Volume *14*

LIBIDO *TO* MARY, DUCHESS OF BURGUNDY

LIBIDO, defined by Freud as "the energy of those instincts which have to do with all that may be comprised under the word 'Love."' Jung enlarged the concept so that for him it describes the energy resident in all instincts. Libido is usually considered to be synonymous with other such vague concepts as *élan* vital and psycho-physiological energy.

It is claimed that the energy of intellectual processes is measured by intelligence tests in terms of clearness and speed; but the measurement of the conative energy of a "uish" is more difficult, because the wish, which may be considered to be the inner feeling of need together with motor sets appropriate to its appeasement, may fail to find expression in measurable overt conduct because of opposing repressive (unconscious) and suppressive (conscious) forces.

See PSYCHOANALYSIS; MOTIVATION.

LIBITINA, Roman goddess of funerals. She had a sanctuary in a sacred grove (perhaps on the Esquiline). where by an ordinance of the legendary Roman king Servius Tullius a piece of money nas deposited whenever a death took place. There the undertakers (libitinarii), uho carried out all funeral arrangements by contract, had their offices, and everything necessary was kept for sale or hire; there all deaths were registered for statistical purposes. The word Libitina then came to be used for the business of an undertaker, funeral requisites and, by poets. for death itself. By antiquarians Libitina was sometimes identified nith Persephone. but more commonly (partly or completely) with Venus Lubentia or Lubentina, an Italian goddess of gardens—a mere confusion. The similarity of name and the fact that Venus Lubentia had a sanctuary in the grove of Libitina favoured this idea. Further, Plutarch mentions a small statue at Delphi of Aphrodite Epitymbia (Aphrodite of Tombs = Venus Libitina), to which the spirits of the dead were summoned. Libitina may have been originally an earth goddess, connected with luxuriant nature and the enjoyments of life; then, all such deities being connected with the underuorld, she also became the goddess of death, and that side of her character predominated in the later conceptions.

LIBO, in ancient Rome, the name of a family belonging to the Scribonian gens. It is chiefly interesting for its connection with the Puteal Scribonianum or Puteal Libonis in the forum at Rome, dedicated or restored by one of its members, perhaps the praetor of 204 B.C., or the tribune of the people in 149.

Puteal was the name given to an erection or enclosure on a spot which had been struck by lightning; it was so called from its resemblance to the stone curb or low enclosure round a well (*puteus*). In the vicinity of the Puteal Libonis the praetor's tribunal, removed from the comitium in the 2nd century B.C., held its sittings, nhich led to the place becoming the haunt of litigants and business people.

LIBON, a Greek architect, born at Elis, who was employed to build the great temple of Zeus at Olympia (*q.v.*) about 460 B.C. (Pausanias, v, 10, 3).

LIBOURNE, a town of southwestern France, capital of an *arrondissement* of the *département* of Gironde, at the confluence of the isle with the Dordogne, 22 mi. E N.E. of Bordeaux on the railway to Angoulême. Pop. (1954) 14,581. The river is tidal and vessels drawing 14 ft. can reach the town at the highest tides. Libourne stands on an ancient site. Under the Romans Condate stood a mile to the south of the present Libourne; it was destroyed in the 5th century. Resuscitated by Charlemagne, it was rebuilt in 1269, under its present name and on the site and plan it still retains, by Roger de Leybourne (of Leybourne in Kent), seneschal of Guienne, acting under the authority of King Edward I of England.

It suffered considerably in the struggles of the French and English in the 14th century. The church of St. Jean, restored 15th-century Gothic, has a stone spire 232 ft. high. On the quay a 14th-century clock tower survives from the old ramparts, and the *hôtel* de ville is a quaint relic of the 16th century. Libourne is the seat of a subprefecture and of tribunals of first instance and of commerce.

Trade is in local wines and brandies. Printing and cooperage are carried on.

LIBRA (the "Balance"), in astronomy, a constellation and sign of the zodiac (*q.v.*). The constellation was pictured as a pair of scales; its stars are faint and present little of interest to the naked eye. The name suggests the equality of day and night when the sun arrives at the autumnal equinox and enters the sign Libra. The sign itself has been shifted westward into the adjoining constellation Virgo by the earth's precessional motion.

(R. H. BR.)

LIBRARIES. A library (from Lat. liber, book) is a collection of printed or written material arranged and organized for the purpose of study and research or of general reading or both. Many libraries also include collections of films, microfilms, phonograph records, lantern slides and the like within the term "written or printed material." Libraries may be roughly classified in two ways: by ownership or use; *e.g.*, national, municipal, county, university, research, school, industrial, club, private, etc.; or by contents; *e.g.*, general, special (including medical, legal, theological, scientific, engineering, etc.). General libraries frequently contain special collections. The organization ranges from a system of great complexity, with catalogues and indexes and other records, a binding department, a secretariat and a large staff, to the simple arrangement with perhaps a list of his books which suffice for the owner of the smaller private library.

ANCIENT LIBRARIES

The earliest libraries probably consisted of archive collections preserved in temples and palaces. In the course of his excavations at Nineveh in 1850, Sir Austen Layard came upon tablets of clay, covered with cuneiform characters. These varied in size from 1 in. to 12 in. square. It is estimated that this library consisted of about 10,000 distinct works and documents. The tablets appear to have been methodically arranged and catalogued, and the library seems to have been public. (See BABYLONIA AND ASSYRIA; NIPPUR.)

Egypt.—At an early date Heliopolis was a literary centre of great importance, with a culture akin to the Babylonian. Attached to every temple were professional scribes. There is a record relating to "the land of the collected works (library) of Khufu," a monarch of the 4th dynasty, and a similar inscription relating to the library of Khafra, the builder of the second pyramid. At Edfu the library was a small chamber in the temple, on the wall of which is a list of books (Brugsch, *History of Egypt,* i, 240 [1881]). The exact position of Ikhnaton's library (or archives) of clay tablets was found. A library of charred books was found at Mendes (Egypt Expl. fund, *Two Hieroglyphic Papyri),* and there are references to temple libraries on the Silsileh "Nile" stelae and, perhaps, in the Harris papyri. The most famous of the early Egyptian libraries, that of King Osymandyas (Rameses II, 1300–1236 B.C.), described by Diodorus Siculus, was probably in the Ramessaeum at western Thebes.

Greece.—Among known collèctors of books were Pisistratus, Polycrates of Samos, Euclid the Athenian, Nicocrates of Cyprus and Euripides. At Cnidus there is said to have been a special collection of works upon medicine. Plato is known to have been a collector, and Xenophon tells us of the library of Euthydemus. The earliest recorded collection worthy of the name of "library" was that of Aristotle, who is described by Strabo as having been "the first man known to have collected a library" and is, moreover, credited by the same authority as having "taught the kings of Egypt to do likewise." Aristotle bequeathed his collection to his disciple Theophrastus, and it is known that Demetrius of Phalerum, a pupil of Theophrastus, had great influence on Ptolemy I, the founder of the library of Alexandria.

Alexandria.—Under Ptolemy I's son, Ptolemy Philadelphus, the Alexandrine library rapidly became the intellectual centre of Hellenistic culture. Manuscripts were collected from all parts of the then known world and scholars flocked in ever-increasing numbers to work on them. The main library, with the museum, was situated in the Brucheum; in Roman times the collection overflowed into another building in the Serapeum.

The number of volumes was very large, although it is difficult to attain any certainty among varying accounts, such as those of Tzetzes (42,800 in the Serapeum and 490,000 in the Brucheum), Aulus Gellius (700,000) and Seneca (400,000). It should be observed that, as the ancient roll or volume usually contained less matter than a modern book, these numbers must be discounted for comparison with modern collections. The first five librarians appear to have been Zenodotus, Callimachus, Eratosthenes, Apollonius and Aristophanes; they cover about a century. The catalogues of the Alexandrine libraries were among the earliest experiments in bibliography. Among other lists, two were prepared by order of Ptolemy Philadelphus, one of tragedies, the other of comedies. The *pinakes* (tablets) of Callimachus formed a catalogue of all the principal books, arranged in 120 classes. After the time of Aurelian, the Serapeum became the principal library. The importance of the libraries decreased with the political decline of Alexandria itself, and the usual statement that the libraries continued to flourish until they were destroyed in A.D. 640 can hardly be supported.

The **Pergamum.**—German researches in the acropolis of Pergamum (1878–86) revealed four of the rooms of the Attalid library (Alexander Conze, *Die pergamen. Bibliothek* [1884]). Despite the embargo, reported by Pliny, placed by the Ptolemies upon the export of papyrus, the library, when it was transported to Egypt, numbered 200,000 volumes. We learn from Suidas that in 221 B.C. Xntiochus the Great summoned the poet and grammarian Euphorion of Chalcis to be his librarian.

Rome.—It is not until the last century of the republic that we hear of libraries in Rome, with the exception of the writings of Mago upon agriculture. The first considerable collections of which we hear in Rome were brought there as the spoils of war. The library of Perseus was all that Aemilius Paulus reserved from the prizes of victory (167 B.C.) for himself and his sons. Next came the library of Apellicon the Teian, brought from Athens by Sulla (83 B.C.). The zeal of Cicero and Titus Pomponius Xtticus in adding to their collections is well known. Tyrannion is said to have had 30,000 volumes of his own, and Cicero wrote to M. Terentius Varro: *"Si hortum* in *bibliotheca habes, nikil deerit"* (If you have a garden in the library. nothing will be lacking). Julius Caesar is recorded as having proposed to establish a public library in Rome, but the honour of being the first actually to dedicate a library to the public is said by Pliny and Ovid to have fallen to G. Asinius Pollio, who erected a library in the Atrium Libertatis on Mount Aventine. Augustus erected two libraries, the Octavian and the Palatine. The forrner was founded (33 B.C.) in honour of his sister, the charge of the books being committed to C. Melissus. The Octavian and Palatine libraries perished by fire; the story that the Palatine was destroyed by order of Pope Gregory the Great in the 6th century is now generally rejected. Tiberius, the immediate successor of Augustus, established on the Palatine what Gellius refers to as the "Tiberian library." Vespasian established a library in the Temple of Peace erected after the burning of the city under Nero. Domitian restored the libraries then destroyed, and he, or Hadrian, founded the Capitoline library. The most famous and important of the imperial libraries was that created by Ulpius Trajanus, known as the Ulpian library, afterward moved to the baths of Diocletian. The library of Domitian, which had been destroyed by fire in the reign of Commodus, was restored by Gordian, who added to it the 62,000 books bequeathed to him by Serenus Sammonicus. In the 4th century there are said to have been 28 public libraries in Rome.

Roman Provincial Libraries.—The library which the younger Pliny gave to Comum cost 1,000,000 sesterces; Hadrian established one at Athens, described by Pausanias, and in modern times identified with the Stoa of Hadrian. At Ephesus and at Timgad in Algeria, the structural plan of the library buildings is clear (R. Cagnat, "Les Bibliotheques municipales dans l'Empire Romain," *Mém.* de *l'Acad. des Insc.*, tom. 38, pt. 1 [1906]). A private library discovered at Herculaneum contained 1,756 rolls on shelves to a height of about 6 ft. around a room approximately 12 ft. square, with a central press, or shelved case.

The names of several librarians (generally slaves or freedmen) are preserved to us in inscriptions, including that of C. Hymenaeus, physician and librarian to Augustus.

Constantinople.—When the seat of empire was removed by Constantine to his new capital upon the Bosporus, the emperor established a collection there. Constantine's library, which contained 6,900 volumes, was perhaps mainly intended as a repository of Christian literature; it was greatly enlarged by Julian and Theodosius, at whose death it is said to have increased to 100,000 volumes. Julian not only augmented the library at Constantinople, but founded others.

As Christian literature grew, libraries became part of the ecclesiastical organization, and it became the rule to attach one to every church. The largest of these libraries, that founded by St. Pamphilus (d. A D. 309) at Caesarea, and said to have been increased by Eusebius to 30,000 volumes, is frequently mentioned by St. Jerome. St Augustine bequeathed his collection to the library of the church at Hippo, which was fortunate enough to escape destruction at the hands of the Vandals. Even the hermit communities of the Egyptian deserts, out of which developed the later monastic orders, accumulated books.

With the removal of the capital to Byzantium the libraries of Rome ceased to collect the writings of the Greeks, while the Greek libraries had never cared much to collect Latin literature. The church became increasingly hostile to pagan letters. The repeated irruptions of the barbarians soon snept the old learning and libraries alike from the soil of Italy. With the close of the western empire in 476 the ancient history of libraries ceased.

MEDIAEVAL PERIOD

Learning had little place in a barbaric Europe. Nevertheless, in spite of persecutions, Christians all over the Roman world quietly went on amassing in their churches and monasteries collections of their own literature, and scriptoria began to be established in which the monks produced their own books. The use of vellum instead of papyrus resulted in the supersession of the roll of classical antiquity by the bound book as we know it today.

Monastic Libraries.— It is to St. Benedict that we owe the development of the monastic library. The abbey of Monte Cassino, founded *c.* 529, mas the first of a long line of houses in which the establishment of a library of religious works was obligatory and daily reading and study were enjoined upon the monks. and the influence of this wise and simple rule rapidly spread throughout all Christendom.

Of the reformed Benedictine orders the Carthusians and the Cistercians were those most devoted to literary pursuits. The abbeys of Fleury, of Melk and of St. Gall were remarkable for the splendour of their libraries. The Augustininns and the Dominicans were scarcely less active than the Benedictines! the libraries of Ste. Geneviève and St. Victor, belonging to the former order, being among the largest of the monastic collections.

Independently of the Benedictine influence! the monasteries of Ireland and of Anglo-Saxon England were amassing noteworthy collections, and the missionary zeal of the monks spread their influence to northern Gaul and to the Rhineland while that of St. Benedict was spreading northward from Italy to meet it. Even in Italy itself. the monastery of Bobbio owed its foundation to an Irish monk. Columban *(c.* 613). The greatest name of the period is that of Alcuin of York, the English monk who went to the court of Charleinagne in the late 8th century and did so much to develop, in his monastery at Tours. the Carolingian minuscule hand which forms the basis of modern European writing and printing. Among the few private collectors of this period, Louis I the Pious, son of Charlemagne. Charles II the Bald and Gerbert (afterward Pope Sylvester II) may be mentioned here.

Of the other monastic libraries of France the principal were those of Cluny, St. Riquier, Corbie. Bec and St. Martial (Limoges). The library of St. Riquier, in the time of Louis the Pious, contained 2 j6 manuscripts, with more than 500 works. Of the collection at Corbie in Picardy we have two catalogues dating from the 12th and from the 17th centuries. In 1638, 400 of its choicest manuscripts were removed to St. Germain-des-Prés. The remainder were removed after 1794, partly to the national library at Paris, partly to the town library of Amiens.

The chief monastic libraries of Germany were at Fulda, Corvey, Reichenau and Sponheim. The library of Corvey on the Weser, after being despoiled in the Reformation, was presented to the University of Marburg in 1811. The library at St. Gall, formed as early as 816 by its second abbot, still exists. Reference: to monastic libraries occur throughout the sections on various countries.

England.— In England, the principal collections were those of Canterbury. York, Wearmouth, Jarrow, Whitby, Glastonbury, Crowland. Peterborough and Durham. The library of Christchurch, Canterbury, originally founded by Augustine and Theodore and destroyed by the Danes about 867, contained, in the 13th or 14th century. about 5,000 works. Sir Richard Whittington built a library for the Grey Friars in London. and this order possessed considerable libraries at Oxford. Of Whitby there is a catalogue of the 12th century. The catalogue of Glastonbury was printed by Thomas Hearne in his edition of John of Glastonbury. The library of Crowland perished by fire in 1091; Peterborough, from a catalogue of about the end of the 14th century. had 344 volumes, with nearly 1,joo titles. The catalogues of Durham were printed by the Surtees society. (The oldest catalogue of a western library is that of the monastery of Fontanelle in Normandy [8th century].) Many catalogues may be found in the collections of D'Achery, Edmond Martène and Ursin Durand. and Bernhard and Hieronymus Pez, in the bibliographical periodicals of Robert Naumann and Julius Petzholdt and the *Zentralblatt für Bibliothekswesen.* Joseph Hunter collected some particulars as to the contents of the English monastic libraries; E. Edwards printed a list of the catalogues *(Libraries and Founders of Libraries,* pp. 448–454 [1865]. *See* also G. Becker, *Catalogi Bibliothecarum Antiqui* [1885].) In the 14th century the Franciscans compiled a general catalogue of the manuscripts in 160 English libraries, and about 1400 John Boston, a Benedictine monk of Bury, catalogued the libraries of 19j religious houses in England and part of Scotland (Thomas 'Tanner, *Bibliotheca Britannico-Hibernica* [1748]). John Leland's list of the books he found during his visitation of the houses in 1539–45 is printed in his *Collectanea.*

The identification of the early provenance of mediaeval manuscripts was greatly advanced in modern times, especially by the works of M. R. James, both by catalogues of existing collections and by publications of surviving monastic catalogues; *e.g.,* those of Canterbury and Dover (1909). *(See,* generally, J. W. Clark, *The Cave of Books* [1909], and E. A. Savage, *Old English Libraries* [1911].) These catalogues. with many others. afford abundant evidence of the limited size and character of the monkish collections.

The Development of Library **Arrangements.**—Modern library methods began with the Rule of St. Benedict. early in the 6th century. In the 48th chapter the monks were ordered. for their daily reading. to borrow a book apiece and to read it straight through. The Carthusians and Cistercians. among others, had a system of interlibrary loans; the Cluniacs had an annual stocktaking; and some of the Benedictine houses had, by the end of the 11th century. separate reference and lending divisions. In some monasteries the books were housed in a press located in the cloisters, as at Worcester; elsewhere they were in the treasury. Books used by the reader in the refectory might be kept in a press near the infirmary. By the end of the 15th century the larger monasteries found it necessary to establish a separate library apartment.

Libraries were specially built at Canterbury, Durham, Citeaux, Clairvaux and elsewhere. and there grew up increased liberality in the use of books. During this period, collegiate and monastic libraries were on the same plan. the books being laid on desks or lecterns and chained to a horizontal bar. As the books increased the accommodation was augmented by one or two shelves erected above the desks, each bay being lighted by its own window. The library at Cesena is still in its original condition and that of Merton college, Oxford, is nearly so. The Laurentian library at Florence was designed by Michelangelo on the monastic model. There were no chains in the library of the Escorial, erected in 1584, which was the first library to dispense with bays and arrange its books in cases lining the walls of a great hall. Chains continued to be used in England in church libraries down to the early part of the 18th century, as at Wimborne. Triple desks and revolving lecterns: raised by a wooden screw, formed part of the library furniture. The English cathedral libraries were fashioned after the same principle. By the end of the 17th century the type of public library developed from collegiate and monastic prototypes became fixed in Europe. (H. R. Tedder, "Evolution of the Public Library," *Trans. of 2nd Int. Library Conference* [1897, 1898].)

Islam. — Greek manuscripts were eagerly sought for and translated into Arabic, and colleges and libraries arose everywhere, notably at Baghdad, Cordova, Cairo and Tripoli. The royal library of the Fatimites in Africa and that collected by the Omayyads of Spain are reported, perhaps with exaggeration, to have contained, respectively, 100,000 and 600,000 manuscripts. It is said that there were no fewer than 70 libraries established in the cities of Andalusia.

Renaissance. — In the 9th century, under Leo the Philosopher and Constantine Porphyrogenitus, the libraries of Constantinople awoke into renewed life. Meanwhile, in the west we find arising outside the monasteries a taste for collecting books and within them a gradual broadening of the intellectual horizon. Charles V of France formed a considerable library of 910 volumes, including much newer literature, and had a catalogue of them prepared in 1373. Guy, earl of Warwick, formed a collection of French romances, which he bequeathed to Bordesley abbey in 1315. Richard of Bury, the doubtful author of the *Plzilobiblon,* amassed a noble collection. A reviving taste for secular literature and for the classics gave a fresh direction to collectors, and a disposition to encourage literature began to show itself. Cosimo de' Medici formed a library at Venice while living there in exile in 1433, and on his return to Florence laid the foundations of the great Medicean library. Niccolo Niccoli had already, in 1436, left his library of more than 800 volumes for the use of the public. Frederick, duke of Urbino, and Poggio Bracciolini were among the chief collectors of the Latin manuscripts buried in monastic libraries. Beyond the Alps, Matthias Corvinus, king of Hungary, formed a great collection of splendid manuscripts.

When the fall of Constantinople in 1453 converted into a full stream the former trickle of Greek scholars into western Europe, the impact of Greek learning and philosophy upon Latin Christianity produced a vast surge of intellectual activity and scientific inquiry and a pressing demand for books—a demand satisfied by one of the miracles of history, the invention of printing almost within the same year. From the enormous increase in library stocks. and the new catholicity of subject interest: resulted the substitution already described above of the new plan of a large hall, with bookcases all round it, for the old arrangement of a library in bays. The modern history of libraries had begun.

MODERN BRITISH LIBRARIES

State Libraries, British **Museum.**—The British museum ranks in importance before all the great libraries of the world, except the National library of France, and excels in the arrangement and accessibility of its contents. The library at mid-20th century consisted of about 6,000,000 printed volumes (including 10,000 incunabula) and 75,000 manuscripts. Its expansion was mainly the result of the energy of Sir Anthony Panizzi (*q.v.*).

The foundation of the British museum dates from 1753, when effect was given to the bequest (in exchange for £20,000 to be paid to his executors) by Sir Hans Sloane, of his books, manuscripts, curiosities, etc., to be held by trustees for the use of the nation. A bill was passed through parliament for the purchase of the Sloane collections and of the Harleian manuscripts, costing £10,000. To these, with the Cottonian manuscripts, acquired by the country in 1700, was added by George II. in 1757, the royal library of the former kings of England, coupled with the privilege of obtaining a copy of every publication entered at Stationers' hall. A lottery having been authorized to defray the expenses of purchases, as well as for providing suitable accommodation, the museum and library were established in Montague house, and opened to the public on Jan. 15, 1759. In 1763 George III presented the Thomason collection (in 2,220 volumes) of Civil War and Commonwealth tracts. C. M. Cracherode bequeathed his collection of choice books in 1799, and Sir Joseph Banks his library (16,000 volumes) of natural history and travels in 1820. Of other libraries subsequently incorporated in the museum, the most valuable were George III's collection, 15,000 volumes of tracts and 65,259 volumes of printed books, which was transferred (for a pecuniary consideration) by George IV in 1823, and that of Thomas Grenville (20,240 volumes of rare books, bequeathed in 1846). The Cracherode, Banksian. King's and Grenville libraries are preserved as separate collections. Among notable later accessions are the Ashley library of original editions of the English poets from about 1625 onward, formed by T. J. Wise (1937), and the Hirsch library of musical scores and literature (1946).

The newspaper collections are housed in a large repository at Hendon. The Burney and Thomason collections of early British newspapers are almost complete. Many of the British provincial newspapers (30,000 bound volumes) were lost when the repository was bombed during World War II.

A General Catalogue of Printed Books was printed in 108 volumes between 1881 and 1905; a second edition was begun in 1931 (vol. 1–51 [A-Dez] had appeared by mid-century). Monthly lists of accessions are issued. A *Subject-Index of Modern Works* (3 vol., covering accessions during the years 1881–1900) was followed by quinquennial supplements. Large numbers of special catalogues (*e.g.,* of incunabula and of early English printed books) have been published, and there are interleaved working catalogues of maps and music. For a full account of the British Museum catalogues of printed books and manuscripts *see* articles by F. C. Francis in *Journal of Documentation,* vol. 4 (1948) and by T. C. Skeat in *Journal of Documentation,* vol. 7 (1951).

The department of manuscripts is equal in importance to that of the printed books. The collection of European manuscripts at mid-20th century contained 57,000 volumes, more than 100,000 rolls, a rich series of charters, etc., and a vast quantity of papers, ranging from the 3rd century B.C. down to modern times and including the old historical chronicles of England, the charters of the Anglo-Saxon kings, the Xrthurian romances and also unprinted works by English writers. To the *Codex Alexandrinus* of the Bible, which came to the museum along with the old Royal library, was added in 1933 the *Codex Sinaiticus,* purchased from the soviet government for £100,000 (partly raised by private subscriptions and partly contributed by the government). The famous collections of manuscripts made by Sir Robert Cotton and Robert Harley, earl of Oxford, have already been mentioned, and from these and other sources the museum became rich in early Anglo-Saxon and Latin codices, such as that containing *Beowulf;* the charters of King Edgar and Henry I to Hyde abbey, which are written in gold letters; and the Lindisfarne Gospels (A.D. 700), containing the earliest extant Anglo-Saxon version of the Latin gospels. The museum can boast of an eariy copy of the *Iliad,* and one of the earliest known codices of the *Odyssey.* Arnong the unrivalled collection of Greek papyri are the unique manuscripts of several works of ancient literature, such as Aristotle, *On the Constitution of Athens,* the *Mimes* of Herodas and the *Odes* of Bacchylides. Irish, French and Italian manuscripts are well represented. For illuminated manuscripts special reference may be made to the Lindisfarne Gospels, the Bedford Hours: the Sforza Book of Hours and Queen Mary's Psalter. The Luttrell and Bedford Psalters were bought for £64,000 in 1931. The collections of local and family history, of maps and of music are also very rich.

Oriental printed books (130,000) and manuscripts (18,000) formed, from 1892, a separate department. The collection includes the library formed by C. J. Rich (resident in Baghdad in the early part of the 19th century); the Chambers collection of Sanskrit manuscripts; and a library of Hebrew manuscripts, including that of the orientalist H. J. Michael, of Hamburg, and codices of great age brought from Yemen. The collection of Syriac manuscripts is important.

The building in which the library is housed was designed by Panizzi and opened in 1857. The circular reading room is surrounded by book stores placed in iron stacks, the origin of the more modern steel stacks; in these are fitted hanging and rolling auxiliary bookcases. The presses inside the reading room contain approximately 60,000 volumes; to those on the ground floor (20,000) readers have direct access. The maps and music and certain other sections of the library were transferred in 1914 to the new King Edward building; in 1923 one quadrant of the iron stacks received an extra story; and a reconstruction designed to double the stack-room capacity was begun as a result of the report of the Royal Commission on National Museums and Galleries (3 vol. [1928–30]). This work was interrupted by World War II. Serious air raid damage was suffered by the museum library during the war, the loss of books amountihg to 150,000 volumes, of which a large number were later replaced. The reading room was damaged. but was reopened in 1946. a service having been maintained in the meantime in the north library.

The Natural History museum, Soufh Kensington, a division of the British museum now under separate management. had books on the natural sciences numbering more than 300,000 volumes at mid-century.

Other State Libraries.— One of the largest technical libraries in the country is that of the patent office in Southampton buildings, London, with 325,000 volumes at mid-century. The Science library in the Science museum at South Kensington (founded 1857) has 400,000 volumes and 20,000 sets of periodicals. It publishes weekly accessions lists and specialized bibliographies, and runs an interlibrary loan service and a photocopying service. The Kational Art library in the Victoria and Albert museum contained about 300.000 volumes and 325,000 photographs in the mid-1950s. Among other state libraries in London may be noted those of the India office (260,000 volumes and 25.000 manuscripts) and of the admiralty. the two houses of parliament, the foreign office, the war office and the ministries of education and of health (each having between 80.000 and 150,000 volumes). The library of the Royal Botanic gardens at Kew (1853) had 50,000 volumes in 1954.

Outside London the most important state libraries are the national libraries of Scotland, Wales and Ireland. Sir George Mackenzie of Rosehaugh may be regarded as the founder of the Faculty of Advocates' library, afterward the National Library of Scotland. The first librarian was appointed in 1684. The library retains the copyright privilege conferred upon it in 1709. Of the special collections the most important are the Astorga (Spanish), purchased in 1824; the Thorkelin collection, relating chiefly to the history and antiquities of the northern nations: the Dietrich collection of German pamphlets and dissertations; and the Barnbougle Scottish collection. presented in 1928 by Lord Rosebery. hlanuscripts numbered more than 8,000 at mid-century. There are 13 monastic chartularies which escaped the destruction of the religious houses to which they belonged. The manuscripts relating to Scottish church history include the collections of Spottiswoode, Wodrow and Calderwood. Sir James Balfour's collection and the Balcarres papers consist largely of original state papers of James V, Queen Mary and James VI. The most important manuscripts of old poetry are the Bannatyne manuscript. written by George Bannatyne in 1568, and the Auchinleck manuscript.

In 1922 the faculty, finding the maintenance of the general library increasingly onerous. offered it to the government as a national library of Scotland. The government accepted the offer in 1923. when an institution toward which movements had been made in Scotland since 1870 received a gift of £100.000 from Sir Alexander Grant, and the necessary act was passed and the library transferred in 192j. The library at mid-century contained more than 1.500,000 volumes. The Advocates retain the law section.

The National Library of Wales at Aberystwyth, founded in 1907, was opened in 1915. It enjoys the copyright privilege, and in 1954 contained about 1,500,000 volumes and 160.000 manuscripts and documents, largely of Welsh interest. Francis Bourdillon's Romances, and C. Thomas-Stanford's Euclids are among special collections of printed books. The National Library of Ireland! Dublin, was founded in 1877, and incorporates the library of the Royal Dublin society. It had *c.* 700,000 volumes in 1950.

University **and** Collegiate **Libraries.**—*Oxford.*—The earliest library of the University of Oxford was in existence in 1337; the second was founded by Humphrey, duke of Gloucester (d. 1447) and refounded in 1598 and endowed in 1611 by Sir Thomas Bodley (*q.v.*). He opened the library in 1603 with about 2.000 volumes. In 1610 he obtained a grant from the Stationers' company of a copy of every work printed in the country, a privilege still enjoyed under the Copyright acts. Other chief benefactors were Archbishop William Laud. John Selden, Richard Gough, Francis Douce, Lord Sunderlin (brother of Edmund Malone) and Richard Rawlinson. The library at mid-century had about 2,000,000 printed volumes and about 40,000 manuscripts (other than charters, rolls, etc.). In oriental manuscripts it is. perhaps. superior to any other European library. and it is exceedingly rich in other manuscripts. especially in English literary and local history, and in early printing. A new building to house 5,000,000 volumes, with underground book stacks, designed by Sir Giles Gilbert Scott (*q.v.*), was opened in 1946.

The Radcliffe library of natural science. founded by John Radcliffe (d. 1714) and opened in 1749 in the domed building known as the "Radcliffe Camera." was transferred to the University museum and laboratories in 1860. when the trustees offered the use of the Camera to the curators of the Bodleian; the building was transferred absolutely in 1927. In the Camera are the modern books. and it also serves as a reading room, especially for undergraduates. The Indian institute, the Law library, the Maitland library (social and legal history) and Rhodes house (colonial history) are administered by the Bodleian.

The Taylor institution for modern languages is due to the benefaction of Sir Robert Taylor, an architect (d. 1788). The Finch collection (bequeathed in 1830) is kept with it.

The library of All Souls was established in 1443 by Archbishop Henry Chicheley; it possessed 40,000 printed volumes and 300 manuscripts at mid-century. and is rich in law. The library of Christ Church is rich in divinity and topography. Corpus possesses a fine collection of Aldines, with about 400 manuscripts. Keble college has the manuscripts of many of John Keble's works. Magdalen college has about 50,000 volumes and a50 manuscripts with scientific and topographical collections.

Merton college possesses the earliest surviving college library building. St. John's college library is largely composed of theology and law before 1750, and medical books of the 16th and 17th centuries. Wadham college has the botanical books bequeathed by Richard Warner (1775) and Benjamin Wiffen's collection on the Spanish reformers.

Cambridge.—The University library at Cambridge dates from the earlier part of the 15th century. Two early catalogues are preserved, the first embracing 52 volumes and dating from about 1425, the second a shelf list, apparently of 330 volumes, made in 1473. The library, with about 2.000.000 volumes, has the copyright privilege. It includes a fine series of *editiones principes* of the classics and of the early productions of English and Netherlandish presses. The manuscripts number more than 12,000, in which are included a considerable number of adversaria or printed books with manuscript notes, which form a leading feature in the collection. The most famous of the manuscripts is the Codex *Bezae* of the four Gospels and the Acts. which was presented to the university by Theodore Beza himself. A new building: with bookstacks on 12 floors in the tower, was opened in 1934.

There is a library attached to the Fitzwilliam museum; bequeathed to the university in 1816. It contains printed and manuscript music and a collection of illuminated manuscripts, chiefly French and Flemish. Catalogues and reprints have been published.

The library of Trinity college at mid-century had more than 120,000 printed and nearly 2,000 manuscript volumes. Among special collections are the Capell collection of early dramatic and especially Shakespearean literature, German theology and philosophy. and the Grylls bequest in 1863 of 9.600 volumes. including many early printed books. There are printed catalogues of the Sanskrit and other oriental manuscripts by S. T. Aufrecht and E. H. Palmer. of the incunabula by Robert Sinker and of the Capell collection by W. W. Greg. 1903.

The library of Corpus Christi college is famous for the bequest of Anglo-Saxon and illuminated manuscripts made by Archbishop Matthew Parker in 1575. Magdalene college possesses the library of Samuel Pepys (*q.v.*). The library of Peterhouse. the oldest in Cambridge, possesses a catalogue dating from 1418 of 600 or 700 books. It has a unique collection of manuscript music. The library of St. John's college is rich in early printed books and English history.

Other British Universities.—The library of the University of London, founded in 1837, had more than 600,000 volumes in the mid-1950s and included the Goldsmiths' library of economic literature (60,000 volumes). University College library, Gower street, established in 1824, had about 550,000 volumes before World War II, including Jeremy Bentham's library, G. E. Morrison's Chinese library and H. C. Barlow's Dante library. Approximately 70,000 volumes were destroyed when the library was bombed.

In close association with the University of London is the London School of Economics and Political Science (1896). in mhich is housed the British Library of Political and Economic Science, with 350,000 books and 150,000 pamphlets and official reports. The School of Oriental and African Studies library was established in 1916 in the building of the Royal institution.

Among other English university and college libraries may be mentioned the following: Birmingham, Leeds, Liverpool and Manchester (350,000–500,000 volumes each); and Bristol. King's college (Newcastle) and Nottingham (150,000–200,000 volumes each). The oldest university library in Scotland is that of St. Andrews (14j6); Glasgow and Aberdeen mere founded in the late 15th century and Edinburgh in 1580. All are large libraries. having between 250,000 and 500,000 volumes each at mid-century and containing valuable special collections. The combined libraries of the several colleges of the University of Wales (Aberystwyth, Bangor, Cardiff and Swansea) hold about 750,000 volumes. In Ireland, the Queen's University of Belfast has an important library of nearly 240,000 volumes; the library of the University of Dublin. possessing 750,000 volumes at mid-20th century. was founded in 1601 by a subscription raised by the English army to commemorate their victory at Kinsale. This library continued to enjoy the copyright privilege after the establishment of the Irish Free State.

In 1946 the University and Research section of the Library association published a report, *University and Research Libraries of Great Britain: Their Post-War Development.*

The most important theological college library is that of Sion college (1635, 300.000 volumes), which is rich in liturgiology; of public school libraries, those of Eton and Winchester are outstanding, while that of Shrewsbury, though small: has an exceptional collection of bindings.

Cathedral and Church Libraries.—Nearly all cathedrals possess libraries of interest. Intended for the cathedral or diocesan clergy, they are in most cases open to persons suitably introduced. Many have valuable manuscripts, but most were ravaged in the Great Rebellion, and the printed collections are the work of antiquarian deans of the 18th century. That of St. Paul's cathedral was founded in very early times. and by the mid-1950s numbered about 25,000 volumes and pamphlets, with a good collection of early Bibles and Testaments, Paul's Cross sermons and works connected with the cathedral (catalogue 1893).

The library of Christ Church, Oxford, which belongs alike to the college and the cathedral, has been mentioned above. That of Durham, 20.000 volumes, dates from monastic times, and possesses many of the books which belonged to the monastery. The collection is fairly general, and is kept up to date. It is especially rich in very early manuscripts, written at Durham. The library at York is open to the public, and has many valuable manuscripts and early printed books. J. Raine in *Testamenta Eboracensia* (1836) quotes many bequests to this library. The foundation of the library at Canterbury dates probably from the time of Augustine, but nothing of the pre-Conquest library survives. Many of the manuscripts originally here were transferred by Archbishop Parker to Corpus Christi college, Cambridge (catalogue 1743 and 1802, of manuscripts 1911).

The Lincoln cathedral library (catalogue 1859, of incunabula 192j. of manuscripts 1927) was refounded by Dean Michael Honywood, at the Restoration, in a building by Sir Christopher Wren. Chichester dates from the Restoration only. Ely is rich in the literature of the nonjurors. Exeter possesses many Saxon manuscripts, including *The Exeter Book* of Old English poetry, the gift of Leoiric, the first bishop. At Lichfield the library is post-Restoration, but includes the famous Evangelistary of St. Chad. The collection at Norwich is chiefly modern. The earlier library at Peterborough being almost destroyed in the Great Rebellion, Bishop White Kennett refounded it, but many of his books were lost. Salisbury is rich in incunabula (catalogue 1880). Winchester cathedral library is mainly the bequest of Bishop George Morley (17th centuryj. The library at Bristol was burned and pillaged in the riots of 1831. At Chester in 1691 Dean James Arderne bequeathed his books and part of his estate "as the beginning of a public library for the clergy and city." The library of Hereford (catalogue of manuscripts 1927) is a good specimen of an old monastic chained library; Worcester has fine manuscripts (catalogue 1906, and of incunabula 1910).

The four Welsh cathedrals were supplied with libraries by a deed of settlement in 1709. All are small. That founded by Archbishop Robert Leighton in 1654 in Dunblane cathedral is the only cathedral library in Scotland of any historic interest. The public library established about 1699 at St. Sepulchre's, close to St. Patrick's cathedral, Dublin, by Archbishop Narcissus Marsh, was incorporated in 1707, and endowed by its founder at his death in 1713. The books are chiefly theological and include the libraries of Bishop Edward Stillingfleet and of Elias Bouhereau, the first librarian. In 1849 Beriah Botfield published *Notes on the Cathedral Libraries of England.* A union catalogue of English cathedral libraries was begun under the auspices of the Bibliographical society.

The best Catholic libraries in London are those of Brompton Oratory and Westminster cathedral. The archiepiscopal library at Lambeth palace (damaged in World War II) was enriched by the gifts of Archbishops William Laud, Thomas Tenison, Charles Manners-Sutton and others of his successors. It is rich in theology and Church history. Of illuminated manuscripts and early printed books, catalogues were issued by S. R. Maitland (1792–1866). The manuscripts were described in H. J. Todd's catalogue. 1812, and the older volumes by M. R. James, 1900. The Jews' college has an important library of Judaica.

Endowed Libraries.—In London the Bishopsgate institute (1891), founded out of City charities, contains about 50,000 volumes and a fine collection of prints, drawings and maps of London. The Cripplegate institute (1896) in Golden lane was also founded out of charity moneys. The St. Bride Institute Technical Reference library (1895) is a very complete collection of about 40,000 volumes on printing and allied arts. Dr. Williams' library (more than 90,000 volumes in 195j), founded in 1716 by the will of Daniel Williams, is primarily theological, and has been enlarged to include philosophy, history and literature, with collections of theosophy and of the works of Jakob Boehme, William Law and other mystics. The manuscripts include the original minutes of the Restminster assembly, letters and treatises of Richard Baxter and the journals of Henry Crabb Robinson.

Forerunners of the modern public library were established during the first half of the 17th century at Coventry, Norwich, Bristol, Leicester and elsewhere; but the most notable of the English provincial endowed libraries are those of Manchester. That founded by Humphrey Chetham in 1653 is still housed in its old collegiate buildings (100,000 volumes and manuscripts). More important is the John Rylands, founded in 1899 by the widow of a cotton merchant in memory of her husband. By mid-20th century the John Rylands had 500,000 volumes and 12,000 manuscripts, including the 6,000 Crawford manuscripts from Haigh hall, bought in 1901, and 20,000 French Revolution broadsides, etc., presented by the earl of Crawford in 1924. Other considerable endowed libraries are the William Salt, Stafford (Staffordshire history), opened 1874; the Solon Ceramic library, Stoke-on-Trent (20,000 volumes); St. Deiniol's (1894), Hawarden, founded by W. E. Gladstone; and the Shakespeare Memorial (1881), Stratford-on-Avon.

The oldest endowed library in Scotland is the Innerpeffray, Perthshire (1680), founded by David Drummond, 3rd Lord Madertie. The most important is the Mitchell in Glasgow, founded by Stephen Mitchell (1874), opened in 1877. It contains valuable collections of Scottish poetry, Robert Burns's works, Glasgow printing, and art. It contained more than 600,000 volumes in 1954, and is the reference library for the Glasgow public library system.

Libraries of Societies and Learned Bodies.—Of the law libraries, that at Lincoln's Inn; London! is the oldest and the largest (75,000 volumes). That of the Middle Temple contained 70,000 volumes before it was bombed during World War II. The library of the Inner Temple is known to have existed in 1540. Its chief collections are William Petyt's manuscripts, received in 1708, John Adolphus' historical pamphlets and the Crawford collection on crime. There were 90,000 volumes before the bombing, in which half the stock was lost. Gray's Inn library was established before 1555; it was completely destroyed in 1941. The Law society (1828) has 75,000 volumes. The Royal Institution of Great Britain (1803), possessing a general reference subscription library of about 150,000 volumes, was closed in 1916, its oriental section remaining to help found the London University School of Oriental and African Studies. while its western books went to the university and college libraries.

The best library of arcbaeoiogy is the Society of Antiquaries, Burlington house. 100,000 volumes, many manuscripts and early prinrcd books. For natural sciences there are the libraries of the Koyal society (1667) in Burlington house, with more than 145,000 volumes, mainly publications of scientific bodies (the celebrated Arundel bequest, dating rrom the society's infancy. was dispersed); the Geological society (1807); the Linnean society (1788); and the Zoological society (1829).

Medicine and allied sciences are served by the libraries of the Royal Society of Medicine (1805); the Royal College of Physicians (1525); the British Medical association; the Royal College of Surgeons of England (1800); the Chemical society (1841); and the Pharmaceutical society. Other important London society libraries are the Royal Geographical society (1830), open to the public for reference; the Royal Empire society (1868), 280,000 volumes of British colonial literature; and the Royal United Service institution, Whitehall (1831), 32.000 volumes, belles-lettres, politics and history. Libraries are owned by the British and Foreign Bible society (largest existing collection of printed Bibles—catalogue 1903–11), the Institution of Civil Engineers, the Institution of Electrical Engineers, the Royal Academy of Arts, Royal Institute of British Architects. etc.

The library of the Society of Writers to His Majesty's Signet (1722), Edinburgh, contained about 160,000 volumes in the mid-1950s, with early prints and other rare books, especially in British topography. The library of the Royal Irish academy at Dublin (1785, 50,000 volumes and more than 2,000 Irish manuscripts) is partly supported by a government grant and is freely open.

Among subscription libraries, the London library (600,000) stands first in order of importance. It was founded in 1841 as a lending library for the use of scholars, largely at the instance of Thomas Carlyle. Author and subject catalogues have been printed, the latter of great value. Severe damage was suffered by this library in World War II.

The first circulating library in Birmingham was opened in 1757, and was followed by Liverpool Lyceum (1758) and Warrington's (1760), both merged in the museum, and by Leeds (1768).

Other proprietary libraries were established at Leicester. Liverpool (Athenaeum, 1798), Manchester, Newcastle, Belfast (the Linen Hall library), Nottingham and elsewhere. In Scotland the first subscription library was started by Allan Ramsay, the poet, at Edinburgh in 172j. Commercial subscription libraries increased greatly, W. H. Smith's, Boots' and the *Times* Book club being typical modern examples.

Many of the principal clubs possess libraries. That of the Athenaeum (London) is by far the most important. It numbered about 80,000 volumes of choice books in the mid-1950s. The pamphlets (of which also there is a complete printed catalogue) include those collected by Edward Gibbon and Sir James Mackintosh. The Reform club had about 45,000 volumes at mid-20th century. The Gladstone library of the National Liberal club may be used occasionally by nonmembers. The Carlton club also has an important library. Libraries on international affairs were established by the Royal Institute of International Affairs and by the United Nations association.

Public Libraries— The earliest public libraries have already been referred to in the description of endowed libraries. The first act of parliament authorizing the establishment of rate-supported public libraries by local authorities was passed in 1850 and was largely a result of the efforts of William Ewart, M.P., and Edward Edwards. later first librarian at Manchester. Norwich was the first city to adopt the act; Manchester and Liverpool, though adopting the act later, were first in the field with actual libraries (1852). In 1853 the act was extended to Scotland and Ireland. Rapid progress was made after the formation of the Library association in 1877. Various amending acts were passed, one of which (1919) removed the rate limitation of one penny in the pound for England and Wales and permitted local authorities to spend as much as they wished on their public libraries. The same act empowered county councils also to provide a library service (see below, *County Libraries*). In Ireland, the rate limitation was abolished in 1947; in Scotland it was continued until 19jj.

The main points in British library legislation are as follows: (1) The acts are permissive and not compulsory. (2) Municipal libraries are managed by committees appointed by the iocal authorities, who may delegate to them all their powers and duties. Glasgow has contracted them out by a special act. In Ireland, committees are appointed much as in England. (3) Power is given to provide libraries, museums, schools for science, art galleries and schools for art. (4) The regulation and management of public libraries are entrusted to the library authority: which may either be the local authority or a committee with a full or partial delegation of powers.

An immense stimulus to progress was given from about 1900 by Andrew Carnegie (*q.v.*), who began to present library buildings to towns in England as well as in Scotland and the United States. All local authorities possessing power to adopt the 1850 act did so. In the year 1955–56 more than 500 municipal and approximately go county library authorities in Great Britain and Northern Ireland were operating about 2,000 library buildings and 30,000 rural service points (*e.g.*, in schools). Total book stocks amounted to about 63,500,000 volumes and total issues to about 399,000,000, or rather more than 7.8 per person (compared nith 5.3 per per-son in 1938). At approximately £13,870,000 the total ccst represented about js. $5\frac{1}{2}$*d*. per person (against 1*s*. 4*d*. in 1938).

The first library to adopt the open access system was that of Clerkenwell in 1894, and, largely under the influence of the Carnegie trust, this system became universal in British public libraries. Lster developments included the provision of children's and hospital libraries and commercial and technical divisions or departments (notably those of Birmingham. Manchester, Sheffield and Glasgow). Many Iibraries publish reading lists and bibliographies and arrange exhibitions and courses of lectures. Great attention has been paid to local collections and to the preservation of archive material.

The Dewey decimal system of classification was largely adopted in public libraries (though many learned libraries still preferred the Library of Congress method and scientific libraries turned toward the universal decimal classification). Catalogues are almost invariably compiled on cards, but some libraries use slips bound in adjustable binders (the "sheaf" system). Issues of books to borroners are registered by various systems of slips, forms and cards. Some libraries (*e.g.*, Bristol and Hull) have their onn binding departments, while others prefer to have their binding done by commercial firms.

A departmental committee on public Iibraries published in 1927 a valuable report, aimed at stimulating backward authorities by showing mhat could be done in more enlightened places. An authoritative survey was that done for the Library association by L. R. McColvin in 1942 (*The Public* Library System of Great *Britain*) which proposed the merging of smaller units in the interests of greater efficiency. Later, the question of nationalizing the public library service was raised.

There is one important municipal library which is not tax-'supported under the Public Libraries acts. This is the Guildhall reference library of the Corporation of the City of London. A library was established for London by Sir Richard Whittington between 1421 and 1426. But it did not remain without accident; about 1549 the lord protector Edward Seymour, duke of Somerset, carried off three cartloads of books, and during the great fire of 1666 the remainder together with the buildings were destroyed. The loss was unrepaired until a new library was opened in 1828.

The library (nearly 130,000 printed volumes and nearly 21,000 manuscriptsj includes a special collection of books, prints and drawings about London, the Solomons Hebrew and rabbinical library, the National Dickens library. etc., and the libraries of the Clockmakers' and Gardeners' companies and of the Old Dutch church in Austin Friars. It was severely damaged during World War II and in the immediate postwar years only about 35,000 volumes were available for use.

County **Libraries.**—While the library movement made notable headway in the towns during the last quarter of the 19th century, largely through the generous financial encouragement of Andrew Carnegie, the half century that followed witnessed a greater, and, after 1918, a much more rapid advance in the smaller centres of population and in rural areas. Before this date the service was severely handicapped by two restrictions: the one penny rate limit, which, except in the largest cities, precluded anything like adequate expenditure on books and salaries, and the almost total impossibility of applying the Public Libraries acts outside the big towns. An admirable statistical report, setting forth in detail the anomalies and difficulties of the situation, was prepared by W. G. S. Xdams and published by the Carnegie United Kingdom trust in 1915. From this it was manifest that the position in the towns could not be remedied without the removal of the rate limit, and the only hope for the rural areas was in some broad scheme of co-operation. The Library association had persistently agitated for new legislation, with the former object as the most urgent item. Pending action by the government, the Carnegie trustees set up a number of circulating systems on a regional basis, as an experiment and an object lesson to show how the rural problem should be solved.

Legislation. — The position of these rural systems was regularized in Scotland by the Education (Scotland) act of 1918, empowering county education authorities to make book provision for children and young persons attending schools or classes: and for adults. The subject was also dealt with in an interim report by the adult education committee of the ministry of reconstruction; and, almost immediately, the Public Libraries act of 1919 was passed, authorizing county councils to adopt the acts, to levy a rate and provide a library service through their education committees. Similar powers were granted in Northern Ireland by the Public Libraries act of 1924, and in the Irish Free State by the Local Government act of 1925.

Success of the County Library System. — Hitherto, such rural library systems as had been established were financed by the Carnegie trustees, who continued to offer to defray the capital expenditure of county councils which were willing to adopt the acts. During the period 1915–27, the grants made by the trustees for this purpose in Great Britain totalled £263,78j, with some supplementary grants for the period ending in 1930. In their report issued in March 1928, the trustees showed that 22 English, 3 Welsh and 6 Scottish counties were already independent of their assistance. The rate of this expansion is indicated by the figures given in the report of the Public Libraries committee set up by C. P. Trevelyan, then president of the board of education, in 1924, which completed its proceedings in 1927. In 1911 the population in England and Wales resident in library areas amounted to 62.5% of the total. The percentage rose to 68.8 by 1921, to 90.4 by 1924 and by 1926 to 96.3. Of this last figure, the urban library service accounted for 64.1%, and the county systems for 32.2%. By the mid-1950s scarcely any area remained without some kind of public library service. Admittedly, however, facilities varied, from the excellent to the ineffectual.

The system began with the periodical supply of boxes of books to village centres, usually in schools, and the boxes were sent by railway or other carriers. An increasing number of counties acquired their own motor vans, fitted with shelves to form small travelling libraries and thus afford the local volunteer librarian some opportunity of choosing books on the spot. Other vans, in charge of driver-librarians, make regular visits to individual farms and cottages. Here and there, local interest or the philanthropy of some well-wisher resulted in the formation of small stocks of reference books, and even the opening of a village reading room. Special provision is usually made, so far as resources permit, for adult classes. and special collections are formed for teachers. Middlesex provided an excellent example of the policy of co-ordinating the municipal library and the rural system. In Cornwall, seven borough and two urban district libraries were brought into a co-operative scheme for the whole county. The Belfast library was encouraged by a liberal grant from the Carnegie trustees to become the centre of a regional scheme of co-operation for the whole of Northern Ireland. Merely fractional rates, as low as one-tenth to one-fourth of a penny, were raised by the county authorities in the first instance. In some places these rose to threepence or fourpence or even more. By the mid-1950s. some counties were spending 5s. per person on the service, though some were still spending less than 1*s.*

Public Library Developments after 1919.—The main provisions and effects of the 1919 act have already been referred to. Prominent among other developments were the persistent endeavours made to obtain more satisfactory scales of pay for library staffs. Salaries at mid-century were still inconsistent with the fact that librarianship is a learned profession—though much improved by the establishment of a national scale. The effects! however, both of the increased amount of money obtainable from the rates and of the improved salary scales: were largely offset by the vast increase in the cost of living during and after the 1920s.

During World War II hundreds of libraries of all kinds were hit by bombs and rockets, 60 being completely destroyed. Municipal and county libraries lost nearly 1,000,000 volumes, particularly at Coventry. Exeter, Liverpool, Manchester, Plymouth. Portsmouth and Southampton. Nevertheless, no public library ever completely suspended its services; indeed, they issued more books than ever before and many of them provided air-raid shelter libraries and emergency services of all kinds. Sheffield and others established advice and information services, and many contributed in one way or another to the needs of research for war purposes. Moreover, the public libraries did much work in supervising collection of books for the fighting forces and for the restocking of war-damaged libraries, and rendered invaluable service in preventing the indiscriminate pulping of books collected as "salvage" for papermaking.

Special Libraries. — Many special libraries (*e.g.,* those of the Science museum and other government departments and those of learned societies) have already been mentioned. The term "special libraries" came to include in particular the libraries of scientific and research institutions and of industrial undertakings, which began as a group to evolve a technique of their own, based upon their function as suppliers of information to inquirers rather than as places where inquirers seek it for themselves. Great use is made of indexes, filing systems, photocopying equipment and microfilms for the storage of information likely to be required at a moment's notice, and experiments were made with punched-card systems. The Association of Special Libraries and Information Bureaux (Aslib), established in 192j, published a directory of special libraries in 1928 (new ed. in preparation, 1955).

Library Co-operation: The National Central Library. — A central library for students was started in London in 1917, largely to provide books for adult classes. This grew into an organization for interlibrary lending covering the whole country and including libraries of all types. The country was divided into ten regions, each with its own lending organization and most with regional union catalogues in various stages of development. The National Central library in London, as the headquarters institution, had a combined union catalogue of 4,800,000 entries at mid-century. It handles a large volume of direct inquiries and in addition passes on to other regions inquiries which cannot be satisfied within the region where they originate. Scotland and Ireland have their own central libraries for students linked with the National Central library. In 1954–55 the whole system supplied about 305,000 volumes to readers. The system includes about 250 "outlier'! libraries, most of them special or research libraries, which are willing to lend specialized material for advanced research. The contribution of the university libraries to this work is noteworthy. The National Central library is financed by a treasury grant (£34,000 for 1954–55), small grants from the British Council and other bodies and subscriptions from libraries (£5,000); libraries' subscriptions provided an acldditional £8,000 for the upkeep of the regional bureaus. An international interlibrary loan service was resumed on a small scale after the end of World War II. The National Central library's building was damaged in an air raid: and 110,000 of its reserve stock of books were destroyed.

Other aspects of library co-operation included the furnishing by individual libraries of material for such co-operative enterprises as the *British Union Catalogue of Periodicals,* the *World List of Scientific Periodicals,* the *Union Catalogue of Periodicals in British Universities* and A. W. Pollard and G. R. Redgrave's *Short-Title Catalogue of Books Printed in England, Scotland and Ireland and of English Books Printed Abroad, 1475–1640* (London, 1946). The metropolitan borough libraries of London adopted a scheme for co-ordinating their purchases of books whereby each library tried to cover one or more special subjects in addition to building up its general stock. A scheme propounded by the University and Research section of the Library association for a nationwide survey of research library resources was held up for lack of funds. Co-operation in the buying of foreign books on the lines of the U.S. "Farmington plan" was studied, with a view to achieving a wider coverage xi-ithout excessive duplication, and many surveys of resources in special branches of literature were produced. The London Uni 'ersity School of Librarianship conducted an inquiry into co-(peration in April 1949 the results of which were published in the *Journal of Documentation,* vol. 5 (1949), and R. F. Vollans made a detailed survey of the National Central librsry and the regional systems in *Library Co-operation in Great Britain* (1952). The resumption of international contacts after 1945 led to much activity in the field of international standardization of bibliographical terms and library practice.

Other Developments.—World War II witnessed the establishment of large numbers of libraries in government research institutions directly concerned with the conduct of the war, such as the ministriesof information and of economic warfare. Many thousands of books were collected for the recreational reading of men and women in the fighting forces, and the value was seen of providing libraries for study as well. Toward the end of the war courses were instituted for the education and training of those about to be demobilized and the Army Library service in particular grew rapidly.

An army library advisory committee was formed in 1949 by the Library association and the Institute of Army Education to assist the war office in the efficient carrying on of this service. Libraries continued to be provided for the mercantile marine by the British Sailors' society and for the blind by the National Library for the Blind: both services had already been developed greatly after World War I.

Much attention was paid to the provision of libraries in schools, hospitals, prisons and other types of institutions, and for the use of adult education classes. The universities and the National. Central library took a prominent part in adult education library work.

The building and equipping of new libraries was hampered after World War II by high costs and shortages of materials, and research was stimulated in substitute materials, prefabrication and standardization. Staff shortages led to re-examination of administration and routine.

A central bibliographical and cataloguing service had long been desired by British librarians, and in 1950 appeared the first issue of a meekly *British National Bibliography,* published under the joint auspices of the British museum, the Library association. Aslib and bodies representing publishers, booksellers and other interests.

'BRITISH COMMONWEALTE

The majority of the dominions have permissive library laws. In Africa, Australia and Canada the governments make grants to public libraries. The Canadian and Australian libraries are administered more or less on U.S. and those of the Union of South Africa, India. etc.. on English lines.

Africa. — There are several important libraries in the Union of South Africa. The oldest library is the South African Public library at Cape Town, established in 1818, which enjoys the copyright privilege for the Cape (310,000 volumes). This library contains the collection of colonial books bequeathed by Sir George Grey. This and the Pretoria state library (200,000 volumes) form together the National Library, the Pretoria library serving as the national centre for interlibrary lending. The Library of Parliament. Cape Town. is the reference library of the Union legislature; it includes the Mendelssohn collection of Africana. At Cape Town also is the University of Cape Town library (275,000 volumes), which doubled in size in the decade 1940–50. There were nearly 300 public libraries in Cape province at mid-century, all receiving state financial aid, and another 80 in other parts of the Union, Johannesburg having the largest and most valuable' collection (600,000 volumes). The University of the Witwatersrand, Johannesburg. has large collections of Africana and medicine. Cape province and Transvaal had established rural library systems.

The university colleges of Makerere (Kenya), Ibadan (Nigeria) and Achimota (Ghana), and Gordon college. Khartoum, all have rapidly growing collections, and employ a high proportion of native staff.

Australia, — The various states legislate for libraries independently, and maintain libraries. The Commonwealth library at Canberra was founded in 1927. The state public libraries circulate books to institutes, etc., in the country. The local public libraries are those of Victoria at Melbourne (1853) (760,000 volumes); of New South Wales at Sydney (1867) (650,000 volumes, including the Mitchell library; this was an old subscription library bought by the government); of South Australia at Adelaide (253,000 volumes); of Queensland at Brisbane (1896) (173,000 volumes); and of Western Australia at Perth (1860) (196,000 volumes). The university libraries are those of Sydney (350,000 volumes, including the fine Fisher collection, 1885), Adelaide, which assists in control of the public library. Melbourne and Brisbane.

Tasmania. — Only Hobart (State Library of Tasmania, 1849) had in 1925 used the large powers given by the act of 1867. A new Library act of 1943, however, stimulated considerable activity. The University of Tasmania has collected a library of about 80,000 volumes.

New Zealand. — There are more than 400 public libraries in New Zealand, some of them operating on a free lending basis. The National Library service co-ordinates a supply of books and reference material to most libraries in the dominion, as well as to schools. The four universities and university colleges have good libraries, as do the agricultural colleges. For historical and cultural research the Alexander Turnbull library at Wellington is pre-eminent. and good New Zealand historical collections are in the Grey collection at Auckland and the Hocken and McNab collections at Dunedin. The general assembly library at Wellington is a copyright depository and one of the best all-round libraries in the country (220,000 volumes).

India and the East. — The chief library in India is the National library at Calcutta (760,000 volumes). Of 17 university libraries, three (Sind. Punjab and Dacca', passed to Pakistan in 1947; a new Pakistan university was founded at Peshawar in 1950. The library of the Asiatic Society of Bengal was founded in 1784, and the Bombay branch in 1804. Another early library of importance is that of the Madras Literary society (1812).

A remarkable library in India is that of the raja of Tanjore, which dates from the end of the 16th or beginning of the 17th century. There are about 18,000 manuscripts written in a wide variety of languages.

The Indian Library association initiated a plan for a comprehensive public library system, of which the first unit, a public library at Delhi. was established by the Indian government and UNESCO in 19jo.

At Rangoon there are several good libraries. The Raffles library at Singapore (now the library of the University of Malaya) has special collections of books relating to the Malayan peninsula and archipelago. In Ceylon there is the Museum library at Colombo and the library of University college. Colombo.

Canada. — The Jesuit college at Quebec had a library as-early as 1632. The most important public library is that of Toronto (1883), which had nearly 860.000 volumes in the mid-1950s, and includes a notable children's department in a separate building. The other most important libraries in Ontario are: Queen's university, Kingston (1841) (295.000 volumes, rich in Canadian history); Legislative library of Ontario! Toronto (1867); University of Toronto (1856) (595,000 volumes and 160,000 pamphlets) ; Library of Parliament, Ottawa (about 500.000 volumes). A national bibliographical centre was established in 1950 and a national library in 1953. By 1956 a union catalogue of 115 important Canadian libraries had been compiled, containing 3,300,000 cards.

In the province of Quebec there are several notable libraries among which are the Fraser institute, Montreal (188j) ; McGill university, Montreal (1855) (650,000 volumes comprising many important collections): the Seminary at St. Sulpice, Montreal; Laval university, Quebec; and the library of the legislature.

British Columbia has important provincial and university libraries in Vancouver.

In Nova Scotia there is a system of circulating books among the school libraries. The Legislative library at Halifax incorporates that of the Nova Scotia Historical society (1878). The school law of New Brunswick provides for grants to school libraries.

The vast distances and sparse population of most of Canada produced highly developed travelling lihrary services.

West Indies. — The Trinidad public library (1851) is the oldest library in the West Indies. The library of the University College of the West Indies in Jamaica is a copyright repository of West Indian official publications.

FRANCE

The great expansion of French libraries was a direct result of the French Revolution. On Nov. 2, 1789, all ecclesiastical libraries were seized by the state and transferred to *dépôts littéraires* (literary depositories). The libraries of the nobility suffered the same fate in 1792. Though many precious volumes and manuscripts mere burned, the total number of volumes seized in Paris and the provinces is estimated at about 7,000,000.

While the *dépôts* were originally intended to be used for the creation of libraries in places not already possessing them! in the end it was the largest existing libraries that benefited most. State control extended. through the minister of public instruction, to nearly all libraries during the 19th century, a decree of 1878 going so far as to establish a procedure in cataloguing and classifying university libraries. Most municipal libraries were subordinated to national authority by a decree of 1897, and school libraries came under the same ministry.

Bibliothèque Nationale. — The Bibliothkque Nationale (formerly Bibliothkque du Roi, Royale or Impériale) is one of the finest libraries in the world. The real foundation of the institution may be said to date from the reign of King John, the Black Prince's captive, who bequeathed his "royal library" to his successor, Charles V in 1364. Charles V removed the library from the Palais de la Cité to the Louvre, where it was arranged on desks in a large hall of three stories by the first librarian and cataloguer, Claude Mallet, the king's *valet de chambre.* His *Inventaire des Livres du Roy nostre Seigneur estans nu chastel du Louvre* is extant. as well as the inventories made by Jean Blanchet in 1380, and by Jean le Bègue in 1411 and 1424. Charles VI added several hundred manuscripts to the library, which, however, was sold to the regent, duke of Bedford, transferred to England and finally dispersed at the regent's death in 1435. Charles VII did little to repair the loss. but under Louis XI another library was created; the first librarian mas Laurent Paulmier, and Jean Foucquet of Tours was named the king's illuminator. Charles VIII enriched it with many fine manuscripts executed by his order, and also with most of the library of the kings of Aragon, seized by him at Naples. Louis XII incorporated into the Bibliothkque du Roi the fine Orleans library at Blois, and further enriched it by plunder from Pavia, and by the purchase of the Gruthuyse collection; it was described at this time as one of the four marvels of France. Francis I enlarged and removed it to Fontainebleau in 1534. He set the fashion of fine bindings. which was still more cultivated by Henry II, and which has never died out in France. During the librarianship of Jacques Amyot the library was transferred from Fontainebleau to Paris. Henry IV removed it to the Collège de Clermont, but in 1604 another change was made, and in 1622 it was installed in the Rue de la Harpe. Under J. A, de Thou it acquired the library of Catherine de Medici, and the Bible of Charles the Bald. In 1617 a decree ordered the deposit of two copies of every new publication, but this was not enforced till Louis XIV's time. The first catalogue worthy of the name was finished in 1622. describing about 6.000 volumes, chiefly manuscripts. Many additions were made during Louis XIII's reign. notably that of the Dupuy collection, but a new era dawned under Louis XIV. J. B. Colbert. one of the greatest of collectors, so enlarged the library that it became necessary to make another removal. It was therefore, in 1666, installed in the Rue Vivien (later Vivienne). The departments of engravings and medals were then created, and were soon important. Nicolas Clément made a catalogue in 1684 according to the arrangement still used (in 23 classes, each designated by a letter of the alphabet), with an alphabetical index. After Colbert's death the marquis de Louvois employed John Mabillon, M. Thévenot and others to procure books, etc., from all parts of the world, and a new catalogue was compiled in 1688 in eight volumes by several scholars. Toward the end of Louis XIV's reign the library contained more than 70,000 volumes. Under the Abbé Bignon the library was moved to its present home in the Rue Richelieu. Between 173j and 1739 a catalogue in 11 volumes was printed, and duplicates were sold. In Louis XVI's reign the La Vallière sale yielded many valuable accessions. A few years before the Revolution the printed books numbered more than 300,000 volumes and pamphlets. Following the Revolution. the library, renamed the Bibliothkque Nationale, and the other state libraries received large accessions, the forfeited collections of those who fled abroad at the Revolution, as well as of the suppressed religious communities, which by enactments of 1789–92 were gathered into the *dépôts littéraires* mentioned above. Napoleon increased the government grant, and by the strict enforcement of the law of deposits, as well as by the acquisition of collections, the library progressed under him toward his idea of universality. At the beginning of the 19th century it held 250,000 printed volumes, 83,000 manuscripts and 1,500,000 engravings. though after 181j the library had to send back many manuscripts plundered by him from conquered capitals.

After World War I the fall in the value of the franc seriously diminished the library's resources. Under P. Roland-Marcel a reorganization took place of which the following mere the main features: (1j a consortium was set up, under a joint council, of the library with the other chief Parisian national libraries (*i.e.,* the Mazarine [which became the fifth department of the Nationale], the Sainte-Genevikve and the Arsenal and. later. the University of Paris). by decrees of Aug. 29, 1923, and Dec. 28, 1926, purchases of books and periodicals being divided between them; (2) the library, and then the group. were by laws of April 28. 1927, and March j, 1928. given the status of "civil personality." carrying the right to hold funds; (3) the law of copyright was amended, with the result of greatly enlarging the receipts of current French books; the weekly catalogue of accessions of new French books was amalgamated with the list of new publications issued by the trade (*Bibliographie de* la *France);* (4) the oval public reading room, rendered less important by the development of the public libraries of the *arrondissements* of Paris. was converted into a periodical room, equipped with a bureau of information the main feature of nhich is an index of the special collections in all French libraries; (5) a central exchange for loans of books between libraries, whether in France or between France and other countries. nas established in 1927; (6) an office of documentation and bibliographical research was established by the Society of Friends of the Bibliothkque Nationale. These developments greatly increased the library's effectiveness. But the sum available for purchases of printed books remained totally inadequate. In 1954 the Bibliothkque Nationale contained more than 6,000,000 printed volumes (apart from maps, music, periodicals, etc.), 155,000 manuscripts, 5,000,000 engravings and 450,000 medals.

Admittance to use of the library is obtained through a card procured from the secretarial office. The slip catalogue bound in volumes dates from 1882, and gives a list of all accessions since that date; it is divided into two parts, one for the names of authors and the other for subjects. Of the *Catalogue général des livres imprimés* (authors only), begun in 1897, 183 volumes, A-Tendil, had appeared by the end of 1955. Anonyma, periodicals, etc.. are reserved for later treatment. The preface to vol. i, by L. Delisle, is a valuable historical account of the library. The place of the unpublished volumes was, from 1925, supplied by a photographic issue of the manuscript slips of the classed catalogue.

Two other exceptionally important catalogues, out of many, are *Catalogue de l'histoire de France,* 11 vol. (1885–89), and H. Omont's *Catalogue général des manuscrits français,* 13 vol. (1895–1918; index, 1928). For the Greek collection important catalogues were made by Omont. and for the Latin by Delisle, Omont and others. For many oriental languages catalogues have been compiled, and those of manuscripts in modern languages are nearly all completed. The Bibliothkque Nationale began publication in 1885 of a *Catalogue général des manuscrits des bibliothèques publiques de France;* this is still not finished. The departments of medals and of engravings possess excellent catalogues. The former department includes vases! bronzes and gems; the catalogues of the Greek and early French series are remarkable. The department of engravings has been described in the vicomte H. Delaborde's *Le Département des Estampes à la Bibliothdque Nationale* (1875); it includes drawings. F. Courboin's *Catalogue sommaire des gravures et lithographies composant la Re'serve* (1900–01) is supported by many fine special catalogues.

A list of works on and of the catalogues of the Bibliothkque Nationale, and most other French libraries, may be found in A. Vidier, *Annuaire des Bibliothèques et des Archives,* 1927, pp. 13–38. Of the two copies of every new French publication deposited by the printer, one is kept by the Bibliothkque Nationale and the other is allotted by the Council of the National Libraries to one of the other institutions represented upon it.

Other National Libraries. — The Bibliothkque de l'Arsenal, administered from 1935 by the Bibliothkque Nationale, was founded by the marquis de Paulmy (Antoine-René d'Argenson) in the 18th century; in 1786 it received 80,000 volumes from the duc de la Vallikre's library. By mid-20th century it contained more than 1,000,000 volumes and 12,000 manuscripts, with the Bastille collection (2,500 fortfolios) of which the inventory is complete, and 120,000 prints; it is the richest library for the literary history of France, with more than 130,000 theatrical pieces, including the Auguste Rondel collection, added in 1925; accordingly, it receives belles-lettres in the allotment of deposited books.

The Bibliothkque Mazarine owes its origin to the great cardinal, who confided the direction to Gabriel Naudé; it was open to the public in 1642. Dispersed during the Fronde, it was reconstituted with 40,000 volumes after Mazarin's death in 1661 and left to the Collège des Quatre-Nations, which, in 1691, made it again public. It was made one of the libraries of the national consortium and the fifth department of the Nationale; in the mid-1950s it had more than 350,000 printed volumes, includicg incunabula, and 6,000 manuscripts.

The first library of the Genovéfains had nearly disappeared when François Cardinal de la Rochefoucauld, who had charge of the reformation of that order, constituted. in 1642, a new library with his own books. The Bibliothkque Ste.-Geneviève, in 1716, possessed 45,000 volumes. It became national property in 1791, and was called the Bibliothkque du Panthéon and added to the Lycée Henri IV under the Empire. It had 1,000,000 printed volumes, 1,500 incunabula, 4,000 manuscripts, 40,000 prints and 4,000 maps and plans in the mid-1950s.

Official Libraries. — The Bibliothkque du Ministkre des hffaires Étrangères at mid-century contained 400,000 volumes; the Bibliothkque du Ministkre de la Guerre, formed by Louvois, more than 200,000; and that of the Ministkre des Finances 150,000. The Bibliothkque de Documentation Internationale Contemporaire, founded in 1917, had 250,000 volumes, apart from periodicals, documents, maps. etc. The Bibliothkque du Ministkre de la Marine is of old formation (catalogue 1838–43). The Bibliothkque de la Chambre des Députés (1796) possesses 900,000 printed books and 1,600 manuscripts (printed catalogue of law and political economy 1883, and of manuscripts 1907). The Bibliothkque du Sénat (1818) contains 175,000 volumes and 1,400 manuscripts. There are also the following law libraries: Office de Législation Étrangère; Faculté de Droit of the university; Ordre des Avocats (1871, printed catalogue 1880–82); Avocats à la Cour d'Appel; and Cour de Cassation. The City of Paris owns, among other libraries, the Bibliothkque Historique de la Ville de Paris, destroyed in 1871 but restored in 1872 (500,000 volumes); the Forney (industrial art); and those of prefectures, hospitals and schools.

Educational Libraries. — The library of the university is that of the Sorbonne (1762), originally including only arts and theology. In 1800 it was the Bibliothkque du Prytanée, in 1808 des Quatres Lycées and in 1812 de l'Université de France. The faculty sections are: (1) sciences and letters, (2) medicine, (3) jurisprudence and (4) pharmacy. Before the separation of church and state there was also (5) Protestant theology. After the Bibliothkque Nationale it is the richest, and it is superior to all in the fields of classics, archaeology and literature, philosophy, mathematics and physics, possessing in all 2,500,000 volumes. Installed since the year 1897 in the New Sorbonne, it is a library of the very first rsnk. The section of sciences and letters has 900,000 volumes. Among important bequests are those of J. V. Leclerc, E. Lavisse, H. Derenbourg and A. Beljame (the last including an important Shakespearean library).

At the Sorbonne are also to be found the libraries of the laboratories, notably the geological. The section relating to medicine, housed since 1891 in the new buildings of the faculty of medicine, includes 490,000 volumes. The library of the faculty of jurisprudence (1772) contains 300,000 volumes. The fourth section, the faculty (formerly Bcole supérieure) of pharmacy, greatly developed since 1882, contains 120,000 volumes. The library of art and archaeology contains 200,000 volumes and 150,000 photographs.

The other libraries connected with higher education include that of the École des Beaux-Arts, 85,000 volumes, 100,000 reproductions, 14,000 drawings; Bcole Normale Supérieure (1794), 600,000 volumes; École Nationale des Chartes, 80,000 volumes. The library of the Muséum National d'Histoire Naturelle (18th century) has 400.000 volumes, 2,300 manuscripts and 19,joo original drawings. The Bibliothkque du Musée Pédagogique (1880) has 200,000 volumes. The other principal museums (Louvre. Cluny, Guimet, etc.) have large working libraries for the curators and students.

In 1760 was founded the Bibliothèque de l'Institut de France, which is very rich; its acquisitions come particularly from gifts and exchanges (1,500,000 volumes, 5,000 manuscripts). Among other libraries may be mentioned those of the Conservatoire National de Musique (1775); Observatoire; Institut Catholique (400,000 volumes); Conservatoire National des Arts et Métiers; Polonaise (attached to the Académie Polonaise des Sciences et Lettres) containing the Musée Adam Mickiewicz; and Comédie Française. The learned societies of Paris possess valuable collections; the Société de Géographie, for instance, has a library of 300,000 volumes and 100,000 maps.

Old **Municipal** Libraries. — In most towns there are, besides the learned and historical "bibliothkque de la ville," popular lending libraries, privately founded, but since 1874 subsidize supplied with books and inspected by the ministry. In one or two departments there is the beginning of a rural circulating system. Many of the municipal libraries owe the greater part of their collections to the *dépôts littéraires,* but some are of older foundation. Thus, Angers owes its first collection to Alain de la Rue about 1376, and that of Bourges dates from 1466. The libr y of Carpentras was established by Michel Anglici between 1452 and 1474. Mathieu de la Porte is said to have been the founder of the library at Clermont-Ferrand, at the end of the 15th century; it contained more than 49,000 volumes at the time of its union with the Bibliothkque Universitaire.

Among libraries dating from the 16th century must be mentioned that at Lyons, founded by François I in 1527; it possesses 700,000 volumes. 900 incunabula and 10,000 manuscripts (many catalogues printed).

In the 17th century were established the following libraries: Abbeville, by Charles Sanson in 1685; Besanqon, by Abbé Boisot in 1694; La Rochelle, by the Consistoire Réformé in 1604; Vesoul, by Antoine Villeque (died 1665).

The principal libraries founded during the 18th century are the following: Xix-en-Provence (1786). Bordeaux (1736), Chambéry (1780), Dijon (1701), Grenoble (1772), Marseilles (1799), Nancy (1750), Nantes (1753), Nice (1786), Nimes (1778), Niort (1771), Perpignan (1759), Rennes (1790) and Toulouse (1782).

Nearly all the other municipal libraries date from the distribution of the *dépôts littéraires* in 1803. Those of Avignon. Montpellier. Caen, Rouen, Tours and Versailles are specially important; in the second rank come Amiens, Auxerre, Beaune, Brest, Douai, le Havre le Mans, Orleans, Pau. Poitiers and Toulon.

The Association des Bibliothécaires Français in 1928 urged a development of popular public libraries in France generally.

The old university libraries, scattered and thrown into the *dépôts* at the Revolution, were re-established by acts of 1875, 1879 and 1882; civic personality, carrying financial autonomy, followed in 1896. The Bibliothkque Nationale et Universitaire, formerly the Universitats- und Landesbibliothek, of Strasbourg, founded in 1871 to replace that burned in the Franco-German war, is the largest provincial university library, with a fine collection of material relating to Xlsace and Lorraine. Others are: Aix, Algiers, Besanqon. Bordeaux, Caen, Clermont, Dijon, Grenoble, Lille, Lyons, Marseilles, Montpellier, Poitiers, Rennes and Toulouse.

Administrative control of the libraries of France is vested in the *direction des bibliothèques,* under the ministry of education (established 1945).

In the French overseas territories the most considerable library centre is Algiers, with national. university and city libraries.

GERMANY, AUSTRIA, HUNGARY, SWITZERLAND

Germany. — By the mid-1950s much of the damage caused to Germany's library system during World War II had been made good. Buildings and collections had been to a large extent restored, in both eastern and western Germany.

There was no law of deposit in Germany covering any area wider than that of individual states, and some states had no law of deposit at all for a long time. The Deutsche Rucherei at Leipzig, founded by the German book-trade association (Borsenverein der deulschen Buchhandler) in 1912 to supply the need for a copyright library for all Germany, had 2,000,000 volumes at the time of the destruction of its building (with 400 000 of its books) in 1943. It operated a central cataloguing service and issued the German national bibliographies. The most important co-operative cataloguing enterprise of Germany was the *Gesamtkatalog der preussischen Bibliotheken* (of which the first volume appeared in 1931), undertaken by a special department of the Preussische Staatsbibliothek. Fourteen volumes of this work had appeared by 1939, but it was then discontinued, perhaps permanently.

In 1924 was promulgated the Leihverkehrsordnung fur die Deutschen Bibliotheken, which authorized and organized mutual lending betneen all libraries in the country.

The state and university libraries are under state control. The earlier distinction between these two classes has become less and less marked, and together they form a great assemblage of learned (*wissenschaftlich*) libraries.

There has always been a sharp distinction between the learned and the popular libraries (Volksbuchereien), which exist in most towns. Karl Preusker formed a plan for setting them up in 1839, and four were founded in Berlin in 1850. After 1890 a number of popular libraries were established, some by municipalities, but many by associations and firms. Most of the states had a consultative office for popular libraries, and the Deutsche Zentralstelle fur Volkstümliches Buchereiwesen acted as a centre. The Verband Deutscher Volksbibliothekare publishes an annual directory (vol 36, 1955). Sometimes these popular libraries were under the supervision of a scientifically administered town library, as in Berlin; elsewhere, as at Magdeburg, an ancient foundation assumed the obligations of a public library. The National Socialist party made great use of the Volksbüchereien for propaganda purposes.

Berlin and Prussia.—The largest of the Berlin libraries is the Deutsche Staatsbibliothek in East Berlin (prior to World War II the State library), which was founded and made public by the "Great Elector," Frederick William, in 1661. From 1699 the library became entitled to a copy of every book published nithin the royal territories, and it received many valuable accessions by purchase and otherwise. It included 2,850,000 printed volumes before World War II and 68,500 manuscripts, 300,000 maps and 6,500 incunabula. The building, erected about 1780 by Frederick the Great, was rebuilt in 1909 and again after 1945, following severe damage in World War II. The State library lost 350,000 volumes in the bombing. Part of its collections, dispersed for safety during the war, was assembled at the Westdeutsche Bibliothek, Marburg, the national library of the German Federal Republic, which had nearly 2,000 000 volumes in the mid-1950s; by that time the Staatsbibliothek also had restored its stock to about 2,000,000. There is a regular system of mutual lending, established by ministerial edict of Jan. 27, 1893, between the State library and a great number of Prussian libraries. The same is true of Bavaria, Wurttemberg and Baden.

Conducted by the Staatsbibliothek were the *Gesamtkatalog der preussischen Bibliotheken* already described, the Auskunftsburo der Deutschen Bibliotheken (founded in 1905 to give information as to where any particular book might be consulted) and the Kommission fur den *Gesamtkatalog der Wiegendrucke* (a complete catalogue of books printed before 1500), of which vol. 1–8, pt. i, had appeared by 1939. After World War II it undertook extensive bibliographical work with particular emphasis on the publications of eastern Europe.

The University library (1831) had about 875,000 volumes and a collection of 560,000 dissertations in the mid-1950s. Its building was damaged during World War II but not more than 20,000 books were lost.

Some of the governmental libraries in Berlin were important; the administrative partition of Berlin has led to the establishment of many new governmental libraries and the splitting of others between Berlin and Bonn.

The former Prussian university libraries outside Berlin include Bonn (59,000 printed volumes, 2,000 manuscripts), Gottingen, from its foundation in 1736–37 the best-administered library of the 18th century (1,100,000 volumes, 9,000 manuscripts), Kiel, Konigsberg, Marburg and Miinster. Largely in consequence of the impoverishment of the years after 1918 the university libraries divided the field of knowledge among them by means of a cooperative purchase scheme. Bonn collected Romance, Gottingen English, Kiel Scandinavian, Heidelberg art and archaeology, Konigsberg philosophy, Leipzig Italian and oriental, Tübingen theology and oriental, Berlin German and foreign academica and Griefswald Low German. Breslau was ceded to Poland and renamed Wroclaw. The buildings of Bonn, Gottingen, Münster and others were destroyed or seriously damaged, but evacuation saved the greater part of the collections in many cases.

Munich and Bavaria. — *The* libraries of Munich include two of great importance. The State library was founded by Duke Albrecht V of Bavaria (1550–79), who made numerous purchases from Italy, and incorporated the libraries of the Nuremberg physician and historian Hartmann Schedel, of J. A. Widmannstadt and of J. J. Fugger. The number of printed volumes was estimated at 2,000,000 and of manuscripts at 50,000 in the mid-1950s. The library had 16,000 incunabula, many from the monastic libraries closed in 1803. The oriental manuscripts are numerous and valuable, and include the library of Martin Haug. The catalogue of the printed books is in manuscript; a printed catalogue of manuscripts was issued in 1858. The University library (700,000 volumes, 2,500 incunabula, 4,000 manuscripts) was founded at Ingolstadt in 1472, and moved with the university to Munich in 1826. Both libraries were severely damaged in World War II.

The chief Bavarian libraries outside Munich are the State library at Bamberg (200,000 volumes. 4,500 manuscripts) and the University library at Würzburg (formerly 600.000 volumes, 1.750 manuscripts); this building, catalogues and 200,000 volumes were destroyed in World War II. The universities of Erlangen, Augsburg and Nuremberg have large libraries (Erlangen and Augsburg undamaged; Nuremberg building destroyed, collections saved).

Other German Libraries. — *In* Dresden the Sachsische (formerly Ronigliche Öffentliche) Landesbibliothek was founded in the 16th century; it specializes in history and literature, and had 710,000 volumes in the mid-1950s of which only 90,000 were organized for use, 250,000 having been destroyed in World War II.

Leipzig University library had 1,600,000 volumes in the mid-19 jos (building severely damaged); the Comeniusbücherei (Pädagogische Zentralbibliothek) was one of the largest educational libraries in the world. The Deutsche Biicherei has already been mentioned. The University library of Tiibingen is the largest library in Württemberg. The Württembergische Landesbibliothek at Stuttgart (1 765) had in the mid-1950s 660,000 volumes. 348,000 pamphlets and 10,000 manuscripts, with a famous collection of Bibles. Half the original collection was destroyed in 1944.

The former grand-ducal library of Darmstadt. the Hessische Landesbibliothek, was established by the grand duke Louis I in 1819, on the basis of a 17th-century library, and included 760,000 volumes and 4,500 manuscripts at the time of its destruction in 1944 with the loss of two-thirds of the collection.

Among the other libraries of Hesse the chief are the Cniversity library at Giessen (destroyed with nearly all its contents) and the Stadtbibliothek at Mainz, including the Gutenberg museum (damaged but restored).

In Baden are the Badische Landesbibliothek at Carlsruhe (156,000 volumes in 1954 after almost complete destruction), and the university libraries at Freiburg (700,000 volumes. 1.800 manuscripts) and Heidelberg (1386), the oldest of the German university libraries. In 1623 the whole collection of the last named was given to the pope, and only the German manuscripts were returned. The library was re-established in 1703, and after 1800 was enriched with monastic spoils; in the mid-I950s it contained 820.000 volumes, apart from dissertations, etc., and manuscripts and papyri, for the most part of great value. Heidelberg was untouched by the destruction of war; Freiburg suffered considerable damage to its building but little to its collections.

In other German states should be mentioned Jena, Rostock, Schwerin and Weimar (all little damaged), possessing rich collections of manuscripts.

The ducal library of Gotha, now the Thiiringische Landesbibliothek, was established by Duke Ernest the Pious in the 17th century. and contained many valuable books and manuscripts from monastic collections. It numbered about 400.000 volumes, with 7,800 manuscripts. The catalogue of the oriental manuscripts, chiefly collected by Ulrich Seetzen and forming one-half of the collection, is one of the best in existence. The greater part of the collection was moved to Moscow by the soviet occupation authorities in 1946. In the mid-1950s there were 120.000 volumes.

The Herzog-August (formerly Landes-) Bibliothek at Wolfenbiittel, founded in the second half of the 16th century by Duke Julius, was made over to the University of Helmstedt in 1614. whence the most important treasures were returned to Wolfenbiittel in the 19th century; in 1954 it numbered 400,000 volumes and 8,400 manuscripts and was exceptionally rich in incunabula.

The chief libraries of the Hanse towns are those of Bremen, Liibeck and Hamburg (Staats- und Cniversitatsbibliothek. formerly Stadtbibliothek). made public since 1648. Of its 850,000 volumes, Hamburg lost 710,000 by bombing in World War II; by 1951 the collection had already been restored to between 500,000 and 600,000. Liibeck was virtually undamaged at the end of World War II, though its evacuated collections were not returned to it from the soviet zone. Bremen (severely damaged) had 250,000 volumes in the mid-19 jos.

Austria. — The *Adressbuch der Bibliotheken der Oesterreich-ungarischen Monarchie,* by Hanns Bohatta and Michel Holzmann (1900), described the libraries of the Austro-Hungarian empire. The largest library in Austria, and one of the chief in Europe, is the Nationalbibliothek (before 1920 Hofbihliothek) (1526), including a portion of the library of Matthias Corvinus. Since 1808 the library has been entitled to the copyright privilege. The number of printed volumes was 1.500,000 (including y.000 incunabula). The manuscripts amounted to 35,000 (2.360 oriental), with 100,000 papyri of the collection of Archduke Rainer. The collection of prints was separated from the books in 1921 and annexed to the Alhertina. The University library of Vienna (1365) (1,360,000 volumes) was established by Maria Theresa.

The number of monastic libraries in Austria is very considerable. They possess altogether more than 2,500,000 printed volumes, 25,000 incunabula and 25,000 manuscripts. The oldest library in Austria is that of the monastery of St. Peter at Salzburg (785–821), with 70,000 volumes and nearly 1,500 incunabula. Kremsmiinster (100,000) dates from the 8th century, Admont (86,000) and Melk (70,000) from the 11th. Accounts of their manuscripts appear from time to time in *Zentralblatt jiir Bibliothekswesen.* Rlany of their librarians are trained in the great Vienna libraries.

While the financial crisis which followed World War I forced a few of these libraries to sell some of their treasures, World War II left them unscathed.

Hungary. — Information about the chief libraries in Hungary under the dual monarchy was given annually up to 1911 in the Hungarian *Statistical Year Book.* The largest library in Hungary is the National Széchenyi library at Budapest, founded in 1802 by the gift of the library of Count Franz Széchenyi. It contained 1,330,000 printed volumes and 20,000 manuscripts*at mid-20th century and had 11 lending and 4 reference branches. The University library of Budapest (1585) included 900,000 printed books and 3,400 manuscripts. Other important university libraries are at Szeged, Pécs and Debrecen.

The central bureau of public libraries produces a general catalogue of accessions (which serves as a current national bibliography).

The library of the Benedictines at Pannonhalma (11th century) was the central library of the order in Hungary. and contained nearly 280,000 volumes in 1951. Its principal treasures nere, on the secularization of the monasteries, distributed among the state libraries in Budapest.

Switzerland. — The University library at Basle (1460), the Cantonal library at Lausanne and the Stadtbibliothek at Berne, which, in 1903, was united to the University library of that city, the Landesbibliothek (Bibliothèque Nationale) at Berne and the City and University library of Geneva are considerable. All Sniss literature since 1848 is collected by the Landesbibliothek at Berne. established in 1895 for this special object (1,000,000 volumes). There is no legal. but only a voluntary, deposit of Swiss books. The monastic libraries of St. Gall (816) and Einsiedeln are of great historical interest. The former League of Nations library at Geneva became the property of the United Nations. Switzerland has a highly developed system of cantonal, communal and travelling libraries, and of interlibrary loans.

ITALY

Italy is the home of the oldest libraries. The Vatican at Rome and the Laurentian at Florence are sufficient in themselves to give Italy prımacy in respect of rare and valuable manuscripts. The local rights which so long impeded the unification of Italy created and preserved many libraries which would hdve been lost under a central state. Italy is still in spite of nars and collectors, rich in books. The destruction and damage during World War II were assessed by the ministry of public instruction in 1946 at a total of 3,480,000,000 lire. Many libraries sent their treasures to the

Vatican for safekeeping.

Governmental Libraries.—Governmental libraries (biblioteche *governative*) are under the minister of public instruction. The prefascist regulation controlling them was issued in the *Bollettino Ufficiale,* Dec. 5, 1907. They consisted of the national central libraries of Rome (Vittorio Emanuele) and Florence; the national libraries of Milan (Braidense), Naples, Palermo, Turin and Venice (Marciana); the government library at Cremona; the Marucelliana. the Mediceo-Laurenziana and the Riccardiana at Florence; the government library at Lucca; the Estense at Modena; the Brancacciana and that of San Giacomo at Naples; the Palatina at Parma; the Angelica. the Casanatense and the Lancisiana at Rome; the university libraries of Bologna, Cagliari, Catania, Genoa, Messina. Modena, Naples, Padua, Pavia, Pisa, Rome and Sassari; the Ventimiliana (with the university library) at Catania; the Vallicelliana and the musical library of the Conservatorio di Musica "Santa Cecilia" at Rome; the musical section of the Palatine at Parma; and the Lucchesi-Palli (added to the national library) at Naples. Each library was to possess a general inventory, an accessions register, an alphabetical author catalogue and a subject catalogue. Catalogues of the special collections mere next to be compiled. A general catalogue of the manuscripts was issued together with catalogues of oriental codices and incunabula.

The general lines of this structure. operating under government supervision, were maintained after World War II, though certain changes were necessitated by the destruction of many libraries and the dispersal of their contents. Rebuilding, however, was pushed forward energetically.

Two publications. the *Bollettino* delle *pubblicazioni* italiane and *Bollettino* delle *opere moderne straniere acquistate dalle* biblio*teche governative,* for many years issued from the national libraries of Florence and Rome. respectively, have taken the place of a collective catalogue of accessions. The former is the current national bibliography.

Vatican.—The Biblioteca Vaticana stands in the very first rank among European libraries as regards antiquity and wealth of manuscripts. We can trace it back to the earliest records of the *Scrinium* Sedis *Apostolicae* (Archive of the Apostolic See). There still survives an inventory made under Boniface VIII. The old library was moved to Avignon, where it was renewed and increased, but this collection has only in part, and in later times. been taken into the library of the Vatican. The latter is a new creation of the I jth century. Eugenius IV planted the first seed, but Nicholas V was the real founder of the library, to which Sixtus IV consecrated an ornate abode, in the Court of the Pappagallo. Sixtus V erected the present magnificent building in 1588, and greatly augmented the collection.

The most noteworthy librarians were Marcello Cervini (the first Cardinale Bibliotecario, later Pope Marcel II), Sirleto and A. Carafa. In 1600 the library was further enriched by the acquisition of the library of Fulvio Orsini. Pope Paul V (1605–21) separated the library from the archives and added the two "Pauline" halls for the new codices. Under him and under Urban VIII many manuscripts were purchased from the Convent of Assisi. the Minerva at Rome, the Capranica college and, above all, the library at Bobbio (see section on *Mediaeval* Period above). Gregory XV (1622) received from Maximilian I, duke of Bavaria, the valuable library of the Elector Palatine, seized by Count Tilly at the capture of Heidelberg. Alexander VII (1658) added the manuscripts of the dukes of Urbino.

The *Libreria* della Regina (*i.e.,* of Christina of Sweden) of ancient manuscripts—some from French monasteries, from St. Gall and elsewhere, and others of importance for French literature from the collection of Petau—was in great part presented by Alexander VIII in 1689. Under Clement XI were purchased 54 Greek manuscripts which had belonged to Pius II. and also oriental manuscripts. In the time of Benedict XIV was bequeathed the Capponi library, rich in Italian books; and by purchase was acquired the Biblioteca Ottoboniana, which. in Greek, Latin and Hebrew manuscripts, mas after the Vatican the richest in Rome. Clement XIII in 1758, Clement XIV in 1769 and Pius VI in 1775 were also benefactors.

After three centuries of uninterrupted growth the Vaticana was to undergo a severe blow. In 1798, after the treaty of Tolentino, 500 picked manuscripts were sent to Paris. These. however, were chiefly restored in 1815, though most of the Palatine manuscripts found their way, not back to Rome, but to Heidelberg. Pius VII acquired the library of Cardinal Zelada in 1800, and among important purchases of the 19th century were the splendid Cicognara (archaeology and art, 1823). Cardinal A. Mai, 40,000 volumes (1856), about 300 Borghese manuscripts from the papal library of Avignon, the Barberini library and the Borgia collection, De Propaganda Fide.

The printed books in the Vaticana numbered about 700,000 at mid-20th century, the manuscripts about 53,000 and the incunabula about 7.000 with many vellum copies; there are 500 Xldines and a great number of bibliographical rarities, including many presentation copies. Among the Greek and Latin manuscripts are some of the most ancient and valuable in the world; *e.g.,* the famous biblical Codex *Vaticanus* of the 4th century, the two Virgils of the 4th and 5th centuries, the Bembo Terence and the palimpsest De *Republica* of Cicero.

Many important catalogues of special classes of manuscripts and important single volumes have been published in facsimile. A new catalogue of the printed books was made in 1927–29 to make easily available the library's rich treasures. This catalogue, made possible by the aid of the Carnegie endowment, was worked out mainly according to the code of the American Lihrary association by four Vatican librarians and four U.S. librarians.

Other Roman Libraries.—The most important library in Italy for modern requirements is the Biblioteca Nazionale Centrale (1875) (more than 1,900,000 volumes, 300,000 pamphlets and 5,200 manuscripts in 1954). This contains the Biblioteca Maior o Secrets of the Jesuit college of Rome and the cloister libraries of the Provincia Romana, and has the right to copies of new Italian books. Noteworthy among the manuscripts are the Farfensi and the Sessoriani of Santa Croce in Jerusalem: some of these last being of the 6th to the 8th centuries. The library was reorganized in 1910. It is rich in the Renaissance, in Roman topography and generally in books of reference and in journals. A monthly *Bollettino* is issued of modern foreign literature received by the libraries of Italy. The library acts as the central bureau of bibliographical information for Italy.

The Biblioteca Casanatense, founded by Cardinal G. Casanata in I joo (280,000 printed volumes, 2.000 incunabula, with many Roman and Venetian editions, and 6,000 manuscripts, some of the 8th–10th centuries), is rich in theology, mediaeval history, law and the social sciences. An incomplete catalogue of the printed books by A. Audiffredi (1761–88) still remains a model.

The Biblioteca Angelica, founded in 1614 by Angelo Rocca (129,000 printed volumes and 3,000 manuscripts), was the first library in Rome to be opened to the public. The Alessandrina, founded by Alexander VII in 1661, with the greater part of the printed books belonging to the dukes of Urbino, is the library of the University of Rome. In 181j Pius VII granted to it the right to receive a copy of every book printed in the states of the church, which grant was continued by Italian law but limited to the province of Rome. The library possessed 800,000 printed books in 1954.

The library of the senate, first established at Turin in 1848, contains 350,000 volumes and is rich in the history and statutes of Italian cities. That of the chamber of deputies (1848) contains 400.000 volumes and specializes in more modern history, law and politics. The Vallicelliana (1581), controlled by the Regia Società Romana di Storia Patria has some important manuscripts, including one attributed to Alcuin; the Lancisiana (1711) is valuable for its medical collections; the Accademia di San Luca possesses a good art library; the Biblioteca Militare Centrale (1893) has 100,000 printed volumes and 72.000 maps; the Bibliotera della Conservatorio di Musica "Santa Cecilia" (1875) has a musical collection of 150,000 volumes and 6.000 manuscripts; the Corsiniana, founded by Clement XII and from 1884 part of the Accademia Nazionale dei Lincei, is rich in incunabula and prints. The Deutsches Institut, École Française and British and U.S. schools may be mentioned. All these and many other Roman libraries are open, at least to advanced students.

Subiaco.—At Subiaco, about 40 mi. from Rome, the Benedictine monastery of Santa Scolastica has only 6,000 printed volumes and 400 manuscripts, but it is remarkable as having been, in 1465, the first seat of typography in Italy, and students may inspect the series of Conrad Sweynheim and Arnold Pannartz's original editions preserved in their first home.

Florence.—The Biblioteca Nazionale Centrale of Florence was formed from the union of A. da M. Magliabechi's library with the Palatina. The Magliabechiana became public in 1714, and in 1861 the Palatina (formed by Ferdinand III, grand duke of Tuscany) was joined with it. It had long had a right to a copy of every work printed in Tuscany. a right maintained more rigorously from 1860. Since 1870 the Nazionale has received, by law, a copy of every book published in Italy. Its monthly *Bollettino* is the current bibliography of the national literature. The manuscripts include the most important extant codices of Dante and later Italian poets and historians. The Galileo collection numbers 308 manuscripts. Of the 2j manuscript portolani, the oldest is dated 1417, and several seem to be the original charts executed for Sir Robert Dudley (duke of Northumberland) in the preparation of his *Arcano del Mare*. Among the early printed books are a great number of 16th-century *Rappresentazioni* (books printed on vellum). municipal histories and statutes. authoritative texts and maps. The library contained 1.500,000 printed volumes in the mid-1950s, more than 1,000,000 pamphlets, and manuscripts, incunabula, prints and maps. A new building was completed on the Corso dei Tintori in 1929.

