Straight-chain terminal olefins yield a mixture of aldehydes consisting of about 40%–60% straight-chain and 60%–40% branched-chain aldehydes. Nonterminal straight-chain olefins yield a mixture of aldehydes practically identical with that given by the isomeric terminal olefins.

The olefin mixture of the greatest commercial interest as a substrate for the oxo reaction is the mixture of heptylenes obtained by the copolymerization of C_3 and C_4 olefins and composed chiefly of 2,2-, 2,3- and 2.4-dimethylpentes. The mixed C_8-alcohols eventually obtained by the oxo process are useful in the manufacture of plasticizers.

Hydrogenation of Elemental Substances.—Hydrogen combines with many elements in the presence of finely divided metals such as platinum or palladium. The elements of fluorine, chlorine, bromine and iodine form the corresponding hydrogen halides. Hydrogen combines also with sulfur, selenium and tellurium. The reaction of nitrogen with hydrogen to form ammonia is of great industrial importance.

HYDROGEN CYANIDE: see PRUSSIC ACID.

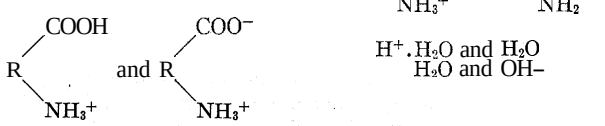
HYDROGEN IONS. A hydrogen ion may be an electrically charged molecule (or atom) of hydrogen in the gaseous state, but the term is applied more often, as it is in this article, to ions in solution arising from acids. acid salts. etc.

According to the theory of Svante Xrrhenius, hydrogen ions are produced in solution by the dissociation of acids. For example,

the acid $CH_3.COOH$ was supposed to dissociate to the anion CH_3COO^- and the hydrogen ion H^+.

The view here adopted is that the proton. the nucleus of the hydrogen atom having unit positive charge and represented by H^+, may transfer from any one of a large number of proton donors to one or another proton acceptor. Examples of proton donors and the corresponding (or conjugate) proton acceptors are:

Donor and acceptor	*Donor and acceptor*
$CH_3.COOH$ and $CH_3.COO^-$	$H^+.H_2O$ and H_2O
NH_4^+ and NH_3	H_2O and OH^-
H_3PO_4 and $H_2PO_4^-$	
$H_2PO_4^-$ and $HPO_4^=$	



In aqueous solution transfer of a proton from a proton donor to water gives the hydrogen ion. $H^+.H_2O$ of an aqueous solution. Likewise, in an ammonia solution the transfer of a proton from a proton donor to a molecule of the solvent, NH_3, gives the hydrogen ion. NH_4^+, of an ammonia solution. (The terms donor and acceptor are discussed in detail in ACIDS AND BASES.)

This article is restricted to aqueous solutions and to an elementary treatment, but the elementary principles presented are widely applicable if due consideration is given to the distinctions between different solvents.

A general, reversible process of proton exchange may be represented by: proton donor A + proton acceptor B $\rightleftharpoons$ proton acceptor A + proton donor B. Confining attention to water solutions, in which H_2O is a proton acceptor and the hydrated proton, $H^+.H_2O$, is a proton donor, we may formulate in the classical way the equilibrium equation (1).

$$\frac{[\text{Proton acceptor}][H^+.H_2O]}{[\text{Proton donor}][H_2O]} = k \qquad (1)$$

Here brackets signify the molar concentration (in the algebraic sense) of a substance the symbol of which is enclosed, and k is a constant.

Strictly. equation (1) is valid only at infinite dilution. Also at infinite dilution $[H_2O]$ is a constant. Then equation (1) may be written as (2), which expresses a limiting relation.

$$\frac{[\text{Proton acceptor}]}{[\text{Proton donor}]} = \frac{K}{[H^+.H_2O]} \qquad (2)$$

It is advantageous to preserve this limiting relation and to use its form as in the following development.

Inasmuch as equilibriums of this sort, when observed under ordinary circumstances. are not strictly determined by the concentrations of the participating substances, but rather by their chemical potentials (see THERMODYNAMICS), it has been found convenient to replace the concentration of each substance by its activity. The activity of a substance **A** may be defined by relation (3)

$$(A) = [A]f_A \qquad (3)$$

where ( ) is used here to represent activity, brackets are used as before to signify molar concentration and f_A is the activity coefficient. If concentration is expressed as molal instead of molar concentration, a different symbol should be used for the activity coefficient. This device is virtually to make equations such as equation (4) exact by definition. Accordingly equation (2) should be written as equation (4)

$$\frac{(\text{Proton acceptor})}{(\text{Proton donor})} = \frac{K}{(H^+.H_2O)} \qquad (4)$$

Introducing relations of type (3) we have:

$$\frac{[\text{Proton acceptor}]}{[\text{Proton donor}]} = \frac{K}{(H^+.H_2O)} \times \frac{f_{\text{donor}}}{f_{\text{acceptor}}} \qquad (5)$$

For a narrow range of conditions the ratio $f_{\text{donor}} / f_{\text{acceptor}}$ may not vary to an extent that will affect seriously the simpler formulation of a set of relations, and then this ratio may be combined with the true ionization constant K to give the "apparent ionization constant" K' of equation (6)

$$\frac{[\text{Proton acceptor}]}{[\text{Proton donor}]} = \frac{K'}{(H^+.H_2O)} \qquad (6)$$

It was virtually with this approximate relation, applied to each of a large number of systems, that the subject was first outlined. We shall use it for the same purpose, but it should be noted that the following comments involve approximations and that more elaborate treatments must be sought in texts.

Equation (6) suggests the fundamental reason for the widespread interest in determining the activities of hydrogen ions in aqueous solutions.

A particular proton donor will have properties that differ from those of its corresponding acceptor. Manifestation of the one or the other set of properties will depend, of course, on the amount of the respective substance, or, per unit volume, on the molar concentration, but the relative degree of manifestation will depend on ratios such as those defined by statements (7) and (8).

$$\frac{[\text{Proton acceptor}]}{[\text{Proton acceptor}] + [\text{Proton donor}]} = \alpha \qquad (7)$$

$$\frac{[\text{Proton donor}]}{[\text{Proton acceptor}] + [\text{Proton donor}]} = 1-\alpha$$

By (6), (7) and (8) one obtains (9)

$$\frac{\alpha}{1-\alpha} = \frac{K'}{(H^+.H_2O)} \qquad (9)$$

Thus, the degree to which the proton acceptor predominates, as expressed by α, is determined by the value of K', which is characteristic of each system in given circumstances, and by the hydrogen ion activity of the solution. When, for example. $K' = (H^+.H_2O)$, $\alpha = 0.5$, or, in other terms. half of the proton donor has been transformed to the corresponding acceptor. Even in solutions so complicated that it is impracticable to determine every set of proton donor and acceptor, control of the hydrogen ion activity will establish certain ratios for all pairs of these substances. This may be favourable or detrimental to complicated processes, such as the growth or metabolism of bacteria or of any of the innumerable organisms in sea water that are directly exposed to this environment. Control of $(H^+.H_2O)$ is indispensable when a particular proton donor, or its corresponding acceptor, is to be brought into prominence for any one of innumerable purposes.

Although in alkaline solutions the transfer of protons to water molecules is so little that the concentration of hydrogen ions might be regarded as of doubtful physical significance and the response of devices such as the hydrogen electrode might be regarded as due to direct transfer of protons to the electrode from proton donors, it is customary to postulate a hydrogen ion activity for all cases. Indeed, from a purely thermodynamic point of view, the postulation of the hydrogen ion as the intermediate is quite legitimate. This leads to the consideration of hydrogen ion activities ranging in values from. say, 10 to 1×10^{-14}. It is inconvenient to plot relations with this large range of values. In 1909 S. P. L. Sørensen used the function $-\log [H^+]$ and designated it by the symbol pH. Later he and others recognized that $-\log [H^+]$ should be replaced by $-\log (H^+.H_2O)$ and accordingly the modern interpretation of pH is often stated to be the "negative logarithm of hydrogen ion activity." There remains a small uncertainty in estimating a hydrogen ion activity so that pH numbers as ordinarily used are somewhat arbitrary.

If this be understood, we may proceed with the conveniences provided by the following definitions.

$$\text{pH} = -\log (H^+.H_2O) \qquad (10)$$

$$\text{pK}' = -\log K' \qquad (11)$$

By (9), (10) and (11) we reach equation (12)

$$\text{pH} = \text{pK}' + \log\frac{\alpha}{1-\alpha} \qquad (12)$$

If α be plotted as abscissa and pH as ordinate, one obtains the

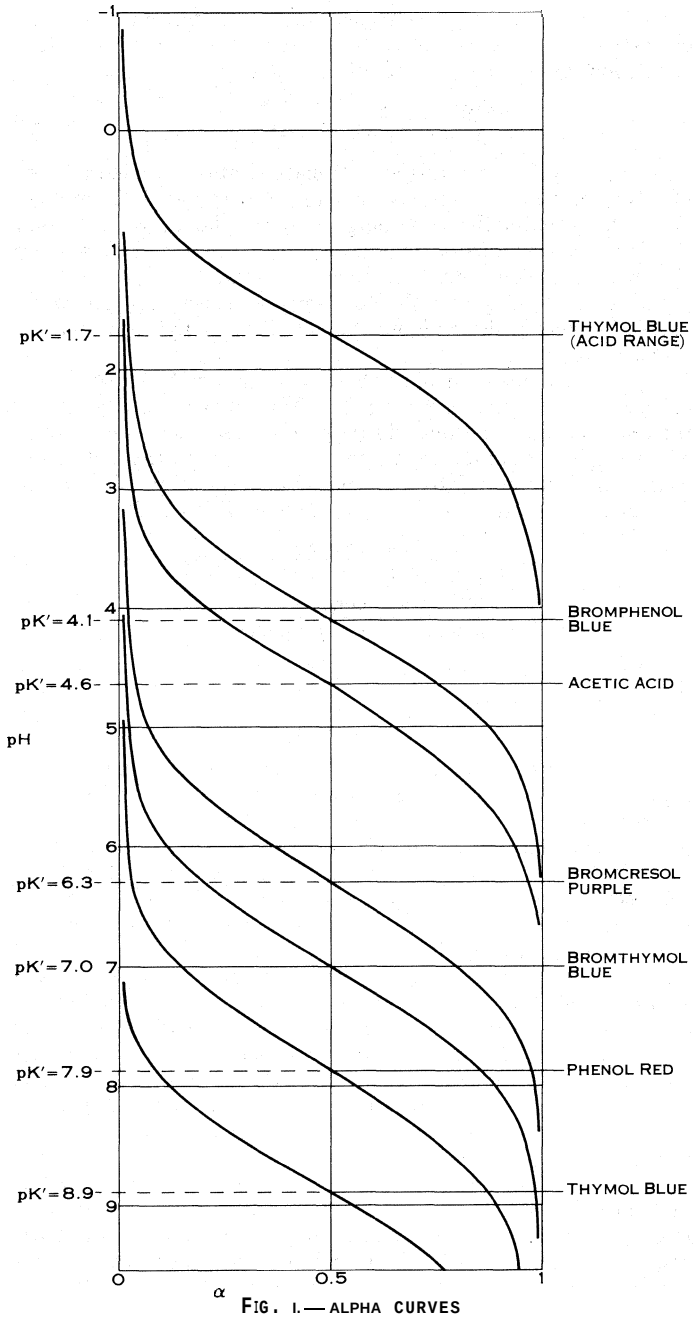


FIG. 1.—ALPHA CURVES

Relation of pH to the degree of transformation of proton donor to conjugate proton acceptor in systems of specified values of pK'

family of symmetrical curves shown in fig. 1, the position of each curve being determined by the value of pK' which is characteristic of each system under the conditions where pK' applies. The mid-point of each curve ($\alpha=0.5$) falls where $pH = pK'$. If the value of pK' is known and pH is measured, one can estimate the degree to which a particular proton donor has been transformed to the conjugate acceptor. The estimate may be made by calculation or by reading values on a carefully drawn curve such as one of those in fig. 1.

Water itself forms both hydrogen ions and hydroxyl ions, $O\bar{H}$, by the process $2H_2O \rightleftharpoons H^+.H_2O + O\bar{H}$. The equilibrium expressed in classical terms is:

$$\frac{[H^+.H_2O][O\bar{H}]}{[H_2O]^2} = k_w$$

At the limiting condition where water is the only constituent, $[H_2O]$ is a constant so that we then have the so-called ionic product of water expressed by (13).

$$[H^+.H_2O][O\bar{H}] = K_w \qquad (13)$$

For present purposes one may neglect the activity coefficients that would have to be applied to make a similar equation valid for ordinary conditions and one may use the approximate value 1×10^{-14} for the value of the "apparent" constant K'_w. Then the hydrogen ion concentration would appear to be equal to the hydroxyl ion concentration $pH = 7.0$. This is a convenient "equator" with which to demark "acid" solutions from "alkaline" solutions. If it be desired to calculate the activity of hydroxyl ions from measured values of pH, an equation similar to equation (13), but properly modified to include the values of activity coefficients for the conditions used, provides the means of calculation.

If attention be confined to simple cases, such as mixtures of an acid and its sodium salt, one can state in simple form some principles that are widely applicable. For this purpose let typography be simplified by using H^+ as the symbol of $H^+.H_2O$. Let HA represent a neutral proton donor, such as acetic acid, and A the conjugate acceptor, the anion of a simple acid. Assume a sodium salt. such as sodium acetate, to be completely ionized in aqueous solution. For a mixture of the acid and its sodium salt define:

$$S = [HA] + [A^-] \qquad (14)$$

$[A^-]$ being the concentration of anions arising from ionizations of both acid and salt, and $[HA]$ being the concentration of the acid that remains unionized. The solution must be electrically neutral. Hence:

$$[Na^+] + [H^+] = [A^-] + [O\bar{H}] \qquad (15)$$

Equations (14), (15) and (6) may be combined to give equation (16).

$$\frac{(H^+)([Na^+] + [H^+] - [O\bar{H}])}{S - ([Na^+] + [H^+] - [O\bar{H}])} = K' \qquad (16)$$

For many purposes it is unnecessary to do more with this equation than make certain approximations. Suppose, for example, in making the solution such an amount of acid and its sodium salt were used that $S = 0.1$ and $[Na^+] = 0.5$ "molar." Suppose also that a crude estimate places the value of $[H^+]$ between 1×10^{-3} and 1×10^{-4} "molar." By use of the value $K'_w \cong 1 \times 10^{-14}$ a crude estimate of the value of [OH] would be that it is between 1×10^{-11} and 1×10^{-10} "molar." Then equation (16) reduces to:

$$\frac{(H^+)[Na^+]}{S - [Na^+]} \cong K' \qquad (17)$$

But $[Na^+]$ is equivalent to the stoichiometrical concentration of salt and $S - [Na^+]$ is equivalent to the stoichiometrical concentration of acid used in making up the solution. Hence

$$pH \cong pK' + \log \frac{[Salt]}{[Acid]} \qquad (18)$$

If in equation (16) $[Na^+] = 0$, that is if the acid alone is present, $[O\bar{H}]$ usually will be negligible in the sum $[H^+] - [O\bar{H}]$ so that equation (16) reduces to:

$$\frac{(H^+)[H^+]}{S - [H^+]} \cong K' \text{ or practically to } \frac{(H^+)^2}{S - (H^+)} \cong K' \qquad (19)$$

For a weak acid the value of $S - (H^+)$ is little different from the value of S so that:

$$pH \text{ approximates } 0.5\ pK' - 0.5 \log S \qquad (20)$$

With the approximations of equations (18) and (20) one can calculate roughly the course taken by pH during the titration of a weak acid by a standard solution of an alkali. More reliable, however, are so-called titration curves obtained by plotting values of pH measured at successive intervals during stepwise addition of alkali, pH being plotted against equivalents of added alkali. Such curves are illustrated in figs. 2 and 3.

Buffer Action.—It will be noted in fig. 1 that the curves do not have as great a slope near the mid-points (where $\alpha=0.5$) as they do near the asymptotes. The flatter sections of these alpha curves correspond roughly to the flatter sections of the

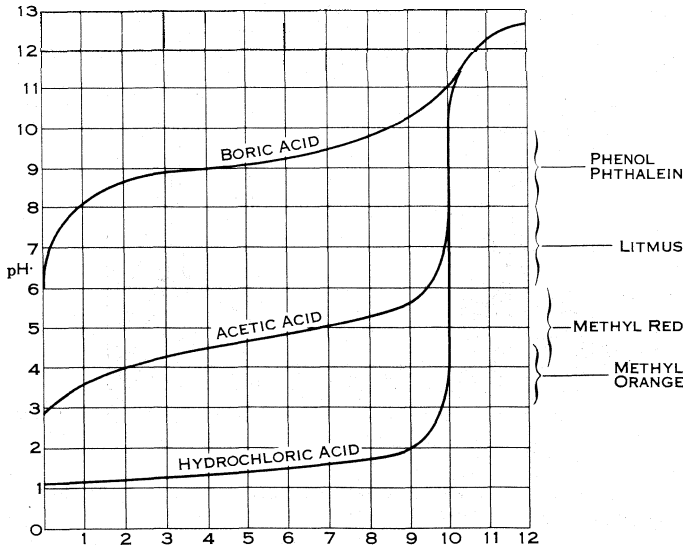

FIG. 2.— TITRATION CURVES OF THREE ACIDS SHOWING BUFFER EFFECTS. THE LIMITED RANGES OF SUCH EFFECTS AND THE DIFFERENT pH-VALUES ATTAINED AT THE EQUIVALENCE POINT

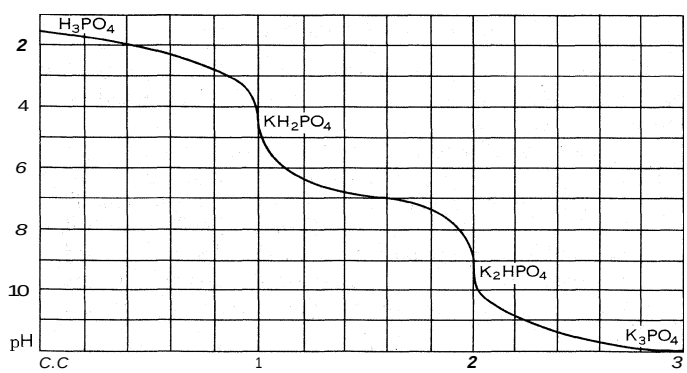
respective titration curves of the weaker acids *(see* fig. 2*)*. In other words a variable degree of stabilization of pH is associated with a mixture of a proton donor and its conjugate acceptor, the stabilization being the more pronounced the greater their concentrations and usually the nearer the ratio of concentrations approaches unity. Stabilization also occurs at each end of the pH scale where, at the one extreme. hydrogen ions as well as the conjugate proton acceptors. water molecules, are abundant. and at the other extreme where hydroxyl ions as proton acceptors as well as the conjugate donors. water molecules. become abundant. This partial stabilization of pH is called buffer action. Systems providing buffer action are called buffers. Some are used as standards of pH for the determination of pH by the indicator method (see *Indicators of* pH, below) or as solutions with which to standardize the glass electrode (see Glass *Electrode*, below). Buffers serve to condition the environments of living cells and to control innumerable chemical reactions. In the titration of an acid with a standard solution of an alkali, such as NaOH, it is necessary to know that pH at which there have been added the number of equivalents of alkali equal to the number of equivalents of acid in the original solution. This pH is called the equivalence point or end point. The calculation is simple in those cases in which both acid and alkali are completely ionized as in the case of HCl and NaOH in water. For example, when HCI is titrated by NaOH the law of electroneutrality requires:

$$[H^+]+[Na^+]=[Cl^-]+[O\bar{H}] \qquad (21)$$

$[Cl^-]$ is equivalent to the number of moles of HCI originally used,



FROM 'THE DETERMINATION OF HYDROGEN IONS" BY W. MANSFIELD CLARK (WILLIAMS AND WILKINS COMPANY)

FIG. 3.— TITRATION CURVE OF PHOSPHORIC ACID

Abscissa: equivalents of alkali per mole H_3PO_4

per litre of the solution as the solution exists at the end of the titration. $[Na^+]$ is equivalent to the number of moles of NaOH used. per litre of solution as the solution exists at the end of the titration. At the equivalence point $[Cl^-]=[Na^+]$. Hence $[H^+]=[O\bar{H}]$. Therefore, if activity coefficients be neglected, the equivalence point in this particular case is approximately at pH = 7.0 *(see* equation [13]).

In the titration of a "weak" acid, one that is only partially ionized. the equivalence point may be calculated with approximations adequate for ordinary purposes as follows. In equation (16) introduce the condition for the equivalence point that $[Na^+]=S$ *(see* equation [14]). The numerator of equation (16) then becomes $(H^+)(S+[H^+]-[OH])$ and the denominator becomes

$$-[H^+]+[O\bar{H}] \text{ or } -[H^+]+\frac{K'_w}{[H^+]} \qquad (22)$$

Usually S is so much larger than $[H^+]-[O\bar{H}]$ that the numerator closely approximates (H^+) S. If we now assume (H^+) to approximate $[H^+]$, a little algebraic manipulation will lead to equation (23):

$$pH=0.5\ pK'+0.5\ pK'_w+0.5\ \log\ (S+K') \qquad (23)$$

or, when S is much greater than K',

$$pH=0.5\ pK'+0.5\ pK'_w+0.5\ \log\ S \qquad (24)$$

Examples:

S molar	pK′	pH of eq. point	S molar	pK′	pH of eq. point
0.1	3.0	8.0	0.1	5	9.0
0.01		7.5	0.01		8.5

The greater the value of pK′ the greater will be the pH of the equivalence point and the nearer an overlap of the titration curve with the curve obtained on addition of NaOH to water. Therefore, in titrating small quantities of a weak acid the volume is kept as small as possible and a microburette is used to deliver alkali of relatively high titre.

Much the same sort of calculation may be used in making a rough estimate of the equivalence point in the titration of ammonia, for example, by a standard solution of HCl. In such cases the equivalence points for various conditions will be at pH values less than 7.0.

The pH of the equivalence point is indicated by the colour of a suitable indicator. In this use of an indicator consideration is given to the fact that in most of the ordinary titrations a large change of pH occurs near the equivalence point. Thus, in the titration of HCI with NaOH, as one equivalent of NaOH per equivalent of HCl is approached the addition of a very small fraction of one equivalent of NaOH causes a large change of pH. At pH values in the region near 6, phenol red will remain yellow. From that point an extremely small fraction of one equivalent of alkali is needed to reach pH 7.0 and within the interval phenol red will exhibit a readily detected, partial colour change. Likewise, if pH 8.5 is to be the equivalence point in the titration of a weak acid. phenolphthalein will remain colourless until this equivalence point is approached and will exhibit a partial transformation to the red form at pH 8.5.

Advanced treatises should be consulted for more elaborate treatments including those dealing with various sources of error.

Indicators of pH.—An indicator of pH is a substance capable of existing in solution as a proton donor and conjugate proton acceptor at least one of which forms absorbs visible radiant energy so that it may be distinguished by the eye. Usually an indicator is employed at a concentration so low as not to affect seriously the pH of buffered solutions.