The world-famed Biblioteca Mediceo-Laurenziana at Florence was formed from the collections of Cosimo the Elder, Pietro de' Nedici and Lorenzo the Magnificent. It mas made public by Clement VII. who charged Michelangelo to construct a suitable edifice for its reception. Opened by Cosimo I in 1571, it grew steadily. The accessions in the 18th century alone were enough to double it. Its printed books number probably only 50,000, and though almost all of them are of the highest rarity and interest. it is the 10,000 manuscripts which give the chief importance to this library. More than joo are earlier than the 11th century. Some of them are the most valuable codices in the world—the famous Virgil of the 4th or 5th century, Justinian's *Pandects* of the 6th, a Homer of the 10th and several other very early Greek and Latin classical and biblical texts, as well as copies in the handwriting of Petrarch, about 100 codices of Dante, a *Decameron* copied by a contemporary from Boccaccio's own manuscript, and Benvenuto Cellini's manuscript of his, autobiography. Administered with the Laurentian is the Riccardiana, rich in manuscripts of Italian, and especially the Florentine, literature.

The Biblioteca Marucelliana (founded 1jog, opened 1753) is remarkable for its early woodcuts and engravings; the printed volumes number 340,000 and the manuscripts 2.000.

Milan.—The Biblioteca Nazionale of Milan, better known as the Braidense. founded in 1770 by Maria Theresa, had 570,000 printed volumes in 1950. Among the manuscripts are letters of Galileo, poems in Tasso's autograph and a fine series of Italian illuminated service books. 12th to 16th centuries.

Among the great libraries not under government control, the most important at Milan is the Ambrosiana, founded in 1609 by Cardinal Federigo Borromeo. It contained 600.000 printed volumes: 2,000 incunabula and 25,000 manuscripts in 1954. Among the manuscripts are a Greek Pentateuch of the jth century, the famous Peshito and Syro-Hexaplar, a Josephus on papyrus. supposed to be of the 5th century. several palimpsest texts and a 7th-century copy of St. Jerome's commentary on the Psalms. full of contemporary glosses in Irish. Gothic fragments of Clfilas and a Virgil with notes in Petrarch's handwriting. Cardinal Mai and Pope Pius XI were former custodians here. The building was damaged during World War II. but the collections remained intact.

Naples.—The oldest library at Naples is the Brancacciana, founded in 1647 by Cardinal F. M. Brancaccio, and opened by his heirs in 1675. The Biblioteca Nazionale at Naples (founded in 1734 and opened in 1804) is the largest library of that city, and was rehoused in 1927 in the Palazzo Keale. To the collection of Cardinal G. Seripando were added, especially in 1848 and 1860, many private and conventual libraries. The biblical section is rich. Other features are the collections of authoritative texts and of books on volcanoes, the best in existence of the publications of Italian learned societies and a nearly complete set of the Bodoni press. The manuscripts include many illuminated books, the autographs of G. Leopardi, and books about the ports of the world. The library in 1954 contained about. 1,400,000 printed volumes. Annexed to it is the Officina dei Papiri Ercolanesi. The Biblioteca della Università at Naples, established by Joachim Murat in 1812 in the buildings of Monte Oliveto, and thence sometimes called the Eiblioteca Gioacchimo, was transferred to the Royal university and opened in 1827. It is strongest in medicine and science; its chief manuscripts and early printed books were transferred about the middle of the 19th century to the Xazionale. The library of the University of Naples was destroyed in World War II; its stock had been restored to 700,000 volumes by 1954.

Palermo.—The Biblioteca Nazionale of Palermo, founded from the Jesuits' libraries, is rich in 15th-century books (catalogue printed in 1875), in Aldines and in Sicilian 16th-century books, many being unique.

Turin.—The Biblioteca Nazionale Universitaria of Turin took its origin in the private library of the house of Savoy, given in 1720 to the university by Vittorio Amedeo II. The fire of 1904 destroyed about 24,000 out of 300.000 volumes, and of the 4,138 manuscripts there survive but 1,500, and those in a damaged condition. Among those that perished were the palimpsests of Cicero, Cassiodorus, the Codex Theodosianus and the famous *Livre d'Heures*. The 1,09j incunabula escaped. After the fire the library was enriched by new gifts, notably Baron A. Lumbroso's of 30,000 volumes, principally on the French Revolution and Empire. The library was in 1910 transferred to a set of rooms in the offices of the Debito Pubblico. It possessed 600,000 volumes in 1954.

Venice.—The Biblioteca Nazionale Marciana, or library of St. Mark, at Venice, was traditionally founded in 1362 by Petrarch's gift of manuscripts (all subsequently lost) and opened by Cardinal J. Bcssarion in 1468. It had 550,000 printed books in 1954, manuscripts of great value (more than 1,000 Greek codices given by Johannes Bessarion), collections on Venetian history, music and theatre, and on early geographical research, a codex of the laws of the Lombards and the autograph manuscript of Paolo Sarpi's History *of the* Council *of* Trent. Many private and conventual libraries were incorporated in the Libreria del Sansovino, from which the library was transferred in 1812 to the Palazzo Ducale. and in 1904 to the Palazzo della Zecca (the mint).

Other Italian Libraries.—First in historical importance among the university libraries comes that of Bologna! founded by U. Xldrovandi (1605). Count Luigi F. Marsili in 1712 increased the library and established an Istituto delle Scienze, reconstituted as a public library by Benedict XIV in 1756. The printed books numbered 270,000 in 1954; the oriental manuscripts are noteworthy. The grand hall, with its fine furniture in walnut wood, merits particular attention. The library escaped damage in World War I Other important university libraries are those of Catania (1755), Genoa (1773), Pavia (1763), Padua (1629) (390,000 volumes). Cagliari (175j) and Sassari (c. 1j50). Messina was destroyed in the earthquake of 1908, but the more important part of the furniture was saved, and two years later the library was restored to active work.

At Modena is the Eiblioteca Estense, founded by the Este family at Ferrara in 1393; it was transferred to Modena by Cesare d'Este in 1598. L. A. Muratori, F. A. Zaccaria and G. Tiraboschi were librarians here. The printed volumes numbered about 300.000 in 19jo. besides incunabula, manuscripts and the Campori collection (5,000 manuscripts and 100,000 autographs).

The Biblioteca Palatina di Parma was founded in 1769 by the grand duke Philip. who employed Paolo M. Paciaudi to organize it. It contained 400,000 volumes in 1950 and several thousand manuscripts, including Giovanni Bernardo de Rossi's biblical and rabbinical manuscripts. Xlso worthy of note are the Biblioteca Governativa or Pubblica of Lucca. and that of Cremona.

At Genoa the Biblioteca Franzoniana (40,000 volumes), founded about 1770 for the instruction of the poorer classes, is noteworthy as being the first European library lighted at night for the use of readers.

The foundation of the monastery of Monte Cassino (529) was a result of the efforts of St. Benedict, and became the prototype of all western religious houses. The library extended to about 70.000 volumes and that belonging to the monks contains about the same number. But the chief glory of the library is the archive, which is quite apart; this includes more than 30.000 bulls, diplomas, charters and other documents, besides 1.000 manuscripts dating from the 6th century on. There are good written catalogues, and descriptions with extracts are published in the *Bibliotheca Casinensis*. The monastery was declared a national monument in 1866. It was completely destroyed in World War II but its collections, which had been moved for safety to the Vatican, survived. At Ravenna the Biblioteca Communale Classense has a 10th-century codex of Aristophanes. At Vercelli the Biblioteca dell' Archivio Capitolare comprises nothing but manuscripts, all of great antiquity and value, among them an evangelarium of St. Eusebius, supposed to be of the 4th century, and a famous codex of Anglo-Saxon homilies.

The Monastero della S. Trinita, at La Cava dei Tirreni, in the province of Salerno (beginning of the 11th century), has only about 10,000 volumes. but these include manuscripts from the 8th to the 14th centuries, among them a codex of the laws of the Lombards, dated 1004, besides a well-known geographical chart of the 12th century, more than 100 Greek manuscripts and about 1,000 charters beginning with the year 840, more than 200 of which belong to the Lombard and Xorman periods. The library is national property, the abbot holding the office of keeper of the archives.

Not a few of the communal and municipal libraries are of great extent and interest: Bologna (1801); Brescia, the Civica Quiriniana (1747); Ferrara (1; 53); Macerata. the Mozzi-Borgetti (1783–1835, united 1855); Mantua; Novara, the Negroni e Civica (1847 and 1890); Padua; Palermo (1760); Perugia (18j2), founded by P. Podiani; Siena (1; 58), founded by S. Uandini. fine art collection; Venice, the Museo Civico Correr (1830); Verona (1792, public since 1802—badly damaged in World War II); Bertoliana (1708). The postwar reconstruction plan of the Federation of Italian Libraries. operated in conjunction with the government, included proposals for co-operative book buying.

SPAIN, PORTUGAL AND LATIN AMERICA

Spain and **Portugal.**—Most of the royal, state and university libraries of Spain and Portugal have government control and support.

The chief library in Spain is the Biblioteca Nacional (formerly Real) at Madrid (1712), with 1,500,000 printed books. Theology, canon law, history, etc.. are very strong. The collection of prints was principally bought from Don Valentin Carderera in 1865. Also in Madrid is the Biblioteca de la Real Academia de la Historia (1738) (50,000 volumes and 8.400 manuscripts), which contains Spanish books of great value, including the Salazar collection. The University of Madrid (550,000 volumes) serves as a central information bureau for the whole country. The Escorial, rich in manuscripts, has the earliest Renaissance library building (1584). The Biblioteca Provincial y Universitaria of Barcelona (1841) contains about 350,000 volumes, and that of Seville (1767j has 200,000 volumes. Among other provincial and university libraries is that of Salamanca (1254). Rural public library systems are being developed throughout Spain.

Among the libraries of Portugal the Biblioteca Nacional at Lisbon (1796) takes first place. In 1841 it was largely increased from the monastic collections, and it has 850,000 volumes of printed books. largely on theology, canon law. history and Portuguese and Spanish literature, 16.000 manuscripts and 40,000 coins and medals. The Academia das Ciências (1779), in the convent of the Ordem Terceira da Penitencia, in 1836 acquired the library of that suppressed convent (210,000 volumes). The University library of Coimbra (1591) (850,000 volumes) is the second largest in Portugal.

The Biblioteca Pública Municipal at Oporto, founded during the siege of 1833, and till 1874 styled the Real Biblioteca do Pôrto, has about 400,000 volumes. The regent gave to the town the libraries of the suppressed convents in the northern provinces. The important Luis de Camoens collection is described in a printed catalogue (1880), as are the manuscripts by H. da Cunha Rivara (1850–70). Most of the other large towns have municipal libraries.

Latin America. — Many of the older libraries of Latin America derive their original collections from monastic and other religious libraries. The republics created their own national libraries! which act as national bibliographical centres. Universities tend to have separate faculty or departmental collections without a general library. The public library system, still generally in an early stage of development, was making steady progress by mid-20th century under the influence of the United Nations Educational, Scientific and Cultural organization (UNESCO) and the United States.

The National library of Mexico was established in 1857 by a decree which suppressed the University of Mexico and transferred its library to the state. The university subsequently accumulated many departmental collections. The National library, which absorbed also the ecclesiastical libraries of Mexico City, possessed 420,000 volumes at mid-century. There are important special libraries, notably those of the National Museum of Anthropology and of the Academy of Sciences. A public library service n-as established in 1921 under the Libraries department of the ministry of education.

Cuba has a National library (1901) at Havana (256,000 volumes) and Havana university has a good library of moderate size. The ministry of education set up a Library office in 1940. The libraries of the other Middle American states were still small at mid-century, that of Panama having been founded as late as 1942.

The oldest national libraries in South America are those of Argentina and Brazil, both founded in 1810 and each having about 700,000 volumes. Argentina was early in the field with its public library system (1870), controlled arid subsidized by a national commission. Brazil possesses in Rio de Janeiro and São Paulo important general and special libraries in addition to the Biblioteca Nacional, among which may be noted the Marine library, the library of the National museum and the Municipal library at Rio de Janeiro and the University and Municipal libraries of São Paulo. At mid-century there were more than 250 municipal libraries in various parts of the country. The National library of Chile at Santiago (1813) contains 500,000 volumes; Chile has an extensive system of public libraries. In Colombia the government and UNESCO established a model public library at Medellín in 1954. in Peru. the National library in Lima (1821) was destroyed by fire with nearly all of its 120,000 volumes in 1943; the opportunity was taken to inaugurate a modern library organization for the whole country. Uruguay established in 1942 a Xational library in Montevideo, where there is also a municipal library system; Venezuela has a National library of 200.000 volumes at Caracas. Bolivia and Paraguay have no libraries of great size; the Bolivian Xational Library and Archives at Sucre, however, is of early foundation (1836).

BELGIUM, NETHERLANDS AND SCANDINAVIA

In Belgium, the older libraries derived their collections largely from the sequestration of monasteries after the French Revolution. In Holland, most of the earlier libraries were destroyed during the religious wars and the war with Spain. The outstanding example is that of the Benedictine monastery of Egmond, which mas completely destroyed. World Wars I and II caused further severe damage.

After 1900 there was considerable progress in both Belgium and the Netherlands in the development of public libraries, and many towns in the latter country established popular libraries after the fashion of the municipal libraries of the United Kingdom and the U.S.

The library systems of Scandinavia also bear close resemblances to those of the English-speaking peoples.

Belgium. — The national library of Belgium is the Bibliothkque Royale at Brussels. based on the Bibliothkque des ducs de Bourgogne, the library of the Austrian sovereigns of the Low Countries in 1772. In 1794 a number of volumes were transferred to Paris, the majority being returned in 1815; in 179j the remainder were formed into a public library under the care of La Serna Santander, who was also town librarian, and who was followed by Van Hulthem. At the end of the administration of Van Hulthem a large part of the precious collections of the Bollandists was acquired. In 1830 the Bibliothkque de Bourgogne was added to the state archives. Van Hulthem died in 1832; his private library (catalogue printed in 1836), mostly relating to Belgian history, was purchased in 1837, and together with the Bibliothkque de Bourgogne and the Bibliothkque de la Ville (open since 1794), formed the Bibliothèque Royale de Belgique. The printed volumes numbered more than 1,600,000 in the mid-1950s, with 32,000 manuscripts and maps, many prints. coins and medals. There are printed catalogues of special collections of manuscripts, of accessions, etc., and entries for books and periodicals acquired by university libraries are incorporated in a union catalogue on cards. There is no free legal deposit of books in Belgium; the government purchases new books from the publishers and deposits them in the Royal library. There are libraries attached to most of the departments of the government.. Other important libraries in Brussels are the Bibliothkque Collective des Sociétés Savantes (1906), with a union catalogue on cards, and the Bibliothkque du Conservatoire Royal de Musique (1832) with 40,000 volumes in 1950. The Bibliothkque de la Société des Bollandistes (1640) (300,000 volumes) is one of the world's outstanding theological libraries. At Antwerp the town library (1505) has 350,000 volumes. The valuable collection of books in the Musée Plantin-Moretus (1640) should also be mentioned. It contains several hundred manuscripts and 2,000 printed books, comprising the works issued by the Plantin family and many 15th-century books, besides the archives of the firm.

The University library of Ghent (declared public in 1797, opened in 1798), was known successively as the Bibliothkque de l'École Centrale and Bibliothkque Publique de la Ville. On the foundation of the university in 1817 the town placed the collection at its disposal, but it remained under state control. The printed volumes amounted to 870,000 and the manuscripts to 7,000 in 1954. The Bibliothkque de l'Université Catholique of Louvain (1636) was based upon the collections of Laurent Beyerlinck, bequeathed in 1627, and of Jacques Romain, professor of medicine. There were more than 211,000 volumes in 1914, when the library was totally destroyed by fire during the German occupation. By 1940, when the library was destroyed for the second time. the collection had been built up to nearly 1,000,000 volumes. In 1954 there were 650,000 volumes. On the foundation of the University of Liége (181;) the old Bibliothèque de la Ville was added to its library (1,100,000 printed volumes and 3.600 manuscripts). The Bibliotheque de la Ville of Bruges (1798) contains 60.000 printed books and manuscripts housed in the old Tonlieu (1477). Every town has a communal library, mostly small and open only part of the day; the chief are those of Alost, Arlon (1842), Ath (1842), Courtrai, Malines (1864), Mons (1797), Namur (1800), Ostend (1861; burned in 1940), Tournai (1794, housed in the Hôtel des Anciens Prêtres. 1755), Verviers (1843j and Ypres (1939). Public libraries receive state subsidies and there is an interlibrary lending system. They are regulated by an act of 1921 for which Jules Destrée was largely responsible.

Netherlands. — The national library of the Netherlands is the Koninklijke Bibliotheek at The Hague (1797). In 1848 the Baron W. Y. H. van Westreenen van Tiellandt bequeathed his library and antiquities to be presen-ed in his former residence as a branch of the royal library. There were more than 1,000,000 printed books and 7,000 manuscripts in 1953. Books are lent all over the country. The library is the richest in the world in books on chess, Dutch incunabula, Elzevirs and Spinozana. In 1800–11 a printed catalogue was issued, and beginning in 1866 a yearly list of additions.

The next most important library is that of the Academia Lugduno-Batava, dating from the foundation of the State University of Leyden in 157j. Valuable additions include those from the libraries of Jacobus Golius, Joseph Scaliger. Isaac Voss, David Ruhnken and Tiberius Hemsterhuis. The library of the Society of Netherlands Literature. placed here in 1877, the Legatum Warnerianum of oriental manuscripts, and the collection of maps bequeathed in 1870 by J. J. Bodel Nyenhuis are noteworthy. Published catalogues are: books and manuscripts, 1716; supplements of books added in 1814–47, and of manuscripts, 1850; and oriental manuscripts, 1851–77. The library in 1954 contained about 1,500,000 volumes and 16,000 manuscripts.

The State University library at Utrecht (800,000 volumes) is based on conventual collections brought together in 1581. The public library thus formed was soon enriched by books bequeathed by the historian Arnoldus Buchelius and transferred to the university on its foundation in 1636. Among the manuscripts is the famous Utrecht Psalter, which contains the oldest text of the Athanasian creed. Printed catalogues are of printed books, 1834 (supplement 1845, index from 1845–55 and additions 1856–70), and of manuscripts, 1887. Titles of accessions are printed.

The University library at Amsterdam began in the 16th century as a city library. In 1881 it was moved to a building modelled on the British Museum library. It includes the best mediaeval collection in the Netherlands and the Bibliotheca Rosenthaliana of Hebraica (30,000 volumes, catalogue 1875). The libraries of the Dutch Geographical and other societies are preserved here. The library contained about 1,500,000 volumes in 1954. Dutch library development has long been hampered by political and religious disagreement. There are, however, popular subscription libraries with reading rooms in all parts of the country, and in Rotterdam there is a society for the encouragement of social culture which has a large library. An advisory board created by the ministry of education in 1921 co-ordinates library services.

The library of the Palace of Peace at The Hague had more than 100,000 volumes of works on international law in 1954.

Since Indonesia achieved independence from the Netherlands, a national library service has been under development with assistance from USESCO, with a National library in Jakarta.

Denmark and Iceland. — The beginning of the great Royal library (Kongelige Bibliotek) at Copenhagen may be credited to Christian III (1535–59); but to Frederick III (1648–70) was mainly due the collection of Icelandic literature and the acquisition of Tycho Brahe's manuscripts, and also the building in the Christiansborg castle, begun in 1667. In 1793 the library was opened as the national library. Two copies of every book published in Denmark must be deposited here. The incunabula and block books form an important series. In foreign literature it specializes in the humanities. There are printed catalogues of the De Thott collection (1789–9j); French manuscripts; Oriental manuscripts (1846); the Danish collection (1875), etc. There were 1,200,000 printed books and 48,000 manuscripts in 1954.

The University library (1382). destroyed by fire in 1728, but soon re-established, has received. since 1894, a copy of every Danish publication, and has 590.000 volumes and 10,000 manuscripts including the Arne-Magnean Icelandic collection. The State and University library of Aarhus (1894) possesses about 500,000 volumes. A state library commission supervises the state-supported libraries which cover the entire population. The Landsbókasafn Islands (National library) of Reykjavik. Iceland, has about 180,000 printed books and several thousand Icelandic manuscripts.

Norway. — The chief library in Norway is the University library at Oslo (Christiania), founded in 1811 by Frederick VI with a large donation of duplicates from the Royal library at Copenhagen. There are about 1,200,000 volumes in the collection, and it is the copyright collection for Norwegian publications.

The Deichmanske Bibliotek at Oslo was founded by Carl Deichmann in 1780 as a free library, and is maintained by endowments and by the city. It now contains about 470,000 volumes. The University library at Bergen (1948) incorporates the Bergen Museum library and has 350,000 volumes. The Kongelige Norske Videnskabers Selskabs Bibliotek at Trondhjem has also a large library. The public library system has a central book-buying agency supported by the state, a travelling library service and a service for ships.

Sweden. — The first Royal library at Stockholm was given to the University of Uppsala in 1576 by Gustavus II. A second Royal library was presented to Uppsala in 1620, and yet a third was begun. This was burned in 1697, and the present library was organized shortly afterward. The Renzelstjerna-Engestrom library (rich in Swedish history) was annexed to it. Among the manuscripts the *Codex Aureus* of the 6th or 7th century. with an Anglo-Saxon inscription, is noteworthy. The library contained 850,000 printed books and about 12,000 manuscripts in 1952. The Royal Academy of Science. Stockholm (founded in 1739 by Linnaeus and others), has a first-rate library of 200,000 volumes.

The University library at Uppsala, originally established in 1477, is the oldest university library in Sweden. The manuscripts chiefly relate to the history oi the country, but include the *Codex Argenteus* of the Gothic gospels of Ulfilas. also published in facsimile. Printed catalogues are: general (1814), foreign accession lists (annually from 1850) and Arabic, Turkish and Persian manuscripts (1846). The library contains about 1,000,000 printed books and manuscripts. The University library at Lund (1668) was based upon the old cathedral library. There are about 900,000 volumes in the library. The Stadsbihliotek of Goteborg (1890) has about 580,000 volumes! and a printed catalogue.

A well-organized public library service covers the country and provides special facilities for adult education and for seamen.

U.S.S.R.

The Saltykov-Shchedrin public library at Leningrad, formerly the Imperial public library at St. Petersburg, the State library of the Union of Soviet Socialist Republics, is one of the largest libraries in the world. It should be noted. however, that the statistics for libraries in the U.S.S.R. may be swollen by the operation of copyright deposit laws. which provide for the deposit of more than one copy of each book. In 1954 it was said to contain 10,000,000 printed books and 260,000 manuscripts and autographs. It originated in the books seized by Peter the Great in Courland in 1714; the library, however, attained to the first rank in 1795, with the acquisition of the famous collection formed by the Polish count ,Joseph Zaluski, who collected 200.000 volumes which were added to by his brother Andrew, bishop of Cracow. At his death it was left to the Jesuit college at Warsaw; on the suppression of the order it was taken by the commission of education; and in 1795 it was transferred by Alexander Suvorov to St. Petersburg as a trophy of war. It then had 260,000 printed volumes and 10,000 manuscripts, but in consequence of the dispersal of many works among other institutions, hardly 238,000 volumes remained in 1810. After World War I part of the Zaluski collection was returned to Poland. By a law passed in 1810 t\\-o copies of every Russian publication must be deposited in the library. Very many valuable special collections have been added, such as the Tolstoy Slavonic collection (1830), L. F. K. von Tischendorf's manuscripts (1858), the Dolgorousky oriental manuscripts (1859), the Abraham Firkovitch Hebrew (Karaite) collection (1862–63) and the national manuscripts of N. M. Karamzin (1867). Some departments are thus exceedingly rich, while others are comparatively meagre.

The *Codex Sinaiticus* of the Greek Bible, brought from the convent of St. Catherine on Mount Sinai by Lobegott Tischendorf in 1859, was sold to the British inuseum by the soviet government in 1933. Other important biblical and patristic codices are to be found among the Greek and Latin manuscripts; the Hebrew include some of the oldest extant: and the Samaritan collection is one of the largest; the oriental manuscripts and the French manuscripts (notably the historical) are of great value.

The library of the Academy of Sciences in Leningrad (1725) is the oldest and largest scientific library of the U.S.S.R. (8,000,000 volumes). The library at the Hermitage was founded by the empress Catherine II's purchase of Voltaire's and Diderot's books and manuscripts. In 1861 it possessed 150,000 volumes. of which nearly all but those on the history of art were then transferred to the Imperial library. There are many large and valuable libraries attached to the government departments, academies and colleges in Leningrad. The library of the university had more than 1,000,000 volumes in 1939.

The largest library in the U.S.S.R. and probably in the world is the Lenin State library in Moscow (formerly Rumyantzov museum collection, renamed after Lenin's death in 1924). At mid-20th century it had more than 14,000,000 volumes, and it is rich in early printed books, Russian history and manuscripts. The latter number 46,000, including many ancient Slavonic codices: historical documents and the archives of the Masonic lodges in Russia between 1816 and 1821; catalogues of the manuscripts and of some special collections are printed. Its enormous growth began after the Revolution of 1917, when confiscated libraries in great numbers were added; a new building was begun in 1930. Moscow has many other large libraries, notably those of the university, the Academy of Sciences, the army, the State Historical museum, the ministry of health (Central Medical library), the foreign office and other government departments.

The Ukrainian National library of the Ukrainian Academy of Sciences at Kiev had 10,000,000 volumes in 1950, and there are large state libraries at Baku, Minsk, Tashkent, Tiflis and other centres. Most of these are copyright deposit libraries. Among the university libraries may be noted those of Baku. Kazan, Kharkov. Kiev and Odessa. The development of "mass libraries," the equivalent of British public libraries, was very rapid after the Revolution, these institutions having been set up in great numbers in towns and rural areas and having school, factory and travelling services. National. research and "mass" libraries are all expected to conform with governmental policy and doctrine. The All-Union Book chamber controls the distribution of soviet publications to the copyright libraries.

Losses of libraries and books during World War II reached enormous proportions, and a central fund was formed for library restoration. The All-Union Book chamber acted as an exchange for duplicates.

EASTERN EUROPE, NEAR EAST

Poland. — Many of the libraries described under this heading were destroyed during World War II. The Germans set up a library administration on German lines at Cracow in 1940, with state libraries in that city and in Warsaw, Lwów, Lublin and Poznan. The subsequent fighting and the ultimate rearrangement of frontiers completely destroyed the former library system of Poland, on which much effort had been expended in the period between World Wars I and II. Poland did, however, gain the important libraries of Breslau (Wroclaw) and Danzig.

A famous group of libraries was established in the late 18th and early 19th centuries, among them the Zaluski at Warsaw (later the basis of the Imperial library at St. Petersburg but partly restored to Poland in 1921), the Czartoryski at Cracow, the Krasiński at Warsaw, the Raczyhski at Poznań and the Ossoliński at Lwów. Warsaw had, in addition, a large university library and a public library of importance, and a national library was founded there in 1928 (opened 1935). The nucleus of this was the material, including part of the Zaluski collection, carried off to Russia from Poiish libraries in 1795 and 1831 and restored under the treaty of Riga of 1921. The National library at Warsaw became a copyright deposit library. The Jagiellon library at Cracow (1400), the oldest in Poland. served as a national library until 1918. There were university libraries at Lwów. Lublin, Poznan and Vilnius. The German administration formed a Warsaw State library by amalgamating the University library with the Krasiński and the National; at Cracow the university libraries were combined with the Jagiellon and the library of the Polish Academy of Science and Letters. Many books from other

Polish collections were carried off to Germany, and important collections of Hebraica at Lublin and elsewhere were destroyed altogether by German governmental order.

After the end of World War II, the National library at Warsaw was re-established (1,300,000 volumes in 1954), and publication of the monthly Polish bibliography was resumed. By the end of 1946, a public library service had been restored in 1,800 centres out of the 9,000 in service in 1939.

Czechoslovakia.—The most considerable libraries in Czechoslovakia are the National and University library. Prague (1773), with 1,530,000 volumes in 1951, and the university libraries at Brno and Bratislava.

During the 19th century, free libraries mere founded by the clergy and school teachers, while the library periodical, *Česká Osvěta* (1904), helped to spread a knowledge of Anglo-American popular library methods. Local authorities were obliged by law to establish public libraries, including special libraries for minorities. under the general supervision of the ministry of education. Damage and dislocation during World War II were very severe (the National and University library lost about 500.000 volumes).

Elsewhere in Eastern Europe.—The chief libraries of the Baltic states were, before World War II: in Lithuania. Kaunas (state and university librariesj; in Latvia, Riga (state, university and municipal libraries); in Estonia, Tartu (state and university libraries) and Tallinn (city library). Finland had the parliament. university and city libraries at Helsinki and those of the Finnish university and the Swedish academy at Turku (Åbo).

In Rumania. Bucharest has the library of the Rumanian academy (now the National library) and Jassy a university library. After World War I Rumania acquired, in Transylvania and Bukovina, the university libraries of Cluj and Czernowitz (Cernăuti). The largest libraries in Bulgaria are the national and university libraries at Sofia. Yugoslavia's National library of 500,000 volumes was destroyed in an air raid on Belgrade in 1941, but the Gniversity library fortunately remained almost undamaged. Other large libraries include the State (formerly University) library at Ljubljana and the library of the University of Zagreb. Albania has a national library at Tirana. The National library of Greece at Athens includes the university library and contains about 600.000 volumes.

The Near East.—Turkey has a national library at Ankara, founded in 1946 and opened in 1948, which possessed more than 200.000 volumes in 1954. Istanbul has a university library of about 140,000 volumes and a number of important mosque, libraries containing enormous collections of Arabic manuscripts. The chief library of Israel is at Jerusalem. the Jewish National and University library. containing the largest collection of Hebraica in the world. Egypt has a national library in Cairo of 600.000 volumes and 500,000 manuscripts, The (Fund I) university at Cairo and the (Farouk I) university at Alexandria have important libraries, the latter founded as late as 1943. The Moslem university at Cairo has a fine collection of manuscripts. The National library of Iran was established in Tehran in 1937. In Ethiopia, a national library was opened at Addis Ababa in 1944.

THE FAR EAST

China.—The earliest notice of a library in China is that of the imperial Chou dynasty whose capital was at Loyang in the modern province of Honan. According to a tradition preserved in Ssu-ma Ch'ien's "Historical Record." the philosopher Lao-tse, who lived in the 7th century before Christ, was keeper of books in this library National collections of books in the modern sense, however, originated with the attempts made to recover the books scattered or destroyed by the so-called "First Emperor" in 220 B.C. Hence. the earliest catalogue of Chinese books is preserved in the "History of the Former Han Dynasty" (206 B.C.–A.D. 23) and written in the 1st century of our era. The histories of nearly all succeeding dynasties have likewise left catalogues of books preserved in their libraries or knonn to their times. After the invention of printing in China private libraries became increasingly numerous. From time to time these were destroyed or dispersed, but catalogues of many of them remain. At mid-20th century there were still about 14 large private libraries in various parts of China, several containing as many as 200.000 volumes each.

The first public library in China was established in Hunan in 1905. According to a survey made by the Library association of China in 1927 there were then 503 public and private libraries in China proper and Manchuria. The National library at Peking (1909) had. in 1954, over 2,500,000 volumes, including the original Ming and Ching collections. Each provincial capital also has its own library. The following universities have large collections of both Chinese and western books: Peking university (formerly the Peking. Tsinghua and Yenching universities)! Canton university (formerly Sun Yat-sen), Amoy university and Nanking university. The most common classification of books in Chinese libraries—the so-called *Ssu-K'u* system in vogue for 15 centuries—divides all Chinese literature into four classes: classics, history. philosophy and belles-lettres. A few of the modern Chinese libraries discarded this system entirely, but most of them combined with it a modified Dewey or Library of Congress classification.

Important libraries were established in Formosa after 1945, including that of the Taiwan university (620.000 volumes in 1953).

Japan.—The ancient history of libraries in Japan is analogous to that of China. The former Imperial library (1872) at Tokyo was reconstituted after World War II as the National Diet library (1948); it acts as a bibliographical centre for Japan and in 1954 possessed about 1,500,000 volumes. Tokyo Cniversity library has 1.800.000 volumes and the library of the Kyoto university (1899) contains more than 1,500,000 volumes, of which a large proportion are in European languages. Kyoto and other towns have considerable municipal libraries.

LIBRARY ASSOCIATIONS AND TRAINING

The first and largest association established for the study of librarianship was the American Library association (1876), which includes Canada (*see* below). The Library association of the United Kingdom was formed in 1877. as an outcome of the first International Library conference, held at London. and in 1898 it received a royal charter "to unite all persons engaged or interested in library work." At mid-20th century it had a membership of 10,000, of which nearly 1,000 were institutional members. A yearbook and the monthly *Library Association* Record are published, and there are an annual general conference and a number of sectional and branch conferences and meetings. The Library Assistants' association, formed in 1895, became a section of the Library association. publishing the *Assistant Librarian.* An Irish Library association was formed in 1928. The Library association is the recognized British examining body in librarianship; revisions in its syllabus went far to meet criticisms from university and research librarians that the association was paying undue regard to the needs of public librarians. The study of archives was added to the syllabus in 1927.

In 1917 the Library association, having for many years held lectures and correspondence classes in librarianship. appealed for the establishment of a day school within the University of London for the regular training of librarians. The Carnegie trustees undertook to provide £1,500 a year for the first five years and the school of librarianship was opened at University college, London. The school provides a one-year postgraduate course and awards a diploma. The study of archive administration was added to its curriculum. Easter and summer schools are held both in Britain and abroad.

The school had great influence in raising the educational standard of librarianship. and the *Report on Public Libraries in England and Wales* produced by an interdepartmental committee in 1927 urged that it should be maintained and considered it to have a strong claim on the funds received by the university from the state. Schools of librarianship were also established at Brighton, Leeds. Loughborough. Manchester. Newcastle-upon-Tyne and Glasgow and at the City Literary institute, London; and evening classes are held in a number of other centres.

In the British Commonwealth, library associations or institutions exist in the Union of South Africa (1930), Australia (1937), New Zealand, India and the provinces of Canada. Schools of librarianship are to be found at Capetown, Pretoria, Achimota (Ghana), Sydney, New Zealand, several Indian universities and a number of centres in Canada.

Aslib (the Association of Special Libraries and Information Bureaux) was formed in 1925 to meet the special needs of technical and industrial libraries. Its scope was later widened to include all special libraries, both in the sciences and in the humanities, and many university and public libraries acquired institutional membership in Aslib. The association has paid special attention to documentation and information work. It has commonwealth and foreign as well as British members.

The Association des Bibliothécaires Français was founded in 1906 to promote library reform. It was particularly active in 1928 in urging the development of a system of popular libraries in France. The French library profession is organized by central legislation, beginning with a royal ordinance of 1839 which assigned one-third of the higher posts to trained "archivistes-paléographes." The École Nationale des Chartes issues a diploma in librarianship, with special emphasis on archive work and historical bibliography. The American Library association ran a library school in Paris from 1924 to 1929, with a curriculum based on C.S. methods.

The professional association of German learned librarians is the Verein Deutscher Bibliothekare, founded early in the 20th century. The Verband Deutscher Volksbibliothekare is the corresponding body for popular libraries. Prussia regulated professional training for service in learned libraries by a decree of 1893, which was followed by similar legislation in other states. Library training institutions were established in Berlin, Munich, Dresden, Leipzig and other centres. Volkesbiichereischulen at Berlin, Cologne and Leipzig gave training for entry into the popular libraries.

Austria had no comprehensive system of training in librarianship before World War II. Many Austrian librarians belonged to the Verein Deutscher Bibliothekare. Hungary has an association of Hungarian librarians and archivists, which began after the mar to organize courses of instruction. Switzerland has an association of Swiss librarians and an association of special libraries; there is a library school at Geneva.

Italy has a federation of Italian libraries, founded in 1908 and refounded in 1948, but little attention appears to have been paid to the formal training of librarians. In Spain, the University of Madrid holds a seminar in librarianship.

In the Netherlands, training is controlled by the Central Society for Public Libraries; there is a four-year course, and no public library in receipt of government money may employ unqualified assistants. There is a professional association of librarians. The Netherlands Institute for Documentation has been very active in the field of international standardization, as has also the corresponding body in Belgium. The Belgian Society of Archivists and Librarians was formed at Brussels in 1907. Large numbers of Scandinavian librarians have received training in U.S. libraries, though Denmark has a system of professional training and certification and an association for promoting public libraries (1905).

The U.S.S.R. has a highly developed system for training library staffs. In the mid-1950s there were more than 50 library schools in the Soviet Union and an elaborate system of grading according to the qualifications was in force. In Poland. library examinations are controlled by the ministry of education. Czechoslovakia has a professional association and also a society of learned libraries; library qualifications are regulated by law and there are two or three library schools. Turkey established a library school at Ankara in 1940. In China, training in librarianship was begun at Boone university, Wuchang, in 1910. In Latin America! Brazil, Mexico, Cuba, Peru and Uruguay have library training schools.

INTERNATIONAL ORGANIZATIONS

The International Library committee was established in 1927 and held annual meetings up to 1939 and after 1948. From 1929 it administered the affairs of the International Federation of Library Associations, its membership being composed of representatives of library associations which were members of the federation. The activities of the International federation were resumed in 1948 International Library congresses were held in Rome (1929), Madrid (1935) and Brussels (1955).

The International Federation for Documentation had held 15 congresses before World War II and resumed its activities with a 16th in Paris in 1946. With the International Standards organization it made much progress toward the establishment of internationally agreed standards in such fields as the terminology of documentary reproduction, the abbreviation of titles of periodicals, the transliteration of Cyrillic characters, the format of periodicals and the development of the universal decimal classification devised by the Institut International de Bibliographie in Brussels in 1927–29.

The Institut International de Bibliographie. founded in 1897, began the compilation of a universal card catalogue of the world's great libraries. About 14,500,000 cards had been compiled by 1934, but little has been done since then.

The work of the International Institute for Intellectual Co-operation set up by the League of Nations was in part revived by UNESCO, with headquarters in Paris. The program of the libraries division of this body included the preparation, in conjunction with the Library of Congress, of a world bibliographical survey, leading to a development program of national bibliographical services. UNESCO's work also included projects in public and learned library improvement; "book coupons" enabling libraries to buy foreign books in spite of exchange restrictions; and the promotion of international conventions facilitating the free flow of all forms of information. Much was also done to restock war-damaged libraries and to encourage the international exchange of publications.

THE UNITED STATES

The earliest libraries of the American colonial period were private; among the more notable were those of William Brewster of Plymouth. Gov. John Winthrop of Connecticut, Cotton Mather of Boston, Col. Ralph Warmeley of Virginia and John Harvard. Toward the end of the 17th century the so-called Bray Parish libraries began to appear. These were collections mainly of religious books sent to America through the efforts of Thomas Bray of London, designed particularly for the use of the clergy, though open to the public. The first subscription library in the colonies was projected by Benjamin Franklin in 1731 in Philadelphia. Many of the early subscription and proprietary libraries became the foundations of public libraries, and a few of them still flourished in the mid-20th century. The Boston Athenaeum (1807) at mid-century had a collection of about 375,000 volumes and was especially rich in historical material. The Providence Athenaeum (1753) had about 135,000 volumes. The New York Society library (1754) had a general collection of 200,000 volumes, with special strength in fine arts. early fiction and Americana.

Throughout the pears libraries increased, and in the 1954 *American Library Directory* 12,478 U.S. libraries were listed, including 6,925 public, 1,920 college and junior college, 293 law, 393 medical. 64 institutional. 309 government, 1,923 special. and 6j1 armed services. In addition, the directory listed 74 libraries of all types in the U.S. territories and dependencies and 1,305 in Canada and Newfoundland.

Endowed Libraries. — The gift or bequest of great private libraries or large sums of money for the erection of library buildings and the organization and maintenance of libraries for free public use became a frequent object of philanthropy in America. John Jacob Astor and James Lenox were the founders of libraries bearing their names! which later became the New York Public library. It was established May 23, 1895, by a consolidation of the Astor (1849) and Lenox (1870) libraries, supplemented by an endowment of $2,000,000 from Samuel J. Tilden. In 1901 Andrew Carnegie gave $5,200,000 for the erection of circulating libraries throughout the city. One of the great libraries of the world. it operates more than 50 branches and contains almost 6.000,000 volumes. The Enoch Pratt Free library (1886) of Baltimore. Md., and the Providence (R.I.) Public library (1878) are typical of the numerous endowed public libraries, many of which are supported in part by municipal appropriations.

At the head of the list of library benefactors stands the name of Andrew Carnegie, whose first library gift was made in 1881 to Dunfermline, his native town in Scotland. His second gift was made in 1890 to Allegheny, Pa. Pittsburgh received a large central building in 1895 and later eight branches. The total amount given by Carnegie and the Carnegie corporation for library buildings in the United States and Canada was $43,665,000. Other philanthropists and the recipients of their gifts were Joshua Bates, Boston Public library; Thomas Jefferson, University of Virginia; B. Rush, Philadelphia Public library; and James Lick, San Francisco libraries. Famous libraries, open to the public, which were also established by individuals include the Pierpont Morgan library and Frick Art Reference library. New York city; John Crerar and Newberry libraries, Chicago; Henry E. Huntington Library and art gallery, San Marino, Calif.; Hoover Library on War, Revolution and Peace, Stanford university; and Folger Shakespeare library, Washington. D.C.

In addition to the Carnegie corporation, several other foundations, including the General Education board, the Rockefeller foundation and the Julius Rosenwald fund, gave generously through endowments and special grants for the furtherance of libraries.

College and University Libraries.—The history of U.S. college and university libraries is also a record of generous gifts from private collectors and friends of education. Their origins can he traced in the early history of the nine colonial institutions of higher learning (Harvard. Yale. Brown. Dartmouth, Princeton, Columbia, Pennsylvania. Rutgers and William and Mary). Harvard university dates its library from 1638. when John Haryard bequeathed his collection of 330 volumes, and by 1800 eight of the institutions had libraries. Two of them, the University of Pennsylvania and Dartmouth college, had libraries that antedate their founding. Most oi the early collections were small, with theology largely represented among the books. Modern college libraries are composed of well-diversified collections and are provided principally through purchase with college funds.

In tbc mid-1950s the approximate number of volumes in leading university libraries were: California (Berkeley), 1,900,000; Chicago, 1,900,000; Columbia, 2~000.000; Cornell. 1,600,000; Duke, 1,125,000; Harvard, 5,700,000; Illinois, 2,600,000; Michigan, 1,500,000; Minnesota, 1,700,000; Northwestern, 1,100,000; Pennsylvania, 1,300,000; Princeton, 1,250,000; and Yale, 4,215,-000.

Particularly after World War I, college libraries developed as instruments of teaching. The Lamont library (1948) of Harvard was probably the best example. Many large university libraries opened their bookstacks to all students and introduced divisional reading rooms providing basic collections in academic subjects.

Library of Congress and Other Governmental Libraries.—Founded in Washington, D.C., on April 24, 1800. the Library cf Congress became in fact if not in name the national library of the U.S. and one of the greatest libraries in the world. It was moved in 1897 from the capitol into an ornate building which, with the ground. cost about $7,000,000. On April 5, 1939, a five-story annex was completed at a cost of about $9.000,000, with ground. In addition to serving members of congress and other officers of the government, it developed into an institution unique among the learned institutions of the world, with magnificent collections of books. manuscripts, music, prints and maps. It provides lectures and concerts. legislative reference service! service for the blind, a union catalogue and catalogue cards for subscribing libraries and institutions, bibliographical, reference and photo-duplication facilities; interlibrary loans and exhibits. By the mid-1950s it had a total of about 35,000,000 books, pamphlets, manuscripts, microfilms, recordings, music, photographic prints, etc.: of this number, about 10,500,000 were volumes and pamphlets. Yearly, it was adding about 500.000 volumes to its collections. many through deposits of the copyright law and exchanges of official publications with foreign governments and learned societies. It had a staff of about 2,400. Among its publications, the library issues a weekly *Information Bulletin*.

Other governmental libraries in Washington include those of the coast and geodetic survey, geological survey, weather bureau, Bureau of American Ethnology. fish and wildlife service, department of agriculture, forest service, Interstate Commerce commission. bureau of foreign and domestic commerce. bureau of labour statistics, department of commerce. treasury department, department of defense (including army medical), Veterans administration. superintendent of documents, supreme court. department of state and Smithsonian institution. In 1938 the Library Service division of the U.S. office of education was established.

Public Libraries.—The modern public library, maintained by the municipality or some other unit of local government from the proceeds of taxation, was scarcely knoivn before 1850 and developed for the most part after the iormation of the American Library Association in 1876. J. H. Shera in *Foundations of the Public Library* (1949) pointed out that "there have been many claimants to the distinction of having created the first truly public library in the United States, but this antiquarian controversy is rooted not in ignorance of historical fact but in uncertainty as to the precise definition of terms . . . If the custodianship of a common collection of books by public authorities be the criterion, then the institution may truthfully he said to have begun in 1629 when the Massachusetts Bay Company authorized the shipment to Salem of those bcoks assembled by the Rev. Samuel Skelton." However. the Bingham Library for Youth. established in 1803 at Salisbury, Conn., represented the first instance in which a municipal governing body contributed active financial assistance to public library service. This was the earliest real recognition by a municipality that aid to library development was a proper function of the town. In the mid-1950s the oldest existing public institution comparable to the modern public library was at Peterborough, N.H., established in 1833. Nevertheless, the real impetus to the expansion of the public library movement was the establishment of the Boston Public library in 1852.

With its law for the "Establishment of Public Libraries" (1849), New Hampshire was probably the first state to enact public library legislation. By the mid-1950s, library legislation was coinmon in all states and federal aid was being sought through congressional legislation for library extension and demonstration controlled by legislation. Each state had its state library and library commission or similar body located in the capital city, to assist public libraries, and every city likewise controlled and supported its library through powers given it by state enabling laws. The governing body of the city public library is generally the board of trustees, appointed by city authorities. Under the board is the chief librarian, who supervises and administers the library or library system and its activities.

Public libraries in the Cnited States are characterized by great similarities in function and basic services. and by wide differences in size, structure, and variety of activities in which they engage. Most of them derive their support. entirely or overwhelmingly, from local taxes; they provide a book stock which is diversified and selected to appeal to the interests of their patrons; the books are classified by subject matter and are listed in a comprehensive catalog arranged to show authors, titles, and subjects. The service is free to all local residents and to others at a slight charge. The differences among them spring largely from the size of the community or area served. and reflect the unique character of each community. Thus, one library may be unusually strong in its technological collection, another in its commercial or industrial or professional holdings. The large city or county library, in addition to its main stock of books: numbering hundreds of thousands of volumes, maintains numerous branches, each of which is a smaller replica of the central library, as well as dozens of smaller book installations in community centers, factories, schools, hospitals, prisons, etc. It may also operate one or more "bookmobiles" to distribute books to areas where such branches do not exist. Through a well-organized system of loans between the central library and its outlets, anyone may borrow any book that the library owns. or he may even obtain books on interlibrary loan from other cities.

Beyond making books available for ccnsulting and borrowing, the large libraries carry on extensive programs to encourage reading. They issue book lists on special topics and publish monthly lists of selected additions to the collections. They sponsor book talks, discussion groups. film showings and record concerts. Staff members visit schools, clubs and business groups to describe the library services, and they review books over the radio; they set up book exhibits at local and county fairs.

Though the library is still primarily concerned with the preservation and distribution of books, it has increasingly recognized an obligation to provide important non-book materials, such as phonograph records for home playing and films for projection in homes and clubrooms. In 1950 the Louisville (Ky.) public library opened the first library frequency modulation (FM) radio station. WFPL, and Is on the air eleven hours a day, broadcasting to schools and homes and carrying programs of particular interest to the residents of its area. It also maintains teievision sets in the library branches.

Since the end of World War II there has been a tremendous resurgence of library building in the United States. The new structures have taken many forms, capitalizing on the latest technical improvements in architecture and engineering. One such building, the new Donnell Regional branch of the New York Public library, opened in Dec. 1955. This library maintains 60.000 volumes for adults on open shelves, lends phonograph records without charge, and arranges film bookings. In addition there is a children's library of 7,000 volumes and one for teenagers with 13,000. A foreign-language center containing books in twenty languages occupies a prominent area, with specialists in charge of the Russian, Italian. French and German collections. Since this regional library serves as headquarters for the branch libraries in Manhattan, it contains a union catalog showing the holdings of 80 New York branches. A basement auditorium with 278 seats is used for concerts, puppet shows, lectures, and similar attractions. This library's close relationship to the New York residents is typical of the American public library as a community-centered institution.

According to statistics on public libraries published by the U.S. office of education! there were 7,477 public library systems operating in the U.S.in 1950. To the 6,028 systems reporting, 9,327,000 volumes were added during that year with a total of 142,931,000 volumes owned (1.24 volumes per capita of population served). A total of 25,361,000 registered borrowers was reported by 5,162 library systems; of these approximately two-thirds were adults. Loan privileges indicated a home circulation of 384,606,-000 volumes from 5,783 systems, to approximately 53% of the adults: 41% of the children, with 6% of circulation unknown. The total income for 5,773 systems reporting was $102,350,000 (87.4% derived from local funds), while operating cxpcnsc was $109,777,-000, or 96 cents per capita of the population served by the libraries reporting. The total personnel employed by 6,028 systems reporting was 44,415—33% professional librarians, 19% subprofessional librarians. 35% clerical and 13% building and maintenance. About 27% of the population, more than 35,000,000 people (mostly in rural areas), was without library service. Only Massachusetts and the District of Columbia provided library service for 100% of their population, although several other states almost reached that goal.

Statistics for 1954 for public libraries in cities with populations of 100,000 or more showed that there were 55,565,923 volumes owned; 163,887,844 volumes circulated, and expenditures amounting to $77,507,482. According to the A.L.A. standards for public libraries, $1.50 per capita was the minimum support recommended for public libraries, $2.25 for good service, and $3.00 for superior service. with $37,500 the minimum budget (for libraries in areas of at least 25,000 population).

Standards and plans for libraries were prepared during the 1940s, and further planning was made possible through a two-year study in 1949 and 1950, the Public Library Inquiry, the findings of which were published in seven volumes. The salaries and working conditions of public library employees were surveyed in 1948–49 by the U.S. department of labour and the A.L.A. The published report showed that $2,350 was the average yearly salary for all public library employees; the average professional employee received $2,825 and the average nonprofessional $1,925. Though no further study was made by the mid-1950s it is safe to assume that these figures would require considerable upward revision. In fact, the entering salary for professionally trained librarians is frequently not less than $3,800.

Increased financial support to provide more adequate personnel, materials and facilities remains the most pressing need of libraries. A second urgent need is recruiting and training of librarians in order to overcome shortages of personnel. Equally importaxit long-term needs are: further development and application of library standards. closer co-operation among libraries and among librarians, more effective enlistment of public interest and speedier enactment of legislation necessary for strengthening library service to all areas and communities.

Children's **Libraries.**—A special library for children was established in New York city as early as 1885. In 1890 a separate room for children was opened in the public library at Brookline, Mass., and in the next few years public libraries began generally to provide special rooms or other facilities for children. By 1900 a separate children's room with specially trained children's librarians to give skilled and sympathetic guidance in the use of books and periodicals, had come to be considered an essential part of every well-conducted public library.

In public libraries with organized work for children, the juvenile circulation amounts to more than one-third of the total. There has been a noticeable increase in work with preschool children and parents and in specialized effort with adolescents.

School Libraries.—In their modern form, U.S. school libraries were a development of the 20th century. Curriculums were changed to require a wide variety of books, pamphlets and magazines. Secondary school libraries, especially those in schools with enrolments of 200 or more, usually include a carefully selected collection of printed materials chosen with the needs of the specific group and community in mind. Some school libraries include film strips, films and recordings among their materials. The library is the school's materials centre.

Growth in elementary school library service has been marked in such cities as Chicago, Detroit: Oakland and Denver and in many suburban and medium-sized communities. Trained school librarians or teacher librarians are assigned to direct the school library service, usually assisted by student library assistants.

Although some rural schools have excellently equipped libraries, the typical pattern is for such schools to receive library services from the county library or directly from the state library. Books may be placed on depcsit in the school for the entire year, to be supplemented by periodic visits by a bookmobile.

Many states have enacted legislation providing that school librarians be certified, just as teachers are certified. an action that has undoubtedly had the effect of improving the quality of school library personnel at the same time that it has aggravated the problem of personnel shortages.

Although remarkable progress had been made in this field, the majority of rural children are still without school library service (as well as public library service) and the quality of that service in at least half of the urban schools is considerably below accepted standards.

Special Libraries.—Specialization in all fields necessarily has its counterpart in library service and, while public libraries built up many special collections in various fields, there was a growing need for the library covering a specific area. After about 1910 there was a rapid development in collections of library materials in special fields. By the 1950s, about 2,000 libraries served special groups such as banks, corporations. manufacturing concerns, newspapers, law firms, advertising and insurance agencies, transportation companies, research organizations, museums, hospitals, governmental bureaus and associations, and organizations in the fields of medicine, business, technology, social welfare, art and science. In 1909 the Special Libraries association was founded; and by the mid-1950s had approximately 5,000 members with headquarters at 31 E. Tenth St.. New York 3, N.Y., and chapters in most large cities. Its official magazine is titled *Special Libraries.*

Library Schools.—The first U.S. library school was established at Columbia college in 1887 by Melvil Dewey, an eminent librarian and educator; by the mid-1950s, 35 were accredited by the A.L.X. and; in addition, library instruction was being offered in hundreds of other institutions. The progress of library education received great impetus over a period of years through grants to library schools and the X.L.A. from the Carnegie Corporation of New York, the General Education board and the Julius Rosenwald fund.

Completion of the first professional curriculum and the general education necessary in preparation for library service usually requires a minimum of five years of study following high school graduation. At most library schools this program leads to a master's degree. It opens with a group of courses which may often bc taken for undergraduate credit, and in the fifth year it combines graduate study in library science and related subject fields. In the mid-1950s study for a doctoral degree was offered by the library schools of Columbia and Western Reserve universities and the Universities of California, Chicago, Illinois and Michigan. Library school enrolments were comparable with figures prior to World War II, but the number of graduates in postwar years fell below the 1940 total. A serious shortage of librarians was in prospect.

American Library Association.—Founded in 1876, from which modern librarianship generally dates, the A.L.A. is the national organization of librarianship, the agency through which the profession speaks with the most authority. In the mid-1950s it maintained headquarters at 50 East Huron St., Chicago 11, Ill., and carried on its activities with a paid staff of 96, assisted by 700 volunteer members of boards and committees. It had more than 20,000 members and an endowment capital of $2,460,000. It is financed by membership dues, endowment income and occasional grants for special projects.

Whether serving as a centre of information on all library subjects, holding conferences, issuing library publications, combating the effects of financial stress on libraries, helping in war or peace or planning for the future of school, college and public libraries, the A.L.A. has the same objective—to increase the use and usefulness of books through improving and extending library service. Continuously the association has concerned itself also with the raising of standards for the library profession. Its international activities are concerned with the interchange of librarians and publications; importation of foreign books and journals in scholarly fields; and preparations for rehabilitating devastated libraries in war areas. In addition to having published about 250 books the A.L.A. issues the following periodicals: *A.L.A. Bulletin, Booklist and Subscription Books Bulletin* and *Hospital Book Guide*. Its divisions publish *Public Libraries, Top of the News, College and Research Libraries, Library Resources and Technical Services,* and the *Public Library Division Reporter*.

One area in which the association has been particularly outspoken is that of preserving the right of free access to reading materials, whether or not of a controversial nature. In 1939, following the imposition of restrictions on reading matter in nazi Germany, the A.L.A. adopted a strong statement known as the Library Bill of Rights, which affirmed belief in the principles of free inquiry. Later on, when pressures were being exerted in the United States on libraries to prevent them from providing books which might prove offensive to certain groups or individuals because of the political views of their authors or for other reasons, the association reinforced its conviction that the library was obligated to present materials reflecting varying points of view. The major elements in the Library Bill of Rights are:

"1. As a responsibility of library service, books and other reading matter selected should be chosen for values of interest, information and enlightenment of all the people of the community. In no case should any book be excluded because of the race or nationality, or the political or religious views of the writer.

"2. There should be the fullest practicable provision of material presenting all points of view concerning the problems and issues of our times, international, national, and local; and books or other reading matter of sound factual authority should not be proscribed or removed from library shelves because of partisan or doctrinal disapproval.

"3. Censorship of books, urged or practiced by volunteer arbiters of morals or political opinion or by organizations that would establish a coercive concept of Americanism, must be challenged by libraries in maintenance of their responsibility to provide public information and enlightenment through the printed word."

Since 1935 the A.L.A. has been active in working for a greater degree of state and federal participation in providing funds for local library operation. It has been instrumental in having bills introduced in congress looking toward financial grants for improvement in library service, especially in areas where local financing is difficult because of lack of population density or of economic resources. It has rallied considerable interest in the problem, and the time may yet come when library service, with its potentialities for contributing to an informed public opinion, will be regarded as a matter transcending the concern of the locality or even of the individual states.

The A.L.A. in the mid-1950s was affiliated with many national library organizations, among them the American Association of Law libraries, American Merchant Marine Library association, the American Theological Library association, the Association of American Library schools, the Association of Research libraries, and the National Association of State libraries. It was also a member of or closely co-operated with the Canadian Library association, the Cuban Library association, International Federation of Library associations, the American Documentation institute, the Catholic Library association, the Educational Film Library association, the Council of National Library associations, the Medical Library association, the Music Library association, the Special Libraries association and the Theater Library association. It works closely with numerous cultural, educational and social agencies throughout the world. The diversity and specialization of library interests are attested by the large number of local and state library clubs and associations to be found all over the U.S.; and many libraries, public and academic, receive support and assistance from groups known as Friends of Libraries.

LIBRARY ARCHITECTURE is concerned with bringing together in agreeable, convenient and practical surroundings, great numbers of books and readers, efficiently served by a library staff. It is a modern problem. The world has long had library materials to use and store, but it was not until after the development of the rotary press in the mid-19th century that the vast quantities of books made new methods essential.

Prior to this time, it was practical to have one large room or gallery for both books and readers. Books were kept in shelves or cupboards with suitable furniture on which the heavy volumes could be rested. Aesthetically the treatment of these rooms was often masterful, as in the Vatican or the Biblioteca Laurenziana in Florence. To meet the challenge of the printing press, reading rooms were. at first. made larger with added tiers of books and galleries. but limits of expansion for a single gallery were soon reached, and some method had to be devised for separating the public in reading rooms from the room for storing books.

As early as 1835, the French architect. Benjamin Delessert. suggested for the Bibliothkque Nationale in Paris a circular reading room with bookstacks surrounding it. This circular reading room allowed librarians (installed on a raised platform in the centre) easier supervision of the readers. Delessert's plan probably suggested that of the reading room of the British museum (R. & S. Smirke. architects. 1852).

When Henri Labrouste was appointed architect of the new Ste. Genevieve library in Paris (1843) the site selected, being long and narrow, almost forced the solution. A reading room occupied the entire upper floor of the building and contained many of the books, as in the old libraries. but other spaces were made for books on the floor beneath. a scheme that in subsequent years was used in many important libraries. Significant was the separation of books and readers.

Later. in the plans for the Bibliothkque Nationale in Paris (1854), where he was less hampered by the exigencies of space. Labrouste designed another remarkable building. The main reading room is square. with an apse where the librarians are installed facing its entrance and commanding that to the stacks. The reading room is surrounded by three tiers of shelves. The light comes through a large opening on the north side. and from nine domes, each of which rests on four light steel columns. The atmosphere of the room is quiet and restful and the light is excellent. The most remarkable part of the composition, however, is the bookstack. a huge room. 90 ft. x 120 ft. Here the principle of the modern bookstack first evolved. The shell of masonry is covered by a glass skylight which allows daylight to penetrate every corner, while inside this shell the metal framework of the book tiers and the passages between are entirely independent construction resting on the basement floor.

Library Planning. — The three types of library plans, represented by the Ste. Genevikve, the Bibliothkque Nationale of Labrouste and the British museum, furnished the patterns for most large libraries of the late 19th and early 20th centuries. To the type of Ste. Genevikve; *i.e.*, with a reading room lighted on both sides. with books along the walls or in alcoves and with storage under the reading room, belongs the New Tork Public library (Carrère and Hastings, architects. 1897). To the type of the Bibliothèque Nationale: *i.e.*, with a reading room parallel or perpendicular to the stacks. belongs the Widener Memorial library at Harvard. To the type of the British museum: *i.e.*, with a circular reading room. surrounded by the bookstacks and lighted by high windows or skylights, belong the old Columbia University library. New York (McKim, Mead & White, architects. 1897), and the Library of Congress. Washington! D.C. (Smithmeyer, Pelz & Casey, architects. 1886–97).

A marked progress in library design was noticeable around 1930. In particular, the Municipal library at Viipuri (Viborg) (1934, Alvar Aalto, architect) incorporated many of the newer ideas in a relatively small building. Here the technical requirements for shadowless lighting, mechanical ventilation and acoustical treatment influenced the shape of rooms and contributed the interest in the wall and ceiling surfaces formerly supplied by surface decoration.

The storage annex at Versailles of the Bibliothkque Nationale in Paris provided one solution to the problem caused by the accumulation and growth of material to be stored by libraries, in this case a separate building outside the city. Discussions at the library congress held in Paris in 1937 led to the system of reduction of certain material by photography (newspapers for example) onto 35 mm. film as a method of saving space. Microprinting is a further development of this idea. Branch libraries and reference libraries specializing in particular fields tend to overcome the unwieldiness of huge central libraries.

U.S. Libraries. — In the United States numbers of people began to borrow books for home reading. This gave rise to a further service, the essential feature of which was the delivery room with its desk in direct communication with the stacks, and its catalogues and open shelves so arranged that readers in the reading rooms were not disturbed by users. In the larger libraries, the increased size of the card catalogue required a special room. In the New York Public library, for example, the catalogue room is on the third floor and readers pass through it on the way to the

FIG. 2.— MAIN FLOOR PLAN OF THE UNIVERSITY OF LOUISVILLE (KY.) LIBRARY

reading room. The influential University of California library (John Galen Howard. architect, 1911), emphasized a single entrance (for control) and a second-floor reading room with a desk betneen it and the stacks. The Baker Memorial library at Dartmouth (Jens Fredrick Larson, architect, 1928) brought forward the principle of the "open stack" where students were free to select their own books from the shelves. At the same time, they got a realistic idea of other material available to them. As the proportion of the stacks to the rest of the library increased. many interesting new plans were devised. In the Sterling library at Yale (James Gamble Rogers, architect, 1931), the tower stack permitted the facilities most used by the students to be available on the ground floor, with the books stored in the tower. In addition seminars were arranged in this tower adjacent to related areas of stack material. This idea of seminar rooms related to the stacks was carried further in the new Columbia University library (James Gamble Rogers, architect. 1934), where an air-conditioned core of books, in several tiers, was surrounded by rooms of normal floor height. (A great disadvantage of this type of enclosed stack is that it cannot be enlarged.) It exemplified the new willingness to depend on artificial light and ventilation.

A still further development was the attempt to break down the size of the large centralized libraries by dividing them into departments which were separately staffed, as in the case of the Cleveland library (Walker and Weeks, architects, 1926). The Enoch Pratt Free library (Clyde Friz and Tilton and Githens, architects, 1933), in Baltimore, was designed primarily for the circulation of hooks rather than their storage. Service was improved and expert staffs were organized to provide the books quickiy.

Another phase of development took place after World War II, particularly in the university libraries. Large enrollments, the extent and variety of the curriculum offered, the emphasis on research, the number of departments to be served, as well as the preservation of the materials, brought recognition of the necessity for flexibility. With the "open stack" principle widely accepted, individual places for the scholar to study, called carrels, were included in the stacks, as well as small reading areas throughout, rather than a concentration of seating in a remote central reading room. To achieve the flexibility that permitted carrels, seminar rooms or stacks to be on the same floor, the multiple tier stacks tended to give way to the loft-type open floor to permit the interchangeable use of the standard dimension stacks or movable partitions. Planning was more frequently modular wherein the uniform spacing of the columns was determined by a unit of space which permitted the efficient use of standard metal shelving units or rooms of reasonable size between the columns. With the perfection of electric lighting, ventilation and air conditioning, dependence on exterior windows was eliminated and solid-block libraries became practical. The student, the book and the teacher could then be brought together as in the Firestone library at

Princeton university (1948, O'Connor and Kilham, architects).

New types of stacks based on sliding or swinging units. known as compact storage, made it possible to recapture some of the storage space lost in aisles between the stacks. A further development was the storage library, shared by several institutions where the least-used books could be stored, yet be available on short notice. The New England Deposit library (1942) was perhaps the first. This idea was expanded in the Midwest Inter-Library centre (1951, Shaw, Metz & Dolio. architects). where the books of several institutions are shared. and certain new acquisitions are co-ordinated. alleviating much duplication.

In the past. libraries have been divided according to types of materials, such as books, films, maps or periodicals, etc. Since the war there has been a tendency toward division by subject bringing various materials from the same field together. With the increasing cost of services, there has been, in planning. increased attention to the efficient disposition of the staff. With the growth of modern audio-visual materials and equipment. libraries also became depositories for slides, tapes, films, discs, etc., with equipment for utilizing them.

The basic relationships of a library are illustrated in the plan of the library of the University of Louisville (1956, architects O'Connor and Kilham). Coming through the library entrance the user finds the circalation desk, and to the left is the catalogue and bibliography area, which is used equally by the readers and the staff. The entrance and desk of the reference room are close to the catalogues. Back of the catalogue area is the processing section where the staff members concerned with the acquisition, cataloguing and shelving of books are located. To the right is the general studies room, a reading room where books are kept on reserve for beginning students who are. generally, in large classes. It also includes listening rooms where audio tapes and discs may be used. Opposite the circulation desk is a top lighted gallery for the exhibition of pictures and sculpture. A lecture lounge is located oft' the vestibule so that its traffic will not disturb the rest of the library and so that the room can be used when the library is closed.

LIBYA, a kingdom of North Africa, bounded on the north by the Mediterranean. on the east by Egypt. on the southeast by the Sudan, on the south by the French African Kepublics of Chad and Niger, on the west and northwest by Algeria and Tunisia. For the geography of Libya *see* the articles on its constituent parts: CYRENAICA; FEZZAN; and TRIPOLITANIA. Total area is 679,3j8 sq.mi.; population (1954) 1,091,830.

The ancient Greek name *Libye* designated northern Africa west of Egypt but was given more precise connotation when the Roman emperor Diocletian divided Cyrenaica into Libya Inferior (Marmarica) and Libya Superior (farther west). Long understood as a geographical expression for what is now the kingdom, Libya became the official name of the Italian colony formed on Jan. 1, 1934, by the union of Cyrenaica and Tripolitania (*qq.v.*), and was incorporated into the metropolitan kingdom of Italy on Jan. 9, 1939. During World War II Italian administration ended in 1942–43, whereupon Cyrenaica and Tripolitania passed under separate British military administrations and Fezzan under a French.

On Nov. 21, 1949, the United Nations general assembly decided that an independent sovereign state'of Libya should be formed by Jan. 1, 1952; the inhabitants, in a national assembly, were to determine its constitution. Adriaan Pelt, a Dutch assistant secretary-general of the United Nations. was appointed UN commissioner, with an advisory council on which Egypt, France, Italy, Pakistan, the United Kingdom, the United States and the three territories of Libya and the local minorities (46,000 Italians and about 22,000 native Jews) were represented. The national assembly, comprising representatives in equal numbers from Cyrenaica, Tripolitania and Fezzan. met in Tripoli on Dec. 2, 1950, and decided that Libya should have a democratic representative, constitutional monarchy. Mohammed Idris as-Sanusi (es-Senussii. whose amirate of Cyrenaica had been recognized by Great Britain since 1946, became King Idris I of the United Kingdom of Libya, created on Dec. 24, 1951.

Libya was admitted to the Arab league on March 28. 19j3. By the 20-year treaty of July 29, 1953, Great Britain was to pay annually a £1.000.000 development grant and a £2.750,000 budget subvention and maintain military bases. A similar treaty with the United States was signed on Sept. 9, 1954. On Dec. 15, 1955, Libya became a member of the United Nations.

LICATA, seaport, Sicily, province of Xgrigento, 24 mi. S.E. of Agrigento direct; 54 mi. by rail. Pop. (1951) 36,570. The river Salso. east of the town. is the ancient *Himera meridionalis*. On the promontory. which has the town at its foot, and is called the Poggio di Sant' Angelo, the Ecnomus of the Greeks, is the site of the town Phintias of Aeragas built after the Mamertines destroyed Gela (281 B.C.). It was off this promontory that the Romans defeated the Carthaginian fleet in the spring of 2j6 B.C., while in the plain to the north, Hamilcar defeated Agathocles in 310 B.C.

The modern port refines and exports sulfur. It was bombed by the Allies in World War II.

LICENCE, permission, leave, liberty! hence an abuse of liberty; in particular, a formal authority to do some lawful act. Such authority may be either verbal or written; when written, the document containing the authority is called a "licence." Many acts: lawful in themselves, are regulated by statutory authority, and licences must be obtained. *See* LIQUOR LAWS AND LIQUOR CONTROL. etc.

LICHENS, a group of plants which are unique in being a combination of plants from two entirely different groups. This is quite unlike the situation in the mosses, ferns, wild flowers or trees, which are single plants. Each of the combinations in the lichens produces a plant body which appears as a distinct "species" despite its dual origin. The plants which unite to produce this combination are an alga and a fungus. These live together in an intimate relationship called symbiosis (*q.v.*) by most biologists and parasitism by others. Although lichens are commonly thought of in connection with the mosses, there is no relationship between these plants.

F. H. BRIGHTMAN

FIG. 1.— LICHENS GROWING ON AN OAK TREE

(A) Fruticose lichen, *Evernia prunastri;* (B) foliose lichen, *Parmelia caperata;* (C) crustose lichen, *Pertusaria* **amara**

Lichens are found throughout the world, often occupying niches in which no other plants can become established. They are most conspicuous in the alpine and arctic tundras, where they are dominant forms of vegetation. The rock outcrops of the world are usually clothed with an abundance of these plants. Lichens are almost the only plants able to survive the severe conditions of life found at high altitudes and latitudes.

In Antarctica, where there are very few flowering plants and perhaps 60 mosses, there are over 400 species of lichens. In more temperate regions the lichens are common in undisturbed habitats in old fields, in bogs and in forests, on the soil and old rotting logs, on tree trunks and branches. In tropical regions lichens are abundant. with different species occupying the ecological niches occupied by other species in other parts of the world. Few species survive in the vicinity of large cities, nhere they are killed by smoke and gases. The higher temperatures and consequent drier conditions of cities may also reduce lichen populations.

USES AND VALUES

Soil Formation. — Lichens are well known as pioneers on bare rock surfaces. Here some of them act by secreting acids which dissolve the material that cements the particles together. On limestone some species of *Verrucaria* and *Caloplaca* may dissolve pits in the rock surface. Other lichens help to fragment the rock by expanding nhen wet, attaching to the rock, then contracting when dry, thereby plucking away particles of the rock Still others may act by a process of chemical binding to remove some of the mineral elements from the crystals of the rock. As the rock becomes broken up by the action of the lichens and by weathering, the debris furnishes a lodging for the growth of mosses and eventually higher plants.

Erosion Control. — Some species of lichen thrive on very sandy soil. Here the undifferentiated plant body or thallus of a species such as *Lecidea uliginosa* will help materially in binding the surface of the soil against the action of the wind. On clay soils in old abandoned roadbeds in the eastern United States, *Baeomyces roseus* helps to protect against water erosion by binding the soil surface.

Food. — In the arctic and subarctic regions lichens are important as forage for reindeer, caribou, musk ox and moose. Lichens of the so-called reindeer moss group, *Cladonia mitis,* C. *sylvatica,* *C. alpestris* and Iceland moss *(Cetraria islandica),* are the most important species. Because growth in these northern climates is so slow 35 to 38 years are required for an area to recover from grazing. The area required to support a herd thus is enormous, and the Laplanders whose reindeer herds subsist mainly on lichens are forced to be a nomadic people. Iceland moss is used in Greenland and Iceland as a supplement in the food of sheep and cattle as well as of human beings. For use as food, the lichen is soaked in soda solution to neutralize the lichen acids, dried and powdered, and then mixed with potatoes. Some of the rock tripes (leafy or foliose forms), *Umbilicaria* species, have been used as emergency foods by explorers, but the action of the lichen substances on the body is generally unpleasant. One of the plants credited with being the manna of the children of Israel is a lichen, *Lecanora esculenta,* of north Africa and Asia Minor. This species sometimes rolls before the desert ninds in great quantities. Numerous small animals feed to a limited extent on lichen thalli; slugs, snails, mites, caterpillars and termites all are reported to feed upon lichens.

Medicine. — The fancied resemblance of lichens to parts of man's body led in earlier times to their use in the treatment of various ailments. For example, the lungwort, *Lobaria pulmonaria,* has the appearance of the surface of the lungs, hence was used to treat tuberculosis, pneumonia and similar afflictions; the yellow *Xanthoria parietina* was deemed valuable in cases of jaundice; the dog lichen, *Peltigera canina,* with its fruits resembling teeth in a jaw, mas used in the treatment of rabies. The skull lichen, *Parmelia saxatilis,* was considered excellent for epilepsy if found on old skulls instead of its usual habitat on tree trunks and rocks; its value was greatly enhanced if the skull happened to be that of an executed criminal. These fanciful treatments — based on the "doctrine of signature" *(see* SIGNATURE), by which nature was believed to have placed a sign indicating the value of the plant to man — have given way to more scientific remedies. Many of the lichens contain usnic acid and other lichen acids which have been shonn to have antibacterial properties. In Scandinavia the reindeer lichens have been used in the manufacture of alcohol, but difficulties in obtaining raw materials for this industry arise because the regronth of the lichen supplies is so slow. The wolf lichen, *Letharia vulpina,* has been used in Russia for poisoning wolves. One of the lichens of the plains of western North America, *Parmelia chlorochroa,* accumulates selenium and is therefore poisonous to livestock.

Perfumes. — The oak moss lichen. *Evernia prunastri,* and related species, is gathered in southern Europe and used in perfumes; it functions as a fixative to assist in controlling the uniform evaporation of the many varied ingredients of the perfumes.

Dyes. — Probably the most familiar use of dyes derived from lichens is in the litmus paper (paper saturated with litmus solution) of the chemist. This reddish-violet dye, litmus, used as an acid-base indicator, is prepared from a purple or reddish-purple dyestuff called orchil, archil or cudbear. In Europe, cudbear, *Ochrolechia tartarea,* a crustose (having a thin flat crusty aspect) lichen, is scraped from the rocks and used in the preparation of the dyestuff. In the Canary Islands, Madagascar, the coast of South America and formerly along the coast of California, various species of orchil lichens, *Roccella tinctoria* and other species of *Roccella,* are gathered, prepared with sodium or ammonium hydroxide solutions and used for dyeing wool and silk. Rock tripes, *Umbilicaria* sp., *Parmelia* sp. and other lichens are used in northern countries as sources of other dyestuffs, giving soft browns, yellows and other colours to wool.

NATURE OF LICHENS

The unusual structure of the lichens (*i.e.,* a composite plant body or thallus composed of two interdependent plants) was not discovered until after the development of the microscope. The name of this group of plants first appears in the writings of Theophrastus, a disciple of Aristotle, about the 4th century B.C. At that time, and for many centuries thereafter, lichens were confused with the mosses (*q.v.*) and the hepatics. The early students of lichens thought that the green cells (now known to be alga) were specialized structures produced by the fungus and probably of reproductive function. Wallroth *(1825)* coined the term gonidia to indicate this reproductive function, but also mentioned the resemblance to some of the well-known free-living algae. It was not until *1867* that Simon Schwendener announced that the green cells were indeed algae, and that the fungi were parasitic upon them. After the introduction of pure culture techniques, the constituents of numerous lichens were isolated and grown apart from each other and then recombined. The resulting lichen, however, appears somewhat different from the original, and the experimental demonstration of the complete life cycle presents difficulties.

Because the lichen appears as a healthy organism which thrives in very severe environments, the interpretation of the relationship as a simple case of parasitism did not satisfy many of the workers in this field. The term consortium (a union or fellowship) was proposed by Johannes Reinke *(1873)* to explain the relationship; then H. A. de Bary *(1873)* suggested that symbiosis would be a more satisfactory term to describe the relationship. Experimentation shows that there is not only manufacture of the food by the alga in the process of photosynthesis and absorption of water from the atmosphere by the fungus, but that there is also an exchange of complex organic compounds between the components of the lichen.

The constancy of the algal host in the lichen relationship is undetermined. Although the same genus of alga is present in a given species of lichen, there are indications that different species or races of the alga may be present. In some lichens there may be two groups of algae represented in the thallus. In *Peltigera aphthosa* and *P. venosa,* for example, the alga in the thallus is one of the green algae, *Coccomyxa,* while the blue-green alga, *Nostoc,* is found in special gall-like growths called cephalodia. In *Solorina crocea* there may be two layers of the two types of algae. The algae of the lichen are often considerably different from free-living algae of the same genus, and only by pure culture can they be definitely identified. Some of the algae may change their colour. Others which normally grow in chains of cells may be broken up into cell units scattered throughout the thallus.

Algal Member. — The algae in the lichens belong to one of two groups, the Cyanophyta or blue-green algae, or the Chlorophyta or green algae. In the case of the association with the blye-green algae, the shape of the lichen is usually determined by that of the alga, and the fungal threads or hyphae are usually nithin the gelatinous sheath of the alga. When the algal component is a branched filamentous type, such as *Rivularia,* *Stigonema* or *Scytonema,* the lichen is of the same form, and the filaments of the fungus grow in a sheathing mass around the algal cells. If the blue-green alga normally forms flat colonies containing threads scattered through a gelatinous layer, the lichen will have the same shape, the threads of the fungus being intermixed with those of the alga, or the algal threads may be broken into single-celled units by the growth of the lichen thallus; *Nostoc* and Gloecapsa are common blue-green algae with such a distribution in the thallus. Lichens formed with such a uniform distribution of the two components are said to have

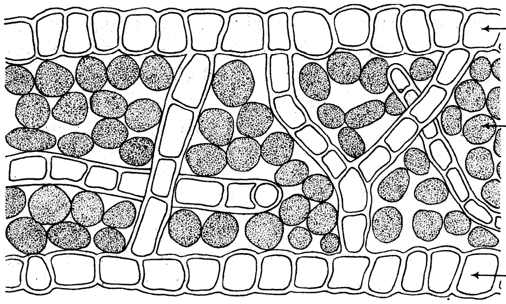

FIG. 2.— SECTION OF THALLUS OF LEPTOGIUM CYANESCENS SHOWING HOMOEOMEROUS TYPE OF THALLUS. (ENLARGED)

a homoeomerous thallus. Collema is a typical lichen of this type. In *Leptogium* the fungus produces a definite layer on either side of the thallus but the internal structure is similar to that of Collenza.

A wide variety of green algae can be associated with the fungi of lichens; Protococcus, *Trentepohlia* and *Trebouxia* (*Cystococcus*) are the commonest, but other genera may also be involved. One of the filamentous types, Cladophora (alga), is involved in *Racodium* (lichen), and in this case the shape of the lichen is influenced by the shape of the alga. In most lichens in which the alga is a member of the Chlorophyta, the fungus determines the shape of the lichen; in the case of flat thalli the algal cells are in a definite layer within the upper part of the thallus, whereas in cylindrical thalli the algal cells are in a layer around the thallus but under the surface. The lichens with layered structure are termed heteromerous. In only a few of the lichens does there appear to be a penetration of the algal cells by special bodies of the fungus called haustoria. In most there is only a close application of the fungal filaments to the algal cells.

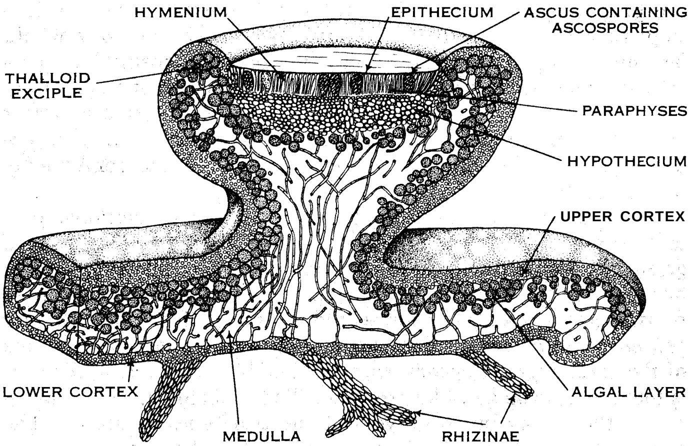

FIG. 3 — SECTION OF PHYSCIA LICHEN SHOWING HETEROMEROUS TYPE OF THALLUS AND LECANORINE APOTHECIUM WITH THALLOID EXCIPLE. (ENLARGED)

Fungal Member. — The lichen fungi belong to a wide variety of groups of the fungi. In a very few tropical lichens such as Cora pavonin and Dictyonenza the fungal symbionts are members of the Basidiomycetes. In most of the lichens, however, the fungal symbionts are members of the Ascomycetes. There are four main groups of Ascomycete fungi involved, with the fruiting structures being the basis of the classification. The Pyrenulales form a fruiting body called a perithecium, a small round enclosed body containing many spore sacs (asci) containing spores and opening by a pore at the tip. The Caliciales form a fruiting body nithin which the asci break down at maturity to release a mass of dry, powdery spores. The Hysteriales form oblong, more or less linear apothecia which open by slits along the top. The largest group of lichen fungi belongs to the Lecanorales, in which the open disklike apothecia are either flat, convex or cuplike.

Evolution. — There is no record in the rocks as to the antiquity of the lichens, but it is obvious that this symbiotic organism must be more recent than its components. It is also obvious that lichens are not primitive but highly developed structures. Both the symbiont are polyphyletic; that is, the algae come from several groups, and the fungi, likewise, are of several widely different origins. Presumably the earliest lichens were a loose association of fungal hyphae with free-living algae. Some lichens are still on this borderline. In Calcium and *Mycocalicium* it is sometimes difficult to be certain of the presence of the alga. Some fungi such as Leotia may contain algal cells in their fruiting bodies. Evolution probably developed from these loose associations to a definite crustose structure, then to the leafy (foliose) structure and finally to the intricate fruticose (shrubby or bushy) type of thallus.

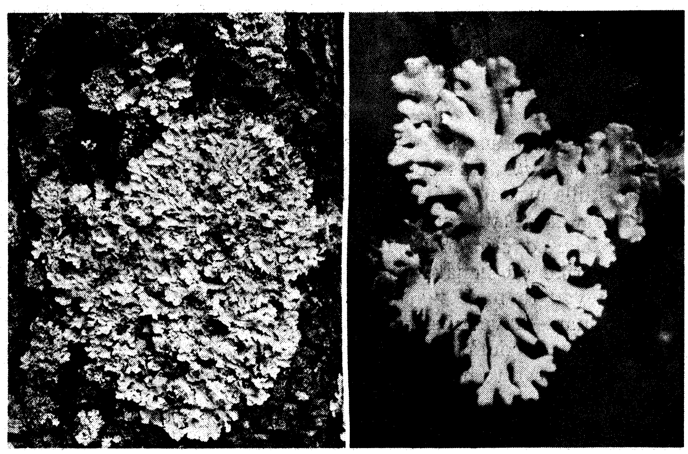
STRUCTURE

General Form and Growth Habit. — There are four general types of growth habit among the lichens: crustose, squamulose, foliose and fruticose.

Crustose.—In the crustose lichens there may be but a thin layer of fungal hyphae with the algal cells scattered among them. This grades into definitely layered structures with an upper cortex of hyphal cells, an algal layer and then an inner layer of loose hyphae, the medulla. The crustose thallus may be granular or smooth, and, if thick may become divided into small, marked-off, angular pieces or elongate lobes; these in appearance approach those of the foliose lichens but are more closely attached to the substratum. If the thallus of the crustose lichen is over the bark surface it is termed epiphloeodal; if it penetrates the bark, only forming the fruits on the surface, it is termed hypophloeodal. Similarly the rock lichens may be epilithic or endolithic. Sometimes the crustose lichens on rocks penetrate them to surprising depths; Biatorella simplex penetrates its rock substrate to a depth of almost half an inch.

Squamulose.—In the squamulose lichens there is a small, leafy, layered thallus which, unlike the crustose type, is more loosely attached, usually toward one edge. *Dermatocarpon*, Lecidea and Cladonia form this type of thallus.

Foliose. — The foliose type of thallus is one of the most conspicuous types of growth of lichens. It is a large leafy type, sometimes in smaller lobes as in Physcia or *Parmelia*, sometimes forming



(LEFT) BY COURTESY OF JOHN W THOMSON, (RIGHT) RUTHERFORD PLATT

FIG. 4 — (LEFT) LICHENS GROWING ON AN OAK TREE SHOWING PARMELIA WITH BROAD LOBES AND STAR LICHEN (PHYSCIA STELLARIS) WITH TINY LOBES. (RIGHT) CLOSE-UP OF PARMELIA

huge plates attached at the centre as in the rock tripes, Unzbilicaria. The typical foliose thallus is definitely layered. The upper layer is of either fibrous or cellular appearance; next below this layer is the algal layer with some of the fungal hyphae running through it; then follows a loose inner layer, and finally the lower layer or lower cortex, which may be cellular or loose, and from which project the rootlike structure or rhizinae which attach this type of thallus to the substratum. The rhizinae are sometimes quite abundant as in some of the *Parmelias*. Growth of these lichens is from the margins, which are oiten lighter in colour as they have not yet accumulated the substances which will darken them.

Fruticose.—The upright shrubby or fruticose forms, rarely exceeding six inches in height, usuaily arise irom a primary thallus of a different growth form, sometimes crustose and sometimes squamulose. The fruticose lichens may be quite simple nith club-shaped, pointed or cup-shaped structures, or they may form intricately branching stalklike structures as in the reindeer lichen *Cladonia rangiferina*. This species in turn forms large mats on the soil. The internal structure of the fruticose lichens is similar to that of the foliose types, except that it is based on the cylinder. There is an outer cortex. an algal layer which is more or less continuous, then an inner medullary layer. In Cladonia and *Dactylina* the stalks are hollow. In some of the fruticose lichens as *Roccella* and *Ramalina* there are longitudinal thick-walled strands This tendency reaches its peak in the *Usneas*, nhich have a central strand of great toughness and strength. enabling the hanging thallus to reach a recorded length of 11 yd. in the case of *Usnea longissima* which hangs from tropical trees.

FIG. 5.—CLOSE-UP OF A PORTION OF THE FRUTICOSE THALLUS OF OLD- .,,, ,,,,, LICHEN ,,,,,,, TRICHODEA), SHOWING NUMEROUS FIBRILS AT RIGHT ANGLES TO THE MAIN BRANCHES AND THE JOINTED APPEARANCE OF THE MAIN BRANCHES. ONE APOTHECIUM IS SEEN IN THE CENTRE

Special **Structures.**—*Cyphellae*.—Replacing the stomata of the flonering plants are the cyphellae and pseudocyphellae of the lichens. which are reputed to be organs of gaseous exchange. The cyphellae have a definite margin and occur as small pores on the underside of some of the Stictaceae. The pseudocyphellae lack the definite cup margins and occur more widely among the lichens, in the Stictaceae, in *Nephroma, Cetraria* and some *Parmelias*.

Cephalodia.—These occur only in lichens with green algae. They contain algae of a blue-green type, different from those of the host. They may originate from algae which land on the surface of the lichen and become the centre of the gall-like growth of the cephalodium. Cephalodia occur on the upper surface of *Lecanora gelida* and Peltigera *aphthosa*, on the underside of Pcltigera cenosa and within the thallus in *Solorina saccata*. In *Stereocaulon* they contain the algae Stigonema or *Scytonema* instead of the commoner *Nostoc*. Cephalodia occur quite widely among the lichens.

Soredia.—These consist of a few algal cells enveloped by a weft of iungal hyphae to form a powdery granule which serves in the reproduction of lichens of many species. In the more primitive lichens the soredia are formed over the surface of the thallus. In the more advanced lichens they are formed in special structures termed soralia. The soralia are sometimes head-shaped and are then commonly found upon the surface of the thallus. In other cases they may be lip-shaped and located at the tips oi the lobes or along the sides of the lobes of the thallus. In some cases. as in *Parmelia sulcata*, they may be formed along ridges on the tops of the lobes. Still other soralia may be iormed on the underside of the thallus.

Isidin.—These are outgrowths on the upper surface or the margins of the lobes of many lichens. They are corallike extensions of the thallus; the internal structure usually includes a central medulla. an algal layer and an outer cortex. Their iunction is usually supposed to be that of increasing the area of the thallus devoted to photosynthesis. They are also usually quite brittle and may serve as organs oi vegetative reproduction.

Rhizinae and Cilia.—Rhizinae are groups of the fungal hyphae which anchor most of the foliose lichens to the substratum of rock. bark or soil. They do not appear to play an important role in transfer of water or minerals to the lichen. The cilia are long hairlike structures which ornament the margins of the lobes of species of *Parmelia, Anaptychia,* Physcia and *Umbilicaria*. Their function is unknown although occasionally they may serve to attach the lobes to each other, thereby strengthening the mass of the plant.

REPRODUCTION AND GROWTH

Probably the commonest means of reproduction of this dual organism, the lichen, is vegetative reproduction. Dry lichens are very brittle and smali bits are readily fragmented from the thallus to blow away, anchor and give rise to new thalli. Special organs which contain both components of the thallus (*i.e.*, soredia, isidia or other small lobes) may also be widely distributed by the wind, by water, or over the surface of the snow.

Rigorous proof of the sexual reproduction of the fungal member of lichens remains to be shown. The difficulties of carrying out experimental culture have limited the studies to examination of the structures present in the lichens and to analogy with the methods of reproduction of similar nonlichen-forming fungi. In *Collema* there is a coiled egg-bearing structure which bears a trichogyne (receptive filament) which may or may not reach the surface of the lichen. Male sex cells (spermatia or pycnoconidia) have been observed attached to the trichogyne and suggest the possibility of sexual union. But the pycnoconidia have also been shown experimentally to be able to germinate into fungal hyphae and there is a distinct possibility that the association of the structures is merely accidental. In Peltigera there is formation of a hook or crozier similar to that in Pezizales, which suggests fusion of nuclei. Asexual reproduction has also been suggested for many lichen fungi in which the sexual process has considerably degenerated. Yet the majority of the lichen fungi produce an abundance of apothecia containing ascospores which suggests that these are important.

The lichen fungi form ascocarps (fruiting bodies) of a variety of types depending on the Xscomycete involved in the lichen. In the Lecanorales there is a disk—or cup-shaped apothecium borne on the upper surface or margins of the thallus. The typical structure of the apothecium consists of a layer of tissue called the hymenium, which contains sterile hpphae (paraphyses) interspersed among the saclike asci containing the ascospores. The usual number of ascospores per ascus is eight, but there may be only one or two as in some of the *Pertusaria* and up to hundreds of tiny spores in *Acarospora*. Below the hymenial layer is a layer oi iungal tissue, the hypothecium, which is extended up the sides of the cup to form the proper margin or proper exciple of the

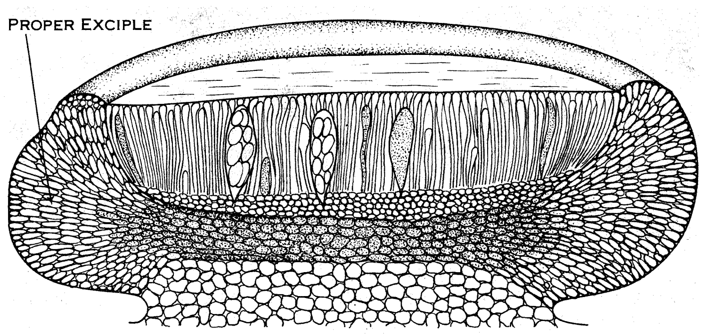

FIG 6 — SECTIONOF APOTHECIUM OF LECIDEA STERIZA SHOWING LECIDEINE APOTHECIUM WITH PROPER EXCIPLE. (ENLARGED)

apothecium, as in the genus Lecidea. Below this layer may be another which is an extension of the thallus usually containing the algae. This grows up in some of the lichens (as *Lecanora*) to form another margin. the thalloid margin or thalloid exciple around the apotheciurn. The tips oi the paraphyses are more or less enlarged and form a layer (epithecium) over the tips of the asci. In the lichen fungi belonging to the Sphaeriales, the asci are formed in a layer inside the flask-shaped perithecium, which is partly, or wholly embedded in the thallus. The outer tissue is usually partly black and carbonized; it may extend entirely around the fruit except for the tiny ostiole or opening, or it may extend only over the upper part of the perithecium. In many species the paraphyses may become gelatinized and disappear as the asci mature. In certain types of lichen fungi belonging to the Hysteriales there is a long, narrow ascocarp with the sides carbonized and the asci and paraphyses in a furrow down the middle. In still other lichen fungi belonging to the Caliciales the asci disintegrate to leave the spores free in a threadlike mass. the mazaedium.

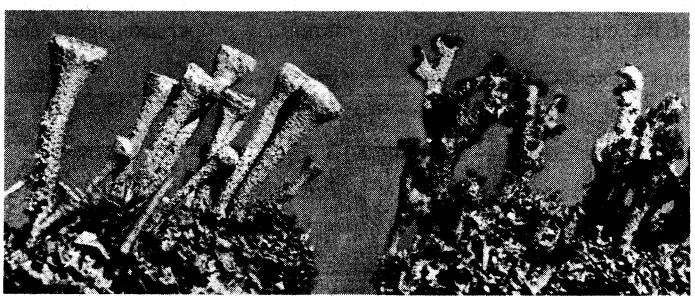
The life of the apothecia and perithecia in the lichens, unlike that of the ascocarp in the nonlichen-forming fungi, may extend over a period of many years. The spores may be shed from the same hymenial layer as in most of the lichens, or there may be an added layer as in the concentric layers of the rock tripes, *Umbilicaria*. When the thallus is moist the spores are ejected from the asci into the wind for distribution. Although there seems to be a greater formation of ripe spores in the spring by some lichens, there are usually some spores present in the apothecium at all times of year.

Among the lichen fungi which belong to the Basidiomycetes the spores, called basidiospores, are borne on the underside of the bracket-shaped thallus.

The spores of lichens are exceedingly varied, and this variability is helpful in the classification of lichens. The spores may be brown or clear, one celled or two celled. or there may be a number of square- or lens-shaped cells placed either lengthwise, or lengthwise and crossnise. The spores may have very thick nalls and the tiny cell cavities joined by a canal as in *Caloplaca*. Spores vary from very small (1 micron, or $\frac{.4}{100,000}$ in) as in *Acarospora* to very large (250 microns, or $\frac{1}{100}$ in.) as in *Pertusaria* and *Thelotrema*. The wall may be smooth or sculptured, and the shape varies from spherical or elliptical to fusiform or needlelike. Most spore cells appear to be uninucleate, but in the large simple spores of *Pertusaria* they are multinucleate

Most lichens produce pycnidia, flask-shaped structures. in addition to the apothecia. The pycnidia may be within the surface of the thallus as in *Parmelia* and *Physcia* or marginal, somewhat barrel-shaped structures as in *Cladonia* and *Cetraria*. They produce spores called pycnoconidia within the pycnidia. These spores can germinate to produce fungal hyphae and possibly represent one additional means of reproduction. The possibility of their being spermatia is uncertain.

Reproduction of the algae in the lichens is usually by ordinary division. In pure cultures the algae may form zoospores or autospores, depending upon the type of alga.



BY COURTESY OF JOHN W. THOMSON

FIG. 7.—PYXIE-CUPS LICHEN (CLADONIA CHLOROPHAEA) SHOWING (LEFT) SIMPLE CUPS AND (RIGHT) CUPS WHICH HAVE SIDE BRANCHES BEARING APOTHECIA

The fungal spore may germinate and form a tiny prothallus which goes into a resting stage. A new lichen thallus may be initiated when an appropriate algal cell or the soredium of the same lichen species alights by chance upon or very close to the resting prothallus stage.

Growth of the thallus of the lichens occurs mainly at the periphery. Sometimes the algal cells are carried out at the edge of the thallus by special fungal hyphae. The fungal hyphae may grow out farther than the rest of the thallus, and algal cells carried on the winds anchor upon the hyphae giving rise to nea parts of the thallus. The rate of growth of a given lobe of a lichen tends to be exceedingly slow, especially among the crustose lichens. Figures of fractions of a millimetre a year are usual. and some single thalli may be estimated to be centuries old. The foliose and fruticose lichens grow more rapidly, one or two centimetres a year being common growth rates for these. Frequently, as the thallus reaches large size, the centre portion will die out leaving a bare area, while the periphery continues to grow. In the centre new thalli may colonize and thus form concentric rings of lichens.

PHYSIOLOGY

Lichens obtain part of their water supply from rains, part from the atmosphere directly, and part from dews and fogs. In desert regions the dews are of special importance. Water can be absorbed by lichens to the extent of 1 to 35 times their own neight. When growing on damp mossy surfaces, the lichens can obtain much of their water from the substratum Although water is easily taken up by the thallus, it is also quickly lost; it has no special ability to retain the moisture. Lichens are able to withstand extreme drying, especially those species growing on the hot dry rocks of deserts. However, they show correspondingly reduced assimilation and respiration.

Respiration of the lichen thallus is of course dependent upon the two components of the lichen. In the dark the CO_2 output rises and O_2 utilization increases; in the light the reverse occurs. The balance of these two measures of respiration depends on the kind of lichen, the temperature and the availability of water. The lichens of shade achieve a balance sooner during the day under loner intensities of light than do the lichens which grow in higher light intensities. The rate of respiration drops rapidly with lowering temperatures until at $-10°$ C. it becomes immeasurable, although the lichens still survive much lower temperatures. Respiration is at a maximum at from 15° to 25° C., then drops as the temperature is raised over 25°. In lichens in the dry condition the gaseous exchange is very slight. With increase in moisture content of the thallus up to a point just short of saturation the gas exchanges increase. They then diminish as saturation is reached. A moist lichen will carry on about five times as rapid a gaseous exchange as a dry lichen. The carbon dioxide and oxygen ratio is not much influenced by the moisture content of the lichen.

Light requirements of lichens are dependent upon the kind of lichen being studied There appear to be two maxima in the rate of assimilation, one at from 7j to 400 lux and another in the more moderate range of 2,000 to 3,500 lux.

Lichens are sensitive to gaseous compounds of sulfur and to ozonated hydrocarbons. This probably accounts for their scarcity in areas around cities nhere such compounds are abundant. Some species as *Xanthoria parietina*, *Evernia prunastri* and *Anaptychia ciliaris* have been suggested as indicators of air pollution.

Because of the difficulty of growing the lichen fungi in pure culture, comparatively little is known about their requirements. They are like the nonlichenized fungi in a preference for common hexose and disaccharide sugars. A deficiency of thiamine has been shown for six species. Ammonium salts are readily utilized by a number of species, but amino acids are apparently poor sources of nitrogen for these fungi. Mineral nutrition is poorly understood. An exchange of organic compounds between the two symbiotic members of the lichen was suggested by the work of Quispel.

CHEMISTRY

The fungal tissues of lichens produce a uide variety of substances. The hyphal walls in many lichens are composed mainly of the polysaccharide lichenin. which does not react with iodine, whereas in other lichens, isolichenin is found. which has a blue reaction nith iodine. Chitin, hemicelluloses. pentosan, dextran and a glucan may also be formed. Lipoid substances are very commonly formed. A number of other types of sugars such as arabitose. sucrose and trehalose and polyhydric alcohols such as mannitol and volemitol, have been reported in lichens. Sixteen amino acids, growth substances and a number of vitamins have also been found in lichens. The constituents of the algal member of the lichens are presumably the same as in the free-living algae of the corresponding genera.

The most interesting of the substances produced by lichens are those which are produced on the exterior of the fungal hyphae. In addition to calcium oxalate, there are formed a large number of peculiar chemical substances with a very wide range of chemical formulas and an interesting variety of crystalline structure. Lichen substances are in some cases formed without the algal partner's being present. Many of the lichen substances are of bright colours, red. yellow or orange. and give the clear colours to the common lichens. They are in most cases unique to the lichens, but in some cases are also formed by independent fungi'. The exact function of these substances in the life processes of lichens was unknown in the late 19jos. Various ideas include: *(1)* they provide protection against animals as a result of the bitter flavour of the substances; *(2)* they give protection against transpirational loss of water; and (3) they are end products of cell metabolism, excretory substances. Some, like usnic acid, have an antibacterial effect. Although commonly called lichen acids, these include a wide series of other types of chemicals.

CLASSIFICATION

Long before the true nature of the lichen thallus was understood, there had been attempts to classify the lichens. Usually they were placed among the mosses, the hepatics and the algae. Even Linnaeus (1753) added other plants to his genus *Liclzen,* which contained all the lichens then known to him.

Modern systems of classification of the lichens show an increasing emphasis upon the fungi which are associated in the lichen relationship. There is an increasing tendency toward distributing the groups which are associated with the blue-green algae among those associated with the green algae according to the type of fungus present. The names are based on the fungus member of the partnership in order to avoid the naming difficulties which would result from basing them on the combination. One system, quoted by M. E. Hale (1956), includes the following:

Class Ascomycetes
- Subclass Bitunicatae (Xscoloculares)
  - Order Hysteriales (Opegraphaceae, Dirinaceae, etc.)
- Subclass Unitunicatae (Ascohymeniales)
  - Order Sphaeriales (Pyrenulaceae, Verrucariaceae, Dermatocarpaceae)
  - Order Pezizales (Graphidaceae, Pannariaceae, Lecideaceae, and nearly all ioliose and iruticose genera)
  - Order Caliciales (Caliciaceae, Cypheliaceae, Sphaerophoraceae)

Class Basidiomycetes
  - Order Thelephorales (Cora, Dictyonema)

Class Fungi Imperiecti (Crocynia, Lepraria)

These larger groups are divided into a large number of families and over 200 genera. There are over 18.000 species of lichens in the world. In North America over 2,200 species have been listed.

PHYTOGEOGRAPHY AND ECOLOGY

Distribution. — So much remains to be done in the collection and study of lichens that only the general outlines of the distribution patterns can be described. For those which have been studied, patterns matching those of the better-known flonering plants can be shown. but some unique patterns have been found. In the arctic there is a circumpolar distribution type containing many widespread species such as *Alectoria ochroleuca, Cetraria nivalis, C. cucullata* and *Parmelia centrifuga.* An Arcto-Pacific distribution type contains species which are found in Siberia and in the western American arctic; *e.g., Cetraria richardsonii* and *Cetraria chrysantha.* A lichen occurring in both arctic and antarctic regions is *Usnea (Neuropogon) sulphureus. A* very large number of lichens of the temperate zone occur around the world, so that manuals of European lichens are of great help in studying North American lichens and vice versa. Such genera as *Alectoria, Cladonia, Caloplaca, Lecidea, Lecanora, Parmelia, Physcia* and *Rinodina* provide many examples of such wide distribution. A few species such as *Lecidea olivacea, Alectoria fremontii, Cavernularia hultenii* and *Lobaria hallii* are found in the western parts of both North America and Europe. Some species such as *Cetraria oakesiana* and *Baeomyces roseus* are found in eastern North America and in Europe. Mediterranean desert lichens such as *Physcia biziana* are also found in the arid regions of western North America. Along the coastal regions of western North America are a number of lichens which also occur in Japan.

Tropical lichens tend to be represented strongly by lichen fungi associated with the algal genus *Trentepohlia.* Although many of the same genera that occur in temperate regions are present, the predominant lichens are different. The families Graphidaceae, Pyrenulaceae, Astrotheliaceae, Paratheliaceae, Coenogoniaceae, Thelotremaceae, Stictaceae and Parmeliaceae are conspicuous among the tropical groups.

In antarctic regions the most conspicuous lichens are the Stictaceae, the Cladoniae and members of the subgenus *Neuropogon* of the genus *Csnea.* In Antarctica there are over 400 lichens, the bulk of them being crustose; the genus *Buellia* is best represented.

Ecology. — Although lichens are to be found in many kinds of habitats in the world, the balance between the two components in each species of lichen is so delicate that any given kind is likely to show a very marked response to the external conditions under which it grows. Thus, lichens make very good indicator plants to deduce the nature of the environment. The substratum, light, temperature, moisture and winds all may play a part in the limitation of a given lichen-to a specific ecological niche.

In Europe and to a lesser extent in North America there is a broad intertidal zone along the coastal rocks in which species such as *Verrucaria maura* and *Caloplaca marina* can grow between the seaweeds in the periodic salt-water bath.

In North America there is one species *Hydrothyria venosa,* which is completely aquatic in fresh-water streams in the eastern mountains and in California. Another species. *Dermatocarpon aquaticum,* occurs along streams of the northern hemisphere in places which are periodically flooded. Just as in the case of the higher plants. lichens may be tolerant of a wider variety of habitats to\\-ard the centres of their ranges, whereas on the periphery of their ranges they may show a stronger limitation to a certain habitat. Some species are indicative of limestone soil or rocks (calcicolous lichens); these include *Cetraria tilesii* and *Dactylina arctica* in the arctic, and *Lecanora crassa* and some species of *Collema, Caloplaca* and *Verrucaria* in more temperate regions. Some prefer acidic rocks (silicicolous lichens); *e.g.,* most of the *Umbilicarias, Rhizocarpon, Lecidea, Stereocaulon* and many *Lecanoras.* Although many lichens grow in very dry habitats, others prefer higher atmospheric humidity; the lace-lichen, *Ramalina reticulata,* for example, festoons the foggy redwood forests of western North America. Studies of tree bark, or corticolous, communities of mosses and lichens show that although such lichens may grow on many kinds of trees there is a marked preference for certain species. The type of bark (rough or smooth), the bark acidity, the amount of shade of a given tree — these are some of the factors determining this selectivity. Because many lichens have very similar habitat requirements, they can be grouped into communitiks of species which frequently occur together. Such studies of lichen communities, or lichen sociology, show them to be quite specific for various parts of the world.

LICHFIELD, a city, county of a city, and municipal borough in the Lichfield and Tamworth parliamentary division of Staffordshire, Eng., 17 mi. N. of Birmingham. Pop. (1951) 10,619. Area 5.6 sq.mi.

The town is on a stream with low hills to the east and south. There is a tradition that "Christianfield" nearby was the site of the martyrdom of 1,000 Christians during the persecutions of Maximian about 286. At Wall, 3 mi. distant, there was a Romano-British village called Letocetum ("gray wood"), from which the first half of the name Lichfield is derived. The first authentic notice of Lichfield occurs in Bede's history, where it is mentioned as the place where St. Chad fixed the episcopal see of the Mercians. At the time of the Domesday survey Lichfield was held by the bishop of Chester, who held the lordship and manor of the town until the reign of Edward VI, when they were leased to the corporation. Richard II gave a charter (1387) for the foundation of the guild of St. Mary and St. John the Baptist; this guild obtained the whole local government, which it exercised until its dissolution by Edward VI, who incorporated the town (1548). The only existing fair is a small pleasure fair of ancient origin held on Shrove Tuesday; the annual fete on Whit Monday claims to date from the time of Alfred. King Edward VI's grammar school was founded in 1495. The cathedral, one of the smallest in England, dates from the 13th and early 14th centuries. Built mainly of red sandstone, its fine exterior has a lofty central and two lesser western spires, of which the central, 252 ft. high. is a restoration attributed to Sir Christopher Wren after its destruction during the Civil Wars. Among numerous monuments are memorials to Samuel Johnson (born in Bread Market street, 1709) and to David Garrick, who spent his early life and was educated in Lichfield. The city has also been the home of some famous men and women, among them Elias Ashmole, Joseph Addison and Erasmus Darwin. It possesses many houses of historic interest and architectural merit. It is well planned, with extensive housing schemes and a remarkable variety of crafts and industries, varying from the production of essences to a wide variety of plastics and light engineering works. The borough was extended in 1934. There is a general museum and two regimental museums.

LICHTENBERG, formerly a small German principality on the Rhine, now belonging to the district of Trier, Rhineland-Palatinate. The principality included parts of the electorate of Trier, and Nassau-Saarbrucken. Originally called the lordship of Baumholder, it owed the name of Lichtenberg and its elevation in 1819 to a principality to Ernest, duke of Saxe-Coburg, to whom it was ceded by Prussia in 1816. The duke restored it to Prussia in 1834.

The area is about 210 sq.mi.

LICINIUS (FLAVIUS GALERIUS VALERIUS LICINIANUS), Roman emperor, A.D. 307–324, of Illyrian peasant origin, was born probably about 250. He was elevated to the rank of Augustus by Galerius, his former friend and companion in arms, on Nov. 11, 307, receiving as his immediate command the provinces of Illyricum. On the death of Galerius, in May 311, he shared the entire empire with Maximinus, the Hellespont and the Thracian Bosporus being the dividing line. In April 313 he inflicted a decisive defeat on Maximinus at Heraclea Pontica, and established himself master of the east while his brother-in-law, Constantine, was supreme in the west. In 314 his jealousy led him to encourage a treasonable enterprise against Constantine. When his perfidy became known a civil war ensued, in which he was twice severely defeated. The outward reconciliation left Licinius in possession of Thrace, Asia Minor, Syria and Egypt, but added numerous provinces to the western empire. In 323 Constantine again declared war against him, and, having defeated his army at Adrianople, succeeded in shutting him up within the walls of Byzantium. The defeat of Licinius' fleet compelled his withdrawal to Bithynia, where a last stand was made; the battle of Chrysopolis, near Chalcedon, resulted in his submission. He was executed in the following year.

LICORICE: *see* LIQUORICE.

LICTORS (Lat. *lictores),* in Roman antiquities, a class of the attendants (*apparitores*) upon certain Roman and provincial magistrates. As an institution they went back to the regal period and continued to exist till imperial times. The majority of the city lictors were freedmen; they formed a corporation divided into decuries, from which the lictors of the magistrates in office were drawn; provincial officials had the nomination of their own. In Rome they wore the toga; on a campaign and at the celebration of a triumph, the red military cloak (*sagulum*); at funerals, black. As representatives of magistrates who possessed the *imperium,* they carried the fasces *(see* FASCES). They were exempt from military service and received a fixed salary; theoretically they were nominated for a year, but really for life. They were the constant attendants of the magistrate to whom they were attached. They cleared a passage for him *(summovere)* through the crowd, and saw that he was received with the marks of respect due to his rank. They stood by him when he took his seat on the tribunal; mounted guard before his house, against the wall of which they stood the fasces; summoned offenders before him, seized, bound and scourged them and (in early times) carried out the death sentence. Directly a magistrate entered an allied, independent state, he was obliged to dispense with his lictors. Each of the consuls had 12 lictors; the dictator, as representing both consuls, 24; the emperors 12, until the time of Domitian, who had 24. The Flamen Dialis and each of the Vestals were also accompanied by lictors. These lictors were probably supplied from the *lictores curiatii,* 30 in number, whose functions were specially religious, one of them being in attendance on the *pontifex maximus.* They originally summoned the *comitia curiata,* and when its meetings became merely a formality acted as the representatives of that assembly.

For the fullest account of the lictors, *see* Theodor Mommsen, *Romisches Staatsrecht,* vol. i, 355, 374, 3rd ed. (1887); *cf.* J. E. Sandys, *Companion to Latin Studies* (1921).

LIDDELL, HENRY GEORGE (1811–1898), English lexicographer, co-editor of *A Greek-English Lexicon,* was born at Binchester, near Bishop Auckland, on Feb. 6, 1811. He was educated at Charterhouse and Christ Church, Oxford, became a college tutor and was ordained in 1838. In 1846 he became headmaster of Westminster school. Early in 1834 Liddell and Robert Scott began the great *Lexicon* (based on the German work of F. Passow) which became his life work, and the first edition was published in 1843. It is still the standard Greek-English dictionary (revised ed. by H. S. Jones and others, 1940). In 1855 he became dean of Christ Church and took an active part in the first Oxford University commission. He resigned the deanery in 1891 and retired to Ascot, where he died on Jan. 18, 1898. It was for Liddell's daughter Alice that Lewis Carroll wrote *Alice in Wonderland.*

See H. L. Thompson, *Henry George Liddell* (1899).

LIDDESDALE or LIDDISDALE is the valley of Liddel water, Roxburgh, Scot., extending 21 mi. from the Peel fell to the Esk, its head being crossed by the Catrail, or Picts' dyke. For 7 mi. it forms the border between England and Scotland. At one period points on the river were occupied with freebooters' peel towers, but many have disappeared. Hermitage castle, a massive H-shaped fortress and one of the oldest baronial buildings in Scotland, stands on a hill overlooking Hermitage water, a tributary of the Liddel. It was built in 1244 and captured by the English in David II's reign. It was retaken by Sir William Douglas, who received a grant of it from the king *(c.* 1353). In 1492 Archibald Douglas, 5th earl of Angus, exchanged it for Bothwell castle on the Clyde with Patrick Hepburn, 1st earl of Bothwell. It passed to the duke of Buccleuch. It was there that Sir Alexander Ramsay of Dalhousie was starved to death by Sir William Douglas in 1342, and that James Hepburn, 4th earl of Bothwell, was visited in 1566 by Mary, queen of Scots, after being severely wounded by the outlaw Little Jock Elliot.

LIDDON, HENRY PARRY (1829–1890), English divine, was the son of a naval captain and was born at North Stoneham, Hampshire, on Aug. 20, 1829. He was educated at King's College school, London, and at Christ Church, Oxford. As vice-principal of the theological college at Cuddesdon (1854–59) and as vice-principal of St. Edmund's Hall, Oxford, he withstood the liberal reaction against Tractarianism, which had set in after Newman's secession in 1845. In 1864 he became prebendary of Salisbury cathedral. In 1866 he delivered his Bampton lectures on the *Divinity of Our Lord* (13th ed., 1889), which established his fame. In 1870 he was made canon of St. Paul's cathedral, London, where his preaching attracted vast crowds. In 1870 he had also been made Ireland professor of exegesis at Oxford. The combination of the two appointments gave him extensive influence over the Church of England. With Dean Richard Church he may be said to have restored the waning influence of the Tractarian school, and he succeeded in popularizing the opinions which, in the hands of Edward Pusey and John Keble, had appealed to thinkers and scholars. His forceful spirit was equally conspicuous in his opposition to the Church Discipline Act of 1874, and in his denunciation of the Bulgarian atrocities of 1876. In 1882 he resigned his professorship and utilized his thus increased leisure by travelling in Palestine and Egypt, and showed his interest in the Old Catholic movement by visiting Johann von Dollinger at Munich. In 1866 he became chancellor of St. Paul's, and it is said that he declined more than one offer of a bishopric. He died on Sept. g, 1890, in the full vigour of his intellect and at the zenith of his reputation. He had undertaken and nearly completed an elaborate life of Dr. Pusey, for whom his admiration was unbounded; and this work was completed after his death by Johnston and Wilson. Liddon's great influence during his life was caused by his personal fascination and the beauty of his pulpit oratory rather than by any high qualities of intellect. As a theologian his outlook was that of the 16th rather than the 19th century; and, reading his Bampton lectures now, it is difficult to realize how they could ever have been hailed as a great contribution to Christian apologetics. To the last he maintained the narrow standpoint of Pusey and Keble, in defiance of all the developments of modern thought and modern scholarship; and his latter years were embittered by the consciousness that the younger generation of the disciples of his school were beginning to make friends of the mammon of scientific unrighteousness. The publication in 1889 of *Lux Mundi*, a series of essays attempting to harmonize Anglican Catholic doctrine with modern thought, was a severe blow to him, for it showed that even at Oxford, the principles of Pusey were being departed from. Liddon's importance is now mainly historical. He was the last great popular exponent of the traditional Anglican orthodoxy. Beside the works mentioned, Liddon published several volumes of *Sermons*, a volume of Lent lectures entitled *Some Elements of Religion* (1870) and a collection of *Essays and Addresses* on such themes as Buddhism, Dante Alighieri, etc.

See J. Johnston, *Life and Letters of Dean Liddon.*

LIDICE, a mining village in Czechoslovakia, near the coal fields of Kladno. This unknown village sprang into world fame at the very day of its complete destruction, announced officially by the Germans on June 10, 1942. The Germans suspected that some inhabitants had supported the patriots who killed the German police general, Reinhard Heydrich, reichsprotektor for Bohemia and Moravia. According to official German statements, all the male inhabitants, irrespective of age. and j6 women mere immediately executed. The other women uere put into concentration camps; the children were carried off to correction schools, "all buildings of the village were levelled to the ground and the name of the village was immediately abolished." These actions aroused world-wide sympathy and protest. Towns in several countries were renamed to commemorate the Czech village. among them Lidice, Ill., near Joliet, U.S., inaugurated July 12, 1942, and Lidice, Mexico, formerly known as San Geronimo, near Mexico City.

LIDNER, BENGT (1757–1793), Swedish poet of the 18th-century romantic movement, was born at Goteborg on March 16, 1757. He studied at Lund, 1774–75, and spent three years in Germany and one in Paris. He died at Stockholm, Jan. 4, 1793.

Lidner's best works were written between 1783 and 1787. His subjects are spectacular. *Spastaras Dod* (1783), the text for a cantata, deals with a woman who attempts to rescue her son during an earthquake. Both are killed, and the poem follows the mother to heaven, where she meets Lidner's own mother, who had died when Lidner was a boy. In the operatic libretto *Medea* (1784), a deceived wife kills her sons on the stage. The heroine of the epic *Yttersta Domen* ("The Last Judgement"; 1788) is Eve: its opening. in which images of sound and light combine to evoke an intense atmosphere of death, is famous. Lidner's motto *"In lacrimis voluptas"* ("there is pleasure in tears") points to the pathetic element in his poetry and in his emotional life. He was musical, and his verse is melodious.

Lidner's *Samlade arbeten,* in 2 vol.. were published in 1788; there is an incomplete critical ed. (1930–39).

LIE, JONAS LAURITZ EDEMIL (1833–1908), Norwegian novelist, was born on Nov. 6, 1833, close to Hougsund (Eker), near Drammen. In 1838 his father being appointed sheriff of Tromso, the family moved to that arctic town. There he gained acquaintance with the wild seafaring life which he was afterward to describe. He went to the University of Christiania (Oslo), where Henrik Ibsen and Bjornstjerne Bjornson were among his fellow students. On completing his studies he began to practise as a solicitor in Kongsvinger. In 1860 he married his cousin, Thomasine Lie. who collaborated with him in his work.

In 1866 he published his first book. a volume of poems. Financial embarrassment drove him to Christiania to try his luck as a man of letters. As a journalist he had no success, but in 1870 he published a melancholy little romance, *Den Fremsynte* (Eng. trans., *The Visionary,* 1894), which made him famous. Lie proceeded to Rome and published *Tales* in 1871 and *Tremasteren "Fremtiden"* (Eng. trans., *The Barque "Future,"* 1879), a novel, in 1872. *Lodsen og hans Hustru (The Pilot and His Wife,* 1874), placed him at the head of Norwegian novelists, and brought him a small government stipend. Lie spent the next few years partly in Dresden, partly in Stuttgart. Back in Norway, he began a series of novels of life in Christiania. He returned to Germany, then moved to Paris (1882–91), and, after a year in Rome, returned to Norway. He died at Christiania on July 5, 1908. Two of his most successful novels were *The Commodore's Daughters* (1886) and *Niobe* (1894). In 1891–92 he wrote. under the influence of the new romantic impulse, 24 folk tales! 2 volumes entitled *Trold.* Some were translated by R. N. Bain in *Weird Tales* (1893), illustrated by L. Housman. His *Samlede Vaerker* were published at Copenhagen in 14 volumes (1902–04).

As a novelist he stands with those minute and unobtrusive painters of contemporary manners who defy arrangement in this or that school. (E. *G.;* X.)

LIE, (MARIUS) SOPHUS (1842–1899), Norwegian mathematician, who made significant contributions to the theories of algebraic invariants and differential equations, was born at Nordfjordeid, near Bergen, on Dec. 17, 1842. Educated at the University of Christiania (now Oslo), in 1869 he went to Berlin and there met Felix Klein. in conjunction with whom he afterward published several papers. In 1871 he was appointed assistant tutor in Christiania university, in the same year submitting for his doctor's degree his famous memoir *Geber Complexe, insbesondere Linien- und Kugel-Complexe, mit Anwendung auf die Theorie partieller Differential-Gleichungen,* in which he advanced the theory of tangential transformations. He was appointed extraordinary professor in 1872, and the following year began his researches on continuous transformation groups and discovered his transformation. making a sphere correspond to a straight line. In 1884 Ernst Engel went to assist Lie, and after nine years' work was published *Theorie der Transformationsgruppen* (3 vol., Leipzig, 1893), a work of wide range and great originality. It was followed by joint works with G. Scheffers *Geometrie der Berührungstransformationen* (1896). In 1886 Lie succeeded Klein in the chair of mathematics at Leipzig, Engel being appointed his assistant. In 1898 he returned to Christiania to accept a special post created for him, but his health was already broken and he died on Feb. 18, 1899. Besides his development of transformations, Lie made contributions to differential geometry; but his primary aim was the advancement of the theory of differential equations.

An analysis of Lie's works is given in the *Bibliotheca Mathematica* (1900); his collected works are contained in *Gesammelte Abhandlungen*, 6 vol. (1922–1937). (O. OE.; X.)

LIE, TRYGVE HALVDAN (1896–), Norwegian statesman, was the first secretary-general of the United Nations. He was born in Oslo, Norway, July 16, 1896. Educated at Oslo university, he became a leading Labour party lawyer and politician, and in 1940 became foreign minister of the Norwegian government-in-exile. On Feb. 1, 1946, he was elected UN secretary-general for a term of five years.

As secretary-general, Lie exercised and developed the political authority of his untried office in the Iran, Palestine and other cases, and, in 1950, undertook a "peace mission" to great power capitals designed to end the Soviet boycott over Chinese representation and to advance his "Twenty Year Peace program."

His important support of the UN police action in Korea led to his denunciation by the Soviet bloc, whose opposition to his renomination was overridden in 1951 by extending his term for three years. The barrier to his mediatorial activities raised by continuing Soviet refusal to recognize him as secretary-general was a principal cause of Lie's submitting his resignation in November, 1952, in a context of criticism of his personnel policies.

LIEBER, FRANCIS (1800–1872), U.S. political philosopher whose code of military regulations for the conduct of the federal troops in the Civil War became the basis of the Hague conventions of 1899 and 1907, was born in Berlin. Ger., on March 18, 1800. After studying mathematics at the universities of Jena, Halle and Dresden in 1820–21, he joined an expedition to free Greece from Turkish rule. On returning to Berlin in 1823, he was soon, as on a previous occasion, imprisoned without trial by the Prussian police on suspicion of being a revolutionary; he emigrated to the United States in 1827.

His first important venture in his new home was the *Encyclopaedia Americana* (13 vol., 1829–33). In 1835 he obtained the professorship of history and political economy at South Carolina college, where he made his reputation as a political theorist with his *Manual of Political Ethics* (2 vol., 1838–39), *Legal and Political Hermeneutics* (1839) and *On Civil Liberty and Self-Government* (1853). In 18j7, when Columbia college in New York city began to expand into a university, Lieber was appointed to the new chair of history and political science, and in 1865 he became professor of constitutional history and public law in the Columbia law school. During the Civil War, while a member of a war department board, he prepared the codified *Instructions for the Government of the Armies of the United States in the Field*, which was issued by the adjutant general's office as *General Orders No. 100* (1863). This codification became international law through embodiment in the Hague conventions of 1899 and 1907.

To Lieber, the national polity was the normal type of government in modern civilization. However, he deprecated "centralization," which he described as the converging of all the "rays of power into one central point"; whereas nationalization was the "diffusion of the same life blood through a system of arteries, throughout the body politic." His most distinctive contribution was the view that civil liberty could be realized only through the development of a "vast system of (self-governing) institutions, where number supports the whole, as the many pillars support the rotunda of our capitol." Lieber died on Oct. 2, 1872.

LIEBERMANN, MAX (1847–1935), painter and etcher, who became a leader of the German Impressionist school, was born in Berlin on July 20, 1847. After studying under Steffeck, he entered the school of art at Weimar in 1869. Though the straightforward simplicity of his first exhibited picture, "Women Plucking Geese" (Berlin, National gallery) in 1872, presented already a striking contrast to the art then in vogue, it was heavy and bituminous in colour. In his course he was confirmed by Michael von Munkacsy's influence in Paris in 1872. A summer spent at Barbizon in 1873, where he became acquainted with Jean François Millet and studied the works of Jean Baptiste Corot, Constant Troyon and Charles Daubigny, resulted in the brightening of his palette. He subsequently went to the Netherlands, where the example of Josef Israels confirmed him in the method he had adopted at Barbizon; on his return to Munich in 1878 he caused much unfavourable criticism by his realistic painting of "Christ in the Temple," which was condemned by the clergy as irreverent. His later work showed the influence of French and German Impressionism, overlaid with his personal style. He devoted himself exclusively to the study of light and to the painting of the life of humble folk. He found his best subjects in the orphanages and asylums for the old in Amsterdam, among the peasants of the Netherlands, and in the beer gardens, factories and workrooms of his own country.

Liebermann did for his country what Millet did for France. His pictures hold the fragrance of the soil. His people move in their proper atmosphere and their life is stated in all its monotonous simplicity. His work being at variance with the academic tradition he became the leader of the *Berliner Sezession (see* PAINTING: *Expressionism and the German school)*. His first success was a medal awarded him for "An Asylum for Old Men" at the 1881 salon. Then followed "The Cobbler's Shop" (1881) and "The Flax Spinners" (1887). In 1884 he settled in Berlin, where he became president of the academy. Liebermann's painting and etchings are represented in many of the leading continental galleries. He died in 1935.

LIEBIG, JUSTUS VON, BARON (1803–1873), German chemist and biochemist, who synthesized chloroform and with Friedrich Wohler established the existence of organic radicals, was born at Darmstadt on May 12, 1803. His father, a dealer in chemicals and colours, occasionally made experiments in the hope of improving his processes and, thus the son early acquired familiarity with practical chemistry. For the theoretical side he read all the textbooks which he could find, somewhat to the detriment of his ordinary school studies. Having determined to make chemistry his profession, at the age of 15 he entered the shop of an apothecary at Appenheim, near Darmstadt; but he soon found how great is the difference between pharmacy and scientific chemistry, and the explosions and other incidents that accompanied his private efforts to increase his chemical knowledge disposed his master to view without regret his departure at the end of ten months. In 1820 he entered the University of Bonn, but migrated to Erlangen when the professor of chemistry, K. W. G. Kastner (1783–1857), was appointed in 1821 to the chair of physics and chemistry at the latter university. He followed this professor to learn how to analyze certain minerals, but in the end he found that the teacher himself was ignorant of the process. Indeed, as he himself said afterward, it was a wretched time for chemistry in Germany. No laboratories were accessible to ordinary students, who had to content themselves with what the universities could give in the lecture room and the library, and though both at Bonn and Erlangen Liebig endeavoured to make up for the deficiencies of the official instruction by founding a students' physical and chemical society for the discussion of new discoveries and speculations, he felt that he could never become a chemist in his own country. Therefore, having been graduated as Ph.D. in 1822, he left Erlangen—where he subsequently complained that the contagion of the "greatest philosopher and metaphysician of the century" (Friedrich von Schelling), in a period "rich in words and ideas, but poor in true knowledge and genuine studies," had cost him two precious years of his life—and by the liberality of Louis I, grand duke of Hesse-Darmstadt, was enabled to go to Paris.

There by the help of Louis J. Thénard he gained admission to the private laboratory of H. F. Gaultier de Claubry (1792–1873), professor of chemistry at the École de Pharmacie, and soon afterard. by the influence of Alexander von Humboldt. to that of Joseph Gay-Lussac. He attended lectures of Gay-Lussac, Thénard, Pierre Dulong, Alexis Petit, Pierre Laplace and Georges Cuvier. There he concluded, in 1824, his investigations of the fulminates. It was on Humboldt's advice that he determined to become a teacher of chemistry, but difficulties stood in his way. As a native of Hesse-Darmstadt he ought, according to the academical rules of the time, to have studied at and been graduated from the University of Giessen, and it was only through the influence of Humboldt that the authorities forgave him for straying to the foreign University of Erlangen. After examination, his Erlangen degree was recognized, and in 1824 he was appointed extraordinary professor of chemistry at Giessen, becoming ordinary professor two years later. In this small town his most important work was accomplished. His first care was to persuade the Darmstadt government to provide a chemical laboratory in which the students might obtain a proper practical training. The laboratory, unique of its kind at the time, in conjunction with Liebig's unrivaled gifts as a teacher, soon rendered Giessen the most famous chemical school in the world; men flocked from every country to enjoy its advantages, and many of the most accomplished chemists of the 19th century (*e.g.*, August W. von Hofmann, Charles A. Wurtz, Sir Edward Frankland, Friedrich A. Kekulé von Stradonitz, Charles F. Gerhardt, *qq.v.*) had it to thank for their early training. Further, it gave a great impetus to the progress of chemical education throughout Germany, for the continued admonitions of Liebig combined with the influence of his pupils induced many other universities to build laboratories modeled on the same plan. Ennobled in 1845, Liebig remained at Giessen for 28 years, until in 1852 he became professor of chemistry at Munich university, and this office he held, although he was offered the chair of chemistry at Berlin in 1865, until his death, which occurred at Munich on April 18, 1873. His grave is in the Alt Süd Friedhof.

Pure Chemistry.—Here Liebig's work includes improvements in technique of organic analysis, his method for determining the natural alkaloids and for ascertaining the molecular weights of organic bases by means of their chloroplatinates, his process for determining the quantity of urea in a solution, and his invention of the potash bulb, formerly known in every laboratory. He did not invent the condenser commonly known as the "Liebig" condenser, but popularized its use. His contributions to inorganic chemistry were numerous, including investigations on the compounds of antimony, aluminum, silicon, etc., on the separation of nickel and cobalt and on the analysis of mineral waters; but they are outweighed in importance by his work on organic substances. In this domain his first research was on the fulminates of mercury and silver, and study of these substances led him to the discovery of the isomerism of cyanic and fulminic acids. Further work on cyanogen and related substances yielded a great number of interesting derivatives. He also described an improved method for the manufacture of potassium cyanide and for the analysis of cyanides by titration with silver nitrate.

In 1832 he published, jointly with Friedrich Wohler (*q.v.*), one of the most famous papers in the history of chemistry, that on the oil of bitter almonds (benzaldehyde), wherein it was shown that the radical benzoyl might be regarded as forming an unchanging constituent of a long series of compounds. Jöns J. Berzelius hailed this discovery as marking the dawn of a new era in organic chemistry. A continuation of their work on bitter almond oil by Liebig and Wohler resulted in the elucidation of the mode of formation of that substance and in the discovery of the ferment emulsin as well as the recognition of the first glucoside, amygdalin. Another and not less important and far-reaching inquiry in which they collaborated was that on uric acid, published in 1837. About 1832 he began his investigations into the constitution of ether and alcohol and their derivatives. These on the one hand resulted in the enunciation of his ethyl theory, by the light of which he looked upon those substances as compounds of the radical ethyl; on the other they yielded chloroform, chloral and aldehyde, as well as other compounds, and also the method of forming mirrors by depositing silver from a slightly ammoniacal solution by acetaldehyde. In 1837, with J. B. A. Dumas, he published a note on the constitution of organic acids, and in the following year an elaborate paper on the same subject appeared under his name alone; by this work Thomas Graham's doctrine of polybasicity was extended to the organic acids. Liebig also did much to further the hydrogen theory of acids.

Animal and Vegetable Physiology.—These and other studies in pure chemistry mainly occupied his attention until about 1838, but the last 35 years of his life were devoted more particularly to the chemistry of the processes of life, both animal and vegetable. In animal physiology he attempted to trace out the operation of chemical and physical laws in the maintenance of life and health. To this end he examined such vital products as blood, bile and urine; he analyzed the juices of flesh, establishing the composition of creatine and investigating its decomposition products, creatinine and sarcosine; he classified the various articles of food in accordance with the special function performed by each in the animal economy and expounded the philosophy of cooking. In opposition to many of the medical opinions of his time he taught that the heat of the body is the result of the processes of combustion and oxidation performed within the organism. A secondary result of this line of study was the preparation of his food for infants and of his world-famous extract of meat.

Vegetable physiology he pursued with special reference to agriculture. His first publication on this subject was *Die Chemie in ihrer Anwendung auf Agricultur und Physiologie* in 1840, which was at once translated into English by Lyon Playfair. Rejecting the old notion that plants derive their nourishment from humus, he taught that they get carbon and nitrogen from the carbon dioxide and ammonia present in the atmosphere, these compounds being returned by them to the atmosphere by the processes of putrefaction and fermentation, while their potash, soda, lime, sulfur, phosphorus, etc., come from the soil. Of the carbon dioxide and ammonia no exhaustion can take place, but of the mineral constituents the supply is limited because the soil can not afford an indefinite amount of them; hence, the chief care of the farmer, and the function of manures, is to restore to the soil those minerals which each crop is found, by the analysis of its ashes, to take up in its growth. On this theory he prepared artificial manures containing the essential mineral substances together with a small quantity of ammoniacal salts, because he held that the air does not supply ammonia fast enough in certain cases, and carried out systematic experiments on ten acres of poor sandy land which he obtained from the town of Giessen in 1845. But in practice the results were not wholly satisfactory, and it was a long time before he recognized one important reason for the failure in the fact that to prevent the alkalis from being washed away by the rain he had taken pains to add them in an insoluble form, whereas, as was ultimately suggested to him by experiments performed by J. T. Way about 1850, this precaution was not only superfluous but harmful, because the soil possesses a power of absorbing the soluble saline matters required by plants and of retaining them, in spite of rain, for assimilation by the roots.

Liebig's literary activity was very great. The Royal society's *Catalogue of Scientific Papers* enumerates 318 memoirs under his name, exclusive of many others published in collaboration with other investigators. In 1832 he founded the *Annalen der Pharmazie*, which became the *Annalen der Chemie und Pharmazie* in 1840 when Wohler became joint editor with him, and *Annalen der Chemie* in 1874. In 1837 with Wohler and Johann Poggendorff he established the *Handworterbuch der reinen und angewandten Chemie*. After the death of Berzelius he continued the *Jahresbericht* with H. F. M. Kopp.

The following are his most important separate publications, many of which were translated into English and French almost as soon as they appeared: *Anleitung zur Analyse der organischen Körper* (1837); *Die Chemic in ihrer Anwendung auf Agrikultur und Physiologie* (1840); *Die Thier-Chemie* (1842); *Handbuch der organischen Chemie* (1843); *Chemische Briefe* (1844); *Chemische Cntersuchungen über das Fleisch* (1847); *Die Grundsatze der Agrikultur-Chemie* (1855); *Über Theorie und Praxis in der Landwirthschaft* (1856); *Naturwissenschaftliche Briefe* (1859). A posthumous collection of his miscellaneous addresses and publications appeared in 1874 as *Reden und Abhandlungen,* edited by his son George (b. 1827). His criticism of Francis Bacon, *Über Francis von Verulam,* was first published in 1863 in the *Augsburger allgemeine Zeitung,* where also most of his letters on chemistry made their first appearance. His autobiographical notes appeared in *Berichte der deutschen chemischen Gesellschaft* (1890).

BIBLIOGRAPHY.—*The Life Work of Liebig* (1876) by his pupil August W. von Hofmann, which is the Faraday lecture delivered before the London Chemical society in March 1875, and is reprinted in Hofmann's *Zur Erinnerung an vorangegangene Freunde;* also W. A. Shenstone, *Justus von Liebig, his Life and Work* (1895); J. Volhard, *Justus von Liebig,* 2 vol. (1909); R. Blunck, *Justus von Liebig* (1938); R. Winderlich, essay in G. Bugge's *Buch der grossen Chemiker* (1929–30); Theodor Heuss, *Justus von Liebig* (1942); H. von Dechend, *Justus von Liebig* (1953); R. E. Oesper, *Journal of Chemical Education* (1927). His extensive correspondence with Wöhler, C. F. Schonbein. K'F Mohr and Berzelius was published, as were his letters to his parents The laboratory at Giessen and the birth house at Darmstadt were made into museums. Imposing monuments were erected at Giessen and Munich.

LIEBKNECHT, KARL (1871–1919), German socialist, was born in Leipzig on Aug. 13, 1871. The son of Wilhelm Liebknecht (*q.v.*), he qualified as a lawyer, and became a prominent member of the extreme left wing of the Social Democrat party. After serving a sentence of 18 months' imprisonment for high treason, in 1908 he was elected to the Prussian chamber of deputies and in 1912 entered the reichstag as a Social Democrat. He was one of a small group who refused to vote war credits in 1914. He violently opposed the war and the successive votes of credit. He organized antiwar demonstrations, and in 1916 gave the police the desired opportunity for arresting him by shouting "down with the war" to some troops passing through the Potsdamer Platz. He was condemned to two years' penal servitude, and was released only on Oct. 22, 1918. Before his imprisonment he had founded the international group, later the Spartacus Union, the policy of which was based on the full execution of the Erfurt program. Liebknecht's condemnation was the signal for a strike of the metalworkers in Berlin organized by the Spartacists independently of the trade unions. On his release in 1918 he placed himself at the head of the Spartacists and demanded a "free socialist republic," but the independent socialists had joined hands with the Ebert party, and Liebknecht's efforts failed. During the insurrection of the Spartacists in Jan. 1919 Liebknecht was arrested; while being conveyed from military headquarters in the west end of Berlin to the prison at Moabit on Jan. 15, he was brutally murdered, on the usual pretext of attempted escape. His comrade, Rosa Luxemburg, perished the same night. Their bodies were thrown into the canal; Liebknecht's was recovered and received a public funeral.

See his *Militarismus und Antimilitarismus* (1908, Eng. trans. 1918); *Briefe aus dem Felde, aus der Untersuchungschaft und aus dem Zuchthaus* (1919); H. Schumann, *Karl Liebknecht, ein unpolitisches Bild* (1919).

LIEBKNECHT, WILHELM (1826–1900), German socialist, was born at Giessen on March 29, 1826. Left an orphan at an early age, he was educated at the *gymnasium* in his native town, and attended the universities of Giessen, Bonn and Marburg. Before he left school he had become affected by the political discontent then general in Germany; he had already studied the writings of St. Simon, from which he gained his first interest in communism, and had been converted to the extreme republican theories of which Giessen was a centre. He soon came into conflict with the authorities, and was expelled from Berlin apparently in consequence of the strong sympathy he displayed for some Poles, who were being tried for high treason. He proposed in 1846 to migrate to America, but went instead to Switzerland, where he earned his living as a teacher. As soon as the revolution of 1848 broke out he hastened to Paris, but the attempt to organize a republican corps for the invasion of Germany mas prevented by the government. In September, however, in concert with Gustav von Struve, he crossed the Rhine from Switzerland at the head of a band of volunteers, and proclaimed a republic in Baden. The attempt collapsed; he was captured, and, after suffering eight months' imprisonment, was brought to trial. Fortunately for him, a new rising had just broken out, the mob burst into the court, and he was acquitted. During the short duration of the revolutionary government he was an active member of the most extreme party, but on the arrival of the Prussian troops he succeeded in escaping to France. Thence he went to Geneva, where he came into intercourse with Giuseppe Mazzini; but, unlike most of the German exiles, he was already an adherent of the socialist creed, which at that time was more strongly held in France. Expelled from Switzerland he went to London, where he lived for 13 years in close association with Karl Marx. He endured great hardships, but secured a livelihood by teaching and writing; he was a correspondent of the *Augsburger Allgemeine Zeitung.* The amnesty of 1861 opened for him the way back to Germany, and in 1862 he accepted the post of editor of the *Norddeutsche Allgemeine Zeitung,* the founder of which was an old revolutionist. Only a few months elapsed before the paper passed under Bismarck's influence. There is no more curious episode in German history than the success with which Bismarck acquired the services of many of the men of 1848, but Liebknecht remained faithful to his principles and resigned his editorship. He became a member of the *Arbeiterverein,* and after the death of Ferdinand Lasalle he was the chief mouthpiece in Germany of Karl Marx, and was instrumental in spreading the influence of the newly-founded *International.* Expelled from Prussia in 1865, he settled at Leipzig, and it is primarily to his activity in Saxony among the newly-formed unions of workers that the modern Social Democrat party owes its origin. Here he conducted the *Demokratisches Wochenblatt.* In 1867 he was elected a member of the north German reichstag, but in opposition to Lasalle's followers he refused all compromise with the "capitalists," and avowedly used his position merely for purposes of agitation while taking every opportunity for making the parliament ridiculous. He was strongly influenced by the "great German" traditions of the democrats of 1848, and, violently anti-Prussian, he distinguished himself by his attacks on the policy of 1866 and the "revolution from above," and by his opposition to every form of militarism. His adherence to the traditions of 1848 are also seen in his dread of Russia, which he maintained to his death. His opposition to the war of 1870 exposed him to insults and violence, and in 1872 he was condemned to two years' imprisonment in a fortress for treasonable intentions. The union of the German Socialists in 1874 at the congress of Gotha was really a triumph of his influence, and from that time he was regarded as founder and leader of the party. From 1874 till his death he was a member of the German *Reichstag,* and for many years of the Saxon diet. In 1881 he was expelled from Leipzig, but took up his residence in a neighbouring village. Liebknecht was the author of: *Robert Blum und seine Zeit* (Nuremberg, 1892); *Geschichte der Französischen Revolution* (Dresden, 1890); *Die Emser Depesche* (Nuremberg, 1899) and *Robert Owen* (Nuremberg, 1892). He died at Charlottenburg on Aug. 7, 1900.

LIECHTENSTEIN, one of the smallest independent sovereign states of Europe, 60 6 sq.mi. in extent. Separated on the west by the Rhine a few miles below Lake Constance from the Swiss canton of St. Gallen, it is bounded on the east by Austrian Vorarlberg, and on the south by the western crests of the Rhatikon, between Liechtenstein and Graubiinden. Snitz. The major physical divisions are (1) a small narron strip along the Rhine valley, widening northnard into the triangular lonland of the confluence of the Rhine and the tributary Ill; (2) the larger upland area, practically bisected by the Samina which feeds the Ill. The highest peaks lie southward, with Falknis (8,399 ft.), central south, and Naafkopf (8,432 ft.), southeast, at the meeting points of the three frontiers. The chief settlements are at the western foot of the uplands and not on the Rhine itself. In order from the south, they are Balzers. Triesen, Vaduz (capital and seat of government, pop. 1960, 3,398), Schaan and Nendeln. They are linked by the road joining Ragaz, Switz.. with Feldkirch, Aus. Two small settlements, Eschen and Mauern, lie in the northern triangular lowland. Liechtenstein's only railway crosses the centre of the western frontier from Buchs, Switz., and then parallels the road through Schaan and Nendeln. The population in 1960 was 16,628. largely German in origin and speech, Roman Catholic in religion and agricultural in interest. Corn, wine and fruit are grown and cattle are reared. There are also small manufactures of cotton, leather and false teeth.

The principality, founded in 1719, consisted of the lordships of Schellenburg and Vaduz, and formed part of the Holy Roman empire. It was included from 1806 to 1815 in the Rhine confederation, and from 1815 to 1866 in the German confederation. In 1866 it became independent. Prince John II (1840–1929) succeeded his father in 1858. The constitution, after 1921, provided a *Landtag* of 1 j members elected by direct vote; suffrage is universal The standing army was abolished in 1868. Until 1919 Liechtenstein was closely allied with Austria; in 1921 it adopted Swiss currency, and after 1924 it was included in the Swiss customs union. Switzerland administers its telegraph and postal services Francis I (1853–1938) succeeded his brother in 1929, and was in turn succeeded by his great-nephew, Francis Joseph II. in 1938.

The principality, not a member of the Cnited Nations. expressed the wish in 1949 to become a party to the statute of the International Court of Justice. On July 27 the Security council agreed by nine votes with two abstentions to grant this request and a similar resolution was adopted in December by the general assembly.

In the early 1960s the yearly average budget revenue exceeded 11,000,000 fr. Most of the revenue comes from taxes, but about one-fourth is derived from the sale of stamps.

LIÈGE,[1] one of the nine provinces of Belgium, the successor of the old prince-bishopric, touching on the east Dutch Limburg and Germany. Its towns are Likge. Herstal, Verviers. Spa, Seraing, Huy, etc. The Meuse flows through the centre. and its valley from Huy to Herstal is one of the most productive mineral districts in Belgium. Agriculture in the Condroz district south of the Meuse has been much developed.

There are four administrative *arrondissements,* 28 cantons and 373 communes. The districts of Eupen, Malmédy, St. Vith and the former neutral district of Moresnet after 1919 became part of the province. Area 1,521 sq.mi. Pop. (1955 est.) 994,185 or 654 per square mile.

LIÈGE[1] (Flemish LUIK, German LÜTTICH), the chief town of the province of Likge, Belg., and between c. 1000 and 1795 the capital of the principality of Liège, lies on the Meuse at its confluence nith the Ourthe. Pop. (1947) 156,208, (195j) 154,924.

Likge is the largest French-speaking city in Belgium and the third most important river port of western Europe. The Meuse, which is deep enough to take Rhenish boats of more than 2.000 tons and some seagoing ships, connects the city with other Belgian industrial districts and with those of northern and eastern France and of the Netherlands. There is a heliport in the town. After Antwerp the most important rail centre of Belgium, Likge is also the meeting place of the great Paris-Berlin and Amsterdam-Basel roads. The Meuse flows through the centre of the town. The old part on the left bank, comprising the residential quarter, is the largest part of the city. There are several parks, one of which, the Square d'Avroy, is close to the large boulevard which runs through the city. To the west of this park are the botanic gardens.

The cathedral, which stands to the north of the Square d'Avroy, is one of many Romanesque and Gothic churches; others include St. Bartholomew's. St. Denis's, St. James's. St. John's. St. Cross and St. Martin's. The city has concert halls. theatres and an opera house. The museums of fine art and of Walloon art have a particularly fine collection of French painting from Ingres to Picasso. The Curtius and Ansembourg museums for archaeology and decorative arts house important examples of Mosan art (artifacts of the Meuse valley) and an international collection of glass. Liège has a university (1816) with well-known faculties in the fields of engineering. philology and history. The Royal Academy of Music nas founded in 188; and is famous for its violin school established by Eugene Isaye. The most important modern building in the city is the Palais des Congres (1957–58); the central university building was finished in the 20th century.

There are also several research laboratories and technical schools associated with the major industries of Liege. such as the Belgian centre for the study of water. the national centre for metallurgical research. the coal industry's national institute and a section of the nuclear sciences interuniversity institute. Liege has been an important industrial centre for many years, due, in great part. to its easy accessibility by water and road and to the presence of coal. The largest finished product is steel and of that almost one half is in the form of rolled steel. The manufacture of weapons is still an important industry.

Men have lived in the area of Liège in Paleolithic. Neolithic, Roman and Frankish times. The city. which came into being during the 8th century nhen a bishopric was established, took advantage of its favourable geographic position near the Carolingian settlements of Jupille, Herstal and Aix-la-Chapelle. About the year 1000, under the ponerful bishop Notger. it grew greatly in importance; it was the centre of Mosan art and it became one of the most famous intellectual cities of the west.

In 1131 Pope Innocent II met King Lothair (later emperor) at Liège at a council attended by St. Bernard. Its status nas that of an independent principality ruled by the prince-bishops. under the Holy Roman emperor. It was given a communal magistracy in 1185 and the strengthening of its municipal power was accompanied in the 13th and 14th centuries by sociopolitical struggles in which the town council, the cathedral chapter and the trade guilds took part.

On June 3. 1208, Philip. duke of Swabia and king of the Romans. confirmed the charter of Bishop Albert de Cuyck (1195–1200) which granted important rights to the citizens. The night of Aug. 3–4, 1312, was disastrous for the nobles and other members of the upper class and on Feb. 14, 1313, a peace was made granting political equality to the labourers and a preponderance of the trades. In the 1 jth century. during the Burgundian domination of the Netherlands, Liege was attacked by Charles the Bold and the city was ruthlessly sacked (1468). After the fall of the Burgundian power in Liège in 1477 the city was rebuilt. In the first part of the 16th century, under the prince-bishop Erard de la Marck, there was a vigorous movement in the arts deriving from the medieval rather than the Italian style. In the 17th century, when industrialization started, internal strife between the Chiroux (the pro-prince party) and the Grignoux was aggravated by the intervention of Richelieu and Mazarin. In 1684, after hard fighting. the prince-bishop Maximilian Henry of Bavaria destroyed all democratic institutions. In 1691 Liege was bombarded by the French artillery. For a century the nobles and upper classes flourished undisturbed. but their rule was ended in 1789 by a bloodless revolution. In 1795, Likge was formally joined to France, becoming chief town of the *département* of the Ourthe, and so remained until 1814 when the first treaty of Paris detached it. In 181j, the whole of the *département* of Meuse-et-Ourthe (created in 1814) was awarded to the kingdom of the Netherlands by the Congress of Vienna.

In the Belgian revolution of 1830, the Liegois under Charles Rogier played an important part: and, on Oct. 28, Liege became

[1] Liege was always spelled with a grave accent until after World War I, when the spelling with the acute accent prevailed. The grave accent was again officially decided upon in 1951.

part of Belgium. From this time, the city expanded, and its arms industry became one of the foremost in Europe. In World War I the battle of Liège (Aug. 4–16: 1914) delayed the advance of the Germans and it was only after fierce fighting that the city fell. During World War II, when Liège was the centre of the Belgian resistance, the city was heavily bombarded but the historic buildings were not badly damaged.

Jean le Bel, the 14th-century chronicler. was a native of Liège, which has numbered among its citizens many men who have made important contributions to industry, music (César Franck) and art. Three dignitaries of the ancient cathedral of Saint-Lambert became popes under the names of Crban IV, Gregory X and Innocent VI.

LIEGE, an adjective of uncertain derivation which seems originally to have meant "simple," "unconditioned." The word is historically important because it was early used as a qualification of legal terms such as homage. In feudal law, liege homage is the homage due from a tenant to his chief lord. In course of time the idea prevailed that liege homage was due to the king. above and beyond the homage done to any immediate lords. From this idea is ultimately derived the employment of the abstract noun "allegiance." to denote the subject's duty to his sovereign.

See F. Pollock and F. W. Maitland, *History of English Law* (2nd ed., 1898). i, 298–300.

LIEGNITZ, a town of Poland, formerly in the Prussian province of Silesia. Ger., on the Katzbach, just above its junction with the Schwarzwasser. and 40 mi. W.N.W. of Breslau (Wroclaw), on the main line of railway to Berlin via Sommerfeld. Pop. (1950) 39,000. Liegnitz is first mentioned in a historical document in the year 1004. In 1163 it became the seat of the dukes of Liegnitz. who greatly improved and enlarged it. and who are buried in the church of St. John. On the death of the last duke of Liegnitz in 1675, the duchy came into the possession of the empire. which retained it until the Prussian conquest of Silesia in 1742. On Aug. 15, 1760, Frederick the Great gained a decisive victory near Liegnitz over the Austrians. It consists of an old town, and several suburbs. The palace. formerly the residence of the dukes of Liegnitz. and rebuilt after a fire in 1835, is used as the administrative offices of the district. The Ritter Akademie, founded by the Emperor Joseph I, was reconstructed as a gymnasium in 1810. The church of SS. Peter and Paul (restored in 1892–94) dates from the 14th century. The manufactures are considerable. the chief articles made being cloth, wool, leather, tobacco, pianos, clogs, sugar, and machinery. Its trade in grain and its cattle markets and market gardens are likewise important. Following World War II, Silesia was annexed by Poland and Liegnitz became Legnica, Wroclaw province.

LIEN. The word lien signifies the right of a person in possession of property belonging to another to detain such property until some debt or demand in connection with the property detained is satisfied. This right of lien arises either by implication of law or by express contract. Where, however, an express contract for security is made between parties such agreement excludes, to the extent of the express contract, any lien upon property to which it might otherwise have been subject. The possessory right conferred by lien is not a right ad rem, that is to say it does not convey to the person in possession of goods any property in them, it merely gives him a legal right to retain them until his demand is satisfied. Consequently, apart from statute or legal process authorizing him so to do, he is not entitled to sell the goods to recover what is due to him.

If the goods be not in possession of the claimant of lien, as in the case of the furniture of a tenant owing rent to a landlord, the law will indeed assist the landlord to seize the property and enable him to sell it in due course in order to pay himself out of the proceeds, but it will not give him any property in the furniture itself.

There are two descriptions of lien recognized by the English law: particular and general. Particular liens exist where persons have a right to retain possession of property in respect of labour or money expended by them on the identical chattel which constitutes the res gestae or subject matter of the dispute. Liens of this description are usually favourably regarded by the court. General liens are claims made in respect of a general balance of account between the parties.

Liens are created in three ways, either (1) by express contract, (2) by usage of trade or (3) by some legal relation between the parties, where there is no express contract, nor any usage of trade. The term legal relation applies either to those persons on whom the law throws an obligation to perform certain services whenever required so to do by any member of the public, such as an innkeeper or a common carrier, or else to a person who usefully expends time, work or money on the reparation of the chattel of another, such as a jobbing tailor, a boot repairer, a furrier, a calico printer, or indeed any person to whom goods are delivered in order to have some service performed in connection with them for which such delivery is necessary. But the mere safeguarding of the article, apart from work done upon it, will convey no right to lien in this particular form of deposit.

Again, a shipmaster (on behalf of the ouner) has a lien upon cargo for freight; and if, upon landing, notice of such lien is given to the wharfinger or narehouseman, the cargo is bound thereby in his hands, and may be subsequently sold by him upon compliance with statutory conditions (Merchant Shipping act, 1894, secs. 494–498). And a like rule applies to passengers' luggage (except wearing apparel actually in use) for unpaid passage money.

A claim to general lien, though, as already stated, not regarded with favour by the courts, may be established by special or necessarily implied agreement, or by the custom of a certain trade. By virtue of accepted custom of trade or profession, wharfingers, bankers, insurance brokers and solicitors have a lien upon the property of their employers, not only for debts arising out of the particular transaction for which the property was delivered to them, but also for a general balance of account between the parties, and this rule has been held to apply to statute barred debts (*Courtenay* v. *Williams*, 3 Hare at p. 552).

A similar principle as to general balance of account has been held applicable to the lien of calico printers and packers and locally (by the custom of Exeter) to fullers. The right to general lien is, however, incapable of transference.

Maritime Lien differs from all other forms of lien in that it neither includes nor requires actual physical possession of the ship in respect of which a maritime lien arises. It presupposes the giving of a credit coupled with a postponement intentionally made of the right to enforce it. It follows as a necessary consequence that unless the creditor has forfeited the right because of his own laches he can take legal proceedings against the ship notwithstanding any change there may have been in the ownership, and he has priority over all other titles to the ship which are not based on superior or equal liens, including mortgages already existing. It is otherwise with an existing possessory lien of a ship repairer. (Carver's Carriage by Sea, 55. 320, 692.)

The principal instances in which the law recognizes maritime liens are bottomry (*q.v.*) (*i.e.,* mortgage of ship's keel), salvage wages, master's wages, disbursements, liabilities, damage from collision, in which case the lien attaches to the wrong-doing ship.

Right of Sale or Transference of Lien.—Apart from statute a mere lien confers no right of sale on the party entitled to retain the chattels against the true owner, even if the detention be attended with trouble and expense (Thames Iron Company v. Patent Derrick *Company,* 1860, 29 L.J., ch. 714). A statutory right of sale, however, of any goods left by a guest in his custody enures, after six weeks, to an innkeeper for the amount of his bill, by virtue of the Innkeepers act, 1878 (sec. 1). By the Merchant Shipping act, 1894 (secs. 497–498), a wharfinger or warehouseman, at the expiration of 90 days from the time when goods are placed in his custody (or a shorter time if the goods be perishable) is entitled to sell them by public auction; and sec. 97 of the Railway Clauses act, 1845, authorizes railway companies to detain and sell any goods delivered to them for carriage upon default of payment of their tolls. Neither the custody of the chattel nor the accompanying lien is capable of legal transference to a third party, who is consequently, after demand and refusal, liable in trover to the true owner of the goods.

The lien of an unpaid vendor for the price of the article which he has sold to an insolvent purchaser subsists until the chattel has either been actually or constructively delivered into the hands of the latter. This lien for the price of specific goods is not determined by the mere delivery of the chattels to a carrier for the purpose of conveyance. Consequently, if the vendor can arrest the goods at any stage of the transit before they reach the hands of the purchaser or his agent the vendor reverts to the same position as if he had not parted with the possession of the goods.

The right is not devested by the purchaser endorsing over a bill of lading of the goods by way of security or for valuable consideration to a third party, with notice of the consignee's insolvency, or by a purchaser's subsale of the goods before the termination of the *transitus*, without delivery of the documents of title to an innocent third party.

Waiver and Determination of Lien.—A lien may be waived, and the right to assert the claim lost, by conduct on the part of the holder of the goods obviously inconsistent with the existence of such a right. A lien is determined by actual payment or tender of the full amount of the legal claim for which the goods are detained, but part payment of such demand is not sufficient, neither is a general tender or offer to discharge the claim without actual tender or what, in point of law, is equivalent thereto. (W. W -P.)

U.S. Differences.—In the United States, speaking generally, the law relating to liens is that of England, but there are some considerable differences occasioned by three principal causes. (1) Some of the southern states, notably Louisiana, have never adopted the common law of England. When that state became one of the United States of North America it had (and still preserves) its own system of law. In this respect the law is practically identical with the Code Napoleon, which, again speaking generally, substitutes privileges for liens, *i.e.,* gives certain claims a prior right to others against particular property. These privileges being *strictissimae interpretationis*, can not be extended by any principle analogous to the English doctrine of equitable liens. (2) Probably in consequence of the United States and the several states composing it having had a more democratic government than Great Britain, in their earlier years at all events, certain liens have been created by statute in several states in the interest of the working classes which have no parallel in Great Britain, *e.g.,* in some states workmen employed in building a house or a ship have a lien upon the building or structure itself for their unpaid wages. This statutory lien partakes rather of the nature of an equitable than of a common-law lien, as the property is not in the possession of the workman, and it may be doubted whether the right thus conferred is more beneficial to the workman than the priority his wages have in bankruptcy proceedings in England. Some of the states have also practically extended the maritime lien to matters over which it was never contended for in England. (3) By the constitution of the United States the admiralty and interstate jurisdiction is vested in the federal as distinguished from the state courts, and these federal courts have not been liable to have their jurisdiction curtailed by prohibition from courts of common law, as the court of admiralty had in England up to the time of the Judicature acts; consequently the maritime lien in the United States extends further than it does in England, even after recent enlargements; it covers claims for necessaries and by materialmen, as well as collision, salvage, wages, bottomry and damage to cargo.

Difficulties connected with lien occasionally arise in the federal courts in admiralty cases, from a conflict on the subject between the municipal law of the state where the court happens to sit and the admiralty law; but as there is no power to prohibit the federal court, its view of the admiralty law based on the civil law prevails. More serious difficulties arise where a federal court has to try interstate questions, where the two states have different laws on the subject of lien; one for example, like Louisiana, following the civil law, and the other the common law and equitable practice of Great Britain. The question as to which law is to govern in such a case can hardly be said to be decided. "The question whether equitable liens can exist to be enforced in Louisiana by the federal courts, notwithstanding its restrictive law of privileges, is still an open one" (Derris, *Contracts* of *Pledge*, 517; and see *Burdon Sugar Refining Co.* v. *Payne*, 167 U.S. 127).

LIEPĀJA (LIPAYA; Russian LIVAVA), a seaport of Latvia in 56° 32′ N., 21° 2′ E., at the northern extremity of a narrow sandy peninsula which separates Lake Libau (12 mi. long and 2 mi. wide) from the Baltic sea. Pop. (1959) 71,000. There are four harbours: the Commercial, with stone quays. storehouses for merchandise and three grain elevators; the Winter, with numerous timber yards round the quays; the Avant pier or New harbour, where regular passenger steamers berth; and the War harbour (closed shortly after the start of World War II) with two dry docks, each 600 ft. Vessels drawing more than 28 ft. can not enter the port. It is open practically the year round with the help of icebreakers.

The chief imports are coal, iron, salt, herring, grain, cotton, machinery, chemical manure and phosphates. The exports include rye, barley, oats, wool, linseed, sleepers, deals, pitprops, pulpwood, skins and hides, wheat and eggs. The port also serves as a coaling and oiling station.

Primarily because of the loss of Russian commerce, trade fell in 1920 to approximately 20% of the 1913 level. Industries before 1913 included iron and steel works and engineering yards, veneering, flour-milling, bacon-curing, tobacco manufacture, the extraction of vegetable oils, the making of colours and varnishes, brewing, distilling and leather work. Many of the factories ruined during World War I were never repaired and put into production. An immense state-owned factory, dominating the water front, produces agricultural and other heavy machines.

The port of Libau, Lyra portus, is mentioned in 1263, when it belonged to the Livonian order or Brothers of the Sword. In 1418 it was burned by the Lithuanians and in 1560 mortgaged by the grand master of the Teutonic order, to which it had passed, to the Prussian Duke Albert. In 1701 it was captured by Charles XII of Sweden, and in 1795 annexed to Russia. After 1872, when it was brought into railway connection with Moscow, Orel and Kharkov. Liepāja became an important port and developed rapidly. The Russians constructed an extensive naval port, protected by moles and breakwaters in 1893–1906. The Latvian government removed here when Riga was in German occupation in 1917–19, and Liepāja itself was occupied by German troops in 1919.

Certain areas were still in ruins in 1941, when the Germans again reoccupied the town, following the Russian occupation of 1940–41. Liepāja served as a German naval base from 1941 to 1945.

LIERNE: *see* ARCH AND VAULT.

LIERRE (French for LIER), a town in the province of Antwerp. Belg., 9 mi. S.E. of Antwerp. Its church of St. Gommarus was completed in 1557; three fine windows were given by Archduke Maximilian to celebrate his wedding with Mary of Burgundy. The cutlery and beads industries became important.

The population in 1955 was 28,9jo.

Midsummer Eve Tradition.—In the community of Lierre, according to Sir James Frazer in The *Golden Bough*, it became customary for the people to take precautionary measures to protect themselves from the "nefarious pursuits" of witches and warlocks on Midsummer eve, or St. John's eve, the day before Midsummer day (June 24), near the summer solstice.

Frazer reported that it was thought that supernatural creatures convened on that night at a designated field, where they conducted rites and were imbued with fresh powers. Hence it was necessary to secure doors and windows and seal all openings in houses, since the witches might be anxious to experiment with their newly acquired powers on the inhabitants.

LIETZMANN, HANS (1875–1942), German Protestant theologian and church historian, who combined the disciplines of classical philology and theology in order to show the connection of the Christian faith with its historical foundation, was born at Dusseldorf, on March 2, 1875. He studied at the universities of Jena and Bonn, where he became a lecturer in church history in 1900. From 1905 he was professor at the University of Jena and in 1924 was appointed professor at the University of Berlin, succeeding Adolf von Harnack. He died at Locarno, Switz., on June 25, 1942.

Lietzmann's works include *Der Menschensohn* (1896); *Catenen* (1897); *Apollinaris von Laodicea und seine Schule*, vol. i (1904); *Das Leben des heiligen Symeon Stylites* (1908); *Petrus und Paulus in Rom* (1915; 2nd ed., 1927); *Messe und Herrenmahl* (1926; Eng. ed., 1953–57); *Geschichte der alten Kirche*, 4 vol. (1932–44; Eng. ed., 1937–52), and many other books and articles. He edited *Kleine Texte für theologische Vorlesungen und Übungen* (1902 *et seq.*); *Handbuch zum Neuen Testament* (1906 *et seq.*); and *Zeitschrift fur die neutestamentliclze Wissenschaft und die Kunde der älteren Kirche* (1920 *et seq.*).

Lietzmann's autobiography to 1924 is in *Die Religionswissenschaft der Gegenwart in Selbstdarstellungen*, vol. ii (1926); a bibliography of his writings may be found in *Zeitschrift fur die neutestamentliclze Wissenschaft und die Kunde der älteren Kirche*, vol. xli, pp. 12–33 (1942). (JK. F.)

LIEUTENANT. In general use, a lieutenant is an assistant, a deputy, or one who acts in lieu of another. The term appears in this sense in the title of Douglas Southall Freeman's classic work on the American Civil War, *Lee's Lieutenants*. More specifically, in most armies of the world, a lieutenant is the lowest rank of commissioned officer; he normally commands a small tactical unit such as a platoon. The modern British pronunciation, "leftenant," stems from various Old English spellings such as *lie ftenant.*

In the British army and in the U.S. army, air force and marine corps, a *second* lieutenant is the lowest ranking commissioned officer. Above him in the U.S. services comes a *first* lieutenant (lieutenant in the British army), then a captain. In the Soviet army there is still another rank, *senior* lieutenant. The term has a somewhat different meaning in the U.S. and British navies where the lowest ranking commissioned officer is an ensign (U.S.) or commissioned officer (British). The next higher rank is lieutenant junior grade (U.S.) and sublieutenant (British) folloned by lieutenant and lieutenant commander. A navy lieutenant (U.S.) is thus equal in rank to an army, air force or marine corps captain; a navy ensign (U.S.) is equal in rank to a second lieutenant in the other services. In the Royal Air Force a flight lieutenant ranks below a squadron leader and above a flying officer.

The word also appears in combination with other military and civilian titles to denote a second-in-command or one of lower rank. A lieutenant colonel, for example, ranks below a colonel and above a major. This use of the term stems from the period of English history when colonels raised and literally owned regiments but turned over their administration to lieutenant colonels. A lieutenant general ranks below a general and above a major general. In the U.S. and British navies a lieutenant commander, as noted above, ranks between a lieutenant and a commander. The term lieutenant governor in the United States describes an elected state official who may act for the governor or take his place if the governor dies or is incapacitated. In Canada the governors of provinces bear the title of lieutenant governor. The same term in British usage describes a governor who represents the sovereign in a given area. In similar fashion the lord lieutenant of a county in England or a province in France was originally the sovereign's deputy in that area for military affairs. *See* also INSIGNIA, MILITARY; OFFICEKS.

LIEVENS (LIVENS, LIEVENSZ), **JAN** (1607–1674), versatile Dutch painter and etcher, was born in Leyden on Oct. 24, 1607. A contemporary of Rembrandt, he was a pupil of Joris van Schooten in Leyden (1615–18) and of Rembrandt's teacher Pieter Lastman in Amsterdam (1619–21). In Leyden Prince Frederick Henry bought one of Lievens' paintings and gave it to the British ambassador Sir Dudley Carleton; this probably was the cause of Lievens' stay in England (1632–35). From 163j to 1644 he lived in Antwerp. In 1644 he returned to Amsterdam, where he received important commissions and was greatly admired. Yet his last years were troubled by debts, loneliness and wandering. He was buried in Amsterdam on June 4, 1674,

Lievens is remembered primarily for the works of his Leyden period; they derived occasional greatness from the influence of, and the competition with, his friend Rembrandt. The diary of the connoisseur Constantijn Huygens, who visited the young men about 1629, contains a fascinating estimate of their respective abilities; while he correctly sensed a certain grandiloquence in Lievens' works, some of them do approach Remhrandt's rather closely. and there were cases of collaboration. He painted biblical, allegorical and mythological subjects, figures of saints, old men and children. portraits and genre scenes. During his stay in Antwerp his art acquired a strong flavour of the style of Van Dyck. Some of his excellent landscapes were long attributed to his friend Adriaen Brouwer. During his later years in Holland, the Flemish element in his art recommended him to official circles, and he was commissioned to paint decorative canvases for the town hall in Amsterdam and other buildings. Some of his early etchings are worthy of Rembrandt. He also made eight woodcuts of surprising originality. (W. Sw.; X.)

LIF AND LIFTHRASIR. In Scandinavian mythology, Lif, a man, and Lifthrasir, a woman ("Life and Vitality"), are the human couple who survive the period of chaos when the world comes to an end. According to the myth, Lif and Lifthrasir are destined to become the progenitors of a new race on the earth. *See* RAGNAROK.

LIFE: *see* BIOLOGY; DEATH (BIOLOGICAL); LIFE EXPECTANCY; REPRODUCTION.

LIFEBOAT AND LIFESAVING. Lifeboats are specially constructed for the purpose of saving lives in peril on the water. They usually measure from 25 to 52 ft. in length. The type of lifeboat carried aboard a vessel for use in an emergency has special features for survival on the open sea, but it seldom has the characteristics which provide safety when proceeding through heavy surf to the shore. Shore-based lifeboats are designed to put out from land and aid persons in distress. They are used by governmentally supported lifesaving organizations and by privately sustained lifesaving institutions; they are constructed to stay afloat under adverse sea conditions in which other boats would be helpless. The ability to meet these conditions requires special characteristics such as sturdiness, self-righting ability, reserve buoyancy, and maneuverability in surf particularly in reversing direction.

Figures 1 and 2 illustrate the self-bailing, self-righting design

FIG. 1.—PROFILE OF SELF-BAILING AND SELF-RIGHTING MOTOR LIFEBOAT

of the motor lifeboat which accommodates survivors in watertight compartments. This U.S. version is 36 ft. 8 in. long, 9 ft. $5\frac{1}{4}$ in. wide, and has a draft of 3 ft. 5 in. and weighs about $10\frac{1}{2}$ tons. It is constructed of $1\frac{1}{8}''$ wood planking and has watertight decks and compartments. It is powered by an 85–110 h.p. diesel engine. The keel is bronze and weighs about one ton. It operates from sheltered inlets. Figure 3 shows a motor surfboat of smaller size than the lifeboat. It is self-bailing but not self-righting. The pulling surfboat illustrated in figure 4 can be hauled along the shore and launched directly into the surf.

British lifeboat design does not stress the self-righting feature. As most British lifeboats go well out to sea, they sacrifice self-righting ability for a broader beam and greater stability. They are built in the following lengths: 36, 42. 47, and 52 ft. They are powered by diesel engines, with the smaller boats having 20 h.p. and the larger boats having 60 and 72 h p. The speed varies from seven and one-half knots in the smaller boats to nine knots in the larger craft. The capacity of the 36-ft. boat is 37 persons; the 42-ft boat accommodates about 85 persons; the two larger boats can carry over 100 persons.

The term lifesaving, when considered in connection with lifeboats, refers to the organized efforts of specially trained groups of individuals for aiding persons in danger on the water, in the water and even over the water. (*See* also DROWNING AND LIFE-

SAVING.) Before World War II the meaning of the term was limited to efforts to save life or render assistance by use of the lifeboat. the line-throwing and breeches-buoy apparatus and the application of resuscitation for the apparently drowned. During the war there were many mass flights of aircraft over water and airmen were frequently forced down offshore. Great Britain and the United States both recognized the importance of saving these highly trained men, as well as the crews of numerous torpedoed surface vessels. Great efforts were made to improve lifesaving techniques and equipment. "Air sea rescue" was the name originally applied to the highly co-ordinated system of a rescue direction centre controlling all communications, electronic devices, rescue ships. airplanes, lifeboats and other equipment capable of assisting in saving such lives. Following World War II when air transportation became a globe-encompassing industry, finding the exact location of a disaster scene in the vast ocean spaces became a paramount consideration, and the term for lifesaving throughout the world became "search and rescue."

HISTORICAL BACKGROUND

Records indicate that organized lifesaving was inaugurated by the Chinese centuries before its establishment in the occident. Certain Chinese benevolent institutions supported lifesaving services on the Yangtze and other large rivers. These services succoured those in danger. prevented casualties by ferrying passengers and accompanying junks across rivers in stormy weather, and provided rest houses where shipwrecked persons could find shelter and food. Special "red boats" were built and manned for rescue purposes. As a final service. arrangements were made with associated institutions to provide coffins and decent burials for persons found drowned.

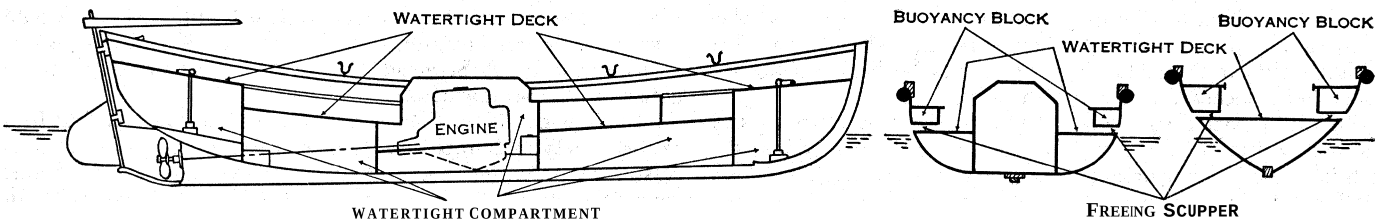
In the western world the need for action to prevent loss of life from drowning and shipwreck was recognized by several nations at about the same period. The French are credited with a number of original ideas which were not always put to practical use. In 1757 René de Réaumur sent a report to the Academy of Sciences at Paris regarding the resuscitation from drowning of several persons in Switzerland. The first "insubmergible" boat was constructed and tested on the Seine by M. Bernières in 1765. It was decked over at the bow and stern and contained airtight boxes under each deck for reserve buoyancy. Although the test found this boat to be practical it was not put into service at that time. About this same period M. Gelacy designed a life belt that would support its wearer in water. In 1796 M. La Fbre of France was a contemporary of Sergeant Bell of the royal artillery in the design of a line-throwing gun.

The Netherlands has the distinction of establishing the first lifesaving society in Europe shortly after Réaumur reported his successful resuscitation cases. Established at Amsterdam, it mas named Society for the Recovery of the Apparently Drowned. In 1773 the records of the Dutch society were translated into English and the following year a group of 32 prominent Londoners, headed by B. Hawes who had been paying rewards personally for saving life from drowning, founded the Royal Humane Society for Recovery of Persons Apparently Drowned or Dead. In the United States, similarly interested individuals founded the Massachusetts Humane society in 1785. The chief aim of these societies was the saving of life by swimming and resuscitation, but it is interesting to note that rescue from shipwreck quickly became part of their plan. As early as 1787 the Massachusetts Humane society launched a program which resulted in the construction of 17 huts for the shelter and succour of persons shipwrecked on the shores of that state. In England a comparatively early annual report of its society contains a short chapter describing a life raft, and a long chapter on Captain Manby's method of rescuing shipwrecked persons by means of his line-throwing gun. These early efforts by humane societies led to the establishment of the Royal National Life-boat institution operating in the British Isles and Ireland, and of the U.S. lifesaving service (now coast guard).

Great Britain.—Some of the first practical steps in both lifesaving and lifeboat construction were taken by Great Britain. The start was made in 1785 by a London coachbuilder, Lionel Lukin, who converted a Norway yawl into an "unimmergible" boat by adding airtight cases in the ends of the boat and along the inside above and below the thwarts (seats). He also added an iron keel for stability, and a thick layer of cork outside the gunwales for added buoyancy and protection against buffeting. This boat was stolen during tests, but the same principles of construction were used in rebuilding a Northumberland coble which became the first European boat used solely as a lifeboat; it was assigned to the first lifesaving station, established in 1786.

The activation of the first lifesaving station in England and the western world resulted from the philanthropic work of John Sharp, archdeacon of Northumberland, who administered the trust funds left for charitable purposes from the Bamburgh, Northumberland estates of Lord Crewe, bishop of Durham. Sharp instructed Lukin to convert the coble mentioned above into the first lifeboat. In order to get the most efficient use from his lifeboat Sharp placed a continuous watch in the tower of Bamburgh castle, and during bad weather he had two men patrol the coast on horseback for the purpose of locating and giving fast notice to his lifeboat crew of any shipwrecked vessel. Also, during fog, he had his men toll a bell and fire a cannon at intervals as a preventive warning signal. Thus, Archdeacon Sharp recognized and put into operation the basic duties of a lifesaving station—lookout watch, beach patrol, rescue by lifeboat, and preventive warnings.

Still other practical developments in the lifesaving field which originated in England are of interest. Following the tragic shipwreck in 1789 of the "Adventure" at the mouth of the Tyne, witnessed by helpless crowds on shore, a group of gentlemen from Newcastle sponsored a competition for the design of a boat that would right itself when capsized and would retain its buoyancy when manned and nearly full of water. William Wouldhave, a house painter, won half the prize for his model of the first English self-righting boat. Not fully satisfied with Wouldhave's design, the prize committee then drew up plans of its own and instructed Henry Greathead, uho had also entered the contest, to build the first boat designed solely for lifesaving. Greathead added to the design submitted by the committee by using a curved keel, but Wouldhave's self-righting principle was not included, probably because of the extra weight. When completed in the latter part of 1789, this go-ft., 10-oared, double-ended lifeboat was named the "Original." She remained in service in the vicinity of Newcastle



BY COURTESY OF THE UNITED STATES COAST GUARD

FIG. 3.—PROFILE AND SECTIONAL VIEWS OF 25-FT. SELF-BAILING MOTOR SURFBOAT

for 40 years, and because of her early successful rescues she became the prototype for 30 other lifeboats built by Greathead.

In 1807 Capt. George Manby, an artilleryman, developed the first practical line-thrcwing mortar with a range of from 250 to 320 yd. After firing a line to the wreck a life cot was hauled back and forth between the ship and the shore to bring the crew and passengers to safety. This mas the forerunner of the breeches buoy, and the completely enclosed life car. A similar line-throwing apparatus propelled by a rocket was invented in 1821 by Trengrouse. In addition to its greater range, it was much lighter than the mortar and could be transported along the shore with greater ease. This apparatus was further perfected in 1832 by John Dennett.

The most important development in the history of lifesaving in England took place in 1824 following a crusading campaign by Sir William Hillary of the Isle of Man for action to reduce the terrible loss of life from shipwreck occurring at that period. Chiefly through his efforts, prominent London citizens founded the National Institution for the Preservation of Life from Shipwreck. In 1854 this voluntarily supported society was named the Royal National Life-boat institution. It has served as a model for the formation of lifeboat societies in many other countries. In 1924, on the 100th anniversary of the founding of the institution, the first international lifeboat conference met in London; it was followed at four-year intervals by similar conferences in other cities.

During World War II, lifeboats of the institution were launched on service 3.760 times and rescued a total of 6,376 lives. By the end of the 1950s the institution controlled 151 lifeboat stations of which 78 were in England, the Scilly Isles and the Isle of Man; 31 in Scotland; 22 in Ireland; 18 in Wales; and two in the Channel Islands. The crews of the lifeboats consisted mainly of part-time volunteers, though the institution paid retaining fees to coxswains and other officers, and wages to part-time and full-time coxswains and mechanics.

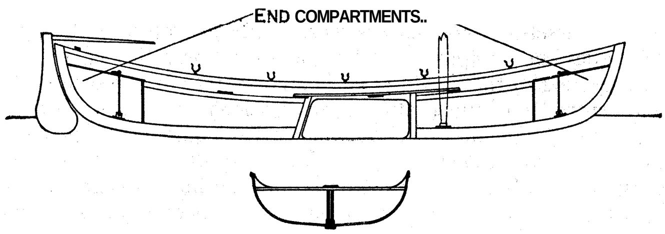
United States.—In tracing similar developments in the United States we must consider the difference in coastal topography and density of population in shore areas as compared mith that of Europe. In the United States during the 18th and 19th centuries most of the shore was a flat, uninhabited beach extending for miles and separated from the populated region by swamps and inlets. These conditions affected the development of lifesaving in three ways. First, there were fem people to witness a shipwreck and arouse public interest in remedial action. Second, because of the sparse coastal population there were only a few capable volunteers available for operating lifesaving equipment. Third, because rescue boats were usually launched from the beach. most surfmen preferred a lighter and more maneuverable boat than the heavier lifeboat with its self-righting and self-bailing characteristics. Because of these conditions, organized lifesaving lagged somewhat behind that in Europe. It is also noteworthy that when interest in rescue was aroused help had to be obtained from governmental sources.

The Massachusetts Humane society, as noted above: took the first step in 1787 with the construction of shelter huts on uninhabited beaches. This society next built and maintained a lifeboat, manned by volunteers, at Cohasset, a potentially dangerous spot on the approaches to Boston harbour. This boat was in service from 1807 to 1813. She was a 30-ft. whaleboat type of craft with a 10-ft. beam and considerable cork added for reserve buoyancy.

In 1816 a New York boatbuilder, Joseph Francis, built his first lifeboat. This boat's design was improved during the next few years when it became known as the "hydrogen lifeboat" because it obtained its reserve buoyancy from hydrogen tanks secured in the double bottom. The inner cockpit deck was made higher than the level of the sea so that water entering the cockpit would flow overboard through freeing ports in the boat's double bottom. It became popular as a lifeboat carried aboard ship.

In 1832 the national government showed its first interest in lifesaving when the secretary of the treasury ordered several revenue cutters to cruise along the Atlantic coast and give seaborne commerce special protection during the winter season. This winter cruising mas made a regular duty of the revenue marine by an act of congress passed in 1837, and it was continued until radio communication made such cruising unnecessary. Joseph Francis built his first life car in 1837, but it was ten years in development; when finally perfected it was a completely covered corrugated metal boat. This ten-foot life car held three or four people and was used in connection with a line-throwing mortar to haul shipwrecked crews and passengers through the surf from stranded vessels to the shore. Shortly after being put into service one of these life cars saved 201 persons from a ship wrecked on the New Jersey shore.

In 1840 the Massachusetts legislature appropriated $5,000 to assist the Massachusetts Humane society in the building of lifeboats. Of these ten were financed with state funds and one with funds from the society. A national humane organization known as



BY COURTESY OF THE UNITED STATES COAST GUARD

the American Shipwreck and Humane society was founded in 1843. Although James Fenimore Cooper and a number of other prominent New York men mere original board members: the society did not appear prominently in later lifesaving records. The federal government acted again in 1847 by appropriating $5,000 for furnishing lighthouses on the Atlantic coast mith means of rendering assistance to shipwrecked mariners, but because of a technicality in the law the money could not be spent as originally intended. The funds were later used to provide lifesaving equipment for the Massachusetts Humane society. More federal aid came from congress in 1848 with the appropriation of $10,000 for the purpose of placing lifesaving equipment along the New Jersey coast. These two appropriations were chiefly the result of efforts of congressman William A. Newell of Imlaystown, N.J., who was dedicated to the work of saving lives from drowning by shipwreck and who campaigned and was elected on such a platform.

Capt. D. Ottinger of the revenue marine was directed to put into effect the 1848 act of congress, and with the funds appropriated he built several small boathouses and equipped each with a fisherman type of surfboat, a line-throwing mortar, a metal life car, and necessary marine supplies. Similar boathouses mere built along the shores of Long Island in 1849, and another was established on the Rhode Island coast in 1850. Since no provision was

made for crews or even caretakers this equipment rapidly deteriorated or was stolen. To remedy this situation congress made provision for paid keepers in 1854, but since the crews of these stations depended on volunteers from a sparsely settled coast. good surimen were not always available and the system was far from satisfactory. There was some change for the better in 1870 when congress authorized crews at each alternate station for the three winter months.

The real beginning of a modern lifesaving organization was established in 1871 by Sumner I. Kimball who had just been appointed chief of the revenue cutter service (coast guard). He secured appropriations to rebuild the boathouses to accommodate lifeboat crews. Inefficient keepers were replaced by men selected for their skill and experience. Additional stations were established; and all stations were manned by capable surfmen who were appointed and promoted under a merit system. A beach patrol was instituted and maintained during darkness and thick weather for the purpose of warning vessels and for the prompt discovery of wrecks or castaways. As a result of this efficient management only one life was recorded as being lost during the next two years within the area of responsibility of the service. Thus the era of groping for an efficient lifesaving organization in the United States came to an end.

Later Developments.—Following the establishment of the parent organizations in both England and the United States there have been only a few basic changes in administration and duties. In Great Britain the Royal National Life-boat institution experienced a period of diminishing interest in the 1840s. This decline was rectified in 1851 when the fourth duke of Northumberland was elected president. Under his able leadership there was an active revival of the service. other lifeboat societies joined the institution. and steps were taken to maintain a continuing public interest. It should be noted that this institution remained a voluntary service. supported and directed entirely by private individuals.

Complete search and rescue co-ordination depends upon co-operation of the Life-boat institution with the coast guard, the Royal Air Force and the Royal Navy.

In the United States the management of the service following its founding was under the direction of the chief of the revenue cutter service until 1878. at which time it was organized as a separate bureau under the treasury department and titled the U.S. lifesaving service. In 1915 this service was reunited with the revenue cutter service under a new name—the U.S. coast guard (*q.v.*). For further efficiency, congress joined the lighthouse service with the coast guard in 1939, and placed the bureau of marine inspection and navigation in this group of amalgamated bureaus in 1946 The addition of these latter two organizations to the coast guard stressed the modern concept of saving life through preventive measures.

hfodern science has vastly improved rescue facilities and lifesaving techniques throughout the world. The invention of radio communication, the airplane and helicopter, and amphibious vehicles now enable rescue forces to locate and reach persons in peril with greater speed and ease. When the helicopter cannot operate because of lack of range, darkness or high winds, rubber life rafts. food and survival gear may be dropped from planes until other assistance can arrive. Medical aid is sometimes parachuted where there is vital need at inaccessible locations.

The greatest advancement in lifesaving is the international trend to pool resources under the operational control of the most strategically located rescue co-ordination centre. where information is quickly evaluated and assistance directed to the scene. This aid may be the nearest merchant or naval vessel. air facility. weather station vessel, or the specially designed fast patrol craft and the modern lifeboat.

(M. H. I.)

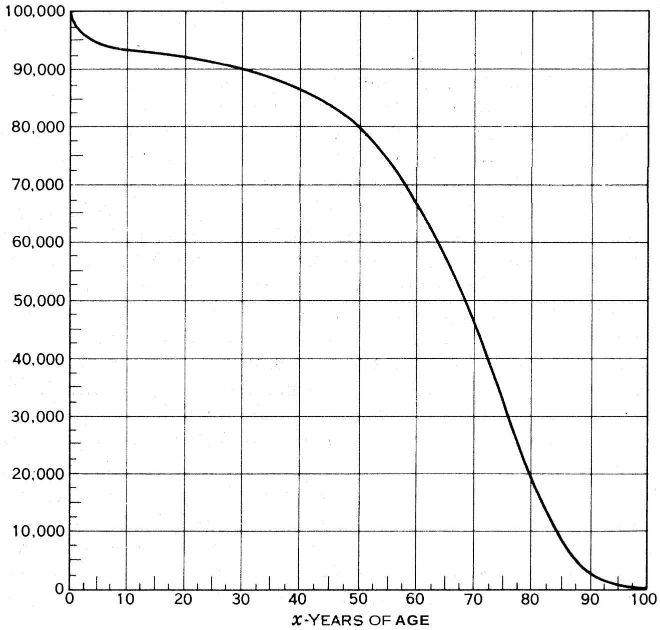
LIFE EXPECTANCY, or expectation of life, as used in actuarial work and vital statistics, means the average length of life after any given age; it is based on death rates shown in mortality tables.

Life expectancy statistics are related to an idealized conception or model. We consider hypothetically an indefinitely large number l_0 of individuals just born and observe their number as it is diminished by death with the passage of time. From birth until some years x later, a certain number of them will have died; those surviving will be aged x and their number is represented as I,. The time x just prior to which the last surviving individual has died (that is, the time at which $l_x = 0$) is represented as w. The value of l_x plotted against x is assumed to form a smooth curve, and this curve is called the survivorship function. A typical survivorship function is shown in the figure, to exhibit its general form. Between any age x and a small increment dx—that is, between ages x and (x + d~)— number of individuals dl, will have died, and if dx is taken as infinitesimally small dl, may be regarded as the number who die at exactly age x. The average age at death for all individuals who have survived to some specified age x—from which x, the age already attained, is subtracted—is the mean afterlifetime at age x, and is represented as $\mathring{e}_x$. The mean afterlifetime at birth, $\mathring{e}_0$, is the average age at death for the total l_0 births, and this is what is referred to as the expectation of life. The expectation of life as thus defined should not be confused with the age at which half the number beginning life at $x = 0$ have died (that is, the age x at which $l_x = \frac{l_0}{2}$); this is the median expectation of life.

An extension of the model just described of following some l_0 individuals just born. as they are diminished in time by death. is another model, referred to as a stationary population. In this model there is visualized not just one group of l_0 births but a succession of such births evenly occurring in time following the original set of births. From $x = 0$, when there are I, individuals, to an infinitesimally small time dx later: there will have died a certain number dl, individuals. The survivors, diminished to number $l_1 = l_0 -$ dl,, advance to age (o + dx). while the original group is replaced by l_0 new births. With the passage of the next small interval of time. the first group will have been diminished to a number I, — dl,, the second to the number $l_0 - dl_0$, and there will be a third group of births l_0 replacing the second. With the passage of time to $x =$ w, when the first group will have been reduced to $l_x = 0$, there will have accumulated at each age x just the number that had survived to this age from the first group. From this time forward the population will be stationary in respect to the distribution of the number of individuals present at each age, for as some individuals at any age die, the survivors grow older, while the entire group is replaced by the survivors from the just younger age. In this model of a stationary population, there is, at any time, the same number of persons living at any particular age x. The total population at any time is equal to the same number as the total number of person-years lived by any l_0 individuals as they pass from birth to x = w, when the last survivor is eliminated by death. In this way there is a mathematical identification between the model of following a particular cohort of l_0 individuals from birth to death. and the stationary population. The total number of person-years lived by any l_x individuals. who have survived to age x, as they pass in time from age x to age w, the final age of the life span, is equal to the total population, aged x and older, present at any time in the stationary population. This number is equal mathematically to the area under the curve representing the survivorship function shown in the figure, from age x forward. If this number is divided by the value of I, the number living at age x, it gives $\mathring{e}_x$. Accordingly $\mathring{e}_0$, the complete expectation of life at birth, is equal to the total area under the survivorship function divided by 1,.

The model of a stationary population brings one closer to the actualities of existing populations for which values of the expectation of life are regularly calculated than the model of following a particular group of I, births. but still there is a fundamental discrepancy. If a population such as that of England and Wales or that of the United States at a given time is considered, there is a particular age distribution which is the actual census of individuals at specified ages. This is not the age distribution of the model stationary population that defines the calculated expectation of life, and the calculated expectation of life is not the same as the actual mean age of death occurring in the population over a year. In order that a population become stationary, it is required that there be no immigration into and no emigration from the population, and that the age-specific death rates remain constant over a period at least equal to w, the total life span. Obviously, in modern times for countries of western civilization these conditions are not fulfilled. The age distribution actually obtaining in these populations is the resultant of just such changes, and the age distribution is therefore not that of a stationary population. It is then natural to ask the questions: Why should the expectation of life be calculated if it is bound up with a stationary population that is not that of the population in question? How is the expectation of life calculated? The answer to the question "why" is that although the expectation of life calculated for a specified population does not estimate the actual mean duration of life of that population as of that time, it does provide a defined index of the prevailing death rates, and so serves as a general measure of prevailing hygienic conditions, insofar as these are reflected in mortality. This is the chief use to which the calculated expectation of life has been put.

The calculation of the expectation of life in terms of the model described is effected by way of the construction of a life table for



THE NUMBERS OF PERSONS (l_x) SURVIVING TO AGE x OUT OF EVERY 100.000 BORN ALIVE

the population at hand. Only the essentials of the calculations, so far as they pertain to the evaluation of the expectation of life, will be referred to. The basic information required is the probability of dying within a year after the attainment of any age of life. That is, we wish to know for the population in hand how many individuals who have just attained, say, age 40 years die before the attainment of their 41st birthday, and we wish such information for every integral year of life. The probability of dying in the year from age x to the next year $(x + 1)$ is symbolized q_x, and its complement, the probability of surviving, is $p_x = 1 - q_x$. The data from which these required quantities are obtained are (1) the number of persons of various specified ages living at a given time and (2) the number of deaths occurring in a year by age at time of death. The sources of these data are the government enumerations made in censuses and death certificate reports. The figures as recorded in these reports must be adjusted to obtain the required values of q_x. The census figures are available only for census years and are subject to inaccuracies of reporting. Certain corrections must be made, and interpolation must be effected in available census figures, to obtain the population estimate for the required specific age, sex and year. If the number of deaths in the year which have occurred at, say, age 40 (that is, between the 40th and the 41st birthdays) is divided by the number of persons age 40 living in the middle of the year (that is. on July 1), we obtain m_x the central death rate for that year. This, it should be observed, is not quite q_x which has reference to the number of deaths in a year among individuals who had their xth birthday within a year before their death. Individuals who died in the year at age 40—that is, at an age between 40 and 41 years—were not necessarily 40 years old at the beginning of the year.

If the 40th birthday was on July 15 and the person died in August of the year, his death certificate would be marked age 40 years, but the census would have included him in the age group 39 since that was his age on July 1 when the census was estimated. The estimate of m_x can be converted to an estimate of q_x if it is assumed that the survivorship function between ages x and $(x + 1)$ is linear, by use of the formula

$$q_x = \frac{2\, m_x}{2 + m_x}$$

One then begins with a hypothetical number of births, usually taken as 100,000 and called the radix of the table. This is the value of the survivorship function l_x at age $x = 0$ and therefore is represented as l_0. Multiplying l_0 by q_0 yields d_0, the number of deaths, out of the 100,000 births, which occur in the first year of life, and these deaths subtracted from 100,000 give the number surviving to age one year. In this way l_1 is evaluated. In the same way l_2 is obtained by multiplying l_1 by q_1 to give d_1, the number of deaths among the l_1 who die between age one year and age two years. We may formulize this calculation by noting that

$$l_1 = l_0 - l_0\, q_0 = l_0\,(1 - q_0) = l_0\, p_0;\ l_2 = l_1\, p_1 = l_0\, p_0\, p_1$$

and so forth, so that in general

$$l_x = l_0\, p_0\, p_1\, p_2 \dots p_{x-1} \text{ or } l_x = l_0 \prod_{0}^{(x-1)} p$$

where Π represents the continued product of the p's. In this way is calculated, from the determined quantities q_x the value of l_x corresponding to each integral year of age x from $x = 0$ to $x = w$, the final year of the life span at which $l_w = 0$.

It will be remembered that the expectation of life after age x is given by the area under the survivorship function from x to w, divided by the initial value l_x. For purposes of calculating the area required, with the values of the survivorship function l_x calculated at each integral year of life, it is considered that a sufficiently good approximation is obtained if it is assumed that the survivorship function between each age year x and the next is linear.

On this assumption the area under the curve over a single year of age is half the sum of the values of the bounding l's. Thus the area from $x = 0$ to $x = 1$ is

$$\frac{l_0 + l_1}{2}$$

the area from $x = 1$ to $x = 2$ is

$$\frac{l_1 + l_2}{2}$$

and so forth. The total area from x to w is therefore

$$A = \frac{l_x}{2} + \sum_{x+1}^{w} l$$

where Σ represents the continued sum of l values from l_{x+1} on. The expectation of life from age x, or mean afterlifetime, is A divided by l_x; so

$$\mathring{e}_x = \frac{1}{2} + \left(\sum_{x+1}^{w} l\right) \Big/ l_x$$

and the expectation of life at birth is

$$\overset{\circ}{e}_0 = \frac{1}{2} + \left(\sum_{1}^{w} l\right) \Big/ l_0$$

From the development given, it is seen that the value of the expectation of life, as calculated, depends only on the values of the age-specific death rates obtaining in the population. It may be viewed as the actual mean age at death of a population in which these death rates prevailed indefinitely at the values they had in the year in question. It may thus be seen why it is regarded as a useful summary index of the mortality rates characteristic of existing conditions. This has been its chief usefulness.

Fairly reliable estimates of the expectation of life in western communities have been made for periods since the middle of the 19th century. Females are found always to have a longer expectation of life than males. For both, great progress has been made in its extension as general sanitary conditions have been improved, food has become more abundant and better in quality and advances in medical science have been achieved. The accompanying table gives some values of the expectation of life for England and Wales and for the United States. The period covered is roughly the 100 years extending from the middle of the 19th century to the middle of the 20th century. Values of the expectation are given at approximately ten-year intervals. The phenomenal extension of the duration of life is notable. Expectation of life in Roman times has been estimated to have been about 30 years. From that time to the middle of the 19th century it was increased to about 40 years. In the next century the increase in expectation of life was about 25 years, so that by 1950 the expectation of life was more than double that of ancient times. See DEATH RATE; LONGEVITY; POPULATION; see also Index references under "Life Expectancy" in vol 24. (JH. B)

Expectation of Life, in Years

United States			England and Wales		
Period	Male	Female	Period	Male	Female
1850	38.3	40.5	1838–54	39.9	41.9
1900–02	47.9	50.7	1901–10	48.5	52.4
1909–11	49.9	53.2	1910–12	51.5	55.3

1929–31	57.7	61.0	1930–32	58.7	62.9
1939–41	61.6	65.9	1937	60.2	64.4
1949–51	65.5	71.0	1952	67.1	72.3

LIFE INSURANCE, in the usual sense, means the business of issuing policies of insurance on human life. A policy on human life has been defined as any instrument by which the payment of money is assured on death (except death by accident only) or the happening of any contingency dependent on human life, or any instrument evidencing a contract that is subject to payment of premiums for a term dependent on human life.