The degree of transformation, α, of an indicator from a particular form as proton donor to the conjugate acceptor is related to the pH value of a solution by an "alpha curve" such as those shown in fig. 1.

Some indicators can form two sets of conjugate proton acceptor and donor. Such is the case in each of the sulfon-

ephthaleins. At low pH (near pH 0) each exhibits a colour change distinct from that observed in passing through a region of higher pH.

Inasmuch as a particular indicator will exhibit change of form over a limited range, or over limited ranges. of pH, as defined by its alpha curve, or curves, it is necessary to have a series of indicators for each of the various purposes.

There are two principal uses of indicators of pH. One is to determine the pH of a solution whatever it may be: the other to detect that particular pH called the equivalence point for the titration of a particular acid with a standard solution of an alkali or the equivalence point in the titration of a proton acceptor (such as NH_3) with a standard solution of an acid.

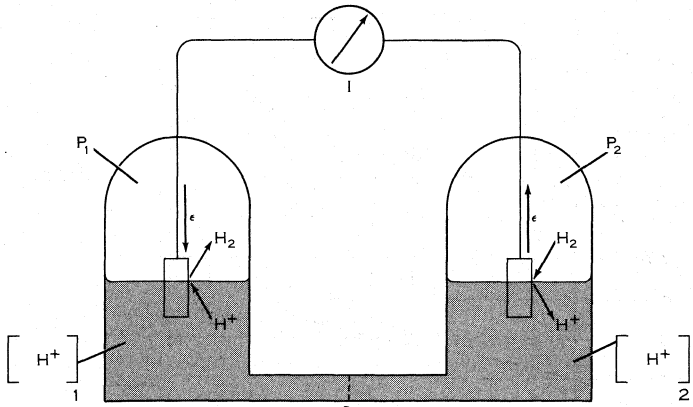
The simplest of several methods for the determination of pH with indicators is the following. It is necessary to select that indicator which shows a definite and appreciable degree of transformation when added to the solution under test. A suitable indicator having been selected by preliminary trials, one prepares a few buffer solutions having pH values within the expected range, the pH values differing by 0.2 pH unit or 0.1 pH unit. Tables giving the composition and pH values of standard buffer solutions are given in various treatises. Apportion equal volumes of these buffers in test tubes of the same internal diameter. To each of these buffer solutions and to the same volume of the tested solution in a tube of the selected. uniform bore, add precisely the same volume of the same stock solution of indicator. Illuminate compared tubes equally. When a tested solution and a standard solution have the same appearance (the same colour to a normal eye) the degree of transformation, a, of the indicator will be the same in both solutions provided no change of indicator takes place other than change between proton donor and proton acceptor forms. If the colour of the tested solution is intermediate between the colours of two standards, a judgment can be made of the standard that should match. It usually is presumed that the pH values of tested solution and standard are the same when a colour match is found. However, such a presumption would be based on equation (9) and, as noted in developing this equation, the apparent constant, pK′, includes a ratio of activity coefficients. These coefficients will vary with the salt content of the solution. Hence pK′ may not be the same in standard and tested solutions if the compositions differ considerably. The difference of pH associated with the same value of α is often called the "salt error." Among other sources of error are the combination of an indicator with proteins, precipitation by various agents and the superposition of the natural colour of the tested solution. Compensation for the latter can sometimes be made satisfactorily by devices described in texts.

Use of indicators to determine equivalence points in titrations has been noted briefly above. in the section Buffer Action.

Hydrogen Electrode (Hydrogen Cell).—A hydrogen cell is an electric cell which is conveniently regarded as made up of two half cells (see fig. 4). Each half cell contains an electrode of a noble metal, such as platinum, coated with platinum black or palladium black as catalyst. Each electrode dips into a buffer solution which maintains a constant activity of the hydrogen ions and the solution is brought into equilibrium with some definite partial pressure, **P,** of hydrogen. The process occurring at the interface between electrode and solution is one of oxidation-reduction, specifically that represented by $2H^+ + 2\epsilon \rightleftarrows H_2$ where ϵ represents an electron. This reversible process is catalyzed by the platinum, or palladium black. Postulation of the intermediate $H^+.H_2O$ will not affect the final result, if attention is confined to water solutions.

If the two solutions are joined directly there may be a large liquid junction potential. When a solution saturated with respect to KCl is interposed, the liquid junction potential is reduced to an uncertain value which is small and is frequently neglected. We shall, for the moment, neglect this junction potential.

The hydrogen at an electrode serves as an electron donor and the hydrogen ion as an electron acceptor. If the partial pressures of the hydrogen are the same in both half cells, that solution having the greater activity of hydrogen ions will have the greater



FROM "THE DETERMINATION OF HYDROGEN IONS" BY W MANSFIELD CLARK (WILLIAMS AND WILKINS COMPANY)

FIG. 4.—A HYDROGEN CELL. SCHEMATIC

L. Liquid junction (see text)
I. Current indicating instrument when cell is allowed to operate. Should be replaced by potentiometer when measurements are made

tendency to withdraw electrons from the metal of the electrode. Therefore the terminal of this electrode will be positive relative to the other. Consequently if the electrodes are joined by a wire, electrons will flow from the electrode in the solution of lesser hydrogen ion activity to that in the other solution, through the wire. To allow this to happen would violate the condition of maximal work under which condition the difference of potential between electrodes will be maximal. Therefore this potential difference is balanced by the oppositely oriented potential difference of a potentiometer both for the purpose stated above and to measure the potential difference between the electrodes (see INSTRUMENTS, ELECTRICAL MEASURING).

There are several ways of formulating the relation between the activities of the hydrogen ions in the half cells and the electromotive force of the cell. The following is based on the use of J. Willard Gibbs's chemical potential as extended to electrons and on the thermodynamic relation between the chemical potential, μ_A, of any substance A and the activity **(A)** of that substance; *i.e.*,

$$\mu_A = RT ln(A) + \mu_{0A} \qquad (25)$$

where μ_{0A} is a constant, dependent only on temperature and pressure, and is the value of μ_A when **(A)** = 1.

For the oxidation-reduction process

$$2H^+ + 2\epsilon \rightleftarrows H_2$$

there will subsist a comparable relation between chemical potentials. Distinguish by primes and double primes the cases for half cells 1 and 2, respectively

$$2\mu'_{H+} + 2\mu'_\epsilon = \mu'_{H_2} \qquad (26)$$

$$2\mu''_{H+} + 2\mu''_\epsilon = \mu''_{H_2} \qquad (27)$$

By (26) and (27):

$$\mu'_\epsilon - \mu''_\epsilon = 1/2(\mu'_{H_2} - \mu''_{H_2}) - (\mu'_{H^+} - \mu''_{H^+}) \qquad (28)$$

The difference of electron chemical potentials must be distinguished sharply from electrostatic difference of potential or electromotive force. E.M.F.

If chemical potentials are defined in terms of free energy per equivalent. $\mu'_\epsilon - \mu''_\epsilon$ has the dimensions of energy per equivalent and can be expressed in volt-faradays **EF.** Now when the E.M.F. of the cell is balanced by that of the potentiometer there is equality of the chemical potentials of the electrons in adjacent phases between which there is no passive resistance to electron transfer. Therefore the potential difference, **E,** measured at the potentiometer is given by $\frac{\mu_\epsilon - \mu_\epsilon}{\mathbf{F}}$. On the right of (28) substitute (25) in appropriate form for each item. Thus is obtained (29).

$$\mathbf{FE} = RT ln \frac{\sqrt{(H_2)'}.(H^+)''}{\sqrt{(H_2)''}.(H^+)'} \qquad (29)$$

For the ratio of proton activities in equation (29) there may be substituted the ratio of hydrogen ion activities. but to simplify typography we may let H^+ represent the hydrogen ion of a water solution. With no serious error, the ratio of the partial pressures of hydrogen, P' and P'', may be substituted for the ratio of the activities of hydrogen and we have (30).

$$\mathbf{E}=\frac{RT}{\mathbf{F}}ln\frac{(H^+)''}{\sqrt{P''}}-\frac{RT}{\mathbf{F}}ln\frac{(H^+)'}{\sqrt{P'}} \qquad (30)$$

The normal hydrogen half cell is defined as the hydrogen half cell where the partial pressure of hydrogen is one normal atmosphere and the hydrogen ion activity is 1. This is the half cell to which all other half cells are referred in systematic accounts. Therefore it is convenient and agreed that the single potential difference between electrode and solution of the normal hydrogen half cell shall be called arbitrarily zero at all temperatures.

Accordingly we shall regard the half cell identified in (30) by single primes as the normal hydrogen half cell and we shall consider E of (30) as if it were the potential of the other hydrogen half cell. To designate this system of comparison $\mathbf{E}_h$ will be used in place of E. Then:

$$\mathbf{E}_h=\frac{RT}{\mathbf{F}}ln\frac{(H^+)}{\sqrt{P}} \qquad (31)$$

The following values of R and **F** were selected by J. W. M. DuMond and E. R. Cohen (*Rev.* Mod. Phys., 25:691 [1953]):

R (gas constant) = 8.31439 absolute volt-coulombs/degree gram equivalent.

F (faraday) = 96,494 abs. coul./deg. g. equiv.

And according to a report of the National Research Council Committee on Physical Constants (issued July 1, 1949):

T (degrees Kelvin) = t (° C.) + 273.16.

The modulus for converting a logarithm with base e to the corresponding logarithm with base 10 is 2.30258j. Hence

$$\mathbf{E}_h=0.00019840T\ \log_{10}\frac{(H^+)}{\sqrt{P}} \qquad (32)$$

According to the derivation of the coefficient in this equation $\mathbf{E}_h$ should be expressed in absolute volts and not in international volts, as was the custom prior to Jan. 1, 1948 (see Circular of the National Bureau of Standards, C459 [1947]); 1 absolute volt = 0.99967 international volt.

If $P=1$ atmosphere and $t=25°$ C.

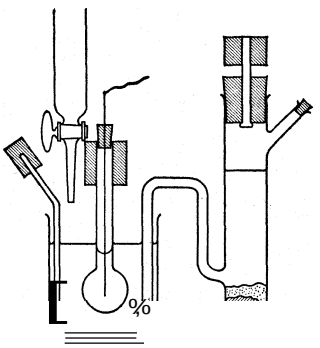
$$\mathbf{E}_h=-0.059156\ \text{pH}$$

A difficult problem is that of establishing either the conditions under which the activity of the hydrogen ions is unity as demanded in the use of the primary. standard, hydrogen half cell or a definite hydrogen ion activity in any other half cell used as a secondary standard. The difficulties are fundamentally two aspects of the same problem, that in the use of any process in which two kinds of ions are concerned it is impossible to determine experimentally the individual activity coefficients. Thus. if two hydrogen half cells are joined in liquid junction, with or without the intervening saturated solution of KC1 customarily used to reduce the potential difference at the liquid junctions. the calculation of a junction potential with the highest precision requires knowledge of the individual activity coefficients of all diffusing ions. Invaluable data can be obtained regarding solutions of HCl, for example, by the use of a cell without liquid junction, one electrode responding to the activity of the hydrogen ions and the other (such as the silver-silver chloride electrode) responding to the activity of the chloride ions. But then it is necessary to use the mean activity coefficient for these two sorts of ions. In practice it is convenient to use a "saturated calomel half cell" in place of one of the hydrogen half cells, the potential of this half cell having been determined by using a solution of known pH in the hydrogen half cell. The saturated calomel half cell is one in which the solution is saturated with KCl and Hg_2Cl_2 (calomel) and the electrode is mercury.

For precise measurements with a hydrogen cell many items of technique must be given attention.

Glass Electrode (Cell with Glass Membrane).—This is an amazingly successful device for the measurement of pH. It has been developed so largely by empiricism that its theoretical treatment will be left to advanced treatises. The description that follows outlines a method used in practically all laboratories concerned with aqueous solutions and in plants concerned with control of many industrial processes.

The cell with glass membrane may be used with solutions that cannot be studied with the hydrogen electrode. These include solutions containing substances that poison the catalyst of a hydrogen electrode or substances easily reduced. While special provisions must be made in measuring with the hydrogen electrode solutions containing CO_2, no special provisions are necessary with the glass electrode other than prevention of loss of CO_2. Coloured solutions, the pH of which cannot be measured well by the indicator method, present no special difficulty.



REPRINTED BY PERMISSION FROM M. DOLE'S "THE GLASS ELECTRODE" (JOHN WILEY AND SONS, INC.)

FIG. 5.—A CELL WITH GLASS MEMBRANE IN BULB FORM

On the other hand, it must be appreciated that the method is essentially one of comparison between solution tested and a series of solutions standardized by hydrogen electrode measurements. Therefore, the precision depends primarily upon reproduction of the standards. There are also factors other than a difference of hydrogen ion activities that affect the glass membrane; in particular other cations have an effect that is prominent in alkaline solutions. Furthermore, the very high electric resistance of a cell with glass membrane makes necessary both a special null-point instrument in the potentiometry of such a cell and special precautions by the user of the instrument.

In fig. 5 a special cell containing a glass membrane is represented diagrammatically. The corresponding conventional statement of constitution is:

$$\underset{a}{Ag}\ |\ AgCl(s).HCl\ (0.1\ M)\ |\ \underset{b}{\text{Glass membrane}}\ |\ \underset{c}{\text{Solution x}}\ |\ \underset{d}{KCl\ (sat.)}\ |\ \underset{e}{Hg_2Cl_2}\ |\ Hg$$

Up to b there is a silver electrode, coated with silver chloride, immersed in a 0.1 molar solution of hydrochloric acid.

On the right is a mercury electrode overlaid by solid calomel and a solution saturated with potassium chloride. The latter is in contact with solution x. A thin glass membrane separates solution x from the 0.1 M HCl solution. In fig. 5 this membrane is the thin wall of a bulb blown with a special glass.

Although the only difference of potential made aware of by experiment is that between the silver and mercury electrodes which is to be measured by a potentiometer, it is reasonable and convenient to assume potential jumps at *a*, *b*, c, *d* and *e*. With well-prepared electrodes. a given glass membrane and constant temperature, the potential jumps at *a*, b and *e* are constant. We may assume also that the liquid junction potential at d is practically a constant. At least it will be usually the same as that involved in the measurement of the pH of a standard by the hydrogen electrode method when such a standard is placed in the position of solution x. But if solution x be very different in nature from the standards, a new error may be introduced.

With the above assumptions, the variable potential jump at *c* is found to be a function of the pH of solution x. Indeed, the remarkable fact is that with special glasses and in the pH range of about 1 to 9 the potential difference across the glass membrane varies as

$$\frac{RT}{\mathbf{F}}ln\frac{(H^+)_1}{(H^+)_2}$$

where $(H^+)_1$ is the activity of the hydrogen ions on one side of the membrane and $(H^+)_2$ is the activity of the hydrogen ions on

the other side of the membrane.

Accordingly, for the cell illustrated, there is usually a linear relation between the E.M.F. of the cell and the pH of solution x and the slope of the line relating E.M.F. to pH is

$$\frac{\Delta \text{E.M.F.}}{\Delta \text{pH}} = 0.05916 \text{ at } 25^\circ \text{ C.}$$

or other appropriate values at other temperatures. Individual glass membranes may not give such a relation exactly'and may change in behaviour from time to time.

TABLE I.—Standard Buffer Solutions. Values of pH
(M = molar. *See* original references for values at other temperatures)

Solution	pH		
	10° C.	25° C.	38° C.
0.05M K tetroxalate	1.67*	1.68*	1.70*
KH tartrate, satd. at 25° C.	—	3.56*	3.54*
0.05M KH phthalate	4.00*	4.01*	4.03*
	—	4.010†	4.025†
	—	4.000‡	4.015‡
0.025M KH_2PO_4, 0.025M Na_2HPO_4	6.92*	6.86*	6.84*
	—	6.855†	6.835†
0.01M $Na_2B_4O_7$	9.33*	9.18*	9.08*
$Ca(OH)_2$, satd. at 25° C.	13.00§	12.45§	12.055

*Standard values recommended by the National Bureau of Standards. For original references *see* R. G. Bates, *Electrometric pH Determinations* (1954).

§Bates, Bower and Smith, *J. Res. Natl. Bur. Standards*, 56:305 (1956).

For this reason, and because the method is essentially comparative and secondary. it is wiser to rely upon standardization with standard buffer solutions than to depend upon the above "ideal" relation. To this end. each of a series of standard buffer solutions is placed in turn at the position of solution x, the E.M.F. of the cell is measured and the values of E.M.F. are plotted against the corresponding values of pH supplied in the specifications of the standard buffers. (See Table I.) Then. on testing an unknown, the observed E.M.F. of the cell will give on the line chart the value of pH. If the standard values of pH lie on a straight line, interpolation by calculation may be made. Under these conditions, the pH is given by the operational definition

$$\text{pH}_x = \text{pH}_s + \frac{\mathbf{E}_x - \mathbf{E}_s}{0.059156} \text{ at } 25^\circ \text{ C.} \qquad (33)$$

where x and s refer to solution x and the standard buffer solution, respectively. The national bureau of standards in Washington, D.C., supplies certified materials for the preparation of the standard buffer solutions.

Particularly in alkaline solutions the potential becomes a function not only of pH but also of the concentration of other cations such as Na^+.

There have been several systematic studies of the relation of the compositions of glasses to the behaviour of glass electrodes. Several satisfactory glasses are available commercially. The bulb form illustrated in fig. 5 is the most frequently used but with certain modifications to lower electrical leakage around the thin glass membrane. The bulb form is especially convenient because the silver-silver chloride electrode and hydrochloric acid solution (or other electrode-solution pair) may be placed on the inside and the standard or test solution on the outside.

By reason of the high electric resistance of the glass membrane, a galvanometer usually cannot be used directly as null-point instrument in the potentiometry of these cells.

Accordingly, in commercial instruments for the potentiometry of cells with glass membrane the electron valve is nearly always used to amplify the extremely small currents which flow at imbalance. A common glass electrode p~ meter is shown in fig. 6.

HYDROGEN PEROXIDE is a compound composed of hydrogen and oxygen. the formula for the molecule being H_2O_2. It was discovered in 1818, and in dilute solutions has been a familiar product since the turn of the 20th century, but high concentrations were considered too unstable to be practicable until World War II, when new techniques of storage and handling were developed. Hydrogen peroxide was used as a propellant for the launching of Germany's V-I missile; it has been a factor in postwar rocket experiments; and it has been used as the oxidant in a propellant mixture for submarines. Important industrial applications have also been found.

Hydrogen peroxide is of special interest in a comparison of its properties with those of water, because of its chemical relation to oxygen and water, because of the diverse reactions it undergoes and because of the numerous catalytic phenomena encountered in a study of these reactions. It is seldom prepared in the pure state. for in this condition mechanical shock or contact with many kinds of matter can result in violent explosion by decomposition. It is ordinarily handled as a solution in water, for in this state its sensitivity is much reduced.

The pure substance is a colourless liquid of melting point −0.9° C., and of density 1.442 g. per cubic centimetre at 25° C. It is considerably less volatile than water, its vapour pressure at 25° C. being 2.0 mm. as compared to 23.7 mm. for water. Hydrogen peroxide decomposes before the normal boiling point is reached. but by an extrapolation using measurements of its vapour pressure at lower temperatures, the normal boiling point has been estimated to be 151.4° C. The latent heats of vaporization and of fusion are 326 calories per gram and 79 calories per gram. respectively. The dielectric constant of hydrogen peroxide is 73.6 at 20° C. which is almost as high as that of water. As might be expected from the high value of the dielectric constant hydrogen peroxide is also a strongly dissociating solvent. Many simple salts are dissolved by the liquid and are highly dissociated in the resulting solution. Water and hydrogen peroxide are miscible in all proportions. A solid of composition $H_2O_2.H_2O$ and melting point −51° C. can be separated from the solution on lowering the temperature.

Speculation about the structure of hydrogen peroxide has been abundant, but reasoning based on purely chemical data has not led to a unique assignment of structure. However, by a combination of physical methods it has been shown that in the hydrogen peroxide molecule the oxygen atoms are directly bonded to each other, with one hydrogen atom on each oxygen atom. The molecule is not linear, but the line from a hydrogen atom to an oxygen atom makes an angle of about 100° with the line joining the two oxygen atoms. Furthermore. the hydrogen atoms do not lie in a single plane with the two oxygen atoms, but the plane defined by one hydrogen atom and the oxygen atoms makes an angle of about 100° with the plane defined by the other hydrogen atom and the oxygen atoms.

Uses of Hydrogen Peroxide and Its **Derivatives.**—Most applications of hydrogen peroxide exploit the properties it possesses as an oxidizing agent. It is a powerful oxidizing agent but is sufficiently slow so that the rate of its oxidizing action can conveniently be controlled by adjusting the conditions. Furthermore. water, the product resulting from its reduction, is not a harmful ingredient in most processes.

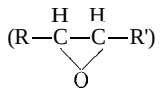
Hydrogen peroxide has been used in the bleaching of wool, silk, linen. furs, hair and hair products and fats. The bleaching action on animal fibres is particularly important, since such fibres

sustain less damage from the action of hydrogen peroxide than from other moderately priced oxidizing bleaches. The substance has also been applied as a preservative and as a disinfectant, since it possesses strong bacteriocidal properties. Many of the derivatives of hydrogen peroxide also are used as bleaches.

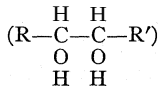
Peroxyhydrates of sodium carbonate. sodium borate and sodium phosphate are used in pharmaceutical, cosmetic and laundry preparations.

The use of peroxides as catalysts for polymerization reactions has become of great importance. Their catalytic property depends on the fact that on decomposition. or reaction with some reducing agents. unstable substances are formed which readily attack the molecules to be polymerized. Benzoyl peroxide. acetyl peroxide and peroxydisulfates have been used extensively for this type of reaction. Hydrogen peroxide and its derivatives find use in synthetic organic chemistry. for example, in converting a double bond grouping

to an epoxy grouping



or in hydroxylating it to form



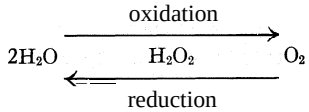
Such reactions are of importance in the chemistry of fats, waxes, terpenes and steroids.

Important developments in the use of hydrogen peroxide as a propellant appeared during World War II. The reaction $2H_2O_2 \rightarrow 2H_2O + O_2$ is exothermic. the decomposition to water vapour and oxygen of 1 g. of liquid hydrogen peroxide yielding *c.* 380 calories of heat. This reaction, catalyzed by manganese salts, was used by the Germans during World War II as a source of energy for the launching of the V-1 missiles.

The heat of reaction of hydrogen peroxide with combustible materials is greater than that of the corresponding reactions of oxygen. With methyl alcohol for example, the heat of the reaction $CH_3OH + 3H_2O_2 \rightarrow CO, + 5H_2O$ is greater than that of the reaction $CH_3OH + 3/20, + CO, + 2H_2O$ by a factor of 1.2j. This suggests the use of hydrogen peroxide as the oxidizing component of combustible mixtures, particularly where conservation of space is important. Such applications also began to be developed during World War II.