In Great Britain the word "assurance" is in common use in connection with life contracts. In the United States the word "assurance" is rarely used, although it does appear in the names of a few life insurance companies.

Life insurance companies may be classified in two types: stock or proprietary. and mutual. Stock companies are controlled by the shareholders; mutual companies are without shareholders and are controlled by the policyholders.

A policy that shares in the profits of the company is called a participating policy. A policy that does not share in the profits of the company is called a nonparticipating policy. A stock company may issue both participating and nonparticipating policies. A mutual company's policies are usually participating, although there are some exceptions.

Mutual companies in Great Britain almost without exception issue both participating and nonparticipating policies. In the United States. for example, annuity contracts issued by mutual companies are likely to be nonparticipating.

Life insurance contracts map be classified as group or individual, the latter being further classified as ordinary or industrial. In an individual contract the policy is issued on an individual basis to the owner of the policy. The owner may or may not be the person whose life is insured. Before issuing an individual policy the company usually requires some evidence of insurability (see INSURANCE: *Risk* and *Insurance*). Under group insurance (*q.v.*) a large number of persons are insured under one blanket policy, the individuals insured receiving certificates and being called certificate-holders rather than policyholders. The commonest group contract is issued to an employer on the lives of the employees, although many contracts have been issued to labour unions, associations and other groups. Individual evidence of insurability is usually not required under a group contract.

The essential distinction between ordinary and industrial insurance (*q.v.*) is that, under industrial, the sum insured is comparatively small and premiums are payable at comparatively short intervals, the premium being commonly collected by the agent in the home of the insured.

In Great Britain the Industrial Assurance act (1923) defined industrial assurance as "assurances upon human life, premiums in respect of which are received by means of collectors and are payable at intervals of less than two months."

The New York state insurance law has defined industrial insurance as "that form of life insurance, either (a) under which the premiums are payable weekly, or (b) under which the premiums are payable monthly or oftener, but less often than weekly, if the face amount of insurance provided in the policy is less than $1,000, and if the words 'industrial policy' are printed upon the policy as a part of the descriptive matter."

The Ontario Insurance act defined industrial insurance in the following language: " 'Industrial contract' means a contract of life insurance for an amount not exceeding $2,000, exclusive of any benefit, surplus, profit, dividend or bonus also payable under the contract, and which provides for payment of premiums at fortnightly or shorter intervals, or, if the premiums are usually collected at the home of the insured, at monthly intervals."

This article is divided into the following sections and subsections:

I. TYPES OF INSURANCE

1. One-Year Term Insurance and Ordinary Life Insurance. — The simplest form of life insurance is one-year term insurance under nhich the premium collected for one year is enough to pay the cost of insurance and expenses for that year. This type of insurance is sometimes called pure protection, indicating that there is no investment element. Since the cost of insurance increases with age, the premium for one-year term insurance increases every year. becoming prohibitive at the very advanced ages.

The disadvantages of increasing premiums were solved by the development of level premium life insurance. Perhaps the simplest and most familiar form is that known as ordinary life or straight life. This form provides a benefit of the face amount of the policy on the death of the insured and calls for a level premium at the beginning of every year during the lifetime of the insured.

The table below shows the premiums for one-year term insurance for $1,000 at quinquennial ages from 35 to 95 inclusive. The corresponding annual premium for ordinary life, issued at age 35, is $17.67. The premiums are based on the 1958 Commissioners Standard Ordinary table with $2\frac{1}{2}\%$ interest, and are net premiums (*i.e.,* no provision for expenses).

TABLE I.—Premiums for One-Year Term Insurance, Ages 35–95
(per $1,000)

Age	Premium	Age	Premium
35	$2.45	70	$48.58
40	3.44	75	71.58
45	5.22	80	107.30
50	8.12	85	157.21
55	12.68	90	222.58
60	19.84	95	342.67
65	30.98		

There are a number of types of life insurance in addition to one-year term and ordinary life. Some of the more common types are described below.

2. Limited Payment Life Insurance.—The benefit under limited payment life is the same as under ordinary life: namely, the payment of the face amount (or sum assured) on death. The difference is in the premium payment period. Under ordinary life, premiums are payable for life; under limited payment life, premiums cease at death or at the end of the premium paying period specified in the contract, whichever comes first. Under a 20-payment life policy, for example, no premiums are payable after 20 years in any event. After the 20th annual premium has been paid the policy is said to be paid up. The sum insured under the policy is payable at subsequent death.

3. Endowment Insurance.—Under this type of policy the benefit is the payment of the face amount on the death of the insured if he dies before the end of the term (specified in the contract), or the payment of the face amount as an endowment if the insured lives to the end of the term. A continuous premium endowment insurance policy calls for premiums payable during the entire term—or until prior death. A limited payment endowment insurance policy is similar to a limited payment life policy in that the premiums are limited to some period less than the term of the policy. Under a 20-payment, 30-year endowment insurance policy, for example, premiums are payable for 20 years—or until prior death—but the term of the policy is 30 years; thus the benefit is payment of the face amount on death, if death occurs within 30 years, or the payment of the face amount at the end of 30 years, if the insured is then living. Limited payment endowment insurance is not generally written in Great Britain.

4. Term Insurance.—The one-year term insurance contract described above is a special case of term insurance. Term insurance may be defined more generally as a promise to pay the face amount on death if death occurs during the specified number of years, called the term of the policy. Premiums for term insurance are almost always level and payable during the entire term.

5. Pure Endowment Insurance.—A pure endowment benefit is a promise to pay a certain sum if a specified person is alive at some specified future date. Issued as a separate contract in Great Britain, it is usual for the premium paid under a pure endowment to be returnable—sometimes with interest—at death during currency of the policy. This benefit is rarely granted by itself but is an important adjunct to surrender benefits, discussed in a later section. Mathematically, endowment insurance is a combination of pure endowment and term insurance. It is known in Great Britain as reduced premium optional assurance.

6. Modified Life Insurance.—Usually this refers to a policy for which the premium for the first few years is less than the ultimate premium but more than the term premium would be.

7. Income Endowment Insurance.—Under this type of policy the death benefit is the face amount, or the reserve if that is greater, if death occurs during the term of the policy. At the end of the term the insurance contract is in effect exchanged for an annuity contract. A common form of income endowment calls for annuity payments to begin at age 65, with monthly payments of 1% of the face amount of the insurance policy guaranteed for 10 years, subsequent payments being made only if the policyholder is alive at the time the payment is due. There is no generally accepted name for this type of insurance. Terms in common use, in addition to income endowment, include retirement endowment, retirement income, life income, insurance and income, income to insured. In Great Britain endowment insurance with guaranteed annuity option at maturity is written freely.

8. Family Income Insurance.—This benefit usually has a family income period of from 10 to 40 years, 20 years being very common. If death occurs during the period, a monthly income is paid from the date of death to the end of the period. At the end of the period the face amount of the policy is paid. The amount of the monthly income is commonly 1% of the face amount of the policy but may be some other percentage. The fact that the face amount is paid at the end of the period rather than at death results in some saving in interest to the insurance company, a saving that is used to reduce the premium from what it would be if the face amount were paid at death. A family income benefit is an example of reducing term insurance. In Great Britain a sustained demand for family income insurance led to the issuance of a variety of contracts written as installments of a capital sum, the income benefits being free of British income tax.

9. Double Indemnity Benefit and Disability Benefit.—Many life insurance policies provide supplementary benefits in the event of accidental death or disability. A common accidental death benefit, frequently called double indemnity, calls for a death benefit of twice the regular death benefit in the event that death occurs before age 60 and is due to an accident as defined in the policy. A common disability benefit provides that the company will waive payment of any premiums that come due while the insured is disabled within the meaning of the contract. Some contracts provide that the company will not only waive premiums during disability but will pay an income in addition.

There are a number of types of life insurance not described above; but most of them amount to combinations of the types described.

See also *History: U.S.: Credit Life Insurance and Family Insurance* below.

II. RESERVES

The company must set up a reserve in the early years of a policy in order to avoid a financial deficiency in the later years. From a comparison of one-year term premiums (see Table I above) with the premium for an ordinary life policy taken out at age 35, it can be seen that a person becoming insured at age 35 would pay less for his insurance on the one-year term plan than on the ordinary life plan until some age between 55 and 60, whereupon the one-year term premium would become more expensive than the ordinary life premium. Since the one-year term premium is the amount the insurance company needs to pay the death claims for the particular age group, the company is collecting more than enough to pay claims in the early years of a policy but less than enough to pay claims in the later years.

Actuaries customarily analyze reserves from two points of view: retrospective and prospective. From the retrospective point of view the reserve is the accumulated amount of that part of the premiums already collected that is not needed to pay the death claims already incurred. From the prospective point of view the reserve is the present value of future benefits less the present value of future premiums. Various actuarial techniques have been developed to calculate reserves. In most life insurance companies the policy reserves constitute by far the major portion of the company's liability. The subject of reserves is therefore extremely important.

There are essentially three systems in common use for valuing a company's reserve liability: (1) full net level; (2) modified net premium; and (3) gross premium. Under the full net level method (1), a net level premium for a policy is calculated on certain assumptions regarding interest and mortality and with no provision for expenses. The reserve for the policy at a given time is computed as the present value of future benefits less the present value of future net level premiums. Under the modified net premium method (2), a modified net premium is calculated in accordance with a formula. In the United States the formula is specified by state law. This modified premium is greater than the net level premium, so that reserves under this method are less than corresponding reserves under the full net level method. Under the gross premium method (3), the reserve is computed as the present value of future benefits and expenses less the present value of future gross premiums, the term "gross premium" meaning the premium actually collected.

In the United States state laws require that a company use either the full net level method or the modified net premium method in computing reserves for the annual statement. In Great Britain the gross premium method is in common use. Many U.S companies also use the gross premium method for internal purposes.

III. SURRENDER VALUES

Under most policies other than term insurance a company will, after a certain number of premiums have been paid, pay a sum of money on surrender of the policy, this sum being known as the cash value or surrender value.

In the U.S. and certain continental countries the laws require that the policy state the amount of the surrender value for various policy years or state the method of calculation or both. It is customary for a company to grant a loan on the security of the policy, the amount of the loan being limited by the surrender value and the interest charge. An alternative to surrender for cash is the election of paid-up insurance. There are two common paid-up insurance options, commonly called nonforfeiture options. Under the reduced paid-up option, the benefit is paid-up insurance on the same plan as the original policy but for a reduced amount. The reduced amount is such that the paid-up insurance and the surrender value are actuarial equivalents; *i.e.*, the present value of the reduced paid-up insurance is equal to the surrender value.

Under the extended term insurance option the benefit is term insurance for the amount of insurance in force at the time the policy was surrendered. The length of the term is such that the paid-up term insurance and the surrender value are actuarial equivalents. In the case of endowment insurance the term for the paid-up insurance will not extend beyond the original term of the policy. Thus if the surrender value is large enough, the extended term insurance consists of term insurance for the original amount plus a pure endowment for a reduced amount.

IV. PARTICIPATION IN PROFITS

A mutual company returns to the policyholders any profits not needed to strengthen reserves, contingency funds and surplus. A stock company's relation with its holders of participating policies is the same except that the shareholders may take a small part of the profits.

The method of distributing profits to the policyholders varies from country to country. In Great Britain some companies make annual distributions while others make distributions every three or five years; the distribution is called a bonus distribution and takes the form of an addition to the sum insured. Two common bonus plans are: (1) the simple bonus plan, which provides additions at a given rate for each £100 of original insurance; and (2) the compound bonus plan, which provides additions to the sum insured, calculated on original insurance and accrued bonuses.

In the United States and Canada annual distributions are the rule. The distribution to an individual policyholder is called the dividend. Policies provide that a dividend may be taken in various forms. called dividend options. The more common options available are: (1) cash; (2) reduction of the next premium; (3) leaving with the company to accumulate at interest; and (4) use for purchase of a paid-up addition to the policy, the paid-up addition being similar to the British bonus.

V. HISTORY

The beginnings of life insurance—that is to say, the payment of certain benefits on death, against certain periodical subscriptions—are to be found in the Roman collegia (artisans' associations). The guilds of medieval times would, in many cases, make provision for the decent burial of a member, but this was not life insurance in the full sense. Marine insurance is generally believed to have had an earlier origin than life insurance, and it is therefore natural that the first definite contracts of life insyrance should have been on the lives of mariners.

1. Great Britain and the Commonwealth.—The earliest life insurance transaction recorded to have been made in England was in 1583, when a number of merchants of the city of London subscribed to an insurance on the life of William Gybbons, described as a citizen and salter of London. This insurance was for a period of 12 months at a premium rate of £8 sterling per £100. During the folloning century insurance for temporary periods, such as might be required to protect the policyholder against the perils of travel and other risks arising during a limited period, was granted by individuals and certain civic guilds.

The history of life insurance companies in England commenced in 1706 when the Amicable Society for a Perpetual Insurance Office mas formed. The insurance method was rudimentary and provided merely for the dividing up of certain sums among the representatives of those members who died each year. After a separate existence of 160 years, during which time it adopted a graduated scale of premiums according to age, the Amicable in 1866 became merged with the Norwich Union Life Insurance society.

A number of minor companies became defunct during the period of speculative financial schemes which resulted in the crisis of 1720. popularly known as the South Sea Bubble (*q.v.*). Speculation was common throughout the century, and in order to counteract the improper use of life insurance the Life Assurance act, known as the Gambling act, was passed in 1774. This act, which still remained on the statute book in the second half of the 20th century, provided that no insurance should be effected unless the person in whose favour the policy was taken out had a pecuniary interest in the life to be insured.

The Equitable society, founded in 1762, was the first to issue whole life insurance. The premium rates varied with age and were originally based on a mortality table constructed from the registers of Breslau, Germany. for the years 1687–91. The rates were later based on a mortality table deduced from the London bills of mortality for 1728–37; and still later on the Northampton tables which nere prepared from a record of baptisms and deaths obtained from the registers of the town of Northampton during the years 1735–80. When experience showed that rates could be reduced, policyholders paying the original higher rate were granted an addition to the sum insured.

Many new concerns were floated during the closing years of the 18th century, while between 1800 and 1870 some 500 new offices were established. A number of these companies had little hope of long surviving and some were of definitely fraudulent intent. This activity in company promotion was followed by a period of amalgamation, also marked by many abuses. The financial difficulties of two companies, the Albert and the European, were a factor in hastening much needed legislation. The Life Assurance Companies act (1870) was designed to prevent effectually a repetition of such disasters. Under the provisions of this act companies transacting life assurance business were compelled to submit annual accounts in a prescribed form to the board of trade for subsequent publication, and no new office was allowed to issue life policies until it had deposited £20,000 with the court of chancery. This act governed the business in Great Britain until it was practically re-enacted in the Assurance Companies act (1909), which was amended in turn by the Assurance Companies act (1946), and by certain provisions of the Companies acts (1929 and 1948).

The Married Women's Property act (1882) and the Married Women's Policies of Assurance (Scotland) act (1880) conferred certain powers on married women, enabling policies to be effected on their own lives or on the lives of their husbands for their own separate use. Similarly, married men were enabled to effect policies on their own lives for the benefit of their wives or their children, or both, and such policies were protected against their creditors absolutely.

British income tax laws encouraged life insurance ownership by providing that a policyholder who pays premiums for insurance on his own life, or on that of his wife, is entitled to claim relief from taxation in respect of such premiums paid. The relief took the form of a deduction from the policyholder's assessable income before income tax liability is calculated. The deduction represented the premium or a percentage of it, subject to a maximum percentage of income and to a maximum percentage of the amount guaranteed by the policy to be paid at death. Premiums for deferred annuities were also allowed as a deduction, subject to certain limitations and restrictions concerning the premium amount and policy use.

Life insurance in Australia, New Zealand and South Africa developed in the main in accordance with the practice followed in the United Kingdom. British mortality experience is largely used in these countries. In Canada life insurance was modeled very largely on the U.S. system (see below). In all these countries the industry functions under varying degrees of legislative control, such legislation being in general more restrictive than British legislation, which is based on the principle of freedom combined with publicity. In India and Pakistan the general pattern of life insurance is British, but at a much earlier stage of development than in Australia, New Zealand, South Africa and Canada. Life insurance in India was nationalized at the beginning of 1956 and business transferred to the Life Insurance Corporation of India. In the same year British and French life insurance interests in Egypt were sequestrated.

See also FRIENDLY SOCIETIES.

2. Europe.—Life insurance on the continent developed later than in Great Britain. The first successful venture in France was made in 1819 when the Compagnie d'Assurances Générales sur la Vie was founded. In Germany branches of English offices were operating before the end of the 18th century but the first German company was not founded until 1828.

Detailed governmental control is the general rule in continental countries, the control extending in many countries to premium rates, reserve bases and investment policy. In France all insurance companies with premium incomes exceeding a prescribed amount are nationalized. British insurance companies operating in France, although otherwise free from nationalistic control, are obliged to reinsure a small proportion of all business written in that country with the French state reinsurance institute—La Caisse Centrale de Réassurance. British companies maintained an interest in France, Belgium and Spain in the second half of the 20th century, but had ceased to operate in Germany.

Although the years immediately after World War II witnessed a considerable growth in life insurance in continental countries. the expansion did little more than bring the average sum insured into line with the higher level of values. Continental practice included the issue of policies with the right to participate in profits.

(RT. E. L.)

3. United States.—Early History.—What little life insurance there was in the United States during the colonial and confederation periods was furnished by British companies. Though the Corporation for the Relief of Poor and Distressed Presbyterian Ministers (and their survivors) was chartered by Pennsylvania in 1759 and issued life insurance con'tracts in 1761, it was in part a charitable organization, and limited in its scope of activity. Not until more than a century later was it authorized to do a general life insurance business under the name of the Presbyterian Ministers' fund. A few life insurance policies also were written by fire and marine insurance companies prior to 1800.

Between 1800 and 1843 scientific life insurance in the United States got its start by way of the proprietary (stock) and trust companies. The first commercial company for life insurance exclusively was the Pennsylvania Company for Insurance on Lives and Granting Annuities, chartered in 1812; it was also the first to use U.S. mortality statistics. The Massachusetts Hospital Life Insurance company (1818) was from the beginning more concerned with its trust business than life insurance, but the New York Life Insurance and Trust company (1830) actively promoted the sale of life insurance by way of the agency system. The Girard Life Insurance, Annuity and Trust company (Pennsylvania, 1836), following the example of some of the British companies, provided for policyholders' participation in the income of the company. There were various other stock companies chartered prior to 1840.

Life insurance in the United States made its first important growth with the organization of the mutuals in the 1840s. The mutual principle made it possible for resourceful men to form companies and give protection to the policyholder without the necessity of raising a sizable sum of capital to invest in the business. Eight of the more important companies founded in this period are still in business. They are the New England Mutual Life Insurance company (chartered in 1835, began business in 1843) ; The Mutual Life Insurance Company of New York (1842 and 1843); the State Mutual Life Assurance Company of Worcester (1844 and 1845) ; the Nautilus Insurance company (1845), which in 1847 was renamed the New York Life Insurance company; The Mutual Benefit Life Insurance Company of New Jersey (1845); The Connecticut Mutual Life Insurance company (1846) ; the Penn Mutual Life Insurance company (1847) ; and-the Union Mutual Life Insurance company (1848 and 1849). About 40 other companies were organized by 1850, a number of which failed to survive. Companies pioneered in education of the public to the need for and advantages of life insurance and in promotion of volume sales through the agency system. From less than $5,000,000 of life insurance in force in 1840 the amount increased to $96,000,000 in 1850.

Several of the prominent companies which began writing life insurance in the 1850s were stock companies. Among them were the Aetna Life Insurance company, The Manhattan Life, the United States Life, the Charter Oak and the Knickerbocker. The Massachusetts Mutual Life Insurance company (1851), the Mutual Life Insurance Company of the State of Wisconsin (1857; in 1865 it became The Northwestern Mutual Life Insurance company) and The Equitable Life Assurance Society of the United States also began business. The last-named company, founded in 1859 by Henry Baldwin Hyde, a former cashier in the Mutual of New York, was originally a stock company but operated from the beginning as a mutual in regard to distribution of earnings.

Many of the early policies were for term insurance, but by 1860 approximately nine-tenths of the policies issued were level-premium life policies. Endowment insurance payable to the insured at a certain age—or to his beneficiaries—had its beginnings in the middle 1850s. By the late 1850s the application had become a part of the insurance contract and untrue statements made therein could render the contract void. The companies provided their own medical examiners to scrutinize the examinations made by local physicians. Extra premiums were required for hazardous occupations, residence in the less healthful portions of the country, military service or travel beyond the northern and eastern sections. Although most of the companies by 1860 paid some sort of surrender values after the fifth year if the policy was surrendered before it lapsed, there were no provisions in the contract regarding nonforfeiture. In 1860, however, New York Life marketed a policy which recognized nonforfeiture as a right. For calculation of premiums and policy reserves the companies used various British mortality tables and assumed 4% or 4.5% interest on the reserves. Investments were generally confined by law to United States and state and local bonds and to mortgages on improved real estate in the state where the company was chartered.

From the beginning insurance in the United States was under state supervision. Early laws sought to raise revenue and secure publicity by means of company reports, but systematic supervision by a commission or commissioner began in New Hampshire and Massachusetts in 1851–52. Elizur Wright, Massachusetts abolitionist turned mathematician, prepared lengthy tables by which the necessary reserves on policies might easily be calculated and the soundness of the company determined. As one of the insurance commissioners of his state he not only kept check on the companies but helped bring about the first step toward a nonforfeiture law (1861), by which four-fifths of the net value of the lapsing policy was to be used as a single premium for temporary insurance. A more complete nonforfeiture law was enacted in 1880. and most of the states soon followed suit. For this and other work in the field of life insurance Elizur Wright has sometimes been called the "father of American life insurance."

The Civil War stimulated the purchase of life insurance as it stimulated agriculture, industry and business. Approximately 24 nen companies were organized during the war years. One of these. projected in 1863 with the idea of insuring the lives, limbs and health of men in the military service. became in 1868 the Metropolitan Life Insurance company, eventually the largest life insurance company in the world. The Connecticut General Life Insurance company (186 j) pioneered in the writing of substandard risks — that is, the insurance of persons unable to pass the regular medical examinations — a practice later accepted by most companies. Life insurance in force more than trebled from 1861 to 1865.

Growth and Development, 1868–1905.—The years 1868 and 1869 nere important in life insurance history. First, Sheppard Homans. actuary of Mutual Life, compiled the first important mortality table based upon United States data. New York law established it as the standard for calculating reserves and this, the American Experience Table, came to be the most widely used by United States companies until it was superseded in the 1940s. Second. in 1869 the supreme court of the United States in *Paul* v. *Virginia* ruled that an insurance policy was not a transaction in commerce and hence not subject to federal regulation. Third. Henry B. Hyde and Equitable in 1868 introduced the famous tontine policies which helped popularize life insurance but brought on a long and lively controversy. Going back to Lorenzo Tonti for the basic idea, the tontine policy provided for payment of "dividends" or refunds at the end of a definite period such as 15 or 20 years. Those policyholders in each group who lived and maintained their policies collected not only their own accumulated "dividends" but the forfeited "dividends" and reserves of those who dropped out. Tontines of various types proved popular, and those companies nhich aggressively promoted them grew rapidly nhile those which opposed them on principle failed to keep pace or actually diminished in size. The war between the two schools of thought was long and bitter.

The period of the 1870s was a trying one. More than 200 new companies entered the field, but many were caught in the depression which began in 1873. One constructive step was the organization in 1871 of the National Convention of Insurance Comn~issioners(after 193 j the National Association of Insurance Commissioners), an organization which did much to bring order to the conflicting laws of the states Entry of the larger U.S. companies into foreign fields came in the 1870s, and before many years policies of these companies were being sold in practically every country.

The liberalization of the policy continued during the post-Civil War period. Travel and residence restrictions were gradually removed cash loan and surrender values were included in the ordinary life policy, and the contract was made incontestable after three years. Investments in bonds of states and their subdivisions, and of foreign countries in nhich the companies were licensed to do business, were made legal, as were the stocks and bonds of corporations and mortgages on real estate.

Life insurance first began to reach the manual labouring class with the advent of industrial insurance — small policies with neekly premiums collected by the agent—in 1875, when the Prudential Friendly society (after 1878 The Prudential Insurance Company of America) issued its first policy The Metropolitan, John Hancock Mutual, Guardian and other companies also began to sell industrial insurance, and by 1890 industrial insurance in force totalled more than $400,000,000.

Life insurance was also brought to the masses by the development of mutual assessment or co-operative societies and fraternal organizations nith life insurance features. The assessment concerns criticized the high cost of legal-reserve level-premium life insurance and maintained that it was just as safe, and much cheaper, to "keep your reserve in your pocket" and pay death benefits by assessing the remaining members as required. But these organizations inevitably ran into the laws of both arithmetic and human nature; members died more frequently with increasing age. and young members could not be recruited in sufficient numbers to carry the increasing and uncertain assessments. By the mid-1880s there were hundreds of assessment societies; all sooner or later ceased functioning.

As assessment societies waned. the fraternal organizations reached their peak. By the end of the century there were more than 300, with 4,000,000 members and $6,000,000,000 of life insurance. Although in the beginning many of the fraternal organizations differed but little in insurance practices from the assessment societies. eventually they either had to conform to actuarial standards or fall by the way. Some of them mere converted into legal-reserve companies.

The race for size on the part of the "big three" — Equitable, Mutual and New 1⁷0rk Life — reached its height toward the end of the century and in the early 1900s. New types of policies were introduced periodically, extravagant promises were sometimes made regarding "dividends," and, despite various agreements, the companies continued to attract each other's agents and policyholders. Rebating by agents on commissions was a not uncommon practice, the proportion of lapsed policies increased and expenses became high. Then the tremendous surpluses which resulted largely from various types of deferred dividend policies tempted some of the companies to engage in financial operations not properly the function of life insurance companies. These factors—combined with the general tenor of the times that produced the muckraking movement — led to the New York legislative investigation of 1905 by the Xrmstrong committee with Charles Evans Hughes as counsel. As a result, New Tork enacted laws which limited expenses and the amount of new insurance a company might sell annually; provided for annual distribution of dividends; and prohibited the companies from engaging in underwriting syndicates. Other states enacted similar laws.

20th Century — The temporary embarrassment of some of the larger companies in 1905 encouraged the organization of hundreds of new companies, largely in the south and west. In 1911 Equitable wrote the first group insurance policy — insurance without medical examinations on a group of employees, members of a labour union, etc.—and thus opened a new field for life insurance. Life insurance came through World War I and the influenza epidemic of 1918 in sound condition. By 1920 there was more than $40,000,000,000 of life insurance in force in the United States, and in 1930 there was more than $106,000,000,000.

The great depression of the early 1930s did not hit the life insurance companies severely until the banks mere closed in 1933 and moratoria were declared on mortgages, while at the same time death benefits and other claims were expected to be paid promptly. State insurance departments came to the aid of the companies by putting temporary restrictions upon policy loans and surrenders, except for emergencies The companies were further hit by the low interest rates maintained by the government, and the policyholders nere affected by the devaluation of the dollar and the inflation policies of the government Not until 1937 did life insurance in force again equal that of 1931.

In 1936 the National Association of Insurance Commissioners inaugurated a movement for a new mortality table. After several years' work the Commissioners Standard Ordinary (C.S.O.) Mortality Table and a Standard Industrial Mortality Table were completed in 1941. A committee headed by Alfred N. Guertin of the New Jersey insurance department prepared model bills on nonforfeiture benefits and reserve standards which were recommended by the N.A.I.C. in 1942 and generally adopted by all the states nithin the next five years

Meanwhile life insurance came through the investigation of the national economy by the temporary national economic committee of the U.S. senate in 1939–41 — as its chairman, Sen. Joseph C. O'Mahoney put it—"with flying colours." Though the movement for federal regulation desired by some seemed again to have been sidetracked. the whole question was reopened in 1944 by the decision of the supreme court of the United States in *U.S.* v. *South-Eastern Underwriters' Association, et al.,* which overruled the decision in Paul v. Virginia and held that insurance was commerce and hence, when it crossed state lines, subject to federal regulation. To obviate the possible resulting confusion, public law 15 of the 79th congress (the McCarran act) in March 1945 stated that "the continued regulation and taxation by the several states of the business of insurance is in the public interest" but provided that after Jan. 1, 1948, the federal antitrust laws and the like would be applicable to the business of insurance to the extent that such business was not regulated by state laws. Committees representing the National Association of Insurance Commissioners and all parts of the insurance business prepared model bills to meet the intent of the McCarran act, and they were adopted by most of the states by the second half of the zoth century. This legislation together with the standard nonforfeiture and valuation legislation being enacted at the same time gave insurance regulation laws a practical uniformity among the states.

In the second half of the zoth century, life insurance in force was more than four times that in 1940. (R. C. BY.)

Credit Life *Insurance.*—The rapid increase in credit life insurance in force after World War II was a significant development in the history of U.S. life insurance. Under credit life insurance the life of a borrower or installment purchaser is insured to cover payment of a loan balance in the event of death. A specific credit life policy was written for the first time in 1917 on an individual basis. Group credit life was first written in 1926. Credit life insurance in force rose steadily (except for declines in the early 1930s and again in the early 1940s), reaching a total of $1,200,000,000 by the end of 1947. In the second half of the zoth century it reached a total of $21,500,000,000 and was beginning to be considered a fourth major division of life insurance, the others being ordinary, group and industrial.

Family *Insurance.*—In the second half of the zoth century family insurance became an important factor in U.S. life insurance sales, accounting for about 20% of the total purchases of ordinary insurance. The essential idea of family insurance is that all members of a family are covered under one policy. Although the details of the policy vary among insurance companies, a typical policy pays $5,000 on the death of the husband, a lesser amount (depending on the difference in age of husband and wife) on the death of the wife before the husband's age 65 and $1,000 on the death of a child before age 21. The policy covers all children, including those unborn at the time the policy is issued, except that it is usual to restrict or deny the death benefit in the case of infant deaths The premium is, typically, the same regardless of the number of children.

Taxation.—Originally state taxes on life insurance were intended to meet the expenses of the state insurance departments but the taxes soon greatly exceeded the expenses and became sources of general revenue. In the second half of the 20th century every state imposed a premium tax, the average rate of tax among all the states being 1.82% for life insurance and 0.72% for annuities, the total annual premium tax collected by all the states from life companies being about $250,000,000.

Both the rate of tax and the formula for determining the amount subject to tax vary from state to state and are subject to change within a state. A typical premium tax law required a foreign (out-of-state) company to pay 2% of all life insurance premiums collected less dividends returned, with respect to policyholders who are residents of the state in question. The tax on domestic (in-the-state) companies is frequently less than the tax on foreign companies. Many states have a retaliatory law, which says in effect that a company domiciled in state A and doing business in state B must figure its state B tax on two bases and pay the greater: one basis is the tax specified in the statutes of state B; the other is the tax according to state A's formula for foreign companies.

Federal income taxation of life insurance companies is a complicated subject. Since life insurance company commitments run far into the future, the difficulty of accurately measuring taxable income for periods as short as a year is almost insurmountable. Hence federal income tax lams made special provision for liie insurance companies. The Revenue act in effect from 1913 to 1921 sought to tax life insurance companies in the same way as any other corporation, but with certain special adjustments necessitated by the peculiarities of the business. This method was replaced in 1921 by various formulas designed to use investment income as a base for determining a workable approximation of yearly taxable income.

In 1959 a new formula was adopted and made retroactive to results of 1958. Under this formula the tax depended on both investment income and change in surplus as well as some other factors. The formula was designed to produce a total revenue of $500,000,000 as compared with about $290,000,000 for 1957.

No generally acceptable method has yet been found. Many different positions have been taken on the subject. One position is that life insurance premiums are essentially savings and should not be taxed any more than other forms of savings. Another position, taken by persons who do not appreciate the significance of life insurance reserves, is that all investment income should be taxed at the regular corporation rate and that failure to do so constitutes an unfair tax advantage to the life insurance companies.

VI. LIFE INSURANCE FOR U.S. SERVICEMEN

1. War Risk Insurance.—The original World War I insurance was issued under the provisions of a 1917 amendment to the War Risk Insurance act of 1914. War risk insurance was issued for a maximum of $10,000 on the one-year renewable term plan with the option to convert to a permanent plan at the end of the war. The maximum amount in force during the war was about $40,000,000,000 and about $4,000,000,000 worth was converted to permanent insurance after the war.

2. U.S. Government Life Insurance (U.S.G.L.I.).—This life insurance consis'ts of two types: (1) conversions from war risk insurance; and (2) new insurance issued between World War I and World War II to active service personnel and to veterans of World War I. In the second half of the 20th century the amount of U.S.G.L.I. in force had dropped to the still very significant amount of about $1,500,000,000.

3. National Service Life Insurance (N.S.L.I.).—Under the provisions of the National Service Life Insurance act, which became law in Oct 1940, insurance was made available to all servicemen in World War II. Originally issued for a maximum of $10,000 on the five-year term plan, it was convertible to any one of three permanent plans at any time after one year from issue. After the war the term was increased to eight years without increase in premium. In 1948 the right was granted to renew for an additional five years at the premium for the attained age.

Dividends under N.S.L.I. were very generous for two major reasons: expenses were paid by the government and not charged to the insurance fund; and claims ruled as war-connected (88% of deaths during the war) were paid directly from the treasury department and not charged to the insurance fund.

Insurance in force under N.S.L.I. reached about $140,000,000,000 during World War II, an amount approximately equal to the total life insurance then in force in all the private companies combined. In the second half of the zoth century it had dropped to about $35,000,000,000.

In April 1951 congress passed the Servicemen's Indemnity and Insurance acts, which terminated all future sales of both U.S.G.L.I. and N.S.L I. and created a new system, retroactive to the beginning of the Korean war, of free indemnities for death during active service. The indemnity consisted of $10,000 less the amount of U.S.G.L.I. or N.S.L.I. in force.

VII. MORTALITY TABLES

The rate of mortality is the probability that a person will die within one year. The table below shows the rates of mortality at ages 20, 40, 60 and 80 according to seven of the historically more important mortality tables used for life insurance purposes.

The Northampton table, published by Richard Price in 1783, based as it was on a study of death and christening records in Northampton (no census of the population being available), was not really accurate. Mortality according to the Northampton table was excessively high, even for the 18th century.

TABLE 11.—*Rates of Mortality According to Seven Mortality Tables*

Table	*Age 20*	*Age 40*	*Age 60*	*Age 80*
Northampton	.0140*	.0209	.0402	.1343
Carlisle	.0071	.0130	.0335	.1217
Actuaries'	.0073	.0104	.0303	.1404
British Offices' O^M	.0040	.0092	.0289	.1384
American Experience	.0078	.0098	.0267	.1445
1941 C.S.O.	.0024	.0062	.0266	.1319
1958 C.S.O.	.0018	.0035	.0203	.1100

*One hundred and forty out of 10,000 persons age 20 will die within one year.

The Carlisle table, published by Joshua Milne in 1815, was based on two censuses and the death records for two parishes in Carlisle. The table has been very extensively used.

The Actuaries' table was based on a detailed study of mortality among policyholders of British companies. The table was published in 1843. It is sometimes called the Combined Experience table and also the Seventeen Offices' Experience.

The British Offices' Life tables (1893) were based on the experience of 60 British companies from 1863 to 1893. The study showed rates of mortality separately for different classes of policies and for both sexes. The best known and most important of these tables was the O^M table, based on the experience of male holders of whole life participating policies; it remained the standard table from 1903 until supplanted in 1935 by the A1924–29 tables, followed by the A1949–52 tables of mortality for lives insured and the A(55) tables in respect of life office annuitants.

The American Experience table was constructed about 1860 and first published under its present name in 1868. Sheppard Homans, the table's author, once stated publicly that the experience of Mutual Life of New York was the main basis for the table but that the table was not intended to be an accurate interpretation of that experience. Until 1948, most U.S. companies used the American Experience table for reserve and nonforfeiture calculations.

The 1941 C.S.O. table was based on American life insurance experience for the period 1930–40. The 1958 C.S.O. table was based on experience for the period 1950–54.

(RT. E. L.)

LIFE SPAN, ANIMAL. Much of what is known about the length of life of animals derives from observations of domesticated species or animals in laboratories and zoos. One has only to consider how few animals reveal their age to realize the difficulties involved in answering the apparently simple question of how long they live in nature. In many fishes, a few kinds of clams and an occasional species of other groups. growth is seasonal, so that annual zones of growth, much like tree rings, are produced in some part of the organism. Among game species, methods of determining relative age by indicators such as the amount of tooth wear or changes in bone structure have yielded valuable information. Bird bands and other identifying marks also make age estimation possible. But one of the consequences of the fact that animals move is that virtually nothing is known about the life span of most species as they exist in nature. For a discussion of man's life span see LIFE SPAN, HUMAN.

It is therefore reasonable to expect some surprises, as more information accumulates. The extreme claims of longevity that are occasionally made for one species or another have consistently been proven empty when subjected to critical scrutiny. Although the maximum life span that has been observed for a particular species cannot be considered absolute, since at best a limited number of individuals has been studied, this datum probably provides a fair approximation of the greatest age attainable for this kind of animal under favourable conditions. Animals in captivity, which provide most of our records of extreme age, are exposed to far fewer hazards than those in the wild. In the following table of maximum life spans, particular species have been so selected as to encompass the known range of longevity of other members of the taxonomic group to which they belong.

Very few generalizations about maximum life span can be made. Many animals are capable of living several years or decades. Ages of more than 100 years are well established only among the turtles. There are indications that large animals can live longer than smaller ones, but many exceptions to such a rule exist. The box turtle and water turtle, for example, are similar in size—as are

TABLE.—*Maximum Life Span of Animals in Captivity**

Animal	Maximum Life Span in Years	Animal	Maximum Life Span in Years
Mammals:		Amphibians:	
Bat (*Eptesicus fuscus*)	2	European Black salamander (*Salamandra atra*)	3
Grizzly bear (*Ursus horribilis*)	31	Spotted salamander (*Ambystoma maculatum*)	25
Cat (*Felis catus*)	21	Frog (*Rana* species)	5–15
Chimpanzee (*Pan troglodytes*)	37	Fishes:	
Dog (*Canis familiaris*)	34	Eel (*Anguilla rostrata*)	6
Elephant. Indian (*Elephas maximus*)	57	Goldfish (*Carassius auratus*)	25
Goat (*Capra hircus*)	18	Sturgeon (*Acipenser transmontanus*)	50
Golden hamster (*Mesocricetus auratus*)	1.8	Insects:	
Horse (*Equus caballus*)	62	Ant (*Lasius* species)	15
Lion (*Panthera leo*)	29	Buprestid beetle (*Buprestis splendens*)	30
Mouse (*Mus musculus*)	3	Fruit fly (*Drosophila melanogaster*)	0.1
Ox (*Bos taurus*)	30	Spiders:	
Squirrel, gray (*Sciurus carolinensis*)	15	Bird spider (*Avicularis avicularis*)	15
Wild boar (*Sus scrofa*)	27	House spider (*Tegenaria civilis*)	0.01
Birds:		Crustacea:	
Blue jay (*Cyanocitta cristata*)	4	Crayfish (*Astacus fluviatilis*)	30
Canary (*Serinus canaria*)	24	Water flea (*Daphnia magna*)	0.2
Macaw (*Ara macao*)	64	Mollusks:	
Nightingale (*Luscinia luscinia*)	3.8	Clams, various species	1–10
Pigeon (*Columba livia domestica*)	35	Snails, various species	1–30
Titmouse (*Parus major*)	9	Annelid worms:	
Reptiles:		Earthworm (*Lumbricus terrestris*)	10
Alligator (*Alligator mississipiensis*)	56	Medicinal leech (*Hirudo medicinelis*)	27
Garter snake (*Thamnophis sirtalis*)	6	Rotifers:	
Box turtle (*Terrapene carolina*)	123	Various species	0.03–0.1
Giant tortoise (*Testudo elephantopus*)	177		
Water turtle (*Pseudemys scripta*)	7		

*Condensed and adapted from W. S. Spector (ed.), *Handbook of Biological Data* (1956).

the European and spotted salamander—yet their life spans differ markedly. There also are indications that extreme longevity is a characteristic of certain large taxonomic groups. *e.g.,* the reptiles; but every such group also includes some proportion of short-lived species.

Not only do different species differ in longevity, but wide variations commonly exist among individuals of the same species. Knowledge of maximum length of life is therefore not nearly so meaningful as is information about average longevity. Better yet is a set of data that describes the probability of death for individuals of any age in any environment. Before examining what is known about life span in this statistical sense, it is essential that one take a closer look at the meaning of life span itself.

The concept of life span implies that there is an entity; the individual, whose existence has a definite beginning and end. What constitutes the individual in most cases presents no problem: among organisms that reproduce sexually the individual is a certain amount of living substance capable of maintaining itself alive, and endowed with hereditary characteristics that are in some measure unique. In some organisms, however, extensive and apparently indefinite growth and reproduction may occur by division of a single parent organism. If these divisions are incomplete, a colony results. If the parts separate from each other, separate organisms, genetically identical but perhaps exposed to very different conditions of life. are formed. Among the one-celled Protozoa it may be impossible to distinguish between parent and daughter organisms. If we are to consider life span in such animals, the individual must be arbitrarily defined, for the organisms are continually dividing. In a strict sense, life span in these animals is not comparable to that of sexually produced forms.

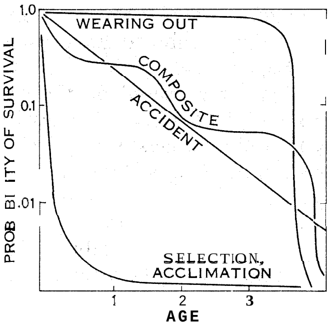
The end of the animal, or death, results when irreversible changes have occurred to such an extent that the individual no longer actively retains its organization. There is a brief period when it is impossible to say whether the organism is still alive. This time is so short relative to the total length of life that it creates no great problem in determining life span. Death, as defined: is an attribute of the individual as a whole. Although it is possible to maintain parts of higher organisms alive indefinitely, the majority of species of animals undergo processes of deterioration with time. (The nature of these aging phenomena is discussed in DEATH. BIOLOGICAL ASPECTS OF.) Some animals, however, are potentially immortal. Unless some accident puts an end to life, they are capable of surviving indefinitely. Without examining the various causes of death in detail, a distinction can be made between death as the result of internal changes, *i.e.,* aging, and death caused by some purely external factor. It is worth noting that the absence of aging processes is correlated with the absence of individuality. Many of those animals wherein the individual is hard to define do not age.

The beginning of the individual can be closely defined by the formation of the fertilized egg; or, in asexual species, by the time when physical separation of the new organism occurs. In practice, birth is commonly considered the beginning of the life span. However, the timing of birth is so different in various kinds of animals that it is only a poor criterion for this purpose. In many marine invertebrates the hatching larva consists of a relatively few cells, not nearly so far along toward adulthood as a newborn mammal. Likewise among the mammals there are large variations. A kangaroo at birth is little more than an inch long, scarcely comparable to a newborn deer. If life spans of different kinds of animals are to be compared, it is essential that these variations be eliminated.

Life span usually is measured by units of time. Although this may seem eminently logical. certain difficulties may arise there also. In cold-blooded animals in general the rate of metabolism that determines the various life processes varies with the temperatures to which they are exposed. If aging depends on the expenditure of a fixed amount of vital energy, an idea first proposed by Max Rubner in 1908, life span will vary tremendously depending on temperature or other external variables that influence life span. There is considerable evidence attesting to the partial cogency of this argument. Cold-blooded invertebrates do live longer at low than at high temperatures, so long as a certain range is not exceeded. Rats in the laboratory live longest on a somewhat restricted diet that does not permit maximum metabolic rate. Of perhaps even greater significance is the fact that many animals undergo dormant periods. Many mammals hibernate; a number of arthropods have life cycles that include periods of diapause during which development becomes arrested. Under both conditions the metabolic rate becomes very low. It is certainly questionable whether such periods should be included in computing the life span of a particular organism. Comparisons between species, some of which have such inactive periods while others do not, certainly are dangerous. It is possible that life span would be measured more adequately by total metabolism; however, data for this purpose are almost entirely lacking.

Length of life is controlled by a multitude of factors, which collectively, may be termed environment, operating on a genetic system that determines how the individual will respond. It is impossible to list all the environmental factors that may lead to death. For analytical purposes it is, however. useful to make certain formal separations. Every animal is exposed to: (1) a pattern of numerous events. each with a certain probability of killing the individual at any moment, and, in the aggregate. causing a total probability of death or survival; (2) climatic and other changes in the habitat modifying the frequency with which the various potentially lethal events occur; and (3) progressive systemic change, inasmuch as growth, reproduction, development and senescence are characteristics intrinsic in the organism and capable of modifying the effect that various environmental factors will exert.

Consider a group of similar animals of the same age. Although no two individuals can have precisely the same environment! let it be assumed that the environment of the group remains effectively constant. If these animals also undergo no progressive physiological changes, the factors causing death will produce a death rate that remains constant in time. Under these conditions, it will take the same amount of time for the population to become reduced to one-half its former number, no matter how many animals remain at the beginning of the period considered. The animals therefore survive according to the pattern of the accident curve of the figure. This is the sense in which many of the lower animals are immortal. Although they die, they do not age; how long they have already lived has no influence on their further life expectation. The situation is equivalent to that observed in the decay of a radioactive substance, wherein one can determine a half-life that indicates the rate of transformation of its atoms.



OF SURVIVORSHIP CURVES
(Numbers are in relative units)

Another group of animals may consist of individuals that differ markedly in their responses to the constant environment. They may be genetically different, or their previous development may have caused variations to arise. Those individuals that are most poorly suited to the new environment will die. leaving survivors that are better adapted. The same result can also be achieved in other ways. If the environment varies geographically, those individuals which happen to find areas in which existence can be maintained will survive, while the remainder will die. Or, as a result of their own properties, animals in a constant environment may acclimate in a variety of ways, thus adjusting to the existing conditions. The pattern of survival that results in each of these cases is one in which the death rate declines with time, as illustrated by the selection-acclimation curve.

In the absence of death from other causes. all members of a population may exist in their environment until senescence sets in. This causes a decline in the ability of individuals to survive. In a sense they can be considered to wear out as does a machine. Their survival is best described by the wearing-out curve. Individual differences among members of the population determine the degree of curvature of the survival line. The more the population varies; the less abrupt is the transition from total survival to total death.

Under the actual conditions of existence of animals the three types of survivorship outlined above all enter as components of the realized survival pattern. Thus in animals which are carefully maintained in the laboratory, survival is approximately that depicted in the wearing-out curve. Environmental accidents can be kept to a minimum under these conditions, and during the major part of the life span survival is almost complete. In all known cases, however, the early stages of the life span are characterized by a noticeable contribution of the selection-acclimation curve. This must be interpreted as a result of developmental changes that accompany the early life of the individuals, and of selective processes that operate on those organisms whose genetic constitutions are ill fitted for that environment.

In some of the larger mammals in nature, the existing evidence points to a similar survival pattern. However, in a variety of other animals, including fishes and invertebrates, mortality of the young stages is so high that the selection-acclimation curve predominates. One estimate places the mortality of the Atlantic mackerel during its first 90 days of life as high as 99.9996%. Since some mackerel do live for several years, a mortality rate that decreases with age is indicated. Similar considerations probably apply to all those animals that have larval stages which serve as dispersal mechanisms.

When the postjuvenile portion of the life span is considered by itself, a number of animals for which such information has been gathered — including primarily fishes and birds — have survivorship curves that are dominated by the accident pattern. In these species in nature, death from old age apparently is rare. Their chance of surviving to an advanced age is so small that it may be statistically negligible. In modern times human predation is a large factor in the mortality of these species in many cases. Since deaths from fishing and hunting are largely independent of age. once an animal has reached a certain minimum size, such a factor only makes the survival curve steeper, but does not change its shape. One consequence of such increased mortality is that fewer old and large individuals are noticed in a population.

More complex survival patterns, such as the hypothetical one illustrated by the composite curve. undoubtedly exist. They should be looked for in those species in which extensive reorganization of the animal is part of the normal life cycle. In effect these animals change their environment radically, in some cases several times during a lifetime. The frog offers a familiar example. During its period of early development and until shortly after hatching, the animal is subject to major internal and some external change. As a tadpole it is adjusted to an aquatic, herbivorous life. The metamorphosis to the terrestrial, carnivorous adult form is accompanied by varied physiological stresses that must be expected to produce a temporary increase in mortality rate. In some insects the eggs, larvae, pupae and adults are exposed to and respond to quite different environments. In these species a survivorship pattern even more complex than that described by the composite curve may exist.

The same species will exhibit changed survival in different environments. In captivity an animal population may approach the wearing-out curve; in its natural habitat survivorship may vary with age in a quite different way. Although one can assign a maximum potential life span to an individual—while realizing that this maximum may not be attained—it is impossible to specify the shape of the survivorship curve unless the environment is also specified. This is but another way of saying that life span is the joint property of the animal and the environment in which it lives.

LIFE SPAN, HUMAN. The human life span may be defined as the interval from conception to the age beyond which a person could not live even under the most favourable conditions. It may conveniently be designated by its maximum limit; as, for example, a life span of 100 years.

The life span frequently is erroneously thought to be synonymous with: (1) the average length of life; and (2) the expectation of life. The average length of life is the number of years lived by a group of persons, divided by the number of persons in the group. It may refer to the average length of life of the members of a group or cohort of persons (*e.g.,* presidents of the United States elected prior to 1900, or veterans of World War I), who are traced until the last member has died and whose deaths usually occur during a period of several years; it also may refer to the average age at death of persons who die during the same period of time (*e.g.,* the average age at death of persons dying in England and Wales during a calendar year).

The expectation of life is a hypothetical number computed from a mortality table. It represents the average number of years that a group of persons. all born at the same time, would be expected to live if they were subject to a fixed set of age-specific death rates from birth until the last person of the group had died. It may be computed for persons of any specified age, but the expectation of life at birth is the number most often cited (see LIFE EXPECTANCY).

The average length of life, average age at death and expectation of life are group characteristics. Except in very rare instances some members of the group will live longer than the average, some will live less than the average and none may have a duration of life equal to the average. In contrast, the span of life is the maximum age beyond which an *individual* cannot live, given even the most favourable conditions.

In this sense, the span of life is a theoretical number whose exact value cannot be determined from existing knowledge. Presumably there is a maximum life span for the human race, but until there is discovered some property of protoplasm that definitely limits the possible duration of human life, the exact duration of man's span of life will remain unknown.

At first thought. this statement seems irrational. Surely no human being can live 1,000 years. Even though all may agree that the likelihood of an individual living 1,000 years is infinitesimal, there is no scientific proof that this statement is, or is not, true. The indeterminacy of the maximum limit of human life may be made more comprehensible if one chooses a number that may appear to many as a more reasonable limit.

Since there is no verified instance of a person having lived 150 years, this number may, for purposes of illustration, be arbitrarily accepted as the maximum limit of the span of human life. But if the possibility is admitted that an individual may live exactly 150 years, there is no valid reason for rejecting the possibility that some other individual may live 150 years and one minute. And if 150 years and one minute is accepted why not 150 years and two minutes. and so on? Thus, based on existing knowledge, a precise figure for the span of human life cannot be given.

The span of life, as defined here, is a biological trait and as such is genetically determined. Its observed expression, a person's length of life or age at death, reflects the lethal effect of environmental factors that continually act upon each individual from conception until death. Although evidence supports the belief that the span of life is genetically determined, the nature of the genetic mechanism is unknown.

Much of the information concerning the inheritance of longevity has come from the study of genealogical records. Among the more important studies are those by M. Beeton and Karl Pearson, B. Stoessiger and S. J. Holmes, based on the genealogical records of nobility and landed gentry; Alexander Graham Bell's analysis of the Hyde family; E. B. Wilson and Carl Doering's study of the Peirce genealogy; and I-Chin Yuan's investigation of the records of a Chinese family for the period 1365 to 1914.

The early genealogical studies were criticized on the grounds that the downward trend in the death rate (attributable generally to scientific advancements) introduced a spurious positive correlation in statistics derived from records extending over long periods of time. It was argued that in some instances records were included of persons who, at the time of the study, had not had the opportunity of living out their possible life span. Yuan, however. excluded all persons born after 1819. His findings supported those of previous investigators in showing that the expectation of life of sons of long-lived (longevous) parents, *i* e., those living to age 70 years or older. was greater than that of sons of shorter-lived parents, *i.e.,* those having attained less than age 50 at the time of death.

Raymond Pearl attempted to avoid the defects of genealogical studies by collecting records of the family histories of 365 nonagenarians and of a comparison group of 143 individuals of varying ages, selected because all of their six immediate ancestors were dead.

Pearl introduced the concept of "total immediate ancestral longevity," or TIAL—the sum of the ages at death of the two parents and the four grandparents of a given person—as a measure of longevity. This number is unlikely to be greater than 600 or less than 90. The average TIAL of the nonagenarians and centenarians definitely exceeded that of the comparison group. This held true not only for the six immediate ancestors as a group, but also for each category—father, mother, paternal and maternal grandparents.

Pearl also computed the expectation of life for sons of fathers classified into three groups by age at death: (1) under age 50; (2) ages 50–79; and (3) age 80 or over. At birth the expectation of life for the three groups of sons was 47.0, 50.5 and 57.2 years, respectively. The same relative ranking continued through the lifetime of the sons, their expectation of life at age 40 being 27.3, 28.9 and 32.0 years, respectively.

Taken at their face value, these data show clearly that longevous persons had parents and grandparents who lived longer than the parents and grandparents of shorter-lived persons. But Pearl's study, like those of earlier investigators, is open to criticism. The comparison group consisted of persons not selected because of longevity, all of whose six immediate ancestors were dead, and who themselves had died at various ages. The failure to impose a lower limit for the age of members of the comparison group greatly increased the likelihood that the average TIAL for this group would be less than that for the longevous group. If all of the parents and grandparents of a person aged 20 are dead, some of them must have died at a relatively young age. Since four persons in the comparison group were less than 20 years of age, the results of Pearl's study must have been influenced by the method of selecting that group.

Pearl recognized this bias and attempted to correct for it. He concluded that it could not account for all of the difference in the length of life of the ancestors of the longevous and comparison groups, and that the data taken as a whole supported the belief that heredity is an important determinant of the longevity of individual human beings.

Since longevity is so important in life insurance underwriting, several studies have been made of the relationship between heredity and the life span by an analysis of life insurance records. The data from these records have a number of defects that limit their usefulness for this purpose. Persons considered to be poor risks because of ill health or a family history of disease usually are excluded. The studies were based upon the age of the parents as shown in the application for insurance. But in many cases one or both parents of the policyholder are alive at the time the application is prepared, so that their age at death is unknown

These defects limit the value of life insurance records for the investigation of the relationship between the length of life of parents and their children. Analyses of life insurance data shoved that policyholders, both of whose parents were living nhen the policy was written, live longer than those whose parents were dead when the policy was written. These results are in conformity with those obtained from genealogical records and family histories.

Each of the various types of studies of the inheritance of longevity—genealogical records, life insurance records and family histories of the general population—has limitations that restrict the generality of the findings. Nevertheless the principal studies indicate that the children of longevous parents are more likely to be longevous than are the children of short-lived parents. Conversely the immediate ancestors—parents and grandparents—of longevous persons on the average are older at death than are the immediate ancestors of persons who die at a relatively young age. These studies support the conclusion, mentioned earlier, that longevity is determined in part by heredity.

It should be observed that this conclusion relates to the inheritance of longevity—the observed expression of the span of life—and not to the span of life itself. The actual length of life is shorter than the possible life span, since the former reflects the effect of unfavourable or morbid environmental factors. It is not practicable to observe directly the effect of heredity upon the human life span, but existing knowledge supports the belief that heredity is the most important determinant of the length of the span of life.

In the absence of any biological data from which the maximum limit of the span of life can be determined precisely. an estimate of this limit must be obtained from observation of the actual length of life of persons who already have died. But such observations cannot establish a fixed limit for the span of life.

The estimation of the length of the span of life from observed data is a form of sampling from a large but incomplete population. The tabulation of the ages at death of a large number of persons from a large general population, such as the population of the United States, will give an asymmetrical frequency distribution with tno modes, or peaks of highest frequency: the first at age zero last birthday. and the second between ages 75 and 80 years. The frequency distribution is bounded by age zero at the lower limit but there is no boundary at the upper limit.

The number of deaths of persons whose length of life is near the upper limit of this frequency distribution (*e.g.*, 100 years or more) varies from year to year. The age of the oldest person dying also varies from year to year

The number of deaths of centenarians depends in part upon the number of deaths counted. For example. during the 16-year period 1930–1945. 1.611 deaths of centenarians were registered in England and Wales. This is slightly smaller than the number (1.631) registered in the United States in one year (1956). In neither country were the ages at death verified. so that the true numbers of centenarians almost certainly were less than those given in the official vital statistics.

Only a very small proportion of the deaths that have occurred throughout the history of the human race have been registered. The potential number of future deaths greatly exceeds the number that already has occurred

Statistical theory supports the expectation that as the total number of deaths continues to increase the death will be recorded of a person nhose length of life will be longer than that of any person previously known.

Observation of the length of life of persons who had died can show that it is possible for a human being to live to the oldest age recorded as of any specified date, and can provide an estimate of the relative frequency or probability of that event. Such observations, however. do not provide a logical basis for fixing any age as the maximum possible limit of the life span.

The continuation of the world-wide decline in the death rate will naturally result in an increase in the number of persons who live until age 100 years or more. Only 7 of every 100 white female babies nho are subject throughout their lifetime to the death rates in the United States registration area during 1900–02 would be expected to attain age 85. On the other hand, more than three times as many, or 24 out of every 100. white female babies subject throughout their lifetime to the death rates recorded in the United States during 1956 would be expected to celebrate their 85th birthdays. In other words, 417,000 of the 1,738,000 nhite female babies born in the United States during 1956 could expect to live at least 85 years even if there should be no further decrease in the death rate. About 6.000 of these should live a century or more.

Comparable mortality rates exist in all of North America. Australia, New Zealand, central and northwest Europe, and soon may be found also in all of Europe. Since the number of persons who may live to an advanced age, such as 110 or 115 years, is directly related to the number of persons nho live to age 100, an increase in the latter number will increase the probability that the death of an individual attaining some greater age (*e.g.,* 11j years) will be recorded at some future date

Many instances have been recorded of persons alleged to have died at an age considerably greater than 100 years Statements concerning the age at death of Biblical characters such as Methuselah can be dismissed, since scientific verification is impossible. Three of the most frequently cited cases of more recent times are: Thomas Parr, who died in Nov. 1635 at the alleged age of 152 years, Henry Jenkins. who died in Dec. 1670 at the alleged age of 169 years; and Catherine, countess of Desmond. who died in 1604 at the alleged age of 140 years. William Harvey, the famous English physician, performed an autopsy on Thomas Parr and the account of the autopsy was cited for many years as evidence that Harvey—in his paper—had confirmed Parr's age. Quite apart from the fact that it is impossible to determine accurately the age of a person by an autopsy. Harvey made no attempt to verify Parr's age but merely referred to the current estimates. Subsequent investigations have revealed that no proof exists of the age at death of any of these three individuals and that their reported ages were based solely upon hearsay

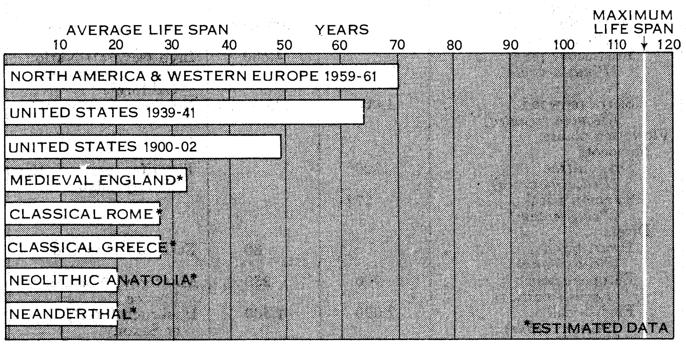
An example with more definite documentation is that of Christian Jacobsen Drakenberg. stated to have been born on Nov. 18, 1626. and to have died on Oct. 9 1772, aged 145 years and 32j days An extensive biographical sketch appears in the *Dansk Biografisk Leksikon,* and the authenticity of his age has been attested to by many persons including tno celebrated Scandinavian actuaries and statisticians, Harald L. W. Westergaard and J. F. Steffensen. However, later investigations cast doubt upon the authenticity of the persons stated to have certified to Drakenberg's date of birth. Furthermore it is difficult to accept the statements concerning Drakenberg's age at death, since this age is more than 30 years greater than the next oldest verified age at death—a difference that in itself casts doubt on its authenticity.

In 1939 W. G Bowerman stated that the oldest known age attained by an insured life or an annuitant in Great Britain or America was 107 years. Bowerman cited eight individuals for whom. in his opinion, records substantiated the fact that each had lived more than 108 years. Seven of these were females. Six of the eight were more than 110 years old at death. The oldest was Pierre Joubert. who was born July 15, 1701, and died Nov. 16. 1814. aged 113 years and 124 days. This is the oldest age at death that has been generally accepted as authentic. It is possible that Drakenberg may have lived longer than this, but his exact age at death has not been reliably determined.

It may be concluded that the span of human life is at least 114 years, but that this is not the maximum upper limit This does not mean that the span of life of each individual now living or to be born in the future is at least 114 years. The span of life, since it is determined by heredity, varies from one individual to another as do other genetically determined traits.

A significant proportion of human embryos and fetuses die before birth (*see* ABORTION). Other infants at birth have defects that limit their span of life to a few years Some malformations, *e.g.*, certain cardiovascular defects. are developmental rather than genetic in the strict sense of the word and can be corrected so that the length of life of such persons is extended (*see* FETAL DISORDERS; MONSTER).

In the past the length of life of most individuals has been con-



H. F. DORN, AFTER EDWARD S. DEEVEY. JR. IN "SCIENTIFIC AMERICAN"

AVERAGE AND MAXIMUM LIFE SPAN OF MAN

siderably shorter than their possible span of life because of unhealthful environmental factors. As these factors are increasingly brought under control or eliminated the actual length of life will approach more closely the span of life.

At the end of the 18th century the expectation of life at birth in North America and northwestern Europe aas about 35 or 40 years. By 1960 it had just exceeded 70 years. At some future date the death of a person at an authenticated age of more than 114 years can be expected.

There is no evidence that the span of human life has increased since the beginning of recorded history. Neither is there any evidence that the death rate of centenarians has decreased. The remarkable increase in the average length of life during the past 2.000 years—from 20–25 years to 70 years under favourable conditions—has increased the likelihood that a person may live to the maximum limit of his span of life. The expected increase in the number of centenarians results from a decrease in the death rate at ages under 100 years and not from any demonstrable increase in the maximum length of the span of life.

LIFE SPAN, PLANT. Plants grow old as surely as do animals; however, a generally accepted definition of age in plants has not yet been realized. If the age of an individual plant is that time interval between the reproductive process which gave rise to the individual and the death of the individual, the age attained may be given readily for some kinds of plants but not for others.

Problem of Defining Age in Plants.—An English oak that has 1,000 annual rings in the trunk is 1,000 years old. But how old is an Indian lotus plant that germinated from a seed which, containing the embryo lotus plant, had been lying in peat deposits for 1,000 years?

How old is a cultivated banana plant? Cultivated bananas produce seeds incapable of germination. Propagation of bananas is carried out by separating offshoots from a mature plant. The offshoot matures and in turn produces new offshoots. This process of growth and development has been continuing for thousands of years uninterrupted by sexual reproduction.

The mushroom caps that appear in some fairy rings persist for only a few days, but the network of fungus filaments in the soil (the mycelia) may be as old as 400 years. Because of important differences in structure, the life span of higher plants cannot be compared with that of higher animals. Normally, embryonic cells (that is, cells capable of changing in form or becoming specialized) cease to exist very early in the life of an animal. In plants, however, embryonic tissue—the plant meristems—may contribute to growth and tissue formation for a much longer time in some cases throughout the life of the plant. Thus the oldest known trees, bristlecone pines of California, have one meristem (the cambium) that has been adding cells to the diameter of these trees for about 4,600 years, and another meristem (the apical) that has been adding cells to the length of the tree for the same period. These meristematic tissues are as old as the plant; they are derived from the pine embryo that existed in a seed 4.600 years ago. The wood, bark, leaves and cones, however, live for only a few years. The wood of the trunk and roots, although dead, remains part of the tree indefinitely, but the bark, leaves and cones are continually dying and sloughing off.

Life Span in Some Major Plant Groups.—Because reproductive processes and vegetative structures vary greatly among the major plant groups, the life span of each must be considered separately.

Blue-Green Algae.—Among living things, blue-green algae have one of the longest fossil records. Sexual reproduction in this group is not known; multiplication is only by cell division and fragmentation of the algal filaments. Since there is no fusion of sex cells, each new individual is a continuation of an already existing one. For this reason some botanists have said that blue-green algae have indefinitely long life spans.

Diatoms.—Each diatom consists of a cell that secretes two half shells. One of the half shells fits into the other to make a miniature pill box that encloses the cell substance. When cell division takes place, one of the new cells receives the larger shell, the other the smaller. Each new cell then secretes a smaller half shell to fit into the existing half shell. The smaller shells may expand in some species, but for others, each division results in one offspring being smaller than the parent. The trend toward reduction in size ends with sexual reproduction or a discarding of the old shells with increase in size of the cell. In either case there is a clear ending to the old generation of cells and a beginning of a new generation. Reduction in size can continue past the point of reversal by sexual reproduction or discard of shells. In this event the cell that has reached minimum size dies. For many species of diatoms, then, there is a fairly definite life span, which depends upon the number of cell divisions that have taken place.

Bacteria.—For these forms, as for many other one-celled organisms, there is a problem as to what, in the absence of injury, constitutes death. Some students of microorganisms regard the appearance of a lifeless residue as a mark of death. When a bacterial cell is subjected to certain unfavourable conditions, it dies, and the entire cell comprises a lifeless residue. Sometimes a portion of the cell becomes a spore, a resistant structure that may be capable of resuming growth after many years of inactivity. The longevity of an individual cell, however, is figured from the time of the appearance of the cell by division until the cell itself divides. This interval is sometimes as brief as 20 minutes.

Brown Algae.—One of the giant seaweeds (*Macrocystis*) of the Pacific coastal zones may attain a length of 200 ft. Estimates of the time required to reach this length range from 100 to 800 years.

Mosses.—Only a few mosses possess structures that enable an estimate of their age to be made. The haircap moss (*Polytrichum*) grows through its own stem tip each year leaving a ring of scales which marks the annual growth. Three to five years' growth in this moss is common, but life spans of ten years have been recorded. The lower portions of such a moss are dead. though intact. Peat moss (Sphagnum) forms extensive growths that fill acid bogs with a peaty turf consisting of the dead lower portions of mosses whose living tops continue growing. Mosses that become encrusted with lime (calcium carbonate) and form "tufa" beds several metres thick also have living tips and dead lower portions. On the basis of their observed annual growth some tufa mosses are estimated to have been growing for as long as 2,800 years.

Ferns.—No reliable method for determining the age of ferns exists. On the basis of size attained and growth rate, however, some tree ferns are thought to be several decades old.

Club Mosses.—Some club mosses have a "storied" growth pattern similar to that of the haircap moss. Under favourable conditions some specimens live five to seven years.

Higher Plants.—The woody seed plants, such as conifers and broadleaf trees, are the most amenable to determination of age. In temperate regions. where each year's growth is brought to an end by cold or dryness, every growth period is limited by an annual ring—a new layer of wood added to the diameter of the tree. These rings may be counted on the cut ends of a tree which has been felled, or a special instrument, an increment borer, can be used to obtain a cylinder of wood for the purpose of counting and studying growth rings. In the far north growth rings are so close together that they are difficult to count. In the moist tropics growth is continuous so that no rings are formed.

Often the age of a tree is estimated on the basis of its diameter, especially when the average annual increase in diameter is known. The source of greatest error in this method is the not infrequent fusing of the trunks of more than one tree. Thus the famous Montezuma cypress of Santa María del Tule, a little Mexican village near Oaxaca, is 31 metres in circumference, measured 1¼ metres above the ground. This tree, described by Cortés, was earlier estimated on the basis of its great thickness to be 6.000 years old; later studies, however, proved it to be actually three trees grown together. Estimates for the age of English yews have been as high as 3.000 years; these figures also have been found to be based upon the fusion of close-growing trunks, none of which is more than 250 years old.

Seed Plants Classified According to **Life** Span.—Annuals.—Plants, usually herbaceous, that live for only one growing season and produce flowers and seeds in that time are called annuals. They may be represented by such plants as corn and marigolds, which spend a period of a few weeks to a few months rapidly accumulating food materials. As a result of hormonal changes—brought about in many plants by changes in evironmental factors such as day length and temperature—vegetative (leaf-producing) meristems change abruptly to flower-producing meristems. The formation of flowers, fruits and seeds rapidly uses up food reserves and the vegetative portion of the plant usually dies. Although the exhaustion of food reserves often accompanies death of the plant, it is not necessarily the cause of death.

Biennials.—These plants, too, are usually herbaceous. They live for two growing seasons. During the first season, food is accumulated, usually in a thickened root (beets, carrots); flo ering occurs in the second season. As it does in annuals, flowering exhausts the food reserves, and the plants die after their seeds mature.

Perennials.—These plants have a life span of several to many years. Some are herbaceous (iris, delphinium), others are shrubs or trees. The perennials differ from the above-mentioned groups in that the storage structures are permanent, or are renewed each year. Perennials require from one to many years growth before flowering. This preflowering (juvenile) period is usually shorter in trees and shrubs with shorter life spans than in those with longer life spans. The long-lived beech tree (*Fagus sylvatica*), for example, passes 30–40 years in the juvenile stage, during which time there is rapid growth but no flowering.

Some important crop plants—cotton, for example—are perennials in their native tropical regions, but are capable of blooming and producing seeds or other useful parts in their first year. Such plants are often grown as annuals in the temperate zones.

Changes Accompanying Aging.—For all plants, the transition from vegetative growth to flowering (adult) is sharp, but conditions within the plant move gradually toward the flowering state. In English ivy, mulberry, acacia and eucalyptus, leaf shape changes. Characteristics of juvenile and adult stages have also been distinguished for apples, apricots, pecans, beech, oaks, rubber (Hevea) and citrus. Juvenile oaks retain their leaves longer in the winter than do adult oaks; young citrus are thorny, whereas

Maximum Ages for Some **Seed** *Plants*

Plant	Maximum age in years		Locale of verified specimen
	Estimated	Verified	
Conifers			
Common juniper (*Juniperus communis*)	2,000	544	Kola peninsula, north-eastern Russia
Norway spruce (*Picea abies*)	1,200	350–400	Eichstatt, Bavaria
European larch (*Larix* decidua)	700	417	Riffel alp, Switz.
Scotch pine (*Pinus sylvestris*)		584	
Swiss stone pine (*Pinus cembra*)	1,200	750	Riffel alp, Switz.
White pine (*Pinus strobus*)		400–450	
Bristlecone pine (*Pinus aristata*)		4,600	Inyo (several) National forest, east central California
Sierra redwood (Sequoia *gigantea*)	4,000	2,200–2,300	Northern California
Flowering plants			
Monocots			
Dragon tree (*Dracaena draco*)	200*		Tenerife, one of the Canary Islands
Solomon's-seal (*Polygonatum*)	17†		
Dicots			
Dwarf birch (Betula *nana*)		80	Eastern Greenland
European beech (*Fagus sylvatica*)	900	250	Montigny, Normandy, France
English oak (*Quercus robur*)	2,000	1,500	Hasbruch forest, Lower Saxony
Bo tree (Ficus *religiosa*)	2,000–3,000‡		Buddh Gaya, India; Anuradhapura, Ceylon
Linden (*Tilia*)		815	Lithuania
English ivy (*Hedera* helix)	440		Ginac, near Montpellier, Prance

*Exaggerated estimates for this historic specimen reach 6,000 years. †Scars on rootstock counted. ‡According to Buddhist and Roman history.

adult citrus are thornless or nearly so. It is often possible to observe juvenile and adult areas on a single plant. Thus in some specimens of beech and oak, during the early winter, leaves may be seen on the inner branches. which still exhibit their juvenile characteristics, while the outer branches, which are adult, are barren.

English ivy gro s from seed as a creeping, nonflowering vine with five-lobed leaves and aerial roots; after about ten years. erect flowering branches with oval leaves and no aerial roots are formed. Heavy pruning or treatment with the growth substance gibberellic acid may cause the adult form to revert and produce juvenile shoots. In many woody plants cuttings from juvenile portions form roots more readily than cuttings from adult portions.

Seeds.—Although there is great variety in the longevity of seeds, the dormant embryo plant contained within the seed will lose its viability (ability to grow) if germination fails to occur within a certain time. The frequent reports of the sprouting of wheat taken from Egyptian tombs are unfounded. but some seeds do retain their viability for a long time. Indian lotus seeds (actually fruits) have the longest known retention of viability (see above).

On the other hand, seeds of some willows lose their ability to germinate within a week after they have matured.

The loss of viability of seeds in storage, although hastened or retarded by environmental factors, is the result of changes that take place within the seed itself. The changes that have been investigated are: exhaustion of food supply; gradual denaturing or loss of vital structure by protoplasmic proteins; breakdown of enzymes; accumulation of toxic materials resulting from the metabolism of the seed. Some self-produced toxic materials may cause mutations that hamper the ability of the seed to germinate. Since seeds of different species vary greatly in structure, physiology and life history (conditions under which they normally reside between maturation and germination), no single set of age factors can apply to all seeds. (See also SEED TESTING.)

Aging of Tissues and Cells.—Tissues of higher plants are layed down in meristems, areas of continuous cell division, in the stem root tips and elsewhere. All the specialized cells of leaves, fruits and other plant parts eventually undergo senescence and die. During senescence the ability of cell membranes to retain or allow passage of certain substances changes, exudation of cell materials occurs, the cementing materials between cells break down chemically. air spaces become liquid logged and cell proteins become denatured.

The meristems themselves usually remain unchanged in appearance. Only when a shoot tip meristem becomes a flower does an apparent change take place. Functional changes, however, are thought by many botanists to occur with age. The functional change may be in the meristem cells themselves, which utilize salts, carbohydrates, nitrogenous materials and hormones in one way during juvenile stages and in another way during adult stages; or the meristem may remain physiologically the same but the materials coming to it from the rest of the plant may change with age of the plant. Whichever of these suggestions is correct, the meristems of the oldest bristlecone pines are remarkably long-lived tissues that have been alive for 4,600 years. *See* also PLANTS AND PLANT SCIENCE.

LIFE TABLES. This name is applied to tables showing the number of survivors to each successive age out of a stated number (usually 100,000) of live, human births, on the basis of a given set of death rates for the various ages.

The earliest life tables. such as the table of expectation of life given about the third century A.D. by Ulpian and the table of survivors based on death records in London published by John Graunt in 1662, were based either on conjecture or on death records alone. As reliable death rates at the various ages cannot be obtained in this manner, these primitive tables must be regarded, at best. as rough approximations. The first approximately accurate life table was published in 1693 by Edmund Halley, and was based on the records of baptisms and deaths in the city of Breslau. Ger. The earliest table to be constructed on correct scientific principles. using both death records and population data classified by age, was the Carlisle table (1815) by Joshua Milne.

The compulsory registration of births, deaths and marriages in England and Wales began in 1837, and the resulting statistics, taken in conjunction with successive decennial censuses, led to the publication of the valuable series of English life tables, the first of which was prepared by William Farr and published in 1843.

The earliest U.S. mortality table, published in 1793 by Edward Wigglesworth of Harvard and based entirely on death records of a number of Massachusetts and New Hampshire towns, was constructed by faulty methods and seriously understated the average length of life. The first general population life tables for the U.S. founded on adequate statistics were prepared by James W. Glover and published by the bureau of the census in 1916. They covered only ten states and the District of Columbia. The first official life tables for the entire U.S. were those issued in connection with the 1930 census.

See DEATH RATE; LIFE EXPECTANCY; see also LIFE SPAN, HUMAN.

LIFT, see ELEVATOR.

LIGAMENT, anything which binds or connects two or more parts; in anatomy a piece of tissue connecting different parts of an organism. It consists of a cord. band or sheet of connective tissue between two or more structures which it helps to support and strengthen. These structures may be bones, cartilages, other fasciae, muscles and viscera such as the uterus, liver and others. *See* CONNECTIVE AND SUPPORTING TISSUES; JOISTS AND LIGAMENTS. (F. L. A.)

LIGGETT, HUNTER (1857–1935), U.S. soldier, was born at Reading. Pa., on March 21, 1857. He graduated from the U.S. Military academy. West Point. N.Y., in 1879, and saw service in the west against the Indians. In the Spanish--American war in 1898 he served on the staff of the adjutant general, and later was in the Philippines where, as major of volunteers he served for three years. In 1902 he was appointed a major in the regular army and spent several years with the department of the lakes and at Fort Leavenworth. In 1909 he attended the War college, and on being graduated in 1910 was appointed a director there, and in 1913 president, becoming brigadier general in the same year. From 1915 to 1917 he was again in the Philippines, being for one year commander of the department.

In 1917 Liggett was made major general and commander of the western department, but in September went to France as commander of the 41st division of the American expeditionary force. He was at the second battle of the Marne, at St. Mihiel and in the Argonne, commanding the 1st army corps and later the 1st army, and commanded the 3rd army of occupation on the Rhine. In 1919 he was commander of the western division, and in 1920 commander of the 9th corps area, retiring on March 21, 1921, with the rank of major general.

LIGHT, subjectively, the sense impression formed in the eye. (See VISION.) The present article deals with it purely objectively and is concerned with the more fundamental characteristics of light and optical instruments.

For the more practical applications which are not here discussed in detail *see* INTERFEROMETER; MICROSCOPE; OPTICS; PHOTOMETRY; TELESCOPE.

The subject is conveniently still further subdivided as to whether we are more interested in how the light originates or how it behaves after it has been emitted. The present article is chiefly concerned with the behaviour of light after it has been emitted, a branch of the subject often called physical optics, dealing almost entirely with the wave theory of light.

Following are the main sections and divisions of the article:

I. Introduction
- A. Light Waves and Photons
- B. Types of Radiation
- C. The Appearance of Ordinary Things

II. History
- A. The Age of Newton and Huygens
- B. The Age of Fresnel
- C. The Dynamical Theories of the 19th Century
- D. The Experimental Discoveries of the 19th Century
- E. Developments in the Early 20th Century

III. Waves and Interference
- A. General Characteristics of Waves
- B. The Velocity of a Group of Waves
- C. The Pressure of Light
- D. The Doppler Effect
- E. The Colours of Thin Plates

IV. Diffraction
- A. Fresnel's Construction
- B. The Formation of Shadows
- C. The Fraunhoier Diffraction Phenomena
- D. The Nature of White Light
- E. Resolving Power

V. Polarization and Electromagnetic Theory
- A. Types of Polarized Light
- B. Methods of Producing Polarization
- C. The Analysis of Polarized Light
- D. The Electromagnetic Equations

VI. Refraction and Double Refraction
- A. The Electromagnetic Equations for Refracting Media
- B. Refraction in Transparent Media
- C. Refraction in Absorbing Media

I. INTRODUCTION

It might perhaps be expected that we should begin by saying what light "really" is and should then develop its characters from such a starting point; but this procedure is not possible, since light is essentially more primitive than any of the things in terms of nhich we might try to explain it. The nature of light is describable only by enumerating its properties and founding them on the simplest possible principles. As these principles transcend our ordinary experience they must be cast in a purely logical—that is to say mathematical—form. But that is never enough. for, though logic tells us what deductions must be right, it does not tell us nhat will be interesting, and so gives no guidance as to the direction the theory will take. In choosing this direction much help is derived from analogies and models. which are often loose and incomplete but without nhich no proper understanding of the subject can be acquired. We shall therefore describe, largely by means of analogies, the behaviour of light, and this is the "real" nature of light.

A. Light Waves and Photons.— In our review of the history of the theory of light, we shall see that two very different models have vied with each other from the outset. On the one hand light mas pictured as a wave motion of some sort. and on the other as a flight of fast-moving particles. During the 19th century the former model gained almost universal acceptance, thnnks to a remarkable series of developments on both the experimental and theoretical sides. These culminated in J. Clerk Maxwell's celebrated demonstration of the electromagnetic character of light waves. At the opening of the 20th century. however. a number of new properties were discovered which apparently can be explained only by a corpuscular theory. The nature of these corpuscles. now called photons, is considerably more subtle than was imagined in the early days, but it is found that they possess energy and momentum localized in discrete packets. so that in this respect at least they resemble ordinary material particles. The existence of these two diametrically opposed models of light, each very successful in dealing with the phenomena in its own domain, presented a formidable dilemma to physics. It has led to the realization of the inadequacy of any models of the fundamental entities such as light and the elementary particles of matter. The interpretation of this dual character of light, and also of matter. which possesses wave properties as well, has been an important achievement of quantum mechanics. (See QUANTUM MECHANICS.)

In those phenomena requiring the concept of photons, the property most readily measured is the energy of the photons. The different colours of light represent photons of different energy, those of blue light having nearly twice the energy of the red. The connecting link between the corpuscular and wave models lies in the fundamental postulate of quantum theory that the energy of the photons is directly proportional to the frequency of the light waves. The latter quantity fixes the wave length, or the distance between successive crests, so that on the wave picture the various pure colours correspond to various wave lengths. Several of the wave phenomena of light can he used to measure the wave length, in some cases with a remarkable accuracy, which can exceed 1 part in 1,000,000. This is in spite of the fact that the wave length itself is very minute, amounting to only one fifteen-thousandth of a centimetre for red light. When light is dispersed into a spectrum, as by a prism, the range of colours between red and violet represents wave lengths covering somewhat less than one octave. It is therefore not surprising to find that there are invisible radiations possessing both longer and shorter wave lengths than those capable of affecting the eye.

B. Types of Radiation.— Light would be taken strictly speaking to mean only that which is seen, but it is customary to include in the term the various types of invisible radiation, because, though they cannot be seen, in all other respects their behaviour is similar. These are the ultra-violet and infra-red radiations, which lie just beyond the limits of the visible spectrum, and, more remotely, on the side of the ultra-violet. the X-rays or roentgen rays and the y-rays (see RADIOACTIVITY, NATURAL); while on the side of the infra-red we have the electromagnetic vibrations used in radio. All these radiations have an important property in common, an equal speed of propagation. The most accurate measures of the velocity of light (see VELOCITY OF LIGHT) assign the value $(2\ 997930 \pm 0\ 000003) \times 10^{10}$ cm. per second. The distinction between the various types of radiation is merely one of convenience and is based upon the different methods used for production and detection. They all represent a single phenomenon, and the differences lie only in the matter of wave length. or energy of the photons. Rough values of these quantities are given in the table.

It is not convenient to use the same units of wave length throughout such an enormous range. It is customary to measure radio waves in metres. The infra-red rays are measured in units called microns or μ, the thousandth of a millimetre, but for light the unit universally used is the Ångström unit (Å), which is 10^{-8} cm. This unit is also most frequently used for X-rays, though in precision work X-units of 10^{-11} cm. have been introduced. Much of nhat we shall say here applies to the whole range. but it is not unnatural that there should be differences, and when these occur we shall restrict ourselves to the case of light, visible, ultra-violet and infra-red.

	Wave length	Photon energy
Electric waves		
Radio broadcasting	1×10^{4} cm.	2×10^{-17} erg
: waves.		
Shortest electric waves	2×10^{-2}	1×10^{-14}
Infra-red rays		
Longest heat waves	3×10^{-2}	7×10^{-15}
Longest "rest-rays"	1.5×10^{-2}	1.3×10^{-14}
Average "rest-rays"	5×10^{-3}	4×10^{-14}
Infra-red down to	7×10^{-5}	3×10^{-12}
Visible light		
Limit of red	7.2×10^{-5}	2.8×10^{-12}
Yellow	5.8×10^{-5}	3.4×10^{-12}
Green	5.0×10^{-5}	4.0×10^{-12}
Blue	4.5×10^{-5}	4.4×10^{-12}
Limit of violet	4.0×10^{-5}	5.0×10^{-12}
Ultra-violet rays		
Limit of transparency of glass	3.5×10^{-5}	5.7×10^{-12}
Limit of transparency of quartz	1.8×10^{-5}	1.1×10^{-11}
Lyman rrgion	1×10^{-5}	2×10^{-11}
"Hot spark" region	1×10^{-6}	2×10^{-10}
X-rays		
Longest X-rays	1×10^{-7}	2×10^{-9}
Average X-rays	1×10^{-8}	2×10^{-8}
Shortest X-rays	1×10^{-9}	2×10^{-7}
y-rays	2×10^{-10}	1×10^{-6}

C. The Appearance of Ordinary Things.— In many branches of science, though we start with familiar and crude observations, we very soon find it necessary to discuss much more recondite questions, and this leads to an elaboration of the theory until the most important things in it are quite different from what is familiar to us. This situation is very emphatically true of light. For example, the most familiar thing about light is that it goes in straight lines, and hardly any of our ordinary experiences disagree with this fact. But by more refined experiments it is easy to exhibit that light is sometimes bent (diffracted), and such cases prove more important to the theory than the commonplace observations. Almost the only example of these phenomena, diffraction and interference, which is a matter of common experience is the iridescent colours that appear on soap bubbles and on the surface of greasy water.

So it comes about that the theory of light is not much concerned with the appearance of ordinary things, and. as we shall later have very little to say about them. we may consider them briefly here. In things we see, we may distinguish between the luminous and the nonluminous—in daylight between the sun and everything else. The nonluminous objects are visible only by light reflected from some luminous source. the sun or a lamp, and their different appearances are attributable solely to the different mays in which they reflect light. Thus a black object is one which does not reflect at all. A coloured object is one which reflects some colours but not others. This is easily proved by illuminating a piece of red paper by light passed through a green glass, when it will appear black because there was no red light for it to reflect. White being a mixture of all the colours. a white object is one which reflects all colours about equally. and so it looks coloured if lighted by a coloured light. When two pigments are mixed together the resulting colour will be that which they are *both* capable of reflecting, and may be quite different from the colour seen when the light of two coloured lamps is projected together onto a white screen; for exainple if the light from red and green lamps is compounded in this way the result is a brilliant yellow\,but red and green paints when mixed give a dark muddy colour because there is little light which they can both reflect (see COLOUR).

Many substances are really nearly transparent, but appear opaque because they are not homogeneous, so that the entering light is reflected and refracted many times until it is completely scattered. The most obvious example of this is ground glass, but the same is largely true of paper and white wood. An easy test of whether a substance is opaque in this way or by an inherent opacity to light is to see whether it is of the same colour for reflected and transmitted light. A sheet of red paper looks red whether we look at it or through it at a light, because in both cases what we see is light which has got tangled in the fibres and at each reflection has lost a little of the green and blue light by absorption, so that only the red emerges on both sides. On the other hand. if a substance is truly opaque the'colours on the two sides will be quite different. For example the yellow colour of gold is a result of the fact that it reflects the yellow light more effectively than other colours, and. by a paradox which we shall explain later, this means that it absorbs the yellow more strongly. If then we take a very thin sheet of gold, the yellow light will not penetrate it so easily and the transmitted light will be bluish green.

II. HISTORY

The ancients were acquainted with mirrors and with the burning glass, hut their theories of optics were rather of the metaphysical character so much more congenial than experiment to the Greek temperament. The Pythagoreans believed in an emission theory, supposing that the seen object emitted particles which bombarded the eye, but the Platonists complicated the matter by supposing that vision was produced by a triple interaction between rays emitted by the sun, the object viewed and the eye itself. Among these speculations we can distinguish the discovery of only one real scientific law, cnunciated by Hero of Alexandria, who saw that the equality of the angles of incidence and reflection at a mirror could be expressed by saying that the ray took the shortest possible course between object and eye. This law is the first statement of the general "principle of least action," a principle which now dominates not only geometrical optics but also dynamics.

We may omit the other speculations of the Greeks, Romans and Arabs and come to the Revival of Learning. The earliest developments were practical, such as the invention of spectacles and later of the telescope, with which we shall not be concerned here. The first great theoretical discovery was the law of refraction discovered by Willebrord Snell in 1621 but not published until after his death by René Descartes. This law asserts that when a ray of light passes from one medium to another, the plane of the two rays contains the normal to the surface, and the sines of the angles of incidence and refraction are in a constant ratio, the refractive index. Descartes was led by a metaphysical argument to maintain that light was some sort of pressure in a medium (in a very indefinite way something like the present wave theory) and thought that the velocity of light must be greater in a denser medium. This view was combated by Pierre de Fermat, also on metaphysical grounds, and modern theory supports Fermat though not his reasoning. It seems to be the rule rather than the exception that correct results are first obtained from quite incorrect arguments. Fermat asserted that nature performs its operations always by the most direct path, and that therefore a ray of light between two places must take the shortest possible time. Now it is easy to show that there are many examples, both for reflection and refraction, in which the time of transit is not a minimum. but a maximum: The generalization of Fermat's "principle of least time" subsequently made by Sir William Hamilton rnerely states that the actual path shall be stationary with respect to other closely adjacent paths. Snell's law then implies that the velocity of light in the medium is inversely proportional to its refractive index, in agreement with Fermat's conclusion.

A. The Age of Newton and **Huygens.**—The first great era in the theory of light is the second half of the 17th century. Francesco Grimaldi discovered (and named) the phenomenon of diffraction, that light going through a fine slit cannot be prevented from spreading on the farther side, and that no matter how small the source of light, the edge of a shadow cannot be perfectly sharp. Robert Hooke independently discovered the same thing and offered a theory approaching closely to the wave theory in that he had the idea of wave fronts and of light's being some sort of oscillation; but it was more than a century before it was seen that the strongest possible argument for this theory lay in the discovery of diffraction. During the same era Olaf Roemer measured the .velocity of light for the first time, by a comparison of the calculated and observed times of the eclipses of Jupiter's satellites.

Of all the founders of the theory of light, undoubtedly the greatest were Sir Isaac Newton and Christiaan Huygens (*qq.v.*). Newton discovered the theory of the spectrum. By passing a fine beam of sunlight through a glass prism he resolved it into its component colours: red. orange. yellow, green, blue, indigo and violet. It had already been known that white light was resolved into colours on passing through glass or water (for example the rainbow had been explainedj. but it was supposed that the glass had produced a definite alteration in the light. Newton showed that, if the light passed through a second prism reversed. the coloured lights would recombine into white, but that if a single colour were selected from the spectrum, no subsequent treatment could change it in any way. He was thus led to the correct explanation of white light as a compound of all the colours, but the further details of this question would lead us into physiological optics (see VISION OR SIGHT).

Newton also investigated the colours of thin plates such*as soap bubbles. He placed a slightly convex lens on a flat piece of glass and observed the reflected light. At the centre the surfaces are in contact and nothing is reflected, but round this point, where they are very close, though not in contact, there appears a succession of brilliantly coloured rings, the succession of colours being black, faint blue, strong white, orange, red, dark purple, violet. blue, faint green, vivid yellow, etc. The rings become narrower and fainter as we go outward and soon become invisible. These are not the colours of the spectrum, and their origin is better appreciated by considering the case where the illumination is by monochromatic instead of white light. There is then a dark centre surrounded by a large number of rings of the colour used. The sizes of the rings depend on the colour of the light; they are closer together for blue than for red. If then we illuminate simultaneously with red and blue light there will be places where the rings fall together, so that we get alternately purple and dark rings, and other places where they fall apart and we get alternate rings of red and blue. Where the two ring systems coincide they look sharp; otherwise they are blurred. The rings in white light can be explained in the same way as resulting from a superposition of all the colours, and at no great distance from the centre so many of the coloured rings overlap that they become completely blurred.

Newton was very cautious in making theories, and he did not really succeed in explaining his rings, but he attributed them to certain "fits" of reflection and transmission which later were seen to be very like the "phases" of the wave theory. As to the general theory of light he was also very noncommittal, but he criticized the wave theory as being unable to explain rectilinear propagation, and his followers, interpreting his views in a much narrower way than he intended, adopted a complete corpuscular theory of light which held the field for more than a century. This theory supposed that light consists of minute particles, or corpuscles, shot out from the luminous body, and attempted to explain all the phenomena by suitably modifying the properties of these corpuscles. The theory implies that the velocity of light must be proportional to the refractive index, not inversely proportional as in Fermat's principle and the wave theory, and this distinction later provided a critical test which condemned it.

Huygens is the real founder of the wave theory of light. He based his belief in it primarily on the fact that, if a beam of light were like a flight of arrows, then when two beams cross there should be collisions between the arrows. He succeeded in explaining reflection and refraction, and we may consider his construction, as it lies at the foundation of modern methods. The general idea is that light is a disturbance in a medium, but it need not be specified what is the character of the disturbance; for purposes of rough visualization we may think of the medium as a jelly which is distorted so that its particles move out of their usual places. Any disturbance then acts as a centre causing the propagation of a wave of disturbance to go out at a constant speed, so that at any subsequent time the effects of the initial disturbance will be found on a sphere surrounding it. When the initial disturbance is not confined to a single point, each point of it is to be regarded as a source, and the subsequent disturbance is the geometrical envelope of the spheres surrounding all these sources. Refraction is explained by supposing that the velocity of light is different in different media. Consider light obliquely incident on a flat surface, say of water (*see* fig. 1). The velocity of propagation outside is c, the velocity of light; in the water it is v, a slower velocity. The advancing disturbance is at one moment spread as a pulse over the surface AB. Each point of AB gives out a spherical pulse, and, to reconstruct the wave later, we draw spheres of equal radii round all the points of AB. Obviously one such set of spheres will give the line CD as its envelope, and this shows that the light goes in the direction AC outside the water. But if we repeat the construction starting at CD we have to allow for the fact that the velocity is less in water than in free space. Thus, corresponding to the sphere of radius DF about D, we draw round C a sphere of radius $CE=(v/c)DF$, and it is evident that EF will be bent round more nearly parallel to the face than was CD. After this both spheres are in the water and the propagation goes straight again on to GH. This construction immediately gives Snell's law of refraction, for $\sin ACM/\sin GCN=DF/CE=c/v$, and the refractive index is simply the ratio of velocities. The construction fails in the case of very oblique incidence if v is greater than c, for then the circle round C may have a radius actually greater than CF itself. Refraction is then impossible, and all the light is reflected. This is the phenomenon of total internal reflection which we shall discuss later. A simpler construction than that we have given applies for reflection, and the same principle also explains diffraction, but Huygens did not find this out.

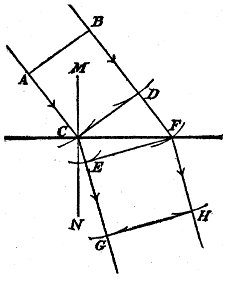

FIG. 1.—HUYGENS' CONSTRUCTION FOR REFRACTION

Huygens' other great investigation is connected with double refraction. Certain crystals of calcium carbonate, from Iceland, called calcite or Iceland spar, have the extraordinary property that objects viewed through them appear double. To reduce the matter to simpler terms it can be expressed thus: a crystal of calcite resembles a cube that has been compressed along one of its diagonals. Suppose that a narrow beam of light is incident on one face perpendicularly. If the crystal were glass the beam would emerge from the opposite face in the same line. Actually two beams emerge, one in the same way as for glass, but the other in a new line though in a direction parallel to the first (*see* fig. 2). These two beams are called the ordinary and extraordinary rays. Huygens successfully applied his wave construction to explain them by supposing that two surfaces must be constructed round each point, one a sphere which would give the ordinary ray, but the other a spheroid with its axis of revolution determined by the crystal axis (that is, by the shortened diagonal of the cube) which would give the extraordinary ray. This is illustrated in fig. 3. Round the points C and D we draw not only a sphere but also a spheroid, which is such that the two surfaces touch at the points that lie in the direction of the crystal axis (the point K in fig. 3). The envelope of the spheres is the plane EF, the direction of motion of which shows the path of the ordinary ray, while the plane GH is the envelope of the spheroids and its motion shows the path of the extraordinary ray. Observe that the latter ray is not perpendicular to the wave front. The ray must here be conceived as the direction in which the energy flows.

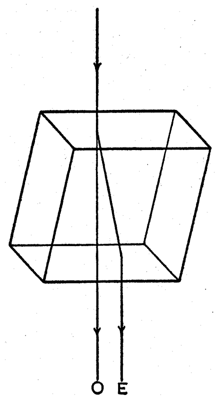

FIG. 2.—DOUBLE REFRACTION, SHOWING TWO RAYS EMERGING WHEN A SINGLE LIGHT RAY STRIKES A CALCITE CRYSTAL PERPENDICULARLY

Huygens also discovered, though he did not explain, the phenomenon of polarization. If we rotate our crystal about an axis in the direction of the beam and observe the projections of the two rays on a screen, the ordinary ray will stay fixed, and the extraordinary, which will be equally bright, will rotate round it. But now suppose that we isolate the ordinary ray and pass it in the same way through a second crystal. In general it will give rise to two rays, ordinary and extraordinary, but this time they will usually be of unequal brightness. If the two crystal axes are parallel, the extraordinary ray will be absent altogether, but as the second crystal is turned it will gradually grow in brightness at the expense of the ordinary, until, when the crystal has turned through a right angle, the ordinary ray will be entirely extinguished. Rotation through a further right angle will restore the ordinary ray and destroy the extraordinary. A similar rule applies for the extraordinary ray from the first crystal; it usually gives both types, but only an extraordinary ray when the crystals have their axes parallel. Newton recognized the essential features of the matter in saying that a ray of light may have *sides;* in fact that this light differs from ordinary light as a thin lath differs from a round stick. This characteristic we now describe by the word polarization. The idea of transverse vibrations had not yet been formulated, so that no further advance could be made at this stage.

We may here remark that the Huygens wave construction explains what some may regard as a philosophic difficulty in Fermat's principle. According to this principle the rays of light between two points A and G (fig. 1) adopt that path which takes the shortest time; and though the only way we have ordinarily of determining a minimum is to try a number of paths and see which is quickest, yet the ray appears to adopt the right course without any alternative trials. The wave construction explains why it does so, for it shows that the wave is, so to speak, all the time trying alternative routes, and is adopting the shortest because the waves in other paths cancel out.

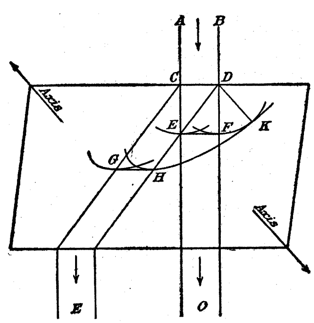

FIG. 3.—HUYGENS' CONSTRUCTION FOR DOUBLE REFRACTION

Each point of C and D sends out a sphere and spheroid wave. The spheres give the ordinary ray through EF; the spheroids the extraordinary ray through GH

In spite of these great advances, the state of knowledge at the end of the 17th century was really insufficient to give a decision between the two theories, and moreover there was hardly the beginning of a mathematical wave theory as yet, so it is perhaps not surprising that the corpuscular theory of light gained the upper hand. The 18th century was singularly barren in optics, and the only first-class discovery appeared strongly to support this theory. This was the discovery of stellar aberration, by James Bradley (see ABERRATION OF LIGHT), which for corpuscles is immediately explained by the idea of relative motion; with waves, though a crude explanation is not hard, the final solution was only obtained in the 20th century with the advent of relativity.

B. The Age of **Fresnel.**—The second great period of discovery coincided with the beginning of the 19th century, and the first successes fell to Thomas Young. He adopted the wave principle of Huygens, but extended its application. Thus Huygens had only considered waves of the form that we should now call pulses, but Young made use of continuous periodic waves, and so was enabled to explain Newton's rings in a manner we shall discuss later. He clearly stated the general principle of superposition, that "when two undulations from different origins coincide, either perfectly or very nearly in direction, their joint effect is a combination of the motions belonging to each." This principle is quite general, but Young perceived that interesting results would follow only when the two sources are coherent, that is to say, when two beams from the same source are brought to superposition, for only so could the irregularities in the process of emission be the same for both. He therefore set up what has proved to be one of the classical experiments of optical theory.

Two holes are made close together in a screen, and light from a distant point passes through them and illuminates another screen. If the holes are large there will be merely two patches of light on the screen, but when the holes are made smaller diffraction occurs, so that the rays of light spread and the patches are larger instead of smaller as might be expected at first sight. When the holes are very small the patches will overlap and it is then observed that they are crossed by a number of fine bands. To understand this, let us suppose the light to be monochromatic (of a single wave length) so that the vibrations of the light wave are in the form of a travelling sine curve. The source of light is equidistant from the two holes A and B (fig. 4), so that at those points the waves are in the same phase (shown diagrammatically in the figure). On passing through the small hole, each beam emerges as a spherical wave. At the central point O of the screen the distances to A and B are equal so that the phases agree at every moment; the effects from the two holes will reinforce one another and O will be illuminated. Consider however a point P which is $\frac{1}{2}$ wave length nearer to A than to B. Here the waves from A and B are at all times in opposite phases (in the diagram when one wave is at the top the other is at the bottom, etc.) and so cancel, with darkness as the result. At the point Q, which is a whole wave length nearer to A than to B, the waves will reinforce each other again, because one wave is exactly a wave length behind the other, and there will be light. Proceeding in this way the whole field is seen to be covered by alternate bright and dark bands. In the case of white light there will be a few coloured bands in the middle and the rest will look white; the colours can be worked out in just the same way as with Newton's rings. Young's interference pattern is by no means easy to observe, as it requires very careful adjustments because of the exceedingly short wave length of visible light. To give an idea of its magnitude, if the holes are 1 mm. apart and the screen is at a distance of 1 m., then for red light the bright bands are a distance 0.6 mm. apart.

The investigation of polarization (see *V.* Polarization *and* Electromagnet-*Theory,* below) at this epoch received a great impetus by the discovery of Étienne Malus that, when sunlight is reflected from glass, the reflected ray may be polarized. Sir David Brewster studied the matter and found the rule that the reflected light was completely polarized when the reflected and refracted rays were perpendicular to one another. In the course of this work he discovered experimentally the formulas for the intensity of the two polarized components of light reflected from a transparent substance. If i is the angle of incidence and r that of refraction, the fraction reflected is $\sin^2(i-r)/\sin^2(i+r)$ or $\tan^2(i-r)/\tan^2(i+r)$, according to the direction of polarization. These expressions are usually called Fresnel's sine and tangent formulas, and have played

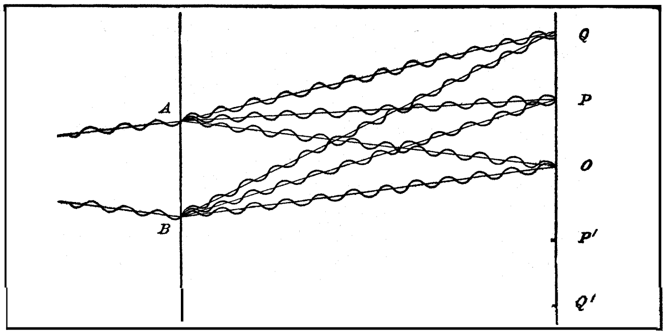

FIG 4 — YOUNG'S INTERFERENCE EXPERIMENT

Monochromatic light falls on the two holes A, B. Point O is equidistant from them, so that the waves reinforce each other. P is ½ wave length nearer to A than to B, so that the waves cancel out, while Q is a whole wave length nearer, and they reinforce again. Bright bands will appear at O and Q,Q′, and darkness at P,P′

a part in the history of optics. In the special case where $i+r=90^\circ$ the tangent expression vanishes and. as the other does not, the reflected light is completely polarized. Brewster also made the important discovery that some crystals exhibit double refraction of a different type from that of calcite investigated by Huygens. In these crystals there are two directions instead of only one for which the light does not become polarized. That is, instead of the single axis shown in fig. 3. such crystals have two, and are called biaxial. We may also here mention the discovery by Dominique F. J. Arago of gyration (formerly called "optical activity"). When a beam of polarized light is sent through a quartz crystal along the axis, or through a sugar solution, it is observed that, on emergence of the beam, the plane of polarization has rotated by an amount proportional to the length of the path it has traversed. We shall discuss all these matters in detail later.

The greatest investigator of this period was Augustin Fresnel, and in his hands optical theory attained the outline nhich it has kept ever since. As we shall have to deal aith his work in detail, we shall here only mention his discoveries without explaining them. First he adapted Huygens' construction to explain diffraction. and thereby established the superiority of the wave theory over the corpuscular. In the course of this work he demonstrated the remarkable fact that there is a bright spot exactly in the centre of the shadow of a circular screen. Like Young he also made various experiments to exhibit the interference of two beams of light. He then turned his attention to the optical effects of moving bodies (including the motion of the earth) and correctly formulated all the principles; this important work had a great influence in connection with relativity theory, but is outside our scope here. Next he made the discovery (with Xrago) that, when two beams of light are differently polarized, even if they arise from the same source, it is impossible to make them interfere. At this period the vibrations of light were thought to resemble those of sound, so that there seemed to be no room for polarization in the theory, but Young hit on the solution that the vibrations were transverse, so that a wave of light may have sides, as Newton had said. Fresnel next turned his attention to double refraction and completely solved the whole problem, uniting into a single system both Huygens' uniaxial and Brewster's biaxial types. Finally he deduced theoretically the laws of refraction and reflection and obtained the sine and tangent formulas to which we have referred. Fresnel's whole work was devoted to establishing rigorous principles for light, and the enormous progress he made is the more remarkable when we remember that the mathematical theory of naves was only in its infancy, and that there hardly existed at all any dynamical theory of continuous media.

C. The Dynamical Theories of the 19th **Century.**—With the discoveries of Fresnel, the more geometrical part of the wave theory of light nas practically complete; but it was still necessary to build a proper dynamical formulation, and this was the chief preoccupation of theorists during most of the 19th century. It was felt necessary to make a model of some sort of matter which should behave like the optical medium. The most obvious model suggested was that of an elastic solid, and, with the help of this, Augustin Cauchy, Franz Neumann and others had considerable success in explaining the phenomena for a single medium, but the theories got into difficulty when it came to the passage of light from one medium to another. Only by highly artificial hypotheses was it possible to obtain the sine and tangent formulas.

The work of George Green on the propagation of waves in elastic solids is the real beginning of the modern mathematical theory of waves. A piece of solid matter can be strained (altered in form or position) in three ways. It may be compressed without other change of form, or it may be sheared so that a square becomes a rhombus, or, without changing its shape, it may be rotated in position. The third type of strain can take place without the necessity of forces, but the first two require the action of forces in order that they may occur. The solid will possess two elastic constants corresponding to these forces (we are thinking of an isotropic body, not a crystal which may possess 21), and can propagate two types of wave, a longitudinal corresponding to compression, and a transverse corresponding to shear. Green showed that when a transverse elastic wave passes from one medium to another it necessarily gives rise to a longitudinal wave, and for this there is no room in the theory of light. Though his result was thus mainly negative, Green's calculus firmly established what conditions a valid theory must satisfy. Under the inspiration of Green's methods, Sir George Stokes gave a rigorous solution of the problem of diffraction in place of Fresnel's approximate geometrical method.

A valid formulation for the dynamic theory of light was first made by James MacCullagh, who assumed that the ether was a new kind of material which opposed no resistance to compression or shear, but which resisted rotation. Such a material satisfies all the necessary conditions, but it suffers from the objection that there is no known kind of matter which has the property, and for this reason it was regarded with great suspicion and its importance was not appreciated till long afterward. During the middle of the 19th century there were many attempts, especially by Lord Kelvin (then W. Thomson), to invent a substance which should satisfy all the necessary conditions, but they were mostly very artificial. The modern theory was finally formulated about 1860 by James Clerk Maxwell, who showed that electric oscillations must involve emitted waves which would have the same transverse character and would travel with the same velocity as light. He therefore identified light with electric waves, and gave the complete system of equations (then seen to be identical with MacCullagh's) which determine the behaviour of light. This theory has firmly held the field ever since, and Maxwell's name ranks as high as any among the contributors to optical theory. The completeness of his theory, and perhaps the familiarity that grows with the lapse of time, has overcome the objection that no known matter conforms to the same rules of vibration as the ether.

D. The Experimental Discoveries of the 19th Century.— During the period of these great theoretical investigations the experimental side had of course not been neglected, and many important discoveries had been made and instruments invented. Joseph von Fraunhofer studied diffraction in a rather different way from Fresnel, and constructed gratings by winding wire between two fine screws and by ruling lines with a diamond on glass. With these he analyzed the solar spectrum, and his work is thus the origin, both in subject matter and in method, of the modern science of spectroscopy. The invention of Nicol's prism (usually called the nicol and described below in connection with fig. 14) made it easy to produce polarized light, and this was for a long time the standard instrument in the study of polarization. Stokes began the study of ultra-violet light, rendering its effect visible by means of the property of fluorescence (see LUMINESCENCE); it is now more usually investigated by photography. Michael Faraday discovered the theoretically very important phenomenon of magnetic gyration—that. when a transparent substance is in a strong magnetic field, a beam of polarized light passing through it along the direction of the field has its direction of polarization rotated. This was the earliest connection discovered between light and electricity. Armand Fizeau and Jean Foucault developed methods of measuring the velocity of light accurately, and among other things showed that light really does go more slowly in water than in air, as is demanded by the wave theory.

We must also mention the slow development of the theory of dispersion; *i.e.*, the dependence of the refractive index on the wave length. Fresnel and Cauchy had propounded a theory which attributed it to the coarse-grainedness of the refracting medium, from which it followed that the refractive index could be expanded in powers of the inverse square of the wave length. This is often possible, but its inadequacy was seen when F. P. Leroux discovered the phenomenon of "anomalous dispersion" (which is not really at all anomalous), that substances exist which refract the red more than the blue. A hint of the modern theory was given by Maxwell, but its real development is attributable to W. Sellmeier, who showed that dispersion was an example of the general phenomenon of resonance. At the end of the 19th century Hendrik Lorentz revised the whole of Maxwell's theory, introducing the idea of electrons, and in the course of his work improved Sellmeier's dispersion formula.

During the closing decades of the 19th century an aspect of the wave theory which has had results of the most far-reaching importance was much studied experimentally. Fresnel had successfully treated the optical theory of moving media up to a point, but many difficulties remained with regard to the movement of the earth as a whole. Stellar aberration suggested a fixed ether through which the earth moved, but then it seemed possible that for terrestrial experiments this motion ought to be detectable. Because of the great velocity of light, none of these experiments was easy, but all gave negative results; particular mention may be made of the experiment of Albert Michelson and Edward Morley, which was of such accuracy that, though it depended on the square of the ratio of the earth's velocity in its path about the sun to that of light, it definitely established the negative. The mathematical theory was developed by Sir Joseph Larmor and Lorentz to deal with this matter, and a very profound interpretation, given to it by Lorentz, led to the promulgation of the theory of relativity by Albert Einstein ***(see*** RELATIVITY).

E. Developments in the Early 20th Century.—As the 20th century opened, it seemed that optical theory had attained a completeness and perfection which hardly left room for further development. But this complacent view was destined to receive a series of rude shocks as a number of new phenomena concerned with the interaction of light and matter were discovered. As was mentioned in the introduction, these apparently could not be reconciled with the theory of electromagnetic waves, but required a return to the corpuscular theory in a modified form. Yet the classical wave picture was so thoroughly successful in dealing with the majority of optical effects that there could be no question of its being supplanted by one so radically different. The way in which these two views of the nature of light have been reconciled will be indicated at the close of the present article, and a more complete discussion will be found under QUANTUM MECHANICS (*q.v.*).

The experimental discoveries that led to the introduction of photons or light quanta are relatively few, although as a result of the mathematical formulation of the quantum theory in 1926 it became clear that they are essential in explaining all phenomena that involve the emission of light, as well as its transmission through and absorption by matter. Foremost among the early discoveries, and the one which showed most clearly the inadequacy of the electromagnetic theory, was the photoelectric effect (see PHOTOELECTRICITY). The work of Philipp Lenard in 1899 had shown that the electrons which are ejected from a polished metal plate when light falls upon it have velocities that are uninfluenced by the intensity of the light. Greater intensity merely increases the number of electrons. Altering the wave length of the light does affect the velocity, and in such a way that the energy of the electrons is inversely proportional to the wave length when the latter is sufficiently short. These facts led

Einstein in 1905 to propose that in its interaction with electrons the light is concentrated in the form of small corpuscles (photons) of energy proportional to the frequency of the light. The entire energy of one photon is absorbed by the electron, and the photon is annihilated Less direct evidence for the absorption and emission of radiation in discrete amounts had already been found by Max Planck (1900) in attempting to explain the distribution of energy in the various wave lengths emitted by hot bodies. The constant of proportionality between frequency and energy found by Planck was exactly the one needed to give the proper energies in the photoelectric effect. Its numerical value is now taken to be $h=(6.6252\pm0.0002)\times10^{-27}$ erg$\times$sec. The energy E of a photon in light of frequency ν is then given by $E=h\nu$.

Other corpuscular effects appeared in rapid succession. The explanation of the spectrum of hydrogen by Niels Bohr in 1913 required an assumption that the frequency is to be determined by equating the change in energy of the atom to $h\nu$. *(See* SPECTROSCOPY.) In X-rays the existence of a sharp upper limit to the frequency of the continuous radiation showed that the energy of the electrons striking the target, if completely converted into radiation, could only yield a certain maximum ν determined by $E=h\nu$. Again, the lowering of the frequency of X-rays when they are scattered by matter mas interpreted by A H. Compton as caused by the loss of energy when a photon rebounds from a collision with an electron. The fact that photons possess momentum was strikingly displayed in this experiment. *(See* COMPTON EFFECT.) These investigations were the first to give rise to the concept of photons, and they have been followed by many others that are readily interpreted by considering the interaction of photons with particles of matter but that are inexplicable on a wave theory.

It is important to notice the characteristic realms of optical phenomena in which the tno models of light, nave and photon, find their applicability. Certain readily observed properties, such as rectilinear propagation, reflection and refraction, fit well with either picture. Interference and diffraction, however. which are cases of the interaction of light with light, are explainable only by waves. The wave theory is also capable of dealing with the transmission of light through matter, provided that the light is of not too high a frequency nor too close to characteristic absorption frequencies of the material. Thus the electromagnetic theory gives a good account of dispersion, polarization and double refraction, as we shall see in the following sections. The corpuscular properties of light come into special prominence when we have to do with the interaction with matter of light of high frequency, which means photons of high energy. As the wave length becomes shorter in proceeding through the electromagnetic spectrum. the wave properties steadily give place to corpuscular properties. At the short wave length end. with X-rays andy-rays. it is even very difficult to detect the wave properties, although the interference of X-rays has been beautifully demonstrated. Radio naves. at the other extreme, can be treated purely as electromagnetic vibrations, and their corpuscular properties are of no importance.

Light occupies an intermediate position on the wave length scale. and correspondingly we find that it displays nave properties under certain conditions, corpuscular properties under others. The fact that the latter remained undiscovered until comparatively recently is an indication that in its commonest aspects light is most suitably represented as a wave motion. This is the justification for presenting the subject, as is done here. exclusively from the point of view of wave theory. It is true that very weighty matters, such as the processes of emission and absorption, cannot be included in such a discussion but are more appropriately treated under SPECTROSCOPY and QUANTUM MECHANICS.

III. WAVES AND INTERFERENCE

The most familiar form of waves is of course the surface waves of water. but the term is extended to cover any vibratory effect propagated through a medium. For example, if we take a long stretched string and strike it near one end, a small hump will form and will travel without change of shape down the string. Though the portion of the string humped is changing all the time, the geometrical form is unchanging. and so we can endow this form with individuality and say that the wave goes at a certain speed. If x denotes the distance of any point on the string from the point of reference, or the origin, and ϕ the displacement of the string at that point, the motion is described by the differential equation

$$\frac{\partial^2\phi}{\partial x^2}=\frac{1}{c^2}\frac{\partial^2\phi}{\partial t^2},$$

the solution of which is $\phi = f\,(x- ct)$. This expresses the fact that. whatever the initial form, the form at time t is the same with the origin shifted a distance ct.

A. General Characteristics of Waves.—The vibration of a string is especially simple because the wave undergoes no change of form, but in most cases, such as water waves, that is not so; for as the wave travels it alters shape, and so it is no longer possible to speak of a definite velocity. It is therefore necessary to analyze the waves into definite types which can be studied separately, and the type which is incomparably the most useful is the sine curve. That such an analysis is useful is a consequence of the principle of superposition enunciated by Young; mathematically this principle follows from the fact that the differential equations of wave motion are linear. so that if we have two solutions of a wave problem we can derive a third by taking their sum. Thus any problem can be solved by expressing the initial state as a sum, or more usually an integral. of sine curves of various wave lengths, then solving the motion for each of these separately and finally recombining them. This is the only method available for water waves; and though plane waves of light are propagated in free space without change of form, any obstacle or refractive medium destroys this simplicity and makes analysis necessary.

In discussing the general characteristics of waves we may conveniently think of a stretched string. but when the appropriate name is given to the dependent variable ϕ everything we shall say applies equally well to water waves. sound or light. Thus, ϕ in the string means the displacement of the string sideways, in water waves the elevation of the surface above its average height, and for sound it might mean the variable part of the air pressure; for light we shall later specialize it rather more and identify it with the electric force. In all these cases the typical solution is

$$\phi=A\cos\left[2\pi\,(\nu t-x/\lambda)-\epsilon\right].$$

First considering the motion of a particle of the string, we keep x constant and see how ϕ depends on t. It is a pure harmonic vibration of amplitude A and frequency ν, frequency meaning the total number of vibrations performed in a second. The expression $2\pi(\nu t-x/\lambda)-\epsilon$, regarded as an angle, is the phase at the time t at the distance x from the origin. It can be interpreted very simply by the consideration that, nhen a point describes a circle at uniform speed, its projection on a diameter describes a harmonic motion: then the angle betneen this diameter and the radius through the point is the phase angle. The term phase. though quite precise, is often used in a looser sense, because its absolute value does not matter. whereas differences in phase are of the very greatest importance in deciding the character of a wave. We next examine the shape of the string at any instant of time and see that it is a sine curve of wave length λ. The amplitude, frequency, wave length and phase are the four quantities characteristic of any wave.

The wave is progressive because of the phase relations between the various points of the string. If at any instant we compare the phases at x and $x+a$, we see that the latter is an angle $2\pi a/\lambda$ behind, and that at a time $a/\lambda\nu$ later it will have arrived at the phase which was at x initially. We therefore take $\lambda\nu=V$ as the wave velocity or phase velocity; it is the rate at which the crests move. Though phase velocity plays a most important part in wave theory, it is misleading to think, of it as a real velocity. For example, it is a general principle that no effect of any kind can be propagated with a speed greater than c, the velocity of light in *vacuo,* but it is always possible to find certain frequencies for which the phase velocity of light is considerably higher. When we say that no effect can travel faster than c, we are thinking of the rate at which waves advance into a region previously undisturbed, but phase velocity has a meaning only in connection with a sine curve. and a sine curve extends indefinitely in both directions, so that there is no undisturbed region to which the principle can apply.

In the case of water waves, and perhaps of electric waves of very long period, we can observe the crests and so can see directly the wave velocity and measure the amplitude, but in general it is impossible to do this. Usually we observe only some dynamical effect. such as that which occurs when the rays of light impinge on the retina of the eye. The exact form of this effect is special to each type of wave, but it is a general principle that the effect depends on the energy of the waves, and this is proportional to the average value of the square of the amplitude of the wave variable ϕ. This quantity is the intensity; it is often quite unnecessary to know the factor of proportionality associated with it. It is important to observe that the amplitude can be deduced from the intensity but that nothing can be said about the phase; this is a consequence of the dynamical fact that only by altering the phase can the wave medium do work on the observing instrument, so that only by spoiling the phase can we observe the wave.

The case of waves in three dimensions is of course more complicated than that in one. In thinking about them the most important idea is that of the wave front, which is any continuous surface over which the phases are all the same. For mathematical treatment such waves are sometimes resolved into sets of plane waves going in all directions, but it is more often convenient to make use of spherical waves. It can be shown that. if a three-dimensional medium propagates plane waves according to the rule

$$\phi = A\cos[2\pi(\nu t - x/\lambda) - \epsilon],$$

then it can propagate a spherical wave of the form

$$\phi = (A/r)\cos[2\pi(\nu t - r/\lambda) - \epsilon],$$

where r is the distance from the origin. The wave fronts are spheres round the origin as centre, and the wave represents an emission from a point source at the origin. The amplitude decreases as the wave spreads out. and is always proportional to the inverse distance. The intensity is therefore proportional to the inverse square of the distance, and this is the fundamental law of photometry (see PHOTOMETRY). This type of wave suffices for the discussion of a great many phenomena in optics, but it may be mentioned that it will require some unessential modifications when we come to discuss polarization and electromagnetic waves.

B. The Velocity of a Group of Waves.—Much of optical theory can be developed by the consideration of pure monochromatic waves, and indeed it may be said that experimental methods have tended to move in directions for which these suffice. The monochromatic wave, however, gives a very incomplete account of events, because it ranges over an infinite extent of time and space, whereas we usually uant to know about events in some limited region. We saw, for instance, in Huygens' construction for double refraction, that the extraordinary wave has its front parallel to the ordinary, but yet that the rays go in a different direction. Even in the simpler case of plane waves of unlimited breadth there is a similar complication when the wave velocity depends on the wave length. as is the case in refracting media. Let us take a group of approximately monochromatic waves of limited length, and find the group velocity with which it travels as a whole. To construct such a group me take a sine curve multiplied by a factor such that the waves are not of uniform height, but fall away gradually to zero on both sides of the centre. The solution then shows that, though the crests travel forward uith the wave velocity appropriate to the wave length. yet they alter in height as they go, so that after a time the crest which was highest at first will have become quite inconspicuous, while another wave originally quite small will have grown up and taken its place as highest crest. Thus the group as a whole moves with a velocity different from that of its component waves. The group velocity U is derived from the wave velocity V by the formula $d(kV)/dk$, where k is the reciprocal of the wave length. The phenomenon of group velocity is easily observed from the deck of a ship, for after a very short time a large wave under observation becomes quite small while another behind it has gronn at its expense. For water the wave velocity is proportional to the square root of the wave length, and our formula then shows that the group velocity is half the wave velocity. For other types of waves it may be greater than the ware velocity. and there is nothing to prevent its even being in the opposite direction, though no case of this is known. Only in the case where the wave velocity is independent of the wave length is it equal to the group velocity; in this case any wave can be propagated without change of form.

The most important application of the idea of group velocity to optics arises in the measurement of the velocity of light. Every type of measure depends in some way on interrupting the light and thus gives the group velocity. In free space the wave velocity of light does not depend on the wave length and so is the same as the group velocity, but this is not so in other cases. The superiority of the wave theory of light over the corpuscular theory was held proved when Foucault showed directly that light goes more slowly through water than air; but he did not in fact prove it, for the refractive index depends on wave velocity, and his work dealt uith group velocity. However, since either can be deduced from the other, it is easy to verify the correctness of his result indirectly. In much of optics these considerations do not arise. and so they are frequently forgotten. Nevertheless they are indispensable for a full understanding of waves, and many difficulties have been caused in the past through neglecting them.

C. The Pressure of Light.— In the course of his theoretical investigations Maxwell discovered the pressure of light. He derived this effect from the electromagnetic theory, but as a matter of fact it can be shown to follow from any wave theory, and was foreseen in the 18th century by Leonhard Euler. If plane waves fall perpendicularly on a surface it may be shown that they exert a pressure on it of a magnitude equal to the density of energy in the naves. This result is exceedingly difficult to observe, as the pressure is very small in practical cases. The first attempt led to the invention of the radiometer by Sir William Crookes. In this instrument freely moving vanes are coated with black on one side and are polished on the other. The side which is black absorbs the radiation while the reflecting side sends it back; so there is more energy in the space in front of the reflecting side and therefore a greater pressure. When the radiometer is illuminated it does go round, but the wrong way! This is the result of a rather complicated effect depending on the heating of the residual gas in the vessel, and in order to observe the pressure of radiation much more delicate means are required. It was eventually measured by P. N. Lebedev by so improving the radiometer that the effect of the gas was eliminated. There are also indirect methods by which the pressure of light can be verified. chief among which is the thermodynamic law for the emission of radiation (see *HEAT*). Light pressure plays scarcely any part in our common experience, but it grows to enormous values in the hot interiors of stars and plays a dominating part in controlling their state.

D. The Doppler Effect.—When monochromatic light passes through any fixed optical system there is one property that is always conserved. the frequency of the vibrations; but this frequency can be changed if the light is reflected by a moving mirror, or if there is a difference in the motions of source and observer. This change of frequency is called the Doppler effect (*q.v.*), after its discoverer, and is easily explained by the wave theory. Consider a fixed source emitting light of frequency ν, and sending it to an observer who is receding at velocity v. Because of his motion the successive crests of the light waves will reach him at longer intervals than if he were at rest, and a simple calculation shows that he will receive them with a frequency $\nu(1-v/c)$; the light will appear to him slightly redder than it really is. If he is approaching, it will appear bluer, and if his motion is oblique to the direction of the source, the change of frequency will depend on the component of his velocity in the line of sight. In the case where light is reflected from a receding mirror it has to traverse the increasing distance twice over. and so the effect is doubled, and the frequency of the reflected light is $\nu(1-2v/c)$. It should be said that these values are not quite precise when v is large. The Doppler effect plays a very important practical part in astronomy. for by its means it is possible to discover the velocity of stars in the line of sight. and thus for example to calculate the motion of the components of a double star which are so close together that they cannot be seen separately. The "red shift" of the lines in the spectra of distant spiral nebulae is usually interpreted as a Doppler effect resulting from the expansion of the universe. If this is correct, it would indicate that the most distant nebulae we can now observe are receding from us at a speed of some 6,200 mi. per second. The Doppler effect has been vital in the theoretical investigation of the distribution of energy in the spectrum. A further consequence arises in practical spectroscopy. In a hot gas some of the atoms will be approaching the spectroscope and so will give light bluer than the average, while others will give a redder light in consequence of their recession. and thus the light will never be purely monochromatic. In some experiments it is necessary to minimize this effect by cooling the gas with liquid air.

E. The Colours of Thin Plates.—When white light is reflected from a film of a transparent material, interference occurs between the light reflected from the top and bottom surfaces. This gives rise to colours. as in Newton's rings, which have an explanation similar to the coloured bands obtained in Young's experiment. In the present case, however. waves from a large number of coherent sources: instead of from only two, are superimposed, as a result of the multiple reflections within the film.

We have already described Huygens' construction for reflection and refraction. When a beam of light falls on a surface, part is directly reflected and part is refracted. Consider now a thin plate, say a soap film. under the action of an incident beam of monochromatic light (fig. 5). The beam refracted at the first surface comes to the second, and a portion emerges, while the rest is reflected back. This second part comes back to the first face, and part of it emerges while part is again reflected. Thus, if we want to know the total amount reflected! we have to consider the compounded effects of all the waves arising from direct reflection and any number of internal reflections. Now, in order to explain the process, fig. j has been drawn as though the rays *AP*, *CQ*, ER . . . were a considerable distance apart. In reality, they are extremely close together, for the film is supposed to be thin, and many of them will be brought together by the lens of the eye of the observer. Evidently this is a case like Young's experiment in which we have to consider the phases of the various waves. If these phases agree we shall have a brilliant reflection; otherwise it will be feeble. We shall see that the phases agree for only one colour at a time. and so the film looks coloured though it is illuminated by white light. In order to see the detail of this we must examine the process of refraction somewhat more closely.

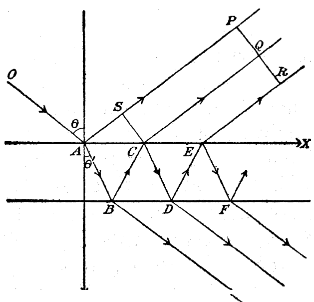

FIG. 5.—COLOURS OF THIN PLATES

The total amount of light reflected will depend on the phase differences of AP, CQ, ER, and these will vary with the colour and inclination of the light

We first consider a single interface illuminated obliquely by a plane wave of light K (see fig. 6). This will be broken into a reflected wave L and a refracted wave *M*. The strengths of these can be calculated exactly in the detailed theory (they are given by Fresnel's sine and tangent formulas), but we do not require their values here. Let us say that. if K has unit amplitude, then L has amplitude *r* and *M* has amplitude *t*. We shall assume (from the more detailed theory) that there is no change of phase at the interface. We also must consider the effect of a beam coming to the surface from the other side. Let us suppose that the reversed wave *M* would give a transmitted wave along K of amplitude t' and a reflected wave along *N* of amplitude r'. Son. there is an important and very general mechanical principle, that. if all the parts of a system are simultaneously reversed in their motions, the system will retrace its course to the point from which it started. Thus, if we fake a wave *r* along L reversed and simultaneously *t* along *M* reversed, they will give rise to unit amplitude along K reversed and no wave along *N*. The wave r from L gives r^2 along K and rt along *N*, while *t* from *M* gives tt' along K and tr' along *N*. We thus have the two equations $r^2+tt'=1$, $rt+tr'=0$. The last implies that r' must be equal to *r*, but that there is a change of phase of 180° at the interface upon reflection from below; me can allow for it completely by simply writing $-r$ for r'.

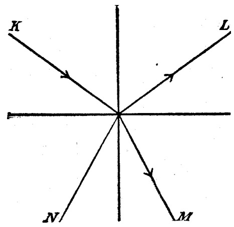

FIG. 6.—REFLECTION AND REFRACTION AT AN INTERFACE

We now return to the film of fig. j. The reflected ray A P has amplitude *r*, the ray AB has *t*. Of this a fraction r' is reflected at *B*, so that tr' arrives at C and CQ has amplitude $tr't'$, while CD has tr'^2. Similarly *ER* will have tr'^3t' and so on. On the other side the waves emerging at *B*, D, F will have amplitudes tt', tr'^2t', tr'^4t', etc. We must now compare the various phases of the paths OAP, *OABCQ*, etc. Let us suppose that θ is the angle of incidence and 0' that of refraction. and that n is the refractive index. If me allow for the difference of the wave velocity in the film, the phase difference for a singular pair of internal reflections will be $\frac{2\pi}{\lambda}(n.ABC-AS)$, where *S* is the foot of the perpendicular from C on *AP*. This is equal to $2\cdot\frac{2\pi}{X}bn\cos\theta'$, if *b* is the thickness of the film; we shall denote it by 26. Thus if the phase at P is ϵ, that at *Q* is ϵ − 28, and therefore that at R is $\epsilon - 4\delta$ and so on. The whole reflected wave thus has amplitude

$$r\cos\epsilon+tt'r'\cos(\epsilon-2\delta)+tt'r'^3\cos(\epsilon-4\delta)+\cdots.$$

This series is now summed and reduces, with the help of the relations between *r*, **/**, etc., to

$$\frac{2r\sin\delta}{1-2r^2\cos 2\delta+r^4}[-\sin(\epsilon-\delta)+r^2\sin(\epsilon+\delta)];$$

and the resulting intensity follows by squaring and averaging over all values of ϵ. The fraction of the incident wave reflected is

$$4r^2\sin^2\delta/[(1-r^2)^2+4r^2\sin^2\delta].$$

It can be shown similarly that the fraction transmitted is

$$(1-r^2)^2/[(1-r^2)^2+4r^2\sin^2\delta].$$

For a soap film the coefficient *r* is not very large. The chief effect is when sin8 vanishes—that is. when $bn\cos\theta'$ is any multiple of half a wave length—for at such an angle of incidence there will be no reflection at all. Hence, nhen a film is lighted by white light, some of the colours will be absent from the reflection and just these will be present in excess in the transmission. Therefore the light reflected by and transmitted through the film will show the complementary colours. The case of Newton's rings is very similar to the above. The film is of air betneen the two glass surfaces. and the distance betaeen these surfaces increases outward from the point where the glasses touch, so that b passes progressively through values where there is no reflection for each colour in turn.

These interference effects have been put to very important practical use in the various types of interferometer. The Fabry and Perot interferometer uses multiple reflections between two lightly silvered glass plates set accurately parallel. Because of the considerably larger reflection co-efficient *r* the transmitted interference rings are quite narrow. The thickness b of the air plate is one to five centimetres, with the result that a telescope must be used in this case to observe the complete ring system In the Lummer-Gehrcke plate the internal reflections occur at an angle close to the critical angle for total reflection, thus affording a large *r* without the necessity of silvering. These instruments are the most powerful tools for the study of spectra, although the modern diffraction grating is a close competitor (see SPECTROSCOPY). In the Michelson interferometer two beams which have traversed widely different paths are brought together by two mirrors to produce interference. The effects are in many ways similar to those that would be obtained with a film or plate of air the thickness of which is determined by the distance between one of the mirrors and the virtual image of the other. (See INTERFEROMETER.)

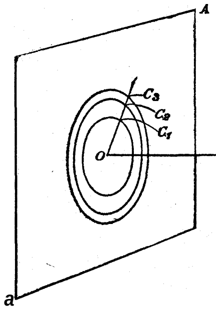

FIG. 7.—FRESNEL'S ZONES
A wave is advancing from plane AB to P. The circle round O is the first zone; the rings outside, the succeeding ones. Zones give nearly the same effect at P, but with alternating signs

The interferometer can be used to measure how nearly any spectral line is truly monochromatic. If the wave emitted by an atom were literally a sine curve, this would imply that, like that curve, it is infinitely long (so the mere fact of switching the light on and off assures that it is not one), but in fact the trains waves given out by the atoms have a limited length and this can be measured by finding how large a difference of path the interfering beams may have before the rings disappear entirely. In practice, this maximum path difference is about 70 cm., implying that after an atom has executed roughly 1,000,000 vibrations it changes phase arbitrarily before emitting again.

IV. DIFFRACTION

There is no essential difference between the phenomena of diffraction and interference, but only a difference in emphasis. Thus the term diffraction is used for phenomena connected with the spreading of waves on passing through a slit, shadow formation, etc., and these are explained as the joint effect of the interference of all the secondary waves emanating from the exposed part of the wave front. The term interference, however, is usually applied to simpler cases, such as Young's experiment, where waves from a finite number of separate but coherent sources are superimposed. When we described Young's experiment, we regarded the two holes in the screen as themselves secondary sources of light emitting spherical waves. A similar construction was applied in Huygens' description of refraction, and may also be used in free space. We shall do this as a preliminary to describing the formation of shadows.

A. **Fresnel's Construction.**—In fig. 7 we have a plane wave with front at AB progressing toward P. We know of course that at P it will in fact be a plane wave too, with phase $\frac{2\pi}{\lambda}\cdot$ OP behind that at O, but we are now supposing that we can take each point in the plane AB as the source of secondary waves, and that the wave at P is due to the superposition of all these waves. In the plane AB describes circles round O of radii OC_1, OC_2 . . . etc., such that

$$PC_1-PO=\tfrac{1}{2}\lambda,\ PC_2-PO=\lambda,\ PC_3-PO=\tfrac{3}{2}\lambda,\ \text{etc.}$$

The central circle and the ring spaces round it are called Fresnel zones and are all of nearly the same area. Each point is supposed to emit light, and this light will arrive at P with a phase depending on the distance to P. The phases of the waves arriving at P from a single Fresnel zone are all the same within half a vibration. If we take the moment when the phase arriving from O is just 90°, then all the phases from points in the central zone will lie between 90° and $-$90°, and they will all make a positive contribution. Those from the second zone will all make a negative contribution, from the third positive and so on., We may represent the total effect as due to the sum of the effects of all the zones and write it as

$$m_1-m_2+m_3-m_4+\ .\ .\ .\ .$$

Each of these quantities is nearly the same because of the nearly equal areas of the zones, but they slowly diminish because of the increasing obliquity, as we shall see. To allow for this decrease we sum the zones in the form

$$\tfrac{1}{2}m_1+(\tfrac{1}{2}m_1-m_2+\tfrac{1}{2}m_3)+(\tfrac{1}{2}m_3-m_4+\tfrac{1}{2}m_5)+\ .\ .\ .\ ,$$

and then, the decrease in the m's being assumed to take place at a constant rate, all the bracketed terms cancel, and the effect at P is equal to half that of the first zone. This argument is of course not a proof, but the full proof requires deeper mathematics than can be given here; for the same reason we shall not check what value must be assigned to the emission of a small area in order to give the amplitude of the reconstructed wave.

In spite of its incompleteness our argument brings out two very important facts. First, as each point of AB has been supposed to give out a complete spherical wave, we should expect the absurd result that there would be emission in the backward direction toward the image point of P in the plane AB. The full solution shows that the amplitude of the secondary wave emitted at angle θ to the primary wave front involves an "obliquity" factor $1+\cos\theta$, and this vanishes in the backward direction. Second, we should expect the phase of the wave at P to correspond to the average of all the phases in the first Fresnel zone, whereas we know that in fact it corresponds to that of the point O. To put this right (and the full theory of course proves it) we make the rule that the secondary waves are to have their phases advanced 90°, or a quarter wave length, in front of the primary wave causing them. These rules may be regarded merely as artifices to avoid a deeper inquiry, but they have important consequences; for, when we have a thin sheet of matter in the plane AB, its particles will scatter the incident light in much the same way as we have been considering, but in this case neither of the two effects will come in. There will be light scattered backward, which constitutes the reflected wave; and the light scattered forward will be a quarter wave length behind the primary wave, and this is the most primitive description of refraction.

The construction of the Fresnel zones explains the bright spot in the centre of the shadow of a circular disk. For, if the screen cuts out the first n zones, the wave at P will now be $m_{n+1}-m_{n+2}+\ .\ .\ .$, and the sum will be $\tfrac{1}{2}m_{n+1}$. In order to exhibit this effect the circle has to be cut with great accuracy, for if half of it is as little as a single zone wrong the amplitude at P will vanish. The same idea has been carried further in the construction of zone plates. If we make a screen which cuts out every alternative zone, we shall get an effect proportional to $m_1+m_3+m_5+\ .\ .\ .$, which will be enormously greater than the effect without screen. Zone plates have been made by drawing them in black on paper and then photographing down to a small scale. A brilliant spot will then be found at a point on the axis. The zone plate illustrates wave principles admirably, but has not found any practical application.

B. The Formation of Shadows.—We may apply the same wave construction to explain the formation of shadows. In fig. 8, AC is a screen with straight edge at C, and we consider the light falling on different points of the screen MN. The wave front is supposed parallel to ACB, and the screen blocks out the part AC, so that we have to consider only the secondary waves emitted by the part CB. First take P, the geometrical edge of the shadow. If we draw the Fresnel zones for this point, they will consist of a semicircle, with C as centre, and half-rings surrounding it. Each will therefore give half the effect of the whole zone, and the resulting amplitude at P will be just half as great as if P were fully illuminated. The corresponding intensity is thus one quarter as great. For a point Q we make the Fresnel construction starting at D; as Q moves away from P the sizes of the exposed parts of the zones diminish steadily, and we therefore conclude that the intensity falls steadily from $\tfrac{1}{4}$ to zero. For a point R outside the shadow we make the construction in the way we did before for free space. There will then be a circle surrounded by rings, but the line through C cuts across them in such a way that some are incomplete. Suppose that R is just so far from P that the central circle is complete but is touched by the line C. Then the central

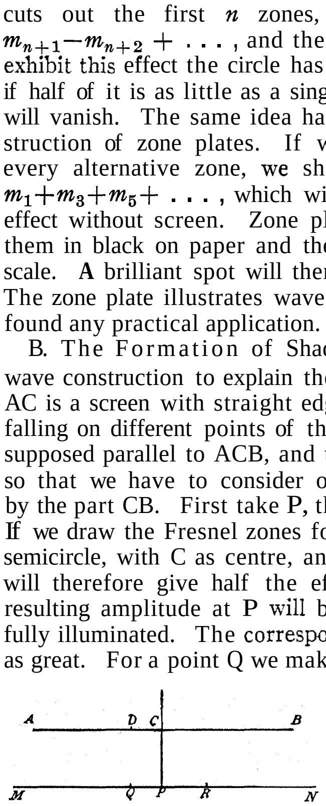

FIG. 8.—THE FORMATION OF SHADOWS
AC cuts off the light from part of the screen MN; P is the geometrical edge of the shadow, and the actual illumination in its neighbourhood is shown in fig. 9

zone gives its full contribution, but the second gives less than its full contribution, as do all the later ones. Consequently there is less to subtract than usual from the central zone, and the light at R will be actually brighter than if there were no screen. Similarly if the circle and the first ring are complete, but the second ring is cut by the line C, the second ring will give a diminished positive contribution and the light will be fainter again. Thus outside the shadow there are a series of alternating maxima and minima of intensity gradually fading into uniform illumination at a distance from the shadow. These light and dark bands are known as diffraction fringes.

The scale of the phenomenon depends on both the wave length of the light X and the distance CP. The intensity at a point R will depend on the numerical value of $PR/\sqrt{\lambda \cdot CP}$. For example if CP is 1 m. and $\lambda = 5 \times 10^{-5}$ cm. for yellow light, the first maximum and first minimum will occur at distances 0.061 cm. and 0.094 cm. outside the geometrical edge, and will have 1.37 and 0.78 of the intensity of the incident wave. Fig. 9 shows how the intensity changes near the edge of the shadow. When the incident light is white the corresponding effect can be calculated by the superposition of all the colours; at the point of geometrical shadow the light will again be white and of quarter intensity, and outside this there will first be a blue fringe. A similar process can be applied to work out the illumination due to a slit. If the slit is many wave lengths wide it can be regarded merely as two straight edges, while if it is only a small fraction of a wave length there will be no shadow at all, but a uniform illumination. For intermediate cases there mill be a rather complicated succession of fringes depending on the ratios of the three quantities, wave length, breadth of slit and distance of screen. In any given case the results are easily calculable.

Showing how illuminative intensity rises from zero inside to unity outside

C. The Fraunhofer Diffraction Phenomena.— There is another way, attributable to Joseph von Fraunhofer, in which diffraction may be studied; this is in fact more important than Fresnel's in the theory of optical instruments. In this method parallel light again falls on a slit or hole, but, instead of observing the illumination on a screen? the light is now observed in a telescope focused for infinity. The essential purpose of a telescope is that it brings all the rays going in a given direction into focus at a point; at this point a photographic plate may be placed, or alternatively the real image may be viewed with the help of a magnifying lens. If the slit is narrow enough, or the hole sufficiently small, the naked eye may replace the telescope. Then the slit or other aperture must be placed immediately before the eye, the latter being focused on a small source some distance away. For observing diffraction by a slit, a single-filament lamp makes a good source. To deduce what will be seen under these conditions. we must find the intensities of the waves passing through a slit in various directions.

In fig. 10, AB is a slit, and we require to know what intensity goes at angle θ into the direction AM. We break up the wave at the slit into secondary waves. That arising at P has to go a distance $PR = AP\sin\theta$ farther than that from A. If the phase of the wave from A is ϵ, that from P is $\epsilon - \frac{2\pi}{\lambda} s \sin\theta$, where $s = AP$.

For a slit of breadth l the whole effect will be

$$\int_0^l \cos\left[\epsilon - \frac{2\pi}{\lambda} s \sin\theta\right] ds.$$

If this is integrated and then squared and averaged, we find the intensity proportional to

$$\left[\sin\left(\frac{\pi}{\lambda} l \sin\theta\right) \Big/ \left(\frac{\pi}{\lambda} l \sin\theta\right)\right]^2.$$

The form of the curve $y = \sin^2 x/x^2$ is shown in fig. 11, so that to find how the observed intensity depends on the angle 6 we require only to equate x with $\pi l \sin 6/\lambda$. Then if f is the focal length, the image corresponding to 6 will be formed at a distance approximately $f\sin\theta$ from the axis of the telescope. From the curve we see there is a very strong maximum at $\theta = 0$, and that no light goes in the directions given by $\sin\theta = n\lambda/l$; that is, when BS, in fig. 10, is any multiple of the wave length. About halfway between these directions of no light there are secondary maxima. which are much weaker than the central one; even the first is less than one-twentieth of it. When the slit is broad the whole figure will be crowded close together. We must also consider narrow slits; *e.g.*, if the slit is exactly one wave length broad the first zero will be at 90°; in any case nothing beyond that angle could be observed. If it is two wave lengths broad, the first zero will fall at an angle of 30° and there will be a secondary feeble maximum at an angle of about 50°.

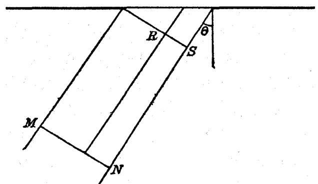

FIG. 10.—DIFFRACTION BY A SLIT

A similar construction can be applied for a hole as well as for a slit. For a small rectangular hole the diffraction pattern is broad in the direction in which the hole is narrow, and vice versa. In the case of a circular hole the pattern consists of a bright central circle surrounded by fainter rings. If the hole has radius R and the telescope focal length f, the bright centre is surrounded by the first dark ring of radius $0.61 \times f\lambda/R$, and five-sixths of the total light falls inside it. The first bright ring has radius $0.82 \times f\lambda/R$, and at its brightest point the intensity is only about one-sixtieth of that at the centre of the central spot. The diffraction pattern of a circular hole is of great importance in connection with the theory of telescopes.

The theory of Fraunhofer diffraction is fundamental to understanding the action of the diffraction grating. In fact, it was through his investigations of this instrument that Fraunhofer's name became associated with these phenomena. The grating is essentially a large number of narrow slits parallel to one another and spaced at equal distances a. The theory of its action is discussed under SPECTROSCOPY, where it is shown that the diffraction pattern consists of a number of very sharp and intense maxima at angles θ such that sin $6 = 0, \pm \lambda/a, \pm 2\lambda/a, \ldots$, called the central image, first order. second order, ... The positions of these depend on the wave length λ, and therefore when the light striking the grating contains various wave lengths they are dispersed into several spectra. one for each order. Two wave lengths very close together may be separated because of the sharpness of the maxima. whose width equals that of the diffraction maximum formed by a single slit of width equal to the total width of the grating. For this reason gratings have largely replaced prisms for the study of complicated spectra.

The curve $y = \sin^2 x/x^2$. The y ordinate measures the intensity of light at angle $where sin θ is proportional to x

D. **The** Nature of White **Light.— It** has been customary since the time of Newton to say that white light is compounded out of all the colours, hut the diffraction grating suggests quite another point of view. Let us imagine that the incident light is a plane wave consisting of a single thin pulse. Each slit of the grating diffracts this pulse into all directions, and, if we observe from a given direction. we shall receive in turn the pulses which have come through each slit. They will be evenly spaced and farther apart, the broader the angle from which we observe. At each position θ there will be something very like a monochromatic wave; more precisely it is a periodic wave composed of wave lengths $a\sin\,\theta$ and all its submultiples; *i.e.*, out of the superposition of light of the first, second and higher orders appropriate to the angle θ. Regarding the matter in this way, we have a perfect right to say that the coloured light has been created by the spectroscope. This is a point of view well worth keeping in mind, for in many branches of physics we determine some property by an experiment and then attribute it to the system, overlooking the fact that it may be the experiment itself that has evoked the property. In the present case the two points of view are reconciled by the fact that the pulse can be analyzed mathematically into an integral composed of lights of all wave lengths, and in this sense it is correct to say that white light contains all the colours, even though it is unnatural to attribute any periodic quality to a single pulse.

It may appear that the argument is special to the case of resolution by a grating, and that the spectrum of white light formed by a prism proves that the colours were there originally. Closer examination shows this to be wrong, though the argument is not so simple; by considering the property of group velocity it can be shown that the prism will convert a single pulse into successions of pulses differently spaced for the different directions, but it would take too long to develop the idea further here. The outcome of the argument is that the analysis of light into wave lengths is chiefly a matter of convenience. largely mathematical convenience; but this is enhanced by the fact that gases usually emit spectra consisting of very nearly pure monochromatic lines, so that it turns out to be also a practically important analysis.

E. **Resolving** Power. — It is of great importance when working with any optical instrument to know its resolving power. Thus the resolving power of a telescope tells us what distance there must be between two stars in order that we may be sure that they are two and not one. For a microscope it determines the fineness of recognizable detail in the object. and for a spectroscope the smallest difference in wave length. Resolving power must be distinguished from magnification, for. as we shall see. it is possible to magnify the images indefinitely, but the only effect is to make a small indistinct image into a large indistinct image. It is as though the image were painted on a sheet of rubber; stretching the sheet reveals no more detail. Diffraction theory determines the resolving power of all instruments, and we shall illustrate this by first considering the resolving power of telescopes.

The principle of the lens is usually discussed by geometrical methods (see OPTICS), but it is quite simple to work it out with the wave theory. In fig. 12 plane waves fall perpendicularly on the lens in the beam, PA,QC. The central ray through BE is retarded in the glass, but not so the extreme rays at A and C. The focus F is the point where all the secondary waves from AEC are in phase; the retardation of the central ray is balanced by the longer path of the extreme ones. The waves at AB are in phase, and the phase changes from there to F are given respectively by AF and $n{\cdot}BE+EF$, where n is the refractive index of the lens. Let BE be d, AB be r and EF be f, supposed much larger, then we have

$$d(n-1)+f=\sqrt{(f^2+r^2)},$$

whence, approximately, $f=\dfrac{r^2}{2d}\,\dfrac{1}{n-1}$, which determines the focal length of a plano-convex lens in terms of its curvature. If another set of waves at a small angle θ falls on the lens. their focus F can be found by the consideration that the waves from A and C must be in phase, while F is near F in a plane at right angles to the axis of the lens. We thus find that $FF'=f\sin\theta$, a familiar result in geometrical optics.

Supposing that the two waves are from stars, we inquire under what conditions they will be resolved. The image of the first star at F is of course not a point because of diffraction We can roughly estimate its size by the consideration that there will be points near F for which the waves from A and C and from other portions of the lens. though not perfectly in phase, are so little out of phase that there will be still a marked intensity. This is a question of the diffraction image of a circular hole and the radius of the central spot is o 61$f\lambda/r$. If the centre of the image of the second star is much closer than this, me shall have only one bright spot and shall not distinguish that there were two stars. Thus the angular distance that can be resolved is 0.61λ'r. For visible light and with the radius of the telescope in millimetres this gives for the angle in minutes of arc

$$\left(\frac{1.17}{r}\right)'.$$

The important thing to notice is that the resolving power in no way depends on the magnification but only on the diameter of the object glass. If the telescope has a short focal length the magnification will be small; but as long as the diameter is large the resolution will be good. and the small magnification can be overcome by the use of a stronger eyepiece. This result requires one qualification, for we have assumed that the whole object glass is operative in bringing rays to the eye. When the magnification is not very great it may happen that the pupil of the eye is the effective limitation and not the object glass, and in such cases the resolving poner will depend on the diameter of that part of the object glass from nhich light enters the pupil.

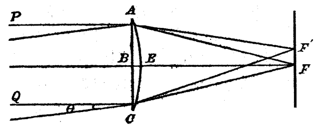

FIG. 12.—THE RESOLUTION BY A LENS
The Dower of resolvinq the imaqes F and F' depends on the size of the lens AC and not on the focal length EF

The tendency to make larger and larger telescopes is to be attributed partly to the fact that they collect more light. but much more to the increased resolving poner. An extreme example is given by the measurement of the diameters of stars. Stars are all so distant that no existing telescope could hope to resolve the separate parts of their surfaces. and the disk seen is never perceptibly larger than that which would be produced by a geometrical point. But if we could have a teleicope 50 ft. in diameter, the resolving poner should be sufficient to show the disk of a large star in the same way that an ordinary telescope does for a planet. It is not of course practicable to make such a telescope, but it is also not necessary; all that is required is two little pieces of such a telescope at the points A and C in fig. 12. In principle this is the way in which it has been found possible to measure the diameters of Betelgeuse and a few other stars.

The eye is an instrument similar to the telescope. Taking the diameter of the pupil as 2 mm., the same calculation shows that its resolving power should be 0.42$'$. The actual limit. about 1', is not very different and is no doubt affected by the structure of the retina. A similar limit would apply for any eye constructed on the same principle as man's; but insects' eyes are compound, being composed of a very large number of very small independent facets. There can be no phase relations between the separate facets, so that the resolving power can depend only on the size of each separately. It thus seems improbable that an insect can discriminate visually between objects less than some degrees apart.

The resolving power of the microscope presents a different problem from that of the telescope. because in the microscope we observe nonluminous objects illuminated usually by paralle! or not very convergent light. The discussion of the theory will be found under MICROSCOPE, and we here give only the result. If the lens can receive light from the object over a range of 180° (and for a good microscope it very nearly does). then some rough impression of form can be detected for an object of the size of half a wave length. By immersing the object in a refractive medium the wave length is shortened and the resolution improved, and it may be further improved by the use of ultra-violet light.

In the case of spectroscopes there are two other factors besides diffraction that must be taken into account. First, we remember that the width of each line is affected by the width of the spectroscope slit, but this limitation may be obviated by so narrowing the slit that it contributes a negligible amount to the width of the diffraction pattern. The second factor is the dispersion. which determines how far apart the centres of tno lines of different wave length will lie. Obviously if the lines have a given breadth, determined by diffraction of a beam of width corresponding to that emerging from the prism or grating. the resolving power will increase in direct proportion to the dispersion. For interferometers, the resolving power is not limited by diffraction, so that very high resolution can be reached with small apparatus. *(See* SPECTROSCOPY.)

V. POLARIZATION AND ELECTROMAGNETIC THEORY

In our review of the history of optics we described some of the earlier work on polarization, and we must now make its character clearer. The phenomena of interference and diffraction were all explained by regarding the light as a wave, leaving it entirely open what it is that vibrates and how it does it. In fact all that we have so far said would, with suitable changes of scale, be just as true for sound as for light. But when we come to the phenomena of double refraction, this is not so; they are explicable only if the vibrations are transverse. Though we saw that, in spite of many attempts, no material model could be found which would carry waves in the way that ether does light, still it is quite possible to visualize polarization. 4 string stretched horizontally may vibrate in a vertical or horizontal plane or simultaneously in both; at any instant a point of the string is displaced from its position of rest in a direction perpendicular to the line of the string, and this position can be indicated by drawing a line in the direction and of the length of the displacement. When a light wave is travelling through space, we can also represent it at any point and time by drawing a line in a definite direction and of a definite length. It should be explained that, unlike the case of the string, here the length is only diagrammatic and can be represented on any scale, as long as we are consistent and adopt the same scale for other points. This line is called the light vector, and the wave is said to be transverse, because the light vector is always found to be at right angles to the direction of the wave; that is to say, it lies somewhere in the plane of the wave front. The reason for this will appear when we come to the electromagnetic theory; we shall first describe the main properties of polarization without justifying them.

A. Types of Polarized Light.—Suppose that we have a wave of plane monochromatic light advancing perpendicular to the paper. At any point in the paper we draw the light vector, and it will go through a series of changes, returning to its original value in the period of the waves. We can represent any motion by giving the x, y co-ordinates of the end of the light vector, and for monochromatic light these must be sine or cosine functions of the time. If ν is the frequency we therefore take

$$X=A\cos(2\pi\nu t-\alpha),\ Y=B\cos(2\pi\nu t-\beta)$$

as the general description of the light. We first consider a few special cases. If $B=0$ we have a vibration in which the vector always lies in the direction of x and ranges between the values $\pm A$. This we call plane polarized in the direction x. Similarly if A = o we have light plane polarized in the direction y. If we have $\alpha=\beta$, we see that at any time $Y/X=B/A$, so that again we have plane polarized light, in direction arc tan (B/A) and with amplitude $\sqrt{(A^2+B^2)}$. Next consider the case $B=A$, $\beta=a+\frac{\pi}{2}$. Then $X^2+Y^2=A^2$, so that the vector describes a circle; this is therefore called circularly polarized light. In the general case we can find the locus of the light vector by eliminating t and get

$$\frac{X^2}{A^2}+\frac{Y^2}{B^2}-2\frac{XY}{AB}\cos(\alpha-\beta)=\sin^2(\alpha-\beta).$$

This is an ellipse of which the axes are determined as to position and magnitude by A, B and $\alpha-\beta$. The most general type of light is therefore called elliptically polarized, and we recognize our previous types as degenerate ellipses.

We next consider the propagation of such waves; that is to say, the phase relations of the light vectors for different positions of the wave front. Our wave is now written as

$$X=A\cos[2\pi\nu(t-z/c)-\alpha],\ Y=B\cos[2\pi\nu(t-z/c)-\beta],$$

and the character of the polarization is the same for all values of z, as it will depend on A, B and

$$(2\pi\nu z/c+\alpha)-(2\pi\nu z/c+\beta)=\alpha-\beta.$$

Next we take t as fixed and consider the way the light vector is drranged for various values of z. We may liken it to the stretched string. If $B=0$ it will be in the shape of a sine curve in the plane of xz with wave length c/ν, and similarly whenever $\alpha=\beta$, though for a different plane. If /?=a+$\frac{\pi}{}$ and $B=A$, the locus is a screw, or helix, of radius A and pitch equal to the wave length c/ν. If the axes are right-handed, so that a man standing with his head toward y and looking forward along z has x on his left, the light is by convention called left circularly polarized. even though the screw is a right-handed one. This convention refers to the sense of rotation of the vector at a given point in space as seen by an observer looking against the oncoming light. Here it is a counterclockwise or "left-handed" rotation. If instead $\beta=\alpha-\pi/2$, the rotation is clockwise and the light is said to be right circularly polarized. The distinction between right and left circularly polarized light is physically very important, as it plays a leading part in the phenomenon of gyration. In the case of elliptically polarized light, the locus of light vectors may be described as a flattened screw, which may again be either right- or left-handed. Fig. 13 shows the forms of vibration for various $a-/?$, the polarization in the first and last pairs of diagrams being left-handed. This suffices to describe the form of the waves. and it remains only to define the intensity. At any point this is given as the average value of the square of the light vector; in the cases we have considered it is the average value of X^2+Y^2. When the waves are travelling in an arbitrary direction instead of along z, we may have three components of the light vector, and in such cases $X^2+Y^2+Z^2$ is to be averaged over the time.

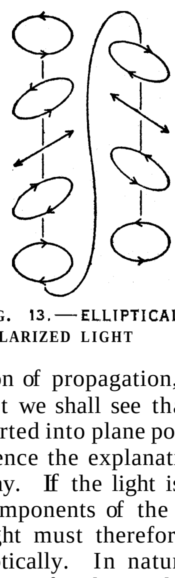

FIG. 13.—ELLIPTICALLY POLARIZED LIGHT

We must also consider the nature of ordinary unpolarized light. This has no "sides" and is symmetrical about the direction of propagation, and in this it is like circularly polarized light; but we shall see that circularly polarized light can easily be converted into plane polarized, whereas for ordinary light this is not so. Hence the explanation of its symmetry must be found in another way. If the light is rigorously monochromatic, the phases of the components of the light vector are maintained forever, and such light must therefore be polarized, either plane, circularly or elliptically. In nature, however, no light is rigorously monochromatic, for the Michelson interferometer fails to show interference for path differences of more than about 1,000,000 wave lengths, and this enables us to explain unpolarized light as being polarized light of which the direction of polarization is changed frequently. We suppose each atom to emit a polarized monochromatic wave which lasts for a time corresponding to 1,000,000 nave lengths, and then changes and emits one of a different polarization. The length of time of each separate type is so short that we cannot distinguish them but merely get an average of all the different types. and this average will be symmetrical about the direction of propagation.

The most general kind of light consists of a mixture of unpolarized light with light that is polarized, either plane, elliptically or circularly. A theorem due to Sir George Stokes states that any beam of light whatever may be exactly described by giving four numbers called Stokes's parameters. These are

$$I=[X^2+Y^2]_{\mathrm{Av.}} \qquad U=[2XY\ \cos(\alpha-\beta)]_{\mathrm{Av.}}$$
$$Q=[X^2-Y^2]_{\mathrm{Av.}} \qquad V=[2XY\ \sin(\alpha-\beta)]_{\mathrm{Av.}}$$

where the brackets indicate time averages. Evidently I measures the intensity of the beam, while Q, U and V specify its state of polarization. For unpolarized light the latter quantities fluctuate rapidly and average to zero. For any completely polarized beam, however: they have constant values. Then $I^2=Q^3+U^2+V^2$, and the intensity need not be known independently of the other parameters. Plane polarized light vibrating along x has $I=Q=X^2$ and $U=V=0$, circularly polarized light $I=V=2X^2$, $Q=U=0$, etc. The Stokes parameters are additive; that is, if two noncoherent light beams are superimposed, each parameter is the sum of the corresponding ones for the separate beams. Thus it is found that the general type of partially polarized light may be resolved into two parts, one of which represents a polarized beam of intensity $Q^2+U^2+V^2$, the other an admixture of unpolarized light given by the difference $I-(Q^2+U^2+V^2)$. We shall see later what types of experiments must be performed in order to determine the Stokes parameters for a light beam.

In describing plane polarized light we have said that it is polarized in the direction x when the light vector vibrates along x. Unhappily there is some confusion in the terminology used. When polarization was first discovered the convention was adopted that the light of the ordinary ray in double refraction is polarized in the plane through the axis of the crystal and the direction of propagation. It later appeared that the light vector must be perpendicular to this plane, so that the old convention would have described the light as polarized in the plane of yz, which we shall call polarized in the direction x. For most optical effects the behaviour is determined by the direction of the vector and not by the direction of propagation of the wave, so that it is practically inconvenient to mention two directions when one would do. The modern tendency. which we shall adopt! is to describe plane polarized light by the direction of the light vector; thus, in double refraction we shall say that the ordinary ray is polarized at right angles to the crystal axis. To avoid confusion with the older terminology, it seems desirable to avoid any reference to a plane of polarization, which we shall do by referring to the direction of polarization.

B. Methods of Producing Polarization. — The polarization of light is by no means uncommon. Its existence in the light transmitted by certain crystals has been mentioned here because this case was important historically, but double refraction is not the only way in which polarization may be produced, and we shall discuss other occurrences in detail later. Chief among them is reflection at a transparent surface set at a suitable angle. At other angles there is an incomplete polarization, which is sometimes very troublesome in experiments; for as light passes through any system of lenses or mirrors! it is almost impossible to prevent its becoming polarized, and this may easily obscure the study of its original polarization. We may also mention the polarization of scattered light, exemplified in the light of the sky. Again, in diffraction of light by a slit, the two components behave rather differently, and so the light is slightly polarized; the theory we have given is sufficiently correct for small angles, and we shall not consider the modification that is required for more exact results. Perhaps the most interesting occurrence of all is in the Zeeman effect (*q.v.*). Here the spectral lines of an atom become displaced and split when the atom is in a strong magnetic field, and the split components are polarized in certain definite ways, from which much information can be obtained about the mechanics of the atom.

There are two standard instruments for converting ordinary unpolarized light into plane polarized light: the nicol and the sheet polarizer. The former was devised in 1828 by William Nicol. and uses the principle of double refraction. One of the two polarized beams is removed by total reflection (see fig. 14). For over a century the nicol and its modifications were used almost exclusively in optical instruments involving the production or detection of polarized light. Beginning in 1932, however. a technique was developed by Edwin Land for producing thin sheets of a material which polarizes by virtue of a property called dichroism. As we shall see in discussing dichroic crystals. such materials exhibit a different degree of absorption for vibrations in two mutually perpendicular directions. Hence under suitable conditions one of these may be almost entirely eliminated from the transmitted light. Improvements in these dichroic sheet polarizers have permitted their use instead of nicols in many applications.

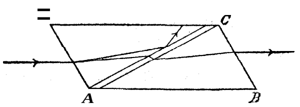

FIG. 14.—THE NICOL PRISM

In the construction of a nicol, a rhomb of calcite which is about three times as long as it is broad is sawed across the line AC (see fig. 14), and, after the cut has been polished, the two faces are cemented together with Canada balsam. The two ends AD and BC are also cut to a slightly different angle (68" instead of 72°). A wave, entering parallel to the axis of the prism, is doubly refracted so that the two waves go in somewhat different directions. the ordinary wave being most bent. Canada balsam has a refractive index intermediate between those of the ordinary and extraordinary waves, and as the ordinary wave meets the balsam layer very obliquely it becomes totally reflected and falls on the side DC, which is blackened so as to absorb it. Nearly all of the extraordinary wave passes through, so that the emergent light is plane polarized. A nicol will polarize light only over a certain range of angles of incidence. The limits are set by the condition that on one side both rays are reflected at AC-and lost. and on the other that a certain part of the unwanted ordinary ray is transmitted; under favourable conditions the range of angles may be 30°. The slight adjustment of the slopes of the end faces mentioned above is for the purpose of making this range extend equally on both sides. A typical experiment with polarized light involves the use of two nicols. The simplest example is the direct use of two "crossed" nicols. The first produces polarized light by eliminating one component; the second is placed with its axis in the same line as the first but is twisted round through 90°, so that the wave which was the extraordinary wave in the first nicol is now the ordinary one and so is not transmitted. This device has been used for secret signalling. The signaller rotates his nicol through 90°, and though to the naked eye his lamp appears to burn steadily, if it is viewed through a fixed nicol it will go out.

The main limitation of the nicol is its restricted size. It is difficult to find calcite crystals sufficiently large and clear to polarize a beam much more than an inch wide. Sheet polarizers are made the areas of which are measured in square feet, a development which opened up new technical uses for polarized light. To mention one, the glare of the headlights of approaching automobiles may be eliminated by covering both the lights and the windshields with such sheets, their axes of transmission both being tilted at 45° clockwise from the vertical. Then the driver may see the light from his own headlights, but that from oncoming vehicles will have its direction of polarization crossed with the axis of transmission of his windshield and will be seen only faintly. Dichroic polarizers consisting of single crystals of the mineral tourmaline had long been used instead of nicols in certain applications. Using the same principle in a different way, sheet polarizers were first made of a suspension of submicroscopic crystals in a cellulosic matrix, the axes of all the needlelike crystals being aligned parallel to one another. These were crystals of herapathite, which is much more strongly dichroic than tourmaline. Later it was found that a better polarizer can be made by stretching a sheet of polyvinyl alcohol and then treating it with iodine. Another polarizer, which has nearly as good polarizing properties and is more stable to heat and radiation, is produced by merely dehydrating a stretched sheet of polyvinylene. One drawback of sheet polarizers is the limited region of the spectrum over which the polarization is reasonably complete. The polyvinyl alcohol type covers the entire range of visible colours very well, so that when a bright light is viewed through two sheets in the crossed position only a feeble blue colour is seen. In other types, the polarization may extend over only a certain part of the visible spectrum; this may actually be put to advantage in certain applications, as for example in the projection of stereoscopic pictures.

C. The Analysis of Polarized Light. — Polarization is chiefly, though by no means exclusively, studied by using the property of double refraction in crystals. We discuss this below, but it will here suffice to say that when a wave goes through a crystal its light vector is resolved in two directions, mutually perpendicular and perpendicular to the direction of propagation, and the components in these directions have different wave velocities. Suppose that we have a plate with parallel faces perpendicular to z and that the wave is going through it along z, while the two special directions are x and y. In such a plate the light vector will be given by

$$X=A\cos[2\pi\nu(t-z/a)-\alpha],\ Y=B\cos[2\pi\nu(t-z/b)-\beta],$$

where a and b are the wave velocities for vibration in the directions x and y. If the incident light is plane polarized along x or y the wave mill go through unchanged, but if it is polarized, say at angle γ on entering the plate at $z=0$, we shall have $\alpha = \beta$ and A= Ccosy, $B=C\sin\gamma$. If the plate is of thickness l the light will emerge from the farther side as

$$X=C\cos\gamma\cos[2\pi\nu(t-l/a)-\alpha],\ Y=C\sin\gamma\cos[2\pi\nu(t-l/b)-\alpha],$$

and so X and Y are no longer in the same phase, and the light is now elliptically polarized. Fig. 13 shows diagrammatically how this transformation comes about. If we had started with elliptically polarized light, the emergent light would in general be elliptically polarized, but in a new direction. In special cases it might become plane polarized, and this illustrates the principle of an important instrument used in the study of polarized light, the quarter-wave plate. A quarter-wave plate is made by taking l so that $2\pi\nu l/a-2\pi\nu l/b=90°$. If the incident light is elliptically polarized, with the axes of the ellipse along x and y, we may write it as

$$X=A\cos(2\pi\nu t-\text{a}),\ Y=B\sin(2\pi\nu t-\alpha).$$

After passing through the quarter-wave plate the emergent light will be

$$X=A\cos(2\pi\nu t-\alpha'),\ Y=B\cos(2\pi\nu t-\alpha'),$$

and it is now plane polarized. As a case of special importance, if the incident light is circularly polarized, the emergent will be plane polarized at 45° to the x direction. and its right- or left-handedness will be indicated according to whether the direction is between x and $+y$ or x and $-y$. Quarter-wave plates are usually made of mica. which is easily cleft into thin sheets. These sheets exhibit a rather weak double refraction, so that a quarter-wave plate is not inconveniently thin. As mica is rather soft, it is often mounted between two sheets of glass, and scratches on these indicate the direction of the crystal axis.

When we want to determine the state of polarization of any given light beam, we must first find whether it is completely polarized or whether it contains some unpolarized light. In the former event the vibration is in general elliptical, and this may be made into plane polarized light by a quarter-wave plate set at the proper angle. It can then be extinguished by a nicol. When this condition is found, the crystal axis of the quarter-wave plate coincides with the major or minor axis of the ellipse. Tao data are thus obtained: the orientation of the plate, which tells the position of the axes of the ellipse, and the angle which it makes with the nicol, the tangent of nhich gives the ratio of these axes. These data suffice to determine two of the four Stokes parameters, the other two representing the total intensity of the light and the admixture of unpolarized light. If some of the latter is present, it will be impossible to extinguish the light by any orientations of the quarter-wave plate and nicol. One setting of the former may be found, however, which gives the largest variation of intensity as the nicol is rotated. The ratio of the maximum and minimum intensities will then give a measure of the degree of polarization of the original beam.

The quarter-wave plate is most useful for analyzing elliptically polarized light when we already know the position of the axes of the ellipse, as is the case in some important experiments; in other cases the making of two adjustments simultaneously is troublesome. The alternative instrument is called the compensator. In this the analysis is in two fixed perpendicular directions, instead of along the axes of the ellipse, and we measure the relative lengths of the components of the light vector in those two directions and their phase difference. The essential part of the compensator consists of two thin wedges of quartz, a crystal with rather weak properties of double refraction. One wedge is cut so that the crystal axis lies in a line parallel to the edge, and the other so that it is at right angles to it and parallel to the face (see fig. 15, where the lines and dots indicate the directions of the axes). Incident light will be broken into two components in the first wedge, of which one will have a higher phase velocity; but on entering the second this will change about, so that, if the thicknesses are exactly equal as at the centre A, there will be no resultant changes of phase. Thus, incident plane polarized light will emerge as plane polarized at A. At any other point B this will not be so, because the light will have gone farther through one crystal than through the other. If elliptically polarized light is incident, there will be places where the transmitted light is plane polarized, and so, if we use an analyzing nicol set at the proper angle, we may observe the field crossed bv dark bands. If one wedge is screwed over the other by means of the micrometer screw M, the bands will shift because of the changing differences in the thickness of the wedges. The reading consists in seeing how far the screw must be turned to bring one of the bands to the centre. This measures the phase difference in the components of the light vector along and across the wedge, while the ratio of their amplitudes is given by the setting of the nicol.

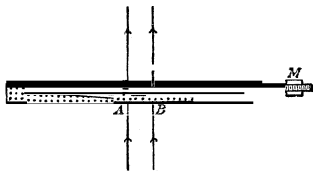

FIG. 15.—THE COMPENSATOR
The dots and lines indicate the crystal axes of the two quartz wedges, and M is the micrometer screw

D. The Electromagnetic Equations. — It was Maxwell who made the great discovery that the equations governing the behaviour of electric waves are equally applicable to light, and this provides a strict formulation for the whole theory, including of course polarization. For the derivation of the theory of electric waves see the article ELECTRICITY; we shall here take it as given and show how it applies for light.

Consider first the case of free space. At every point there may be an electric force $\mathbf{E}$ and a magnetic force $\mathbf{H}$. Each has both direction and magnitude and they can be most conveniently described by the components E_x, E_y, E_z and H_x, H_y, H_z along the directions x, y, z. The vector notation is well adapted to expressing their relations. In this notation

$$\frac{\partial E_x}{\partial x}+\frac{\partial E_y}{\partial y}+\frac{\partial E_z}{\partial z}$$

is written div $\mathbf{E}$ and called the divergence, while the three quantities

$$\frac{\partial E_z}{\partial y}-\frac{\partial E_y}{\partial z},\ \frac{\partial E_x}{\partial z}-\frac{\partial E_z}{\partial x},\ \frac{\partial E_y}{\partial x}-\frac{\partial E_x}{\partial y}$$

are the components of curl $\mathbf{E}$. A vector equation involving curl is thus three equations, when written in terms of the components.

The equations are

$$\frac{1}{c}\frac{\partial \mathbf{E}}{\partial t}=\text{curl }\mathbf{H},\quad \text{div }\mathbf{E}=0;$$

$$-\frac{1}{c}\frac{\partial \mathbf{H}}{\partial t}=\text{curl }\mathbf{E},\quad \text{div }\mathbf{H}=0.$$

In these equations c is originally a rather abstruse quantity, the ratio of a charge measured in electrostatic units to the same charge measured in electromagnetic units. It is a velocity. and one of the strongest evidences for the electromagnetic theory of light is that, when purely electric methods are used to determine the ratio, it is found to be the same as the velocity of light. We shall give a few examples of solutions, but before doing so must complete the theory by giving the rule for intensity. In our previous account of intensity we left a factor of proportionality undetermined, and this was right because we had then no other physical phenomenon to link with light, so that there was no way of fixing the absolute values. Now, however, we have a much more precise formulation, because we can imagine that we might measure (very ideally of course) the electric force in the light by means of an electrometer, and we can therefore make our definition absolute. Electrical theory assigns a value to the flux of energy (*i.e.*, to the rate at which energy is carried across unit area in unit time), and this is a suitable measure for intensity. It is called the "Poynting vector," after its discoverer, and is $\frac{c}{4\pi}[\mathbf{E}, \mathbf{H}]$ where $[\mathbf{E}, \mathbf{H}]$ is a vector product with component $E_y H_z - E_z H_y$ along x, etc.

We now consider some solutions of the electromagnetic equations. One such solution may be verified to be

$$E_x = A\cos\frac{2\pi}{\lambda}(ct-z),\ E_y=0,\ E_z=0;$$

$$H_x=0,\ H_y=A\cos\frac{2\pi}{\lambda}(ct-z),\ H_z=0.$$

We see in the first place that we have a wave travelling along z with velocity c, and purely electrical experiments have shown c to be equal to the velocity of light. Second, we see that it is a transverse wave, but it is ambiguous whether the electric or magnetic force is the light vector. A similar solution is

$$E_x=0,\ E_y=B\cos\frac{2\pi}{\lambda}(ct-z),\ E_z=0;$$

$$H_x=-B\cos\frac{2\pi}{\lambda}(ct-z),\ H_y=0,\ H_z=0;$$

and this evidently represents the other polarized component. A third solution can be formed by superposing these two, or by superposing them with a phase difference between E_x and E_y. The intensity in such a case would be $\frac{c}{8\pi}(A^2+B^2)$.

We must now consider whether the electric or magnetic force is the light vector. Since both always occur in the wave, a theory could be constructed in which either was so taken. and it is a matter of convenience which we choose. A number of phenomena show that the electric force is the more important, primarily because matter is constructed out of electrons and not out of magnetic particles. We may give as one example the case of standing waves. When a plane wave of monochromatic light falls perpendicularly on a mirror and is reflected straight back, the incident and reflected waves interfere with one another and produce a system of stationary oscillations. These may be described by

$$E_x = A\cos\frac{2\pi}{\lambda}(ct-z) - A\cos\frac{2\pi}{\lambda}(ct+z)$$

$$= 2A\sin\frac{2\pi}{\lambda}ct.\sin\frac{2\pi z}{\lambda};$$

$$H_y = A\cos\frac{2\pi}{\lambda}(ct-z) + A\cos\frac{2\pi}{\lambda}(ct+z)$$

$$= 2A\cos\frac{2\pi}{\lambda}ct\cdot\cos\frac{2\pi z}{\lambda}.$$

We see that at points where z is any multiple of half a wave length E_x vanishes all the time, whereas H_y vanishes all the time at points where z is an odd multiple of quarter of a wave length. Suppose that our mirror is coated with a nearly transparent photographic film, of some depth, which is afterward developed and examined in section. Then we shall find places where it is fogged by the action of the light vector, and others where it is unaffected, and the positions of these tell us that it is the electric force that is effective and not the magnetic. From this and similar cases we conclude that it is best to take the electric force as the light vector.

VI. REFRACTION AND DOUBLE REFRACTION

We have already made much use of the idea that the optical effect of a transparent medium can be represented by a refractive index. This is not of course an explanation of refraction; for that we shall have to consider atomic processes, but without doing this we can discuss many of its features. and can describe the experiments which have been used in its investigation. We shall be content for the most part with the description of results; to work them out in detail would involve rather elaborate mathematics.

A. The Electromagnetic Equations for Refracting Media.—The natural starting point for the discussion is the extension of the electromagnetic theory to cover electrical waves propagated through matter. When a static electric force acts on matter it may produce two effects: If the matter is a conductor, a current will flow according to Ohm's law; this is expressed by defining a current density $\mathbf{j}$ (a vector with components j_x, j_y, j_z) which is given by $\mathbf{j} = \sigma\mathbf{E}$, where σ is the specific conductivity of the medium. If the matter is an insulator, the electric force displaces the electricity in the atoms in a way that may be compared to the compression of a spring, and a new quantity has to be introduced to express this, which is called the dielectric displacement. In isotropic media, such as water or glass, the dielectric displacement bears a constant ratio to the electric force. We write $\mathbf{D} = \epsilon\mathbf{E}$, and call ϵ the dielectric constant. General electromagnetic theory then shows that the equations for free space must be altered so as to accommodate either or both of these properties of matter. We now write

$$\frac{1}{c}\frac{\partial \mathbf{D}}{\partial t} + \frac{4\pi}{c}\mathbf{j} = \text{curl } \mathbf{H},\quad \text{div } \mathbf{D} = 0.$$

Matter also has magnetic properties, and this suggests that the other equations should be changed as well. It is found however to be unnecessary, for the alternations of force in light are so rapid that the magnetic properties have no time to take effect. So we adhere to the equations

$$-\frac{1}{c}\frac{\partial \mathbf{H}}{\partial t} = \text{curl } \mathbf{E},\quad \text{div } \mathbf{H} = 0.$$

These equations together determine the behaviour of light in most types of matter, but we must remember that we always have to make observations outside, and therefore require to know how the light will pass from one medium to another. Electric theory again provides the answer; when light goes through a boundary between two media, at every point of the surface and at every instant of time, the tangential components of electric and magnetic force just on one side of the boundary must each be equal to the tangential components of the corresponding forces just on the other side. (See ELECTRICITY.)

B. Refraction in Transparent Media.—In a nonconducting isotropic medium, the equations assume the form

$$\frac{\epsilon}{c}\frac{\partial \mathbf{E}}{\partial t} = \text{curl } \mathbf{H},\quad -\frac{1}{c}\frac{\partial \mathbf{H}}{\partial t} = \text{curl } \mathbf{E}.$$

It is easy to verify that these are satisfied by

$$E_x = A\cos\frac{2\pi}{\lambda}\left(\frac{c}{\sqrt{\epsilon}}t - z\right),\quad E_y=0,\quad E_z=0;$$

$$H_x=0,\quad H_y = A\sqrt{\epsilon}\cos\frac{2\pi}{\lambda}\left(\frac{c}{\sqrt{\epsilon}}t - z\right),\quad H_z=0.$$

The electric force is transverse to the waves and the wave velocity is $c/\sqrt{\epsilon}$, so that the medium has refractive index $\sqrt{\epsilon}$. An apparent difficulty at once arises, for our result seems to imply that the refractive index should not depend on the colour of the light. This will be explained when we come to the atomic theory, where it will appear that the dielectric constant depends on the frequency of the inducing electric force.

We next consider the passage of light from one medium to another. Suppose that they have refractive indexes n and n', and first suppose n to be the lesser; in the case of free space it will be unity. To find the formulas for refraction and reflection we take a given incident wave and assume that there are reflected and refracted waves but without making any assumptions about their wave lengths or directions. The boundary conditions then require that the sum of the tangential components of incident and reflected forces at the boundary in the first medium are everywhere and at every time equal to the corresponding forces in the refracted wave on the other side of the boundary. These conditions lead in the first place to the law that the frequencies of all three waves must be equal, so that the wave length of the refracted wave is $\lambda n/n'$, and then to the law that the angle of reflection is equal to the angle of incidence θ, while the angle of refraction θ' is given by $n\sin\theta = n'\sin\theta'$. These rules can be deduced merely from the fact that there are boundary conditions and would be the same whatever the form of those conditions. Next, with the special conditions of the electrical theory, we can find the amplitudes of the reflected and refracted waves. Taking the component in which the electric force is polarized perpendicular to the plane of incidence, me find as amplitude of the reflected wave $\sin(\theta-\theta')/\sin(\theta+\theta')$, while the component polarized in the plane of incidence gives $\tan(\theta-\theta')/\tan(\theta+\theta')$. These are Fresnel's sine and tangent formulas; their squares give the intensities of reflection. The intensities of the refracted wave may also be given, but are not so important.

We may now consider how the reflection varies with the angle of incidence. Take the sine formula first. For perpendicular incidence the formula becomes indeterminate, but may be shown to equal $(n'-n)/(n'+n)$. For water the refractive index is about $1\frac{1}{3}$, and so, when light falls perpendicularly on water, the amplitude of the reflected wave is one-seventh of that of the incident, and therefore the intensity is only about 2%. With increasing angle of incidence, the reflection increases somewhat (for incidence on water at 45° it becomes about 5%), and, as the incidence approaches grazing, it increases rapidly up to unity, which means perfect reflection. The phase of the reflected light is always opposite to that of the incident. The tangent formula behaves quite differently. For perpendicular incidence it has the same value, but it starts diminishing, and finally vanishes at the polarizing angle, when $\tan\theta = n'/n$, at which angle the reflected and refracted waves are perpendicular to one another. For water this angle of incidence is about 54°. After this it increases again and reaches unity at grazing incidence. The phase is the same as that of the incident light up to the polarizing angle, and from there onward differs from it by 180°.

These phenomena have been much studied experimentally. The behaviour of a transparent medium depends only on its refractive index, which is most accurately determined by the refractometer (essentially, a prism of the substance), so that experiments on reflection do not provide new information, but serve as a very valuable check on the theory. Suppose. for example, that we illuminate a glass surface obliquely with light polarized in some direction neither in nor perpendicular to the plane of incidence. To find the reflection this light must be resolved into two components, one of which obeys the sine and the other the tangent formula. They will be unequally reflected, but in neither case is the phase changed at the reflection (or only through 180°, which does not matter); and so the reflected light will again be plane polarized, but in a new direction. If the light is incident at the polarizing angle, the reflected light will contain only the component polarized in the direction at right angles to the plane of incidence. If ordinary light is incident the same is true, and this process is often used for obtaining polarized light. The most refined experiments have revealed the fact that the polarization is never perfect, but the unwanted component can usually be attributed to the presence of grease on the surface. If elaborate precautions are taken to remove this grease the effect becomes very small, but it never quite vanishes. This is probably to be attributed to the fact that the surface atoms are necessarily in a different state from those inside, so that it is not possible for a medium to remain truly homogeneous up to the boundary.

We have described what happens when the incident light is in the medium of lower refractive index. In the contrary case the intensity of reflection follows similar rules for the two components, but with one very important difference. In this case the angle of refraction is larger than the angle of incidence, and the reflection becomes complete for both polarized components when the refracted ray is at 90°, at which point the inclination of the incident ray is given by $\sin\theta = n'/n$. For greater angles of incidence the phenomenon of total internal reflection supervenes, and this we must now consider.

When $\sin\theta > n'/n$ there is no angle θ' for which the equation $n\sin\theta = n'\sin\theta'$ can be satisfied, and so there can be no progressive wave in the second medium. The appropriate solution involves instead a real exponential factor. If the boundary is the plane $z=0$, and if the incident wave is at angle θ, its phase will be given by $\cos\frac{2\pi}{\lambda}\left(\frac{ct}{n} - x\sin\theta - z\cos\theta\right)$, and the appropriate solution in the second medium is $e^{-(2\pi/\lambda)z\sqrt{(\sin^2\theta - n'^2/n^2)}}\cos\frac{2\pi}{\lambda}\left(\frac{c}{n}t - x\sin\theta - \epsilon\right)$,

which evidently fits the boundary condition and may be verified to satisfy the wave equations. The real exponential implies that the disturbance drops to a very small fraction of its original intensity in a single wave length. When the amplitudes are worked out, the reflected wave is found to have amplitude equal to the incident, but with a changed phase, and the change is unequal for the two polarizations. Thus, if incident plane polarized light is totally reflected, the emergent light is polarized elliptically. Working on this principle, Fresnel devised an instrument known as the Fresnel rhomb, which turns plane into circularly polarized light.

For water and air the angle of total reflection is about 49°. Thus, when the surface of a glass of water is viewed obliquely from below, it looks like mercury. Total reflection has a curious effect on the field of view of a fish, for however close it is to the surface, everything outside the water must be crowded into a cone of angle 49°, the edge of which will represent the horizon; while, because of the total reflection, the fish will be able to see the bottom, except for parts nearly underneath, quite as well reflected in the surface as directly. Total internal reflection is much used in optical instruments, as it provides more perfect reflection than any metallic coating. In many types of binocular the rays are internally reflected no fewer than four times between the two lenses of each telescope (see BINOCULAR INSTRUMENT).

C. Refraction in Absorbing Media.—To discuss the passage of light through metals, we take both a dielectric constant and a conduction current and, by Ohm's law, the latter will be proportional to the electric force. The first electromagnetic equation is now

$$\frac{\epsilon}{c}\frac{\partial \mathbf{E}}{\partial t} + \frac{4\pi\sigma}{c}\mathbf{E} = \mathrm{curl}\ \mathrm{H},$$

while the remainder are unchanged. The presence of the conduction term has an effect something like what we found in total internal reflection, for it compels us to introduce a real exponential. For a wave of frequency ν going along z a solution can be found in which

$$E_x = e^{-2\pi\nu\kappa z/c}\cos 2\pi\nu(t - nz/c),$$

provided that n and κ satisfy the equations

$$n^2 - \kappa^2 = \epsilon,\ n\kappa = \sigma/\nu;$$

n is the refractive index, and κ is called the absorption coefficient. Considered at a given instant of time, the wave is a damped sine curve of wave length $c/n\nu$ and the amplitude decreases to a fraction $e^{-\kappa/n}$ of itself for each successive crest. For actual metals κ/n is quite large, so that the light can penetrate only a very short distance. The value of n could be determined experimentally from the deflection of light by a prism, if one could be made so thin as to transmit light, and κ could be determined by finding how much the light is attenuated in passing through a plate; but in view of the extreme opacity of metals such methods are very troublesome, and it is more convenient to deduce n and κ from experiments on reflection.

The principle of reflection is just the same as for transparent media, but the details are very different because of the real exponential in the internal wave. There is a change of phase in the reflected wave, and it is different for the two polarizations.

Consequently. if plane polarized light is reflected, it becomes elliptic, and the study of this ellipticity is the most powerful method of evaluating n and κ. In the case of perpendicular incidence it can be shown that the intensity reflected is $(n^2+\kappa^2+1-2n)/(n^2+\kappa^2+1+2n)$. For all metals κ is considerably larger than n, and so the reflection is not far from complete. We also see how it comes about that strong absorption, or large κ, means strong reflection. The refractive indexes of metals vary over a much nider range than those of transparent substances. Thus, while the latter range roughly speaking between 1 and 2.4, silver has refractive index 0.18. associated with absorption coefficient 3.67. More remarkable still is sodium, which, if it can be used untarnished. is an even better reflector than silver. For the yellow light characteristic of sodium we have $n=0.005$ and $\kappa=2.61$. and 99.7% of the light is reflected at perpendicular incidence. In so far as wave velocity has a meaning in such a substance, the mave velocity is 200 times the velocity of light.

Other substances besides metals are opaque, quite apart from the opacity due to the repeated scattering of light. Indeed ordinary transparent substances are always opaque for light of some part of the spectrum, and for such light they behave much like metals. In particular, light which is strongly absorbed will be strongly reflected. H. Rubens took advantage of this fact in his study of "rest-rays," which consist of light in the extreme infra-red. For example. rock salt absorbs light of wave lengths around 50 μ, and so reflects it strongly, although the crystal is transparent to other wave lengths. If then the light from a lamp emitting all wave lengths is reflected to and fro several times by rock salt mirrors, the other wave lengths will be eliminated and the reflected light will be nearly pure. After the last reflection its wave length is determined by means of a grating. Unlike the case of metals, here the process of absorption has been fairly completely explained with important consequences for the theory of the solid state.

D. **Double Refraction.**—In crystals the atoms are packed together in a regular manner. and this packing implies that they will fall into rows in certain directions. Consequently the physical characters of the crystal will differ for different directions, and it is said to be anisotropic. The geometrical theory of crystallography only permits of certain definite types of packing, and these are classified according to the types of symmetry they possess. For purposes of electricity and optics we need to know the way in which the anisotropy will affect the relation between electric force and dielectric displacement. It can be shown that in general the displacement need not be in the same direction as the force? but that there must always be three mutually perpendicular directions in the crystal for which they are in the same direction. We take these directions for our axes, and have

$$D_x=\epsilon_1E_x,\quad D_y=\epsilon_2E_y,\quad D_z=\epsilon_3E_z.$$

But the crystal symmetry may make a further restriction. Thus in the regular system of crystals, the three mutually perpendicular axes are equivalent to one another. so that all physical properties in these three directions must be the same, and therefore ϵ_1, ϵ_2, ϵ_3 must be equal. For electrical and optical purposes therefore, though not for others, the regular system is isotropic. In the hexagonal, tetragonal and trigonal systems there is an axis of six-. four- or threefold symmetry. and, if this is taken as the z axis it follows that $\epsilon_1=\epsilon_2$, though they need not equal ϵ_3. Calcite and quartz both belong to this type. In all other crystal clashes all three ϵ's may be different. We thus have three types of crystal, the regular, the uniaxial and the biaxial. The regular behaves for light as though it nere isotropic, and we shall deal with the uniaxial as a special case of the biaxial (*see* CRYSTALLOGRAPHY).

For a transparent crystal the electromagnetic equations assume the form

$$\frac{1}{c}\frac{\partial\mathbf{D}}{\partial t}=\text{curl }\mathbf{H},\quad \text{div }\mathbf{D}=0;$$

$$-\frac{1}{c}\frac{\partial\mathbf{H}}{\partial t}=\text{curl }\mathbf{E},\quad \text{div }\mathbf{H}=0;$$

together with $D_x=\epsilon_1E_x$, $D_y=\epsilon_2E_y$, $D_z=\epsilon_3E_z$.

The whole question can be discussed with either E, H or D as the primitive quantity, and of course exactly the same results would emerge. but it is most convenient to take D. This is the light vector used by Fresnel in his original theory, before it was given an electrical meaning. The process of solution consists first in eliminating E and H in terms of D, and then fitting a plane wave of arbitrary direction so as to satisfy the equations for D. If l,m,n are the direction cosines of the wave front and L,M,N those of the light vector, and if the wave velocity is V, the wave will be of the form

$$D_x=LS,\ D_y=MS,\ D_z=NS,$$

where
$$S=A\cos\frac{2\pi}{\lambda}\,(Vt-lx-my-nz).$$

In giving the results of the substitution we shall write α^2. β^2, γ^2 for c^2/ϵ_1, c^2/ϵ_2, c^2/ϵ_3. Then it is found that the wave velocity V must satisfy the equation

$$\frac{l^2}{V^2-\alpha^2}+\frac{m^2}{V^2-\beta^2}+\frac{n^2}{V^2-\gamma^2}=0.$$

This is a quadratic equation in V^2, and we conclude that for a given direction of the mave front there are two wave velocities. Associated with each of these values there are definite values of L,M,N, and these determine the polarizations of the two waves. They are at right angles to one another and to the direction of the wave. A simple example is given by a wave going along the direction of z, where the two velocities are α and β and the directions of polarization x and y. Another example is given by a uniaxial crystal where $\alpha=\beta$. The wave velocities are then given by

$$V=\alpha \text{ and } V^2=\alpha^2n^2+\gamma^2(l^2+m^2).$$

Thus one wave has velocity independent of the direction; this is the ordinary mave, and its light vector lies in the plane perpendicular to the axis. The other, the extraordinary wave, is polarized in a direction contained by the axis and the wave direction. and its velocity depends on the wave direction and ranges between γ and α. The values of the wave velocities for different directions can be best appreciated by constructing the normal velocity surface. This is a two-sheeted surface constructed by laying off in every direction from an origin two radii proportional to the two wave velocities, which are the phase velocities of plane waves perpendicular, or normal to the plane. Its general form can be seen from fig. 16. which shows a perspective drawing of a portion of it; the complete surface is obtained by reflection in the principal planes.

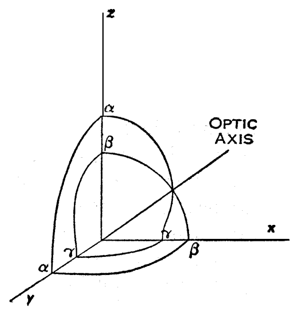

FIG. 16.—PART OF THE NORMAL VELOCITY SURFACE OF A BIAXIAL CRYSTAL

The figure is drawn on the assumption that $\alpha>\beta>\gamma$, and it will be seen that the two sheets meet in four conical points one in each quadrant of the plane of xz; that is, in the plane perpendicular to the intermediate axis. Waves going in the directions of these conical points will have the same velocity whatever their polarization. and so ior these directions light will not be polarized. These are the two optic axes which give rise to the name biaxial. Uniaxial crystals may be regarded as a degenerate case in which the two optic axes have approached one another; the normal velocity surface becomes a sphere and an oval surface, which touch along the direction of the axis. The normal velocity surface does not show how the waves corresponding to the two sheets are polarized. and for this Fresnel gave a very convenient construction. An ellipsoidal surface is obtained by laying off a radius in each direction l, m, n according to the rule

$$r^2=\alpha^2l^2+\beta^2m^2+\gamma^2n^2.$$

When this surface is cut by a plane parallel to the wave front, the longest and shortest radii of the section give the two values of the wave velocity, and their directions give the polarizations. The two circular sections of the ellipsoid are perpendicular to the optic axes.

The phenomena we have so far described suffice to explain many of the features of crystal optics; in particular they are all that is required to understand the action of quarter-wave plates, nicols and other polarizing instruments, but they do not explain the fundamental fact that things seen through a crystal look double. To understand this we have to consider rays, not plane waves of indefinite breadth. In making Huygens' construction it mould be wrong to draw the normal velocity surface round each point and base the construction of fig. 3 on this, for the normal velocity surface is only a diagram describing how plane waves can go, and does not represent the front of a wave emitted from a point. To find the form of this wave front, we imagine that at every point of the normal velocity surface a plane is drawn perpendicular to the radius vector. All these planes will envelop a surface of two sheets, and this we call the ray velocity surface. Like the normal velocity surface, it consists of two sheets and has four conical points lying in the same plane, but now at different angles; these are called the ray axes. Its shape is simpler. however. since the cross sections are ellipses and circles rather than the ovals of fig. 16. Huygens' construction is done with the ray velocity surface, not the normal velocity surface. For uniaxial crystals the ray velocity surface degenerates to a sphere and a spheroid touching the sphere at the ends of the axis.

It will be readily believed that double refraction involves much complicated geometry, and the complete conquest of the subject by Fresnel is one of the greatest feats ever performed in physics. Remarkable effects can be obtained by illuminating crystals with suitably polarized light. We must omit the explanation of many of these effects, which requires a detailed discussion. We can only refer to the curious phenomenon of conical refraction which was discovered theoretically by Sir William Hamilton and afterward verified. When a narrow beam is sent along the axis of a biaxial crystal, the direction for the ray becomes indeterminate so that it can be anywhere on a certain cone. On emergence at the other side this cone is made into a cylinder by the surface refraction, and if this falls on a screen we get a ring of light. Superimposed on this is a narrow dark ring caused by the dispersal of the axial ray into the infinite number of directions represented by the cone.

Double refraction is invariably present in crystals which are not of the regular system, but it is often quite small. Even in a strongly doubly refracting crystal such as calcite the two principal indexes are 1.66 and 1.49 so that their difference is considerably less than the refractive effect of either (which may be represented by its difference from unity). In uniaxial crystals and in biaxial crystals of the orthorhombic system the axes are fixed by the crystal symmetry, though the principal wave velocities may vary with the colour. In biaxial crystals of the monoclinic and triclinic systems the principal axes may vary in position as well, and the most complicated colour patterns may be produced.