Chemical Properties. — Hydrogen peroxide possesses weakly acid character, and a metal peroxide such as barium peroxide: BaO_2, may be regarded as the salt of the acid H_2O_2 and the base $Ba(OH)_2$. In a 1% solution in water, only about 0.0003% of the hydrogen peroxide is dissociated to hydroperoxide ion. HO_2^-, and hydrogen ion. The tendency of H_2O_2 to dissociate does, however, exceed that of water. Besides the metal peroxides mentioned above, many other derivatives of hydrogen peroxide, in which the oxygen to oxygen link is maintained, are known. Some of these derivatives will be discussed below.

Hydrogen peroxide represents an intermediate stage for the transformation of oxygen to water, and for the reverse transformation. This observation is fundamental to an understanding of a large class of the reactions of the substance. The scheme below indicates the relationship of hydrogen peroxide to oxygen and to water.



The scheme also serves to illustrate the application in this system of the general terms oxidation and reduction (*q.v.*). For example, the transformations of water to hydrogen peroxide or to oxygen by the action of suitable reagents are described as oxidations of water. Agents which bring about the oxidation or the reduction of another substance are called oxidizing or reducing agents. respectively. On mutual interaction. the oxidizing agent is reduced and the reducing agent is oxidized. From its relation to water and to oxygen, it may be seen that hydrogen peroxide can function as an oxidizing agent (that is, on interaction with a reducing agent it is transformed to water) and that it can also function as a reducing agent, for on interaction with an oxidizing agent it is transformed to oxygen. This dual role which is readily displayed by the substance, makes its chemistry of unusual interest.

Hydrogen peroxide is a fairly powerful reducing agent and is much more powerful than water in this respect. The oxidizing agents chlorine, ceric salts and potassium permanganate (the last named being used in acid solution) readily oxidize hydrogen peroxide to oxygen, but the oxidation of water by these substances is slow. The reaction with potassium permanganate in acid solution may be used as a basis for the quantitative determination of hydrogen peroxide,

$$5H_2O_2 + 2MnO_4^- + 6H^+ = 2Mn^{++} + 5O_2 + 8H_2O.$$

As an oxidizing agent, hydrogen peroxide is very powerful, more powerful in fact than are oxygen and chlorine. The oxidations by hydrogen peroxide of metal iodides to iodine, of sulfites to sulfates and of ferrous salts to ferric salts, proceed readily even in dilute solution. The reaction in acid solution with potassium iodide is the basis of another method for the quantitative determination of hydrogen peroxide, $H_2O_2 + 2I^- + 2H^+ = 2H_2O + I_2$. When the hydrogen peroxide is concentrated, the oxidation of organic or other reducing substances can proceed as a combustion process and indeed with explosive violence.

Many of the reactions of hydrogen peroxide with even powerful oxidizing or reducing agents are slow, and interesting and diverse cases of catalysis are observable in these systems. For example, the rate of reduction of hydrogen peroxide by iodides is markedly accelerated by strong acids. by iron and copper salts, by soluble molybdates as well as by many other substances. The few substances named represent what are probably three essentially different modes of action for catalysts in this system. Catalysts for the reaction of hydrogen peroxide with certain reducing agents occur also in plant extracts and in blood. and are called peroxidases.

Hydrogen peroxide is unstable mith respect to decomposition into water and oxygen: $2H_2O_2 \rightarrow 2H_2O + O_2$. This reaction may be regarded as a self oxidation-reduction of hydrogen peroxide. So great is the tendency for the decomposition that in order to reverse it at room temperature a pressure of oxygen above a 1% solution of hydrogen peroxide in water in excess of 10^{30} atm. would have to be applied. Hydrogen peroxide exists only because the speed of decomposition under suitably chosen conditions is small. Most important of these conditions is the absence from the sample of catalytic impurities.

The catalysts which enhance the speed of decomposition of hydrogen peroxide are numerous and diverse in nature. Most surfaces increase the rate of decomposition noticeably. Among the more effective ones are the following: some metal surfaces, of silver, gold or platinum, for example, particularly if freshly deposited in a finely divided condition; some solid metal oxides, lead dioxide and manganese dioxide being examples. Accidental impurities such as dust are also catalytically active. Among soluble catalysts for the decomposition are iron and copper salts, particularly a mixture of the two, bromides and iodides under special conditions and alkaline substances. Catalase, an enzyme nhich occurs in plant and animal tissue, is also a catalyst for the decomposition. It has been suggested that an important function of catalase in living tissue is to bring about the destruction of the hydrogen peroxide which forms nhen oxygen is reduced by some substances during the metabolic processes. The effervescence observed when a solution of hydrogen peroxide is applied to a wound is a result of the liberation of oxygen on catalytic decomposition of the solution.

An increase in temperature or absorption of light by the substance also increases the rate of decomposition of hydrogen peroxide.

In many cases the mode of action of the catalysts which function in solution seems to involve both oxidized and reduced forms of the added substance. A schematic representation of the steps involved is given below. X and R stand, respectively, for the oxidized and reduced forms of the catalyst.

$$X + H_2O_2 \rightarrow R + O_2$$
$$R + H_2O_2 \rightarrow X + 2H_2O$$

The net result of the two steps is catalytic decomposition of the hydrogen peroxide, and it is evident, since there is no net consumption of the added substance, that a small amount can bring about the decomposition of large amounts.

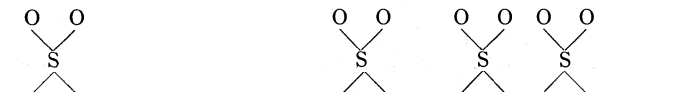
Preservation and Handling.— Hydrogen peroxide has commonly been sold dissolved in water at strengths of about 3% to 30%. Large quantities of a more concentrated product, about 90% or so in hydrogen peroxide, began to be produced at the time of World War II. The handling and storage of the unstable substance utilizes the fact that at room temperature or lower the decomposition of even the concentrated solution proceeds slowly in the absence of catalytic impurities and of light. Solutions of the lower strength are often stabilized by the addition of inhibitors; that is, catalysts which decrease the rate of reaction. A wide variety of substances function as inhibitor.' for the decomposition. One class including many mineral acids functions by keeping the solutions acid. Sodium silicate belongs to a class which functions also in basic solution. Acetanilide is a commonly employed representative of a large class of organic compounds which probably function by destroying catalysts for the decomposition which are produced by the decomposition itself.

The choice of container material is important for the handling and storage of all strengths, and particularly of the concentrated solutions. Containers of specially treated aluminum, block tin or pyrex glass have been used for the 90% solution, and these containers as well as those of ordinary glass or ceramic materials for handling solutions of lower strength.

Preparation and Manufacture.—From the relation of hydrogen peroxide to water its preparation by direct oxidation of water might be expected. No appreciable concentrations of hydrogen peroxide, however, have been built up by reactions of this type. This observation can be correlated with the fact that hydrogen peroxide is both a more rapid and more powerful reducing agent than is water, so that an oxidizing agent which oxidizes water will oxidize hydrogen peroxide even more rapidly, and thus prevent its accumulation in the system.

Production by the Electrolytic *Method.*—The direct oxidation of water to hydrogen peroxide at an anode during electrolysis is vitiated by the process mentioned above, as well as by catalytic decomposition of the substance at the electrode surface. Some derivatives of hydrogen peroxide, from which it can be prepared readily, are not so sensitive to these influences. Such derivatives do appear at high concentration when an appropriate solution is subjected to anodic oxidation, and they are thus used as intermediates in the electrolytic method for manufacture of hydrogen peroxide.

Peroxydisulfates have most commonly been employed as such intermediates. The relation of hydrogen peroxide to peroxydisulfuric acid is indicated by the structural equation below:



Peroxydisulfuric acid

The oxidation of sulfuric acid to peroxydisulfuric acid at the anode has been investigated in some detail, and the following conditions are found favourable for efficient oxidation: shiny platinum as anode material, relatively high current density at the anode, cooling below room temperature and a moderate rather than high or low concentration of sulfuric acid. The presence in the electrolyte of certain substances, among which are hydrogen fluoride and potassium ferricyanide, is found to be beneficial. These substances exert an influence even at low concentration, and probably function by changing the catalytic effect of the electrode surface, so that oxidation to peroxydisulfate rather than to oxygen occurs in the solution. Acidified solutions of ammonium sulfate and of potassium sulfate are also oxidized to peroxydisulfate with high current efficiency.

Other operational features which lead to successful commercial practice are as follo s: All materials must be of high purity to minimize decomposition of hydrogen peroxide during the concentration process. Ammonium bisulfate, potassium bisulfate and sulfuric acid are most often used as electrolytes. To prevent mixing of the anode and cathode solutions, the electrolytic cell is divided into anode and cathode compartments by the use of an unglazed porcelain diaphragm. A battery of electrolytic cells can be arranged to allow continued circulation of anode and cathode solution. This prevents local heating in the cells and leads to a cyclic rather than batch operation of the process.

Hydrogen peroxide is obtained from peroxydisulfates by the reaction with water: $H_2S_2O_8 + 2H_2O \rightarrow 2H_2SO_4 + H_2O_2$. This reaction proceeds with reasonable speed at temperatures of 60° C. or higher, if the solution is fairly acid. Hydrogen peroxide vapour mixed with water vapour is obtained from the heated anode liquor by evaporating the solution, these substances being much more volatile than other components of the solution. To minimize decomposition of hydrogen peroxide at the moderately high temperature of the evaporation step it must be carried out rapidly. One way of effecting this is to allow the anode liquor to flow in a thin film down a heated surface, thus exposing a large area of surface for unit volume of liquid.

Concentrated solutions of hydrogen peroxide can be prepared by introducing the mixed vapours of water and hydrogen peroxide into a fractionating column. Hydrogen peroxide, being less volatile than water, accumulates in the lower part of the column.

To manufacture concentrated solutions of hydrogen peroxide it is necessary to reduce the concentration of catalysts for the decomposition. This can be done by repeating the evaporation step before the final fractionation of the solution is undertaken.

Production by Methods Involving Reduction of Oxygen.—When barium oxide is heated at 500° or 600° C., it absorbs oxygen to form barium peroxide. On treatment with a suitable acid, hydrogen peroxide is obtained from this solid: $BaO_2 + H_2SO_4 \rightarrow BaSO_4 + H_2O_2$. This was the principal commercial process before the electrolytic method was developed. Several modifications have been attempted, differing from each other chiefly in the choice of acid. which in turn influences the method used for regeneration of barium oxide from the spent solid. Sulfuric acid has most often been employed, and in this case it is found desirable to convert the barium peroxide to its hydrate. $BaO_2 H_2O$, preliminary to the acid treatment. Unless this is done, a coating of barium sulfate over the solid prevents complete reaction of the barium peroxide. L. J. Thénard, who in 1818 first proved the existence of hydrogen peroxide. made use of the barium peroxide method in his preparation of the substance.

Sodium forms sodium peroxide directly on burning in excess air. Potassium, rubidium and caesium under the same conditions yield compounds containing oxygen in an oxidation state between that of peroxide and of elementary oxygen. The formulas for these compounds are KO_2, RbO_2 and CsO_2.

The interaction of some reducing agents with oxygen produces hydrogen peroxide directly. This is the case with many organic compounds. For example, the reduction of oxygen by hydrazobenzene to form hydrogen peroxide proceeds almost quantitatively. Hydrogen itself can be used as the reducing agent. Some hydrogen peroxide is formed when a mixture of hydrogen and oxygen, the former at a low partial pressure, is subjected to a silent electrical discharge, or when a mixture of the gases containing also mercury vapour absorbs ultraviolet light. The combination to hydrogen peroxide proceeds also in water containing finely divided platinum or palladium as catalysts. In slightly acid solution at a mercury cathode. substantial reduction of oxygen to hydrogen peroxide can be achieved if the partial pressure of the gas is fairly high. Efforts have been made to exploit all of these types of reaction for the commercial production of hydro-

gen peroxide. The electrolytic method remained most important in the United States at mid-20th century.

Peroxy Compounds.—The unit of structure containing two oxygen atoms bound together. each of these in turn being bound to other atoms, is present in all true peroxy compounds. Almost all true peroxy compounds yield hydrogen peroxide when treated by a strong acid such as sulfuric acid, and this fact can be used to distinguish substances containing the peroxide linkage from others of similar formula, which do not. Thus, barium peroxide, BaO_2, but not lead dioxide. PbO_2, forms hydrogen peroxide on being subjected to the test. The study of the structure of the solids using X-ray methods substantiates the conclusion that only the former is a true peroxide.

Peroxy compounds may be considered derivatives of hydrogen peroxide. and they can be classified conveniently by developing the analogy betneen peroxy compounds and similar simple oxy compounds. The analogous structural units in the two systems are indicated below:

Peroxy compounds	*Oxy compounds*
H—0—0—H	H—O—H
R—O—O—H	R—0—H
R′—O—O—R	R′—O—R

It is seen that the group –O–O– is formally equivalent to –O– and –O–O–H to –0–H.

In the classification below, the common peroxides are considered in their relation to simple oxy compounds.

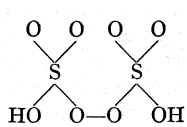
Peroxy *Analogues* of Metal *Oxides* and Hydroxides.—Some well-defined metal peroxides are: Na_2O_2, MgO_2, CaO_2, BaO_2, ZnO_2. There is evidence also for the existence of peroxides of copper mercury and other metals. These substances are solids at room temperature. the solid being compoied of the positively charged metal ions and the negatively charged peroxide ion, $O_2^{=}$.

Among the metal hydroperoxides NaOOH is the peroxy analogue of NaOH. The distinction between this class and the members of the class of the peroxy analogues of the oxyacids is not always sharp, just as a definite classification of a substance as being an acidic or basic hydroxide cannot always be made. Metal peroxides and hydroperoxides are strong oxidizing agents. Some of them, Na_2O_2 for example. react rapidly with water to yield hydrogen peroxide (which decomposes rapidly since the solution becomes basic); others require a strong acid to bring about the reaction.

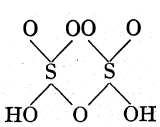
Peroxy Analogues of Oxyacids or *Their* Salts—The peroxides in this class are related to the oxyacids by replacing an –0–H group of the oxyacid by the group –O–O–H. Well-defined examples of such peroxy compounds are peroxymonosulfuric acid, H_2SO_5, peroxymonophosphoric acid, H_3PO_5, and peroxyacetic acid $CH_3CO.OOH$. Other members are derived from chromic, molybdic, tungstic, vanadic, columbic, tantalic, carbonic and germanic acids. from the hydroxides of tin, titanium, zirconium. thorium. cerium, uranium and from many organic acids. The peroxide derivative of titanium hydroxide has a deep yellow colour and is the basis of a qualitative test for the presence of hydrogen peroxide in water solution.

Some of the foregoing examples are known only as the peroxy derivatives of the salts corresponding to the acids. It is of interest to note that the –O–O–H group in the peroxy compounds is in general not so acidic as the –0–H group in the related oxy compound. All the members of this class are powerful oxidizing agents, and most of them oxidize iodides to iodine more rapidly than does hydrogen peroxide. The catalysis of the reaction between hydrogen peroxide and iodides by soluble molybdates probably results from the rapid formation of a peroxymolybdic acid, which in turn rapidly oxidizes iodides.

Peroxy Analogues of Pyroacids or of *Pyrosalts*.—A single example is cited to establish the analogy:



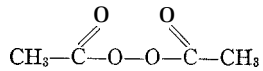
Peroxydisulfuric acid



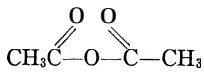
Pyrosulfuric acid

Another member of this class is peroxydiphosphoric acid, $H_4P_2O_8$. Salts of these peroxides exist, examples being $K_2S_2O_8$ and $Na_2C_2O_6$. On hydrolysis. members of this class yield the corresponding peroxymonoacid in the first step. All are powerful oxidizing agents. but are not readily oxidizable.

Peroxy *Analogues* of Acid Anhydrides.—The chemical properties are similar to those of the preceding group, except that the compounds do not possess acid properties.



Acetyl peroxide



Acetic anhydride

Benzoyl peroxide is a second common example of this class.

Peroxy *Analogues* of Alcohols, Ethers and *Other* Oxy Organic Compounds.—Some examples, with oxy analogues, are:

CH_3OOH	CH_3OH
Methyl hydroperoxide	Methyl alcohol
$CH_3—O—O—CH_3$	$CH_3—O—CH_3$
Dimethyl peroxide	Dimethyl ether

The analogy extends to many other compounds but is not complete in every case, since in a few instances the oxy analogue of a known peroxide is not known. Most members of this group are strong oxidizing agents, and in common nith other organic peroxides many are dangerous to handle in the pure state, because of the possibility of explosive decomposition initiated by shock.

Peroxy *Analogues* of Hydrates.--In these compounds, hydrogen peroxide is incorporated into crystals of various substances in the same way that nater is incorporated into hydrates. The substances in this class when dissolved in water yield a solution of hydrogen peroxide and the carrier substance, and they thus provide a convenient means of handling hydrogen peroxide. Examples are: $Na_2SO_4.9H_2O.H_2O_2$ and $Na_3PO_4.2H_2O_2$.

HYDROGRAPHY, the science dealing with all the waters of the earth's surface, including the description of their physical features and conditions; the preparation of charts showing the position of lakes. rivers, seas, the contour of the sea bottom, the position of shallows, deeps, reefs and the direction and volume of currents; a scientific description of the position. volume, configuration, motion and condition of all the waters of the earth. See also OCEAN AND OCEANOGRAPHY. The hydrographic department of the British admiralty, established in 1795, makes charts for the admiralty, and is under the hydrographer to the admiralty. The corresponding hydrographic office in the United States was established in 1866 in connection nith the bureau of navigation in the navy department. (See CHART.)

HYDROLOGY is the science which treats of the occurrence, quality and effects of water on the land areas of the earth. It deals aith snow and ice on the land, liquid water in streams and lakes and water occurring in the interstices of soil and rock. Meteorology (*q.v.*) and oceanography (see OCEAN AXD OCEANOGRAPHY) are related sciences. Various aspects of hydrology are discussed in the separate articles: DROUGHT; FLOOD; GLACIER; RAINFALL; SNOW, etc. In addition to the references to related material given in the several sections of this article, see also GEOCHEMISTRY: Geochemistry of the Hydrosphere; GEOLOGY; GROUXD WATER; SOIL.

Hydrologic Cycle.—The central concept in hydrology is the hydrologic cycle. Water evaporated from the oceans is carried over the continents by moving air masses and precipitated as rain or snow. About one-third of this water returns to the oceans as surface streamflow or subterranean percolation. The remaining two-thirds is returned to the atmosphere by evaporation or by transpiration of plants. The energy of the sun thus serves to distill sea water and distribute the resultant fresh water over the land to supply the needs of plants, animals and man.

This fresh water is not, however, delivered continuously to all

parts of the world at a rate commensurate with local needs. Desert areas receive little or no water, while some other regions receive far too much. Even in areas where the normal precipitation is adequate. there may be prolonged periods of drought or periods when excessive precipitation causes floods. The hydrologist seeks to predict the probable magnitude of droughts and floods and the amount of water available for use in a specific area. He may also make short-term forecasts of floods and water supply for the operation of reservoirs and for emergency flood protection. The science of hydrology is, therefore, basic to planning of projects for reducing flood damage, developing water power. controlling erosion and providing adequate water for domestic, agricultural and industrial use.

Origin of Hydrologic Concept.—The source of the waters of springs and streams constituted a puzzling problem that early aroused much discussion and controversy. Before the 17th century it was generally assumed that the spring water could not be derived from rain because the rainfall was believed inadequate in quantity and the earth too impervious to permit penetration of the rain water far below the surface Some ancient philosophers assumed that the water nas derived from huge. inexhaustible, subterranean reservoirs, but others recognized that there must be replenishment of the reservoirs which supply the springs Thus arose the concept of a hydrologic cycle in which the sea water was supposed to be conducted through subterranean channels below the mountains and then, somehow. purified and raised to the springs. In the middle ages this hypothesis was based on passages in the Bible such as Eccles. i, 7, and for centuries it was heresy to doubt it.

It is now known that the ground water. which supplies the springs. wells and fair-weather flow of the streams. is derived from rain and snow by infiltration from the surface. except a minor part which is juvenile water derived from the hot magma within the earth. Among early champions of the infiltration theory mere the Roman architect Marcus Vitruvius. who lived about the time of Christ, the Italian artist and sage Leonardo da Vinci (1452–1519) and the French potter and pioneer paleontologist Bernard Palissy (1510–89).

The founders of the science of hydrology may be considered to be the French physicists Pierre Perrault (1608–80) and Edmé Mariotte (*c.* 1620–84) and the English astronomer Edmund Halley (1656–1742). First Perrault and then Mariotte made crude measurements of the precipitation in the basin of the Seine river and of the discharge of the river, and thus demonstrated that water which falls as rain and snow is ample to supply the flow of the river. Mariotte also made observations which showed that rain water penetrates the earth Halley made careful tests of the rate of evaporation and crude estimates of runoff, from which he concluded that the evaporation from the Mediterranean sea is ample to supply the inflow from streams.

Precipitation.—Water is always present in the atmosphere as an invisible gas (water vapour). Under favourable conditions this vapour condenses into droplets of water or ice crystals, forming clouds and ultimately rain or snow. If all the moisture in the atmosphere were precipitated it would cover the earth to an average depth of only about one inch However, a continued inflow of moisture-laden air into a storm area may result in precipitation of more than 40 in. in 24 hours The intensity of precipitation, the annual amount and the seasonal distribution vary greatly from place to place and from time to time in a given place. The causes of these variations are the subject matter of meteorology, but their effects on the regimen of surface and underground water create the basic problems of hydrology.

Amounts of precipitation are expressed in terms of the depth in inches or millimetres nhich would accumulate on a flat surface if none of the water nere allowed to run off. The simplest rain gauge consists of a cylindrical vessel surmounted by a funnel of larger diameter so that the depth in the cylinder is multiplied for more accurate measurement. A variety of patterns are used with the funnels ranging from 3 to 8 in. in diameter.

Snon constitutes only a minor portion of the precipitation on the norld as a whole, but in frigid zones and at high altitudes snow may be the most common form of precipitation. The snow pack accumulated in mountains adjacent to arid or semiarid regions may constitute a natural reservoir far larger than any built by man. The melting of this mountain snow during spring and early summer is often an important source of irrigation water. In many such regions snow surveys are conducted to determine the water content of the snow pack as a basis for forecasts of water yield to the adjacent valleys. The water content is determined by extracting a core of snow with a special sampling tube and weighing the tube and the snow core.

Glaciers.—Where snowfall is too heavy and the climate too cold for all of the snow to melt in summer, there is a progressive accumulation until glaciers are formed which creep down the valleys and move into warmer zones, where their fronts are melted off or are pushed into the sea. forming icebergs. Records have been kept of the annual advance or retreat of the ice fronts of many glaciers, especially in the Swiss Alps beginning in 1874. Photogrammetric maps are made of certain glaciers in the Alps, and these show the volumetric changes from year to year.

Various sources of information show that within historic times there were important cycles of advance and retreat, indicating cycles of climatic fluctuation. There was general advance from about 1600 to about 1850, and general retreat after that time. In the Pleistocene epoch (*q.v.*), covering approximately 1,000,000 years, there were four great glacial stages, when the northern parts of Europe. Asia and North America were covered with ice which at some places was thousands of feet thick. In those cold stages so much water was locked up in ice that sea level all over the earth went down a few hundred feet below the modern level. However, there is still so much ice in the polar and mountain regions that if it should all melt, the sea level would rise about 200 ft.

Runoff.—As rain falls to the earth a portion is intercepted by the leaves and stems of vegetation and eventually returned to the atmosphere by evaporation. Still another portion is retained in puddles on the ground surface. Part of this water may infiltrate into the soil but the greater portion is usually evaporated. Much of the remaining water which reaches the ground infiltrates into the soil under the action of gravity and capillarity. The infiltration capacity of soils varies greatly. Water will infiltrate more rapidly into dry soil than into moist soil. Sandy soils are more pervious than clay soils. while broken lava and cavernous limestone terranes are highly permeable. Forests and grasslands usually have a higher infiltration capacity than cultivated soils because cultivation destroys the channels created by decayed roots and by worms, and because the vegetal cover protects the soil from compaction by raindrops. The infiltration capacity of rock outcrops, paved surfaces, buildings, etc., is practically zero. Some of the infiltrated water is absorbed by the soil as soil moisture. When the soil moisture is replenished, water moves laterally through the soil toward the streams and downward toward the ground water. Only when rainfall intensity exceeds infiltration capacity does surface runoff or overland flow occur.

The quantities of water which are distributed to interception, puddles, soil moisture. lateral flow, surface runoff and ground water vary greatly from storm to storm depending on many factors. A key problem in hydrology is to determine the relations governing this distribution, so that it is possible to predict the quantity of inflow to the streams from a given storm for the determination of designs for reservoir spillways, culverts and storm drains and for flood forecasting.

Ground Water.—The term ground water is applied to water found in zones of saturation in the ground where all interstices between soil or rock grains are filled with nater. Soil or rock strata which are sufficiently permeable to yield useful quantities of water to wells are called aquifers. The upper surface of the zone of saturation is called the water table. Artesian aquifers are covered by a stratum of impermeable material and the confined water is under pressure so that it will rise in a well to a level above the top of the aquifer and may even discharge at the ground surface without pumping. Where the water table intersects streams, lakes or swamps, ground water is discharged and becomes surface water. A spring occurs when the water table intersects the ground surface.

Movement of ground water is extremely slow and years or even centuries may elapse between the time a particle of water is added to the ground water and the time it is discharged from the ground water.

Under natural conditions a ground-water basin will remain in approximate equilibrium with the water table rising slightly during wet periods and falling during droughts. When man withdraws ground water through wells this equilibrium is disturbed, A major problem in hydrology is to determine the amount of water which may be withdrawn annually from a ground-water basin without depleting the supply to such an extent that use of the water becomes uneconomical. Where large ground-water reserves exist it may be permissible to mine them in the same sense that other minerals are mined. but this must be recognized in estimating the safe yield. Water level in key wells is observed periodically or recorded continuously by automatic gauges to provide data on changes in ground-water storage. The ground water may be artificially recharged by introduction of surface water through percolation areas or recharge wells. In many areas ground-water basins are operated as reservoirs (*q.v.*) in the same manner as (and sometimes in conjunction with) surface reservoirs. *See* also SPRINGS; WELL.

Evapotranspiration.— Water in lakes and streams, soil moisture and snow on the ground is subject to evaporation. Soil moisture is also subject to transpiration, the process by which plants take up moisture through their roots and discharge it to the atmosphere through their leaves. The total of these water losses from an area is called evapotranspiration. Estimates of probable evapotranspiration from cropland serve as a basis for determining the need for irrigation water. Evaporation loss from lakes and reservoirs in arid regions may amount to as much as ten feet of depth per year. This loss can be an important factor in determining the amount of water which the reservoir can supply for beneficial use. Hydrology is concerned with land management for maximum water yield and therefore is interested in minimizing nonbeneficial evapotranspiration. Evapotranspiration by forests and grassland is a beneficial use of water insofar as the vegetation produces timber or livestock feed and protects the soil from erosion. Brush and stream bank or swamp vegetation may utilize large amounts of water without benefit to man.

There is no method for direct measurement of evaporation from lakes or evapotranspiration from land areas. The evaporation from small tanks of water can be measured, but these measurements must be adjusted to provide estimates of loss from natural water bodies. Potential evapotranspiration can be measured by determining the water loss from tanks filled with soil, planted with vegetation typical of the area and supplied with sufficient water to satisfy the needs of the plants. Actual evapotranspiration from the adjacent area will be less than the measured loss from the tank to the extent that the natural water supply for plant growth is deficient during some parts of the year.

Streamflow.— The aater in surface channels is known as streamflow and for the most part is ultimately discharged into the ocean. Some streams flow in closed basins from which there is no outlet, and their flow is ultimately evaporated or percolated to the ground water. Streams flowing entirely above the water table may lose much or all of their flow to the ground water if the stream bed is sufficiently permeable. Data for annual maximum water level on the Nile river at Cairo, Egy., are reasonably complete from AD. 622 except for the 16th and 17th centuries. However, the earliest systematic measurements of daily discharge of a stream were those on the Rhine river at Basle, Switz.. from 1809 to 1821.

Records of streamflow are usually obtained by periodic measurements of the velocity of flow with a current meter. The cross-sectional area of the stream multiplied by the measured velocity vields the flow rate. The discharge at each such measurement is correlated with the stage (water level) at the time of measurement to obtain a stage–discharge relationship. Continuous records of stage are then obtained by automatic, float-operated recorders, or frequent readings of water level are obtained from a scale set in the stream. The rate of flow at any time or the volume of streamflow for any period can be calculated from this stage record by use of the known relation between stage and flow.

In arid regions streams commonly go dry during rainless periods, while in humid regions dry-weather flows are usually small and derived largely from ground water. In response to rainfall or snowmelt the flow rate increases to a maximum and then decreases when the rain or melting ends. The response of small basins or basins with steep topography is usually very rapid. the peak relatively high and the duration of the response relatively short. Large basins or basins with flat terrane. many lakes or highly permeable soils will show slow increases. relatively low peaks and a slow decline following the peak. Many such increases of streamflow occur each year in most streams but only occasionally does the peak flow exceed the capacity of the stream channel causing a flood.

Much study has been given to the many factors which determine the magnitude and expectancy of floods and droughts. The flood history of streams that have been gauged over a long period of years may be analyzed by statistical methods to determine expectancy. Because of the difficulty of defining a drought precisely. statistical analysis of drought is less successful. Extremes of flow on ungauged streams must be estimated from physical analysis and comparison with similar streams. Despite the geologic evidence of long-term climatic changes, indications are that within the time periods of interest in most engineering designs, extremes of flow may be considered as random processes governed by chance and not subject to cyclic variation.

Water Quality.——Much of the energy of falling raindrops and flowing water is expended in erosion of soil and rock. The impact of raindrops has been shown to be important in initiating soil erosion. Vegetal cover shelters the soil from this impact and thus reduces erosion. Water in streams erodes the bed and banks, carving canyons and forming flood plains. Erosion is a natural process which has created arable valleys and fertile deltas which are important agricultural areas. However, cultivation and other activities of man may accelerate erosion of valuable topsoil, which may ultimately fill useful storage space in downstream reservoirs or clog stream channels. Hydrology is concerned with finding means of minimizing erosion on the land and with estimating the quantity of sediment carried by streams. This requires study of the mechanics of erosion of land surfaces. the influence of various protective measures on the erosion rate and the mechanics of sediment transport in flowing water. The quantity of suspended sediment in a stream is measured by lowering a sampler into the stream to extract a sample of sediment-laden water. The sample is filtered to remove the sediment, which is dried and weighed to determine the concentration of sediment in the sample. The total volume of streamflow multiplied by the concentration ratio yields the total sediment transport.

Sediment is not the only material transported by water. Most natural waters contain dissolved minerals of various kinds derived from the mineral constituents of the rocks and soil of the drainage basin. Some minerals are undesirable in water which is used for irrigation, domestic or industrial purposes. Hence, chemical analysis of natural waters is part of the task of hydrology. These analyses are used to predict the limitations on use of the water and the steps necessary to make its use possible. Chemical analysis of ground water may help in establishing its source.

HYDROLYSIS: *see* SOLUTIONS.

HYDROMECHANICS, the branch of applied physics that deals with the equilibrium and motion of liquids, most commonly water, and with the behaviour of bodies floating or immersed in liquids. Hydromechanics finds application in widely diverse problems ranging from the design of submarines and ocean liners to the study of motion of naval torpedoes. Hydromechanics includes hydrostatics. which is the study of liquids at rest; hydraulics, which is concerned with the properties, behaviour and effects of liquids at rest or (usually) in motion (see HYDRAULICS, APPLIED);

and hydrodynamics. which is concerned with the motion of liquids and the interaction of liquids with boundary surfaces.

Liquids (*e.g.*, water) and gases (*e.g.*, air) are known collectively as fluids. The properties and actions of fluids are determined essentially by the behaviour of the molecules of which they are composed, the major difference between liquids and gases being that in the former the molecules are spaced more closely together (see LIQUID STATE, THE). Because of this similarity of molecular structure, many of the laws governing the mechanics of liquids are identical to those governing the mechanics of gases, and the growing field of study known as fluid mechanics includes both theoretical analyses and experimental results that are applicable to fluids in general (see MECHANICS, FLUID).

HYDROMEDUSAE, an obsolete term for marine animals, particularly jellyfish, of the class Hydrozoa (*q.v.*), phylum Coelenterata (*q.v.*).

HYDROMETALLURGY is the science and technology of extracting and recovering metals chemically from ores by the use of aqueous solutions, as distinct from pyrometallurgy which comprises smelting and other similar high-temperature operations. (For discussion of various methods of extracting metals see METALLURGY.) The principles involved in hydrometallurgy are those of physical chemistry, inorganic chemistry, electrochemistry and analytical chemistry: indeed, the production of metals by hydrometallurgy can be broadly described as extensions of these principles on a commercial and economic scale The procedures commonly employed in hydrometallurgical operations represent combinations of the techniques used in mineral dressing, chemical engineering and electrochemical technology.

The operations usually involved are: the dissolution of a metal or metal compound by a suitable lixiviant (water alone or with added reagents) usually termed leaching; the separation of naste and purification of the leach solution; and the precipitation of metal from the leach solution by chemical or electrolytic means.

Developed initially at the turn of the 20th century for recovering gold from low-grade ores the technology of hydrometallurgy has advanced to the point where not only have the earlier techniques been improved but such procedures as ion exchange, solvent extraction, distillation and high-pressure, high-temperature leaching and precipitation have been proved to the extent that they are recognized as conventional operations.

In addition to the cross references to related articles given under the various headings of this article, see also ELECTROCHEMISTRY; ELECTROMETALLURGY; ION EXCHANGE.

Following are the main divisions of this article:

I. HISTORICAL BACKGROUND

Hydrometallurgical processes are used commercially because they are convenient to operate. the recovery of metals is high and operating costs usually are low, and especially because of the variety of quantitative chemical separations that can be made in aqueous solutions much more readily than is possible nith the melts used in pyrometallurgical processes. The importance of these considerations is attested by the fact that hydrometallurgical techniques are used wholly or in part to produce. in commercial form, all but 6 or 7 of the 82 known metallic elements.

Of the metals produced by the use of aqueous solutions, few are converted from ore to pure metal using only hydrometallurgy: usually the "wet" methods are used in combination nith other procedures. Aluminum, for example, is produced by dissolving the ore (bauxite) in caustic soda solution, precipitating aluminum hydroxide from the solution and calcining the hydroxide to produce aluminum oxide which is treated in an electrolytic cell containing fused salts to produce pure aluminum metal. Some zinc sulfide ores are first oxidized at a high temperature to produce zinc oxide which is then dissolved in weak sulfuric acid and the acid solution electrolyzed to produce pure zinc. Simple tin ores are smelted directly. but complex ores are first treated with acid solutions to remove impurities and the remaining insoluble tin mineral is smelted to produce pure metal. Some copper ores are smelted to produce impure copper metal which is then refined by electrolysis in copper sulfate solutions: others are dissolved directly with acid solutions and the copper metal precipitated from the solutions by various means. Nickel and cobalt are produced either by purely hydrometallurgical processes or by combined pyrometallurgical and hydrometallurgical techniques. Much of the world's gold is recovered from ores by dissolution with cyanide solutions from which the gold is subsequently precipitated as metal. The list could be extended to include uranium, vanadium, chromium, rare earths, alkali metals, platinum metals, gallium, indium, germanium, tantalum, the radioactive metals and many others for which chemical techniques employing aqueous solutions are used, either alone or in combination with pyrometallurgy, to produce metals on a commercial scale.

Because the successful operation of hydrometallurgical processes depends so greatly on a knowledge of metal chemistry and of chemical engineering, it is not surprising that wide commercial application is a comparatively recent development. As early as the 16th century ferrous sulfate was produced by slowly oxidizing pyrite (FeS_2) in the open air to form $FeSO_4$, extracting the soluble sulfate with uater and evaporating to crystallize hydrated ferrous sulfate (green vitriol). During the next three centuries copper sulfate (blue vitriol) was produced in a similar manner at Rio Tinto in Spain. where chalcopyrite ($CuFeS_2$) had been mined since early in the Christian era. Some copper metal may have been produced at Rio Tinto and other copper mines from the copper sulfate solutions by precipitation with iron but the amount was negligible, as iron, which was sacrificed to precipitate the copper, was itself difficult to make and hence scarce.

With the increasing knowledge of chemistry and the advancement of chemical technology in the mid-19th century the first important commercial applications of hydrometallurgy were established. A particularly important factor was the development of commercial direct current generators in the 1860s and 1870s which provided for the first time an efficient low-cost technique for precipitating metals by electrolysis from aqueous solutions. The improvements in mechanical equipment such as extraction vessels, liquid-solid separation units and precipitation techniques devised for the treatment of gold ores following the discovery of the cyanide process (*q.v.*) in 1890 provided the full complement of tools required for broad extension of hydrometallurgical methods.

After the beginning of the 20th century methods were improved and were augmented by the addition of still other techniques such as ion exchange, solvent extraction and superatmospheric pressure extraction and metal precipitation. There evolved the great copper-leaching plants in South America, the United States and Africa; vast aluminum extraction plants throughout the world; the electrolytic zinc industry; the plants producing nickel and

cobalt from sulfide ores and from the lateritic deposits in Cuba and other tropical areas; the gold-producing plants of South Africa. Canada, Australia and the United States; and, by no means last. the gigantic plants in many parts of the world that employ hydrometallurgical techniques to extract uranium from ores that contain as little as $\frac{1}{5}$ lb. of uranium in 2,000 lb. of ore.

The exceptional advances that have been scored by hydrometallurgy in the past century can be attributed almost entirely to one factor — the better understanding of the scientific and technologic principles upon which these processes are based. It is not out of the way, therefore, at this point to review briefly the principles and procedures upon which the industry depends.

II. PRINCIPLES AND METHODS

In treating ores, minerals, scrap metals and similar material by hydrometallurgical methods one inescapable fact that must be constantly borne in mind is that because of the endless variety of sources, no two are absolutely identical. Thus every hydrometallurgical process presents a unique problem, which must be solved on the basis of the chemical, physical and economic factors peculiar to the starting material involved.

A second consideration is that. as all hydrometallurgical operations are carried out using water as a solvent, the reactions that can be used are limited by the physical and chemical properties of water. The freezing point of salt solutions represents a minimum temperature boundary; the boiling point is another boundary which. of course. can be extended if reaction vessels are enclosed and operated under superatmospheric pressure. The specific gravity and viscosity of aqueous solutions have an important bearing on the ease of separation of solids from liquids by settling, filtration, centrifuging and other physical means. Of the utmost importance are the solubilities of gases and metal salts in water or other aqueous solutions containing acids, ammonia, caustic soda, bicarbonates and cyanide at different temperatures and in the presence of various solutes.

Chemically, water can combine with certain metal salts to produce hydrated compounds. Also, it can enter into hydrolysis reactions in which it acts as a source of hydrogen ions (H^+) or hydroxyl ions (OH^-) and into oxidation-reduction reactions. In an electrolytic cell water decomposes to form H_2 at a lower voltage than do the dissolved salts of many of the metals, thus restricting the number of metals that can be electrolytically precipitated from an aqueous solution.

A third factor that influences most hydrometallurgical operations is that, as a rule, one of the reactants is a solid metal or compound which is either dissolved by the solutions during leaching or is precipitated from the leach solution by chemical or electrolytic means. Thus some limitations are imposed by the physical character of the solids present — their crystal form, porosity. particle size, surface area, solubility in the aqueous solutions used and, perhaps most important, the character and state of the solid-liquid interface layer, where the actual reaction of dissolution or precipitation takes place.

The feasibility and successful conduct of a hydrometallurgical operation depend on a variety of factors any or all of which may be critical depending on individual circumstances. The very nature of these processes postulates the need for an adequate supply of water and, because metals are present as ions in aqueous solutions, requires that a source of energy be available to convert the ions to metallic form. Beyond these essential features the practical, physical and chemical factors that must be considered are:

1. The metals or minerals that are to be dissolved must be soluble in the leaching solution used and must be accessible to the solution—*i.e.*, not occluded by insoluble constituents.
2. The solvent used must usually be such that it will dissolve selectively the desired metals or minerals leaving the other minerals or metals as an insoluble solid residue.
3. The solution, when it contains valuable metals, should be such that the metals present can be readily separated from one another.
4. The solution must also be such that the desired metals can be precipitated from it by one means or another producing either pure metal, a mixture of metals or a metal salt.
5. For economic reasons, it is usually necessary that the leach solution be capable of being regenerated and used again, or that it be treated to recover by-products: not infrequently by-product recovery from end solutions is an important source of revenue.

The various aspects of hydrometallurgical processes can be illustrated and explained by discussing in some detail the principle involved in each phase of the operation and outlining the procedures commonly used to carry them out in practice.

A. PREPARATION

The ores, concentrates, synthetic sulfides, alloys and other materials that are to be leached in aqueous solutions must be prepared physically and chemically to provide for accessibility of the lixiviant and for dissolution of the desired constituents. The extent of physical preparation required depends almost entirely upon the size of the grains of the mineral present in the ore. In general, it may be said that from the point of view of increasing rate of dissolution, it is desirable to grind the ore particles as fine as possible and thus present the greatest surface area to the lixiviant The advantages to be gained by grinding are limited, however, by the excessive cost of grinding particles to less than about 40 microns in diameter and by the difficulties involved in separating very fine particles from the aqueous solution when leaching is completed If the ore is porous the surface area is usually large and less grinding is required.

Chemical pretreatment, which is quite another matter, is carried out with the object of decomposing the constituents of the ore, concentrate or other materials to render them soluble or insoluble or to increase their porosity and thus permit access of solvent to fine particles that were originally occluded by a dense constituent. A variety of chemical pretreatments in common use are discussed below.

1. Oxidizing Roast. — Sulfide ores of zinc, copper, cobalt and some other metals are oxidized in air at temperatures above 500° C. to produce the metal sulfates or oxides which, unlike the sulfides, are readily soluble in weak sulfuric acid. Ores containing gold in the presence of sulfides such as pyrite (FeS_2) or arsenopyrite (FeAsS) are roasted in air to convert the dense sulfide minerals to porous oxides, thus permitting access of cyanide leaching solution to gold particles which were originally occluded by the sulfides.

By proper control of temperature and gas concentration cobalt and iron sulfide ore, for example, can be roasted to convert the cobalt sulfide to cobalt sulfate and the iron sulfide to iron oxide, thus giving a product from which the cobalt sulfate can be extracted with weak sulfuric acid leaving an insoluble iron oxide residue.

2. Oxidizing Roast With Added Reagents. — The object of this procedure is to convert some of the metal compounds in an ore to soluble form, leaving others as insoluble compounds. Thus residues from pyrite burning which contain small amounts of copper, cobalt, nickel, zinc, gold, silver and other valuable metals are mixed with salt (NaCl) and roasted to convert the valuable metals to soluble chlorides, leaving the iron as an insoluble oxide. Similarly, nickel oxide containing 0.1% sulfur is mixed with a small amount of soda ash (Na_2CO_3) and roasted at 1,200° C.: the soda ash reacts with the sulfur to form sodium sulfate (Na_2SO_4) which can be dissolved with water, leaving sulfur-free nickel oxide.

Also, with ores containing both uranium and vanadium, the vanadium. normally insoluble after roasting, can be rendered soluble by roasting with the admixture of calcium sulfate or salt which converts the vanadium to a soluble vanadate. In the sulfuric acid "bake" (commonly used in preparing ores, flue dusts and similar materials containing copper, cobalt, germanium and other metals for subsequent leaching) the ore is mixed with concentrated H_2SO_4 and baked at relatively low temperatures to produce soluble sulfates of the metals.

3. Nonoxidizing Roast. — Minerals such as pyrite and arsenopyrite when heated to a suitable temperature without access of air are decomposed, the "free" atoms of sulfur and arsenic being volatilized, leaving a residue which resembles pyrrhotite (Fe_nS_{n+1}). In this form they react with solutions of ferric chloride, chlorine. oxygen or other strong oxidizing agents to produce elemental sulfur.

4. Reducing Roast. — The purpose of the reducing roast is to

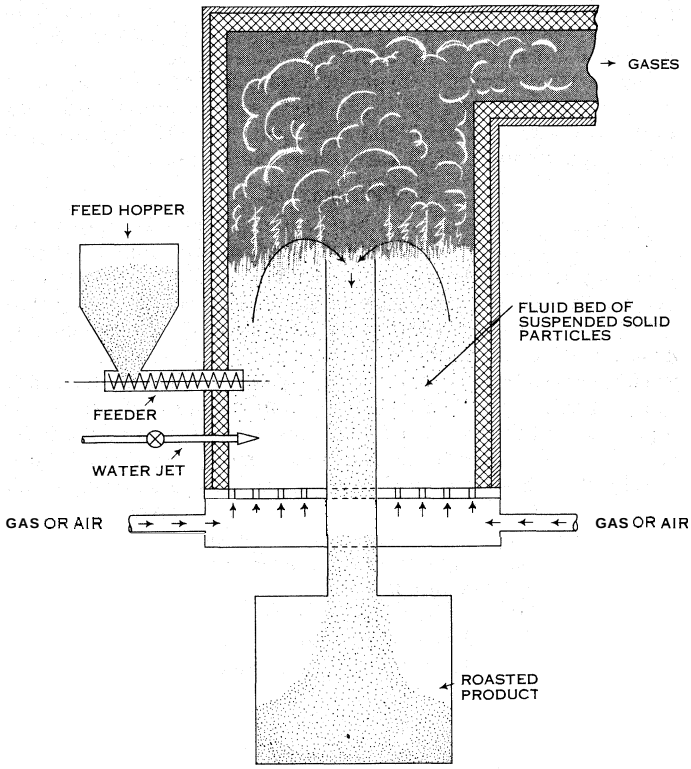

FIG. 1.- -FLUID BED ROASTER

reduce selectively metal oxides to metallic form. Nickel silicate ores, for example, containing magnesia, silica and iron oxide, as well as nickel and cobalt in oxidized form are heated in the presence of reducing gases (H_2 and CO) under such conditions that only nickel and cobalt are reduced to metallic form, the iron, silica and magnesia remaining as oxides. The metallic nickel and cobalt can then be selectively dissolved in oxidizing solutions containing ammonia and ammonium salts.