Coloured crystals. if they are doubly refracting, usually show the phenomenon of dichroism. or a change of colour with the direction in which the light traverses the crystal. The absorption coefficient varies with the inclination between the light vibrations and the axes of the crystal. just as do the other quantities affecting the propagation of light. Hence the colour, which depends upon the portions of the spectrum that are weakened by absorption, will change with the direction of observation. The commonest example is tourmaline, which is extremely opaque to light of any colour that vibrates perpendicular to the optic axis, but transmits light of a greenish hue rather freely if its vibrations are parallel to that axis. As the crystal is turned from a position in which the light travels perpendicular to the axis to one in which it travels along the axis, the colour therefore changes from green to black. with a series of intermediate hues.

Double refraction also occurs when an isotropic solid is in a state of strain, and indeed the chance strains in badly annealed glass are sometimes a cause of trouble in experiments with polarized light. On the other hand advantage has been taken of the effect: for by making a transparent model, say of a girder, it is possible to find the strains set up in it by the appropriate forces in cases where the shape is too complicated for direct calculation. It is only necessary to illuminate the model with the plane polarized light and to view it through a nicol that is crossed with the polarizer. Light is observed in the regions of strain because the vibrations are rendered elliptical by the double refraction. Another occurrence of double refraction is the Kerr effect—an ambiguous name, as there is a second effect of magnetic type also named after this investigator. When light is sent through the glass of a charged electric condenser. double refraction occurs, so that the component polarized in the direction of the electric force has wave velocity slightly different from that transversely polarized; the effect is proportional to the square of the electric force across the condenser. The extreme rapidity with which the effect follows the applied electric field furnishes a valuable means of suddenly interrupting a beam of light. With nitrobenzene between the plates of a condenser placed between crossed nicols, light will be transmitted when the condenser is charged, but will be extinguished in about 4×10^{-9} seconds when it is discharged. This is the principle of the Kerr electro-optic shutter, which has been used to study the transient phenomena in an electric spark, as well as in the measurements of the velocity of light. *(See* VELOCITY OF LIGHT.) Yet another case, predicted and discovered by W. Voigt, is a very small double refraction when light traverses matter placed in a strong magnetic field. This effect, which is observed when the light travels perpendicular to the field, is associated with magnetic gyration which we shall discuss later.

E. Natural Optical Gyration.— Double refraction is not the only optical effect exerted by crystals. The symmetrical properties of a crystal are of two different kinds, corresponding to rotation and reflection respectively. Most crystals have some symmetry elements of both types, but there are some which only have rotations, so that the crystal is not identical with its mirror image. The simplest geometrical form possessing this peculiarity is the screw, which cannot be superposed on its mirror image. and we therefore liken this type of crystal to a screw. Quartz is such a substance, and there exist two types of quartz crystals, which we may call right- and left-handed. Now circularly polarized light has the same quality of a screw, and we should therefore expect that a right-handed quartz crystal would react differently to right- and left-handed circularly polarized light respectively. It is in fact found that the wave velocities are different, and this is the basis of the theory of optical gyration.

Let us suppose that n_r and n_l are the refractive indexes for the two types of circularly polarized light of frequency ν. Then the right-handed wave will be

$$E_x=A\cos2\pi\nu(t-n_rz/c),\ E_y=-A\sin2\pi\nu(t-n_rz/c),$$

and the left-handed

$$E_x=A\cos2\pi\nu(t-n_lz/c),\ E_y=+A\sin2\pi\nu(t-n_lz/c).$$

Suppose that at the plane $z=0$ we have light polarized along the direction x. This is given by simply adding these two solutions together, and then at any value of z we shall have

$$E_x=2A\cos2\pi\nu\left[t-\frac{n_r+n_l}{2}\frac{z}{c}\right]\cos\pi\nu(n_l-n_r)z/c,$$

$$E_y=2A\cos2\pi\nu\left[t-\frac{n_r+n_l}{2}\frac{z}{c}\right]\sin\pi\nu(n_l-n_r)z/c.$$

This means that at the point z we can regard the light as plane polarized in a direction inclined to x at the angle $\pi\nu(n_l-n_r)z/c$. The phenomenon is actually observed by sending plane polarized light through the medium and seeing how an analyzing nicol must be placed in order to extinguish the light. The gyrational constant is the rotation produced by a thickness of one centimetre of the substance.

In quartz the gyration is very strong, being 217° per centimetre for yellow light, but is complicated by double refraction of the uniaxial type, and it is only for light going very nearly along the crystal axis that it can be observed. There are also crystals of the regular system which exhibit the effect, for example sodium chlorate, and here it is present for all directions. It is also shown by liquids when their molecules contain a chemically asymmetric atom; such a liquid is isotropic in that all directions are equivalent, but is not, molecularly speaking, identical with its mirror image, and so it can and does refract the two types of circularly polarized light differently. Since many sugars contain an asymmetric carbon atom, measurement of the gyration is a very convenient method of estimating the strength of a sugar solution and great practical use is made of it.

VII. THE ATOMIC THEORY OF REFRACTION

We have so far treated refraction as an effect of matter in bulk without inquiry as to how it comes about. The gross effect must be a superposition of the effects of the separate atoms and molecules, and we shall now consider how this superposition takes place. The light arising from an atom may have a great variety of characters. but whatever these are it must have one feature, that the wave is a spherical wave with the atom in its centre. We shall therefore first investigate what types of spherical wave are possible. In discussing diffraction we described a spherical wave emerging from a point source with amplitude inversely proportional to the distance. Though that sufficedto give the outline of the theory. it took no account of polarization, and it must be further refined for our present purpose. We naturally build the complete theory by considering what types of electromagnetic waves can emerge from a point.

A. Types of Spherical Waves.—The transverse nature of light makes it impossible to have a wave going out uniformly in all directions. We give the mathematical form of the simplest possible wave. Let

$$S=\frac{A}{r}\cos\frac{2\pi}{\lambda}(ct-r),\text{ where } r=\sqrt{(x^2+y^2+z^2)}$$

and A is a constant. Then the electric and magnetic forces are given by

$$E_x=\left(\frac{1}{c^2}\frac{\partial^2}{\partial t^2}-\frac{\partial^2}{\partial x^2}\right)S,\quad E_y=-\frac{\partial^2}{\partial x\partial y}S,\quad E_z=-\frac{\partial^2}{\partial x\partial z}S,$$

$$H_x=0,\quad H_y=-\frac{1}{c}\frac{\partial^2}{\partial t\partial z}S,\quad H_z=\frac{1}{c}\frac{\partial^2}{\partial t\partial y}S.$$

If these are worked out they lead to expressions which are rather complicated in general, but simpler for points at a great distance from the source, and it will suffice to discuss the latter case. Consider a large globe, surrounding the source, marked with circles of latitude and longitude, the pole being the axis of x. The observer is on this sphere at angular distance θ from the pole. Then the wave that reaches him will have its electric force polarized so as to vibrate in the north and south direction, and the magnetic force will be east and west and equal in magnitude. The electric force is inversely proportional to the radius of the globe and to the square of the wave length, but, most important of all. it varies as $\sin\theta$, vanishing at the pole and having its maximum at the equator. The actual value is

$$E=\left(\frac{2\pi}{\lambda}\right)^2\frac{A}{r}\sin\theta\cos\frac{2\pi}{\lambda}(ct-r).$$

In fig. 17 (a) the observer takes up various positions on the globe (marked by his colatitude) and looks toward the centre; then the diagram shows the vibration of the electric force that will reach him.

In the classical electromagnetic theory this is the wave which would be emitted by an electron of charge e vibrating with frequency c/λ and small amplitude a along the x axis at the origin, provided that $A=ea$. If the observer were to watch this motion, he would see it in perspective, and the electric force at the observer is proportional to and in the same direction as the apparent motion of the electron. It is very convenient to have a name for this type of wave, including the complete distribution in all directions round the source, and in view of the motion of the emitting electron we shall call it a line wave.

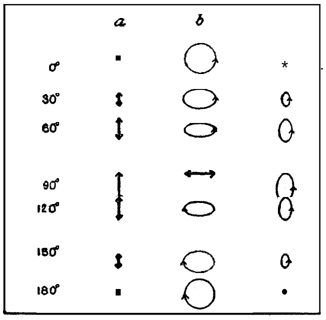

FIG 17 —VIBRATIONS IN SPHERICAL WAVES
The observer, on a sphere in colatitude on the left, looks toward the centre. The amplitude and polarization of light received are shown. (a) Line wave, (b) circle wave, (c) screw wave

If the emitting electron describes a small circle in the y, z plane instead of a line we have what we may call a circle wave. This can be regarded as two superposed line waves along y and z, and having phases differing by a quarter period. The pole of the circle is perpendicular to the poles of both lines. Fig. 17 (b) shows the electric force as seen by the observer for various positions on the globe. Its form again resembles the perspective view he would have of the electron. At either of the poles he receives circularly polarized light, and it is important to notice that they will be of opposite types, one right-handed and the other left-handed. For other directions the light is elliptically polarized and becomes plane polarized at the equator. The intensity is twice as great at the poles as at the equator.

We must also consider a third type of wave which is not so simple. In the electromagnetic equations there is a mathematical symmetry between the electric and magnetic forces, so that we can obtain a solution by interchanging their roles. If we construct a wave by adding to the ordinary line wave a small "magnetic" line wave with the same pole and same frequency, we obtain a wave in which the light is everywhere of the same intensity as for a line wave, but is elliptically polarized with axes in constant ratio and lying in the directions of the circles of latitude and longitude. Such a wave is illustrated in fig. 17 (c). It is important to notice that in this case, unlike the circle wave, the light vector turns in the same direction in both hemispheres. Thus the whole wave has the same screw character and we shall call it a screw wave. The screw wave cannot be emitted by any motion of an electron. It would be emitted if there were a single magnetic pole moving with the electron, but such a thing does not exist, and in fact the wave can arise only from a system itself having the screw character, such as a molecule with a chemically asymmetric atom in it.

B. The Scattering of Light.—When light falls on an atom it sets the electrons in motion and they therefore re-emit light, and the character of this scattered light will depend on the nature of the atom as well as the incident light. But the effect of a single atom is too small to be observable, so that we always have to use a large number and the compounding of their effects produces complications. In fact the scattering of light by matter is a more primitive quality than is refraction, and it is therefore best to reduce everything into terms of scattering before we approach the theory of the behaviour of the single atom. There are several different ways in which an atom may emit light under the stimulus of light. but we can exclude some of them from consideration. Thus certain substances respond by fluorescing; that is to say, absorbing light of one wave length and re-emitting light of a longer wave length. Again, there is the important phenomenon of resonance radiation where the re-emitted light has the same wave length as that absorbed, but where there is no constant phase relation between the incident and scattered light (see FLUORESCENCE AND PHOSPHORESCENCE). Both these phenomena are extremely interesting, but from the present point of view they may be regarded as an absorption and simultaneous re-emission of light, and are outside our scope. We shall also exclude a highly significant type known as Raman scattering, where alterations of wave length occur such that the various frequencies of the scattered light represent combinations between the frequency of the incident light and the different possible frequencies of rotation and vibration of the molecule. These are analogous to the combination tones that are heard when two musical notes are sounded together. Since, however, this phenomenon is intimately related to the structure of molecules it cannot be included in our present account (see RAMAN EFFECT).

The most universal way in which atoms react to light is by the emission of waves of the same frequency as, and having a definite phase relation to, the incident light, and this process, to which we shall limit the name of scattering, is responsible for refraction, double refraction and gyration. In order that all these effects may be explained. we can see one property nhich the scattered waves must always have. The various refractive effects are all due to an interference between the original and the scattered waves, and, since the refraction is independent of the brightness of the light. it follows that the wave scattered by an atom, whatever its other characters. must be proportional in amplitude to the incident force. Another of its properties depends on the fact that for ordinary light the wave length of the light is always far greater than the size of the atom; hence at any instant the atom is practically in a uniform field of force, and so the scattered wave will depend only on the polarization and frequency of the incident wave. but not at all on the direction of its wave front. These conditions must hold for any atom, but apart from them there is great liberty of choice for the form of the scattered spherical wave. We shall see that for some purposes we have to assume circle waves and screw waves, but both ordinary and double refraction are fully accounted for by means of ordinary line waves; moreover for transparent substances the line wave is exactly in phase with the incident. All these results can be deduced by assuming completely general types of spherical waves and then seeing what limitations will give rise to the various refractive effects, but here we shall pursue the opposite course and shall assume the form of the scattered wave and show that our assumption is verified. For the most important case, that of the refraction of a transparent medium, we can summarize our assumptions in the form that under incident light of amplitude E_0 the wave scattered by an atom is a line wave of the form we gave with ρE_0 written for A, and with pole along the direction of E_0. Then p, which depends only on the nature of the atom and on the frequency of the incident light, is the scattering constant of the atom.

C. The Light of the Sky.—The most primitive exhibition of scattering is found not in refraction but in such phenomena as the light of the sky, and it is therefore appropriate to discuss this first. Supposing that the observer looks at a point not very near the sun, the light that he sees will have been scattered through a broad angle, and the phase of the light path, sun–atom–observer, will be different for each atom. Consequently the waves from the separate atoms do not reinforce one another. If the atoms were arranged with perfect regularity their waves would arrive at the eye with regular differences of phase and mould destroy one another so that the sky mould look black; honever the uniform density of gases is due not to systematic regularity but to the unsystematic regularity produced by the enormous number of atoms. The atoms of a gas have no ordered positions, as they have in a crystal, hence the brightness of sky light will depend on compounding a large number of similar waves of quite arbitrary phases and taking the average value of the result. Consider a set of n atoms each of which is giving a wave of the same magnitude, but with phases $\epsilon_1, \epsilon_2 \ldots \epsilon_n$. The resultant amplitude will be proportional to $\cos\epsilon_1+\cos\epsilon_2+\ldots+\cos\epsilon_n$, and the intensity is the square of this. Now the square will consist of terms such as $\cos^2\epsilon_1$ and others such as $2\cos\epsilon_1\cos\epsilon_2$. The latter of these are as likely to be negative as positive, so that they will average out, but the former has average value $\frac{1}{2}$ for each separate term. Thus the average intensity scattered by the n atoms is just n times that scattered by one. If then we want to know the brightness of the sky we only require to calculate the intensity scattered by a single atom and multiply by the number of atoms in the field of view.

We will suppose that N is the total number of atoms in a small solid angle, the illumination from which is to be found. Then, from the formula for line waves, we shall have an intensity proportional to $NE_0^2\rho^2/\lambda^4$, and here E_0^2 is the intensity of the direct sunlight. Now in fact p, the scattering constant of the atom, does not depend very much on the wave length, as long as me only consider visible light, and we can therefore say that the light scattered is inversely proportional to the fourth power of the nave length. This explains why the sky is blue even though sunlight is rather weaker in the blue part of the spectrum than the red. for the wave length of red light is about 1.8 times that of blue, and so factor λ^{-4} is about 10 times as large for blue light as for red.

Another property of the sky light is its polarization. Consider a point of the sky at right angles to the sun. The unpolarized light from the sun may be broken into two polarized components, one of which has electric force pointing at the observer. The line waves induced by this component will have the observer at their poles and so will send no light toward him. He will therefore only receive the light of the other component, and this will be polarized in the direction perpendicular to the line joining the sun to the point observed. At other angles both polarized components are present, one in constant intensity and the other proportional to the squared cosine of the distance from the sun. If the sky is actually observed at right angles to the sun with a nicol, it will be found that the polarization is not complete. This is partly to be attributed to rays that have been scattered several times on their way to the eye, and also to the fact that. though we have spoken only of atoms, the air is mostly cornposed of diatomic molecules, and for these the line wave need not have its pole exactly coincident with the direction of the incident force. There is also usually a complication due to dust, which acts by direct reflection and makes the sky much brighter near the sun than at broad angles.

A most interesting application of the theory of sky light was made by Lord Rayleigh (3rd baron). The barometer shows the mass of the atmosphere, and so, by a direct comparison between the brightness of the sky and that of the sun, it is possible to deduce how much light is scattered by one cubic centimetre of air at ground level. In fact, if N is the number of atoms in one cubic centimetre, we can evaluate $N\rho^2$. Now, as we shall see, we can also find $N\rho$ by a study of refraction, and hence we can estimate N. The process led to one of the earliest good determinations of the fundamental constant of Amadeo Avogadro. the number of molecules in a gram molecule. Similar processes have since been applied in the laboratory, with the advantage that the incident light can be itself polarized. and similar results are obtained.

D. Scattering as the Cause of Refraction.—When we deduce refraction from scattering we are dealing with an incomparably greater effect than in sky light, because here there will be phase relations between the original and the scattered waves. so that we compound the effects of the separate atoms by amplitudes instead of by intensities. We suppose that light waves as they traverse matter have the same velocity as light in free space, but that they set up secondary waves from the atoms which, also proceeding with the velocity of light, interfere with one another and nith the original wave. When the compound effect has been calculated, it is found that it can be expressed by altering the wave velocity of the original nave and disregarding altogether the scattered waves, and in this way refraction is explained.

Take a thin sheet of atoms spread over a plane on which monochromatic light falls perpendicularly. The diagram of fig. 7 will describe the process, provided that we now regard the plane as composed of matter. Each atom will emit a line wave. and the effect at P will consist of the superposition of these waves on the original beam, which is supposed to arrive at P undisturbed. The process is very like Fresnel's discussion of diffraction. though there we imagined that the original nave was suppressed at the plane AB. Suppose that there are N atoms per unit volume, in a thin sheet of thickness l spread over the x,y plane, and let the incident wave be

$$E_x=F\cos\frac{2\pi}{\lambda}(ct-z).$$

The effects that all the atoms produce at P can be summed just as in Fresnel's construction, and the result is an amplitude,

$$-2\pi FNl\rho\frac{2\pi}{\lambda}\sin\frac{2\pi}{\lambda}(ct-z).$$

The important point to notice is that the phase differs by a quarter period from that of the original wave; this is a result of the fact that the scattered waves are in phase with the incident, and is in contrast with Fresnel's construction, in which, in order to get the right result, the phase had to be advanced by a quarter wave length. We now add the two waves together, and, taking advantage of the smallness of the scattered wave, we find

$$F\cos\frac{2\pi}{\lambda}[ct-z+2\pi Nl\rho].$$

If we adopt the ordinary process of refraction and attribute the change of phase to the changed wave velocity during the passage through the thickness l of the sheet of matter, we should say the emergent wave was

$$F\cos\frac{2\pi}{\lambda}[ct-z+(n-1)l],$$

and so we may identify $n-1$ with $2\pi N\rho$. This is the physical origin of refraction. We see also how the reflected wave arises, for the line wave from each atom will be exactly the same at the point which is the image of P in the plane AB as it is at P, and so the total amplitudes of the scattered waves will be the same at the two points; but for the reflected wave there is no interference with the incident light. It is easy to verify that the actual reflected intensity is that which should arise from a thin sheet of refractive index n and thickness l.

We have treated only the small effect of a thin film, and this contains the essence of the process, but it is of course necessary to discuss matter in bulk. Here the scattered wave from every atom acts on every other atom and so complicates the wave scattered by it. Nevertheless the problem proves soluble and leads to a result not very different from the simpler case. The main difference is that we now have $\frac{n^2-1}{n^2+2}=\frac{4}{3}\pi N\rho$; in the special case when $N\rho$ is small, n is near unity, and this reduces to $n-1=2\pi N\rho$ as before. The general solution for oblique incidence verifies all the formulas that are given by the ordinary bulk theory, but the idea of scattering is helpful in seeing directly how reflection and refraction come about. When light falls on a thick slab, the atoms are set in motion and their scattered waves are all in definite phase relations to one another. If we consider a point outside the face of the slab, it will receive all these waves, but those from the interior will have phases spread uniformly round the 360° and so will cancel out. Thus the reflected wave will arise from the atoms in the face where this uniformity ceases to hold. The existence of the polarizing angle becomes immediately obvious, as it is nothing but the rule that in a line wave there is no emission toward its pole, which is perpendicular to the direction of the refracted wave.

The formula $\frac{n^2-1}{n^2+2}=\frac{4}{3}\pi Np$ was discovered by Lorentz (by a rather different method) and becomes the foundation of the theory of dispersion. He deduced an important consequence from it. When a substance can exist in two states, p will be nearly the same for both and N will be proportional to the density, so that, if d is the density of either state, $\frac{n^2-1}{(n^2+2)d}$ should be the same for the two. This relation is verified by comparing the refractive index of a liquid and its vapour. Since their densities often differ by a factor of some hundreds, it is a very stringent test and is often fulfilled to within 1% or 2%. We should hardly expect perfect agreement, because the liquid molecules are being perpetually disturbed by one another, so that there may be a small change in the value of p attached to each molecule.

The explanation of double refraction follows a very similar course. The sheet of matter must now be supposed to react differently under the stimulus of light according as it is polarized along x or along y. In each case there is a line wave emitted with pole along the direction of the incident force, but the amplitudes are different and so the phase changes in the two components of the transmitted wave will be different. The detailed consideration of the effect for matter in bulk is of course more complicated. but leads to Fresnel's normal surface and all its consequences. This part of the theory is complete, but there are difficulties in giving an atomic meaning to ρ, because the adjacent atoms in a crystal are not arranged isotropically and will perturb one another in a complicated manner. As a consequence, the expression $(n^2-1)/(n^2+2)$ ceases to apply; but the full discussion can only be made by a detailed study of the theory of the solid state. With the help of this theory and a knowledge of the arrangement of the atoms in calcite it has been found possible to explain its high double refraction with fair numerical accuracy.

E. Scattering From Absorbing Substances.—A similar process of scattering can be used to explain the action of absorbing substances, but here it is necessary to take the scattered wave in a different phase from the incident. Supposing this phase change to be η, the scattered wave from the thin sheet of atoms will now be

$$-2\pi FNl\rho\frac{2\pi}{\lambda}\sin\frac{2\pi}{\lambda}(ct-z-\eta).$$

If this is added on to the original wave we get

$$F(1-2\pi Nl\rho\sin\eta)\cos\frac{2\pi}{\lambda}(ct-z+2\pi Nl\rho\cos\eta).$$

The first factor means a reduction in amplitude (*i.e.*, absorption), and there is also refraction just as before. Thus by a suitable choice of p and η we can describe the observed behaviour of any absorbing substance. The full theory is best expressed in terms of complex quantities and leads to the equation

$$\frac{(n-i\kappa)^2-1}{(n-i\kappa)^2+2}=\frac{4\pi}{3}N\rho e^{-i\eta},\ (\text{where } i=\sqrt{-1}),$$

so that we can deduce ρ and η from a knowledge of n and κ.

The idea of scattering constants is not really very conveniently applied to metals, because the atoms of a metal are being constantly penetrated by free electrons, so that it is not right to regard each atom as a separate unit. The theory of metal optics is too involved to describe here, but it does show that the conductivity as ordinarily measured for constant electric force can often be applied for infra-red light, though the value is gradually modified at higher frequencies. In fact, silver becomes very nearly transparent at wave lengths near 3,100 Å in the ultra-violet.

F. Natural **Gyration.**—We have seen how gyration arises from the difference between the wave velocities of right- and left-handed circularly polarized light. It is a screw property and can be exhibited only by molecules containing a chemically asymmetric atom. The condition is exactly that which permits of the emission of what we have called a screw wave, and to explain gyration it is necessary only to suppose that, under the influence of plane polarized incident light. the molecule scatters a strew wave. We take as before a thin sheet in the *xy* plane illuminated by plane polarized light,

$$E_x=F\cos\frac{2\pi}{\lambda}(ct-z).$$

Each molecule emits a screw wave which has its axis along x. In any direction a screw wave can be resolved into a main component which is like that of a line wave and a weaker component at right angles and a quarter period behind. Take p for the scattering constant of the line wave and σ for the other component. Then, when we sum all the waves scattered by the molecules, the line waves will compound as before into

$$-2\pi FNl\rho\frac{2\pi}{\lambda}\sin\frac{2\pi}{\lambda}(ct-z)$$

along x, but there will now be a component along y of magnitude

$$-2\pi FNl\sigma\frac{2\pi}{\lambda}\cos\frac{2\pi}{\lambda}(ct-z).$$

If we add these small quantities on to the original wave we find approximately

$$E_x=F\cos\frac{2\pi}{\lambda}(ct-z+2\pi N\rho l),$$

$$E_y=-2\pi N\sigma l\cdot\frac{2\pi}{\lambda}\cdot F\cos\frac{2\pi}{\lambda}(ct-z+2\pi N\rho l);$$

and this means that the light is now plane polarized at angle $-2\pi N\sigma l.2\pi/\lambda$ to the x direction. The rotation is proportional to l, the thickness of the sheet, and the other factors express the gyrational constant. The theory for matter in bulk gives a similar result, but presents it by showing that there are different refractive indexes for right- and left-handed circularly polarized light.

G. **Magnetic Gyration.**—In our discussion of the refraction of isotropic bodies, we saw that plane polarized light might be supposed to stimulate the emission by the atom of a line wave. Sow circularly polarized light can be constructed out of two plane polarized components at right angles and differing by a quarter period in phase, and what we have called a circle wave can be constructed out of two line wares with perpendicular poles and phases differing by a quarter period. Consequently we could have worked out the theory of refraction just as well using circularly polarized light and circle waves, and in discussing magnetic gyration it makes a convenient starting point to do so. When an atom is in the presence of a magnetic field it behaves in a sense as though it were in rotation, about an axis along the field's direction, with velocity proportional to the field strength. We shall see how this comes about when we discuss dispersion, but can explain the gyration without reference to the detailed theory. Ii then the atom is illuminated by circularly polarized light, it will react diiferently according as its magnetic rotation is with or against the rotation of the light vector. We may describe what happens by saying that the atom's scattering constant will no longer be ρ, but $\rho+\tau$ and $\rho-\tau$ ior the two types oi circularly polarized light. Here τ will be proportional to the strength of the field, and it is usually to be regarded as much smaller than ρ.

Suppose that the incident light is

$$E_x=F\cos\frac{2\pi}{\lambda}(ct-z),\qquad E_y=F\sin\frac{2\pi}{\lambda}(ct-z).$$

When the scattered wave from a thin sheet is superposed on this, we have, by the same construction as beiore,

$$E_x=F\cos\frac{2\pi}{\lambda}[ct-z+2\pi N(\rho+\tau)l],$$

$$E_y=F\sin\frac{2\pi}{\lambda}[ct-z+2\pi N(\rho+\tau)l].$$

But if the incident light is of the opposite type it will be

$$E_x=F\cos\frac{2\pi}{\lambda}(ct-z),\quad E_y=-F\sin\frac{2\pi}{\lambda}(ct-z);$$

and the resultant wave will he

$$E_x=F\cos\frac{2\pi}{\lambda}[ct-z+2\pi N(\rho-\tau)l],$$

$$E_y=-F\sin\frac{2\pi}{\lambda}[ct-z+2\pi N(\rho-\tau)l].$$

If we add these two solutions together the incident light is

$$E_x=2F\cos\frac{2\pi}{\lambda}(ct-z),\quad E_y=0,$$

and the transmitted light is

$$E_x=2F\cos\frac{2\pi}{\lambda}(ct-z+2\pi N\rho l)\ \cos\frac{2\pi}{\lambda}(2\pi N\tau l),$$

$$E_y=2F\cos\frac{2\pi}{\lambda}(ct-z+2\pi N\rho l)\ \sin\frac{2\pi}{\lambda}(2\pi N\tau l);$$

so that the plane of polarization has turned through an angle $\frac{2\pi}{\lambda}(2\pi N\tau l)$. This is proportional to the thickness of the sheet and, through τ, to the' strength of the magnetic field. The remaining factors are individual to the substance of which the sheet is made. The constant is oiten called the Verdet constant after one of the earlier investigators who measured it for a number of substances.

The magnetic gyration is usually very small for practicable magnetic fields. It occurs in ail transparent isotropic substances and for light going along the axis of uniaxial doubly rciracting crystals; for other directions it is masked by the double reiraction. There is a very remarkable similar effect, when polarized light is reflected irom the polished pole of a magnet. For perpendicular incidence the plane of polarization rotates, and for other directions there are similar more complicated changes in the rule of reflection. The Kerr effect, as it is called irom its discoverer, is evidently like the magnetic gyration in transparent substances, but its theory is very incomplete.

The two types of gyration, natural and magnetic, are radically different in character, as is shown by the fact that one depends on a screw wave, the other on a circle wave. The consequence is that in natural gyration, if the light is reflected back so as to traverse the sheet again, its direction of polarization turns in each passage like a screw of the same type and so it comes back to its original polarization. On the other hand magnetic gyration is due to a rotation, not a screw, so that if the light is reflected back again it rotates in the same direction as before and the angle of turning is doubled.

VIII. DISPERSION

We have traced the optical effects of matter in bulk to their source in the atoms, and in doing so have found it necessary to use only the ordinary conceptions of the classical theory of dynamics, but as soon as we begin to consider the atoms themselves we get into difficulties, because in fact the atom obeys quite different dynamical rules. These rules, which are the principal subject of the quantum theory (*see* QUANTUM MECHANICS), are fairly well understood, but since our whole practical experience is based on classical dynamics, they are very hard to apprehend in anything but mathematical form; regarded physically they appear to contain an unsatisfying element of irrationality, which is really to be attributed to limitations in our habits of thought. For the purposes of the present subject it is fortunately possible to some extent to avoid these difficulties. The quantum theory gives certain rules, very unlike those of ordinary dynamics, for the intensities and frequencies of the spectral lines emitted by an atom or molecule, and it also predicts how such an atom will behave under the influence of light. Though both these aspects of the theory are quite different from ordinary dynamics, they have this in common with the classical theory, that if we make up a purely classical model to imitate the emission (though in many other properties it will be quite wrong), it will react correctly for the scattering of light. For convenience of calculation we thus imagine that associated with each atom is a phantom virtual atom, which will suffice to work out the optical effects. An actual atom contains only a few electrons, but the virtual atom contains a virtual electron for each line of its spectrum, and the charges on the virtual electrons are usually muck. smaller than the known charge of an electron. Since the spectrum is composed of nearly monochromatic lines, we suppose that each virtual electron is free to execute approximately harmonic vibrations. The relation between the emission and the scattering of light by the atom is then akin to the relation of free to forced vibrations in a harmonic vibrator.

A. Free Vibrations of the Atom.— Let us suppose that we have a virtual electron of mass m vibrating along the axis of x, under a force Kx toward the origin. It will obey the equation

$$m\frac{d^2x}{dt^2}+Kx=0,\ or\ \frac{d^2x}{dt^2}+(2\pi\nu_1)^2x=0\ if\ K=m(2\pi\nu_1)^2.$$

If left entirely to itself such an electron would vibrate with constant amplitude and frequency ν_1 forever; but it cannot be regarded as left alone, because the moving electricity will be perpetually changing the electric forces everywhere in the manner that we have described as a line wave. This wave will carry away enrrgy, which is supplied at the expense of the electron, so that its amplitude must decrease. The electron is always linked with the ether, and it may be shown that the reaction of the ether on it can be represented by introducing a damping term so that the vibration is expressed by

$$m\frac{d^2x}{dt^2}+m(2\pi\nu_1)^2x=\frac{2}{3}\frac{e^2}{c^3}\frac{d^3x}{dt^3},$$

where e is the charge and c as usual the velocity of light. The new term is very small (except for penetrating X-ray frequencies), and the equation may be solved by approximation, and gives

$$x=Ae^{-\frac{1}{3}(e^2/mc^3)(2\pi\nu)^2t}\cos 2\pi\nu t.$$

This represents a vibration which decreases during each vibration by a fraction $\frac{1}{3}\frac{e^2}{mc^3}4\pi^2\nu$, or l/λ where l is $\frac{4\pi^2}{3}\frac{e^2}{mc^2}$; for an ordinary electron it is 3.7×10^{-12} cm., and, as the charge of a virtual electron is usually smaller, the approximation is evidently justifiable for ordinary light of wave lengths about 10^{-5} cm. The line wave emitted by this electron will also be damped with the consequence that, in Michelson's interferometer, when the two light paths differ by a considerable amount the interference will become imperfect. This is in fact observed, but usually for path differences somewhat shorter than might be expected. Ii we imagine the light to be passed through a grating we observe the same phenomenon in a slightly different way; the damping factor gives the line a finite breadth, and in fact spectral lines are nearly aln-ays somewhat broader than is indicated by the theory of purr electromagnetic damping. A variety of causes contributes to this broadening, such as the frequent collisions between the radiating atoms and air molecules, for these collisions will change the phases of the emitted waves and the Doppler effect of the motion of the atoms. which slightlv alters the frequency. Both these effects can be observed directly by alterations of pressure and temperature, but it is uncertain whether they are sufficient causes of the broadening. The whole question is getting very near to the point where the classical conception oi a virtual atom iails, and also to the limits of experimental technique, and all that can be said is that under the most favourable conditions it seems that the damping is not far from the value predicted by electromagnetic theory. We can avoid raising the question by introducing a fictitious damping iactor which replaces the electromagnetic and may write as our equation:

$$\frac{d^2x}{dt^2}+\sigma\frac{dx}{dt}+(2\pi\nu_1)^2x=0,$$

so that the electron's motion is resisted by a small force $m\sigma\frac{dx}{dt}$, and as long as σ is small we do not need to inquire into its origin.

It is necessary next to suppose that the atom contains a number of virtual electrons with different frequencies, and so to adjust their properties that the spectrum lines will occur in the correct relative strengths. Suppose that the first electron, with charge e_1, frequency ν_1, etc., is vibrating with amplitude a_1. Then it emits a line wave, and, at distance r in the equator, we have seen that the intensity will be proportional to $\nu_1^4e_1^2a_1^2/r^2$. In order to compare this intensity with that given by the second electron e_2, we have to consider what their respective amplitudes will be. This requires an assumption, and the appropriate assumption to make (subject to some conditions which we shall not discuss) is the equiparation of energy, that on the average each virtual electron has the same energy. Now the energy of the first electron is $\frac{1}{2}m_1\left(\frac{dx_1}{dt}\right)^2+\frac{1}{2}m_1(2\pi\nu_1)^2x_1^2$, and this is proportional to $m_1a_1^2\nu_1^2$. We thereiore conclude that the intensity of the first line will depend on $e_1^2\nu_1^2/m_1$. It happens that the quantity which is most important in spectrum theory is not the intensity itseli, but the intensity divided by the iourth power of the frequency. This quantity has no name, but is always reierred to as "Einstein's B," by which letter we shall therefore denote it. Then, for the line of frequency ν_s, we so choose e_s and m_s that $e_s^2/m_s\nu_s^2$ is proportional to B_s, and the intensity is proportional to $B_s\nu_s^4$.

B. Forced Vibrations of the Atom.— When the virtual atom is exposed to light there will be an additional force acting on it. The equation of motion of the first electron will now be

$$m_1\frac{d^2x_1}{dt^2}+m_1\sigma_1\frac{dx_1}{dt}+m_1(2\pi\nu_1)^2x_1=e_1F\cos2\pi\nu t,$$

where F is the amplitude of the incident electric force E and ν is its frequency; the direction oi the wave front does not matter. This is the equation which gives the ordinary phenomenon of resonance, and we must consider the form that its solution takes for different frequencies of the incident light. In the first place, σ plays practically no part in the solution when it is small, unless ν is very near ν_1. Excluding that case we have

$$x_1=\frac{e_1}{m_1}\,\frac{F}{4\pi^2(\nu_1^2-\nu^2)}\cos2\pi\nu t.$$

If $\nu<\nu_1$, x_1 is in phase with the electric force E and its amplitude increases strongly as ν approaches ν_1. If $\nu>\nu_1$ the phases are opposite; the amplitude is small for large values of ν, but as ν_1 is approached from above it becomes large (see fig. *18*). There is thus a transitional stage when ν passes through ν_1, and in this stage the amplitude of x_1 has to pass from a large positive to a large negative value. In order to see how it does so we must include the damping term in our equation. There is now a phase difference between x_1 and E, and the solution is

$$x_1=\frac{e_1}{m_1}\,\frac{F}{2\pi\sqrt{4\pi^2(\nu_1^2-\nu^2)^2+\sigma^2\nu^2}}\cos\left(2\pi\nu t-\gamma\right),$$

where $\tan\gamma=\frac{\sigma\nu}{2\pi(\nu_1^2-\nu^2)}$. If ν is much less than ν_1 the phase angle γ is practically zero, and continues so up to values differing from ν_1 by a not very large multiple of σ. From this point on the phase grows rapidly and becomes 90° at $\nu=\nu_1$ and then increases iurther, so that, at an equal distance on the other side of ν_1 it is practically 180°. The amplitude follows the course of fig. *18* nearly up to ν_1, but instead oi becoming infinite it attains a very large maximum at $\nu=\nu_1$ of amount $\frac{e_1}{m_1}\,\frac{F}{2\pi\sigma\nu}$, and then decreases. When well beyond ν_1 it has the same course as in fig. *18*, but with changed sign now because the negative value is allowed ior by the phase. Fig. *19* shows the general features, but it has been necessary to take a comparatively large value of σ in order to show the iorm clearly. In the figure σ is $2\pi\nu_1/5$, whereas for actual spectra it is oi the order of $\nu_1\times10^{-7}$, so that in any diagram which showed the maximum the rest of the figure would be quite invisible. It thus appears that, except for irequencies very near ν_1, the damping can be disregarded, and we shall ior the most part take advantage of this simplification and so make use of the curve of fig. *18* instead of fig. 19.

C. The Dispersion **Formula.**—The motion oi the electron, forced in this may, will cause a line wave to he emitted of which the magnitude is given by multiplying the amplitude of the electron's motion by its charge. Omitting the damping factor, we thus say that the electron has a scattering constant

$$e_1\cdot\frac{e_1}{m_1}\,\frac{1}{4\pi^2(\nu_1^2-\nu^2)}$$

which is proportional to

$$B_1\nu_1^2/(\nu_1^2-\nu^2).$$

The other virtual electrons will give similar effects and they are all to be superposed. Thus the virtual atom will have scattering constant proportional to

$$\rho=\frac{B_1\nu_1^2}{\nu_1^2-\nu^2}+\frac{B_2\,\nu_2^2}{\nu_2^2-\nu^2}+\ldots.$$

This is the best form for theoretical purposes, but experimental work more frequently makes use of wave lengths. Rewriting the equation we have

$$\rho=\frac{B_1\lambda^2}{\lambda^2-\lambda_1^2}+\frac{B_2\lambda^2}{\lambda^2-\lambda_2^2}+\ldots$$

as the dispersion formula, which should apply for any wave length not too close to λ_1, λ_2, etc. The relative magnitudes of the terms are derivable from the intensities of the associated lines in emission spectra. Their absolute values can also be given by carrying the theory somewhat deeper, and we shall touch on this below.

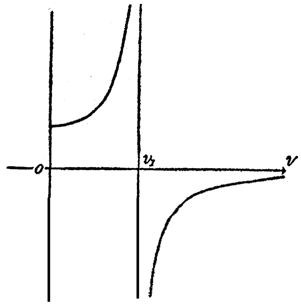

FIG. 18.—THE RESPONSE OF AN UNDAMPED RESONATOR

A periodic force throws a resonator into vibration, and for any frequency of the force the ordinate shows the amplitude of the resonator

We may now consider the march of events when a substance is illuminated by light of increasingly shorter wave length. We will suppose $\lambda_1>\lambda_2>\lambda_3$ . . . . We saw that the reiractive index depends on the product of p and the number of atoms in a cubic centimetre, but, as we have omitted a factor of proportionality already, we may also omit the factor for the number of atoms, and may equate ρ above to $(n^2-1)/(n^2+2)$. For very long waves we shall have practically $(n^2-1)/(n^2+2)=B_1+B_2+$ . . . . Ii n^2 is deduced from this it should agree with the dielectric constant determined by purely electrical means. Though there is little doubt that this would be verified, optical observations are usually lacking ior sufficiently long waves. As λ decreases the first term grows in comparison with the others, because $\lambda^2-\lambda_1^2$ gets smaller more rapidly, and just before λ_1 this term entirely dominates the reiraction. At λ_1 there will be a region of absorption and on the other side the first term will be negative, the rest still positive. As λ decreases further the first term, still negative, shrinks in importance and the second grows until near λ_2 when it becomes dominant. Passing beyond λ_2 it changes sign and later shrinks in importance, its place being taken by λ_3 and so on. Finally when all the lines have been passed, $(n^2-1)/(n^2+2)$ will be negative and proportional to the square of the wave length. For a strict test of the theoretical dispersion against experiment, we should have to work out the value oi n irom that of $(n^2-1)/(n^2+2)$; but for a rough comparison this is not necessary. Where $(n^2-1)/(n^2+2)$ is large, so is n; when the former is negative, n is less than unity; and, if n is plotted against frequency, the curve will have the same general characteristics as has $(n^2-1)/(n^2+2)$. An example of the general course oi the dependence of n on frequency is given without any numerical accuracy in fig. 20. There are supposed to he three lines, of which the middle one is the strongest. In the neighbourhood of each line the rciraction cannot be observed because of absorption. As each line is passed there is a strong decrease in the refractive index, associated with the change of phase oi the corresponding virtual electron by 180°. Whether the refractive index actually becomes less than unity will depend on the breadth of the unobservable region and on the strength oi this line compared with the others. At frequencies higher than the highest frequency of the atom the refractive index will always be less than unity, and such values have been found for X-rays, though, strictly speaking, even here the atom has higher frequencies still.

Much the most striking example of dispersion is the phenomenon called anomalous dispersion, though in iact it is not at all anomalous. There are dyes which strongly absorb certain colours in the spectrum while being transparent to the others; thus if the green is absorbed, the dye will look purple by transmitted light. In consequence of the very strong green absorption there is a reversal in the usual order of refraction. The blue light, which lies on the short wave length side of the green, is much less refracted than the yellow which lies on the side of long wave lengths. Fig. 21 shows with some exaggeration the way in which a prism made of such a colour would fold the spectrum back on itself A similar effect is observed for sodium vapour. Sodium has two very strong lines close together in the yellow, and both of them show anomalous dispersion. A flame containing the vapour is given the form of a prism, and white light is sent through it. This light is then sent through a spectroscope so as to spread out the colours in a direction at right angles to the dispersion of the prism. The colours on opposite sides of either of the sodium lines will be deflected in opposite directions by the prism, so that their images on the photographic plate are shifted up and down. The form of the dispersion curve is thus made directly evident.

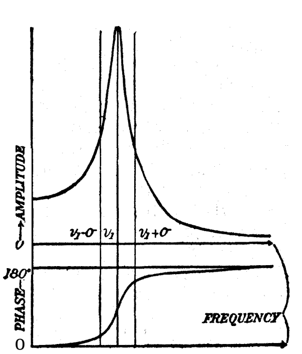

FIG 19 —THE RESPONSE OF A DAMPED RESONATOR, THE ORDINATE OF THE UPPER CURVE SHOWING THE AMPLITUDE, THE LOWER, THE PHASE, OF THE RESONATOR

Because of the brilliance and fineness of the sodium lines, sodium vapour has been used with more success than any other medium in the study of dispersion, and several important results have emerged. It has been found possible to make direct measures of the absorption of light in the immediate neighbourhood of the two lines and so to evaluate the damping factor σ; this was found to be in quite good agreement with the electromagnetic damping factor. Another important experiment consists in finding the absolute value of the scattering constants for these two lines of the sodium atom. The theory of this depends on quantum principles and cannot be given in detail; but, loosely speaking, the two virtual electrons together correspond to a single actual electron, so that, if we can make experiments in which the two lines are indistinguishable, the scattering constant should be given by the use of the ordinary values of e and m. The straightforward way of doing this would be to observe the refraction with light of a very different colour, because then the difference between the influences of two such close lines would he insensible, but this is useless because the refraction itself becomes too small. Indirect means depending on magnetic gyration have been used, and have entirely supported the theoretical prediction that both lines are due to a single electron.

The most accurate measures of reiractive index have been made with transparent substances, substances in which the absorption occurs only far in the infra-red or ultra-violet. To analyze the dispersion the usual procedure is based on the fact that for the inira-red terms, $\lambda^2/(\lambda^2-\lambda_1^2)$ can be expanded in powers of λ^2, while for the ultra-violet terms it can be expanded in inverse powers of λ^2. A formula is thereiore constructed oi the type $A+C\lambda^2+\ldots+E\lambda^{-2}+F\lambda^{-4}+\ldots$, and A, C, E . . . are fitted to the observed values of $(n^2-1)/(n^2+2)$. The term in C corresponds to the infra-red lines, and A, E, F to the ultra-violet. The actual positions of the lines are then found by trial. The infra-red lines, or, more usually, bands, can often be fixed with fair accuracy, both by experiments with rest-rays and by observing the refraction near them; but the ultra-violet are more troublesome, because it is often not possible to get observations very close to the lines Indeed it is usually found that with considerable latitude and can yet give all the observed results with a high degree of accuracy. The whole process is very laborious and has only been carried out for a few substances, such as rock salt and potassium chloride. It is found possible to represent the reiraction by one term for the inira-red and perhaps two in the ultra-violet, together with a third constant term which must correspond to wave lengths so short that $B_s\lambda^2/(\lambda^2-\lambda_s^2)$ does not change perceptibly in value in the whole region accessible to observation. The ultra-violet lines are attributed to electron vibrations of some kind, but those in the infra-red arise through the motions of whole atoms and have been fitted satisfactorily into the general dynamical theory of the crystalline state.

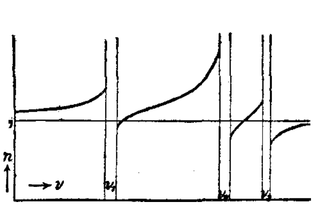

FIG. 20.—A DISPERSION CURVE SHOWING THE WAY REFRACTIVE INDEX DEPENDS ON LIGHT FREQUENCY At ν_1, ν_2, ν_3 there will be absorption

The theory of the refractive indexes of gases is distinctly more advanced, because their emission spectra can be studied without the radical change of state that would be necessary for solids. In the case of metallic vapours, such as sodium, the theory may be considered complete, though its practical verification is somewhat difficult. The spectrum of helium is known, and the measurement of its refraction has led to an interesting result. The lines of all atomic spectra fall into series which converge toward a finite limit λ_h, but beyond this limit there is a region in which there is emission over a continuous range of wave lengths. Corresponding to this it is found that the refraction of helium requires an expression

$$\frac{n^2-1}{n^2+2}=\frac{B_1\lambda^2}{\lambda^2-\lambda_1^2}+\ldots+\int_0^{\lambda_h}\frac{B_x\lambda^2}{\lambda^2-x^2}dx.$$

In the case of the ordinary permanent diatomic gases the spectrum is not so well known, for an electric discharge is required in order that the gas should be made luminous, and this breaks the molecules into atoms. Even without this knowledge, however, one feature can be predicted for a molecule composed of two identical atoms: the atomic vibrations which are of infra-red frequency will have no optical effects at all. This prediction is confirmed by the dispersion formulas which for the permanent gases have only ultra-violet terms.

IX. RECENT VIEWS ON THE NATURE OF LIGHT

In the foregoing account, the principles of optics have been presented as a completed body of knowledge. In so doing, we have entirely disregarded the more recently discovered properties of light that gave rise to the quantum theory. That this could be done rests upon the iact that the above treatment has always concerned rather intense light traversing matter in bulk. Under these conditions the statistical considerations oi the quantum theory may be neglected, and the electromagnetic theory gives a good account of the facts. Only when we leave the macroscopic properties of light and come into the microscopic realm, where we must consider the interaction of faint light with individual atoms, must the theory be revised. The final iorm of this revision was yet to be found in the latter 1950s, but in the search for it our whole point of view with regard to the nature of light, and of matter as well, has undergone a profound change. According to the present view, light has a dual character, such that it may be represented equally well by waves or by corpuscles. The two are merely complementary aspects of one and the same reality. Our discussion has concerned only one aspect of this duality, that of waves. Hence it would not be proper to close without a brief discussion of how photons, the corpuscles of light, have become an integral part of the theory. The logical development of the quantum theory is given elsewhere (*see* QUANTUM MECHANICS), but it will be worthwhile to summarize here the point of view regarding the nature of light that it embodies.

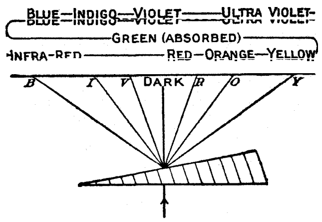

FIG. 21.— ANOMALOUS DISPERSION

The absorption in the green makes the yellow more refracted than the blue

The existence of both wave and corpuscular properties for light was mentioned at the conclusion of our historical summary. It has now been found that electrons, protons and the other elementary constituents of matter show an analogous behaviour in that they also possess wavelike characteristics. A beam of electrons may, with suitable apparatus, be made to exhibit interference, and this property we have seen to be an indisputable proof of the presence oi waves. Since both light and matter may behave either as waves or corpuscles, we must obviously call into question the applicability of models to such basic constituents of nature. All previous experience would lead us to suppose that where a given phenomenon requires two different concepts for its explanation, some crucial experiment could be performed which would decide which of the two is the correct one. In the present case we have been forced to the conclusion that this is impossible. Any given experiment will reveal either the wave aspect or the corpuscular, according to which one it is designed to demonstrate. Thus if light is analyzed by a diffraction grating, the effects are in every detail those predicted by the wave theory. On the other hand ii X-rays traverse the supersaturated vapour of a cloud chamber, tracks of photoelectrons are observed and the localization of energy required to produce these can only be explained as resulting from the annihilation of photons (see CLOUD CHAMBERS). All attempts to design an experiment that could show either property, and hence furnish a decision between the alternatives, have proved to be futile. As was shown by Bohr, the reason for this lies in the unavoidable interaction between the mechanism used for observation and the phenomenon being studied. The quantum theory therefore adopts the novel view that both the waves and the corpuscles are equally real or unreal and that it is meaningless to inquire more closely as to which is the true model to be used.

Quantum theory has further shown that exact calculation of the position and momentum of the particles cannot be made simultaneously, and that the limits of accuracy with which they may be specified are determined by the Planck constant h. The quantitative expression of the fact is the celebrated "uncertainty principle" (*q.v.*) of Werner Heisenberg. For photons and electrons the theory therefore gives no determinate spatial position, but only the statistical distribution, or the probability that they will be found in a given region of space. The reconciliation with the wave theory comes about through the iact that this distribution is calculated by the use of the equations of wave motion. When an interference pattern is produced with light, the density of photons striking the screen, which represents the energy or intensity of the light, is thus distributed in a way governed by the classical wave theory, even though it is impossible to give in detail the path followed by any individual photon. This is, briefly stated, the manner in which the present theory allows for the existence of such contradictory properties as interference and the photoelectric effect. It is a curious fact that the "fits of easy reflection and transmission" with which Newton had to endow his light corpuscles mere periodic in character. One may therefore regard his ideas as a rather vague forerunner of the dual theory established two centuries later.

The development of wave mechanics, which represents the incorporation of the wave aspect into the mechanics of material particles, was originally stimulated by the discovery of the dual character of light. This phase of quantum theory has reached a high degree of completeness, and has been extended by Paul Dirac to include the conditions imposed by the theory of relativity. Unfortunately the progress of the theory of light has been less rapid, and the application of quantum theory to problems of the interaction of light with material particles has been definitely limited. A quantum theory of the electromagnetic field has been formulated by Heisenberg and Wolfgang Pauli which accounts for the existence of photons. It leads to restrictions on the accuracy with which the electric and magnetic fields can be simultaneously measured similar to the uncertainty principle in quantum mechanics. There seems to be no doubt as to the essential correctness of this theory, as long as it is limited to fairly weak electromagnetic fields in empty space. Furthermore if it is restricted to cases of the interaction of light with elementary particles in the first approximation, it is capable of giving a satisfactory account of many experimental facts. Besides the strictly corpuscular properties, such as the photoeffect and Compton effect, which fall naturally into such a theory, many wave properties, such as interference, Doppler effect, light pressure and polarization, are readily interpreted. The theory of dispersion, and of the more recently discovered Raman effect (*q.v.*), have been successfully incorporated within the new theory. The spectral distribution of energy for radiation in thermal equilibrium (Planck's law) is also given satisfactorily provided that the photons are assumed to be indistinguishable from one another. This property is better expressed by saying that the light corpuscles obey the Einstein-Bose statistics, as contrasted with the Fermi-Dirac statistics, which apply to the elementary particles of matter. One of the most striking triumphs of this theory has been in dealing with the conversion of radiation into matter, and vice versa, that occurs in the creation and annihilation of positive electrons.

In spite of these initial successes, which indicate that the quantum electrodynamics is at least as well founded as quantum mechanics, it has become increasingly apparent that both have a limited range of validity. For strong electromagnetic fields and for very short wave lengths, less than the so-called Compton wave length, the theory leads to results that are definitely incorrect. Furthermore it is totally incapable of dealing with the problem of the finite size of the electron. If the theories of light and matter are to be synthesized into a comprehensive whole, it is certain that a fundamentally new approach must be developed in order to attack those phenomena occurring within regions of space comparable with the size of the electron or of atomic nuclei.

The quantum constant h forms the connecting link between the wave and corpuscular concepts, and its size determines the borderline between macroscopic effects where light can be treated as a continuous wave, and microscopic ones where the photon aspect begins to become important. If h were infinitely small, the classical electromagnetic theory would be adequate to account for all optical phenomena, since then we would always be dealing with huge numbers of photons. The same is true when the frequency ν is very small, and the energy $h\nu$ correspondingly small, as in the case of the electric waves from a radio antenna. The electromagnetic theory is entirely self-sufficient in explaining the emission of such radiation, and its absorption by matter. At the other extreme, where h would be large or ν very great, we would have fewer but much more energetic photons and the corpuscular properties of light would be very apparent. The actual value of h, 6.625×10^{-27}, is much nearer the infinitely small on the scale of everyday phenomena, and this explains why the corpuscular behaviour of radiation escaped detection until comparatively recent years. The discovery of X-rays and γ-rays, which lie in the range of very high frequencies (and large photons), made the observation of corpuscular effects inevitable, and hastened our realization of the inadequacy of the wave theory in the microscopic domain.

The fact that a definitive theory of light has yet to be formulated does not detract from the value of the classical electromagnetic treatment given in the present article. The subject matter has been chosen so that this treatment is not only appropriate but rigorously correct in most cases. A broad generalization known as the "correspondence principle" was stated by Bohr in 1916, according to which any quantum theory must give results agreeing with classical theory when the number of quanta (here photons) becomes very great. The difference between the discrete energy states then becomes vanishingly small and they merge into the continuity of classical theory. Thus macroscopic optical phenomena are governed by Maxwell's field theory and macroscopic mechanical phenomena by the mechanics of Newton and Einstein. Only when we encounter problems of the interaction of light with structures of atomic dimensions do they fail, and even here the correspondence principle has acted as an invaluable guide in developing the quantum theory. We may therefore feel confident that however great the changes brought about by a new theory, and however unfamiliar the language, the older work will stand and the new theory will accommodate within itself the wave theory of light.

LIGHT AND RADIATION IN RELATION TO HEALTH. Light and radiation consist of electromagnetic waves which travel at about 186,000 mi. per second in a vacuum, normally propagate in a straight line and are deflected and absorbed by mediums. These electromagnetic waves are classified by frequency vibration and by wave length. The spectrum of these electromagnetic waves includes radiations of wave lengths varying from 0.001 Å (1 angstrom $[Å] = \frac{1}{10{,}000{,}000}$ mm.) to radiations of wave lengths exceeding 100 m. Though all these radiations could be of importance to health, very little is known about the biologic effects of most of them. In medical science the most used and best understood are gamma-rays, X-rays, ultraviolet and infra-red rays All the other radiations have received considerable attention from physicists but comparatively little was known about their biologic effects in the 1950s.

Spectrum of Electromagnetic Waves

	Approximate wave length
Cosmic rays	0.001 Å
Gamma-rays	1.0 Å
X-ray	500.0 Å
Ultra-violet rays	3,000.0 Å
Visible light	6,000.0 Å
Infra-red rays	10,000.0 Å
Hertzian waves	1.0 m.
Radio waves	300.0 m.

Cosmic rays, the shortest and most penetrating of radiation known, are present everywhere on the earth's surface and are more concentrated at higher altitudes. Practically nothing is known of the importance of cosmic rays in health or disease, however.

Visible light has little direct effect on the physiological functions of the individual. However. these radiations penetrate 1–10 mm. of tissue and may increase the temperature of the area penetrated if large energy sources are utilized.

Radioactive elements give off rays which are classed as gamma-rays (very penetrating, short wave length, electromagnetic radiation), beta-rays (negatively charged particles which travel at a speed below that of light) and alpha-rays (positively charged helium nuclei).

X-rays are produced by bombarding a tungsten target with high-speed cathode rays in a vacuum tube. The tungsten target gives rise to electromagnetic radiations called X-rays. The wave length of these radiations depends upon the energy with which cathode rays are propelled to the tungsten target. The greater the energy the shorter is the wave length of the resultant X-rays. X-rays are comparable to the gamma-rays of radioactive elements.

The biologic effect at the site of action of X-rays and of radioactive materials is very similar. Because of vast differences in penetrating power, however, their use in treatment of disease varies greatly. Thus long wave length. less penetrating X-rays are used to treat skin diseases because little penetration is needed; but short wave length X-rays are used to reach internal disorders such as cancer of the stomach.

X-rays as well as gamma-rays, if absorbed in tissues, give rise to electron displacement with resultant electrical charges—a process known as ionization. These radiations are believed to exert their biologic effects by their ionization. Such ionization interferes with the metabolism of the cell resulting in malfunction or death of the cell.

Because some cells are more susceptible than others to the lethal effects of radiation, a selective destruction can be obtained. This fact is employed in the treatment of certain malignant growths because such growths are particularly radiosensitive. In addition to well-known and long-employed radiation therapy with X-rays and radium, radioisotopes have been widely accepted as very useful" in the treatment of leukemia, thyroid disorder, polycythaemia and other diseases. Radioisotopes are artificially created by exposing elements to atomic bombardment. Such radioisotopes as radiophosphorus, radiocobalt and radioiodine are widely used.

The uses of radioactivity in industry are increasing and are creating many problems relating to prevention of overexposure of those working in the industry and those living in the surrounding area.

The Hiroshima and Nagasaki atom bomb explosions with their intense radioactivity exemplified, in miniature, what a war with atomic weapons would mean. It is quite possible that all life on the planet could be destroyed if available atomic resources were applied to that end.

Though there is ample evidence that plants and insects may produce a high incidence of deformed and grotesque descendants secondary to exposures of radioactivity, there was still no evidence in the late 1950s that would justify the application of this observation to humans who have been carefully exposed to the doses and methods that are used in therapy and diagnosis of disease. (This statement should not, however, be taken as a denial of the most serious effect on health which improper exposure to ionizing radiation may have.) Surveys of births in Hiroshima and Nagasaki did not reveal any increased incidence of foetal anomalies in comparison with populations not exposed to an atomic bomb.

There is, however, a significantly higher incidence of leukemia, a fatal blood disease, in people exposed to radioactivity than in those not exposed. Also, excessive radiation applied to the skin or radioactive materials taken internally may lead to the development of cancer.

Though a few experimental conditions have been created in which the destructive effects of gamma-rays and X-rays can be partially counteracted (extracts of spleen, an environment low in oxygen and certain compounds containing sulphur) none of these has been developed to the point where it mould be of practical significance in protection against continuous or mass exposure to radioactivity. The only adequate protection is provided by physical barriers interposed between the radiation source and the subject to be protected. Lead, concrete, and large water tanks are all effective barriers when properly used. The best protection, of course, is to get as far away as possible frsm the source of radiation as the intensity of the radiation diminishes proportionately to the square of the distance.

The maximum amount of radiation to which the total body can be safely exposed has been established as 0.3 of a roentgen per week (a roentgen being the standard unit of measure of ionizing radiation).

As contrasted with the short-wave radiations just discussed, ultra-violet rays may be considered as relatively harmless and quite beneficial though long-term exposure to ultra-violet can also have unfortunate sequels.

The natural source of ultra-violet light is the sun, but only radiations of wave lengths longer than 2,900 Å reach the surface of the earth. Ultra-violet extends in aave length from 1,800 to 3,900 Å. Quartz will filter out all radiation below 1,800 Å and ordinary window glass will absorb any radiation below 3,200 Å (the reason why one cannot develop sunburn behind glass). Human skin absorbs all ultra-violet in the first 1–2 mm. of tissue and all wearing apparel absorbs ultra-violet. Artificial sources of ultra-violet light can be produced by electric arcs between metal and carbon. Low-pressure mercury lamps are effective ultra-violet light sources and are relatively inexpensive.

The amount of ultra-violet that reaches the surface of the earth depends on several factors, including the following: (1) the position of the sun in the sky: the higher in the sky the greater the intensity of ultra-violet light; thus there is a great variation depending on the time of day, the season of the year and the latitude; (2) elevation: the higher the altitude. the greater the intensity of ultra-violet radiation; (3) pollution of the air: smoke, gases and aerial contaminants that fill the atmosphere. especially in cities, greatly diminish the amount of ultra-violet light reaching the ground; and (4) water vapour. On heavily clouded days very little ultra-violet light gets through to the ground. However, on lightly clouded days secondary radiation. skyshine, may deliver large amounts of ultra-violet light to the ground.

The amount of ultra-violet light an object actually receives depends on: (1) direct rays from the sun; (2) reflected rays from the ground (very intense from snow, less intense from water and least intense from coloured, dull surfaces such as grass); and (3) skyshine (diffuse radiation reflected from the sky).

It is generally believed that ultra-violet rays have an invigorating effect on the human body, stimulate the appetite and promote cutaneous circulation. Except for the latter, such claims are difficult to evaluate but may well be true. More specifically it is known that ultra-violet converts ergosterol and its precursors, which are present in the skin, to vitamin D, a compound essential to health and without which children develop rickets. Vitamin D in large doses is an effective drug in the treatment of tuberculosis of the skin and before vitamin D mas used for treating skin tuberculosis, large amounts of ultra-violet light exposure were employed in the management of this disease.

The bactericidal and viricidal properties of ultra-violet light have been well demonstrated and are used rather widely. Ultra-violet light of 2,500 A is the effective bactericidal and viricidal range. Many reports have been submitted concerning the effectiveness of ultra-violet light in sterilizing large rooms. plasma or blood (in which the virus of hepatitis may be carried) and cutaneous surfaces but the absolute value of such procedures has not been entirely substantiated or universally accepted.

One of the most interesting and most publicized harmful effects of ultra-violet light is its role in the cause of cancer of the skin. Fair skinned people and those who sunburn easily and do not tan well are especially susceptible to ultra-violet light induced cancer of the skin. Negroes have a very low incidence of skin cancer compared with Caucasians, probably because of their increased amount of pigment and superficial horny material, both of which filter out ultra-violet light before it reaches the deeper areas of the skin. The incidence of skin cancer is seven times higher in southern than in northern United States and five times higher among farmers than among city workers. Cancer of the skin of body areas not exposed to ultra-violet light is quite rare whereas cancer of the skin of exposed areas (back of hands, neck and face) is very common in Caucasians, especially in the older age groups.

Experimental exposure of mice for Iong periods of time (three–ten months) to ultra-violet light results in cancer of the skin of these mice. These cancers can be prevented if, before each exposure to ultra-violet light, the skin is covered with a compound which absorbs ultra-violet light in the 2,900–3,100 Å range. There is little doubt that ultra-violet light is one of the most important factors in the causation of skin cancer.

The skin reacts differently to different wave lengths within the ultra-violet range. Thus from exposure to 2,500 Å the human skin will only become slightly red and scaly and will not form pigment. At 2,900–3,100 A the skin will become very red, engorged, blister, scale and form pigment subsequent to exposure. At 3,900 Å only a darkening of the skin occurs. This is due to oxidation of preformed melanin rather than the manufacture of new melanin which occurs in the 2,900–3,100 Å range. Melanin is a brownish granular pigment manufactured and deposited within the cells of the epidermis. It is the pigment which largely determines the colour of the skin.

Ultra-violet light may cause severe sunburn in normal people who are overexposed. This is characterized by redness, pain, swelling and sometimes blistering of the skin. Fever, nausea, malaise and systemic illness may follow a severe sunburn.

Many people suffer from severe skin reactions after exposure to very small amounts of ultra-violet light. For example, some people develop cold sores (herpes simplex), some develop hives whereas others may develop eczemalike lesions. Many of these people find complete relief and tolerate large amounts of ultra-violet light if they apply a "sun screen" ointment before exposure. Para-aminobenzoic acid and its esters incorporated in an ointment filter out ultra-violet radiation in the 2,900–3,100 A range.

There are many compounds which when applied to skin in the absence of ultra-violet light give no skin reaction but when applied to the skin in the presence of ultra-violet light cause violent eruptions of the skin. Among these photosensitizers are fluorescent dyes. methoxy psoralens and extracts of a large number of plants. Following these photosensitizing reactions there is frequently intensive pigment formation at the site of the previous eruption. This fact has been applied to the treatment of skin areas uhere more pigment is desired but such attempts at pigment control have not been too successful.

Xeroderma pigmentosum, a rather rare hereditary skin disease in which the individual is extremely sensitive to ultra-violet light, is of interest because sufferers from it develop senile skin which contains many cancers before the victim reaches puberty. The tiniest amounts of ultra-violet light precipitate these changes. Other cutaneous diseases such as lupus erythematosus, a sometimes fatal disease most prominent in young adult females, and porphyria (abnormal fluorescent compounds found in urine, bone marrow. liver and other organs) are definitely aggravated by ultra-violet light. (See also SKIN DISEASES; CANCER.)

Infra-red radiation is more penetrating than ultra-violet light and may be used to increase the temperature of the blood circulating in the skin and of structures lying well beneath the skin. It is most useful in treating disorders of the tendons, joints and muscles which are usually within range of infra-red radiation.

(RD. B. S.)

LIGHTER, a barge employed in ports in loading or unloading the cargoes of ships, the name being derived from the verb "to light"; *i.e.*, to relieve of a burden. The men employed on them are termed lightermen. (See BARGES AND CANAL CRAFT.) Also a small mechanism, used instead of matches. in which a small wheel is twirled against a piece of ferrocerium, throwing off sparks which ignite fluid fed through a cotton wick.

LIGHTFOOT, JOSEPH BARBER (1828–1889), English theologian and bishop of Durham, was born at Liverpool on April 13, 1828. He was educated at King Edward VI school, Birmingham, and Trinity college, Cambridge. He graduated senior classic and 30th wrangler, and was elected a fellow of his college. From 1854 to 1859 he edited the *Journal of Classical and Sacred Philology*. He became tutor of his college (1857), Hulsean professor (1861), chaplain to the prince consort and honorary chaplain to the queen, Whitehall preacher (1866) and canon of St. Paul's (1871). In 1875 he became Lady Margaret professor of divinity in succession to William Selwyn. He had previously written his commentaries on the epistles to the Galatians (1865), Philippians (1868) and Colossians (1875). which marked a new departure in New Testament exegesis in England. Lightfoot was a great grammarian and textual critic; he endeavoured to make his author interpret himself, and by considering the general drift of his argument to discover his meaning where it appeared doubtful. Thus he was able often to recover the meaning of a passage which had long been buried under a heap of contradictory glosses, and he founded a school in nhich sobriety and common sense were added to the industry and ingenuity of former commentators. In 1879 Lightfoot was consecrated bishop of Durham. He continued to work on his editions of the Apostolic Fathers, and in 1885 published an edition of the epistles of Ignatius and Polycarp. collecting also much valuable material for a second edition of Clement of Rome, ahich was published after his death (1st ed.. 1869). His defence of the authenticity of the epistles of Ignatius is an important contribution to that very difficult controversy. He died at Bournemouth on Dec. 21, 1889, and was succeeded in the episcopate by Brooke Foss Westcott, his schoolfellow and lifelong friend who published a sketch of his *Life* (1894).

LIGHTHOUSES. Cnder the general heading of lighthouses this article includes, in addition to a description of marine lighthouse structures and apparatus, some reference to unattended lights, light vessels, lighted buoys, aerial lights, acoustic fog signals and radio and radar aids to navigation. *(See Gnited States,* below, for similar information concerning the U.S.)

A lighthouse is a structure erected to carry a light for the warning or guidance of ships or aircraft.

Early History. — The earliest lighthouses of which records exist were the towers built by the Libyans and Cushites in lower Egypt. beacon fires being maintained in some of them by the priests.

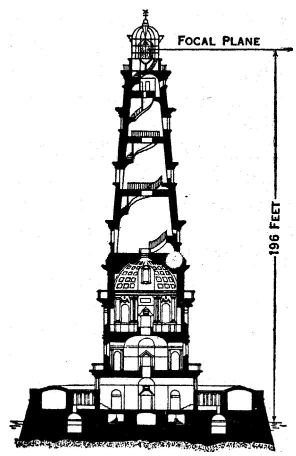

FIG. 1.—CORDOUAN LIGHTHOUSE. EARLIEST EXTANT WAVE-SWEPT TOWER
The lighthouse was begun in 1584 and stands on a rock in the Bay of Biscay near the mouth of the Gironde river

Lesches, a Greek poet (c. 660 B.C.), mentions a lighthouse at Sigeum (now Cape Incihisari) in the Troad, which appears to have been the first light regularly maintained for the guidance of mariners. The famous Pharos of Alexandria, built by Sostratus of Cnidus in the reign of Ptolemy II (283–246 B.c.), was regarded as one of the wonders of the world. A full account of it is given in Hermann Thiersch's *Pharos, Antike Islam und Occident* (Leipzig and Berlin, 1909). The tower, which took its name from that of the small island on which it was built, is stated to have been 600 ft. in height, but the evidence in support of this is doubtful. It was destroyed by an earthquake in the 14th century; the remains are said to have been visible as late as 1350. The name pharos became the general term for all lighthouses, and the term pharology has been used for the science of lighthouse construction. The tower at Ostia was built by the emperor Claudius (A.D. 50). Other famous Roman lighthouses were those at Ravenna, Pozzuoli and Messina. The ancient pharos at Dover and that at Boulogne. later known as La Tour d'Ordre, were built by the Romans and were probably the earliest lighthouses erected in western Europe. ,Both are now demolished.

The light of Cordouan, on a rock in the sea at the mouth of the Gironde, provides the earliest example existing at mid-20th century of a wave-swept tower. Two earlier towers on the same rock are supposed to have been built, the first by Louis the Debonair (c. A.D. 80j) and the second by Edward the Black Prince. The existing structure was begun in 1584 during the reign of Henry III of France and completed in 1611. The upper part of the beautiful Renaissance building was removed toward the end of the 18th century and replaced by a loftier cylindrical structure rising to a height of 207 ft. above the rock (fig. 1). Until the 18th century the source of light was an oak-log fire, and subsequently a coal fire was used for many years. The ancient tower at Corunna, known as the Pillar of Hercules, is supposed to have been a Roman pharos. The Torre del Capo at Genoa originally stood on the promontory of San Berrique. It was built in 1139 and first used as a lighthouse in 1326. It was rebuilt on its present site in 1643 and rises 236 ft. above the cliff. The pharos of Meloria was constructed by the Pisans in 1154 and was several times rebuilt until it was finally destroyed in 1290. On the abandonment of Meloria by the Pisans, they erected the still-existing tower at Leghorn in 1304, which has well borne the brunt of time.

In the 17th and 18th centuries numerous towers, on which were erected braziers or grates containing wood or coal fires, were established in various positions on the coasts of Europe. Among such stations in the United Kingdom were Tynemouth (c. 1608), the Isle of May (1636), St. Agnes (1680), St. Bees (1718) and the Lizard (1751).

The oldest lighthouse in the Gnited States is believed to be the Boston light situated on Little Brewster Island on the south side of the main entrance to Boston harbour, Mass.

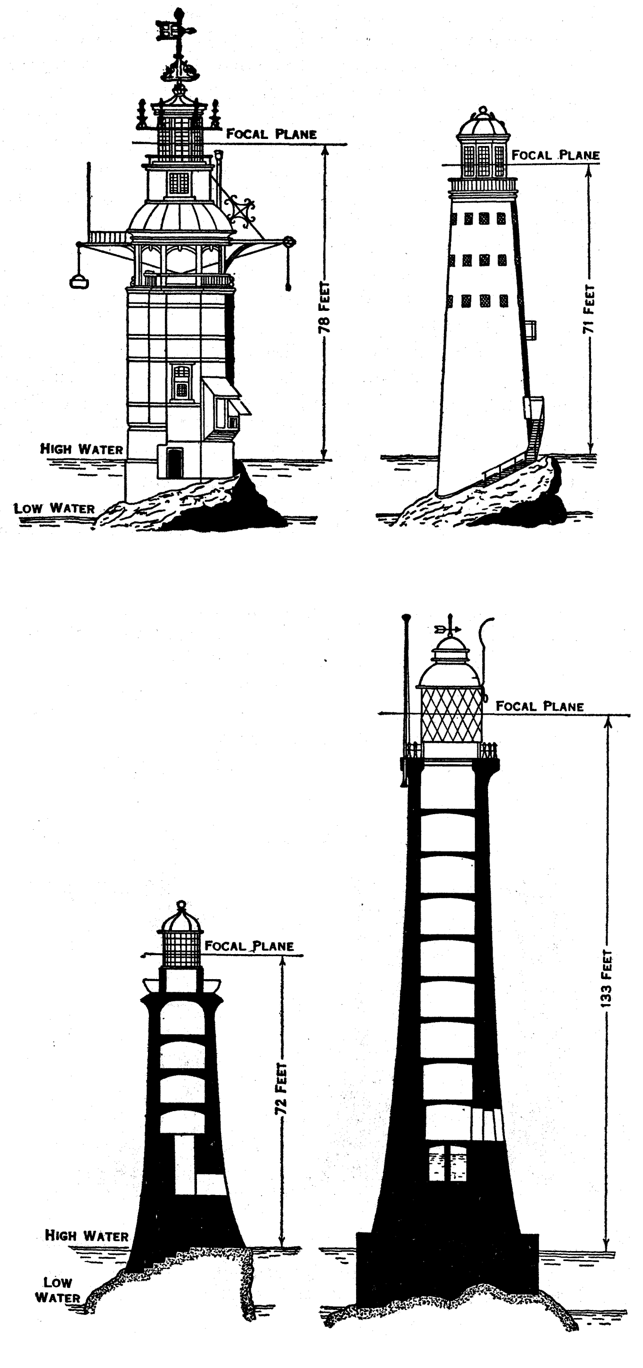

FIG. 2.— THE FOUR LIGHTHOUSES ON THE EDDYSTONE ROCKS
The towers are drawn to the same scale. The first tower was destroyed in the great storm of 1703, and the fourth tower was completed in 1882

It was established in 1716, the present structure dating from 1856. Other early lighthouses on the New England coast were those at Beavertail near the entrance to Newport harbour. R.I. (1749), and Brant point at the entrance to Nantucket harbour (1746). A watchhouse and beacon appear to have been erected on Beacon or Lighthouse Island as well as on Point Allerton hill near Boston before 1673, but these structures would seem to have been in the nature of lookout stations in time of war rather than lighthouses for the guidance of mariners.

LIGHTHOUSE STRUCTURES

The structures of lighthouses may be divided into two classes: (1) those on rocks, shoals or in other situations exposed to the force of the sea; and *(2)* land structures; these last are more numerous.

Wave-Swept Towers.—In determining the design of a lighthouse tower to be erected in a wave-swept position consideration must be given to the physical features of the site and its surroundings. Towers of this description are classified as follows: (1) masonry and concrete structures; *(2)* openwork steel and iron-framed erections on pile or other foundations; (3) cast-iron plated towers; (4) structures erected on caisson foundations.

1. Masonry towers are generally preferred for erection on wave-swept rocks affording good foundation. and have also been constructed in other situations where adequate foundations have been made by sinking caissons into a soft sea bed. Smeaton's tower on the Eddystone rock is the model upon which most later designs of masonry towers have been based, although many improvements in detail hdve been made. In situations of great exposure the following principles in design should be observed: (a) The centre of gravity of the tower structure should be as low as possible. (b) The mass of the structure superimposed at any horizontal section must be sufficient to prevent its displacement by the combined forces of wind and waves without dependence on the adhesion at horizontal joint faces or on the dovetailing of stones introduced as an additional safeguard. (c) The structure should be circular in plan throughout, this form affording the least resistance to wave stroke and wind pressure in any direction. (d) The lower portion of the tower exposed to the direct horizontal stroke of the waves should, preferably, be constructed with a vertical face. The upper portion should be either straight with uniform batter or continuously curved in the vertical plane. External projections from the face of the tower, except in the case of a gallery under the lantern. should be avoided, the surface throughout being smooth. (e) The height from sea level to the top of the tower should be sufficient to avoid the obscuration of the light by broken water or dense spray driving over the lantern. (f) The foundation of the toner should be carried well into the solid rock and secured to it. (g) The materials of which the tower is built should be of high density and of resistant nature. *(h)* The stones used in the construction of the tower should be dovetailed or joggled one to the other in order to prevent their being dislodged by the sea during the process of construction and to afford additional stability. Cement concrete has been used to an increasing extent for maritime structures, including lighthouses, either alone or faced with masonry. Reinforced and prestressed concrete have also been employed.

2. Many examples of openwork steel and iron lighthouses exist. Some typical examples are described below. This form of design is suitable for situations where the tower can be carried on a foundation of iron or steel piles driven or screned into an insecure or sandy bottom; *e.g.,* on shoals, coral reefs and sandbanks or in places where other materials of construction are exceptionally costly and where facility of erection is a considerable advantage.

3. Cast-iron plated toners have been erected in many situations where the cost of stone or scarcity of labour would have made the building of a masonry tower excessively expensive.

4. Cylinder or caisson foundations have been used for lighthouse toners in numerous cases where such structures have been erected on sandbanks or shoals. A remarkable instance is the Rothersand tower. Two attempts were made to sink a caisson in the outer Diamond shoal off Cape Hatteras on the Atlantic coast of the United States, but these endeavours proved futile.

Famous Wave-Swept Towers.—The following are brief descriptions of some of the more important wave-swept toners in various parts of the world.

Eddystone *(Winstanley's* Tower).—The Eddystone rocks. nhich lie about 14 mi. off Plymouth, are fully exposed to southwestern seas. Four towers have been constructed on the reef uhich is submerged at high-water spring tides. The first lighthouse (see fig. 2, upper left) was polygonal in plan and highly ornamented with galleries and projections which offered considerable obstruction to the sea stroke. The work was begun by Henry Winstanley, a gentleman of Essex, in 1696 and finished in 1698. In the following year, in consequence of damage by storms, the tower was increased in diameter from 16 ft. to 24 ft. by the addition of an outer ring of masonry and made solid to a height of 20 ft. above the rock, the tower being raised from 80 ft. to nearly 120 ft. This work was completed in 1700. The lower part of the structure appears to have been of stone. the upper part and lantern of timber. During the great storm of Nov. 26, 1703, the tower was swept away, those in it at the time, including the builder, being drowned.

TABLE I.—*Comparative* Cost of Exposed Rock Towers

Name of structure	Total cost, £	Cu.ft.	Cost per cu.ft. of masonry
Eddystone (Smeaton) (1759)	40,000	13,343	£2 19*s.* 11*d.*
Bell rock, Firth of Forth (1811)	55,620	28,530	1 19 0
Skerryvore, Scot. (1844)	72,200	58,580	1 4 8
Bishop rock (first granite tome;) (1858)	34,560	35,209	19 7
Smalls, Bristol channel (1561)	50,124	46,386	1 1 7
Hanois, Guernsey (1862)	25,296	24,542	1 0 7
Wolf rock, Land's End (1870)	62,726	59,070	1 1 3
Dubh Artach, Scot. (1872)	72,584	42,050	1 1, 6
Longships, Land's End (1872)	43,869	47,610	18 5
Eddystone (Douglass) (1882)	59,255	65,198	18 2
Bishop rock (reconstruction) (1887)	64,889	45,080	1 8 9
Great Basses, Ceylon (1873)	63,560	47,819	1 6 7
Minots ledge, Mass. (1860)	62,500	36,322	1 17 2
Spectacle reef, Lake Huron (1874)	78,125	42,742	1 16 2
Ar'men, Fr. (1881)	37,692	32,400	1 3 3
Fastnet, Ire, (1904)	79,000	62,600	I S 5

Eddystone *(Rudyerd's* Tower).—This lighthouse was begun in 1706 and completed in 1709 (see fig. 2 upper right). The structure consisted principally of oak timbers securely bolted and clamped together. the lower part being filled in solid with stone to add weight to the building. The simplicity of the design and the absence of projections from the outer face rendered the tower very suitable to withstand the onslaught of the waves, but the lighthouse was destroyed by fire in 1755.

Eddystone (Smeaton's Tower).—This famous work, which consisted entirely of stone, was begun in 17j6, the light being first exhibited in 1759 (see fig 2, loner left). John Smeaton was the first engineer to use dovetailed joints for the stones in a lighthouse structure. The stones, which averaged one ton in weight, aere fastened to each other by means of dovetailed vertical joint faces, oak key wedges, and by oak treenails wedged top and bottom extending vertically from every course into the stones beneath it. During the 19th century the tower was strengthened on two occasions; but in 1877, partly because of the undermining of the rock on which the tower was built and the insufficient height of the structure, the Corporation of Trinity House determined on the erection of a new lighthouse in place of it.

Eddystone (J. N. Douglass' Tower).—The site selected for the new Eddystone tower (see fig. 2, lower right) is 120 ft. S.S.E. from Smeaton's lighthouse, where a suitable foundation was found, although a considerable section of the lower courses had to be laid below the level of low water. The base is vertical, 44 ft. in diameter, and all the stones are dovetailed, both horizontally and vertically, on all joint faces, those of the foundation course being secured to the rock by Muntz metal bolts. The lantern is a cylindrical helically framed structure with domed roof, gun-metal astragals and cast-iron pedestal. The optical apparatus in this lighthouse consists of tao superimposed tiers of refracting lens panels. The burners originally fitted in Eddystone tower were of six-wick pattern, but these were replaced in 1904 by incandescent oil-vapour burners. At the time of the completion of the lighthouse two bells, weighing two tons each and struck by mechanical power, were installed for fog-signalling purposes; these were later replaced by an explosive guncotton fog signal. The work of preparing the foundation was begun on July 17, 1878, and the light was first exhibited on May 18, 1882. The upper portion of Smeaton's tower was removed on completion of the new lighthouse and re-erected on Plymouth Hoe, where it replaced an old Trinity House seamark. One of the principal features in the design of the new Eddystone lighthouse tower is the solid vertical base. Heavy seas are immediately broken up or reflected by it, spray alone rising to the height of the lantern gallery. The shock to which the gallery cornice of the old tower was exposed was so great that stones were sometimes lifted from their beds. Its successor presents another point of dissimilarity from Smeaton's structure in that the stones forming the floors consist of single corbels built into the wall instead of stone arches the thrust of which, in the earlier tower, was taken by the walls strengthened by building in chains in the form of hoops. The system of constructing corbelled stone floors was first adopted by R. Stevenson in the Bell rock lighthouse.

Bell Rock.—The Bell rock tower (fig. 3), which lies 12 mi. off the coast of Forfarshire, stands on an exposed reef, dry at low water and submerged to a depth of about 16 ft. at high water of spring tides. The rock is of hard sandstone. The lighthouse was constructed by R. Stevenson in 1807–11.

Skerryvore.—The Skerryvore rocks, 12 mi. off the island of Tiree in Argyllshire, are wholly open to the Atlantic. The tower, 158 ft. in height and designed by Alan Stevenson, was begun in 1838 and finished in 1844.

Bishop Rock.—The lighthouse on Bishop rock, the westernmost landfall rock of the Scilly Isles, occupies perhaps a more exposed situation than any other in the world. The first lighthouse erected there was begun in 1847 under the direction of N. Douglass. The tower consisted of a cast- and wrought-iron openwork structure having the columns deeply sunk into the rock. On Feb. 5, 1850, when the tower was ready to receive the lantern, a heavy storm swept away the whole structure. In 1851 the erection of a granite tower mas begun and the light was first exhibited in 1858. This structure also proved insufficient to withstand the heavy seas to which it was exposed. Soon after its completion the five-hundred-weight fog bell, fixed to the lantern gallery 100 ft. above high-water mark, was washed away and the tower vibrated considerably during storms. In 1874 it was strengthened by bolting continuous iron ties to the internal wall surfaces. In 1881 further signs of damage appeared and the structure was encased from its base upwards with granite blocks dovetailed to each other and to the

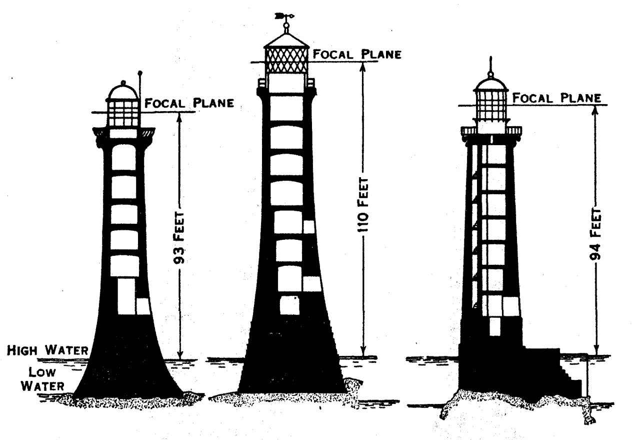

FIG. 3.—SECTIONS OF ROCK LIGHTHOUSES DRAWN TO SAME SCALE

existing work. At the same time the elevation of the light was increased. The work was begun in 1883 and completed in 1887. Profiting by the experience gained in the construction of the new Eddystone tower. Sir James N. Douglass decided to build the lower portion of the improved Bishop rock tower in the form of a cylinder, but with considerably increased elevation (fig. 4).

Wolf Rock.—This much-exposed rock lies midway between the Scilly Isles and Lizard point, and is submerged to the depth of about six feet at high water. The tower was erected in 1862–69 (fig. 3). The lower part of the base has projecting steps or scarcements in order to break up the sea.

5. "Ambrose" lightship, stationed at the entrance of New York harbour

mater, is 14 mi. S.W. of the Island of Mull. The tower occupied six years in erection and was completed in 1872. The focal plane is at a level of 145 ft. above high water.

Ar'men.—The masonry tower, erected by the French lighthouse service on the Ar'men rock off the western extremity of the fle de Sein, Finistère, occupied 15 years in construction (1867–81). The rock is barely uncovered at low water and of small area: which made it impossible to construct a tower having a base diameter greater than 30 ft. (fig. 3).

Fastnet. — The first lighthouse on the Fastnet rock, off the south-west coast of Ireland, was a circular cast-iron tower 86 ft. in height completed in 1854 It was erected on the summit of the rock which in 1895 was found to be considerably undermined. In 1899 a granite structure of increased height and founded upon a sound ledge of rock on one side of the higher but undermined portion of the reef, with its foundation laid near high water, was commenced. It was completed in 1904. The focal plane is at a level of 158 ft. above high-water mark.

Maplin.—The screw-pile lighthouse erected on the Maplin Sand in the estuary of the Thames in 1838 is the earliest of its kind and served as a model for numerous similar structures in various parts of the world. The piles, nine in number, were of solid wrought iron with screws four feet in diameter. This structure developed a serious list as a result of scour jo to 60 ft. deep near the piles. The lighthouse was abandoned in 1931 and overturned in a' gale shortly afterward.

Rothersand.—This lighthouse, off the entrance to the Weser river in Germany, is a structure of great interest on account of the difficulties encountered in its construction. The tower had to be founded on a bottom of shifting sand 20 ft. below low mater and in an exposed situation. Work was begun in May 1881, when attempts were made to sink an iron caisson under pneumatic pressure. Because scour removed the sand from one side of the caisson it tilted to an alarming angle, but eventually it was sunk to a depth of 70 ft. below low water. In October of the same year the whole structure collapsed.

Another attempt, made in May 1883, to sink a caisson of biconvex shape, in plan 47 ft. long, 37 ft. wide and 62 ft. in height, met with success, and after many difficulties the structure was sunk to a depth of 73 ft. below low water, the sides being raised by the addition of iron plating as the caisson sank. The sand was removed from the interior by suction. Around the caisson foundation were placed 74,000 cu.yd. of mattresswork and stones. the interior being filled with concrete. The lighthouse (fig. 5) was completed in 188j.

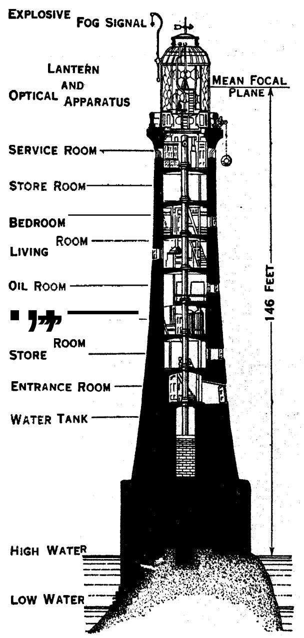

FIG. 4.— BISHOP ROCK LIGHTHOUSE, SCILLY ISLES
This is the second granite tower. The first granite tower was encased and raised in haiaht in 1883–87

Other well-known wave-swept towers are those at Haulbowline rock. Carlingford Lough, Ire., 1823; Héaux de Brehat, Brittany, 1839; Horsburgh, Singapore, 1851; Minots ledge, Mass., 1860; Bayes d'Olonne, Bay of Biscay, 1861; Smalls, Bristol channel, 1861; Hanois, Guernsey, 1862; Daedalus reef (iron tower), Red sea, 1863; Alguada reef, Andaman sea, 1865; Longships, Land's End, 1872; Great Basses, Ceylon, 1873; the Prongs, Bombay, 1874; Spectacle reef, Lake Huron, 1874; Chicken rock. Isle of Man, 1874; Fowey rocks, Fla., 1878; American shoal, Fla., 1880; Wolf Trap. Chesapeake bay, 1887; St. George reef, Calif., 1892; Rattray head, Aberdeenshire, 189j; Beachy head, Eastbourne, 1902; the Graves, Boston, Mass., 1905; and Jument d'Ouessant, Brittany. 1911. See also United Sta es below.

Jointing of Stones in Rock Towers, — Various methods of jointing the stdnes in rock towers are employed in building. The great distinction between the towers built by successive engineers to the Trinity House and other rock lighthouses is that in the former the stones of each course are dovetailed together both laterally and vertically and are not connected by metal or wooden pins and wedges and dowelled as in most other cases. This dovetail method was first adopted at the Hanois rock at the suggestion of N. Douglass. The cement mortar in the joint formed between the faces so locks the dovetails that the stones cannot be separated nithout being broken.

Effect of Waves. — The wave stroke to which rock lighthouse towers are exposed is often considerable During the erection of the tower at Dubh Artach, 14 joggled stones, each of two-tons weight, were washed away after having been set in cement at a height of 37 ft. above high water, and similar damage was done during the construction of the Bell rock tower. The effect of waves on the Bishop rock and Eddystone towers has been noted above.

Land Structures for Lighthouses. — The erection of lighthouse toners and other buildings on land presents no serious difficulties of construction; such buildings are usually of simple architectural character. Besides being built of stone, brick or reinforced concrete, land towers are frequently constructed of cast-iron plates or open steelwork with a view to economy. Fine examples of the former are to be found in many British colonies and elsewhere. that on Dassen Island. Cape of Good Hope, being typical. A cast-iron tower erected at Kijkduin, near Helder, Neth., in 1875 is 197 ft. in height to the focal plane. Many openwork structures up to 200 ft. in height have been built. Examples are the towers erected at Cape São Tomé, Braz., in 1882, 148 ft. to the focal plane; Mocha, Red sea, in 1903, 180 ft.; and Sanganeb reef, Red sea, 1906, 165 ft.

DISTINCTION AND DISTRIBUTION OF LIGHTS, ETC.

The following are the various light characteristics which may be exhibited to the mariner:

Fixed. — Showing a continuous or steady light. Seldom used in modern lighthouses and generally restricted to small port or harbour lights. A fixed light is liable to be confused with lights of shipping or neighbouring shore lights.

Flashing. — (I) Showing a single flash at regular intervals, the duration of light being always less than that of darkness. (2) A steady light with, at regular intervals. a total eclipse, the duration of light being always less than that of darkness.

Group **Flashing.**—Showing at regular intervals a group of two or more flashes.

Occulting. — A steady light with, at regular intervals, a sudden and total eclipse, the duration of darkness being always less than, or equal to, that of light.

Group Occulting. — A steady light with, at regular intervals, a group of two or more sudden eclipses.

Fixed Flashing. — A fixed light varied, at regular intervals, by a single flash of relatively greater brilliance.

Fixed and Group Flashing. — A fixed light varied. at regular intervals, by a group of two or more flashes of relatively greater brilliance.

Quick Flashing. — A light which flashes continuously more than 60 times a minute.

Interrupted Quick Flashing. — A light which flashes at a rate of more than 60 times a minute with. at regular intervals, a total eclipse.

Group Interrupted Quick Flashing. — A light which shows groups of quick flashes, as defined above, separated by relatively longer periods of total eclipse.

Alternating. — Lights having any of the foregoing characteristics and which alter in colour are indicated by the addition of the word "alternating" to the appropriate description. When used alone in describing a light the word indicates two distinct colours alternating without any intervening eclipse, Alternating lights are not to be recommended (see Coloured Lights below).

Colour.—The colours usually adopted for lights are red and green. A nhite light is to be preferred whenever possible because of the great absorption of light by the use of red or green glass screens.

Sectors.—Where coloured lights are used to distinguish cuts or sectors they should be shown from apparatus of fixed section and not from revolving apparatus. In marking the passage through a channel or between sandbanks or other dangers, coloured-light sectors are arranged to cover the dangers, white light being shown over the fairway with sufficient margin of safety between the edges of the coloured sectors next to the fairway and the dangers.

*TABLE 11.—Distances at Which Objects Can Be Seen at Sea, According to Their Respective Elevations and the Eleaation of the Eye of the Observer**

Heights, ft.	Distances, nautical miles	Heights, ft.	Distances, nautical miles
5	2.565	120	12.56
10	3.628	150	14.02
15	4.443	200	16.22
20	5.130	250	18.14
30	6.283	300	19.87
40	7.255	400	22.94
50	8.112	500	25.65
60	8.886	600	28.10
70	9.598	700	30.28
80	10.26	800	32.45
100	11.47	900	34.54
		1,000	36.28

*Example: A light 200 ft. high will be visible 22.50 nautical miles to an observer whose eye is elevated 30 ft. above the water; thus, from the table:

30 ft. elevation, distance visible 6.28 nautical miles
zoo " " " " 16.22 " "
22.50 " "

Source: A. Stevenson

Choice of Characteristic and Description of Apparatus.—In determining the choice of characteristic for a light, due regard must be paid to existing lights in the vicinity. No light should be placed on a coast line having a characteristic the same as, or similar to, another in its neighbourhood unless one or more lights of dissimilar characteristic and at least as high power and range intervene. In the case of landfall lights the characteristic should differ from any other within a range of roo mi. In narrow seas the distance between lights of similar characteristic may be less. Landfall lights are the most important of all and the most powerful apparatus available should be installed at such stations. The distinctive characteristic of a light should be such that it may readily be recognized by a mariner without the necessity of accurately timing the period or duration of flashes. For landfall and other important coast stations flashing dioptric apparatus of the first order (920-mm. focal distance), or its equivalent in power, with high intensities are required. In countries where the atmosphere is generally clear and fogs are less prevalent than on the coasts of Britain, second- or third-order lights suffice for landfalls, having regard to the high intensities available by the use of improved illuminants. Secondary coast lights may be of second. third or fourth order of flashing character, and important harbour lights of third or fourth order. Less important harbours and places where considerable range is not required, as in estuaries and narrow seas, may be lighted by flashing lights of fourth order or smaller size. Where sectors are requisite, occulting apparatus should be adopted for the main light; or subsidiary lights, fixed or occulting, may be exhibited from the same tower as the main light but at a lower level. In such cases the vertical distance between the high and the low light must be sufficient to avoid commingling of the two beams at any range at which both lights are visible. Such commingling or blending is caused by atmospheric aberration.

Range of Lights.—The range of a light depends first on its elevation above sea level and secondly on its intensity. Most important lights are of sufficient power to render them visible at their full geographical range in clear weather. On the other hand there are many harbour and other lights which do not meet this condition.

The distances from which lights are visible, given in lists of lights—except in the cases of lights of low power for the reason given above—are usually calculated in nautical miles as seen from a height of 1 j ft. above sea level, the elevation of the lights being taken as above high water. Under certain atmospheric conditions, and especially with the more powerful lights, the glare of the light (by reflection from the clouds) may be visible considerably beyond the calculated range.

Elevation of Lights.—The elevation of the light above sea level need not, in the case of landfall lights, exceed zoo ft., which is sufficient to give a range of more than 20 nautical miles. For coast lights 150 ft. is usually sufficient. Lights on high headlands are liable to be enveloped in banks of fog at times when at a lower level the atmosphere is comparatively clear (*e.g.*, the old Beachy head light). No definite rule can, however, be laid down, and local circumstances, such as configuration of the coast line, must be taken into consideration in every case.

Choice of Site.—Landfall stations should receive first consideration and the choice of location for such a light ought never to be made subservient to the lighting of the approaches to a port. Subsidiary lights are available for the latter purpose. Lights installed to guard shoals, reefs or other dangers should, when practicable, be placed seaward of the danger itself, as it is desirable that seamen should be able to make the light with confidence. Sectors marking dangers seaward of the light should not be employed except when the danger is in the near vicinity of the light. Outlying dangers require marking by a light placed on the danger or by a floating light in its vicinity.

OPTICAL APPARATUS

Optical apparatus in marine lighthouses is employed for concentrating the rays of light derived from a light source: (1) in the vertical plane only, to show a fixed belt of light all round the horizon, which can be made either flashing or occulting by eclipsing the light or by mechanically interposing a screen; (2) in both the vertical and horizontal planes simultaneously to produce a high-powered beam or cone of light which can be revolved, to show a flashing light, or fixed, to mark an isolated danger or narrow channel where a limited azimuth suffices; and (3) in the vertical plane and afterward in the horizontal plane for diverting or condensing a portion of the fixed belt of light to strengthen a sector.

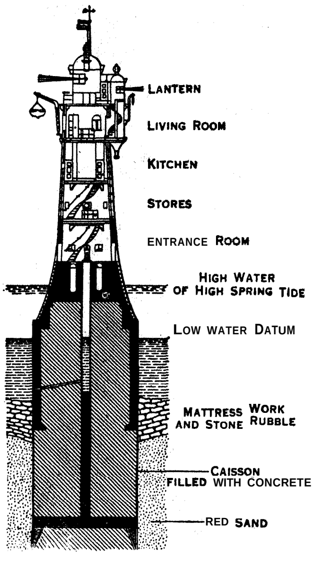

FIG. 5.— ROTHERSAND LIGHTHOUSE. NEAR THE MOUTH OF THE WESER ESTUARY, GER.

Three types of apparatus are used to effect these concentrations: (1) catoptric, in which the rays undergo reflection only at the surface of a mirror; (2) dioptric, in which the rays pass through a glass medium and are bent or refracted as they enter and emerge from it (fig. 8); and (3) catadioptric, in which the rays after entering the glass medium suffer total internal reflection before emerging from it (fig. 7). The object of these several forms of optical apparatus is not only to produce characteristics or distinctions in lights to enable them to be recognized readily by mariners. but to utilize the light rays to the best advantage by their condensation. This is accomplished more effectively by the use of revolving annular lenses than by fixed belts, as greater intensities are thereby attained. Fig. 7 shows in diagrammatic form the various sections and dispositions of glass elements commonly used in lighthouse optical apparatus.

Catoptric System.—Paraboloidal reflectors, consisting of small facets of silvered glass set in plaster of paris, were first used about the year 1763 in some of the Mersey lights by William Hutchinson, who was then dockmaster at Liverpool. Spheroidal metallic reflectors were introduced in France in 1781, followed by paraboloidal reflectors of silvered copper in 1790 in England and France, and in Scotland in 1803. The earlier lights were of the fixed type, a number of reflectors being arranged on a frame or stand in such a manner that the emergent rays overlapped and thus illuminated

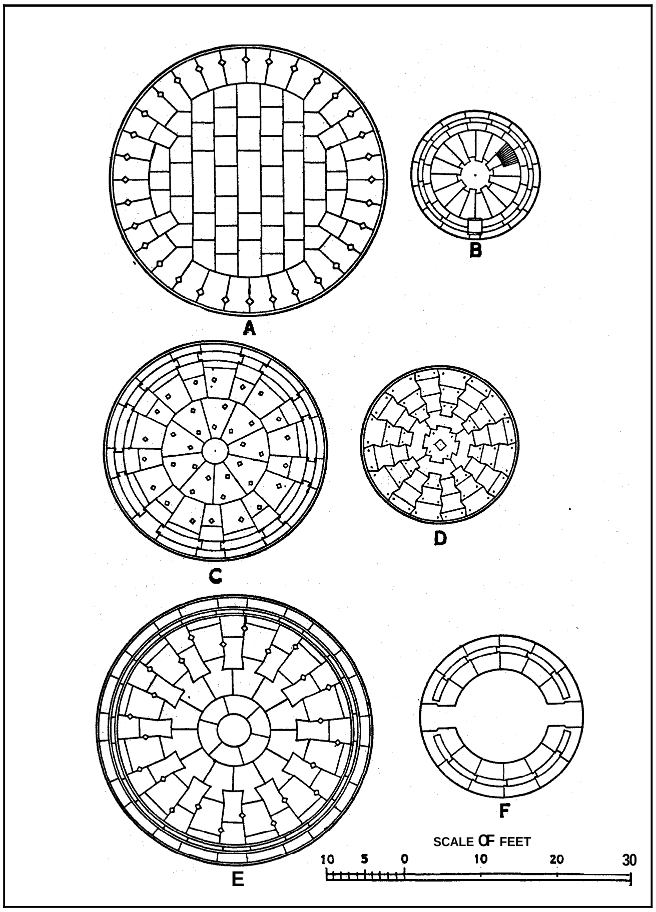

FIG. 6.— COURSES OF STONES OF VARIOUS TOWERS

the whole horizon continuously. In 1783 the first revolving light mas erected at Marstrand in Sweden. Similar apparatus was installed at Cordouan (1790), Flamborough head, Yorkshire (1806), and at the Bell rock (1811). To produce a revolving or flashing light the reflectors were fixed on a rotating carriage having several faces. A type of paraboloidal reflector is still used for light-vessel illumination.

About the year 1900 reflecting mirrors were used in the Heligoland lighthouse in combination with electric arc lamps.

Dioptric System.—The first adaptation of dioptric lenses to lighthouses was probably made by T. Rogers, who used lenses at one of the Portland lighthouses between 1736 and 1790. The comte de Buffon had in 1748 proposed to grind out of a Solid piece of glass a lens in steps or concentric zones in order to reduce the thickness to a minimum (fig. 8A). The marquis de Condorcet in 1773 and David Brewster in 1811 designed built-up lenses consisting of stepped annular rings. Neither of these designs, however, was intended to apply to lighthouse illumination. In 1822 Augustin Fresnel constructed a built-up annular lens in which the centres of curvature of the different rings receded from the axis according to their distances from the centre, so as practically to eliminate spherical aberration; the only spherical surface being the small central part or bull's-eye (fig. 8). These lenses were intended for revolving lights only. Fresnel next produced his cylindric refractor or lens belt, consisting of a zone of glass generated by the revolution round a vertical axis of a medial section of the annular lens (fig. 8). The lens belt condenses and parallelizes the light rays in the vertical plane only, while the annular lens does so in both planes. The first revolving light constructed from Fresnel's designs was erected at the Cordouan lighthouse in 1823. It consisted of eight panels of annular lenses of 45° vertical aperture and having a focal distance of 920 mm. To utilize the light nhich would otherwise escape above the lenses, Fresnel introduced a series of eight plain silvered mirrors on which the light was thrown by a system of lenses. At a subsequent period mirrors mere also placed in the lower part of the optic. The apparatus was mounted on rollers and revolved by clockwork. This optic embodied the first combination of dioptric and catoptric elements in one design (fig. 9). Fresnel also designed for the Chassiron lighthouse a dioptric lens with catoptric mirrors for giving a fixed light, which was the first of its kind installed (1827) in a lighthouse. This combination is geometrically perfect, but not practically so because of the great loss of light by metallic reflection; this is 25% greater than that resulting. from the use of glass elements. Shortly before his death in 1827 Fresnel devised his totally reflecting or catadioptric prisms (fig. 7) to take the place of the silvered reflectors previously used above and below the lens elements. In these the principle of internal reflection from the face of a glass prism is made use of as well as the principle of refraction. Thus a ray of light falling on the prismoidal ring is refracted as shown in the enlarged detail of the reflecting prism and then'is totally reflected. emerging after a second refraction in a horizontal direction. Fresnel devised these prisms for use in fixed-light apparatus, but the principle was applied to flashing lights by T. Stevenson in 1850. Both the dioptric lens and catadioptric prism invented by Fresnel were still in general use at mid-20th century. the mathematical calculations of the great French designer still forming the basis upon which lighthouse opticians work.

Fresnel also designed a form of fixed and flashing light in which a fixed light. varied by flashes, was produced by placing panels of straight refracting prisms in a vertical position an a revolving carriage outside the fixed-light apparatus. The revolution of the upright prisms periodically increased the power of the beam by condensation of the rays, emergent from the fixed apparatus, in the horizontal plane.

The lens segments in Fresnel's early apparatus were of polygonal form instead of cylindrical, but subsequently manufacturers succeeded in grinding glass in cylindrical rings of the form later generally used. The first apparatus of this description was made by the Cooksons of Newcastle in 1836 at the suggestion of Alan Stevenson, and erected at Inchkeith, Fifeshire. The first dioptric apparatus erected by the Trinity House to show a fixed light was the one formerly at Start point in Devonshire. It was constructed in 1836.

Azimuthal Condensing Prisms.—To condense the rays from a fixed-light apparatus in certain azimuths, T. Stevenson devised in 1850 his azimuthal condensing prisms which have been variously applied in the construction of optical apparatus as, for instance, for the strengthening of coloured sectors. Applications of this system are discussed below (sae fig. 10).

Dioptric Mirror.—An important improvement in lighthouse optical work was the invention of the dioptric mirror by (later Sir) James T. Chance in 1862. This mirror is a modification of a spherical mirror devised by T. Stevenson in 1850, in which double reflection from the internal surfaces of a catadioptric prism was employed. Chance generated the zones of prisms round the vertical axis, separated the elements and set them at increasing radii, thus producing an instrument of practical utility. By the use of the dioptric mirror, rays of light which would otherwise be lost are reflected back through the focus of the source of light and are refracted or reflected with the main rays. This form of mirror was still in general use in the late 1950s. It is constructed for vertical angles up to 100°.

Spherical Lens.—C. A. Stevenson devised in 1888 annular lens panels consisting of lens elements spherical in the horizontal and vertical planes. and these, with equiangular prisms. have been used in a number of apparatus for Scottish lighthouses.

Optical Glass for Lighthouses.— In the early days of lens lights the only glass used for the prisms was made in France at the

St. Gobain and Prémontré works, long celebrated for the high quality of their optical glass. The early dioptric lights erected in the United Kingdom, 13 in all, were made by the Cooksons. who were instructed by Léonor Fresnel, the brother of Augustin. At first they tried to mould the lens and then to grind it out of one thick sheet of glass. The manufacture of lenses was abandoned by

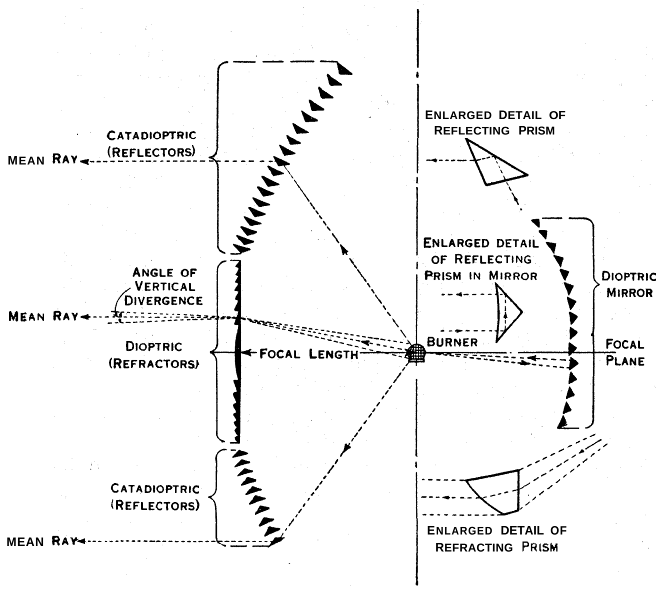

FIG. 7.— DIAGRAM SHOWING THE GLASS ELEMENTS COMMONLY USED IN LIGHTHOUSE OPTICAL APPARATUS. ELEMENTS ARE IN VERTICAL SECTION

Cooksons' successors in 1845 and in 1850 Chance Brothers and company of Birmingham began to make optical glass. assisted by Tabouret, a French expert who had been a colleague of Augustin Fresnel himself. The first light made by the firm was shown at the Great exhibition of 1851. After that time numerous dioptric apparatus were constructed by Chance Brothers, who remained the only manufacturers of lighthouse glass in the United Kingdom.

The glass generally employed for lighthouse optics has a mean refractive index of $\mu = 1.51$. the corresponding critical angle being 41° 30'. Chance Brothers used dense flint glass for the upper and lower refracting rings of high-angle lenses (up to 97° vertical angle) and for dioptric mirrors in certain cases. This glass has a value of $\mu = 1.62$ with critical angle 38° 5′. The use of refracting elements for an angle greater than 60° aperture is not attended by any advantage over reflecting prisms.

TYPES OF LIGHTS

Occulting Lights.—During the last quarter of the 19th century the disadvantages of fixed lights became more and more apparent and they fell into disuse except in the case of the less important harbour and river lights. The necessity of providing a distinctive characteristic led to the conversion of many of the fixed lights into occulting lights, or to their replacement by more modern and powerful flashing apparatus. The occultation of a light is produced either by a cylindrical screen lowered and raised around the burner; or by a revolving screen; or. when some form of gas burner or electric lamp is used. by intermittently extinguishing the light itself. Varying characteristics. comprising one or more occultations, may be procured by means of such contrivances. "Otter" screens are sometimes employed in cases where it is desired to produce different periods of occultation in two or more positions in azimuth, in order to differentiate sectors marking shoals. etc. The screens are of sheet metal blacked and arranged vertically, somewhat in the manner of the laths of a venetian blind, and operated by mechanical means.

Leading Lights.—In the case of lights designed to act as a lead through a narrow channel or as direction lights, it is undesirable to employ a revolving apparatus. Fixed-light optics are used in such cases, generally fitted with an eclipsing mechanism. A typical apparatus of this description is that at Woodman point, Fremantle, Western Australia (fig. 10). The occulting white light covers the fairway and is flanked by sectors of occulting red and green lights marking dangers and intensified by vertical condensing prisms. A good example of a holophotal direction light is that at Suzac lighthouse, Fr. The apparatus consists of an annular lens of 500-mm. focal distance. 180° horizontal angle and 157° vertical, with a reinforcing mirror of 180°. The lens throws a red beam, of about $4\frac{1}{2}°$ amplitude in azimuth and 50,000 candle power, over a narrow channel. The illuminant is an incandescent petroleum-vapour burner. Holophotal direction lenses of this type can only be applied where the sector to be marked is of comparatively small angle. Silvered metallic mirrors of parabolic section are also used for the purpose. The establishment of a direction light frequently renders the construction of separate towers for leading lights unnecessary. If two distinct lights are employed to indicate the line of navigation through a channel or between dangers they must be sufficiently far apart to afford a good lead, the front or seaward light being situated at a lower elevation than the rear or landward one.

Coloured Lights.—Colour is used as seldom as possible as a distinction. entailing as it does a considerable reduction in the power of the light. It is, however, necessary in some instances for differentiating sectors over dangers and for harbour lighting. Alternating colours for flashing lights are not to be commended on account of the unequal absorption of the coloured and bright rays by the atmosphere. Where such a combination has been employed, the red and white beams have been approximately equalized in initial intensity by constructing the lens and prism panels for the red light of larger angle than those for the white beams. As a result of absorption by the red colouring of the glass screen the poner of the red beam varies from 0.15 to 0 3 of the intensity of the white light depending on the colour temperature of the light source and whether 'the filter is flashed with selenium, gold or copper red. The corresponding intensity of green light varies from 0 12 to 0.20 depending upon the colour temperature of the source. When red or green sectors are employed in conjunction with a white light from a fixed apparatus. they should if it is practicable be reinforced by mirrors, azimuthal condensing prisms or other means to raise the coloured beam to approximately the same intensity as the white light. With the introduction of group-flashing characteristics the necessity for using colour as a means of distinction for landfall lights disappeared. In situations such as a river fairway where a large number of buoy or beacon lights have to be provided with distinguishing characteristics, coloured lights are, however, frequently employed.

Group-Flashing Lights.—One of the most useful distinctions consists in the grouping of two or more flashes separated by short intervals of darkness, the group being succeeded by a longer eclipse. Thus two, three or more flashes of, say, half-second duration or less follow each other at intervals of about two seconds and are succeeded by an eclipse of, say, ten seconds. In 1874 John Hopkinson introduced the improvement of arranging the lenses of a dioptric revolving light, together with their panels of reflecting prisms, asymmetrically, setting them at an angle to produce the group-flashing characteristic.

The first apparatus of this type constructed were those at Tampico, Mex. (triple flashing), and the Little Basses lighthouse, Ceylon (double flashing). A modification of the system consists in grouping two or more lenses together and filling the remaining angle in azimuth by a reinforcing mirror. A sectional plan of the quadruple-flashing first-order apparatus at Flamborough head, Yorkshire, is shown in fig. 11.

Hyperradial Apparatus.—In 1885 the Barbier company of Paris constructed the first hyperradial apparatus (1,330-mm. focal distance) to the design of D. and C. Stevenson. Apparatus of similar focal distance were subsequently established at a number of other lighthouses. That at Manora point. Karachi, India (later Pakistan) (1908), is illustrated in fig. 12. The introduction of incandescent oil burners and electric lamps of focal compactness and high intrinsic brightness rendered unnecessary the provision of optics of such large dimensions.

Fixed and Flashing Lights.—The use of these lights. which show a fixed beam varied at intervals by more powerful flashes, is undesirable, though a large number were constructed in the earlier years of dioptric illumination and some were still in existence in the late 1950s. In certain conditions of the atmosphere it is possible for the fixed light of low power to be entirely obscured while the flashes are visible. Thus the true characteristic of the light is vitiated.

Screens and Cuts.—Screens of coloured glass. intended to distinguish the light in particular azimuths, and of sheet iron! when it is desired to cut off the light sharply on any angle. should be fixed as far from the centre of the light as possible in order to reduce commingling, in the first case: and the escape. in the second case, of the light rays caused by divergence. These screens are usually attached to the lantern framing.

Divergence.—A dioptric apparatus designed to bend all incident rays of light from the light source in a horizontal direction would, if the flame could be a point, have the effect of projecting a band or zone of light (in the case of a fixed apparatus) and a cylinder of light rays (in the case of a flashing light) toward the horizon. Under such conditions the mariner in the near distance would receive no light as the rays would pass above the level of his eye and be visible only on the horizon. In practice this does not occur, sufficient natural divergence being produced ordinarily because of the magnitude of the source. When the electric arc or an incandescent electric lamp of small focal diameter is employed it is sometimes necessary to design the prisms so as to produce artificial divergence.

The approximate formula for finding the angle of divergence of the beam is $w=\frac{d}{f}$ radius, or $57\frac{d}{f}$ where w = angle of divergence, d = width of the light source in centimetres for horizontal divergence and height of light source in centimetres for vertical divergence and f = focal distance of the system in centimetres. In fixed dioptric lights there is, of course, no divergence in the horizontal plane. In revolving lights the horizontal divergence is a matter of considerable importance, determining as it does the duration of flash; *i.e.,* the length of time the flash is visible to the mariner.

Feux-Éclairs or Quick-Flashing Lights.—One of the most important developments in lighthouse illuminating apparatus was in the direction of reducing the length of flash, initiated by the French lighthouse authorities about 1891 and shortly afterward followed in other parts of the world. The early *feux-éclairs,* designed by the French engineers and others, usually had a flash of $\frac{1}{10}$- to $\frac{1}{3}$-sec. duration. As a result of experiments carried out in France in 1903–04, $\frac{3}{10}$ sec. was generally adopted as the minimum duration for white flashing lights. If shorter flashes are used the reduction in duration is attended by a corresponding, but not proportionate. diminution in effective intensity. In the case of many electric flashing lights the duration is of necessity reduced but the greater initial intensity of the flash permits this loss without serious detriment to efficiency. The apparent intensity of rhythmic light may be calculated by the Blondel-Rey formula given in clause 11 of British Standard 942, 1949. Red or green requires a considerably greater duration than do white flashes. The intervals between the flashes in single-flashing lights of this character are also small, usually $2\frac{1}{2}$ to j sec. In group-flashing lights the intervals between the flashes are about 2 sec. or even less, with periods of 7 to 1 j sec. between the groups, which may be arranged to show any number up to six flashes, as in the older forms of apparatus. The *feu-éclair* type of apparatus enables a higher intensity of beam to be obtained by reason of the greater ratio of condensation of light, the employment of panels of greater angular breadth than those formerly used being possible with a higher rotatory velocity.

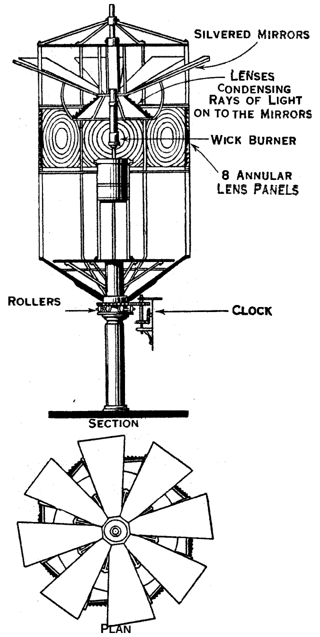

FIG. 9.—FRESNEL'S FIRST REVOLVING LIGHT, ERECTED IN 1823

This apparatus of 920-mm. focal distance, formerly at Cordouan lighthouse, Gironde river, was the first dioptric revolving light to be established

It has been urged that short flashes are insufficient for taking bearings, but the utility of a light in this respect does not seem to depend so much upon the actual length of the flash as upon its frequent recurrence at short intervals.

It was soon found impracticable to revolve an optical apparatus with its mountings, sometimes weighing as much as seven tons. at the higher rate of speed required for *feux-éclairs* by means of the old system of roller carriages, though for a certain number of small quick-revolving lights ball bearings have been successfully adopted. It therefore became almost the universal practice to carry the rotating portions of the apparatus upon a mercury float. This application of mercury rotation mas the invention of O. Bourdelles. The arrangement consists of an annular cast-iron trough containing mercury with a similar but slightly smaller annular float immersed in it and displacing a volume of the liquid metal whose weight is equal to that of the apparatus supported. In all cases provision is made for lowering the mercury bath or raising the float and apparatus for examination.

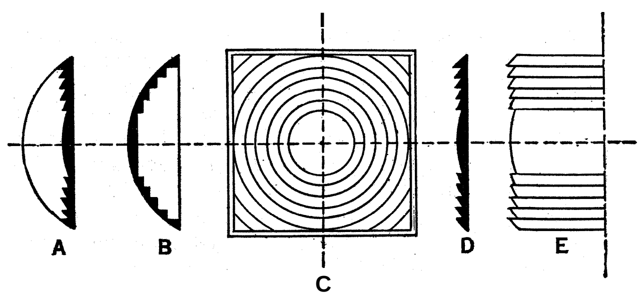

FIG. 8.— THEDEVELOPMENT OF FRESNEL'S LENSES

(A) Buffon's lens; (B) derivation of Fresnel's lens; (C), (D) elevation and section of Fresnel's annular lens; (D), (E) section and half elevation of Fresnel's lens belt

Multiform and Twin Apparatus.—In order to double the power to be obtained from a single apparatus at stations where lights of high intensity were desired, the expedient of superimposing one complete lens apparatus on another was sometimes adopted, as at Bishop rock (fig. 4), Hartland point, Devon, and at the Fastnet lighthouse in Ireland. Triform and quadriform apparatus have also been erected in Ireland. The adoption of the multiform system of lens apparatus involves the use of lanterns of increased height.

Another method of doubling the power of a light is by mounting two complete and distinct optics side by side on the same revolving table. This expedient has been frequently adopted by French designers and a modern example is the small third-order biform optic by Chance Brothers. installed at Longstone in the Farne Islands off Northumberland in 1952, giving an intensity of 2,200,000 candles.

Orders of Apparatus.—Augustin Fresnel divided his dioptric lenses into orders or sizes depending on their focal distance. This division is still used, although two additional orders known as hyperradial, which is rapidly becoming obsolete, and small third order have been introduced. The modern tendency is toward the adoption of optics of third order or less. which with modern electric lamps can give intensities of more than 1,000,000 candle power. The following list gives the focal distance of the several sizes:

Order	Focal distance, mm.
Hyperradial	1,330
First order	920
Second order	700
Third order	500
Small third order	375
Fourth order	250
Fifth order	187.5
Sixth order	150

Lenses of smaller focal distance are also made for buoy and beacon lights.

Light Intensities. — The figures given in the admiralty lists of lights for intensity multiplied by 1,000 give the candle power in candelas. The candela is the international unit of luminous intensity and is equivalent to the former British standard candle. The Hefner candle is equivalent to 0.9 candelas.

Formulas for calculating the intensities of lighthouse beams and beams from cognate projection apparatus will be found in British Standard 942, 1949. Deductions must be made in the case of coloured lights (see *Coloured* Lights, above).

The mathematical theory of optical apparatus for lighthouses and formulas for the calculations of profiles will be found in the works of the Stevensons, Chance, E. Allard, F. L. Reynaud, Hopkinson, C. Ribière and others.

ILLUMINANTS

The earliest form of illuminant used for lighthouses mas a fire of coal or wood set in a brazier or grate erected on top of the lighthouse tower. Until the end of the 18th and even into the 19th century this primitive illuminant continued to be almost the only one in use. The coal fire at the Isle of May light continued until 1810 and that at St. Bees lighthouse in Cumberland to 18.23. Fires are stated to have been used on the two towers of Nidingen in the Cattegat until 1846. Smeaton was the first to use any form of illuminant other than coal fires; he placed within the lantern of his Eddystone lighthouse a chandelier holding 24 tallow candles. each of which weighed $\frac{2}{5}$ lb. and emitted a light of 2.8 candle power. The aggregate illuminating power was 67.2 candles and the consumption was at the rate of 3.4 lb. per hour.

Oil. —Oil lamps with flat wicks were used in the Liverpool lighthouses as early as 1763. A. Argand, between 1780 and 1784, perfected his cylindrical-wick lamp which provides a central current of air through the burner, thus allowing the more perfect combustion of the gas issuing from the wick. The principle of the multiple-wick burner was devised by Count Rumford. Fresnel produced burners having two, three and four concentric wicks. Sperm oil was used in English lighthouses until 1846, but about that year the much cheaper colza oil was employed generally. Olive, lard and cocoanut oils have also been used for lighthouse purposes in various parts of the world.

Table III.—*Particulars of* **Oil** *Burners*

Mantle diameter, mm.	Service intensity, candelas	Intrinsic brightness per sq.cm. of projected area, candelas	Consumption of oil, pints per hour
35	675	53	0.75
50	1,200	52	1.1
75	2,200	50	2.2
100	3,200	48	3.3

The introduction of mineral oil, costing a mere fraction of the expensive animal and vegetable oils, revolutionized the illumination of lighthouses. It was not until 1868 that a burner was devised which successfully consumed hydrocarbon oils. This was a multiple-\lick burner. invented by Captain Doty, which was quickly taken into use by lighthouse authorities. The Doty burner, and other patterns involving the same principle, remained practically the only oil burners in lighthouse use until the last few years of the 19th century.

Coal Gas. —Coal gas was introduced in 1837 at the inner pier light of Troon, Ayrshire, and in 1847 it was in use at the Heugh lighthouse, West Hartlepool. In 1878 cannel-coal gas was adopted for the Galley head lighthouse, County Cork, Ire.. with 108-jet Wigham burners. Sir James N. Douglass introduced gas burners consisting of concentric rings, two to ten in number, perforated on the upper edges.

The invention of the Welsbach mantle placed at the disposal of the lighthouse authorities the means of producing a light of high

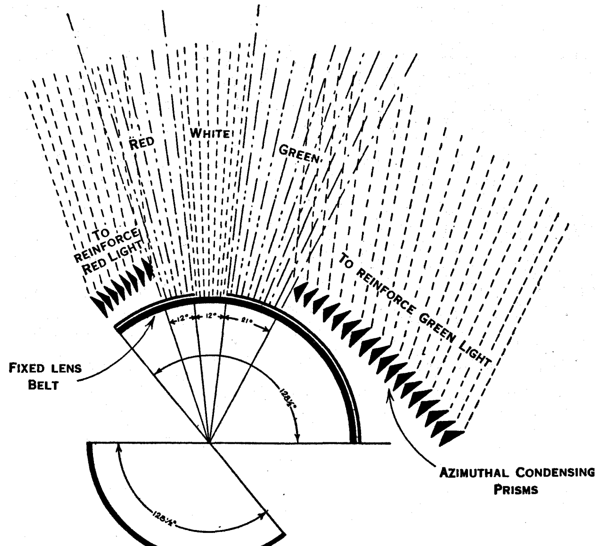

FIG. 10. — WOODMAN POINT DIRECTION LIGHT, FREMANTLE. WESTERN AUSTRALIA

The diagram is a plan of the optical apparatus at the level of the focal plane. The light is condensed and directed over the channel, the dangers at the sides of which are covered by the red and green lights

intensity combined with focal compactness. For lighthouse purposes gaseous illuminants other than coal gas are as a rule more convenient and economical and give better results with incandescent mantles. Mantles have, however, been used with ordinary coal gas in instances where a local supply of suitable types is available.

Incandescent Mineral-Oil Burners. — Incandescent lighting with high-flash mineral oil was first introduced by the French lighthouse service in 1898 at L'fle Penfret lighthouse. The incandescent burners in use in lighthouse services the world over are all made on the same principle, but differ in details. The principle consists in injecting the liquid petroleum under pressure into a vaporizer where it is heated by subsidiary jets and converted into vapour. This vapour issues from a nozzle and, drawing in air, passes into a chamber in the head of the burner where it mixes to form a combustible gas for the incandescence of the mantle; at the same time a small proportion of the gas is diverted to the subsidiary jets. A small reservoir of compressed air — charged by means of a hand-pump — is used for providing the necessary pressure for injection. On first ignition the vaporizer is heated by a spirit flame to the required temperature.

The candle power of apparatus in which ordinary multiple-wick burners were formerly employed is increased more than six times by the substitution of suitable incandescent-oil burners. In 1902 incandescent-oil burners were adopted by the general lighthouse authorities in the United Kingdom. The Hood burner used in the Trinity House service is illustrated in fig. 13. The mantles are of the soft autoform (or self-forming) type which took the place of the collodion mantles employed in the older forms of burner. Particulars relating to the burners in ordinary use are shown in Table III.

Oil **Gas.**—Pintsch's oil-gas system introduced in the 1870s is the prototype of the several methods of gas lighting employed for the majority of buoy and other unattended lights and before the end of the 19th century it was in general use in many countries. Incandescent oil-gas burners were introduced both for buoy and beacon lighting as well as for a few attended lights early in the 20th century. The use of ordinary oil gas necessitates its periodical supply by means of large transport containers in which it is stored at a pressure of from nine to ten atmospheres, a disadvantage which led to its gradual replacement by acetylene or other forms of oil gas (see below).

An oil gas, known by the name of its inventor. Blau, of Augsburg, was employed to some extent. particularly in Germany and the Netherlands, after about 1906 as a substitute for ordinary oil gas. It is produced in retorts in much the same manner as the older variety but at a lower temperature (550°–600° C.) and can be compressed to 100 atm., at which pressure the hydrocarbons are liquefied. This liquid gas is stored and transported in cylinders weighing about 130 lb. and is expanded from them at about nine atmospheres pressure into the body of the buoy or the receivers at the beacon or lighthouse. When it is used with an incandescent mantle of large size an intrinsic brightness of about 2; candle power per square centimetre or about 40% more than ordinary oil gas is obtainable.

Propane came into standard use in France for lighted buoys. It is burned in conjunction with an incandescent mantle and this system is used to some extent in Great Britain.

Acetylene. — Acetylene (*q.v.*) was first experimented with for buoy and beacon lighting about 1896, open-flame burners being used. An incandescent-mantle burner consuming acetylene mas used at the Chassiron lighthouse, Fr., in 1902. Oil gas, enriched by the addition of 20% of acetylene, was for a time used in Germany and the Netherlands for buoy and beacon lighting. It was not, however, until about 1906, when the difficulties associated with its employment had been overcome by the introduction of dissolved acetylene! that the gas came into general use for coast lighting. Acetylene in this form is stored at a pressure of 10 to 15 atm. in cylinders, usually weighing about two hundredweights, filled with a porous material and charged with acetone in the presence of which the gas is dissolved. Because of the higher intrinsic

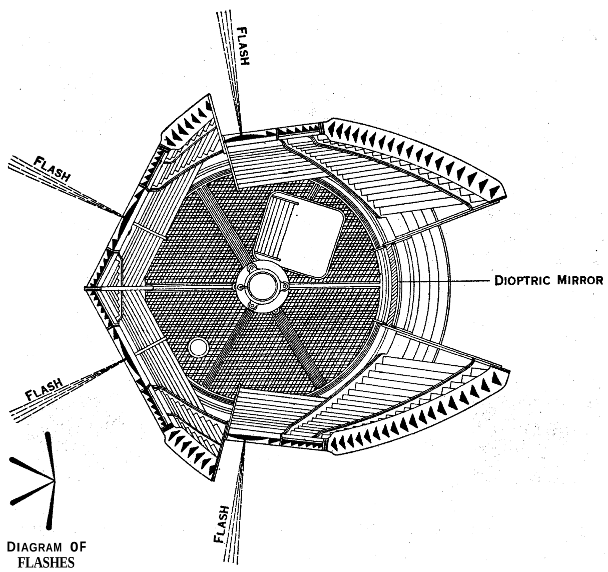

FIG. 11.—FLAMBOROUGH LIGHTHOUSE, YORKSHIRE

Sectional plan of the first-order optical apparatus at focal plane. The light shows four flashes every 15 sec.

brightness of the flame and the convenient transport of the gas it came into common use throughout the world not only for buoy and beacon lighting but also for many coast lights of secondary importance and unattended revolving lights. mantle burners being sometimes employed.

Acetylene generated on the spot on the carbide-to-water principle nevertheless continued to be used by some lighthouse authorities for unattended lights. Comparatively frequent attention in renewing the charge is, however, required in these cases. The intrinsic brightness obtained in some incandescent-acetylene burners is about equal to that of autoform-mantle petroleum-vapour burners.

Electricity. — Electricity for lighthouse illumination mas first experimented with in England in 1858 at South Foreland. Kent, by Trinity House. This mas followed by its adoption at Dungeness, Kent, in 1862 and at Souter point on the coast of Durham in 1871. Both these installations were later abandoned, the former in 1874 and the latter in 1923 when a first-order biform flashing light with incandescent-oil burner replaced it. Electricity was installed at St. Catherine's point in the Isle of Wight in 1888 and was also in use at the Isle of May lighthouse at the mouth of the Firth of Forth from 1886 to 1924. Arc lamps formerly provided the illuminant in all large apparatus, but the development of high-power, gas-filled electric-filament lamps caused their replacement for lighthouse use. British Standard 1546, 1949, Lighthouse Lamps (Electric), lists and gives complete specifications for lamps rated from 100 v. 100 w. to 100 v. 4,500 w. giving an average brightness of from 100 to 1,100 stilbs.

Economies have been effected by the introduction of these lamps combined with automatic electric equipment, and where in addition a local supply of current is available the reduction of maintenance charges at electric stations is considerable. For instance at South Foreland. which became a permanent electric station in 1872, an engineer and four keepers were formerly required to maintain the establishment, which included a steam electric-generating plant. With the introduction of the filament lamp and automatic equipment in 1926 the establishment was reduced to one keeper. High-tension cables were brought from Dover to the lighthouse. The clock machine revolving the lens is wound electrically, and a lamp changer automatically replaces a lamp when the filament of the one in service burns out or brings a stand-by acetylene burner into focus if the electric supply fails. A telltale device in the keeper's quarters warns him if any derangement takes place. The filament lamp is 8,000 candle power, 80 v. and 50 amp., and has a mean intrinsic brightness of 1,000 candles/cm^2. A somewhat similar installation was substituted for the arc lamp at the Lizard (1926), but in this case the current was generated at the lighthouse, the personnel being reduced from five to three. In 1951 this station was converted to mains operation. At 16 other important coast lighthouses, including St. Catherine's (6,000,000 candle power) and Lizard (3,000,000), mains electricity was brought in and electric light introduced in place of the petroleum-vapour burners. The apparatus in the lantern was made automatic.

At a further seven rock stations electric generators were installed and the lights changed over to electric with greatly increased candle power.

All modern Trinity House light vessels employ high-power electric lamps in the multicatoptric optical apparatus.

Electricity was used at the old south lighthouse at La Heve, Fr., in 1863, and after 1897 there were 13 major electric lights on the French coast. Arc lamps were employed and a generating plant, usually steam driven, was provided at each station. The high cost of maintaining such stations prevented any extension of their use on a large scale in France as in other countries; but after 1920 the conversion of some of the then existing electric stations to incandescent-filament lighting was effected. In all places where power could be taken from the public mains the lights were electrified. Gas is sometimes employed for the stand-by burners in French electric lighthouses.

Similar conversions to mains electricity took place in the Netherlands and other countries.

MISCELLANEOUS LIGHTHOUSE EQUIPMENT

Modern lighthouse lanterns usually consist of a cast-iron or steel pedestal. cylindrical in plan, on nhich is erected the lantern glazing. surmounted by a domed or conical roof and ventilator (fig. 12). Adequate ventilation is of great importance, and is provided by ventilators in the pedestal and a large ventilating dome or cowl in the roof. The astragals carrying the glazing are of wrought steel or gun metal. They are frequently arranged helically or diagonally, thus causing a minimum of obstruction to the light rays in any vertical section and affording greater rigidity to the structure. The glazing is usually $\frac{1}{4}$-in.-thick plate glass curved to the radius of the lantern. In situations of great exposure the thickness is increased. Lantern roofs are of sheet steel or copper secured to steel, gun-metal or cast-iron rafter frames. At certain lighthouses it is found necessary to erect a grille or network outside the lantern to prevent the numerous sea birds attracted by the light from breaking the glazing by impact. Lanterns vary in diameter from 5 to 16 ft. or more, according to the size of the optical apparatus. For first-order apparatus a diameter of 14 ft. is usual and 12 ft. for second-order. The lantern. gallery handrails and principal metallic structures in a lighthouse should be connected to a copper lightning conductor carried to a point below low water or terminating in an earth plate embedded in wet ground.

Revolving-light apparatus are rotated by clockwork mechanism actuated by weights or spring driven. The clocks are fitted with speed governors and also warning apparatus to indicate when rewinding is required. Where current is available small electric motors are often employed either for automatic rewinding of the clockwork or for driving the rotating mechanism direct. In modern gaslit apparatus the pressure of the gas is sometimes made use of to revolve the lens table.

At rock and other isolated stations, accommodation for the keepers is usually contained in the towers. In the case of land lighthouses, dwellings are provided in close proximity to the tower. The watch room should be situated immediately under the lantern floor. Oil is generally stored in lead-lined concrete or steel tanks.

UNWATCHED AND UNATTENDED LIGHTS

Electric. — Since 1884, when an iron beacon lighted by an incandescent electric lamp supplied with current from a secondary battery was erected on a tidal rock near Cadiz, Sp., various forms of electric unattended lights have been experimented with. By the end of the 1920s many such lights were in permanent use where current could be obtained from a local supply circuit.

Storage batteries, small automatic generating sets and stand-by gas burners are alternatively provided to guard against the failure of the main supply. Automatic devices are also fitted for changing one lamp for another if the lamp in focus should fail. and for switching in the stand-by apparatus when necessary. Both revolving and fixed optics are used. In the former case the optic is rotated by a small electric motor and in the latter some form of automatic interrupter produces the flashing characteristic. In cases where the optic is too small for a lamp changer to be accommodated, two lenses are employed. one superimposed on the other. In one of the lenses is focused the electric lamp in normal use and in the other the stand-by gas or electric lamp. An example of secondary lights, formerly attended and now converted to electric, is at Burnham in Somerset where two leading lights more than a quarter of a mile apart were so altered in 1928 and are unwatched at night. In this case the optics are of fixed section, and the automatic features include a flashing device for giving the lights their respective characteristics. Major conversions to unwatched electric lights are Southwold, Suffolk (1938, 243,000 candles), and Happisburgh. Norfolk (1948. 15,000 candles).

Other Forms of Beacon Lighting. — Among other systems of unattended beacon lighting; adopted in lighthouse services after about 1880, but now little used, may be mentioned the Lindberg light, a Swedish invention employing a volatile spirit; the Benson-Lee lamp having a carbon-tipped wick; the French permanent-wick la'mp; and the Wigham lamp in which a flat wick immersed in petroleum travelled over a horizontal roller so that the petroleum was volatilized from a constantly renewed surface.

Acetylene Lights. — The gas is provided either by an automatic generator or else in the form of compressed acetylene dissolved in acetone. In order to reduce the consumption and at the same time give a distinctive characteristic to the light, the gas is usually passed through an automatic flashing mechanism which works continuously until the supply is exhausted. Waste of gas during daylight is sometimes obviated by using a sun valve, which is a device to turn off the gas at daybreak and turn it on at dusk. Sun valves depend for their automatic action on the differential expansion of two distinct metals under the influence of light rays or on the difference in the absorption of light rays by black and bright bodies respectively. The movement of a lever arm, brought about by a small movement of the light-sensitive element, actuates a valve which opens and closes the gas supply.

Acetylene in unattended lights is burned either as an open flame or in conjunction with a mantle.

The Aga system of acetylene lighting, developed in Sweden about 1904, has been extensively used both in that and other countries for all classes of unattended lights, including buoys. It was first adopted in England in 1913, together with the Dalen incandescent-mantle burner. This embodies a mix flasher which automatically

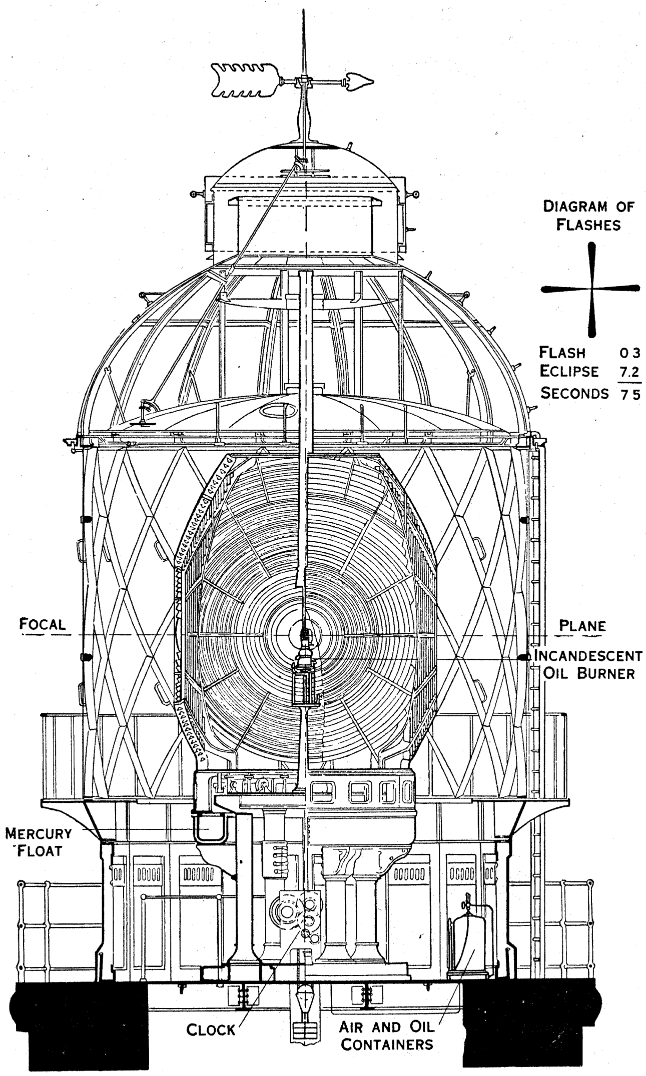

FIG. 12—MANORA POINT (KARACHI) APPARATUS AND LANTERN

The apparatus is of 1,330-mm. focal distance; it is rotated on a mercury float and has an incandescent oil burner at its focus. The right-hand half is shown in elevation and the left-hand as a vertical section

controls the character of the light and regulates the mixing of air and gas for consumption in an inverted soft-mantle burner.

In some unattended lights with acetylene illumination the lenses are rotated by a gas pump as the gas passes to the mixer and burner, the lens table moving on ball bearings or a mercury float. The sun valve automatically controls the duration of lighting; a pilot jet serves to reignite the main burner at sunset; and an automatic changer provides for the replacement of a broken mantle. Incandescent-mantle burners and acetylene equipment have also been installed in a number of lighthouses of secondary importance, formerly attended by keepers and now converted to unwatched or semiwatched lights. Among such in England are the lights at the Rock, Liverpool; Great Ormes head and

St. Tudwall's, Caernarvonshire; Berry head, south Devon; Peninnis head, Scilly Isles; East Usk, Monmouthshire; and Great Castle head, Pembrokeshire. The Menai lighthouse, Anglesey, was fitted with open-flame acetylene equipment. In some cases, where the consumption of gas is large, acetylene generators on the carbide-to-water system have been installed, as at the Farne Island and Bamburgh lights on the coast of Northumberland, and the two first-order leading lights at Hurst, on the mainland opposite the Isle oi Wight.

Acetylene in the dissolved form was, in the late 1950s, the best and most economical illuminant ior entirely unwatched lights when electric current was not available. Its use enabled many unattended lights to be established and maintained at a comparatively small cost in positions where a light attended by keepers would be impracticable as, ior example, on some parts oi the Australian coast.

LIGHT VESSELS

The earliest light vessel established in English waters was that placed at the Nore in the Thames estuary in 1732. The early lightships were small and carried lanterns of primitive construction suspended from the yardarms. Modern light vessels are usually of steel construction and are of various dimensions. The following may be tahen as the limits in the Trinity House service:

Length	112 to 137 ft.
Beam	24 to 25 it.
Depth moulded	15 ft.
Full load displacement	190 to 560 tons

The larger vessels are employed at outside' and exposed stations, the smaller ships being stationed in sheltered positions and in estuaries. The moorings usually consist of three-ton mushroom anchors and 13-in. or 19-in. stud-link cables. The lanterns used in some of the older vessels are eight feet in diameter surrounding the mast upon which they are hoisted at night and lowered to the deck level during the day. Fixed lanterns mounted on a steel lattice structure or tubular mast later displaced the older type. The first English light vessel with fixed lantern was constructed in 1904.

Self-propelled light vessels, some of which are of much larger dimensions than any British light vessel, are employed at the majority of stations in the United States, and there are a few in exposed situations in other countries including France, Sweden, the Netherlands and Germany.

Until about 1895 the illuminating apparatus used in light vessels was almost exclusively oi catoptric form, consisting for the most part of 21-in. silvered paraboloidal reflectors, having mineral-oil burners in focus, hung in gimbals to preserve the horizontal direction of the beam. In a few cases incandescent-mantle burners or electric-filament lamps were substituted for the wick burners in old catoptric apparatus. Dioptric apparatus is provided in some lightships, not only in Britain but in other countries also. The French lighthouse service in 1896 devised the first dioptric revolving light ior a light vessel. This ship, the "Talais,"[1] was lit by an incandescent oil-gas burner. A much larger vessel, the "Sandettié," of 342 tons displacement, was completed in 1902. The new type of floating light mas afterward adopted by other lighthouse authorities, and many vessels constructed on the lines of the "Sandettié" were built during the first decade of the 20th century. In England the first of this class was brought into service in 1905. Some of these vessels were fitted with revolving dioptric lenses suspended in gimbals below the lens table and counterbalanced by a heavy pendulum weight. The apparatus was mounted on ball bearings in some cases and on a mercury float in others, the lenses being revolved by clockwork or gas. Another method of suspending the dioptric apparatus mas developed, the design being a Swedish invention. This device, known as the constant-level table, was fitted in four vessels in the Trinity House service in 1928. In these vessels the illuminant, formerly acetylene employed with a mantle, was changed to electricity. The lens is mounted on a table made to revolve on ball bearings by the gas on its way to the burner. The lens table is balanced, near the centre of gravity, on a pivot in the lantern, and connected by three vertical pull wires to a pivoted counterbalance weight, placed in the hull of the ship at the rolling centre of the vessel, which controls the movement of the upper table. As the motion imparted to the lower balance weight is small, the swinging of the lens table is less than with the former arrangement of pendulum and gimbal suspension. In 1936 Trinity House evolved the multicatoptric pendulum apparatus comprising eight silvered mirrors of 18 in. diameter, illuminated by high-power electric projector type lamps, the optic apparatus heing rotated by electric motor and mounted in gimbals, the pendulum maintaining the light horizontal. This apparatus with subsequent improvements became standard equipment on all new Trinity House vessels. The arrangement oi the mirrors is such that they can readily be regrouped so as to exhibit a range of different characters. By this means modern light vessels can be placed for duty at many different stations according to the needs of the service, and a minimum of spare vessels is required: One such multicatoptric pendulum apparatus was installed in the Ambrose light vessel for the United States coast guard. In the older vessels illumination by oil-gas, incandescent-acetylene or incandescent-oil burners was formerly employed but these were largely replaced by high-powered gas-filled electric lamps.

[1]The "Talais" and another similar vessel constructed in 1899 were later converted into unattended light vessels.

An experimental electric-light installation on board a Mersey light vessel in 1886 proved unsuccessful.

Fog signals, where provided on modern light vessels, are generally in the form of sirens or diaphones worked by compressed air. The compressors were driven by steam or oil engines in the older installations but modern vessels have high-speed diesel engines.

Unattended Light Vessels.—In 1881 an unattended light vessel illuminated by Pintsch's oil gas was constructed for the Clyde. The light was occulting and the vessel carried a gasholder containing a supply of gas under a pressure of six atmospheres sufficient to maintain the light for three months. Bells are often fitted on this class oi light vessel. the clappers being swung by the roll of the ship or worked by a gas-operated machine.

The improvements made in the design and construction of unwatched lights made it possible for some attended lightships in positions of secondary importance to be replaced by unwatched vessels.

Communication Between Light Vessels and the Shore.—As far back as 1886 experiments were instituted at the Sunk light vessel, off the coast of Essex, with the object of providing telephonic communication mith the shore by means of a submarine cable. In spite of great difficulties experienced in maintaining the cables, several light vessels were ultimately equipped with this means of communication, and cables were also laid to many pile lighthouses and isolated rock and island stations.

Wireless telephone installations later superseded all the cable communications with light vessels and rock stations.

LIGHTED BUOYS

Pintsch's oil gas was first used for a light carried on a buoy in 1878. An automatic occulter, worked by the gas passing from the reservoir to the burner, was introduced in 1883. The majority of buoy lights lit by oil gas are fitted with multiple-jet or Argand burners, but incandescent mantles are also employed. Ordinary oil gas has been largely superseded by other forms of gas illumination (*see* above). Gas buoy lights are usually provided mith sufficient storage capacity to run the light unattended ior three months or longer. The lanterns used ior all forms of buoy lighting are self-contained with cylindrical dioptric lenses of fixed-light section usually 150 to 37j mm. diameter. Some oi the largest types of gas buoy in use have an elevation from water level to the focal plane of more than 26 ft. and a beam intensity of more than 1,000 candle power. One buoy, placed at the entrance to the Gironde in 1907, has an elevation to the focal plane oi 34 ft.

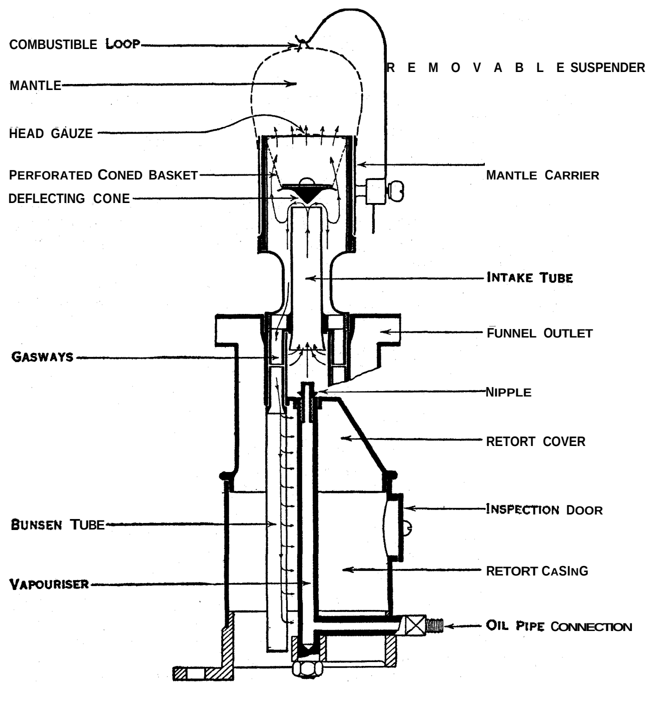

FIG. 13.— HOODPETROLEUM-VAPOUR BURNER

Spar buoys may be adopted for locations mith strong tides or currents.

Gas Buoys.—Although experimental work mas done as early as 1896, acetylene gas was first regularly used for buoy lighting early in the 20th century when automatic water-to-carbide generators were employed in Canada for producing the gas, the generators being placed in the buoy body. This system never gave entirely satisfactory results and its use was attended by danger oi explosion. It was superseded almost everywhere by the dissolved acetylene system first applied to buoy lighting in Sweden. The normal acetylene buoy equipment maintains the light without recharging up to 12 months (fig. 1;) and is adopted as standard in the Trinity House service. Propane filled direct into the buoy body is used in France in coniunction with an incandescent mantle.

Electric Buoys.—Buoys have been fitted with electric lights both fixed and occulting. Six spar buoys were laid down in the Gedney channel, Lower New York bay, in 1888. The wear and tear of the cables, by which current was supplied from a shore station, caused considerable trouble and expense, and the lights were replaced by gas-lighted apparatus in 1904. Electric buoys were also used extensively in Germany early in the 20th century. With the advent of reliable long-service batteries electricity became widely used by some authorities, the lanterns being equipped with automatic lamp changers in case of lamp failure.

Bell and Whistling Buoys.—Bells or whistles are frequently fitted to gas buoys as well as to unlighted marking buoys. An acetylene-lighted whistle buoy is illustrated in fig. 1;. Bells may be wave actuated in which case little or no warning may be given under dead calm conditions. A definite character may be obtained by the use of a CO_2-operated bell-striking mechanism.

(N. G. G.; J. P. Bo.; P. W. H.)

AERIAL LIGHTS

The light beacons provided to aid aircraft crews at night fall into two categories: aeronautical beacons, a term which embraces so-called aerodrome beacons and identification beacons; and hazard beacons. In some countries special light beacons are provided to assist aircraft to follow certain routes but this function has now largely been replaced by radio navigational aids and the use of lights for this purpose in the United Kingdom has been discontinued.

Aerodrome beacons show either as a continuous succession of white flashes of equal duration or white flashes alternating with coloured flashes of equal duration, the intensity of flash being such as to render them visible in clear weather at night up to ranges of 30 nautical miles. Beacons of this type are always sited near aerodromes, the coloured flash heing green when they are located near a land aerodrome and yellow when they are positioned near a water aerodrome.

Identification beacons emit a relatively low-powered coloured light which shows as a sequence of flashes conforming to two letters of the international Morse code Beacons of this type are almost invariably sited on aerodromes, a different letter combination being allotted to each aerodrome. When the light serves a land aerodrome the colour of the flash is normally green but may be red; when it is located at a water aerodrome the colour of the flash is yellow

Hazard beacons are used for marking objects which by virtue of their height and location constitute a possible serious danger to aircraft in flight. The beacon shows a succession of red flashes and is employed in situations where it is necessary to mark an object more conspicuously than would be achieved by the normal method of affixing to it a number of steady red lights.

One form of beacon, which is in general use both as an aerodrome beacon and as a hazard beacon, comprises an optical system consisting of a 100-v $2\frac{1}{4}$-kw. projector lamp in conjunction with four 20-in diameter prismatic lenses. An automatic lamp changer is incorporated, which in the event of failure of the main lamp immediately brings a stand-by lamp into position and automatically switches it into use The lantern housing the optical system and the lamp-changing mechanism is rotated at three revolutions per minute by a $\frac{1}{2}$-h p. repulsion start induction motor and thus gives 12 flashes of light per minute.

Another type of beacon widely used as an aerodrome beacon comprises an outer optic consisting of a condenser lens system of 375-mm. focal distance made up of two vertical panels with their axes arranged at 180° and an inner optic consisting of a dioptric drum lens system of 187.5-mm. focal distance. The light source which is at the common focal point of the inner and outer optical system consists of a a-kw. 60-v. gas-filled incandescent lamp which is replaced automatically in the event of failure. The vertical distribution of beam intensity is shown in fig. 16.

Identification beacons differ irom the types described above in that, being required to be seen at short ranges only, they do not incorporate any optical system. The type in most general use comprises a number of 30-mm. diameter, cold cathode mercury arc discharge lighting tubes mounted in the form of a truncated cone on a fabricated-steel structure. The tubes are energized from a three-phase supply at high voltage derived irom a series of step-up transformers. The coded flash is obtained by means of a motor-driven character disk operating a heavy-duty three-phase contactor connected to the low-tension side of the mains transformer. Such a beacon is normally rated at about three kilowatts, though at London airport, for example, the beacon used is rated at seven kilowatts. (X.)

FOG SIGNALS

The introduction of coast fog signals is of comparatively recent date. They were, until the middle of the 19th century, practically unknown except so far as a few isolated bells and guns were concerned. In times of fog the mariner can expect no certain assistance from even the most efficient system of coast lighting, since beams of light of high power are frequently entirely dispersed and absorbed by the particles of moisture forming a sea fog of even moderate density at relatively short distances from the shore. The careful experiments and scientific research which have been devoted to the subject of aerial-acoustic fog signalling have produced much that is useful and valuable to the mariner, but unfortunately the practical results which had been obtained at mid-20th century were not as satisfactory as might be desired because of: (1) the very short range of the most powerful signals yet produced under certain unfavourable acoustic conditions of the atmosphere; (2) the difficulty experienced by the mariner in judging at any time how far the atmospheric conditions are against him in listening for the expected signal; and (3) the difficulty in locating the position of a sound signal by phonic observations. The future of marine fog signalling may lie in the direction of radar and radio beacons, but it is unlikely that acoustic signals will be dispensed with even if reduced in number.

Bells and Gongs are the oldest and, generally speaking, the least efficient forms of fog signals. Under very iavourable acoustic conditions the sounds are audible at considerable ranges. On the other hand, two-ton bells have been inaudible at distances of a few hundred yards. Bells are frequently used for beacon and buoy signals. When employed in conjunction with a lighted beacon they are sometimes rung mechanically either by clockwork or by compressed CO_2 gas. Electric striking mechanism has also been employed where current is available.

Explosive Signals.—Guns were long used at many lighthouse and light-vessel stations in Great Britain, and continued to be used at some stations in other countries. In 1878 sound rockets charged with guncotton were first employed at Flamborough head and were afterwards supplied to many other stations.[1] The nitrated guncotton or tonite signals in general use at rock and other lighthouses where accommodation is limited are hung at the end of an iron jib or pole attached to the lantern or other structure, and fired by means of a detonator and electric battery. An example will be noticed in the illustration of the Bishop rock lighthouse, the jib being attached to the lantern (fig 4). Sometimes the explosive is combined with aluminum in the charge to give a brilliant flash in addition to the detonation.

The acetylene fog gun is an automatic or semiautomatic signal in which a mixture of air and acetylene is exploded at short intervals in a gun chamber. It is economical in working cost and occupies little space, but its power cannot be compared with that of a compressed-air siren. The admission of air and acetylene is controlled by an automatic gas valve and the charge is fired by a spark. Signals can be sounded as frequently as every ten seconds.

An acetylene gun was established at the Dubh Artach rock lighthouse in 1912. The gun continues in action without attention from the time when it is started until it is stopped by the keeper. The gas is generated automatically on the carbide-to-water principle.

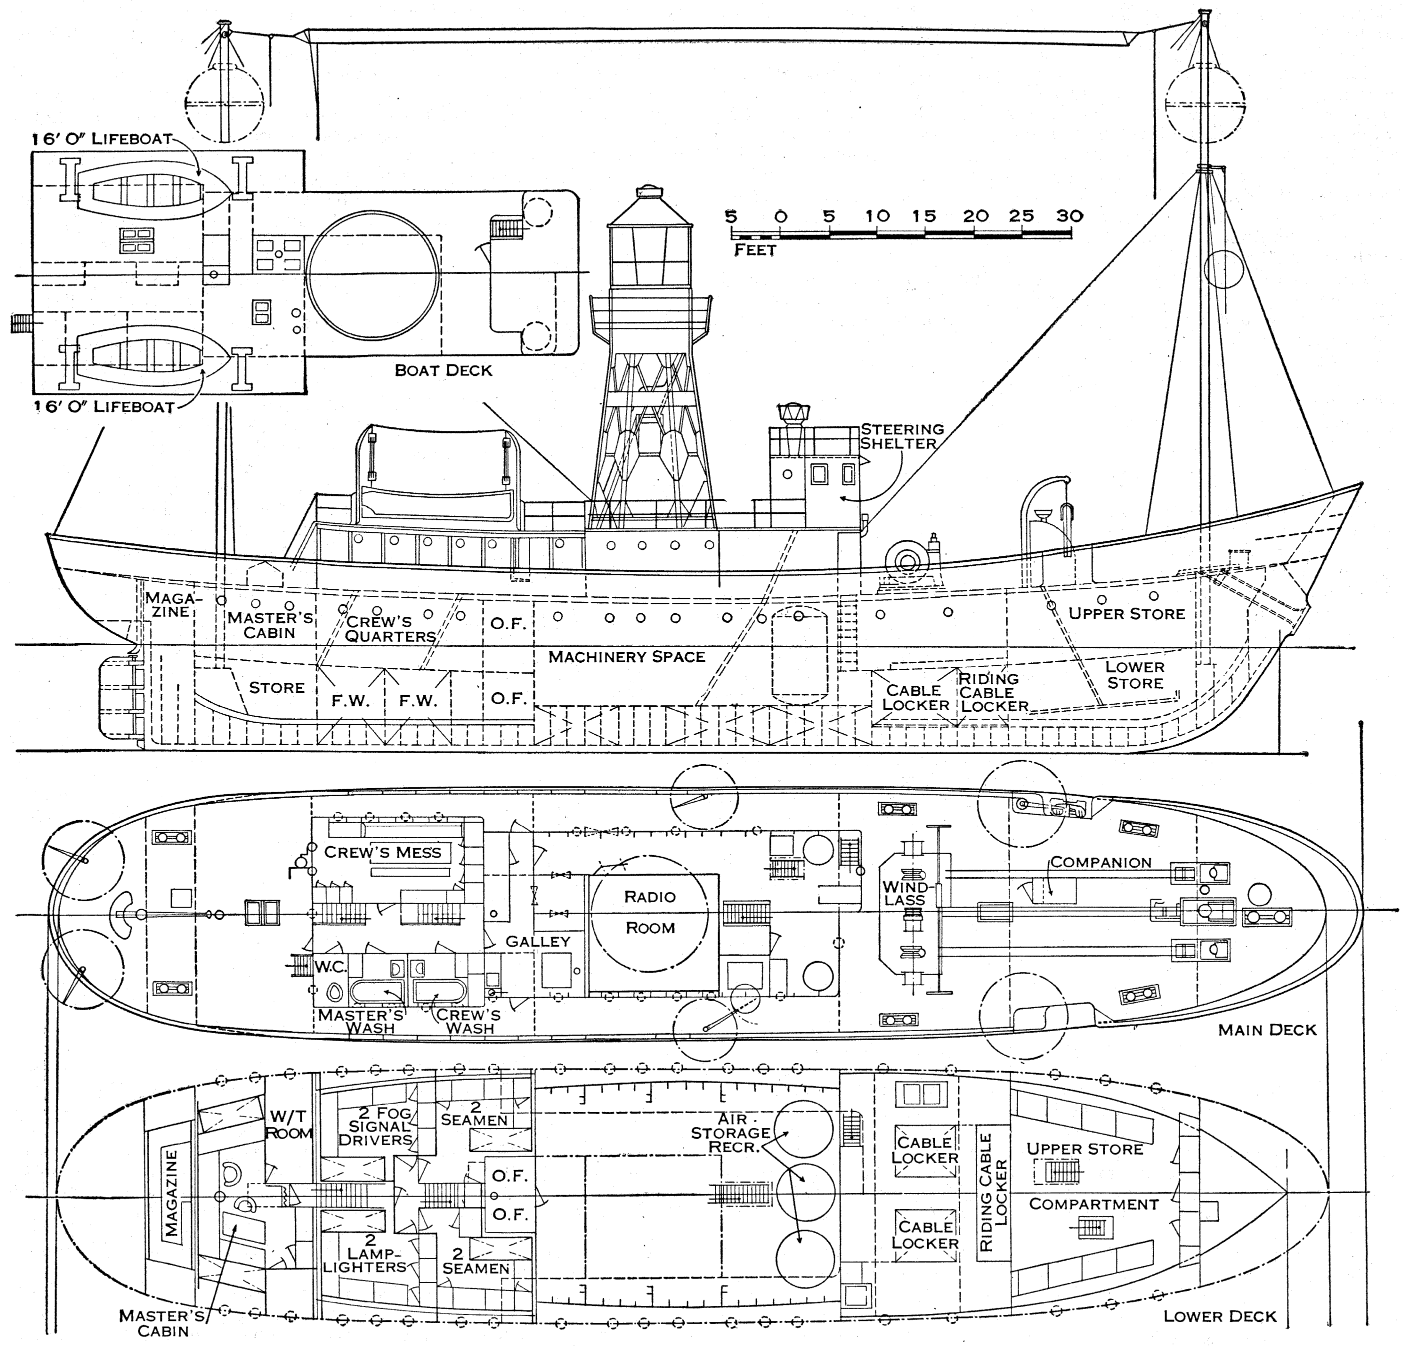
On the Clyde there are two isolated beacon structures which are equipped with automatic guns started and stopped by wireless control from Gourock pier. Several other stations in Scotland and elsewhere are provided with these guns.

Whistles and Reed Horns.—Whistles, whether sounded by air or steam, are not used in Great Britain although they have beer, employed as fog signals in the United States, Canada and Sweden. It has been objected that their sound bears too great a resemblance to steamers' whistles; and they are wasteful of power.

Reed horns, in their original form, where the invention of C. L. Daboll, an experimental one of his manufacture being tried in 1851 by the United States lighthouse board. The reed horn was adopted by Trinity House in 1862 after being improved by W. Holmes and many examples from his designs remained in use at secondary stations in Britain and America. Normally they are sounded at a pressure of 15 lb. per square inch with air furnished by power-driven compressors, semidiesel engines being commonly used in modern installations. When operated by hand the working pressure is five pounds per square inch.

Sirens and **Diaphones.**—These are considered to be the most efficient aerial sound signals which can be obtained for lighthouse purposes. One or other of them is usually employed when first-class signals are required and space is available for the accommodation of the necessary plant. Both are compressed-air instruments, but differ somewhat in operation. The diaphone, in its modern form the more powerful instrument, was invented in Canada by J. P Northey about 1903, and consists of a piston reciprocating in a cylinder, around both of which are cut circumferential slots or ports. The piston is fitted with an operating head to which air is admitted, first on one side and then on the other, for giving to it the reciprocating motion. As the slots in the two units pass and repass one another, air is being admitted through them to produce the impulses or sound waves, and upon the number of times these ports open and close each second depends the note. In the case of the siren the piston revolves in the cylinder instead of having a reciprocating motion, but otherwise the principle of air admission is the same in both instruments. Each is fitted with a trumpet horn or resonator and the working air pressure is 3j lb per square inch for the diaphone and 25 lb. per square inch

[1]The Flamborough head rocket was superseded by a siren fog signal in 1908.



COURTESY, TRINITY HOUSE, LONDON

FIG. 14.— GENERAL PLAN OF BRITISH LIGHTSHIPS

for the siren. The diaphone note is usually about 180 vibrations per second or F sharp in the tenor clef; it terminates with a quick descending note termed the grunt at the end of each blast. This grunt is a valuable distinctive feature as it can sometimes be heard when the remainder of the signal is inaudible.

To provide the air for these instruments compressing machinery and large capacity air storage receivers are required. In some Trinity House installations two instruments with their axes approximately 120° apart horizontally are fitted for distributing the sound over a wide arc. In the diaphone installations at Flamborough, Hartland point, Devon, and Sherries, off Anglesey, the mouths of the two trumpets are placed on a common vertical axis with their centres half a wave length apart, to give effect to the theory propounded by the 3rd Lord Rayleigh that vertical dispersion of sound was by this means avoided. A similar arrangement was introduced at some French stations. Experimental work was being carried out in the 1950s on horns of exponential and hyperbolic form designed to give directional qualities to the signal. Fog signals equipped n-ith exponential horns hare been set up in France and in Great Britain.

The siren in a primitive iorm was invented by John Robison (1739–1805). Cagniard de la Tour evolved the disk iorm and gave it the name of siren. The first steam siren was patented by Brown of New York. The cylindrical form and the centrifugal governor commonly used are credited to G. H. Slight.

Nautophones.—The nautophone is a form of aerial-acoustic instrument which consists of an electrically vibrated diaphragm sounding a high note. An electric emitter of this type was installed at St. Anthony's point, Cornwall, in 1954. This instrument comprises two diaphragm units each with two horns set at an angle of 90°, mounted vertically one above the other; a note of 300 cycles per second is emitted. Such instruments are widely used in Scandinavian countries and elsewhere.

Multihorn electric fog signals were being experimented n-ith in Great Britain in the 1950s. They have been installed in the United States and elsewhere.

Submarine Bell and Oscillator Signals.—As early as 1841 J. D. Colladon conducted experiments on Lake Geneva to test the suitability of water as a medium for transmission of sound signals and was able to convey distinctly audible sounds through water for a distance of more than 21 mi. It was not until 1904, however, that any successful practical application of this means of signalling was made. Submerged bells were used principally in connection with light vessels and were struck by clappers actuated by pneumatic or electrical mechanism. They mere also fitted to buoys and beacon structures and placed on the sea bed. In the first case the bell was actuated by the motion of the buoy and in the others by electric current, transmitted by cable from the shore.

The oscillator or electromagnetic submarine fog signal mas actuated electrically from the lightship to which it mas attached or irom the light station with which it was connected. The instrument, which came into use during World War I, comprised a vibrating diaphragm of large dimensions, and its principle of operation mas similar to that of a telephone. It sent out a high note to which could be given a characteristic code notation. The instrument was fitted in several light vessels in European and American waters. The underwater range of the oscillator has been known to exceed 50 mi. as compared with 10 mi. for the bell.

To take full advantage of the signals thus provided it was necessary for ships approaching them to be fitted with special receiving microphones installed below the water line and in contact with the hull plating. The signals were audible by the aid of earpieces similar to ordinary telephone receivers. Not only could they be heard at considerable distances and in all conditions of weather, but their direction in reference to the moving ship could be determined approximately. These signals became obsolete and were superseded by radio aids. (N.G.G.; J. P. Bo.; P. W. H.)

RADIO AIDS TO NAVIGATION

Radio Beacons.—Beiore World War II the most widely used marine navigational aid was the shore-based medium-frequency radio beacon, in the range 200-400 kc. per second. Reception of signals irom two or more oi these beacons by the use of direction-finding aerials fitted in a vessel enable the vessel's position to be found relative to the charted sites of the transmitters. Although the determination of position is not rapid, and errors map occur at night or at low ranges as a result of interference by radio waves reflected by the ionosphere, the system continued to be extensively used. Each beacon consists of a medium-frequency transmitter radiating modulated continuous-wave signals which are keyed with the identification letters of each station.

From Aug. 1, 1953, by international agreement a series of stations were put into operation along the Atlantic seaboard from Gibraltar to Norway. These stations, of which there are 64 in the United Kingdom and Ireland, transmit on one or other of 14 frequencies in the frequency band 285 to 315 kc. per second. Generally they are grouped in two ways: (1) in navigational groups oi six in which each station radiates for one minute in six recurrently 24 hours a day; or (2) in marker groups of two or three which radiate for a one minute period in turn and which are arranged to come into operation only in fog. Adjacent groups are arranged to transmit on different frequencies so as t~ avoid interference and the note frequency is varied according to the station between 354 and 1,052 cycles per second, thus making identification more certain.

The composition and length of the radiated signal is as follows: (1) the identification signal (two letters) transmitted from three to six times for approximately 22 sec.; (2) a long dash lasting for 25 sec.; (3) the identification signal transmitted once or twice for approximately 8 sec.; (4) a silent period of at least 5 sec.; total 60 sec.

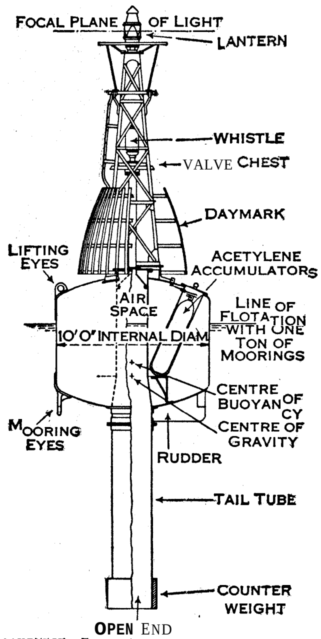
All stations have a radiated field strength of 50 μv per metre (root mean square value over water) at the nominal range of the station which varies from 20 to 200 mi. according to its location. Each transmitter is put into operation and closed down automatically by a clock which is capable of maintaining an accuracy of at least two seconds per day.

All units, including the coding mechanism, are duplicated and automatic alarms are fitted to indicate the failure oi any particular unit.

In addition to the omnidirectional type of beacon, a number of rotating-beam systems at medium frequency are in use, typified by the Oriord Ness, Suffolk, installation. This enables bearing to be found without the need for a direction-finding loop aerial by measurement of the time interval between a transmitted timing signal and the occurrence of a signal minimum at the vessel.

Shore-Based Radar Auxiliaries.—During and after World War II the development of radiolocation systems took place at an unprecedented rate. The most widely used system, now known as radar (*q.v.*), is fitted in the majority of vessels oi 10,000 tons and more. Normally no shore-based installation is required but auxiliary equipment may be added to targets which have poor reflecting properties for radar signals. Radar systems may be of two types:

1. Passive Reflectors.—To increase the radar detection range of small targets such as buoys and fishing vessels, or of targets which have a shape unsuited to efficient radar reflection such as tapered lighthouses, metal reflectors may be fitted to the structure. These may be dihedral, consisting of two perpendicular flat sheets with their common edge vertical! or trihedral corner reflectors, consisting of three flat sheets, mutually perpendicular, which reflect a radio beam back in the direction from which it came on the same principle as the cat's-eye reflectors familiar to motorists. By this means, buoy detection range can be increased from perhaps two-three miles to six-ten miles. Large dihedral reflectors may be set up on coast lines which have no clearly identifiable features when viewed on a radar screen.



COURTESY, TRINITY HOUSE. LONDON

FIG. 15.—HIGH FOCAL PLANE ACETYLENE-LIGHTED WHISTLE BUOY

Generally of all mild steel construction, the buoy weighs about 9) tons, complete with four dissolved acetylene accumulators and daymark superstructure

2. Radar Beacons.—Direct transmission of radar signals from certain important sites, such as channel-marking buoys, can give large detection ranges. Experimental work has been carried out on ramarks, which transmit continuously, and on racons, which transmit on reception of a radar signal from a vessel nearby. In the latter case, both bearing and range of the racon from the vessel are obtainable, and the signal may be given a code pattern, visible on the radar display ior identification purposes. In the United States such beacons have been extensively used, but require the addition of extra units to the radar set of each vessel. In Britain it was decided to avoid this necessity by ensuring that the racon transmits a signal which can be received by any ship's radar in the "merchant radar" band of frequencies, 9,320–9,500 mc. per second. This requires the transmission simultaneously or in sequence of the entire band of frequencies. In the mid-1950s equipment of this type had reached the trial stage, but no permanent installation existed.

Hyperbolic Navigational Aids.—The difference in time of arrival of radio signals from two fixed sites may be measured at the vessel in order to determine a position line on which the vessel is located. The line joining all positions at which the same time interval is measured is approximately a hyperbola, one of a family all having food at the transmitter sites. If a second position line is obtained from a second pair of transmitters, a fix is obtained ior the vessel which may be read from specially prepared charts. This principle is adopted in a number of radio navigational aids requiring shore-based transmitters and special receiving installations in the vessel. The most commonly used systems are:

1. Loran.—This system was developed in the United States during World War II as a long-range aid, and employs pulsed transmissions at a carrier frequency of about two megacycles per second. Time intervals between corresponding pulses from pairs of transmitters are measured by a special cathode-ray tube display technique. Reflections from the ionosphere appear at night but are separable and may even be used ior measurement at long ranges. Performance is generally much better over sea than over land. The effective range is about 750 mi. by day and 1,400 mi. by night. Extensive chains of Loran transmitters cover the eastern American seaboard, Greenland, Iceland, the Hebrides and Shetlands and the North sea, and are primarily used by the United States navy and Atlantic passenger liners.

2. The Decca Navigator.—This system has been more widely adopted in Europe. Continuous-wave signals at frequencies near 100 kc. per second are transmitted, time-difference measurements being replaced by phase-difference measurements which are directly and continuously indicated on dials. Because oi ambiguity which arises when the measured phase differences exceed 360°, approximate position must be known when starting

TABLE IV.—*Light* and Fog Signal Authorities, British Isles, *1954*

Authority	Lighthouses		Light vessels		Acoustic fog signals		Bells	Radio beacons
	More than 1,000 candle power	More than 200 and less than 1,000 candle power	Manned	Unmanned (light floats not included)	Explosive	Sirens, diaphones, reef horns, electric, etc.

Clyde Lighthouse trust	3	14	—	—	2	3	2	2
Humber conservancy	4	11	5	—	—	2	3	1
Other local lighting authorities	57	66	2	1	3	75	65	

Note: Lighted buoys and some harbour and river lights of minor character are not included in the above list.

the equipment. To assist in this, and to give a permanent check on approximate position, lane-identification transmissions are made periodically. Fixes are obtained more simply than with Loran, but errors occur when ionospheric reflections are strong, viz., at long ranges and by night. The official limit of range is 240 mi. but much larger ranges are often obtainable without error. In 1954 three chains of transmitters were in operation in Britain, covering the whole area of the British Isles, the English channel and the North sea. Further chains were in use in France, Denmark and Germany and more European chains were being planned. (*See* also NAVIGATION.) (K. H. G.)

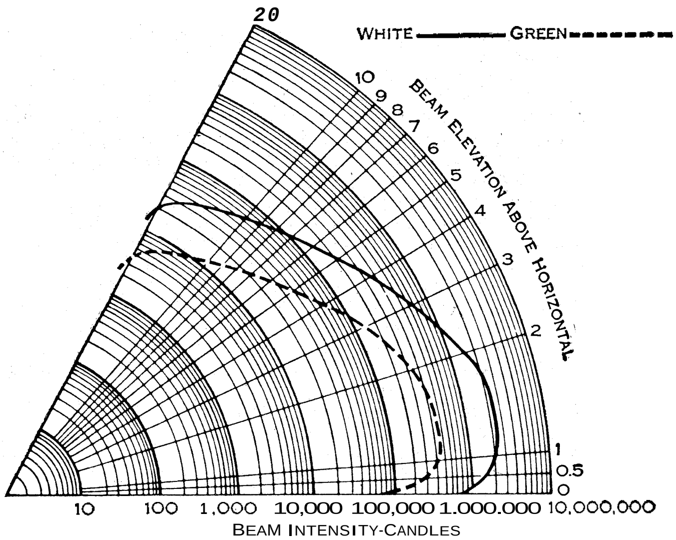
LIGHTHOUSE ADMINISTRATION

The principal countries of the world possess organized and central authorities responsible for the installation and maintenance of coast lights and fog signals, buoys and beacons.

British Isles.—In England Trinity House is the general lighthouse authority. The Corporation of Trinity House or, according to its original charter, the "Master Wardens and Assistants of the Guild Fraternity or Brotherhood of the most glorious and undivided Trinity and of St. Clement, in the Parish of Deptford Strong, in the county of Kent," existed in the reign of Henry VII as a religious house with certain duties connected with pilotage, and was incorporated during the reign of Henry VIII. In 1565 it was given certain rights to maintain beacons, etc., but not until 1680 did it own any lighthouses. After that date it gradually purchased most of the ancient privately owned lighthouses and erected many new ones. The act of 1836 gave the corporation control of English coast lights with certain supervisory powers over the numerous local lighting authorities, including the Irish and Scottish boards. The corporation consists of a master, deputy-master and 23 "elder brethren" (11 of whom are honorary), together with an unlimited number of "younger brethren" who, however, perform no executive duties. In Scotland and the Isle of Man the lights are under the control of the commissioners of northern lighthouses, constituted in 1786 and incorporated in 1798. The lighting of the Irish coast is in the hands of the commissioners of Irish lights, formed in 1867 in succession to the old Dublin Ballast board. The principal local light authorities in the United Kingdom are the Mersey Docks and Harbour board and the Clyde Lighthouse trustees. The three general lighthouse boards of the United Kingdom, by the provisions of the Mercantile Marine act of 1894, are subordinate to the ministry of transport and civil aviation, which controls all finances.

On Jan. 1, 1954, the lights and fog signals in service under the control of the several authorities in the British Isles were as shown in Table IV.

In the Trinity House service at shore lighthouse stations where there is no fog signal there are usually two keepers, and at rock stations four, one being ashore on leave. At a shore fog signal station there is an additional keeper. The crews of light vessels as a rule consist of 11 men, 3 of them and the master or mate going on shore in rotation.



BY COURTESY OF MESSRS. CHANCE BROTHERS

FIG. 16.—VERTICAL DISTRIBUTION OF BEAM INTENSITY (STATIONARY) OF AN AERODROME BEACON

Other Countries.—The lighthouse authority of France is known as the Service des Phares et Balises (which is controlled by the Administration des Ponts et Chaussées) and was set up in 1792. The Commission des Phares was set up in 1811. The director of the Service des Phares et Baiises is secretary to the Commission des Phares. The service controls marine signalling throughout the French union; *i.e.,* about 1,000 lights in France and 600 overseas. In Denmark, Austria, the Netherlands, Italy, Sweden, Norway and many other countries the minister of marine has charge of the lighting and buoying of coasts; in Belgium the public works department controls the service, and in Spain the lighthouse service is established on lines similar to that of France. In Canada the coast lighting is in the hands of the minister of marine, and in most of the other British dominions and colonies the public works departments have control of lighthouse matters.

UNITED STATES

The first lighthouse in the United States, a tall masonry tower, was built in 1716 by Massachusetts at the entrance to Boston harbour. The original Colonies on the Atlantic, largely dependent on water traffic, gave early attention to lighthouses. Congress, in 1789, immediately after the national government's organization, provided for lighthouses and buoys, 12 having been built by the colonial governments. In 1852 congress established the lighthouse board, substituting for it in 1910 the lighthouse service. On July 1, 1939, the lighthouse service was consolidated with the U.S. coast guard in the treasury department.

The problems of lighthouse construction are similar everywhere in the world, but the Great Lakes and North Atlantic ice action, southern coast hurricanes and some earthquake areas need particular attention. The United States has about 30 important lighthouses on submarine or unusually exposed sites, some involving difficult engineering; only a few of these are wave-swept lighthouses of primary significance. The following are important or typical wave-swept U.S. lighthouses:

Minots Ledge (1860), south of Boston harbour, is built on a reef, bare only at low water, exposed to the Atlantic's sweep; its construction took about five years. Steps were cut to receive the foundation. The conical-shaped tower is of granite, the first 40 ft. solid, base 30 ft. diameter, the light elevated 8; ft. The stones are dovetailed in each course, connected vertically by bonding bolts, and eight long iron posts pass through the lower courses into holes in the ledge. This station was changed to automatic operation in 1947.

White shoal (1910) marks a shoal in northern Lake Michigan. A timber crib 72 ft. square, towed to the site and filled with stone, was sunk in 22 ft. of water; this supports concrete pier, tower and light 125 ft. above water. Martin reef (1927), in northern Lake Huron, has a similar substructure.

On the Great Lakes important structures on submarine foundations mark shoals, usually replacing the original lightships. Timber crib foundations, economical and satisfactory in fresh water, are favoured. Another type consists of concrete caissons towed to site, sunk on bottoms previously levelled and filled in with stone; *i.e.,* Lansing shoal (1928), Lake Michigan. Spectacle reef (1874) in Lake Huron and Stannard rock (1882) in Lake Superior have cofferdams in protecting piers, the former for a stone tower on rock, the latter for a wrought-iron cylinder foundation pier fitted to rock and concrete filled.

Sabine bank (1906), marking a sandbank about 14 mi. off the Gulf coast, is a cast-iron tower and substructure standing in 18 ft. of water. The iron caisson was towed to the site and sunk 20 ft. in sand by pneumatic process, the only U.S. lighthouse foundation so placed in the open sea. There are others in protected waters. This station was changed to automatic operation in 1923.

Pacific reef (1921) marks the outer edge of coral reefs off the southern Florida coast. It is supported by nine iron piles, each driven nine feet into the coral reef. The piles pass through and are partially supported by iron disks four feet in diameter resting on the coral surface. In seven feet of water, it supports an iron openwork structure. Although only an automatic acetylene light, 4; ft. high, it illustrates recent practice; it was built at moderate cost. Six other lights along the Florida reefs, on similar foundations, are notable structures, the tallest being Sombrero Key (1858), 160 ft.

Tillamook rock (1881), a stone structure on a small rock islet a mile off the Pacific coast south of the Columbia river's mouth, is the most notable lighthouse on the western United States coast because of its position on extremely exposed rock, in deep water and open to the Pacific sweep. Landing is impossible directly on the rock and can be made only by hoisting from a boat. Seas sometimes break over the lantern, 133 it. high. St. George reef (1891) off the California coast is in a similarly difficult position.

Many lighthouses in water were formerly built on screw-pile foundations. One, Sand Key light (1853), Fla., is 120 ft. high. Of many handsome masonry lighthouses along the coast, especially the low-lying Atlantic seaboard, Cape Hatteras is the highest, 193 ft. Reinforced concrete has been extensively used to construct light towers, wharves and buildings. The most notable is Navassa Island light (1917) on a desert West Indian island; tower 162 ft., cylindrical shaft 15 ft. diameter. Another primary light of reinforced concrete is Kilauea point (1913), Hawaii. The tower, 52 ft. high, is on a cliff.

Apparatus, Illuminants and Other Characteristics.— U.S. practice is similar to standard world practice, but there are some diverging developments. Concentrating light by using rapidly revolving lenses with few panels and superior illuminants gives beams of sufficient power with smaller lenses. No lenses larger than third order (500 mm., 20 in. radius) were installed after 1913. Numerous large lenses were replaced by more efficient optical apparatus.

The primary light standard, the electric incandescent lamp, using commercial current generated at the station, has replaced the older kerosene oil-vapour apparatus. Incandescent electricity is most satisiactory because of its power, convenience and adaptability. It is efficient to electriiy certain stations for illuminant, operating sound fog signal and radio beacon and lighting buildings.

Electricity is very convenient for signals controlled remotely, as those near jetty ends. Small plants or primary cells generate electric energy ior minor lights. The principal difficulty in putting incandescent electric lamps in old lenses is the too concentrated light source and insufficient divergence of beam. This may be overcome by various methods.

Batteries and acetylene gas compressed in cylinders are used for unwatched, automatically operated lights of minor importance. All new installations are made with batteries, and acetylene aids are gradually being replaced by electric aids. By the mid-1950s about 97% of all lighted aids to navigation were automatic. Automatic apparatus extended lighthouse facilities to remote regions like Alaska.

The distinguishing of principal coast lights by flashing or occulting characteristics and the elimination of fixed lights progressed steadily. Characteristics are simple and are quickly and easily recognized without timing. Preierred limitation is that a single light flash be not less than 0.2 sec. in duration. An exception to this limitation is permitted in the instance of rapidly recurring flashes.

Colour is valuable for reasons of distinctiveness against a background of competing lights, for identification or for imparting a definite meaning. The illumination is reduced. approximately 80% where colour other than white is used which is a serious drawback. Red, green and white are the oniy three colours of lights used in the United States lighthouse system.

Uniformity of Buoyage.— The United States has long had a fairly standardized system to show the relation of buoys to channels, by colours, shapes and numbers, this system having in part been prescribed by lam in 1850. International uniformity in buoyage and lights would add safety and convenience to navigation. Limited but important action on this at the International Marine conference, Washington, D.C., 1889, resulted in considerable uniformity.

The United States system, based largely on the 1889 conference, is: for vessels coming from sea, red buoys, .conical-shaped (nun), even numbers on right side of channel, cylindrical black buoys, flat tops (can), odd numbers on left side; horizontal red- and black-banded buoys mean shoals or dangers; vertical black and white stripes show clear channels; with coloured lights, red on right and green on left of entrances or channels, but white may be on either side.

Colour and shape to mark the relations of buoys to channels are in nearly world-wide use; shape alone is not enough, because it is not readily applicable to important classes of buoys, such as lighted, whistle, bell and spar. Colour is the most obvious, readily applied characteristic. The American buoyage system, light characteristics and apparatus are as simple as possible, in order to avoid coniusion and to be more definite and reliable.

Lightships are placed on foggy coasts to mark outstanding dangers or port approaches. The first was placed in Chesapeake bay (1820).

Fixed structures on shoals or lighted buoys replaced many lightships originally placed in inland waters. Great Lakes lightships were thus being gradually retired, only one, on Lake Huron, being maintained in the mid-1950s. There were 27 lightship stations, with 9 relief ships. Of these, 23 mere located off the Atlantic and Pacific coasts, where it is impracticable to build lighthouses but where lights are vital to traffic. Nantucket lightship, for example, moored in 32 iathoms 50 mi. from land, guards shoals to the north, and most transoceanic vessels approaching the United States Atlantic coast steer for this vessel, one of the world's most important seamarks. A full-powered vessel, 148 ft. long, with an authorized complement of 20 men, it has a flashing incandescent electric light of 20,000 candle power, compressed-air diaphone iog signal and a radio beacon synchronized with the fog signal for distance finding. It is an oil-burning steam vessel. Most lightships have diesel engines and five ships have diesel-electric propulsion.

Ambrose lightship, at the entrance to New York harbour, shows a powerful white light the intensity of which is increased, as visibility conditions get poorer, from a minimum of 250,000 candle power in fair weather to more than 2,000~000candle power in bad weather.

Lightships moored in the sea off the Atlantic coast, exposed to tropical hurricanes and other severe storms, receive special attention as to vessel design and moorings to ensure station permanency. Severe storms have sometimes torn lightships from their moorings. For greater security, cast-steel chain and mushroom anchors up to four tons are used.

BUOYS.—The great length and intricacies of the U.S. coasts require more than 22.000 buoys. The increase in lighted buoys is a notable advance. In the mid-1950s more than 3,000 lighted buoys mere on station, of which about half were operated by acetylene gas compressed in tanks set in the buoy pockets and half by batteries. Steel buoys of various sizes are extensively used to mark channels and shoals. Wooden spars are being replaced advantageously by small inexpensive steel buoys. In the mid-1950s there were more than 900 bell buoys, about 300 whistle buoys and 140 gong buoys. All new buoys then being constructed had radar reflectors built integrally into the superstructures to increase the reliability of detection by radar-equipped vessels.

All buoys and moorings are relieved at least biennially, old buoys brought to depots, cleaned and repainted. Their great number makes this an important and time-consuming task.

Sound Fog Signals.— Radio beacons (see below) are the most effective fog signal. Various types of sound signals, using compressed air or electricity, are employed, but their value is limited because of their short and undependable range and the impracticability of taking accurate bearing on them. But sound iog signals nevertheless remained indispensable. Steam whistles, once used extensively, mere replaced by more efficient apparatus. Variously actuated electric sirens, air horns and bells serve for minor sound signals.

A number oi automatic fog signals operated by carbon dioxide gas or electricity are located in areas where only a moderate signal is required during the foggy season each year. Nearly all fog signal machinery and apparatus is installed in duplicate for greater reliability.

Radio Beacons.— These stations emit distinctive identifying coded tone radio signals. When used with radio direction finders, usually installed on board ships or in aircrait, they enable navigators to take bearings on targets with known charted positions. They were the first generally available means ever provided ior taking accurate bearings on invisible targets at considerable distances.

The first successiul radio beacons were placed at three stations near New York in 1921. The system grew in the United States and outlying territories to include almost 200 by the mid-1950s. These radio beacons are classed as follows:

Class A, having a normal useful range of 200 mi.
Class B, having a normal useful range of 100 mi.
Class C, having a normal useful range of 20 mi.
Class D, having a normal useful range of 10 mi.

A navigator skilled in the use of the radio direction finder can, with favourable conditions, obtain radio direction finder bearings accurate to within two degrees.

The radio beacon transmitters transmit on an even frequency in the frequency band between 285 and 315 kc, (1052.6 to yj2.4 m.). Signals are usually transmitted ior one minute and off for two minutes throughout each hour of fog or low visibility. Durinp clear weather signals are usually transmitted one minute on and two minutes off ior one or two ten-minute periods oi each hour. This scheduling enables synchronized groups oi stations to operate on the same radio frequency without interierence and requires accurate timing of the transmissions. During clear weather and between regular scheduled clear weather transmissions, any station operating in a group will transmit continuously when requested by the navigator for the purpose of calibrating radio direction finders.

During these calibrating transmissions; regular scheduled transmissions of one minute on and two minutes off are resumed during the regular scheduled operating period. Stations not operating in a group transmit continuously upon request for the duration of a calibrating period. At some stations, special radio direction finder calibrating transmitters are installed. These transmitters are placed in operation at the request of the navigator and remain in operation as long as calibrating signals are desired. These special calibrating transmitters are adjusted to transmit on an even frequency in the band between 285 and 315 kc. and on 480 kc. This provides for calibrating the radio direction finder on a frequency in the regular radio beacon band and on the international frequency of 500 kc.

Class D radio beacons transmit continuously.

For the use of aircrait equipped with automatic radio direction finders, some radio beacons are adjusted to send continuous carrier signals with identifying characteristic tone modulation applied for one minute on and two minutes off throughout the 24-hours. A few other selected stations are adjusted to send continuous carrier signals with identiiying characteristic tone modulation applied continuously throughout the 24 hours. All other radio beacons transmit keyed, continuous carrier, characteristic tone modulated signals.

Administration.— The maintenance of aids to marine navigation is a function of the United States coast guard, having been placed under that organization on July 1, 1939, and consists of the maintenance of lighthouses, lightships, radio beacons, fog signals, buoys and beacons on all navigable waters of the United States, the Great Lakes, the Mississippi river and its tributaries, Puerto Rico, the approaches to the Panama canal, the Hawaiian Islands and Alaska.

The chief administrative officer is the commandant of the coast guard, with headquarters at Washington, D.C. Under his direction the functions of establishment, construction, maintenance and operation of aids to navigation are carried on through administrative and engineering divisions in Washington and by the various district offices. Because of the wide geographic distribution of aids to navigation on the seacoasts, the Great Lakes and the navigable rivers of the United States, with an aggregate coast line of more than 40,000 mi., the field work of the service is carried on by district organization? There are 12 coast guard districts, carrying on lighthouse work as well as other functions of the coast guard. Each district is under the supervision of a commander, assisted by a suitable engineering and administrative force and equipped with the necessary supply and buoy depots and with suitable vessels for the maintenance of the navigational aids.

LIGHTING. Man in his social and economic development has been engaged in continuous effort to utilize the hours of darkness through the application of artificial illumination to human needs. Methods of producing light remained primitive and crude in design over long periods of time, and, when new and improved methods were introduced, the use of the earlier forms continued so that at no time has one method completely replaced another. In the middle of the 20th century more than half of the world's inhabitants still had only flame sources for artificial light.

Artificial illumination is obtained as a result of combustion, incandescence or electric discharge with or without fluorescence. Sources of light may be divided into three classes: (1) vegetable and animal fatty substances; (2) carbonaceous matters, gases and oils; and (3) electrical.

Light as a physical phenomenon is discussed in the article LIGHT, while its perception is dealt with in VISION.

This article is divided into the following sections:

I. HISTORICAL DEVELOPMENT

The earliest form of artificial illumination was the fire used by primitive man for warmth and for protection against wild beasts, and flaming faggots from the campfire mere the first torches. From this beginning, thousands of centuries before written history, the torch in various forms has continued as a source of illumination throughout the world.

The flambeau of the middle ages, carried by pedestrians at night, was a torch consisting of twisted fibre coated with some inflammable substance. These torches provided the earliest form of street lighting, being fastened in metal holders to the outside walls of houses. Pieces of resinous wood, stuck between the stones of the fireplace, gave forth bright but smoky flames for lighting the homes of early New England.

Unusual sources of artificial illumination are the glowworms, beetles and fireflies supposedly confined in lanterns in the West Indies or stuck in wax in shallow saucers in Java. Oily carcasses of various animals with wicks drawn through them have been used; the penguin has been most frequently used in this manner.

1. Oil Lamps.—The earliest prehistoric lamp dates to the Mousterian Age. This was a hollowed piece of stone, very crude, found at Le Moustier, Fr., in 1928. Terra-cotta lamps of 7000–8000 B.C. have been found on the Mesopotamian plains, and Egyptian and Persian copper and bronze lamps of about 2700 B.C. have been discovered at various times.

By 1000 B.C. an advancement in lighting efficiency was provided by a nick of vegetable fibre burning in a saucer-type vessel holding olive or nut oil, and by 500–400 B.C. oil lamps had come into general domestic use. Roman lamps of unglazed and glazed terra cotta had tno or more spouts, and later bronze and iron lamps were introduced. with designs becoming more elaborate. About 100 B.C. the Romans developed the first true lantern of horn, cylindrical in form with a perforated top. Vegetable-oil lamps were in general use among the early Jews, Greeks and Romans.

The first record of mineral-oil lamps was made about A.D. 50 when Pliny mentioned this use of oil found on the Adriatic shores. Japanese history in A.D. 615 mentions "burning water" and Marco Polo wrote in the 13th century of Baku oil springs furnishing oil satisfactory for lighting purposes.

Early attempts were made to improve the efficiency of oil lamps. About the latter half of the 1st century A.D., Heron of Alexandria devised a lamp in which pressure of brine acting through a column of air raised the oil to the wick. In 1490 Leonardo da Vinci added a cylindrical glass chimney fitted into a glass globe filled with water. The light burned steadily, and through lens action the work surface was brightly lighted for night study. Da Vinci also devised water lenses for correcting near vision, the first recorded analysis of the fact that seeing is a combination of light and vision.

Various types of oil lamps were used through the 14th to 17th centuries, but with little improvement of efficiency. The Betty lamp of the Pilgrims (1620), a metal receptacle with a wick lying in a slot and protruding from one side, was equipped for hanging from mantelpieces or shelves. Fish oil was the chief illuminant.

In 1784 the Swiss physicist Aimé Argand patented a lamp with round burner and tubular wick and a chimney for directing and regulating the flow of air to the flame. An accident led to the discovery that a round glass chimney reduced flickering, and the Argand lamp marked the greatest advancement in artificial illumination to that date. In 1800 Bertrand G. Carcel added a clockwork pump for raising and feeding oil to the wick and, because of the steadiness of the light produced, the Argand lamp in this form became a photometric standard. Benjamin Franklin discovered that two wicks side by side a small distance apart gave more light than two single-wick lamps.

Distilled coal oil produced by James Young in 1850–51 was an improvement, but the discovery of petroleum by Edwin L. Drake in 1859 provided an inexpensive illuminant of high lighting efficiency. and the crude-oil lamp mas practically superseded. In the following 20 years an average of 80 patents per year were granted for various types of improved oil lamps. One of the most important was the duplex burner lamp introduced in 186j by Joseph Hinks. In 1868 the Wells light combined an oil spray with vaporized oil through the use of pressure, giving a highly luminous flame, the principle used in modern flare lamps. The Kitson lamp of 188j was a pressure-type lamp using platinum mantles, replaced later by Welsbach mantles.

During the latter half of the 19th century oil lamps underwent many changes and improvements intended to make them more attractive for domestic use and more efficient for industrial purposes. They were mounted on elaborate bases and the oil reservoirs were decorated; some were designed for suspension from ceilings and others were portable. The latter designs carried over into the 20th century, and the kerosene lamp with a flat wick in a perforated metallic holder and a plain glass chimney came into extensive use in rural districts.