5. Fusion in Molten Salts. — Refractory minerals of tantalum and columbium are usually insoluble even in the strongest acid or alkaline solutions. It is common practice to fuse these minerals in molten caustic (NaOH) or sodium bisulfate ($NaHSO_4$), thus converting the metals to the corresponding sodium salts (sodium tantalate. columbate, etc.) which can then be dissolved in aqueous solutions, separated and recovered.

6. Technology of Preparatory Methods. — As the principal object of preparatory operations is to provide a product that is chemically and physically adapted to subsequent leaching procedures it follows that the equipment used for this purpose must be such that it can operate effectively and efficiently to give a product with controlled chemical composition, preferably in the form of finely divided, porous particles. In roasting. the temperature and chemical composition of the atmosphere surrounding the particles must be closely controlled.

The units which have been found most efficient and which are commonly used for roasting include the multiple hearth roaster, flat hearth roaster, suspension (flash) roaster and fluid bed roaster.

In the multiple hearth roaster the fine ore or concentrate is charged to the top hearth of a series of six to sixteen superimposed circular hearths each equipped with a raking mechanism. Suitable provision is made for controlled access of air and flow of gases as well as for addition of heat or reducing gases when required. The fine ore follows a zigzag path through the roaster, dropping from hearth to hearth, and is discharged from the bottom hearth.

The flat hearth roaster comprises a single circular or rectangular hearth equipped with raking mechanisms, access doors for air or reducing gases and suitable heating arrangements. In the rectangular furnaces fine ore enters at one end and is raked to the opposite end of the furnace where it is discharged.

In the suspension roaster, dry finely pulverized sulfide ore is mixed with air in a burner and is blown into a large combustion chamber where the sulfides ignite and burn in much the same way as pulverized coal burns in a steam boiler plant. The oxidized particles drop to the bottom of the combustion chamber while the gases are discharged at the top.

In the fluid bed roaster (fig. 1), which is usually circular, a mixture of sulfides and water is injected into a moving fluid bed of gases and oxidized particles kept in motion by a current of air supplied through orifices in the flat bottom of the roasting chamber. The sulfide particles are almost instantaneously oxidized by the gases, the water being evaporated equally rapidly. The heat of combustion of the sulfides maintains the necessary temperature in the roasting chamber. The oxidized particles in the moving bed may be discharged through a pipe placed halfway up the roasting chamber or with the hot gases which leave at the top of the roaster.

Each type of roaster has characteristics that determine its usefulness in hydrometallurgical operations. The multiple hearth unit is usually used where close temperature and gas composition control are not essential; the flat hearth unit is much the same but permits better control of roasting atmosphere. The suspension roaster has the advantage of high capacity, prevention of contact between roasting particles and close control of temperature, but requires the inclusion of extensive dust-handling equipment to recover the dust leaving with the gases at the top of the roaster. Also the mineral fed to the burner must be perfectly dry. The fluid bed roaster accepts very wet feed and gives excellent control of temperature and atmosphere; the output is governed by the volume of air required to maintain proper fluid characteristics in the moving bed; dust handling is an important aspect of operation.

All four types are widely used and have been found efficient in the preparation of fine porous materials chemically suited for hydrometallurgical processes.

. See also FURNACE, METALLURGICAL.

B. LEACHING

The term leaching, which is generally applied to the selective dissolution of metal compounds and minerals from ore mixtures, originated in the soap industry where, in early times, it was common practice to recover caustic potash from wood ashes by mixing the ashes with water and separating the soluble potash from the insoluble ash residue. Such a process, the dissolution of a desired metal compound with water alone, represents the simplest form of leaching. It is apparent, however, that the usefulness of this technique can be greatly extended if reagents such as acids, alkalis and salts are used in combination with the water to form a leaching solution which will convert metals and metal compounds normally insoluble in water to a water-soluble form. This, indeed, forms the basis for the whole hydrometallurgical industry.

Whatever leaching solution is used there are certain factors that affect the rate and efficiency of a leaching process. In the first place, the process involves a reaction between a solid and a liquid which can proceed only by diffusion in the very thin layer of liquid at the point of contact between the liquid and the solid. If, as sometimes occurs, it is also necessary to have present at the solid-liquid interface a dissolved gas, such as oxygen, the solubility of the gas in the leaching solution has an important effect on the rate of reaction. Thermodynamic and kinetic considerations imply that, in the majority of cases, higher temperatures provide increased reaction rates.

1. Reaction Types. — The character of a leaching operation is determined not only by the factors mentioned and the general properties of the leach solution but by the specific type of reaction involved. These types may be classified as follows:

Dissolution With All *Products* Soluble. — The metal compound is completely dissolved by the leach solution and all products of reaction are soluble. A typical example is the dissolution of zinc oxide in sulfuric acid as represented by the equation:

$$ZnO + H_2SO_4 \rightarrow ZnSO_4 + H_2O$$

Simultaneous Oxidation and Dissolution. — The solid metal or mineral must be oxidized and, upon oxidation, is then soluble in

the leach solution, all products of reaction being soluble. Examples are the dissolution of gold in cyanide solution or of uranium in a sodium carbonate solution in the presence of oxidizing agents as follows:

$$2Au + \tfrac{1}{2}O_2 + 4NaCN + H_2O \rightarrow 2Na[Au(CN)_2] + 2NaOH$$

$$U_3O_8 + \tfrac{1}{2}O_2 + 3Na_2CO_3 + 6NaHCO_3 \rightarrow 3Na_4[UO_2(CO_3)_3] + 3H_2O$$

Simultaneous Oxidation and Dissolution, One Product *Being Insoluble.*—An example of this type is the leaching of pentlandite (NiS.FeS) in an oxidative ammonia leach according to the reaction:

$$NiS\,FeS + 3FeS + 7O_2 + 8NH_3 + xH_2O \rightarrow [Ni(NH_3)_4]SO_4 + 2Fe_2O_3\,xH_2O + 2(NH_4)_2S_2O_3$$

Here the $Fe_2O_3.xH_2O$ is insoluble and forms a porous layer on the surface of the leaching particle.

Chemical Reaction With *Production* of a Soluble and a Gaseous Product.—An example is the treatment of iron sulfide with sulfuric acid: $FeS + H_2SO_4 \rightarrow FeSO_4 + H_2S$.

2. Leach Solutions.— The solutions commonly employed are chosen with a view to providing the most efficient and least costly operation. In general they should have the following characteristics:

a. The solution should be selective to the extent that it dissolves the desired metals and does not react nith valueless minerals.

b. When added reagents are used in aqueous solution they should be such that their solubility in the solution is high enough to insure adequate reaction rates.

c. The leach solution should not be reactive to the extent that corrosion of leaching vessels becomes excessive. Hydrochloric acid solution, for example, although it is a good selective solvent that can be prepared in concentrated form, is greatly restricted in use by the iact that it very readily attacks all common base metals and can thus be used only in vessels constructed of glass, stoneware, plastics or hard rubber—all costly and weak materials.

d. Reagents should be readily available at low cost or be such that they can be easily regenerated or converted to useful by-products.

Of the acidic reagents, sulfuric acid is usually lowest in cost and most readily available, largely because it can be produced as a by-product in roasting sulfide minerals or by burning elemental sulfur in air. Also dilute sulfuric acid has the advantage that it can be easily regenerated by electrolysis or by other means; it is nonvolatile at ordinary temperatures in aqueous solutions; it is reasonably selective; it can be contained in metal or wooden vessels: and it can be prepared in any desired concentration. If sulfides are present in an ore that is to be leached. sulfuric acid can be generated by oxidation of the sulfides in *situ* if the leaching is carried out at a high enough temperature in the presence of oxygen.

Providing the mineral compound reacts with sulfuric acid to produce a soluble sulfate the many properties named make sulfuric acid a desirable leaching reagent. Kot unexpectedly, sulfuric acid solution is used as a solvent for most of the copper, cobalt, zinc, cadmium, vanadium and uranium ores that are treated by hydrometallurgical processes.

Nitric acid finds little use as a leaching medium for ores, largely because of its volatility and its tendency to decompose to nitrous oxides, etc., necessitating reoxidation if the acid is to be regenerated for subsequent use. The cost is much higher than that of sulfuric acid and regeneration is essential if it is to be used for treating low-grade ores. Its use is restricted to treating alloys or oxidized ores as it is decomposed with the production of elemental sulfur and sulfates when in contact with metal sulfides. It is used for "parting" gold-silver alloys, i e , converting the silver to soluble silver nitrate and leaving the gold unattacked in the metallic form.

Hydrochloric acid is, like nitric acid, restricted in use by its tendency to volatilize. It dissolves many oxides readily and reacts vigorously with sulfides to produce H_2S and metal chlorides, but is difficult and costly to regenerate from the chlorides. The corrosive effect of chloride ions in solution, as mentioned above. limits the commercial usefulness of hydrochloric acid in leaching operations. It is used, however, successfully in two important operations: (1) in combination with NaCl in a brine solution, to leach copper, zinc. cobalt, nickel, lead and other metals from pyrite residue which has been given a chloridizing roast; (2) in treating impure tin ores containing sulfides as well as cassiterite (tin oxide) to dissolve the sulfides: leaving a residue of pure tin oxide for subsequent smelting—a "reverse" type of leaching in which the desired metal is undissolved. Hydrochloric acid and chlorides are used in other hydrometallurgical procedures in the production of magnesium, for removal of impurities from tungsten ores and, in an unusual fashion, in the production of germanium and gallium by treating the concentrates with hydrochloric acid to produce chloride solutions. These solutions are then extracted and fractionally distilled to separate pure chlorides from which the pure metals can be prepared by electrolysis or other means.

There are several less important acidic reagents that have found restricted use, among them ferric sulfate, ferric chloride, sulfur dioxide (sulfurous acid) and hydrofluoric acid. The principal use of ferric sulfate is in leaching copper ores containing both copper oxide and copper sulfide minerals. Here a leach solution containing both sulfuric acid and ferric sulfate is employed: the sulfuric acid to dissolve the copper oxides and ferric sulfate to dissolve the sulfides. Ferric chloride has been used to dissolve copper-iron sulfide minerals, producing copper sulfate. ferrous sulfate and elemental sulfur. Sulfurous acid is used to leach manganese dioxide (MnO_2) from certain ores by forming soluble manganous sulfate, together with thionates and other soluble compounds. Hydrofluoric acid is used to dissolve silica from pulverized magnetite ores where the latter are to be used for iron powder manufacture and must be substantially free of silica. These and other acid solvents are restricted in use by cost, volatility, chemical instability or other characteristics; they are used only in specific operations where the required result can not be obtained by using a cheaper, more convenient reagent.

A group with entirely different properties comprises the basic reagents—caustic soda, sodium carbonate and bicarbonate, sodium cyanide and ammonium salts in the presence of free ammonia. The general characteristic of leach solutions containing these reagents is that, differing from acid solutions, they tend to form soluble metal compounds containing oxy-anions such as CrO_4^{--}, anionic complexes such as $[UO_2(CO_3)_3]^{-4}$ or cationic complexes of the form $[Ni(NH_3)_x]^{++}$. Basic leach solutions do not generally react with basic constituents, such as carbonates. in an ore. Thus, if an ore contains a high percentage of carbonates, the useless consumption of acid solely to decompose (*e.g.*, calcium carbonate) could easily reach such proportions as to make acid leaching economically impossible. In such cases basic leaching is the first and often the only choice.

Of the basic reagents, caustic soda (NaOH) is the most widely used. It is relatively inexpensive, nonvolatile, chemically stable, selective. not too difficult to regenerate and it can be prepared at any desired concentration. Thus. where it is chemically suited, it is the preferred basic leaching reagent. Its use is limited, however, to the extraction of metals such as zinc, aluminum, silica, gallium, antimony, chromium, tungsten and other similar metals. The hydroxides of these metals are soluble in an excess of caustic soda to form the corresponding zincates, aluminates, gallates, tungstates, etc., which have various solubilities in aqueous solutions depending on the NaOH content of the solutions. Caustic soda has the added advantage that it is stable at temperatures up to 1,000° C. and can thus be used to fuse refractory minerals, such as those of tungsten, vanadium. chromium and others, forming the corresponding sodium salts (tungstate, vanadate. chromate, etc.) which, on cooling, can be leached with water or weak caustic solution.

Another useful and practical basic reagent is sodium carbonate which has the same desirable properties as caustic soda. However, because it is not so strongly basic, it forms basic salts less readily and is for that reason much more selective than caustic soda. A more unusual, much more selective and yet better-known basic leaching agent is sodium cyanide which, in an oxidizing solution dissolves gold, silver, copper and a few other metals.

Another important basic solvent is ammonia which in the presence of anions such as sulfate, carbonate. nitrate or chloride forms, with certain metals, cationic ammine complexes. Because the

number of metals that will form ammine complexes is small—copper, cobalt. nickel, zinc, cadmium, magnesium, ferrous iron, mercury, palladium, silver, etc.—ammonia is a selective reagent. It is more costly, more volatile and less stable than caustic soda or sodium carbonate, but can be very easily regenerated and has the advantage that, for example, the ammonium sulfate formed in oxidative leaching of sulfides with ammonia is itself a valuable by-product.

3. Technology. — The procedures and equipment used in commercial operations are designed primarily to provide the most efficient operation at the lowest cost. All the factors relating to reaction rate, choice of leach solution and character of the reaction are taken into consideration but the selection of equipment is also influenced by climate, labour costs, size of operation, location, grade and character of ore to be treated and other similar factors. Depending on the importance of one or more of these factors the units and techniques commonly employed are as follows:

Percolation. — When the ore is such that the desired mineral particles are exposed by relatively coarse crushing—from a coarse sand to ▮ in. maximum size—it can be leached by percolation. Tanks, usually rectangular, are constructed of mastic lined reinforced concrete with a filter bottom several inches thick consisting of silica or other inert material with jute sacking laid on the upper surface. (See fig. 2.) The crushed ore is placed in the tank to a depth of from 2 to 1 j ft. and the leach solution pumped in at the top. As the solution percolates through the bed the mineral is dissolved and clear solution is withdrawn from below the porous filter bottom. This is continued in several cycles, including washing, until the ore is completely leached and washed, when the last of the wash water is drained off and the tank excavated mechanically in preparation for a new charge. In some large copper-leaching operations each tank may hold as much as 12,000 tons of ore. requiring a week or more to leach, mash, excavate and refill.

Fine Particle *Leaching.*—In keeping nith the principle that the maximum surface area, and hence highest leaching rate. is provided by agitating a mixture of finely ground solids and leach so-

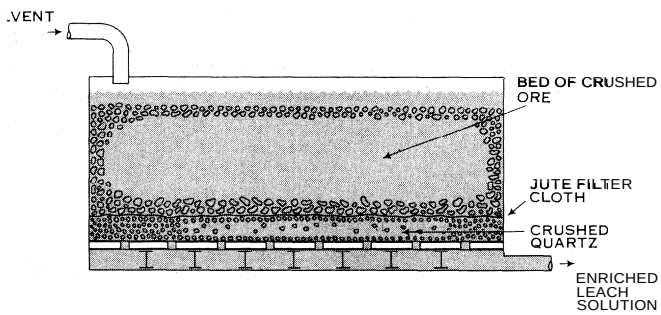

FIG. 2.— PERCOLATION LEACHING TANK

lution, the majority of leaching operations involve the treatment of a "slime." One of the simplest devices used for this purpose is the pachuca tank, first develsped in a gold ore treatment plant in Pachuca, Mex. (See CYANIDE PROCESS.) It comprises a tall circular tank, with a conical bottom, in which the leaching pulp is both aerated and vigorously agitated by a jet of compressed air entering at the bottom of the cone. In some models agitation is assisted by installing a vertical tube in the centre of the tank to give an air-lift effect. The pulp to be leached is fed and discharged continuously.

Another type of slime leaching unit consists of a large tank (up to 20 ft. in diameter) with a short central draft tube, the top being at the level of the pulp in the tank. A motor-driven impeller within the tube forces the pulp and entrained air downward through the tube thus both aerating and agitating the pulp.

When leaching is to be carried out under pressures above atmospheric pressure an autoclave of some type is required. This may take the form of a horizontal cylinder with internal impellers suspended on shafts protruding through the upper surface of the cylinder or having a slow-moving paddle type agitator. (See fig. 3.) The pulp fed to the first compartment by a pump is agitated vigorously by a mechanical agitator in the presence of compressed air. Overflowing the baffle walls into the second and third compartments it is finally discharged through an automatic valve actuated by a level controller. The gases (mostly nitrogen) leave through an automatic pressure release valve. Simple cylindrical vertical towers agitated by steam or air are also used.

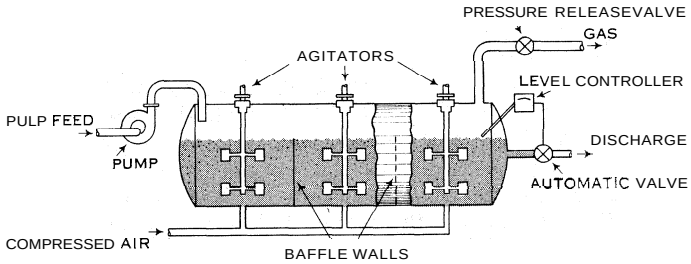

FIG. 3.— CONTINUOUSAUTOCLAVE FOR LEACHING WITH AIR OXIDATION

For certain difficult leaching operations where one of the products of reaction is a solid. such as copper sulfide in the leaching of iron-copper-cobalt-sulfide with sulfuric acid, it is customary to conduct the leach in a ball mill or other grinding unit. This removes the solid layer as it is formed and continually provides a fresh surface for reaction with the leaching solution.

Countercurrent Leaching.—If an ore, whether coarse or fine, is mixed with fresh solution, the concentration of reactants (ore and leach solution) will be high initially. As the reaction proceeds the concentration of soluble material in the ore and that of the reagent in the leach solution both decrease, thus reducing the reaction rate and rendering the operation less efficient. Theoretically the best plan would be to treat partly leached ore with strong solution and fresh unleached ore with a weaker solution. This is carried out in practice by using countercurrent leaching techniques.

In such an operation fresh ore in a first stage is leached with partially depleted solution from a second stage—this partially leaches the ore. The pulp is then filtered, the strong (pregnant) solution proceeding to metal recovery and the partially leached solids being mixed with strong leaching solution and placed in a second-stage unit. When leaching in the second stage is complete the liquids and solids are again separated by filtration, the liquid returned to mix with fresh ore in a succeeding cycle and the solids sent to waste or to such subsequent treatment as may be required. A countercurrent operation may involve as many as five individual stages.

Liquid- solid^ Separation. — When leaching is complete the liquids and solids must be separated; also the solids that are to be discarded must be nashed to prevent loss of entrained leach liquors. This can be accomplished in a variety of ways by combining settling units with filters and centrifuges.

An efficient settling unit is a thickener, a circular tank up to 200 ft. diameter nith a central feed for the pulp and an overflow trough or launder at the periphery. As the solids settle to the flat inverted conical bottom they are moved to a central discharge orifice at the bottom of the cone and removed by pumping. The overflow is substantially clear while the thickened pulp may contain 50% to 60% solids by weight even though the pulp entering at the top may have been only 1% to 2% solids by weight. By arranging several thickeners in series and by advancing thickened pulp in one direction and overflows in the opposite direction the washing process known as countercurrent-decantation is efficiently performed.

Where solids are semicolloidal or so fine that they will not settle readily, flocculating agents such as "Separan," "Aerofloc." certain natural gums, causticized starch, carboxyl methyl cellulose and other similar materials added in very small amounts to the pulp cause the fine solid particles to adhere to one another forming flocs which settle readily.

Filters may be of several types—either batch or continuous.

vacuum or pressure—but large-scale operation is carried out most efficiently and at least cost by using continuous vacuum filters (fig. 4) in which the pulp is pulled onto the surface of a rotating drum or leaf covered with a woven cloth which is immersed in the pulp. At a point in the rotation of the drum where the liquid has been drained from the solids by the vacuum and the solids washed, if necessary, by a spray wash, air pressure is substituted for the vacuum and the moist cake of solids discharged from the drum. As the drum re-enters the pulp, vacuum is substituted for compressed air and the cycle repeated.

In pressure filters which are used for pulps containing a relatively small percentage of solids, or for solids that are difficult to filter, the pulp is charged to a pressure vessel containing cloth filter diaphragms, the vessel closed and the pressure applied. When the cake has built to a suitable thickness on the diaphragms the pressure is removed, the filter opened, the cake removed mechanically or by hand and the cycle repeated.

The centrifuge, which is usually used for separating crystals and coarse oxide from liquids is a rapidly spinning circular basket with perforated sides. The pulp is fed to the centre and liquid is forced by centrifugal force through the perforations, the solids being retained. When a sufficient amount of solids has accumulated on the perforated sides the feed is discontinued and the solids removed. usually by a mechanical scraper and the cycle is repeated; continuous units are also used.

Another device that provides a somewhat less efficient but nevertheless useful liquid-solid separation is the hydroclone or hydrocyclone (see ORE DRESSING) in which the rapid circular motion of the pulp in a cylindrical vessel effects partial separation of solids and liquids by centrifugal force.

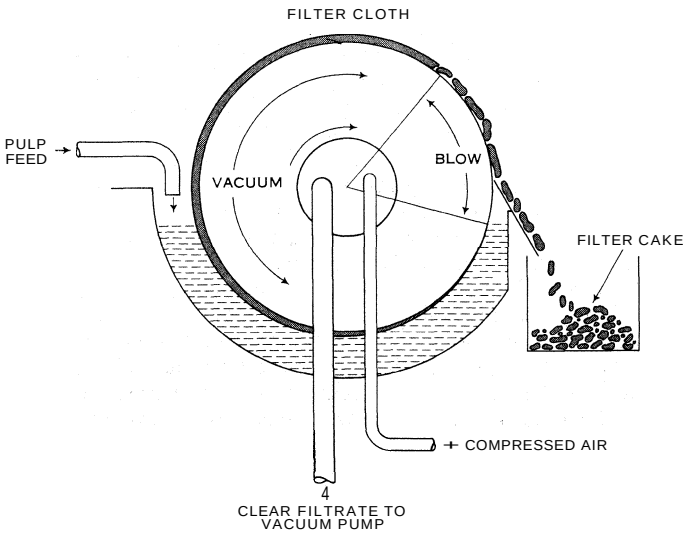

FIG. 4.— CONTINUOUS ROTARY VACUUM FILTER

Other Techniques.—In some specialized operations, such as those which require the addition or removal of heat, provision must be made for preheating the pulps or for cooling the leaching vessels. Also, with volatile solvents, condensers or other recovery units are required: if hydrogen or hydrogen sulfide is generated the gas must be effectively removed from the leaching vessel. Consideration must always be given to materials of construction: they must be inert with respect to the leach solution, to prevent corrosion and sufficiently hard or resilient to prevent erosion by sharp solid particles. Mild steel, wood, stainless steel, rubber coatings, mastic, lead, glass, stoneware, brick and combinations of two or more of these materials are used depending on the temperature, abrasive quality of the solids and the character of the solvent.

C. SOLUTION PURIFICATION

With the exception of the very few leaching operations in which the leaching solution is used to remove soluble impurities from a valuable solid, the filtered liquid resulting from the leaching step is further treated to separate and recover the metal values contained in it. The extent of treatment required depends not only upon the amount and variety of metals dissolved during leaching, but much on the chemistry of the cations and anions present in the solution. Because no two ores are similar in composition every leach solution is unique and thus requires the application of a procedure specifically suited for it. This may vary from a simple precipitation of a metal salt by pH (acidity-alkalinity) change, by hydrolysis or by addition of other metals, to separations effected by organic reagents, fractional crystallization or adsorption. The key to success in this field may be said to be a thoroughly sound knowledge of the principles of inorganic and physical chemistry and of chemical engineering.

1. The pH Change.—The solubilities of metal salts and their tendency to hydrolyze are affected in different ways by variations in pH. In commercial hydrometallurgical operations the number of reagents that can be economically used to change pH is usually restricted by cost as well as by the physical character of the precipitates produced and the possible contamination of solution or precipitate with undesirable impurities.

Acid solutions are adjusted by the addition of caustic soda, calcium carbonate. sodium carbonate, lime, magnesia or ammonia, depending on the metals present and the result desired. In solutions containing ferrous sulfate and cobaltous sulfate, for example, the ferrous sulfate can first be oxidized to ferric sulfate, the pH raised by addition of ammonia or calcium carbonate to about 4.2, and the iron precipitated as hydrated ferric oxide which can be separated from the cobaltous sulfate by filtration. If the solution contained copper it would be necessary to raise the pH to about 5.0 to precipitate the copper as hydroxide but at this pH cobalt hydroxide would also begin to precipitate and thus destroy the effectiveness of the separation.

In solutions containing ferric iron, aluminum, magnesium and uranium in the form of sulfates, it is possible, by adding ammonia to bring the pH up to about 4.0, to precipitate ferric hydroxide, aluminum hydroxide and uranium hydroxide and thus separate the uranium from the solution leaving magnesium sulfate in soluble form. Addition of ammonia to raise the pH to 5.0 instead of 4.0 would precipitate the hydroxide of magnesium along with the iron and uranium and thus not only add to the cost (for additional ammonia) but give a much more impure precipitate.

Basic solutions can be adjusted by acid additions or, in some cases, by dilution or boiling. For example, an ammoniacal solution containing nickel ammine and cobaltic ammine can be treated with sulfuric acid to reduce the pH from 8.0 to 6.j forming nickel ammonium sulfate which is relatively insoluble in the presence of ammonium sulfate at pH 6.j and leaving the cobaltic ammine in soluble form. The nickel ammonium sulfate can then be easily separated from cobaltic ammine solution by filtration or centrifuging, thus effecting a substantially quantitative separation.

In the saturated sodium aluminate solution produced by leaching bauxite in strong caustic soda, cooling to lower temperatures causes the aluminate to hydrolyze and precipitate aluminum hydroxide which can then be separated and recovered, the caustic solution being regenerated.

The pH of basic solutions containing free ammonia and copper ammines can be lowered by boiling off the ammonia to the point where the ammines hydrolyze and copper hydroxide is precipitated. A similar reaction forms the basis of the ammonia-ammonium carbonate process used in Cuba to treat oxidized nickel ores, the product of boiling being basic nickel carbonate, in this case the desired end product.

In the hydrometallurgy of zinc small amounts of arsenic, antimony. ferric iron, silica and alumina are removed from solutions by oxidation and hydrolysis at controlled pH.

2. Reduction.—In the electromotive series, if a metal high in the series is placed in contact with an aqueous solution of a metal lower in the series the general tendency is for the lower metal to be reduced and the higher metal to be oxidized and dissolved. Metals below cadmium. when reduced, mill precipitate in metallic form. Thus it is possible, for example, to precipitate copper metal from copper solution by adding iron metal to the

solution. the iron being oxidized to ferrous ion. which is soluble.

Advantage is taken of this property of metals to remove impurities from leaching solutions in the hydrometallurgy of zinc where small amounts of copper and cadmium present in the zinc sulfate solution are precipitated by the addition of zinc ponder. Similarly, in weakly acid nickel sulfate or chloride electrolytes and other similar solutions containing copper ions, the copper can be precipitated by the addition of nickel ponder, leaving a pure nickel solution.

In another comparable situation chlorine is removed from a solution in which it is present as cupric chloride by agitating the solution mith metallic copper, reducing the cupric to cuprous chloride which is insoluble and can thus be separated.

The order of some more common metals in the electromotive series is: potassium, sodium, magnesium, aluminum, zinc, iron, tin. lead, hydrogen. copper, mercury. silver, platinum and gold.

3. Reagent Additions. — An endless variety of separations can be effected by reagent additions but the commercial application is restricted by cost, physical properties of precipitates and avoidance of unwanted impurities. Hydrogen sulfide and similar sulfur-bearing reagents such as thiosulfate, thionates, SO_2 and sulfur, alkali sulfides and metal sulfides can all be used in the appropriate alkaline or acid environment to effect separations that depend on the relative solubilities of the metal sulfides.

Carbon dioxide. sulfur dioxide and chlorine can also be used where selective solubility of the products can be obtained. Carbon dioxide, for example, added to ammoniacal solutions of calcium sulfate will quantitatively precipitate the calcium as calcium carbonate.

In special circumstances salts or organic compounds can be used to effect separations. Gold, for example, can be separated from a chloride solution containing gold and platinum metal chlorides by adding to the solution ferrous sulfate which reduces and precipitates gold metal but not the platinum group metals. Thorium can be separated from small amounts of other rare earths by precipitating it as the oxalate. In the hydrometallurgy of zinc, traces of cobalt can be removed from the neutral leach solutions by the addition of α-nitroso-β-naphthol.

4. Ion Exchange.—Certain resins consist of porous rigid frameworks having replaceable hydrogen atoms or hydroxyl groups exposed: those with hydrogen ions are known as cationic exchangers and those with hydroxyl groups as anionic exchangers. When a solution containing cations is brought into contact with a cationic resin the cations replace hydrogen in the resin and hydrogen ions enter the solution. The reaction may be represented as follows:

$$\text{Hydrogen-resin} + Cu^{++} \rightarrow \text{Cu-resin} + 2H^{+}$$

The reaction is reversible and Cu-ion and hydrogen-resin can be regenerated by adding strong acid to the Cu resin. Also, the tendency of different species of cations to replace hydrogen varies. Thus, if a dilute solution containing a mixture of cations is brought into contact with a hydrogen resin, it is possible for one species of cation to react selectively and be adsorbed by the resin leaving other cations in solution. The resin can then be removed from the solution and treated with strong acid (*e.g.*, HNO_3) forming a concentrated metal nitrate and regenerating the hydrogen resin for subsequent use in another cycle.

This type of separation has proved exceptionally useful in separating rare earths, in separating hafnium from zirconium and in recovering uranium from acid solutions containing only a few milligrams per litre of uranium in the presence of salts of iron, silicon, aluminum, magnesium and other metals, all of which are largely unaffected by the resin.

Ion exchange techniques offer the prospect of obtaining separations that can not be effected by any other means. For that reason the development of new types of resins, both anionic and cationic, is a continuing objective of research in the hydrometallurgical industry.

5. Solvent Extraction. — Another method of separating metals from aqueous solutions depends on the ability of certain organic liquids to dissolve, selectively, specific metal salts by the formation of complexes which are more soluble in organic solvents than in aqueous solutions. A typical example, long recognized by analytical chemists, is the procedure in which a mixture of the chlorides of ferric iron. cobalt, copper, nickel, vanadium and chromium in a strongly acid aqueous solution is vigorously shaken with ether and allowed to settle, forming two separate layers. The upper layer of ether selectively dissolves ferric chloride leaving the chlorides of the other metals named in the aqueous layer which can be removed by decantation and an efficient separation thus effected.

This principle has been extended and applied in the separation of uranium from acid solutions in uhich it is present in amounts of 1 to j g. per litre together with salts of iron, aluminum, vanadium, magnesium, etc. In one application, the leach solution is first treated with H_2S or aluminum metal to reduce Fe^{+++} to Fe^{++} and is then agitated mith a kerosene solution of an alkyl phosphoric acid which selectively reacts with uranyl ions leaving Fe^{++} and other ions in the aqueous phase. An extractant commonly used is dodecyl phosphoric acid (DDPA). The uranium can be removed from the extractant by treatment with strong hydrochloric acid and the extractant regenerated for use in a subsequent cycle. The uranyl chloride solution is distilled, the HCl distillate recycled to a subsequent cycle and the concentrated uranium residue further treated to produce uranium metal.

As a solvent extraction process is fully cyclic and can be operated continuously, and as extractants can be developed comparatively easily. it is not unexpected that this type of separation continues to find new applications in hydrometallurgy.

6. Technology. — The equipment used for separation processes is relatively simple and is usually selected on the basis that it will provide the specific conditions required for the desired separation.

Mechanically stirred open tanks, pachuca tanks, steam-heated boilers, packed towers and similar units are used for reactions that take place at atmospheric pressure. Where high temperatures, high pressures or volatile reagents such as SO_2, CO_2, NH_3 and H_2S are involved, autoclaves or enclosed towers are used. The solid and liquid products are separated by settling, screening, filtration, centrifuging or other mechanical means.

The ion exchange process operates intermittently in such a way that the solution to be treated is passed through columns of resin until the resin becomes saturated, at which point the solution is diverted to a second similar series of resin towers. In the process used for removing the metal from the saturated resin (known as eluting), acid, etc., is passed through the first (loaded) tower to remove metal ions in an acid solution and regenerate the resin. The column then is ready for reuse in a subsequent cycle while the metal is recovered from the acid solution which is termed the eluate.

A useful variation of this technique is the resin-in-pulp (RIP) process in which the leached pulp, from which the coarser barren solids have been removed but which still contains barren slimes, is brought into contact with resin which extracts the desired metal ions from the aqueous portion of the pulp, the solids being unaffected. When the resin is saturated it is removed, eluted and regenerated; the pulp, consisting of barren leached solids and depleted solution, is discarded. This procedure which avoids the need of filtering the solids before separating and recovering the valuable metal ions from the leach solution offers a distinct advantage in certain operations where the solids are so finely divided or colloidal in nature that settling or filtration would be difficult if not impossible.

Solvent extraction is carried out in a continuously operating mixer-settler in which the pregnant leach solution and organic solvent are fed through a tube into a reaction area-at the centre of a vertical vessel, suitable agitation being provided at the point of entry. The organic extractant overflows the top of the vessel while the depleted aqueous solution is removed at the bottom.

D. Precipitation

The principal objective of many hydrometallurgical procedures is to produce the extracted metals in metallic form. As the metals

are present in solutions as cations carrying a positive charge the essential mechanism of precipitation is reduction which means the addition of electrons. This can be accomplished in several ways: by electrolysis with direct current; by using a metal higher in the electromotive series; or by treating the solution with a reducing gas such as hydrogen.

The processes in which the product is a metal hydroxide, sulfide or other insoluble metal salt have been considered in the preceding section on separations and need not be further described.

1. Electrolytic Precipitation. — The electrolytic cell used for precipitating metals from solutions comprises essentially a container for the solution (electrolyte) in which is placed (a) a cathode upon which the metal is to be plated, and (b) an anode made of some conducting material — metal or carbon — which is not soluble in the electrolyte used. The reaction can be simply represented by the following equation:

$$\text{Metal ion} + H_2O + \text{electrons} \rightarrow \text{Metal} + \tfrac{1}{2}O_2 + 2H^+$$

The net result of electrolysis is that metal is deposited on the cathode, oxygen is evolved at the anode and an equivalent amount of acid (hydrogen-ion) is generated. The amount or weight of metal plated, and of water decomposed to O_2 and hydrogen ions, is determined by Faraday's law which states that a current flow of 96,540 coulombs (ampere-seconds) will deposit an amount of metal equal to its atomic weight divided by its valence. The voltage required is at least the "decomposition voltage" of the metal salt in the electrolyte, to which must be added the voltage necessary to overcome ohmic resistance of the electrolyte and electrical contacts and the overvoltages that may be developed at either anode or cathode.

The conduct of an electrolytic operation is profoundly affected by the cations present in the electrolyte. The salts of metals below hydrogen in the electromotive series have a lower decomposition voltage than that of water and can be electrolytically decomposed and the metal readily deposited from an acid or basic solution. For the metals that lie above hydrogen the difficulty is encountered that water, which is always present. has a lower decomposition voltage than the metal salts, thus creating a tendency to produce hydrogen at the cathode instead of the desired metal, although under certain conditions the deposition of hydrogen may be suppressed. Any hydrogen produced reduces, by an exactly equivalent amount. the metal that should be precipitated according to Faraday's law and in this way reduces the current efficiency of the cell. To electrolyze these metals with high efficiency requires the provision of special conditions such as careful control of pH in the electrolyte, or the use of electrolytes in which the decomposition voltage of the metal salt is, in effect, below that of hydrogen.

It may be inferred from the above that electrolytic precipitation is selective: the metal salt having the lowest decomposition voltage of any salt present will be electrolyzed and the metal plated out in preference to all metals above it in the electromotive series. Where more than one metal salt is present the metal salt having the next highest decomposition voltage will react and deposit the second metal after the lower metal has been removed from solution. If the decomposition voltages of two metals are close, there will be some overlapping in their deposition.

Certain impurities (other cations) present in an electrolyte tend to catalyze the decomposition of water and hence to reduce the efficiency of electrolytic precipitation of metals above hydrogen in the electromotive series. For this reason and also to prevent contamination by other metals which would plate out preferentially. leach solutions must be carefully purified before being electrolyzed. The higher the metal is in the electromotive series, the more important and at the same time the more difficult, is the purification.

Notwithstanding these difficulties, leaching and purification followed by electrolysis with insoluble anodes is widely used commercially in the production of manganese, zinc, cadmium, cobalt and copper and a number of other metals.

2. Cementation. — The precipitation of metal from a solution by the addition of a more reactive metal, with dissolution of the latter, is termed cementation. A typical reaction is:

$$\underset{\text{metal}}{Fe^o} + \underset{\text{ion}}{Cu^{++}} \rightarrow \underset{\text{metal}}{Cu^o} + \underset{\text{ion}}{Fe^{++}}$$

The reactivity of a metal in this context is related to its position in the electromotive series — the higher the metal is in the series the more reactive it is. Metals higher than cadmium in the series can not be precipitated in metallic form from aqueous solution by cementation with a more reactive metal as the equilibrium between H_2O and the ions of metals above cadmium is such that the oxidation of the metal, and hence its retention as an ion, is favoured.

If a cementation reaction is to proceed to completion it is essential that the precipitated metal should not form a continuous nonporous layer on the surface of the reactive metal. Otherwise the precipitated metal would soon reach equilibrium with the surrounding metal salt solution and prevent contact between the reactive metal and the metal ions in solution and thus stop the reaction.

Reaction rates in this system are improved by increased surface area of reactive metal, by increased temperature, by increased agitation and by concentration of the ions of the less reactive metal in the solution. Thus it is advantageous to carry out cementation with finely divided reactive metal at the highest convenient temperature in an agitated mixture. Concentration of the less reactive metal in solution must decrease as the metal is precipitated and total reaction time is restricted largely by the extent to which it is desired to reduce the metal content of the solution. It is possible to precipitate metals quantitatively from solution by cementation. (The term cementation is also used to designate an outmoded process of making steel by heating iron in contact with carbon.)

3. Reducing Gases. — Under certain conditions hydrogen serves as a source of electrons to precipitate metals from aqueous solution, its behaviour in this respect resembling in some measure that of a reducing metal. It appears that metals which lie below or just above hydrogen in the electromotive series and which are either homogeneous or heterogeneous hydrogenation catalysts can be precipitated readily by molecular hydrogen. The list of these metals includes nickel, cobalt, copper, mercury, silver, gold and the platinum metals.

The precipitation by hydrogen of metals lower in the series (silver, gold, palladium, platinum etc.) can be effected at room temperature and atmospheric pressure, although the rate of precipitation is higher with increased hydrogen pressure. Copper, nickel and cobalt, however, can be rapidly precipitated with hydrogen only at temperatures above 100°–125° C. and under a pressure of at least 5 atm. of hydrogen. The rate of precipitation of nickel and cobalt is directly proportional to the surface area of the nickel or cobalt metal present to catalyze the dissociation of hydrogen. The reduction of copper salts occurs homogeneously in solution.

Hydrogen can also be used in the presence of nickel catalyst to reduce uranium from the hexavalent to the tetravalent form in carbonate solutions and to produce uranium dioxide which is insoluble in these solutions. In this way uranium and, by a similar procedure vanadium, can be quantitatively separated from carbonate solutions.

In all hydrogen reduction reactions the hydrogen is converted to hydrogen ion thus tending to increase the acidity of the solution as the reaction proceeds.

4. Technology of Precipitation. — The generators, cells and other equipment used in metal precipitation are similar to those employed in electrolytic refining. The unique characteristic of metal precipitation by electrolysis, termed "electro-winning," is the use of insoluble anodes with accompanying evolution of oxygen at the anode.

The considerable amount of gas (*e.g.*, 180 l. per kilogram of zinc) emanating from the solution carries with it a small amount of acid vapour which causes a loss of acid that tends to corrode metal parts in the cell room. Another factor that occasionally assumes serious proportions is that in an electrolyte containing chlorides, chlorine is generated at the anode which makes it necessary to use for the anode an alloy that is not at-

tacked by the chlorine.

In the electrolytic precipitation of cobalt from sulfate solutions it is necessary to maintain the pH of the electrolytic cell at about 4.5. Acid generated by electrolysis, which would tend to lower the pH of the electrolyte, is effectively neutralized by the addition to the electrolytic cell of pure cobalt hydroxide, a unique but effective procedure in electrolysis.

Electrolytic precipitation finds its principal use in the hydrometallurgical production of zinc, copper, manganese, cadmium and cobalt.

Cementation. — Precipitation by cementation, which is usually more efficient in acid solutions (below about pH4), can be effected by displacement by electropositive metal powders or metal scrap. Precipitation by cementation is used chiefly in recovering copper from acid sulfate or chloride solutions by the addition of scrap iron. Powder cementation is used to precipitate silver and gold from cyanide solutions. copper from solutions containing zinc, cobalt or nickel, cadmium from zinc sulfate solutions and silver from nitrate solutions.

Metal powder cementation is carried out by adding a slight excess of the reactive metal powder to the solution, which is agitated in an open tank. The precipitated metal and any undissolved powder are filtered off and recovered. Batch operation is preferred, the treatment being continued until precipitation is complete. If a two-stage countercurrent precipitation is used, it is possible to produce a high-grade metal precipitate with a very small excess of the reactive metal powder. The reactive metal will reduce oxidized salts such as ferric sulfate in the leach solution, to their lowest valence. It is therefore advantageous to keep oxidation at the lowest possible level and to remove dissolved oxygen from the solution before cementation. Gold cyanide solutions are deaerated by a vacuum technique before adding powdered zinc or aluminum to precipitate the gold.

When scrap metals are used for cementation the technique employed is adapted to suit the character of the scrap used. Normally the solution is poured over coarse scrap contained in launders or perforated baskets. In some important installations batches of solution are treated with bulky, irregular-shaped scrap, such as old oil drums or structural steel scrap, in large inclined rotating acid-proof vessels.

Hydrogen Precipitation. — The principal use of hydrogen precipitation is in the recoverv of nickel, cobalt and copper from ammoniacal leach solutions. For example, a suitably purified nickel solution is introduced into a horizontal cylindrical autoclave fitted with mechanically operated stirring mechanisms. A minute amount of ferrous sulfate catalyst is added (to initiate the reaction), the solution heated to 100–200° C. and hydrogen is introduced at about 400 lb. per square inch pressure. The nickel ammine sulfate present reacts rapidly with the hydrogen to produce metallic nickel powder and ammonium sulfate, the nickel content of the solution being reduced from 50 g. per litre to 0.1 g. per litre in 10 to 15 min. The agitators are stopped, the powder settled and the barren solution discharged. A second charge of nickel-rich solution is added, the agitators started and the cycle repeated. At intervals the autoclave is discharged with the agitators operating, thus removing the nickel powder with the barren solution. The powder is allowed to settle out of the barren solution and is filtered, washed, dried and packed in drums. A high-purity nickel metal is produced by this procedure. Copper and cobalt metals can be similarly precipitated: uranium and vanadium can be precipitated from carbonate solutions as UO_2 and V_2O_3 in a similar manner in the presence of a nickel catalyst.

E. Regeneration

Unless the solvent used is cheap or can be converted into a useful by-product it is desirable to regenerate it for reuse in a succeeding cycle of the leaching process. An important advantage of electrolytic precipitation of metals from acid solutions is that acid is regenerated equivalent to the metal precipitated. Thus the reagent consumption is only that necessary to make up for mechanical losses — there is theoretically no chemical consumption of reagent. The hydrometallurgical processes for producing copper and zinc depend for their economic success upon this feature.

In cyaniding gold ores the amount of sodium cyanide (NaCN) consumed is very small, theoretically only that necessary to react with the gold and silver dissolved. However, if excessive amounts of copper, cobalt, nickel or other metal salts that react with the cyanide are present, the cyanide can be regenerated by treating the solution after gold precipitation with acid to produce hydrocyanic acid (HCN) which is absorbed in caustic soda to regenerate NaCN.

Carbonate solutions of uranium are treated with caustic soda to precipitate the uranium as an insoluble uranium salt leaving a small excess of caustic in the barren sodium carbonate solution. The necessary amount of sodium bicarbonate required for leaching a succeeding lot of uranium ore is regenerated by treating the barren solution with carbon dioxide.

When cementation is used to precipitate metals the barren solutions contain the corresponding salt of the reactive metal. If the purpose of cementation is simply to remove small amounts of an undesired metal for purposes of purification, such as precipitation of copper and cadmium from zinc leach solutions or copper from cobalt solutions, the resulting solution is treated for recovery of the remaining metal. When, however, the objective is to strip the major metal constituent from the solution, as in precipitating copper from leach solutions with scrap iron, the resulting solution is usually valueless, containing (in the case mentioned) only ferrous sulfate and it is therefore discarded.

Ammonia leaching of copper-nickel-cobalt sulfides under pressure in the presence of oxygen (compressed air) with final precipitation of nickel powder by hydrogen under pressure results, as noted above, in the formation of ammonium sulfate. After removal of the nickel the barren solution can be evaporated to produce pure ammonium sulfate which can be marketed as fertilizer. If desired the ammonium sulfate solution could be reacted with lime (CaO) to precipitate calcium sulfate and regenerate ammonia for reuse in a succeeding cycle.

Leaches conducted with ammonium carbonate (*e.g.*, to dissolve copper, nickel or uranium) result in the production of an ammine solution of these metals. Upon boiling, the oxides, hydroxides or basic salts of the metals are precipitated and the volatilized NH_3 and CO, recombined to regenerate fresh ammonium carbonate solution.

In the treatment of many valuable metals to form concentrated leach solutions, as in the production of chromium salts, lithium compounds, thorium, zirconium, etc., the leach solution is usually destroyed by added chemicals and regeneration is not attempted.

III. Examples of Commercial Processes

The principles and methods of hydrometallurgical processes can best be illustrated by reference to important commercial applications. The processes described below have been selected to represent specific applications of different techniques and are intended to give one hydrometallurgical method of producing the metal concerned but not necessarily the only one.

A. Copper

In some of the great copper mines of the world which are located in semiarid areas in South America, Africa and the southwestern United States, the ores consist largely of oxidized copper minerals such as cuprite (oxide), brochanthite (sulfate), atacamite (chloride), etc., which, unlike copper sulfide minerals, are not readily amenable to concentration by froth flotation. These minerals are however all soluble in dilute sulfuric acid, which provides a basis for recovering the copper economically by leaching processes.

The largest mine of this type was at Chuquicamata, Chile, where, until a sulfide smelting plant was added in the 1950s, more than 200,000 tons of copper was produced annually from an ore containing 2% copper of which about 90% was present as oxidized copper minerals. Such an operation provides an outstanding example of countercurrent percolation leaching and electrolytic precipitation with regeneration of sulfuric acid solvent.

In an operation of this kind the ore is crushed to about 1 cm.

maximum diameter and is charged into tanks with filter bottoms, each tank holding as much as 11,000 tons of ore per charge. Several tanks are operated in series, the fresh sulfuric acid leach solution from the electrolytic cells being fed to a tank containing nearly spent ore, percolating through the interstices in the charge and passing through the filter bottom. The filtrate goes forward to the next tank. etc., until in the final tank the copper-bearing leach solution is brought into contact with fresh ore. The leaching cycle requires about four days, after which the liquor is drained from the spent ore nhich is then washed with dilute water solutions, again by percolation. The washed spent ore is excavated and discarded. By changing the flow of leach liquors each tank is in turn filled. leached, washed and excavated.

The pregnant leach solution contains some cupric chloride resulting from the dissolution of small amounts of copper chloride in the ore. To reduce the chlorine content the solution is passed through towers containing metallic copper which reduces the cupric chloride to insoluble cuprous chloride which is removed by settling and filtration.

The purified solution is electrolyzed in mastic-lined, reinforced concrete cells nith 60–70 lead-antimony anodes in each cell. The solution entering the cells contains about 3% H_2SO_4 which is increased to 6% by electrolysis and then returned to the percolation leaching plant to treat a succeeding batch of ore.

B. Zinc

Up to 1916 substantially all the world's zinc was produced by distillation of zinc vapour at high temperatures from a mixture of zinc oxide and carbon. Hydrometallurgical processes (first introduced in the U.S. at Anaconda, Mont., and in Canada at Trail, B.C.) resulted in the production of high-purity electrolytic zinc which found special application in brass manufacture and die-casting. Within a few years die-casting alone required more than 200.000 tons of high-purity zinc per year. Electrolytic zinc is profitably produced in many countries — Canada, the United States, Australia, Poland and others — where abundant low-cost electrical energy is available.

One process comprises roasting a high-grade (50%–60%) zinc sulfide concentrate, preferably with a low iron content, in such a nay that the sulfide is converted to fine porous particles of zinc oxide. The roasted oxide usually contains small amounts of the oxides of lead, copper, cadmium, arsenic and antimony as well as silica and precious metals.

The oxide is leached with sulfuric acid in a two-stage countercurrent system to produce a neutral zinc sulfate solution containing sulfates of cadmium, copper, manganese and cobalt. Iron, arsenic, antimony, lead, silica and precious metals are separated in an insoluble residue and further treated by smelting methods to recover the valuable metals present.

The neutral zinc sulfate solution is treated with zinc powder to precipitate copper and cadmium and with α-nitroso-β-naphthol to remove cobalt, leaving a pure neutral solution containing zinc and manganous sulfates. The purified solution is electrolyzed, using insoluble lead anodes, to produce pure zinc on the cathodes and manganese dioxide at the anodes and to regenerate sulfuric acid at about 10% strength, which is returned to the leaching plant to treat a succeeding lot of zinc oxide.

In this process, because of the position of zinc in the electromotive series relative to hydrogen, great care must be taken to remove impurities from the neutral zinc sulfate solution fed to the electrolytic cells. Germanium, cobalt, nickel and antimony must be maintained at very low levels as they tend to catalyze hydrogen deposition at the cathode and thus impair current efficiency.

C. Aluminum

The principal useful ore of aluminum is bauxite — a mixture of aluminum hydrates of the form $Al_2O_3.xH_2O$ in which the average ratio of H_2O to Al_2O_3 is about 2 to 1. The ores also contain, in varying amounts, iron oxides, silica, lime and magnesia as well as small but measureable amounts of vanadium and gallium.

The ore after grinding to a fine powder is treated in continuous autoclaves with strong caustic soda solution at 160° C. which rapidly dissolves the aluminum hydrates to form a hot, concentrated solution of sodium aluminate. On cooling and "seeding" with particles of aluminum hydrate the sodium aluminate decomposes to form aluminum hydrate and sodium hydroxide. The aluminum hydrate is separated by thickening and filtration and is washed and heated to remove the H_2O. The resulting pure Al_2O_3 is charged to cells containing a molten sodium aluminum fluoride electrolyte for electrolytic production of aluminum metal.

In the dissolution of aluminum ores with caustic soda some of the silica, vanadium and gallium present also dissolve. One of the most important aspects of this process is the control of temperature, concentration and seeding techniques in the various stages to hold to the lowest practical level the silica content of the precipitated aluminum hydrate. At regular intervals the caustic leach solution must be specially treated to remove vanadium, gallium and other impurities to prevent their reaching a level where they would precipitate with, and contaminate, the aluminum hydrate.

D. Nickel

There are two important types of nickel ore: (1) nickel-iron sulfides mixed with copper and cobalt sulfides and frequently platinum metals, that occur in temperate areas such as the Canadian Pre-Cambrian shield; and (2) iron-nickel-magnesium silicates found in such great abundance in tropical areas in Cuba, New Caledonia, Brazil, the East Indies and elsewhere. The sulfide ores are easily treated by pyrometallurgical methods to produce nickel; the silicate ores less easily so. Both types can be treated by hydrometallurgical processes designed to suit the requirements of each.

The silicate ores at the Nicaro mine in Cuba are first treated with reducing gases (H_2 and CO) at red heat to reduce selectively the nickel oxide present to nickel metal particles, without fusion The reduced material is leached in closed vessels with aerated ammonia-ammonium carbonate solution to oxidize and dissolve the nickel as nickel ammine carbonate. The iron, magnesia and other impurities are separated, washed and discarded.

The nickel ammine solution is boiled to drive off ammonia and carbon dioxide and to precipitate a mixture of nickel hydroxide and nickel carbonate which is dried and ignited at a red heat to remove H_2O and CO_2 and produce nickel oxide which is briquetted and sold in this form. The ammonia and carbon dioxide driven off during the boiling operation are reabsorbed in water to regenerate ammonium carbonate for a succeeding leach.

The Cuban ores contain no copper and, as relatively little cobalt is dissolved under the conditions used, the nickel oxide produced is pure enough to meet market requirements without the necessity of introducing extensive solution purification steps. These ores are a potential source of cobalt which can be recovered, if required, by varying operating techniques.

A nickel-iron-copper-cobalt sulfide concentrate from the Sherritt Gordon mine in Manitoba, Can., which contains no platinum metals, is treated by another type of ammonia process. The procedure comprises leaching the mixed sulfides in continuous autoclaves with ammonia solution and compressed air. The minerals dissolve to produce nickel, copper and cobalt ammines and ammonium sulfate. Cpon boiling to remove part of the ammonia, copper is quantitatively precipitated as sulfide. The copper-free solution is treated in autoclaves at 200° C. and 500 lb. per square inch pressure with hydrogen to selectively precipitate nickel in the form of high purity powder which is sold either in this form or as small briquets.

The cobalt remaining after nickel precipitation is removed by H_2S addition and recovered separately in metallic form while the solution (now free of metals) is evaporated to produce fertilizer grade ammonium sulfate.

E. Gold

The first hydrometallurgical process to be used widely on a commercial scale was the recovery of gold by extraction with aerated sodium cyanide solutions. developed in 1889 and 1890. The apparatus devised for this process and still in use in modern hydrometallurgical plants, such as pachuca tanks, thickeners, coun-

tercurrent washing systems and vacuum filters, provided the stimulus for the development of a, variety of other leaching processes. The procedures used have been changed but little in modern practice. For details see CYANIDE PROCESS.

F. URANIUM

One of the great triumphs in modern technology was the development of hydrometallurgical processes for extracting uranium from low-grade ores that took place during the years immediately following World War II. Because of its chemical behaviour uranium can not be separated from silica and other minerals by pyrometallurgical methods. Up to the end of World War II the production of uranium depended upon concentration of low-grade ores by physical methods (as tabling, jigging, etc.) to produce a concentrate containing 10% or more uranium, together with silica, sulfides and other gangue minerals. The concentrate was then treated by hydrometallurgical processes involving the use of sulfuric acid with sodium nitrate and other costly reagents to dissolve the uranium which was then recovered from the solutions by chemical separations.

However, ores containing pitchblende or other uranium mineral in such form that it can be efficiently concentrated by physical processes, occur only in limited quantities. The major source of uranium in the world is the disseminated ores containing from 0.01% to as much as 0.5% uranium, which are not amenable either to physical concentration or pyrometallurgical treatment.

As a result of intensive research a variety of new and useful processes were developed in a surprisingly short time. By 1954 large plants in Africa, Canada and the United States were recovering uranium successfully from phosphate liquors, gold mill tailings, low-grade ores and similar materials containing (in the case of gold mill tailings), as little as 0.01% uranium. An important outgrowth of this activity was the development and introduction on a commercial scale in metallurgical operations of the ion exchange and solvent extraction techniques.

The processes for leaching uranium ores are varied but the majority conform to the following general pattern:

The finely ground ore is leached in agitators or pachuca tanks with a dilute sulfuric acid solution to which is added an oxidizing agent, such as sodium chlorate or manganese dioxide, to convert the lower-valence uranium minerals present to the higher-valent soluble form. The, insoluble portions of the ore are separated by countercurrent decantation or filtration from the uranium sulfate solution which contains small amounts of iron, copper, aluminum and other sulfates.

The sulfate solution is passed through ion-exchange resin columns where the uranium ions become attached to the resin preferentially to the other ions present. The barren solution is discarded.

The loaded resin is eluted with nitric acid or sodium chloride solutions to produce a concentrated solution of uranium (the resin being simultaneously regenerated for reuse) which is neutralized with caustic soda or ammonia to precipitate an insoluble uranate. This high-grade precipitate is then further treated by solvent extraction and other methods to produce high-purity uranium metal.

Other methods involving the use of alkaline sodium carbonate solutions at atmospheric or elevated pressures are also employed, and there is a wide diversity in detail of both acid and alkaline procedures depending on the character of the uranium mineral in the ore and the impurities and gangue minerals associated with it.

(F. A. FD.)

HYDROMETEOR, an aggregation of particles of water or ice in the atmosphere. This includes all precipitation but excludes cloud forms (see CLOUD), nonaqueous meteors such as lithometeors (smoke, dust, sand), photometeors (halos, coronas, rainbows) and electrometeors (northern lights, lightning and thunder).

Types.—The new *International* Cloud Aflas (Geneva. 1956) lists the following hydrometeors and their definitions (abridged):

Rain.—Precipitation of liquid water particles, usually in the form of drops of more than 0.5 mm. (0.02 in.).

Drizzle—Fairly uniform precipitation composed exclusively of fine drops of water—diameter less than 0.5 mm. (0.02 in.).

Freezing *Rain* or Drizzle.—Rain or drizzle, the drops of which freeze on impact.

Snow.—Precipitation of ice crystals, most of which are branched.

Snow Pellets.—Precipitation of white and opaque spherical grains of ice. with diameters of about 2–5 mm. (0.1–0.2 in.).

Snow Grains.—Precipitation of very small, fairly flat, white and opaque grains of ice; their diameter is generally less than 1 mm. (0.04 in.).

Ice Pellets.—Precipitation of transparent or translucent spherical pellets of ice which have a diameter of 5 mm. (0.2 in.) or less.

Hail.—Precipitation of small balls or pieces of ice with a diameter ranging from 5 to 50 mm. (0.2 to 2.0 in.).

Ice Prisms.—A fall of unbranched ice crystals, in the form of needles. columns or plates, often so tiny that they seem to be suspended in the air.

Fog.—A suspension of very small water droplets in the air, generally reducing the horizontal visibility at the earth's surface to less than 1 km. ($\frac{5}{8}$ mi.).

Ice Fog.—A suspension of numerous minute ice crystals in the air, reducing the visibility at the earth's surface.

Mist.—A suspension in the air of microscopic water droplets, reducing the visibility at the earth's surface.

Drifting Snow and *Blowing Snow.*—An ensemble of snow particles raised by the wind.

Spray.—An ensemble of water droplets torn by the wind from the surface of an extensive body of water.

Dew.—This is a deposit of water drops on objects at the ground.

White dew.—Adeposit of white frozen dew drops.

Hoarfrost.—A deposit of ice having a crystalline appearance, which generally assumes the form of scales, needles, feathers or fans.

Rime.—A deposit of ice, composed of grains more or less separated by trapped air.

Glaze (Clear Ice).—A generally homogeneous and transparent deposit of ice formed by the freezing of supercooled drizzle droplets or raindrops on objects, the surface temperature of which is below or slightly above 0° C. (32° F.).

Spout.—A phenomenon consisting of an often violent whirlwind, revealed by the presence of a cloud column or inverted cloud cone (funnel cloud), protruding from the base of a cumulonimbus.

(E. M. Bs.)

HYDROMETER. A hydrometer is an instrument for measuring the density of a liquid. The first account of the use of hydrometers in England is in a paper published by Robert Boyle in the *Philosophical* Transactions in June 1675, and fig. 1 is reproduced from an illustration of a hydrometer contained in that paper.

The recognition of the fact that such an instrument provides a ready means of determining liquid density dates from early times, and there is evidence that Archimedes (287–212 B.C.) was familiar with it. The hydrometer remained of little importance until it was developed for industrial purposes. This development began with the use of hydrometers in the 18th century for determining

the strength of spirits and has gone on until at the present time hydrometers have widespread industrial applications.

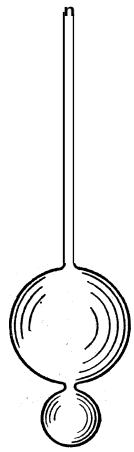

FIG. 1.—BOYLE'S HYDROMETER

Boyle's hydrometer (fig. 1) was made of glass and differs in no essential feature from modern glass hydrometers (fig. 2). The principle on which the construction of hydrometers is based is that a body floating partially immersed in a liquid is in equilibrium when the volume of liquid displaced. which is equal to the volume of the submerged portion of the body. has a mass equal to that of the floating body. A hydrometer placed in a liquid is read by noting the intersection of the level liquid surface with the stem of the hydrometer when the hydrometer is at rest and floating freely in the liquid. The reading is taken on a scale sealed inside the stem of the hydrometer. If V' is the volume of that portion of a hydrometer which is below a particular graduation mark on the scale, then $68'$ is the mass of liquid, of density 6, displaced when the hydrometer is floating freely with this graduation in the level of the liquid surface. If M is the mass of the hydrometer it follows that $\delta V' = M$ and $6 = M/V'$. Consequently if V is the volume of that portion of a hydrometer which is below the lowest graduation mark on the scale, and v is the volume of the portion of the stem between the highest and lowest graduation marks, the range of densities that can be determined is that lying between the values $6 = M/V + v$ and $6 = M/V$.

A Logical System of Hydrometry.— Neglecting, for the moment. the comparatively small effects of surface tension and changes of temperature, the plane of intersection of the level of a liquid surface with the stem of a hydrometer is determined solely by the density of the liquid. If, therefore, a scale is sealed inside a hydrometer stem having graduation marks suitably spaced and numbered to enable the density corresponding to any point on the scale to be easily read, the hydrometer will indicate directly the property of the liquid that determines the reading of the hydrometer.

These densities are generally most conveniently expressed in terms of grams per millilitre, which is therefore a convenient basis for the density scale of hydrometers.

The next thing to consider is the practical use of such a hydrometer. In the petroleum industry, density (often expressed as the equivalent specific gravity $\frac{S_{60°\,F.}}{60°\,F.}$) is used as one of the criteria of quality of petroleum products. Since these liquids have comparatively high coefficients of expansion. it is necessary to use the density at some specified temperature as a criterion for comparative purposes. The temperature generally adopted is 60° F., and a hydrometer adjusted to indicate densities at this temperature will give directly the desired density if read in a sample at 60° F. It is not always convenient, however, to bring the temperature of the sample to 60° F., and it is often more economical in expenditure of time to take the hydrometer reading at the prevailing temperature of the sample and to use tables to obtain from the hydrometer reading the density of the sample at 60° F. The correction tables can conveniently take the form shonn in Table I.

In using a density hydrometer for ascertaining the percentage composition of sugar solutions, the hydrometer is read in the solution, whose temperature is also noted, and then. by means of tables prepared as indicated in Table II, the required percentage of sugar is obtained.

Summarizing the scheme, the hydrometer is used to determine density and tables are used to convert the observations to a standard basis; *i.e.*, to percentage composition, etc. The advantages of such a system are: (1) The hydrometer scale is clearly defined and not dependent on the properties of a particular liquid; (2) the onus on the manufacturer is simply to produce accurate density hydrometers; *(3)* the conversion of density to percentage composition, etc., is left to the users, who should be in the best position to employ the most reliable data relating to the liquids in which they are interested; *(4)* tables can be revised without making hydrometers obsolete; (5) hydrometers can be used in a variety of liquids provided there are not too great variations in surface tension.

	10	11	12	13	14	15	16	17	18	19	20
1.050 g./ml.	12·38	12·41	12·46	12·50	12·54	12·59	12·63	12·68	12·73	12·78	12·84

The wide use of arbitrary scale hydrometers in the U.S., in preference to the more "scientific" instruments graduated in terms of density or specific gravity, results from the recognized advantage of using simple, easily remembered whole numbers instead of long. not so easily remembered decimals For example "62 A.P.I" motor fuel, "66 BC" sulfuric acid and *"190* proof" ethyl alcohol are more conveniently designated in terms of the arbitrary scales than they would be if designated respectively as "motor fuel having a specific gravity of *0.7292* at 60°/60° *F.,"* "sulfuric acid having a specific gravity of *1.8354* at 60°/60° *F* " and "ethyl alcohol having a specific gravity of *0.81603* at 60°/60° *F."* or as "95% ethyl alcohol by volume at 60° F."

Construction of Glass Hydrometers.— Relation Between *Volume* of *Stem* and *Volume* of Bulb.—Let M = the mass of the hydrometer in grams.

δ_0 = the density corresponding to the highest graduation mark in g./ml.

δ_1 = the density corresponding to the lowest graduation mark in g./ml.

V = volume of portion of hydrometer below the lowest graduation mark.

v = volume of stem between highest and lowest graduation marks in ml.

Then we have $M=\delta_0(V+v)=\delta_N V$,

whence $V=v\times\frac{\delta_0}{\delta_N-\delta_0}$.

Spacing of Graduation Marks on Density Hydrometer.— Let δ g /ml. be the density corresponding to any graduation mark intermediate between those corresponding to the limiting densities δ_0 and δ_N and let v' be the volume of the stem between the marks corresponding to the densities δ_0 and δ. Then we have

$$M=\delta_0(V+v)=\delta(V+v-v')=\delta_N V,$$

and by eliminating M and V we obtain

$$v'=v\times\frac{\delta-\delta_0}{\delta_N-\delta_0}\times\frac{\delta_N}{\delta}.$$

If the stem is of uniform diameter and L is the distance between the marks corresponding to δ_0 and δ_N and l is the distance from the highest graduation mark to the mark corresponding to δ then

$$l=L\times\frac{\delta-\delta_0}{\delta_N-\delta_0}\times\frac{\delta_N}{\delta}.$$

For a hydrometer of range 1.000 g./ml (δ_0) to 1.050 g./ml. (δ_N), having L = 150 mm., the above relation gives the following values:

Density corresponding to graduation mark g./ml.	1.000	1.010	1.020	1.030	1.040	1.050
Distance of graduation mark from highest graduation mark mm.	0	31.2	61.8	91.8	121.2	150.0

From the above values are derived

Distance from 1.000 g./ml. mark to 1.010 g./ml. mark = 31.2 mm.
" " 1.010 " " " " 1.020 " " " = 30.6 "
" " 1.020 " " " " 1.030 " " " = 30.0 "
" " 1.030 " " " " 1.040 " " " = 29.4 "
" " 1.040 " " " " 1.050 " " " = 28.8 "

The length corresponding to a change in density of 0.010 g./ml. therefore decreases toward the lower end of the scale; *i.e.*, the graduation marks on a density hydrometer became more closely spaced toward the lower end of the scale.

Temperature Corrections for Density Hydrometers.— Suppose a density hydrometer is adjusted to indicate densities in g./ml. correctly at t° C., to read δ g./ml. in a liquid having a temperature t° C. and also to read δ g./ml. when placed in a second liquid having a temperature t'° C.

The density of the first liquid is δ g./ml. at t° C. where $\delta=M/V$, M g. being the mass of the hydrometer and V the volume of the portion of the hydrometer below the mark δ.

When the hydrometer is reading δ g./ml. in the second liquid having a temperature t'° C. the volume of the submerged portion of the hydrometer is $V\{1+\alpha(t'-t)\}$ ml. nhere α is the coefficient of cubical expansion of the glass from which the hydrometer is made. The density δ g /ml. at t'° C. of the second liquid is therefore given by the equation

$$\delta'=\frac{M}{V\{1+\alpha(t'-t)\}},$$

or to a close approximation $\delta'=\delta\{1-\alpha(t'-t)\}$.

Let c be a correction to be applied to the reading δ g./ml. in the second liquid in order to give the density δ' g./ml. of that liquid at t'° C. Then $\delta'=\delta+c$,

whence $c=\delta\alpha\cdot(t-t')$.

An average value for a is 0.000026, so that if $(t-t')$ is equal to 10° C. we obtain the following values of c for various values of δ:

δ	0.6	1.0	1.5	2.0
c	0.0002	0.0003	0.0004	0.0005

Sow an error of 0.0005 g./ml. in density is negligible for most purposes for which hydrometers are used and so the above values of c are negligible in magnitude. Hence a density hydrometer which indicates densities correctly in g /ml. at its standard temperature t° C. may be used at any temperature within the range $(t\pm10)^\circ$ C. and will still indicate densities *at the temperature of observation* with a sufficient degree of accuracy for all ordinary purposes. It is possible to prepare tables by means of which corrections to standard temperature for individual liquids can be made, and corrections for change in volume of hydrometer as well as for density change of liquid can be included.

Effects of Surface Tension on Hydrometer Readings.— When a hydrometer is floating in a liquid the surface of the liquid does not remain level up to the point of contact with the emergent stem of the hydrometer; liquid piles up against the stem as shown in fig. 3. There is a downward pull on the stem of the hydrometer equal to the product of the surface tension of the liquid and the perimeter of the stem; *i.e.*, equal to $(T\times\pi\times d/10)$ dynes for a stem of circular cross section where T is the surface tension in dynes per centimetre and d mm. is the diameter of the stem. The effect of this is virtually to increase the mass of the hydrometer by an amount equal to $\frac{\pi dT}{10g}$ g. where g cm./sec.^{2} is the acceleration due to gravity.

Suppose that a hydrometer reads δ g./ml. in a liquid having a surface tension T, dynes/cm. and that this reading correctly represents the density of the liquid. Now suppose the hydrometer to be placed in a second liquid having the same density δ but a greater surface tension T_2 dynes/cm. The virtual increase in mass due to surface tension in the second liquid will be greater than that in the first liquid by an amount equal to

$$\frac{\pi d}{10g}\cdot\{T_2-T_1\}.$$

Hence the hydrometer will sink further in the second liquid than in the first until the increase in the mass of liquid displaced by the hydrometer is equal to the increase in the mass of liquid in the meniscus. If 1 mm. is the additional length of stem submerged in the second liquid the increase in the mass of liquid displaced by the hydrometer is

$$\frac{\pi}{4}\cdot\frac{d^2}{100}\cdot\frac{l}{10}\cdot\delta.$$

Hence we have

$$\frac{\pi d}{10g}\{T_2-T_1\}=\frac{\pi}{4}\cdot\frac{d^2}{100}\cdot\frac{l}{10}\cdot\delta,$$

from which

$$l=\frac{400}{d\delta g}\{T_2-T_1\}.$$

Let λ be the length of a subdivision on the hydrometer scale near the point corresponding to the density δ and let $\phi=l/\lambda$.

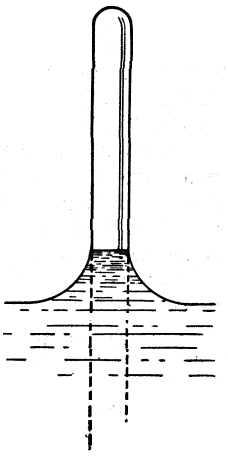

FIG. 3.— SURFACE TENSION ON A HYDROMETER

From the above equations we have

$$\phi=\frac{400}{\lambda d\delta g}\{T_2-T_1\},$$

and ϕ represents the error in terms of subdivisions corresponding to a' change in the surface tension amounting to $\{T_2-T_1\}$. It is obviously desirable that ϕ should be as small as possible; *i.e.*, that λd should be as large as possible.

The following example illustrates the magnitude of surface tension effects. For a hydrometer of range 1.000 g./ml. to 1.040 g./ml. having λ = 1.5 mm. and equivalent to 0.001 g./ml. we have if δ = 1.030 g./ml. and d = 5 mm. $\phi=0.053\{T_2-T_1\}$.

If such a hydrometer were to be adjusted to read correctly at 1.030 g./ml. in dilute sulfuric acid having a surface tension of 70 dynes/cm. and were subsequently to be used in milk of the same density but having a surface tension of 50 dynesicm.. then ϕ is 1.03, so that the hydrometer would be in error when used in milk by slightly more than one whole subdivision; *i.e.*, slightly more than 0.001 g./ml.

Some liquids. notably dilute aqueous solutions, have high surface tensions when the liquid surface is perfectly clean, but even very slight contamination may lower the surface tension considerably; *e.g.*, by as much as 20 dynes/cm. The errors consequent upon such variations in surface tension are the most serious of the limitations to the accuracy attainable with hydrometers.

Definitions of Hydrometer Scales in Common Use.— Specific *gravity*, written $S_{\frac{t_1^\circ}{t_2^\circ}}$, is the ratio of the density of the liquid at a temperature of $t_1°$ to the density of water at $t_2°$.

Hydrometers for *Ascertaining* the Strength of *Alcohol*.—Sikes's hydrometer is a metal hydrometer the mass of which can be changed by the addition of weights; it is used in Great Britain. The hydrometer reading. referred to special tables, gives the percentage of "proof spirit" (in Great Britain, 49.28% by weight of pure alcohol). Per cent of proof spirit at 60° F. is a scale widely used in the Cnited States, where proof spirit contains 50% by volume of pure alcohol). Other hydrometers for alcohol have scales indicating percentages by weight or by volume.

Saccharometers.—Bates's hydrometer is a metal hydrometer used in Great Britain: with a form of specific gravity scale. The Brix scale indicates percentage of sugar by weight at 17.5° C. In the United States, other temperatures are used as standard, the most common being 20° C.

The Twaddle scale registers degrees Twaddle

$$\text{at } 60° \text{ F.} = \frac{200(S_{\frac{60°\text{F.}}{60°\text{F.}}} - 1)}{}.$$

The *Baumé hydrometer* was invented in **1768.** Attempts to standardize this convenient, evenly spaced scale have been unsuccessful; they are graduated according to many different formulas in various countries. In the United States, the following are recognized by the national bureau of standards

For liquids heavier than water:

$$S_{\frac{60°\text{F.}}{60°\text{F.}}} = \frac{145}{145 - \text{degrees Baumé}}.$$

For liquids lighter than water:

$$S_{\frac{60°\text{F.}}{60°\text{F.}}} = \frac{140}{130 + \text{degrees Baumé}}.$$

For petroleum oils:

$$S_{\frac{60°\text{F.}}{60°\text{F}}} = \frac{141.5}{131\,5 + \text{degrees Baumé}}$$

This scale is known as the API (American Petroleum institute) scale.

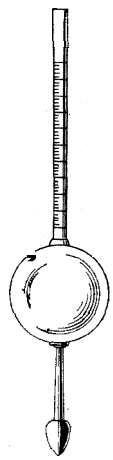

FIG 4.—SIKES S HYDROMETER

Relative Merits of Metal and Glass Hydrometers. — Disadvantages of metal hydrometers are: (1) they are liable to change in weight due to corrosion and wear; (2) the stem is not so readily wetted as that of a glass hydrometer; (3) joints are apt to develop leaks; (4) the bulbs are necessarily made of thin metal and are very liable to become dented. Through wear, slight leakage or a small dent, a metal hydrometer may become seriously in error without this being suspected unless its accuracy is checked at frequent intervals. A glass hydrometer is free from such disadvantages and provides a much more reliable instrument than a metal one. It is more liable to breakage than a metal hydrometer, but once broken the damage is apparent and there is no risk of using a hydrometer that has become seriously out of adjustment, which is one of the most important objections to a metal hydrometer.

Standardization of Hydrometers. — Since the readings on any hydrometer scale can be converted into equivalent densities, the errors of a hydrometer obviously may be obtained by reading the hydrometer in a liquid of known density. It is more convient, for example, to determine the errors of a hydrometer indicating percentages of sugar by weight by determining the densities corresponding to various points on the scale rather than by making up a series of sugar solutions to definite concentrations and reading the hydrometer in them.

The best method is to determine the density of the liquid and to observe simultaneously the reading of the hydrometer in the liquid. This can be done most conveniently by employing the sinker method of determining density. (See DENSITY.) The hydrometer and sinker can be placed side by side in the liquid and the hydrometer reading observed under precisely the same conditions as those under which the density is determined. Thorough stirring immediately previous to the observations and efficient temperature control are essential to secure uniform density throughout the liquid and to bring the temperature of the liquid to that at which the corrections to the hydrometer are required.

FIG. 5.—BATES'S SACCHAROMETER

The direct standardization of hydrometers by the above method takes considerable time and generally is employed only for hydrometers intended for use as standards for verifying other hydrometers. Given a hydrometer whose scale errors are known, a similar hydrometer may be verified by floating it side by side with the standard and taking simultaneous readings on both hydrometers. The difference between the readings combined with the known error of the standard gives the correction to the scale of the hydrometer under test. If the two hydrometers differ appreciably in dimensions, due allowance must be made for surface tension effects unless they are compared in the same liquid as that in which the hydrometer under test is to be used and the corrections to the standard in this liquid are known.

The extensive use of hydrometers in industry and the necessity for accuracy in construction has led to arrangements being made nhereby hydrometers may be submitted for verification to national institutions — in England to the National Physical laboratory: in the U S. to the national bureau of standards, Washington; in France to the Laboratoire d'Essais, Paris; and in Germany to the Physikalische Technische Reichsanstalt. Charlottenburg.

HYDROPATHY, the treatment of disease by water, commonly called the "water cure." is a system that professes to cure all disease by water. The use of water medicinally both by application and by drinking was recognized by the ancient Greeks and Romans and older civilizations. Hydropathy as a formal system, however, came into vogue about **1829** under the leadership of Vincent Priessnitz (1801–1851), a Silesian farmer who believed in and nidely publicized the medicinal values of the water upon his paternal homestead. It became a popular and accepted form of medical treatment during the 19th century both in Europe and in America.

The term hydropathy is not widely used in modern times; the formal system of hydropathy is divided into two categories: spa therapy and hydrotherapy. Spa therapy, much more accepted medically in Europe than it is in the United States, is based on both drinking and bathing in certain waters containing agents believed to be of medicinal value. Many United States authorities believe that most of the medicinal effects of spa therapy are indirect, resulting from the relaxation of the patient as the result of the environmental factors of the spa.

There is much more widespread medical acceptance of the scientific value of hydrotherapy, the external application of water for specific therapeutic purposes. Its primary values are found

through its versatility as a medium for the external application of heat, which brings about an increase in the temperature of the tissues, vasodilation and an increase in circulation. Sedation and relief of pain and muscular tension are the best-accepted effects of heat therapy. The hydrotherapeutic means of applying heat most usually used are whirlpool baths, the Hubbard tank (underwater mechanical massage), hot packs, contrast baths and paraffin.

Because the effects of superficial heating are practically the same regardlesss of the source and type selected, its application is based on availability of source, extent of area to be treated, depth of effective penetration, time necessary to produce desired effects, ease of application, margin of safety and individual preference.

Hydrotherapy is a therapeutic modality usually employed by specialists in physical medicine and rehabilitation and by physical therapists.

HYDROPHOBIA: *see* RABIES.

HYDROPHYLLACEAE (materleaf family), a family of dicotyledonous flowering plants belonging to the Polemoniales, containing annual or perennial herbs and shrubs *(Eriodictyon, Wigandia)* with regular five-merous sympetalous flowers, the ovary usually unilocular with parietal placentae, and a several- to many-seeded capsule. The flowers. often showy and mostly insect pollinated, are chiefly blue, purple or white in one-sided (helicoid) cymes.

Similarities and affinities are perhaps greatest to Boraginaceae, from which they differ principally in the capsular fruit, an unlobed ovary and bifurcated terminal styles. They comprise a small family of about 18 genera and 250 to 300 species, found chiefly in western United States, the best-known genera being *Nemophila* (baby-blue eyes), *Phacelia* (the largest genus), *Eriodictyon* (yerba santa), *Hydrophyllum, Wigandia, Nama* and *Hydrolea* (pantropical). *(L N. C.)*

HYDROPHYLLUM, commonly called waterleaf, a small genus of mostly perennial North American herbs of the Hydrophyllaceae family. They have large, attractive, palm-shaped leaves, about a foot across, and clusters (one-sided cymes) of small bell-shaped, greenish white, blue or purple flowers. *H. canadense* and *H. virginianum* are often planted in partial shade in the wild garden.

HYDROPLANE: *see* MOTORBOAT; SEAPLANE.

HYDROPONICS, from the Greek *hydro,* water, and *ponos,* labour, refers to the groning of plants nithout soil and is sometimes called soil-less culture.

UNITED PRESS INTERNATIONAL

SPRAYING SEEDLINGS AT A COMMERCIAL HYDROPONICS EXPERIMENTAL FARM IN PUERTO RICO. PLANTS ARE GROWN IN CONCRETE BEDS FILLED WITH GRAVEL; THEY ARE FED A SOLUTION OF CHEMICALS IN WATER

For many years in the study of their nutrition, plants were grown with their roots immersed in solutions. but the commercial adoption of this method of culture mas not entirely successful because of difficulties in plant support and solution aeration. Gravel culture therefore largely supplanted solution or water culture as a means of groning plants without soil. An inert medium such as gravel of various kinds. fused shale and clay, granite chips or other such materials with a particle size of one-fourth inch to three-eighths inch in diameter serves as a support for the plants This medium is placed in a watertight bed or bench and a fertilizer solution is periodically pumped each day into the bench or bed, the frequency depending upon the prevailing light intensity and temperature. and other weather factors, the size of plants or concentration of the fertilizer solution, stronger solutions being pumped more frequently. The solution drains back into a tank and the frequency of pumping usually is controlled automatically.

The solution is composed of different fertilizer-grade chemical compounds containing varying amounts of nitrogen, phosphorus and potassium, the major elements necessary for plant growth. These fertilizers also contain compounds of various trace or minor elements. such as sulfur, magnesium, calcium, etc. There are many satisfactory formulas for fertilizer solutions; one proved successful with florist crops is:

Chemical	Per 1,000 gal. of water
Potassium nitrate	5 lb. 13 oz.
Ammonium sulfate	1 lb.
Magnesium sulfate (Epsom salts)	4 lb. 8 oz.
Monocalcium phosphate	2 lb. 8 oz.
Calcium sulfate	5 lb.
Total	18 lb. 13 oz.

The chemicals can be mixed in dry form and stored if desired. The concentration of the solution is increased as the plants grow larger by using 1½ or 2 times the amount of chemicals per 1,000 gal. of water. To the above solution is added each week four ounces of iron (ferrous) sulfate and one ounce of manganous sulfate dissolved in a gallon of water acidified with several drops of sulfuric acid. Other trace elements are added if necessary. Tests of the solution are made every two or three weeks for pH (acidity) and the major elements and additions of the necessary chemicals are made as needed. The solution can be used indefinitely with the necessary additions of water and chemicals.

The main advantage of gravel culture is in the labour saved by automatic watering and fertilizing, though installation costs are higher than costs for plants grown in soil. No greater yields may be expected than from similar plants in soil in the same environment. A wide variety of vegetables and florist crops can be grown satisfactorily in gravel culture. Commercial acceptance of hydroponics is impeded by high installation costs, the necessity for frequent testing of the solutions and the greater familiarity of plant cultivators with soil. For further discussion of the elements necessary for plant growth *see* FERTILIZERS AND MANURES. *See* also PLANTS AND PLANT SCIENCE: *Metabolism.*

HYDROSPHERE, the whole mass of oceanic waters filling the major depressions in the earth's crust, and covering about 72% of its surface. The name is used in distinction from the atmosphere (*q.v.*), the lithosphere (*q.v.*) and the centrosphere or mass within the crust.

HYDROSTATICS, the branch of hydromechanics which deals with the equilibrium of fluids *(see* MECHANICS, FLUID).

HYDROXIDE, a term used in its most general sense to designate any chemical compound containing oxygen and hydrogen bonded together in the OH group. One or more of the OH groups are in turn linked to another element or radical. Employed in this broad sense the name is indicative of the composition but not

necessarily the nature of the compound. In practice it is therefore preferable to restrict the term to those compounds containing the hydroxide ion. OH^-, and the positively charged ion of a metal or a radical. *e.g.,* sodium hydroxide; it is also preferable to characterize the presence of the hydroxyl radical, OH, by hydroxy. as in the organic compound hydroxy acetic acid, $CH_2OHCOOH$, and in co-ordination compounds by hydroxo, as in potassium tetrahydroxoaurate. $KAu(OH)_4$.

The hydroxides include the familiar bases of the laboratory and industrial processes. Those of the alkali metals, lithium, sodium, potassium, rubidium and cesium. are the strongest bases, the most stable and the most soluble of the hydroxides. Lithium hydroxide is somewhat unlike those of the other metals of this group, being less soluble and less stable; it decomposes at red heat. losing water to form the oxide Li_2O, whereas the others may be volatilized without loss of water. Sodium hydroxide (see ALKALI). NaOH, also known as caustic soda or lye, is of great industrial importance. Calcium, barium and strontium. alkaline earth metals, form soluble hydroxides which are strong bases but less stable than the alkali hydroxides. Of these calcium hydroxide or slaked lime is the most common. With the exception of thallous hydroxide, TlOH, the hydroxides of other metals such as magnesium, iron, bismuth. nickel. cobalt and copper are only sparingly soluble in water but react with acids. The hydroxides of beryllium. lead, zinc, aluminum, chromium (trivalent): tin (divalent), gold (trivalent) and certain other metals show both acidic and basic properties; that is, they dissolve in water solutions of either bases or acids. Hydroxides and other substances, *e.g.,* oxides and sulfides, with these dual properties are called amphoteric.

Oxygen acids. although structurally represented to show the presence of hydroxyl radicals, *e.g.,* boric acid. $B(OH_3)$, sulfuric acid. $SO_2(OH)_2$, and hypochlorous acid, Cl(OH), are not designated as hydroxides. (J. B. Ps.)

HYDROXYLAMINE, represented by the formula NH_2OH, was first prepared in 1865 by W. C. Lossen as the chloride by the reduction of ethyl nitrate with tin and hydrochloric acid. Hydroxylamine reacts with aldehydes and with ketones to form the important class of organic compounds known as oximes (*q.v.*). Oximes can be reduced easily to amines: they find use in the manufacture of dyes. plastics, synthetic fibres and medicinals.

The synthesis of hydroxylamine may be effected by the following general procedures: (1) chemical or electrochemical reduction of nitric acid. nitrous acid, nitrates and nitrites. and of oxides of nitrogen; (2) interaction of nitrites with acid sulfites in 1:2 molar proportions to yield the hydroxylamine disulfonates which are easily hydrolyzed to form hydrosylaminonium sulfate

$$(NO_2- + 2HSO_3- + H+ \rightarrow HON(SO_3)_2= + H_2O;$$
$$HON(SO_3)_2= + 2H_2O \rightarrow NH_2OH.H^+ + 2SO_4=);$$

(3) oxidation of ammonia; and (4) hydrolysis of nitroparaffins ($RCH_2NO_2 + H^+ + H_2O \rightarrow RCOOH + NH_2OH.H^+$). Although electrolytic reduction of nitric acid in presence of sulfuric acid at low temperatures using amalgamated lead cathodes once furnished most of the hydroxylamine, methods (2) and especially (4) have gradually assumed greater technical importance. These technical processes may. however. be supplanted by a procedure which entails the catalytic hydrogenation of nitric oxide in the presence of acid ($NO + 3[H] + H^+ \rightarrow NH_2OH.H^+$) to yield hydroxylamine salts.

Pure anhydrous hydroxylamine was first obtained by C. A. Lobry de Bruyn from the chloride by treating an absolute methyl alcoholic solution with sodium methylate ($NH_2OH.HCl + NaOCH_3 \rightarrow NaCl + NH_2OH + CH_3OH$). The precipitated sodium chloride is filtered and hydroxylamine recovered after removal of alcohol by distillation under reduced pressure. Butyl alcohol and sodium butylate are preferred since addition of ether to the solution of hydroxylamine and cooling yields the free base as a solid product. The pure compound is a colourless. odourless crystalline solid. melting at 33° C.. boiling at 58° C. (at 22 mm.) and decomposing readily at higher temperatures, sometimes with explosive violence. It is very soluble in water to give solutions which are moderately stable and less basic than aqueous solutions of either ammonia or hydrazine, both of which it resembles chemically. The dissociation constant for hydroxylamine as a base (*e.g.,* $NH_2OH.H_2O \rightleftarrows NH_2OH.H^+ + OH-$) is $K = 6.6 \times 10^{-9}$. Hydroxylamine inflames in dry chlorine and is reduced to ammonia by zinc dust. It combines with sulfur dioxide to give sulphamic acid ($NH_2OH + SO_3 \rightarrow NH_2SO_3H$). It is a strong reducing agent, giving a precipitate of cuprous oxide from alkaline copper solutions and depositing metallic silver from solutions of silver salts. Under certain conditions it may act as an oxidizing agent, as in the conversion of ferrous hydroxide to ferric hydroxide. It is highly probable that two structures may be assigned to hydroxylamine. viz., H_2NOH in acid solution and H_3NO, the amine oxide formulation. in alkaline solution (F. Haber). Although many methods have been suggested for the estimation of hydroxylamine, most of them depend on careful adjustment of the acidity of the solution. That of F. Raschig. however. is less sensitive to conditions and is the most trustworthy; the hydroxylamine solution is boiled with a considerable excess of ferric sulfate in sulfuric acid, and the ferrous salt thus formed by reduction [$2Fe_2(SO_4)_3 + 2NH_2OH = 4FeSO_4 + 2H_2SO_4 + N_2O + H_2O$] is titrated with potassium permanganate.

Hydroxylammonium salts form readily. the sulfate and the chloride being best known. Like ammonia. hydroxylainine forms co-ordination compounds such as $ZnCl_2.2NH_2OH$ and $[Co(NH_2OH_6]\ Cl_3$ (see CO-ORDINATION COMPOUNDS). The hydroxylamine derivatives of sulfuric acid include salts of the hydroxylamine mono-, di-, tri-. isodi- and isomono- sulfonic acids with the respective formulas: $HONH(SO_3H)$, $HON(SO_3H)_2$, $(HSO_3)NO(SO_3H)_2$, $(HSO_3)ONH(SO_3H)$ and $H_2NO(SO_3H)$. The hydroxylamine isoinonosulfonic acid, more properly designated as O-hydroxylamine sulfonic acid. is a powerful oxidizing and aminating agent, prepared by reaction of hydroxylamine sulfate with oleum (see G. T. Moeller Led.]. *Inorganic* Syntheses, vol. V [1958]).

Hyponitrous acid, HON = NOH, may be regarded as one of the hydroxylamine derivatives of nitrous acid. and its salts are readily prepared from hydroxylamine and an alkyl nitrite in alcoholic solution in the presence of a base. The related nitrosohydroxylamine. HN(NO)OH, is known only in the form of organic derivatives such as "cupferron." a widely used analytical reagent, which is the ammonium salt of N-phenylnitrosohydroxylamine, $C_6H_5N(NO)ONH_4$.

The organic hydroxylamines are compounds in which one, two or all three hydrogen atoms are replaced by organic radicals. Their structure may be indicated using the older convention by specifying substitution either in the α or β positions:

$$\overset{\beta}{H_2N} - \overset{\alpha}{OH}$$

but preferably by prefixing N or O to designate the point of attachment. Thus. NH_2OCH_3 is O-methylhydroxylamine, whereas C_6H_5NHOH is N-phenylhydroxylamine. Trisubstituted hydroxylamines are generally considered to be amine oxides, R_3NO (see above) and are obtainable by the action of hydrogen peroxide on tertiary amines (see AMINES). Other well-known organic derivatives include the hydroxamic acids,

$$RC(=O)-NHOH$$

and the amidoximes. $RC(NH_2)NOH$, both derivable from, and related generically to. the carboxylic acids.