2. Candles.—The use of candles dates as far back as the beginning of the Christian era, and candlemaking is probably one of the oldest industries of mankind. Among aboriginal races in Africa oily nuts were burned in clay saucers; later they were strung on twigs, thereby providing continuous illumination.

In A.D. 100 Greek and Roman true candles were made of flax threads coated with pitch or wax, although the Phoenicians are credited with the first use of wax candles about A.D. 400. The candle was not in as common use as the oil lamp for several centuries, but returned during the middle ages. Throughout the 16th to 18th centuries and until the discovery of petroleum, candles provided the only method of artificial illumination available to people of average means. Their use has been closely related to religious ceremonies and customs throughout Christian history. The earliest candles were rush piths dipped in tallow. Later, splinters of wood, also dipped in tallow or beeswax and called kindle lights, mere used. Homemade candles of Pilgrim days were of tallow. The whaling industry in the 18th century brought spermaceti into use. The spermaceti candle, because of its clear, steady flame, was used as a standard measure for artificial light, the term "one candle power" being based on the light given by a pure spermaceti candle weighing one-sixth of a pound and burning at the rate of 120 grains an hour. The development of stearine in 1823 and of paraffin in 18jo furnished improved materials for candles.

Candleholders have assumed various forms. The Prickett chandelier introduced in Italy in 1492 was a multiple-spiked holder mounted in groups around a decorative figure on the wall, with mutton-fat candles forced on the spikes. In the 15th century crystal chandeliers with small cups for holding wax candles lighted homes, ballrooms and public gathering places. Of these candles, 120 would have been required to equal the light of one 100-w. electric lamp, and the number required to illuminate a large room produced considerable heat. Candles in elaborate chandeliers were used for illumination of the house of commons in England as late as 1834, and their replacement by gas was strongly opposed by members. With the advent of gas as an illuminant, the use of candles was gradually confined to church ceremonies, decorative domestic purposes and festive occasions.

3. Gas.—Ancient records of Egypt and Persia provide numerous instances of spontaneous discharge of combustible gases from fissures in the earth. Natural gas was employed as an illuminant by the Chinese centuries before the Christian era. The gas was brought to the surface from beds of rock salt 1,500 to 1,600 ft. deep, conveyed through bamboo pipes and used for lighting salt mines and homes in Szechwan province.

In 1664 near Wigan, Lancashire, Eng., John Clayton discovered a pool of natural gas near a coal mine, and later described satisfactory experiments in extracting coal gas by distillation. In 1726 Stephen Hales reported that 158 g. of Newcastle coal would yield 180 cu.in. of "inflammable air," and in 1733 Sir James Lowther sent specimens of distilled coal gas to the Royal society for experimentation.

In 1784 Jean Pierre Minckelers first used gas for lighting. Contemporaneously, in Paris, Philippe Lebon experimented with distillation of gas from various materials for domestic use, and in 1799 Lebon patented a "thermo-lampe," using gas distilled from wood.

The first extensive use of illuminating gas is ascribed to William Murdock, who. in 1792, lighted his home in Redruth, Cornwall, Eng. The gas was produced in large iron retorts and conveyed 70 ft. through metal pipes. In 1798 Murdock installed gaslighting in a factory near Birmingham, Eng., and soon was providing gas commercially for several shops in the vicinity.

The new illuminant was denounced as dangerous and impractical, slowing its adoption. Through the efforts of F. A. Winsor, a German, the first public installation of gaslights was made in London in 1807. For dispelling the public prejudice against illuminating gas, Winsor is referred to as the father of gaslighting. Westminster bridge, London, was illuminated by gas in 1813; Paris adopted gas for street lighting in 1818; and most cities in England and Europe soon had gaslighting systems. The first domestic use of gas in the Cnited States was in 1806, when David Melville, of Newport, R.I., lighted his home and the street directly in front. The first interior commercial use mas in the New theatre, Philadelphia, Pa., where gaslights were installed in 1816.

Between 1820 and 1880, many improved burners were developed, the batwing or fishtail type being most commonly used. The Bunsen burner was invented by Robert Wilhelm von Bunsen in 1855, and in 1879 William Sugg developed the Sugg-Argand burner giving an economical light of high intensity. Carl Auer von Welsbach experimented for ten years on the Welsbach mantle, and his system of lighting was first exhibited in London in Feb. 1887. By 1900 incandescent gaslighting was firmly established.

The Welsbach mantle consisted of a cylinder woven of sea-island and Egyptian cotton soaked in a solution of 99% thoria and 1% ceria. After various manufacturing processes, a metallic-oxide skeleton remained, and in use the mantle was suspended over a Bunsen burner so that the metallic oxides composing the mantle were heated to incandescence, emitting a brilliant greenish light. By using varying combinations of rare earths in solution for impregnating the mantles, different colours of light could be obtained. Welsbach mantles have continued in use with various types of lamps.

4. Acetylene Gas.—Although the existence of this gas had been known since 1836, its manufacture and use as an illuminant was first described by Henri Moissan in 1892. Simultaneously,

in the U.S., Thomas L. Willson demonstrated that acetylene gas obtained by immersion of calcium carbide in water produced an intense white light. By 1909, 290 towns in the U.S. were lighted by acetylene gas. Later its use was confined to emergency lighting in remote areas. An acetylene light can be charged, lighted and then left unattended for six months or more.

5. Pintsch Gas.—Originally developed for lighting railroad cars by Julius Pintsch of Germany, this gas was used in Europe for many years, and was introduced into the U.S. in 1866. By 1910 there were 93 Pintsch gas works in the U.S., Canada and Mexico. It was used extensively on steamships and for lighthouses. Similar to Pintsch gas were the numerous bottled gases developed in subsequent years to provide illumination with Welsbach-type mantles in areas where electricity was not available.

By 1911 conversion of gas fixtures for use with electricity had begun, and soon electricity was rapidly replacing gas for general illuminating purposes. In England and Europe, however, gas enjoyed aide use for a number of years longer; in 1926 the earlier electric street lighting in Paris was replaced by high-pressure gas lamps, automatically lighted and controlled.

6. Electric Lamps.—In 1650 Otto von Guericke of Magdeburg, Ger., discovered that light was produced by electricity or by electrical excitation. He demonstrated that when a globe of sulfur was rotated rapidly and friction was produced by pressure of the hand during rotation, a luminous glow could be observed. About 1706, the Englishman Francis Hauksbee (Hawksbee) used this discovery, together with a glass globe exhausted by means of a vacuum pump also invented by Guericke, to produce the first electric light. When the globe was rotated at high speed, then rubbed with the hand, it emitted a faint glow of light. In 1802 Sir Humphry Davy demonstrated that strips of platinum or other metals could be heated to incandescence electrically and would give off light for some time. In 1809 he used a battery of 2,000 cells to pass a current through two charcoal sticks four inches apart nhich produced a brilliant arch-shaped flame, thereafter called the arc light.

Throughout the 19th century, development of the arc lamp and the incandescent lamp were parallel. The earliest recorded attempt to make an incandescent lamp was in 1820, when De la Rue enclosed a platinum coil in a piece of evacuated glass tubing. In 1840 Sir William Robert Grove of England lighted an auditorium with feeble, impractical lamps using platinum coils heated to incandescence and covered by inverted tumblers in glass dishes partly filled with water. The cost of the current consumed by the installation was estimated at several hundred dollars a kilowatt hour.

In 1841 Frederick de Moleyns of Cheltenham, Eng., obtained the first patent granted for an incandescent lamp. His lamp was unique, consisting of an evacuated glass sphere containing powdered charcoal nhich bridged the gap between two platinum wires or filaments. Light was produced by passage of current through the platinum filaments, heating the charcoal to incandescence. However, the globe blackened quickly and the lamp was short-lived.

In 1845 Thomas Wright of London obtained the first patent for an arc lamp, and in the same year a young Ohio inventor, J. W. Starr, obtained a British patent for two incandescent electric lamps. Edward G. Shepard in 1850 constructed a lamp using incandescent charcoal. The same year Sir Joseph Swan, English physicist, devised carbon filaments of paper.

During the latter part of the 19th century many scientists tried to produce electrical illumination on a practical commercial basis, and there are records of occasional use of electric lamps throughout the period. In 1849 an opera scene in Paris was illuminated by electric light. In 1856 the French engineer C. de Chagny patented a novel platinum-filament lamp for mines, and in 1857 the first commercial installation of an electric arc light was made in the lighthouse at Dungeness, Eng.

In 1872 Alexandre de Lodyguine, a Russian physician, made a lamp having a V-shaped piece of graphite for a filament, operating in a glass globe filled with nitrogen gas. Two hundred of these lamps were installed about the Admiralty dock in St. Petersburg, but unreliability of operation and cost made them impractical for general use. A contemporary, S. A. Kosloff, used multiple rods of graphite operated in nitrogen. None of the foregoing lamps was practical.

In 1876 Paul Jablochkov, a Russian electrical engineer, introduced the Jablochkov candle, marking an epoch in artificial illumination. The Jablochkov candle was an arc lamp having parallel carbon rods separated by porcelain clay, which vaporized during burning of the arc. Alternating current was used to ensure equal rates of consumption of the two points of the rods. This lamp was widely used commercially. First installation of arc lamps for public lighting in the U.S. was in 1879 when the public square in Cleveland, O., was lighted by a system of 12 Brush carbon arc lamps developed by Charles F. Brush.

Before the Edison incandescent carbon-filament lamp was patented in 1880, numerous scientists directed their efforts toward production of a satisfactory incandescent lighting system, outstanding among them being Sir Joseph Wilson Swan, English physicist. In 1850 Swan had devised carbon filaments of paper; later he used cotton thread treated with sulfuric acid and mounted in glass vacuum bulbs. Utilizing this type of lamp, called the "electric glow lamp," he gave a large-scale public exhibition of electric lighting at Newcastle, Eng., in 1880.

Final development of the incandescent lamp was the result of concurrent work by Swan and Thomas A. Edison, with important contributions by St. George Lane-Fox and William E. Sawyer. The invention of a completely practical lamp ordinarily is credited to Edison, who began studying the problem in 1877 and within a year and a half had made more than 1,200 experiments. Concurrently, recognizing that the series wiring systems then used for arc lights would not be satisfactory for incandescent lamps, Edison directed much effort toward development of dynamos and other necessary equipment for multiple circuits.

On Oct. 21, 1879, Edison lighted a lamp containing a carbonized thread for the filament. The lamp burned steadily for two days. Later he learned that filaments of carbonized paper visiting card (Bristol board) would give several hundred hours' life. Soon carbonized bamboo was found acceptable and was used as the filament material until 1894. Extruded cellulose filaments were introduced in 1894. The first complete incandescent lighting system was publicly demonstrated at Edison's laboratory in Menlo Park, N.J., on Dec. 21, 1879.

The first commercial installation of Edison's lamp was made in May 1880 on the steamship "Columbia." This installation, consisting of 115 lamps, was operated successfully for 15 years. In 1881 a New York city factory was lighted with Edison's system, and the commercial success of the incandescent lamp was quickly established. More than 150 other installations were made in the following two years. In 1882 the Pearl street generating station in New York city was put into service, and is considered the forerunner of the great central stations subsequently developed. In England an exhibition of electric lighting was held in 1882 at the Crystal palace, and by this time incandescent lamps had been installed in numerous public buildings.

When the incandescent lamp was introduced as a public illuminant, fear was expressed that it might be injurious to the eyesight, particularly when used for long periods by indoor workers. In 1898 the oculists of London petitioned parliament to pass laws against the use of unshaded lights, and consequently research was instituted on various types of shades and reflectors. One of the earliest reflectors used commercially was the one-piece silvered glass reflector developed by E. L. Haines and installed in show windows in Chicago and other cities in the U.S.

Closely related to the incandescent gas mantle, and suggested by it, was the Nernst glower, unique among illuminants of its time as the first practical attempt to substitute some other incandescent substance for carbon filaments. Patented in 1901 by H. W. Nernst of Germany, it utilized a filament composed of oxides of rare-earth elements heated to incandescence by passage of electrical current. Mixtures of two or more oxides were found to be most satisfactory, and in 1905 the commercial Nernst glower consisted of 85% zirconia and 15% vitria. The Nernst lamp did not achieve wide use, but investigations carried out to improve it had considerable effect on the development of the incandescent lamp.

Welsbach invented the first commercial metal-filament lamp, but the osmium employed was extremely rare and expensive. The first applications nere in Berlin and Vienna in 1899, but manufacture was discontinued in 1907 when the tungsten lamp appeared. Werner von Bolton, a Russian chemist, discovered the possibility of using tantalum for lamp filaments about 1902, and in 1906 the tantalum lamp was put on the market in the U.S., but disappeared from use about 1913.

In 1904 Willis R. Whitney of Schenectady, N.Y., produced the heat-treated or metalized carbon-filament lamp, with a higher degree of efficiency than any previous incandescent lamp But scientists were concerned with the most efficient conversion of electrical energy into light, and the discovery of tungsten as a material for filaments seemed to achieve this goal. The tungsten-filament lamp represented the greatest advance ever made in the quality and efficiency of incandescent lighting. and quickly replaced carbon, tantalum and metalized carbon filaments for commercial use.

The first tungsten-filament lamps. introduced in the US. in 1907 made use of pressed tungsten, manufactured by a process perfected by Alexander Just and Franz Hanaman of Vienna. By 1910 William D. Coolidge of Schenectady, N.Y., discovered a process for producing drawn tungsten filaments. greatly improving the strength of tungsten lamps. This process was patented in 1913.

In 1913 Irving Langmuir of Schenectady. N.Y., discovered that use of inert gases inside the incandescent lamp bulb would retard filament evaporation, giving increased efficiency. Nitrogen alone was first used, but later lamps used argon and nitrogen in varying proportions, depending on the wattage. Low first cost, ease of maintenance and adaptability gave the gas-filled lamp such importance in the lighting field that other incandescent lamps practically disappeared. Other significant milestones included dumet seal wire (an iron-nickel alloy) developed in 1913; tipless lamps in 1919; inside-frosted bulbs in 1925; photoflash lamps and the copper-to-glass seal in 1930; and vaporized-aluminum reflector lamps in 1936. A further improvement introduced in 1937 was the coiled-coil type of filament for general service lamps.

Tungsten-filament lamps were developed in a variety of sizes and shapes. for domestic and commercial use and for some highly specialized purposes. By 1935 they were available in shapes varying from the common pear-shaped or round bulb type to tubular forms several feet long. A very small lamp, known as the "grain o' wheat" lamp, having a bulb only 2 mm. in diameter and 8.7 mm. long, became valuable to the medical profession. providing a light source for internal investigation and surgical work. A lamp smaller than the "grain o' wheat" lamp was being regularly supplied. and lamps with built-in reflectors were in wide use. Inside silica coatings had improved the diffusing qualities without loss in lamp efficiency.

7. Electric Discharge Lamps.—The observations of Jean Picard in 1675 and Johann Bernoulli about 1700 indicated that light could be produced by agitated mercury. Early research in the field was done about 1850 by Heinrich Geissler, German physicist who invented the Geissler tube, by means of which was demonstrated the phenomenon of luminosity accompanying the discharge of electricity through rarefied gases. An English professor, John T. Way. demonstrated the first mercury arc in 1860; and John Rapieff of London and the French scientist M. Jamin made further contributions in 1879 and 1882 respectively.

In 1887 Geissler tubes were used largely for laboratory demonstrations, but in 1897 tubes of various colours were used successfully for a display commemorating the Diamond Jubilee of Queen Victoria of England.

The Moore tube, developed by Daniel McFarlan Moore between 1891 and 1904 along the principle of the Geissler tube, made use of nitrogen to produce a yellow light and of carbon dioxide for a pinkish-nhite colour approximating daylight. Moore tube lights were most widely used for colour matching, and the first commercial installation was made in a Newark, N.J., store in 1904. The Moore tube was difficult to install and repair, and a complicated valve mechanism was required to maintain the gas at the correct pressure.

The mercury-vapour lamp, originated by L. Arons of Germany in 1892, was not manufactured on a commercial basis. Peter Cooper-Hewitt marketed the mercury-arc lamp in 1901, its efficiency proving to be two or three times that of the contemporary incandescent lamp. Its chief limitation was its peculiar colour quality, with light rays concentrated in three restricted spectral regions and with a complete absence of red. Introduction of other gases failed to produce satisfactory results until Cooper-Hewitt devised a fluorescent screen which converted some of the excess blue and green light and a little of the yellow into red, thereby materially improving the colour. The first practical installation of the Cooper-Hewitt lamp was in the composing room of the *New York Evening* Post in 1903. Creating a nearly shadow-free light and less glare, the lamp immediately found wide use for industrial lighting in the U.S.

Cooper-Hewitt also developed the quartz tube mercury lamp, used extensively in biological research. A later form of the quartz tube lamp. based on research carried on by C. Bol and others in the laboratories of the Philips company in Eindhoven, Neth., led to exploitation in Europe of a small water-cooled or capillary type of mercury-arc lamp, developed in 1935. Subsequently the U.S. type of this lamp was used primarily for photographic work and for searchlights

Research in the use of rare gases for illumination purposes was continuous. In 1910 Georges Claude experimented with electric discharge tubes containing neon, argon, helium, krypton and xenon, and within a decade the neon sign industry had developed. The novel effects obtainable with neon tubes gave them wide use for advertising purposes, their extreme adaptability, high luminosity and brilliant colours making them particularly suitable in this field. Efficiency of light production by use of neon tubes was too low for general illumination, and none of the colours was satisfactory for interior lighting.

A promising source of illumination among electric discharge lamps was the high-intensity sodium-vapour lamp, although it was not satisfactory for commercial or domestic use because of its characteristic yellow colour. Major applications were for highway lighting and general outdoor lighting where colour rendition was not important; and by mid-20th century sodium-vapour lamps were being used for highway lighting and illumination of bridges and vehicular tunnels all over the world.

In 1934 the low-voltage fluorescent lamp was under development in the U.S. Fluorescent and phosphorescent phenomena had been recorded centuries earlier, and many scientists had worked on fluorescent sources. Offering a highly efficient low-power source in various colours, the fluorescent lamp afforded the nearest approach to "cold" light ever devised in practical form. Fluorescent lamps produce light not by heating a filament to incandescence but by fluorescence of certain chemicals when excited by ultraviolet energy.

The early fluorescent lamp consisted of a low-pressure mercury arc of about 15 w. in a cylindrical glass tube coated inside with mineral salts having fluorescent qualities (phosphors). The efficiency and colour of the light were determined by the vapour pressure and the particular chemicals used. Fluorescent lamps were introduced commercially in 1938, and their rapid application on a large scale marked a major development in the field of artificial illumination. In the following year numerous permanent installations were made, and general lighting by these lamps was completed in two large factories in the U.S. Fluorescent lighting was an integral part of the decorative scheme of the New York and San Francisco world's fairs in 1938 and 1939.

During the ensuing years research designed to improve fluorescent sources was carried on extensively, and low- and high-voltage fluorescent lighting found many new applications in interior lighting and luminous decorative design. The adoption of fluorescent lighting was relatively rapid for industrial plants, stores and offices, but not until 1942 was it used to any extent for home lighting, although many specialized applications had been made. In 1944 experimental installations of fluorescent lamps for street lighting were made, and many installations were made in subsequent years. Other developments included rapid-start lamps, which eliminated the disturbing initial flicker; dimming and flashing circuits for special applications; and high-frequency systems which eliminated the need for expensive lamp ballast units. Intensive efforts also were devoted toward increasing lamp efficiency and light output so that the number of lamps needed in a given installation could be reduced.

II. MODERN ELEGTRICAL LIGHT SOURCES

A. Arc Lamps

By mid-20th century the atmospheric arc lamp was used chiefly in large-wattage units for searchlights, for projections calling for a high intensity and concentrated source, and for other special applications requiring small but powerful sources of blue and ultraviolet energy. The colour of the arc light may be controlled to some extent by use of various materials in the electrodes.

Arc lamps may be classified as: (1) low-intensity arcs, using solid carbon or neutral-cored electrodes and producing light by the incandescence of the electrode; (2) flame arcs, using mineralized carbon electrodes and producing the light from a luminous arc with some incandescence at the electrode ends; (3) high-intensity arcs, where much of the light comes from the gaseous region immediately in front of the carbon.

When arc lamps operating at atmospheric pressure are operated in parallel, it is necessary to control the flow of current by a ballast or series inductance. Arcs have a negative volt-ampere characteristic and operate at voltages lower than the starting value. Arc lamps must be equipped with automatic mechanisms for starting the arc and adjusting the electrodes. The maximum brightness obtained depends upon the size of the carbons and operation of the arc, and brightnesses exceeding 1,300,000 candles per square inch have been recorded with high-intensity arcs. The carbon-arc lamp operates at an efficiency of from 40 to 65 lumens per watt (l.p.w.). The objectionable noise and unsteady operation of the earlier types were overcome. Special arc electrodes and construction are used for wave-length standard measurements, and the line at the red end of the cadmium arc (6432.5696 Å) has been so accurately measured that the standard of length could be reproduced by using this wave length as a base.

Low-intensity arcs are used for motion-picture projection, photoengraving illumination and other photochemical effects, therapy, ultraviolet irradiation, black-light effects, etc. Uses for the flame arc are related to the spectral characteristics which result from the electrode material used; for example, carbons cored with cerium compounds produce light closely approaching natural sunlight.

High-intensity arcs are widely used for searchlights and large area floodlights and for coloured motion-picture photography and projection. Properly positioned with respect to a large parabolic mirror, the high-intensity arc makes possible searchlights of very narrow beam spreads and intensities exceeding 1,000,000,000 cp.

B. Incandescent Lamps

Edison developed a 100-w. carbon-filament lamp having an efficiency of 1.6 l.p.w. and a life of 600 hr. This efficiency was sufficient for the early lamp to compete with existing flame sources, but within 50 years manufacturers were offering 100-w. lamps with an efficiency of 16.4 l.p.w. and a life of 750 hr.

1. Losses.—Losses in the incandescent lamp are caused by: (1) heat conduction by lead-in wires and filament supports; (2) heat conducted and convected to the gas of gas-filled lamps; (3) voltage loss in the leads; and (4) light absorption by the glass and the base. After lamps have been in service, the lamp produces less light because of (1) decreased power consumption as the filament becomes thinner because of tungsten evaporation and (2) bulb blackening. Higher-temperature filaments produce whiter light and increased efficiency lamps, and progress has been marked by increased filament temperatures. Drawn tungsten wire, because of its favourable radiating characteristics, low rate of evaporation, high melting point, high tensile strength and ductility, became the preferred material for lamp filaments. This metal is available in sufficient quantity for all lighting needs; filaments for 75,000 40-w. or 1,000 500-w., 115-v. lamps can be made from one pound. No readily available substance exists with the efficiency of tungsten for converting electrical energy into light with no reservations as to cost, manufacturing difficulties or other considerations. The introduction of automatic machines into the manufacture of incandescent lamps aided in the production of a superior, uniform lamp at a nominal cost; and the high quality of the lamp is maintained by rigid specifications and tests.

2. Gas-Filled and Vacuum Incandescent Lamps.—Air is exhausted from the lamps to eliminate oxygen, thereby preventing filament vaporization. Air seepage into an incandescent lamp causes rapid deterioration of the filament.

Attempts to introduce inert gases into the carbon lamp for increasing filament temperatures failed because the resultant losses by conduction neutralized filament temperature gains.

The first major improvement of the tungsten lamp was the introduction of an inert gas into the bulb. Nitrogen was first used because the rarer gases were too expensive to obtain; however, by improved processes enough argon became available so that the atmosphere surrounding the filament is composed of 88% argon and 12% nitrogen. Krypton has lower heat conductivity than either nitrogen or argon, but it is too scarce and expensive to be used generally. Because the gas used must be very pure and free from moisture, getters are used during lamp manufacture for removing harmful gases and water vapour.

Higher lamp efficiency can be obtained by increasing the size of the filament because the protective sheath of hot gas is of nearly constant thickness. Coiling the filament made gas-filled lamps practical, and the next step in reducing filament loss was an apparent increase in filament size produced in 1935 by winding the coiled filament around a mandrel. The coiled-coil filament thus formed had an additional 10% to 15% increase in efficiency.

Materials used for lead-ins and supports were improved and the number of supports reduced until end losses from these sources had been reduced to about 2%. Elimination of a support increased the efficiency approximately 0.5%. In the 40-w. lamp, supports were reduced from 11 in the vacuum tungsten lamp to 3 in the gas-filled lamp.

3. Mechanical Features.—The incandescent lamp is an assemblage of a mount, a glass bulb and a base. Standard-voltage lamps of 40 w. or larger contain gas which permits higher filament temperature and thus improved efficiency. The complete mount for a standard large lamp consists of: (1) the stem which carries the molybdenum support wires held in a glass button at the end of the stem; (2) the exhaust tube; (3) the tungsten filament; and (4) lead-in wires. In the press (the sealing point at which the wires pass through the glass) the lead-in wires are made of a nickel-iron core clad in copper, this combination having the same coefficient of expansion as glass; nickel lead-ins are used from the press to the filament, and copper from the press to the base. In some of the larger sizes a mica disk on the stem protects the stem press, stem and socket from the excessive temperature by retarding the circulation of hot gases from the filament when the lamp is burned base up. The base is used for the connection to the electrical circuit. To open the circuit and protect line fuses when the filament arcs, many sizes of lamps have a small fuse just outside the stem press on the mount.

The filaments are supported in many ways for various types of duty. The filament form determines the position in which the lamp may be burned and its resistance to vibration. The filament form also controls the incandescent plane important in projection service. The base of the lamp adapts it to the holder of the equipment, and is cemented except where greater strength and higher base temperatures require a mechanical base without cement. When the screw lacks carrying capacity in large lamps, it can be replaced by the bipost base which forms a pin-type positive connection and accurate location of the light source. In other cases when precise filament positioning is essential, prefocus bases are used so that lamps may be interchanged in an optical system with the filament remaining in the same place. Bayonet, disk and pin bases are used on smaller types and tubular lamps.

Many shapes and sizes of glass bulbs are employed, depending on the wattage and service intended. The bulbs may be clear, coloured, inside-frosted or coated with diffusing or reflecting materials.

4. Spectral Quality of the Incandescent Lamp.—The light emitted from the incandescent lamp is deficient in blue radiation and strong in the red, the exact distribution depending on filament temperature. If additional radiation is desired in the blue region. lamps are operated at voltages higher than normal, resulting in shorter lamp life. The enclosing bulb influences the spectral distribution, the daylight lamp using coloured glass for correcting this region (blue-green glass); this lowers lamp efficiency about 35% because of the light absorbed by the glass.

5. Other Factors Affecting Light Output.—The electrical frequency of the system supplying the incandescent lamp will influence its output. The light from a lamp filament varies as the current decreases from maximum to zero. This is noticeable at the lower frequencies, but invisible to the unaided eye for 60-cycle systems. The larger the lamp. the more carry-over there will be. A 40-w. lamp has 13% variation at 60 cycles, while a 500-w. lamp has only 2%, and the same sizes range from 29% to 6% with 25 cycles. Flicker in lighting will be noticed if a 3% change of voltage is applied for a two-cycle duration.

Lamps should be operated at the voltage for which they were designed. though at ordinary rates for electric energy the cost of producing light is often less if lamps are burned at increased voltage. A 10% increase of voltage gives the following results: watts 116%, lumen output 135% and considerably reduced lamp life. A 10% decrease of voltage causes an 85% wattage consumption, gives 71% of lumens and increased lamp life. The selection of rated life for a lamp is determined by a balance between lamp cost, power cost and cost of maintenance and overhead.

As the temperature of the filament was increased, lamp brightness was also increased, so the bulb of the lamp was given special treatment. Early enameling processes were inefficient and increased the collection of dirt. Inside frosting provided reasonable diffusing and reduced the light output less than 1%, compared with 5% to 20% for outside coatings. Later, silica coatings gave excellent diffusion mith virtually the same light output as with inside frosting.

A certain amount of blackening inside the bulb is inevitable and is removed in some of the high-intensity short-life lamps by sealing coarse tungsten powder inside the bulb. By shaking the lamp at intervals, the inside of the bulb can be scoured by the tungsten particles, increasing both the light output and useful life of the lamp. In some lamps the vaporized tungsten is removed by passing the hot gases, carrying the vapour from the filament through a screen above the filament.

C. Gaseous Vapour Lamps

1. Low-Pressure Mercury-Vapour Lamps.—The Cooper-Hewitt source was the first of the commercial low-pressure lamps. These have been built in zoo-w. to 1,600-w. sizes using mercury vapour at 1 to 2 mm. pressure and a mercury cathode. The tubes had a rated life of 4.000 hr., but poor colour characteristics. The tube operated on either A.C. or D.C., but auxiliary equipment was required for starting and operating. Few low-pressure Cooper-Hewitt lamps are still in service. An 85-w. Cooper-Hewitt fluorescent lamp which was introduced around 1938 used phosphors on the inner surface of the tubular bulb. Called the R.F. fluorescent lamp. it operated as a full-wave rectifier, giving no stroboscopic effect. R F. lamps are still being made, but largely for replacement purposes.

Much experimental work has been done in an effort to correct the poor colour quality of the mercury arc. The combination of Cooper-Hewitt tubes with incandescent lamps was an additive method of colour correction. Although this correction did not produce a colour-matching light, it did produce a soft white light which for a time found favour in commercial and industrial fields. For adaption to desired luminaire design, tubes were produced in straight, round and square forms mith a possibility of obtaining U and M tubes. Pleasing results were obtained with a ratio of 2 w. of incandescence to 1 w. of mercury-vapour light. The development of the fluorescent lamp with its excellent colour and light control possibilities superseded this more complex and expensive means of producing a pleasing colour quality in lighting.

2. High-Pressure **Mercury-Vapour** Lamps.—The radiation from a mercury arc changes with pressure, and ranges of pressure up to about 280 atm. have been investigated. At high pressures the spectral lines of mercury radiation are no longer sharp but are broadened, giving a background radiation. This broadening is greater toward the red end of the spectrum, which improves colour quality, although it still does not give a balanced spectrum.

One disadvantage of this source is that it requires a starting time ranging from a few seconds for one special 1,000-w. unit to approximately 7 min. for the 400-w. A-HI type. Any interruption requires a repetition of the starting cycle. Although efficient in itself, mercury lighting is often used in combination with incandescent lighting to ensure continuity of light and to correct the colour of the light source by additive means. The combination should be made on an equal-lumen basis between the high-pressure mercury and incandescent lamps.

Table I gives the characteristics of the general high-pressure mercury lamps a hich, besides being used for general lighting, have many special applications.

Table I.—Characteristics of General Service Higlz-Pressure Mercury-Vapour Lamps

watts	Lumens at 100 hr.	Lumens per watt*	Rated	Starting time (min.)	Restart time (min.)	Pressure (atmospheres)	Brightness (c./sq.mm.)
100	3,300	33	1,000	3	3	8	7
250	11,000	44	4,000	10	4		4.6
400	15,000	37	4,000	7	7	1.2	1.4
400	20,000	50	3,000	8	5		5.1
3,000	120,000	40	5,000	8	7	0.7	1,0

*Efficiency of the lamp only. To compare with the inrandescent lamp it is necessary to reduce the lumens per watt, because of transformer loss, approximately 20%.

†For five burning hours per start. In many cases rated life is increased for less frequent startings.

The 1,000-w. lamp with its quartz envelope enclosed in a water jacket is one of the brightest compact lighting units available. It is a relatively cool light because the heat is conveyed away by the circulating water. Initially there are 65,000 lumens or 65 l.p.w., and the rated life is 75 hr. It requires 4 sec. for starting and 2 sec. for a restart, and operates at 110 atm. with a brightness of 300 candles per square millimetre. The same lamp is rated at 900 w. when air-cooled.

3. Other Gaseous-Vapour Discharge Lamps.—In addition to the principal types of discharge lamps there is a subsidiary group of special lamps which includes photochemical, ozone, germicidal, black-light, glow and sunlight lamps, flash tubes and high-voltage neon lamps. The first four are not light sources, strictly speaking, although they do emit some visible light; however, they are produced by light-source manufacturers and are customarily installed by lighting engineers.

Photochemical Lamps.—The characteristic ultraviolet radiation of mercury-vapour discharges is useful for many photochemical processes, such as testing the fastness of dyes and the weathering of paints, water disinfection, photographic reproduction and ultraviolet therapy. Cylindrical mercury-vapour lamps, with walls of quartz or of glass especially compounded to transmit ultraviolet, are manufactured in sizes from a50 to 3,000 w. The quartz types emit energy below 2,800 Å, and the lamps must be shielded from the eyes. Photochemical lamps operate with ballasts similar to those employed with standard mercury-vapour types.

Ozone-Producing Lamps.—There are mercury-vapour lamps that consume 4 w. and operate at 10.5 v. The bulb of the lamp transmits radiation at 1.849 Å, producing ozone which eliminates odours by combining chemically with odorous constituents in the air.

Germicidal Lamps.—The radiation at 2,537 Å produced by this type of lon-pressure mercury-vapour lamp is the most effective in producing germicidal action.

LIGHTING FOR VARIOUS KINDS OF INTERIORS

1. Continuous rows on 10-ft. centres light a factory room. Each reflector contains two 40-w. fluorescent lamps mounted approximately 9½ ft. above the floor. Rows at right angles form a grid pattern, producing 80 foot-candles maintained in service on the work plane
2. Public-school classroom lighted with 72-in. fluorescent lamps located above metal louvers which extend from wall to wail. The illumination level is 60 foot-candles
3. Kindergarten room of an elementary school with two-lamp glass-covered troffers to provide 30-35 foot-candles in service. The artificial lighting supplements natural light entering through the glass blocks on both sides of the room
4. Recessed fluorescent units provide almost 50 foot-candles for a high-school gymnasium, with filament downlighting luminaires for additional light at the centre and at the baskets
5. Large louvered unit over the desk area of a private office. Twelve 96-in. fluorescent lamps on 8-in. centres produce 125 foot-candles, and cove elements on the side add to the general lighting of the office
6. Recessed troffers in continuous rows at right angles to the nominal direction of view deliver 60 foot-candles of lighting for a general office. Each troffer unit contains a single 40-w. fluorescent lamp

LIGHTING

MODERN LIGHTING **ARRANGEMENTS**

1. Shop windows lighted by 40-w. fluorescent and 150-w. integral-reflector lamps above louver grid ceilings, producing 750 foot-candies. The central panels are transilluminated with fluorescent lamps

2. Store interior using fluorescent- and filament-lamp general lighting of 40 foot-candles with showcases and wallcases illuminated bv built-in fluorescent lamps giving about 100 foot-candles. Filament lamps with integral reflectors provide higher brightness and colour patterns for featured displays

3. Louvered fluorescent luminaires containing 40-w. lamps furnish direct and indirect lighting for a library. The resultant illumination is 40 foot-candles in service

4. Single-lamp trough reflectors recessed in the ceiling of a bowling alley to provide about 15 foot-candles of illumination. Supplementary units over the pins give 60 foot-candles for good visibility

5. Television studio using adjustable fluorescent lighting units mounted on a trolley channel to supplement the general illumination produced by the luminaires recessed in the ceiling

6. Major league baseball at night, played under 780 1,500-w. floodlights mounted on 8 towers 150 ft. in height to provide intensity of 185 foot-candles on the infield, 120 on the outfield (Shibe park, Philadelphia, Pa.)

VARIOUS TYPES OF STANDARD LIGHTING UNITS

1. A porcelain enamel steel reflector known as the RLM Dome. Made to uniform minimum specifications by many manufacturers, it is of high-quality construction, has an efficiency of at least 70%, uses inside frosted or white bowl lamps preferably, and is usually mounted 9 to 12 ft. from the floor
2. The Glassteel Diffuser — similar to fig. 1 but producing a more diffused light as a result of the lamp-enclosing glass globe. Used at medium low mounting, for general industrial areas
3. An elliptical angle reflector used for lighting vertical and inclined surfaces, usually constructed of porcelain enamel steel. In general the above three industrial units are available for 100- to 1,000-w. lamps
4. Housing for a 150- or 300-w. integral-refiector lamp of the type widely used in store lighting
5. An open top luminous bowl unit for indirect lighting. The prevailing trend in office, school and similar commercial applications is toward semi-indirect and indirect units which can produce high intensities with minimum glare discomfort
6. One of many varieties of show window reflectors. Individual design is based on the aeneral proportions of show windows, with due consideration for both horizontal and vertical illumination
7. Luminaire for business and arterial streets
8. A special type of outdoor unit — an airport landing field floodlight whose output must be spread over large horizontal areas, usually employing 3,000- or 5,000-w. lamps
9. A typical commercial fluorescent lighting unit
10. A 3-lamp, 40-w. closed-end industrial fluorescent unit

BY COURTESY OF (1, 2, 6) LAMP DEPT., GENERAL ELECTRIC COMPANY, (3-5) WESTINGHOUSE ELECTRIC & MANUFACTURING COMPANY, LAMP DIVISION

MODERN HOME LIGHTING ARRANGEMENTS

1. Living room. The window valance uses one 20-w. and two 40-w. fluorescent lamps mounted on a channel behind the shielding strip. A 40-w. fluorescent lamp covered by a frosted glass panel is recessed in the mantel
2. The recessed box in the overhang (three 25-w. filament bulbs) is especially effective with this simple architectural treatment
3. A kitchen entirely lighted by fluorescent lamps. Sink, range and work counters are locally lighted. In the section over the sink two 30-w. fluorescent lamps are recessed and covered by glass. Under the front edge of the cabinets are single 15-w. fluorescent lamps
4. Across the top of the recess are two rows of three 30-w. fluorescent tubes covered by frosted glass and a valance of fabric. The niches are lighted by long, slender fluorescent tubes mounted vertically in the front and at the sides of each niche. These tubes are 42 in. long (approximately 25 w. each)
5. General lighting is produced from a continuous cove that conceals an unbroken line of fluorescent lamps (10 w. per running foot). The sectional davenport is backed by a fluorescent-lighted ledge
6. Ceiling luminaire for a dining room using a 150-w. integral-reflector lamp to send light directly down to the table area. Fluorescent lamps in the window valances supply general room illumination

Black-Light Lamps.—These emit radiation from 3,200 Å to 4,000 Å, beyond the visible range, that produces fluorescence in certain chemicals (see LUMINESCENCE). The lamps have been used in such divergent applications as advertising displays, theatrical productions, the identification of minerals, crime detection, medical and chemical research, and industrial inspection for quality control. Black-light lamps are available in all sizes in ahich mercury-vapour lamps radiating ultraviolet are made; however, the radiation from any mercury-vapour lamp can be used if a proper filter eliminates the visible light.

Glow Lamps.——Electrodes sealed in a small bulb filled with neon or argon gas produce lamps that will work on voltages as low as 60 D.C. or 42 A.C. The lamps are used as signal, pilot, indicator and night lights. They have a low current consumption and a life ranging from 3.000 to 25,000 hr.

Sunlight Lamps.——Mercury lamps equipped with special glass bulbs to transmit the middle ultraviolet energy generated by the vapour discharge are used to produce sun tan. Various types of mercury sun lamps are available; the most popular for home use is a 275-w. lamp with built-in reflector and self-contained filament ballast for operation on standard 110- to 125-v. X.C. circuits. More powerful sources of erythema-producing ultraviolet are employed for solaria and other specialized applications. Fluorescent sun lamps use phosphors which convert the resonant 2,537-Å energy generated in the arc to longer ultraviolet wave lengths.

Flash *Tubes.*—Straight or coiled sections of glass or quartz tubing, filled with a rare gas and discharged across capacitors, produce a brief flash of white light for high-speed photography. Xenon is the gas most frequently used. Voltages from 800 to several thousand are accumulated on the capacitors by a D.C. rectifier, and a high-voltage pulse initiates the brilliant flash which produces up to 90,000,000 peak lumens and lasts from $\frac{1}{1000}$ to $\frac{1}{1,000,000}$ sec. For ordinary operation a tube lasts thousands of flashes. The power supply depends on the size of the flash tube; several hundred pounds of equipment are necessary for the larger models, while portable lightweight power packs are available for the smaller flash tubes. With special auxiliary equipment, flash tubes can be flashed repeatedly, some at frequencies up to 30,000 per second.

High-Voltage Neon Lumps.—The neon lamp is associated with the cold-cathode group, with the luminescence produced by an electrical discharge through gases. These lamps are efficient when of considerable length and contain a high percentage of neon gas, giving the characteristic orange-red colour. To obtain other colours, mercury, argon, carbon dioxide and xenon are used, and coloured glass tubes are used in conjunction with the gases. The voltages range from 8,000 to 12.000 v. The operation of the high-voltage cold-cathode and the high-voltage hot-cathode fluorescent lamp is the same except at the cathodes, where the cold-cathode lamp has the higher voltage loss.

TABLE 11.—Comparative Data on Light Sources

Source	Candles per sq.in.	Lumens per watt	Luminous efficiency (%)
Sun	- -		16
Candle	3.5	0.1	
Kerosene flame	9.0	0.3	
Gas flame	2.7		
Acetylene flame	40	0.7	
Welsbach mantle	31		
Carbon arc	92×10^3	7	1.1
Flaming arc	5×10^3	17	2.7
Magnetite arc	4×10^3	90	14.5
Mercury arc	8×10^2	12.7	2.0
Cooper-Hewitt	20		
Cold-cathode			
Red	0.5		
Green	0.16		
Blue	0.1		
Hot-cathode, 40-w.			
Warm white	4.2	63	9.7
Daylight	3.5	53	
Soft white	2.9	44	
Carbonfilament	340	2.6	0.42
Gemfilament	615	4	
Nernst glower	1,660		
Tantalum filament	750		
Tungsten filament (vacuum)	1,328	10	1.6
Tungsten filament (gas!, 500-w.	7,500	19.8	3.2
Tungsten filament, coated lamp, 25-w.	11		
Tungsten filament, inside frost, 25-w.	22	10.5	1.69

Prior to the introduction of the fluorescent coating, sign tubing had little application for illumination purposes, its low lumen output being used for signs and to create luminous patterns. With mercury vapour and fluorescent coating, and depending on diameter, current rating and length, efficiencies approaching those of standard hot-cathode fluorescent lamps are obtainable. The units are from 4 to 10 ft. long and are connected in series to operate from 1,000- to 15,000-v. transformers.

D. FLUORESCENT LAMPS

The fluorescent lamp is a glass tube coated on the inside with a phosphor (fluorescent chemical) and filled with mercury vapour, with a small amount of argon to facilitate starting. After starting the current is carried essentially by the mercury vapour. The design adjustment is such that the desired resonant radiation of mercury at 2,537 Å is produced. Small coils of 'tungsten wire (electrodes) are sealed into each end and these filament cathodes are coated with an active electron-emissive material.

The ultraviolet radiated from the conducting mercury gas excites the phosphor which radiates light in the visible region. Different mixtures of the powders forming the phosphors control the colour of the emitted light. Most lamps are white when unlighted; the gold and red lamps have a pigment coating on the bulb interior to give the desired colours. In the 40-w. fluorescent lamp approximately 1% of the light is delivered directly by the mercury vapour. Of the input wattage 20.5% is converted into visible radiation, nearly three times that from the 40-w. incandescent lamp, which delivers only 7.4% of its wattage in the visible region.

1. Operation.— The operation of the preheat-start fluorescent lamp requires two switches, one for normal on-off switching of the primary power as in the incandescent lamp; and the other for closing the circuit on the cathodes for an instant. allowing the cathodes to preheat, then opening, producing an inductive voltage which causes the arc to strike.

In the typical circuit shown in fig. 1(A), the sockets hold the lamp; the ballast (a coil of wire wound on an iron core) furnishes the inductive "kick" to start the arc and limits the flow of current through the arc; and the filter reduces feedback into the electric supply circuit which may cause radio interference; the starter, wired across the lamp sockets (terminals T_1 and T_2), may be any of three types. The glow switch (fig. 1[B]) consists of a bulb containing neon or argon gas and a bimetallic switch element. When power is applied, the voltage is high across the terminals, and the glowing gas heats the bimetallic switch, closing it; this places the lamp cathodes into the circuit. heating them and reducing the voltage across the glow switch; the switch opens, and the inductive "kick" from the ballast strikes an arc through the lamp. The glow switch remains open while the lamp is in operation because the voltage across its terminals is too low to cause a glom.

The non-blink starter (fig. 1[C]) functions in much the same manner as the glow-switch starter except that an additional locking switch is provided; this removes the lamp from the circuit if it fails to function properly after a few attempts at starting. When the lamp is replaced, the starter may be returned to service by pressing the reset button, which protrudes through the end of its case.

The thermal-switch starter (fig. 1[D]) consists of a bimetallic switch, normally closed when power is off. In starting, a small heating element opens this switch after a brief period during which the lamp cathodes heat; the inductive "kick" from the ballast starts the lamp, and the operating current holds the switch open.

Circuits have been designed for the elimination of starter switches, which are always a source of operating trouble. Several standard sizes of hot-cathode fluorescent lamps are available for instant-start service without starters.

The fluorescent lamp has high efficiency, up to 73 l.p.w., but introduces several operating characteristics which necessitate a lighting installation less simple in theory and function than that

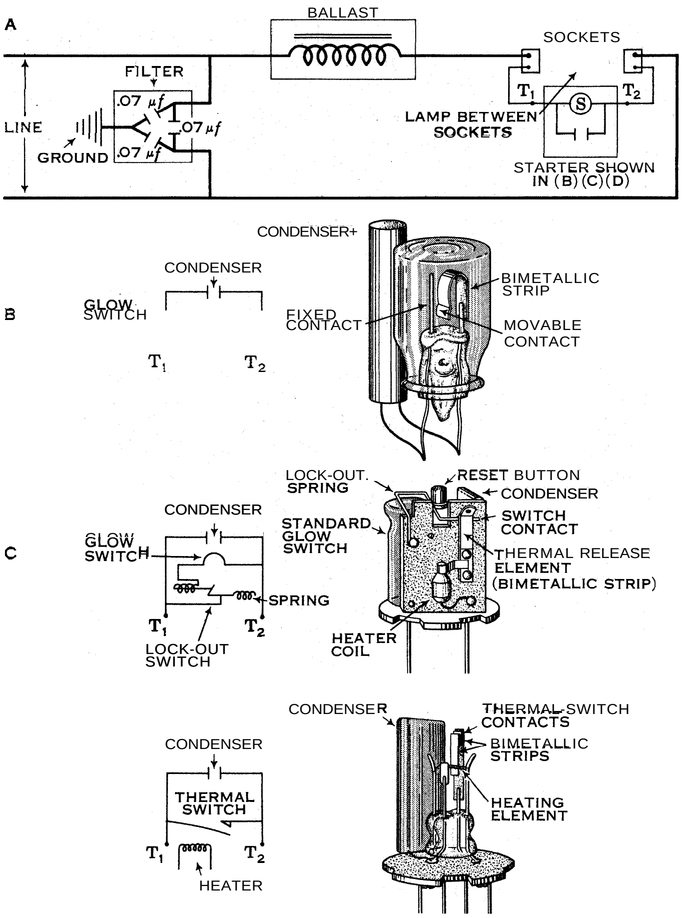

FIG. 1.— (A) DIAGRAM OF TYPICAL LAMP CIRCUIT, (B) GLOW-SWITCH STARTER. (C) NON-BLINK STARTER. (D) THERMAL-SWITCH STARTER (SEE TEXT)

needed for the incandescent lamp.

2. Characteristics.— Diameter and length of the fluorescent lamp depend upon several factors. Design has been centred about $\frac{5}{8}$-in., 1-in., $1\frac{1}{2}$-in. and $2\frac{1}{8}$-in. tubes for the lower voltages; and $\frac{3}{4}$-in., 1-in. and $1\frac{1}{2}$-in. tubes for instant starting at higher voltages. Long lamps are more efficient than short ones, other conditions being equal. The fluorescent lamp is more sensitive to surrounding temperature than the incandescent lamp; many sizes of fluorescent lamps generate light most efficiently when the surrounding air is 70° to 80° F. The lamp voltage divides between the electrode drop (12 to 18 v.) and the voltage gradient, which is the voltage per inch of tube required to neutralize the ions at the walls, plus the conversion of the energy into radiation. For preheated-cathode operation, the open-circuit voltage should be at least twice the lamp voltage. Somewhat higher ratios are required for instant-start lamps.

When a single lamp is being used, the stroboscopic effect caused by the vapour discharge being extinguished twice during each cycle is annoying in some operations. This may be eliminated by using two lamps in the same or adjacent luminaires, with the circuit so arranged that the lamps do not produce their minimum output at the same time. This effect is different from swirling, a type of lamp flicker which is also annoying. The swirl may appear in a new lamp or at any time in its life, but disappear as suddenly as it occurred.

The fluorescent lamp can be the cause of radio interference caused by direct radiation, radiation from the electric supply or feedback from the line. Proper filtering will minimize the last two causes, while removal of the radio from the field or proper screening will eliminate the first.

Failure of the lamp to function properly may lie within the lamp itself, in the auxiliary or in the starter. The safest rule to follow in correcting the fault is to eliminate by replacement with spare parts which should be available, in the order of starter, lamp, then ballast; but under no circumstances should the lamp be left in operation if trouble develops.

3. Economic Consideration.— Economic consideration of the fluorescent lamp requires a close study of the cost of both equipment and power. The first cost of fluorescent lamps is relatively high as compared with incandescent lamps of equivalent wattage, but their operating costs are relatively low for a given light output. Replacement of incandescent lamps by fluorescent lamps ordinarily gives two to four times as many lumens per watt.

Since fluorescent lighting systems create less heat, they are valuable in conjunction with modern air-conditioning systems and they are also of great usefulness where colour matching or coloured lighting is required.

Because of the various ways in which efficiencies may be stated, many claims have been made concerning fluorescent lamps, but it is necessary to include all the losses in the auxiliary with the lamp wattage to arrive at a correct evaluation. Brightness of the fluorescent lamp is much less than that of the incandescent lamp, but it is still so bright that neither the eye nor the work should be directly exposed to it.

TABLE III.—Characteristics of "Cool White" Fluorescent Lamps

Watts	Life (hr.)	Lumens	Length (in.)
For use with starters			
4	4,000	100	6
6	6,000	210	9
8	6,000	330	12
13	6,000	700	21
14	6,000	540	15
15	7,500	730	18
20	7,500	1,000	24
25	7,500	1,600	33
30	7,500	1,890	36

22	7,500	1,550	12" O.D.
40	7,500	2,200	16" O.D.

Any comparison of lighting systems must be on the basis of equal quality of lighting (see Table III).

III. ILLUMINATING ENGINEERING

In applying lighting to any task, consideration must be given to both the human and the mechanical elements involved. In the design of a lighting installation, the opinions and requirements of the eye specialist, the architect and the interior decorator must be considered, as well as the control and the amount of lighting. A successful lighting system must be a part of the building or activity for which it has been designed.

1. Measurement of Light.—Light is measured by its capacity to produce a sensation. The eye interprets this sensation in that region of the electromagnetic spectrum which extends from 7,600 Å to 3,800 A. The eye does not respond equally to the radiant energy in this octave, responding more efficiently to the green and yellow than to the reds, blues and violets. (See also VISION.)

There are three units of special importance in the application of lighting in practice: the lumen (unit of luminous flux). the foot-candle (ft.-c.) (one lumen incident per square foot) and brightness. Brightness is measured by foot-lamberts (ft.-L.) for surfaces of low intensity and by candles per square inch for sources of high intensity. In the metric system the corresponding units are the lux (one lumen incident per square metre), and the lambert (one lumen per square centimetre) for brightness. The lumen is used in lighting calculations, while field measurements are made of illumination (foot-candles) and brightness (ft.-L. or candles per square inch).

Illumination is measured by means of a light meter (foot-candle meter), usually of the photoelectric type.

Measurements of brightness are made with some form of brightness meter which the observer is required to adjust for photometric balance. In the past, average illumination was relied upon to a great extent, but the modern tendency is to give serious consideration to brightness, and future design will continue in this direction.

2. Lighting Environment. — The act of seeing depends upon visual acuity, the size of the object and its brightness, the contrast between object and background, and the length of time the object is exposed for viewing. The first essential to proper seeing conditions is that the eyes be corrected; the second essential is the proper amount and quality of lighting.

Period of Exposure. — If the object is large and long periods of time are allowed for exposure, the task can be adequately lighted with little illumination, but for small objects and short exposure periods, the illumination must be correspondingly increased. If the amount of illumination varies, the retina will still retain an image with no consciousness on the part of the observer that the lighting is not continuous if the flicker is rapid. Motion-picture projection bears witness to this fact. However, sudden changes of light at long intervals will cause blurring of moving objects, which becomes more pronounced at low foot-candle levels of illumination. The stroboscopic effect from fluorescent lamps and the 25-cycle flicker are examples of a lack of continuity of light.

Size of Object. — The size of an object establishes the lighting requirements. By size is meant visual size, which is a combination of dimensions of the smallest detail which must be observed and the distance of the object from the eye. More foot-candles are needed for smaller objects, all other factors being equal. The normal eye can distinguish any object which subtends an angle of 1′. This is an important factor in the design of signs which are to be seen from some distance.

Contrast. — An object is seen more clearly if background and object are of different colours. A white object against a black background can be more readily seen than a black object against a black background. This fact is utilized in industry to obtain contrast between the machine and its moving parts, the material being worked and the surround (visual field).

Brightness. — Brightness leads directly to the visibility of the object. A very dark object requires more foot-candles for illumination than one with a high reflection factor. For many years foot-candles of illumination were the index to lighting design and specifications, and failure to recognize the importance of reflection factor led to faulty lighting. More attention is being paid to the brightness of the task and its surroundings in design.

Glare. — When brightness becomes irritating it is recognized as glare. Glare contributes more to the poor quality of a lighting system than any other factor. Glare may depend upon several conditions present in the lighting system: (1) high brightness of the source; (2) high brightness contrast between the source and the background; (3) location of the source in the field of view; (4) the total volume of the light entering the eye; and (5) the time of exposure to the brightness source. The correction of any one of these contributing factors becomes simple when it is considered individually. Because of the injurious effect of glare, either direct as from a source, or reflected from some object which reflects a specular image, bare lamps exposed in any plane should never be used. It is of prime importance that all forms of glare be controlled properly.

Investigation and experience have established principles for studying the installation in order to control glare. These are not recommended as precise, but are suggestive of order of evaluation: (1) the light output of a source cannot be increased as fast as its area, but it is safe to increase the output as fast as the diameter; (2) increasing the foot-candles ten times in a room permits only doubling the brightness of the light source; (3) doubling the mounting height of a unit allows a lumen output of approximately three times that used previously; (4) brightness ratio of adjacent areas should be within limits of ten to one; (5) there should be more light on the work than at the eye; (6) each light in a row makes the same contribution to glare. All, these specifications are based on equal comfort from the lighting system.

Proper *Amount* of Lighting. — The severity of the task is the first index to the amount of light required. Lighting may be specified as: (1) For severe and prolonged tasks with details small, contrast low and speed of operation high, 100 ft.-c. or more should be used, best obtained by supplementary lighting. (2) For installations in which speed is not a factor and the object is small, 50 to 100 ft.-c. should be used, and again should be obtained by supplementary lighting. (3) For normal industrial and commercial tasks, 20 to 50 ft.-c. will suffice and may be supplied by a well-designed general lighting system; where economy is a factor supplementary lighting should be used. (4) For most recreational needs and ordinary tasks which are not prolonged throughout the working day, 10 to 20 ft.-c. from a general lighting system is satisfactory. (5) Where seeing is important but not prolonged, the contrast good, the object fairly large and the speed of movement slow, j to 10 ft.-c. from a general lighting system is specified. (6) Levels of less than 5 ft.-c. should be specified only for casual and nonhazardous passageways. This is obtainable with a relatively cheap general lighting installation, since for this use the quality of the lighting is of minor importance.

Considering the high foot-candle level to which the eye is accustomed out-of-doors, it is logical to believe that the eye will function best under high foot-candle levels of properly controlled light; that is, light in which quality of distribution approaches that of the out-of-doors. Control of the surround requires a reduction in the foot-candles. The spectral quality of the light source has no influence on seeing, although it does affect the psychological atmosphere; and modern light sources do not emit enough of the harmful wave lengths so that repeated exposures are injurious (this does not hold true, of course, for special lamps such as those emitting ultraviolet). As was the case with the incandescent lamp, the fluorescent lamp when first introduced drew accusations that its light injured the eyes, but any instances of injury or discomfort have been traceable directly to poorly designed lighting systems.

The craft of illuminating engineering has developed more on the basis of rising economic standards and increasing technical control of light than on the ability of the human eye to tolerate light. As methods of controlling light advanced and costs permitted, the amount of illumination has been increased, and successive recommendations of engineering societies have called for higher illumination values.

TABLE IV.—*Specifications for Lighting*[C]

Type of task	Brightness (in ft.-L.)	Foot-candles	
		60% Task reflectance	6% Task reflectance
Most difficult .	420 and up	700	7,000
very difficult .	120–420	200–700	2,000–7,000
Difficult . .	420–120	70–200	700–2,000
Ordinary . .	18–42	30–70	300–700
Easy . . .	18 and below	30 and below	300 and below

*Based on the research by H. Richard Blackwell, director, Vision Research laboratory, University of Michigan, Ann Arbor.

Research on "visual capacity," initiated in 1950 by H. Richard Blackwell of the University of Michigan, Ann Arbor, resulted in a series of 4-min. standard test objects of equivalent degrees of contrast. These equivalent contrast values, divided into five general levels of task difficulty and taking into account brightness and reflectance, lead to foot-candle specifications for any seeing task (see Table IV). The method offers a reliable gauge for determining the need for proper lighting, but this in turn must be adjusted to take account of control of the lighting and the economic feasibility of the required illumination.

Colouv *and Shadow.*—Colour and shadow are not necessarily factors in seeing but are of importance in recognition of objects. Colour must be treated carefully when used in conjunction nith light. If coloured light is used, white or neutral gray makes the best surround. With the incandescent lamp, usually considered as white light, the spectral distribution of the output must be considered when colours are to be extenuated or are to appear in their natural intensity.

Moods are suggested and depth perception is affected by colours. Although the lighting specialist is not to assume the functions of the artist or the decorator, it is necessary in the application of lighting to recognize the effect light has upon colour and atmosphere and to proceed accordingly.

Shadows may be either detrimental or helpful, depending upon the task to be performed. For decoration the shadow removes the monotony of a uniform lighting system and adds atmosphere to areas of relaxation, as in the home. In industry the shadow facilitates inspection tasks, emphasizes surfaces in relief and thereby improves visual conditions. Where there is moving machinery or the work lies within a single plane, shadow is detrimental both to safety and visibility. Small concentrated sources will produce harsh, severe shadows, while large area sources of low brightness will produce, for practical purposes, a shadowless surface. Between these two extremes are gradations adaptable to specific types of tasks. Shadow control on stair treads, at corners and on moving machine parts is an important application of light to safety.

Surround.—The surfaces which the eye encounters as relaxation areas from a severe task should be properly prepared and illuminated both for light reflection and psychological effect. Brightness of the surround should be at least 10% of the brightness of the task, although research has shown that, if it is feasible, the task and the surround should be equally bright.

Ceilings should have a reflection factor of 75% or more, and side walls of from 50% to 70%. Any trim above 30 in. from the floor may be as dark as desired up to a small percentage of the wall surface. The use of narm and cool colours in shades or tints makes little difference if the reflection factors are correct.

Factors Controlling Effectiveness of a Lighting System.—These factors should be considered carefully when analyzing a lighting system: (1) The quantity of light should be such as to produce a desired brightness for the severity of the task. (2) There should be no direct glare from the light source, and the reflected glare should be reduced to a minimum. This can be aided by selection of equipment and work surfaces producing no specular images. (3) Uniformity of the lighting should be controlled. For tasks in one plane, such as writing, drawing and reading, a shadow-free light is desirable. For tasks in three dimensions. such as relief work and inspection, a nonuniform light may be better. (4) Illumination of the surround is essential for the relief of eye strain by providing the proper atmosphere for eye relaxation.

The amount of illumination has been so strongly stressed that frequently quality of lighting is sacrificed by lack of consideration of the elements outside the brightness of the light falling on the task. A lower foot-candle level with proper control is better than a high foot-candle level improperly controlled.

3. Light Control.—Primitive light sources required no shielding, and there was no attempt to control artificial lighting until the 13th century, when mirrors were placed behind the Venetian stand lamp, the *lucerna*. In 1490 Leonardo da Vinci introduced control by refraction, and in 1745 polished metal reflectors were used in the *reverbere*. For the most part, however, control of light belongs to the 20th century.

Classes of Substances.—Transparent materials are not effective with modern light sources because the bare source has a brightness which must be controlled. Transparent material can be used nith lighting equipment having very low candle porer; however, this class of equipment is more for decorative effect than for lighting, and when used for lighting as well as decoration the quality of light is very poor.

Translucent materials are more widely used than any other light-control substance, and the introduction of plastics into this field in 1933 marked a new stage of light-control development. Translucent glasses of the denser types (opal and alabaster) are used for light backgrounds, while the configurated, decorated, structural and architectural glasses are used for decoration where atmosphere rather than illumination of a task is important. The flashed opal, cased, enameled and light opal glasses have a relatively high transmission and good diffusing qualities. These latter two classes of glass have been widely used in the better grade of lighting glassware and luminous elements.

Opaque materials are used primarily as reflectors and shields. Reflectors for beam control should have a high reflection factor, and usually some form of protected metal film or treated metal is used, silver and aluminum ranking high for this application. For industrial equipment, white enamel and paints on opaque surfaces give high reflection with reasonable maintenance and replacement.

Light-Beam *Control.*—There are three ways in which the light beam may be controlled: (1) reflection, (2) transmission and (3) refraction. The opaque materials are of the reflection type, and the translucent of the transmission type. Refraction is redirection of light caused by surface shape of the transmitting material. One of the most efficient means of control is by use of prisms, but control in one direction may cause bright spots in others, if not properly designed.

Nature of the Surface.—Light may be diffused by transmission or reflection from a surface, and diffused light is very acceptable for lighting purposes. Redirected light or even scattered light has its merits in the instance of the special reflector, but may cause specular images or highlights producing objectionable reflected glare. It is recommended that all lighted surfaces within the line of vision (walls and equipment) be of the diffusing type.

Optical *Control.*—Where accurate control of the light is desired, as in projectors or searchlights, optical reflectors or lenses may be used and for fine control these devices must be accurate. For automobile headlights and floodlights the control lenses and the reflectors may be made by molding the glass and drawing or spinning the metal.

Luminaire and Installation.—The design of the lighting equipment and the character of the room and cleanliness are controlling factors in lighting efficiency and light distribution.

Lighting equipment is classified into five groups, as shown in Table V.

TABLE V.—*Lighting Equipment*

Classification	Approximate light distribution	
	% Upward	% Downward
Direct	0–10	90–100
Semidirect	10–40	60–90
General diffusing	40–60	40–60
Semi-indirect	60–90	10–40
Indirect	90–100	0–10

The dimensions of the room and the colour of the ceiling and side walls, as well as the efficiency, depreciation and candle-power distribution of the equipment, control the output. In design the equipment is classified by a coefficient of performance (utilization factor) designating the control in the room of the light from the luminaire; and the coefficient of utilization, which includes the luminaire efficiency and therefore designates control from the lamp to the work surface. These coefficients may be determined accurately for specific equipment or may be grouped into classes for practical use.

Classification of Outdoor Equipment.—Lighting units for outdoor service are classified as floodlights when the area is not restricted in pattern. and may have broad. medium or narrow beams. The broad-beam equipment is used where the surface to be illuminated is in the immediate area; narrow-beam equipment is used for more distant areas. For a controlled beam the projector or searchlight is used, the first lacking the optical accuracy of the latter. Rotating or fixed equipments used for signal systems are classified as beacons.

4. Design **of** Lighting Installation. — There are two methods of lighting design. the point-by-point and the lumen. Each has its specific use, and the accuracy attained with each is satisfactory for practical purposes. The point-by-point method is used to determine the illumination at a point from a specific lighting equipment for which the distribution curve is known. Where there is no interreflection, the point-by-point method gi es the total illumination on the surface at the point; but in an enclosure interreflections will increase the illumination. The point-by-point method is accurate for outdoor lighting, for calculation and design of supplementary lighting and for down lights in interiors. The lumen method is satisfactory for determining the illumination within enclosures and is the procedure accepted in the designing of interior illumination. This is a method of determining average illumination and not specific illumination at a point. Although the method is relatively simple, it considers room proportions, col-

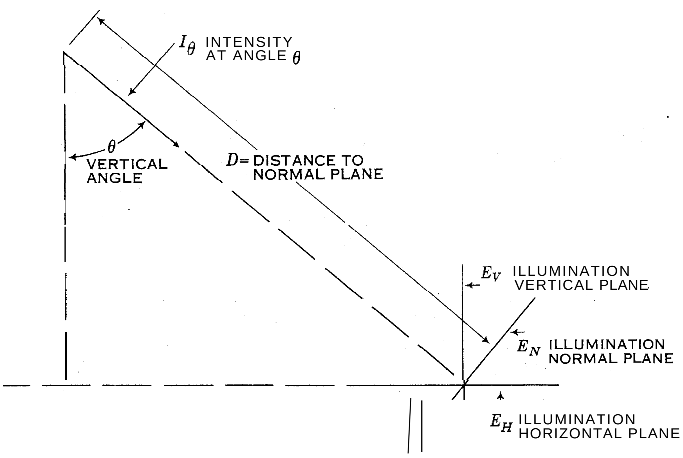

FIG. 2.— POINT-SOURCE ILLUMINATION CALCULATIONS

oration of the room, efficiency of the equipment, type of equipment to be installed and conditions contributing to the depreciation of the lighting system, such as operation and the presence of dirt. The method is based upon empirical data obtained by careful research into the actual performance of lighting systems in controlled installations.

Point-by-Point Method. — This method assumes that for actual conditions the source of light may be considered a point source when the illumination is to be determined on a surface that is at least five diameters from the light source.

The illumination on a point at a distance d from a source (fig. 2) is directly proportional to the intensity of the source and inversely to the square of the distance. This is the illumination on a surface normal to the incident beam of light. When the horizontal or the vertical illumination is desired, the illumination on the normal is corrected by the cosine of the vertical angle for the horizontal and by the sine of the vertical angle for the vertical illumination. Determination of the normal illumination (fig. 2)

$$E_N = \frac{I\theta}{d^2} \tag{1}$$

horizontal illumination,

$$E_H = E_N \cos\theta \tag{2}$$

vertical illumination,

$$E_V = E_N \sin\theta \tag{3}$$

Lumen Method. — The general expression for the determination of the necessary lamp size is:

Lumens per outlet =

$$\frac{\text{Area per outlet X foot-candles}}{\text{Efficiency X utilization factor X maintenance factor}} \tag{4}$$

The following steps are necessary in the logical solution of a specific determination:

1. Have a simple but complete sketch of the room to be lighted, with information as to its use, location and dimensions and any special information as to the placing of work surfaces and machines, with the bay dimensions of the ceiling pattern and the nature of any beam structures at the ceiling.

2. Determine the number of units and the spacing of the units. It is good practice to arrange the units symmetrically and to space the units at the corners of squares dividing the room into a symmetrical pattern. Where beams or other obstructions are present the pattern of outlet arrangement should conform to the general ceiling pattern. Outlet spacing should not exceed 1.5 times the mounting height above the work surface for units of the direct, semidirect and general diffusing type; and not more than twice the height of the ceiling above the work surface for the semi-indirect and indirect units. The spacing to the side wall should be approximately one-half the spacing between units. From the layout with the location of the lamps marked, it is possible to determine the area per outlet.

3. The amount of illumination must be determined for the specific task to be performed. The general requirements previously given will determine in general the foot-candles. To determine the best practice for an installation, reference should be made to the recommendations of engineering societies.

4. Equipment must be chosen for the particular task to be performed. In industrial installations the equipment must usually be relatively inexpensive and easy to clean, and will be of the direct or semidirect type, as the ceiling and walls cannot be expected to reflect much of the light. For commercial installations diffusing types are preferable. In either instance the more successful lighting is obtained where the light source is large and of low brightness. In the indirect system of lighting the ceiling acts as a reflector. Use of luminous elements and cove lighting attains lighting conditions similar to that of indirect lighting. The introduction of the fluorescent lamp requiring many tubes to obtain the desired foot-candles gives a light distribution comparable with an indirect lighting installation. The practice of using bare fluorescent lamps without proper light control will produce lighting with distressing glare while indirect lighting will not.

5. The efficiency and the utilization factor (or their product, the coefficient of utilization) must be determined for the type of equipment chosen. The room proportion, room coloration and type of equipment enter into this coefficient. The manufacturer of the equipment can supply this information for the specific equipment chosen, or values may be chosen for the general type, given in widely published tables. Considering the very light ceiling, and a fairly light side wall colouring, the utilization factors average approximately 0.5 for direct equipment, 0.3 for semi-indirect equipment and 0.25 for indirect equipment. High coefficients are associated with large and light rooms, and the lower coefficients with small and dark rooms. The over-all efficiency utilization factor of a lighting system is relatively poor.

6. The maintenance factor (one minus depreciation factor) is an estimate of the cleanliness of the location and the maintenance of the lighting system. This factor ranges from 60% in relatively poor conditions to as high as 75% under favourable conditions. Direct equipment will maintain better lighting under the adverse conditions of normal industrial usage than will the semi-indirect or indirect lighting systems, which are generally used for commercial purposes.

Having determined the quantities to substitute, the result given is the number of lumens required per outlet (equation 4). From manufacturer or laboratory data a lamp or a number of lamps may be selected which will most nearly approximate the required lumens. These lamps are rated in watts and should be so specified. Since the lumen output is constantly being changed in the manufacture of lamps, it is desirable to refer to the latest tables of lumen output.

The foregoing is applicable to the design for incandescent installations in which lamps in the larger sizes emit approximately 18 to 20 l.p.w.

Lumen Method and *Fluorescent Lighting* Design.—The only difference in applying equation (4) to fluorescent lamp installations is that the total area is used instead of the area per outlet, thereby determining the total number of lumens required in the lamp output. After the lamp has been selected, the number required is determined from the output of the individual lamps. Equipment to house the lamps and the arrangement of the lamps is then guided by the number of lamps needed. This design method is not as direct as for the incandescent system, and usually more trials will have to be made to get a satisfactory arrangement.

Design of *Luminous* Ceilings.—An important development of the 1950s was the introduction of glass and plastic luminous ceilings, either solid or louvered, with lighting sources above them. These simulate artificial skylights and, when properly designed and installed with correct baffling so as not to expose the eye to too large an expanse of lighted surface, represent the best in artificial lighting so far attained.

If a room is large and high, the illumination will be equivalent in value to the brightness of the lighting unit in foot-lamberts. Design of the lighting system embodies design of the light unit as well. The illumination obtained is expressed by:

$$\text{Foot-candles} = \frac{\text{Total lumens} \times \text{utilization factor} \times \text{maintenance factor}}{\text{Total room area}} \qquad (5)$$

The efficiency and the utilization factor are determined for a specific design, and the manufacturer has this information available. Spacing does not enter into the problem since the units are placed in the room either from wall to mall or with a border around the unit which is very narrow with respect to the total ceiling dimensions.

Either incandescent or fluorescent lamps may be used as a source to illuminate the ceiling. If the space above the ceiling is deep enough, the largest types of lighting units may be used, even industrial equipment with very large incandescent or fluorescent lamps.

Cove Lighting.—Where the lighting equipment is concealed by coves, with the ceiling and upper wall used as a luminous surface, the system may be designed by the lumen method. Good reflecting equipment will have an efficiency of approximately 70% while the cove itself may show efficiencies ranging from 25% to 40%. Recessed coves and coves close to the ceiling will have utilization factors of 0.35.

Coves placed too close to the ceiling will give an uneven illumination, a ratio of 1 ft. from the ceiling to every 5 ft. of lighted surface being the minimum that should be used. Plaster coves, finished with the wall and ceiling surface, are very inefficient and will give spotty lighting. The use of reflectors increases cove efficiency, and with the correct design the coves can be moved closer to the ceiling. Where control is obtained by use of some form of prismatic lens it is possible to mount the light source against the ceiling. Relief decorations must be crosslighted to eliminate undesirable shadows and produce uniform lighting.

Luminous Architectural Elements.—Luminous elements are applicable both to the exterior and interior of buildings. The term is applied to large, low-brightness lighting sources under which it is correct to consider all forms of indirect lighting as well as architectural elements. The correct application of this type of lighting demands close study, with consideration of the design of the structure as a whole. Luminous elements may take the form of panels, recesses, cavities, niches, pylons, columns, pilasters, parapets, spandrels, soffits, beams, coves, coffers or moldings, or may be incorporated into any architectural design. The light may be controlled by diffusing glass, reflectors, louvers or grillwork or by design of the element shape.

The lumen method is used in the design of the luminous element. Projecting elements have utilization factors of 0.5 and maintenance factors of 0.75, while the flush types have utilization factors of 0.7. Efficiency varies from 10% to 90% depending on the reflection material, the shape and the transmission mediums. In brightness the element should be so proportioned that when it is in direct exposure to the eye it does not exceed 75 ft.-L. If the element is on the ceiling and at such an angle as not to be directly exposed to the eye, a brightness of 500 ft.-L. is allowable. For exteriors the brightness depends upon the illumination of the surroundings and ranges from 30 to 400 it.-L, on buildings to as high as 600 ft.-L. in letter strokes for signs, on applications for which luminous elements are used extensively.

Glass blocks.—Used in structures for decorative purposes and lighting, glass blocks may be considered as luminous elements and must be so designed. The blocks will have transmission values ranging from 10% to 85%. Their obscuring value varies inversely as their efficiency. The transmission of an individual block cannot be considered, as the transmission value of a wall or surface built of glass blocks is largely controlled by the construction. These surfaces may be constructed for both daytime and night use. The lighting equipment must not interfere with light transmission during the day and must be so placed that the rudiments of good lighting are not violated.

It is commonly accepted by the lighting specialist that the providing of illumination is the least successful function performed by windows. Glass blocks allow light to enter but eliminate the normal view from the window. Sunlight falling upon glass blocks will produce a brightness surface which must be controlled, and the removal of a window which can be opened makes it necessary to remove the building heat by some other means. Consideration of glass walls or surfaces exposed to the outside requires careful co-ordination of functional design by the architect and the illuminating engineer.

Floodlighting—Floodlighting should be designed to produce an effective harmony with the object to be lighted. Daylight effect cannot be reproduced by floodlights, and the effect produced must be studied carefully. The simple straight lines of modern structures are excellent subjects for floodlighting. Statues and monuments should be lighted in collaboration with the artist, while recreational areas and sports fields should be lighted to satisfy the requirements of those participating in the particular sport.

In locating equipment, the surrounding buildings, topography, area to be lighted and economical aspects of the installation must be considered. If not located directly on the building to be illuminated, the equipment may be located on adjacent buildings, electric service poles, street lighting standards (for buildings not higher than three floors), in shrubbery or trees or on poles installed for the purpose. On the building itself, ledges, cornices and parapets will provide concealment. When sports areas, construction and airstrips are lighted it is usually necessary to supply towers, poles or special mounting elements.

For illumination at a distance, narro -beam equipment is used, ranging from searchlights with optical control to standard narrow-beam (15° or less) equipment. For near areas, broad-beam (30° and over) equipment is used. Intermediate ranges and surface areas may use medium-beam (16° to 29°) equipment. The lumen method of design is used for determination of the average illumination with a standard maintenance factor of 0.7 and the output is determined from the beam lumens of the equipment. Since little if any light can be obtained by interreflection, such light as does not strike the specific area to be illuminated is lost. There must be provision for control of the "spill light" which may become objectionable, and there must be about 10% overlapping of beam pattern so as to attain some degree of uniformity. Tables of recommended foot-candles should be used, and buildings with reflection factors of 20% or less will prove uneconomical to illuminate.

5. Operation and Maintenance of Lighting Systems.— The success of a lighting system depends upon selection of the proper installation and lighting source and upon maintenance. The lighting source should be the most economical, determined from first cost of the equipment, its installation and the power and labour costs in the community where the installation is to be made. Frequently there may be a choice of several schemes and systems which will be adequate and satisfactory as to lighting quality; and no general rule can be applied which definitely determines any combination as superior.

For "seeing," even the monochromatic lights seem to prove equally efficient and comfortable to users. Research has not been able to determine any one source quality which is superior to another for the usual seeing tasks. When colour matching is involved in production, daylight sources of artificial light have proved more satisfactory than natural daylight. No artificial source for ordinary lighting, either incandescent or fiuorescent, radiates wave lengths which under continued usage are harmful to the eyes; neither has it been found that any of these, including daylight sources, has superior qualities for seeing.

Lamp Selection.—The general service lamp, in the voltage rating of the electric system, satisfies the usual conditions. For severe tasks under conditions of vibration, heat, extremes of weather, and unusual position, the type of lamp designed for the particular service should be selected. Special usage lamps vary in their base construction, cementing and filament suspension.

Proper *Voltage.*—Since the electric lamp is critical to the applied voltage, to be efficient, lamps should be operated at their rated voltage. To maintain the voltage at the lamp it is necessary to install adequate wiring systems. The voltage at the lamp, when the system is fully loaded, should not deviate more than 2%. Wiring systems that are inadequate are expensive for reasons of output loss and extra losses in the wiring system. A 120-v. incandescent lamp burned at 11j v. gives only 86.4% of the normal lumen output and will be operating at 92.3% efficiency. The fluorescent lamp is even more critical to voltage change than the incandescent lamp, to the extent of becoming inoperative at incorrect voltages.

Maintenance.—From the first hour that a lighting system begins to operate it deteriorates through darkening of the lamp, dirt accumulation on the lighting equipment and general depreciation of the reflecting surfaces. When this depreciation of the system reduces the initial illumination about 30% it is necessary to consider some form of maintenance. The loss can be partially restored by renewing the darkened lamps, cleaning the equipment and, if these fail, by either washing or painting the reflecting surfaces. A schedule of washing equipment monthly and walls every two years (this requires painting every six years) is satisfactory in the average commercial installation. The installation must be designed so that maintenance is possible at low unit costs.

The "smashing point" of lamps, at which it is economical to replace the lamp even though it is still operative, is reached when the lumen output of the lamp has been reduced to the point at which the cost of energy consumed per 1,000,000 lumen-hours exceeds the average cost of light produced up to that time, including initial cost of lamp and energy.

Study has shown that the renovated lighting system could gain 12% by repainting of reflecting surfaces, 20% by cleaning and 19% by using new lamps with proper voltage ratings, a total of 51%.

IV. SPECIFIC LIGHTING APPLICATIONS

World-wide interest in artificial illumination gathered momentum with the beginning of the 20th century. Great expositions held in many parts of the world featured spectacular lighting, using the latest developments. Festivals of light were held in many cities. Widespread interest was shown in the psychological and physiological aspects of higher levels of illumination as related to human welfare, one evidence of this being the adoption in 1937 of a factories bill in England containing provisions for compulsory adoption of standards of lighting in all factories and workshops.

Artificial illumination has been accepted as an architectural medium, and lighting is no longer a thing of utility alone, but an intrinsic part of the architectural design of buildings. Specialized types of lighting for various industrial, agricultural and domestic fields have been investigated and adopted.

1. Home Lighting.—Entrance lighting should be such as to illuminate the person outside the door. The front entrance may have a bracket or soffit light which not only illuminates the entrance but contains an illuminated house number. Back entrances and grade entrances should be lighted along the same principles. The lighting should be such that all stairways and offsets in the approaches are illuminated for safety.

Hall lights should be simple in construction and properly selected to become a part of the passage area. Selection and location of equipment should be such that it is not unsightly from above if located where it can be seen from a stairway. The average hall can be adequately lighted with 40- to 80-w. equipment.

Living Room Lighting.—There should be a central fixture with 150 w. or more, and bracket lighting may be used for both decoration and useful lighting. Portable lamps usually make up a major portion of the working light, and floor types should have from 150 w. to 500 w., with table types using from 100 w. to 150 w. Built-in lighting may be used for lighting recesses or dark areas and if properly planned may reduce the need for portable lights. If there is more than one entrance to the room, lighting should be controlled from each entrance.

Dining *Room Lighting.*—The dining table being the centre of interest in this room, illumination of the table surface is the principal function of dining room lighting. When used for dining purposes only, little attention need be given to any requirements other than desires of the occupants, but it is often necessary that the dining room table serve as a study centre or work surface. When this is the case, illumination from either the centre fixtures or portable lamps must be increased and controlled for this purpose.

Choice of equipment for the dining room is similar to that for living rooms, and all outlet and switching requirements are the same. Suspended centre fixtures should be from 30 to 36 in. above the table top. Some form of "down lighting" should be used to illuminate the table when set. A minimum of 150 w. should be used in a central fixture.

Kitchen, Launduy, Workshop and *Garage Lighting.*—The utility areas need the illumination level specified for the difficulty of work to be performed in them. The equipment can be less decorative and less expensive, but it must have equal if not better lighting characteristics than for other areas of the home.

The kitchen should have a central light of 150 w. or more in incandescent lighting or equivalent light output from fluorescent lamps. Each of the work surfaces (stove, sink and counter surfaces) should be independently illuminated. A minimum of 40 w. each for these supplementary lights will usually prove satisfactory. Shadows caused by using a central fixture alone are annoying and may be dangerous.

In the laundry, direct lighting equipment is inexpensive and efficient. In the home workshop this same type of lighting, either incandescent or fluorescent, can be used over the workbench or where some constructive hobby is in progress. The garage, coal-storage area and furnace room each require adequate light, not so much for work purposes as for safety. There should be an outlet available for a portable lamp.

Bathrooms.—The important light centre in the bathroom is the mirror, which may be illuminated by an encircling light or by side brackets providing shadow-free light on the person reflected and not upon the mirror. Fluorescent lamps in the brackets distribute the light most evenly. The light in the bathroom should be controlled by a switch located away from any grounded plumbing or other grounded metallic conductor. For economy in the small bathroom, the bracket light may be the only one, but a ceiling light is desirable and in the large room it is essential. Ceiling lights of 100 w. and bracket lights of 60 w. for incandescent and 15–20 w. for fluorescent are satisfactory. If fluorescent lamps are used, the larger-diameter tubes are of a lower brightness and, therefore, better. Switches should be located at each door. An additional convenience is a night light which may be incorporated in the switch assembly or as an additional baseboard light.

Bedrooms.—Since the modern bedroom is frequently used for sewing, reading, writing and study purposes, as well as for sleeping, the lighting must be adapted to these various needs. A ceiling fixture with a relatively low brightness should be installed to reduce glare. This is particularly important for rooms to be occupied by children. For small rooms the ceiling fixture should use a 40-w. lamp and for large rooms 100 w. should be used. If all or part of the furniture is of the built-in type, lighting equipment may be incorporated in the design at a relatively low cost. Bracket lights for mirrors and dressing tables and trough lights for full-length mirrors are desirable. Supplementary lighting may be obtained by portable lamp stands or pin-up lamps installed over the bed, either of which should provide sufficient illumination for reading. Closets should have a simple but adequate lighting system, usually a bracket light with a pull-chain socket and a 60-w. lamp. Drop cords should not be used because of the danger of fire if clothes come in accidental contact with the lighted lamp. Door switches can be used for turning the light on and off.

2. School and Public Building Lighting. — Although children attend school during daylight hours, it is during the season of the year in which days are short and frequently cloudy, requiring additional artificial light to illuminate the desks farthest from the window to a minimum level, though not equal to that at the window. In sight-saving rooms, artificial illumination is necessary even on the brightest day to illuminate writing boards and desks more than ten feet from the window. In elementary grades the eyes are subjected to tasks incompatible with the natural accommodation of the eye. Poor lighting will influence the posture of the student, who seeks positions of least discomfort for the eyes and at the same time attempts to balance out strains upon body muscles. Every effort should be made to furnish the amount of illumination that is needed, the light being given off from the source and secondary surfaces in such a way as to eliminate all elements of discomfort. High levels of illumination without proper control are more detrimental than properly controlled low levels.

The amount of lighting should range from 50 ft.-c. for the sight-saving room (and in some instances for drafting rooms which are to be used for long periods) to 5 ft.-c. for passageways and locker rooms. The average classroom should have a minimum illumination of 30 ft.-c. For high over-all efficiencies ceilings should reflect 75% of the light and side walls 50% to 60%. Matte finishes should be used on all surfaces, and any glass doors, glass in picture frames or any other specular material should be eliminated to avoid reflection of images to any other position in the room. Desk tops and floors should have light, matte finishes.

Natural lighting seems essential in the school, not so much because of the light itself as for the psychological atmosphere which is created by windows. Orientation of the building controls the benefits to be obtained from the lighting. Orientation depends upon climatic and seasonal conditions, and no standard rules can be applied. Rooms with unilateral lighting are least difficult to control. Lighting should come from the left, rather than the right and front of the room. Window structures should be reduced to a minimum so as to avoid casting shadows. Even in corner rooms there is little value to windows in the rear of the room. The top of the window should be as near the ceiling as possible, not less than a distance above the floor equal to one-half the room width. To increase the glass area in a room it is better to add height than width. The glass area should be as large as possible, not less than 18% of the floor area when starting 3 ft. from the floor, or 16% when starting 4 ft. from the floor. These percentages are for rooms in which all glass area is exposed to the sky; if trees or buildings obscure the light, the glass area is increased proportionately.

Window light control must intercept the direct sunlight and diffuse it throughout the room, eliminate the glare from any exterior surfaces and control the relative illumination at different points in the room. The venetian blind, which may be classified as a louver control, may be used to deflect the light to the ceiling, thereby diffusing the light over the room, at the same time intercepting the direct or annoying reflected light from the outside. A double shade, drawing up and down from the centre of the window, is also employed as a light-control device. To use projection equipment the room may be darkened by a second set of dark shades running in light-sealing guides.

3. Office Lighting. — Severe and prolonged visual tasks in the office dictate the recommendation of 50 ft.-c. of illumination for auditing, accounting, operating business machines, transcribing, bookkeeping, drafting and designing. For general office work involving moderately fine detail, better contrast conditions and intermittent work periods, 30 ft.-c. is a satisfactory illumination level. In addition, careful attention should be given to lighting quality by reducing light source brightnesses in the direction of the eyes and minimizing brightness ratios in the field of view. Glossy work surfaces should be avoided, especially glass desk tops. Small area local lighting is often unsatisfactory because of the strong contrast produced in illumination. However, properly designed supplementary lighting can improve the visibility of operations at business machines.

Large or moderate-size general offices where workers are oriented in various directions require careful attention to minimize annoying direct glare. In general, the brightness of luminaires should not exceed 400 ft.-L. in the 45° zone below horizontal. Equipment with luminous glass or plastic sides should usually be oriented for endwise viewing. Recessed direct-lighting luminaires, called troffers, are frequently used for office lighting. For best appearance and comfort such luminaires should ordinarily be mounted for crosswise viewing of the rows. Suspended luminaires with opaque sides are also usually most comfortable when viewed crosswise and frequently have the best appearance when so oriented. Intermittent rows can be used to break up the "bowling alley" impression of long rows of luminaires, and lighting equipment sufficiently low in brightness can be arranged in rectangular and other patterns for added interest.

All office room surfaces should have light-coloured matte finishes to help minimize reflected glare and to provide the best environmental conditions. Desk tops should reflect 30%–35% of the light; ceilings 85%; walls 50%–60%; furniture 30%–35%; floor 20%–30%; and woodwork and trim 30%–35%.

4. Library Lighting. — The development of higher-efficiency lamps and improved luminaires for controlling and utilizing light started the trend toward adequate overhead general lighting of library reading rooms, rather than table lamps. The latter, however, may properly supplement general illumination to give added light at individual study tables where the occupancy is relatively infrequent. Such table lamps should be designed to minimize shadows and reflected glare. Book stacks have been successfully lighted with rows of concentrating louvered reflectors containing one-inch diameter fluorescent lamps. The reflector is slotted to emit light at the higher angles, thus providing good illumination for top shelves and good uniformity of lighting for the bottom shelves.

5. Retail Shop Lighting. — Lighting practice in shops and other merchandising interiors is based on the principle that the more customers see, the more they buy. The shopper is on a visual exploration trip through the store, and his attention is directed to objects of higher brightness. This concept calls for steps of brightness, using higher values for the most important sales areas or the particular featured displays which the merchant wishes the shopper to see.

Steps of brightness are ordinarily achieved by controlling the illumination level over specific areas of the store. For wide aisles, lobbies and other circulation areas, 15 to 30 ft.-c. are considered adequate. For general sales areas, 30 to 50 ft.-c. are prescribed. For displays in cases, on shelves and counters, 70 to 150 ft.-c. are recommended to draw attention to the merchandise, while 150 ft.-c. and more are employed for feature displays which stimulate impulse buying and influence circulation through the store.

Illumination for circulation and general sales areas is ordinarily provided by overhead general lighting systems. All types of luminaire distributions described previously are applicable for store lighting; and the lighting engineer can frequently orient such luminaires to influence the flow of traffic, fit the layout of the store equipment, increase apparent store dimensions and suit the unique architectural characteristics of the interior.

Treatment of the display window is an important phase of lighting for selling. Steps of brightness are appropriate, and both filament and fluorescent equipment are usually needed to secure these desirable brightness patterns. Wide use has been made of incandescent lamps with built-in reflectors for accenting featured items of merchandise.

6. Theatre Lighting. — The marquee which identifies the entrance often contains light sources to provide a high foot-candle level at the box office. The lobbies or passageways between the street and the foyer should have an illumination of 20 ft.-c. In the foyer an illumination level of ten foot-candles is considered adequate. This lower level helps make the adaptation to the relatively dark auditorium, where 0.1 ft.-c. is recommended during a performance. A brightness of approximately one foot-lambert on surfaces next to a motion-picture screen will add to the comfort conditions by relieving brightness contrast. The auditorium lighting equipment should be flexible enough to permit illumination levels in the order of five foot-candles during intermissions.

7. Church Lighting. — Illumination systems for church auditoriums should be keyed to both the architecture involved and the type of church service. An average in-service illumination level of five foot-candles is frequently recommended, with supplementary illumination on the pulpit or rostrum to focus attention during portions of the service. In many cases provision is made for switching or dimming the auditorium lighting systems. Local illumination is needed at the altar, and additional light on art glass windows will bring out their beauty and colour.

8. Industrial Lighting. — Good lighting in industry should correlate with plant safety, improved quality of product, increased production with decreased costs, better use of floor space, better seeing conditions for employees, more cleanliness and neatness, better supervision of the work and less eyestrain, and with a decrease of labour turnover because of improved morale.

Because it is necessary to see easily and accurately and often quickly, the glare, diffusion, direction and distribution of the light must be given special consideration and definitely controlled. Where severe tasks are performed or where economics does not justify a high level of illumination, extensive use must be made of supplementary light. Attention must be directed toward specular images and veiling glare. This must be controlled by using large low-brightness lighting equipment or systems.

Light colours will give high utilization factors, and painting of recessed work areas of machines will, by interreflection, illuminate details of the work. Use of colour contrast is an aid to speed and safety in production. For ceilings and side walls light colours should be used; for machines, a corresponding reflection factor in a contrasting colour, so that masses, either moving or stationary, can be recognized. White-reflecting surfaces should be used on all enclosures tending to cast a shadow on the task.

Recommended levels of illumination in industrial plants are based on the difficulty of specific visual tasks involved. The finest precision work involving poor contrast for long periods of time will call for 100 ft.-c. or more, while 30 ft.-c. are ordinarily prescribed for more ordinary seeing tasks involving only moderately fine details, normal contrasts and intermittent work periods. Other foot-candle levels between the values mentioned are appropriate for intermediate difficulty of the visual task. General lighting systems often used to attain 20 to 40 ft.-c. include industrial-type reflectors for fluorescent lamps, dome or diffuser-type incandescent luminaires and integral-reflector filament lamps. For 40 to 60 ft.-c., fluorescent lamp reflectors or high-bay luminaires employing filament lamps or combination filament-mercury systems are often employed. The method frequently used to obtain 60 to 100 ft.-c. of general lighting is a grid system of fluorescent lamp luminaires, where continuous rows of luminaires run in two directions. This latter technique minimizes annoying shadows and gives a pleasing appearance, and the relatively large-area, low-brightness luminaires provide good visibility for metal scales and machine-tool dials.

Where the seeing task requires more light than the overhead general illumination system provides, or if some directional quality is needed, supplementary lighting should be incorporated. Luminaires designed for this service are of two types: (1) those which supplement the general lighting in a limited area; and (2) the small concentrated units which direct light at a specific, difficult visual task. With either type, care should be exercised that bright work and dark surroundings do not produce discomfort through great contrast. Such brightness ratios should not exceed ten to one.

Natural lighting should be utilized to the greatest possible extent. Lighting from a window decreases very rapidly, the horizontal illumination falling from 200 ft.-c. near the window to 5 ft.-c. at 20 ft. from the window. Although windows present a surface of low brightness or are reduced to one of low brightness by controlling means, the extent of the surface in itself produces deleterious glare effects. A worker should never face directly into a window, because even a large low-brightness surface becomes annoying with time. Saw-tooth, monitor or skylight illumination in modern factory construction offers better light control than large glass side walls. Natural lighting should be considered in proportioning the room in factory design. If one wall contains windows, the room should have a depth perpendicular to this wall of less than twice the window height above the floor. When two parallel sides have windows, the room depth should not exceed six times the window height. Monitor window width should be one-half the monitor width. The height of the saw-tooth window should be one-third the span. As a general rule, window area should be approximately one-third the floor space.

When using natural lighting, glare from windows, as well as that produced by any object on the outside, must be controlled. Because daylight is so variable this lighting must be used in conjunction with proper arrangement and switching of artificial light. Photoelectric control of lighting circuits is desirable to maintain a minimum level of illumination at machines. When portions of the shop must be lighted by artificial lighting, and the remainder uses natural lighting, it is necessary to have the illumination in the artificially lighted area much brighter than normal night lighting because of excessive brightness contrast between the areas under the two arrangements. Industrial plants are being built without windows and operated entirely under artificial lighting with satisfactory results. Windows are not considered good lighting sources by illuminating engineers; however, windows have a psychological value.

9. Street Lighting. — Street lighting design should lead to recognition of the presence of an object and not necessarily to distinguishing fine details. Objects on the street or highway are discerned by silhouette when the illumination on the object is lower than the background, as when the object lies between two approaching cars; the reverse silhouette occurs when the object is more brightly lighted than the background, which requires relatively high illumination, usually in the vicinity of the lighting equipment. If details and colour of the object are discernible very high illumination is responsible. When the object emits specular light the visibility is caused by glint. Shadow and shadow pattern are important in recognition of the presence of an object. This effect depends upon the amount of relief and the angularity of the light.

Utilization and recognition of these factors are more important in adequate street lighting than production of the equivalent of daylight. The problem requires the best visibility consistent with a relative low cost per unit of light. Some traffic centres require more than usual visibility lighting, because of the presence or congregation of pedestrians. In these localities both the pedestrian and the driver must quickly discern objects with enough distance of visibility to react safely.

Equipment should direct the greater portion of the light toward the street, not skyward or into adjoining properties. Sufficient spill light should illuminate the sidewalk for protection and travel. There should be a proper adjustment between mounting height, spacing and lamp size. Mounting height may vary from 20 to 30 ft. and will depend upon glare, foliage interference and appearance. High mountings are associated with wider spacing and larger lamps, thereby reducing the first cost and operating cost. In residential districts, lower mounting heights, though not desirable, are used because of foliage. The spacing-mounting height ratio should not exceed eight to one. Lighting standards may be placed opposite one another or staggered on the two sides of the street: in alleys and outlying side streets, standards along one side of the street may be used. The equipment should either eliminate glare, or the time exposure to glare should be reduced to a minimum. Avoidance of pavement surfacing which does not reflect light mill aid street lighting; even black surfaces can be improved by correct top dressing.

Streets are classified according to the volume of maximum night traffic per hour (going both ways). Class divisions recommended are: (1) very light traffic, (2) light traffic, (3) medium traffic. (4) heavy traffic. (5) very heavy traffic and (6) heaviest traffic. ranging from 150 vehicles per hour and fewer to 4.000 per hour and more. The street illumination, for average values. ranges from 0.1 ft.-c. to 1.5 ft.-c. Business districts, street intersections, boulevards and park drives. alleys, bridges. traffic circles, tunnels and other unusual problems must be subjected to a detailed analysis and lighting specified to meet the needs. See also Index references under "Lighting" in vol. 24.

BIBLIOGRAPHY.—For information concerning past practice and later illumination techniques, consult the publications and periodicals of the American and British Illuminating Engineering societies. Illumination practice in the U.S. is summarized in the IES *Ligizting Handbook.* Detailed information can be found in: John O. Kraehenbuehl, *Electric Illumination,* 2nd ed. (1951) ; Howard M. Sharp, *Introduction* to *Lighting* (1951) ; C. L. Amick, *Fluorescent Lighting Manual,* 2nd ed. (1947) ; W. B. Boast, *Illuminating Engineering,* 2nd ed. (1953).

LIGHTNING. It is an accepted belief that lightning is a secondary phenomenon brought about by the abnormal meteorological conditions always associated with thunderstorms. However, lightning strokes have been observed on what appeared to be a clear day (giving rise to the expression "a bolt from the blue") and lightning also has been observed in connection with tornadoes, volcanic eruptions, dust storms and snowstorms. (See also THUNDER; THUNDERSTORM.)

This article, which deals with both the nature of lightning and protection against it, is divided into the following parts:

As one of the most impressive of natural phenomena. lightning has been not only a subject of scientific investigation but a source of fear, superstition and myth. Some of the nonscientific aspects of the subject may be found in the article LIGHTNING, FOLKLORE OF.

I. FORMS OF LIGHTNING

There are many forms of lightning. such as sheet, streak, bead, ribbon, forked, heat and globular (ball) lightning.

Sheet lightning, as the name implies, appears as a discharge over a considerable area, usually in clouds between the upper and

BY COURTESY OF U.S. WEATHER BUREAU

LIGHTNING FLASH AND SHEET LIGHTNING BEHIND DENSE CLOUDS

lower atmosphere. It is differentiated from the usual streak form by the area involved and its persistence. Little is known about this type of lightning discharge.

Streak lightning is the type normally observed and is the type dealt with by most investigators. The types called ribbon, bead. heat and forked lightning are probably of the same character. Such lightning strokes may or may not have branches and may occur between clouds. or between cloud and earth, or between a cloud and the surrounding atmosphere.

Bead lightning is seen in photographs as consisting of more or less regular increases and decreases in illumination along the stroke path. These may be related to the step leader mechanism. F. Wolf suggested that bead lightning is a special brush arc, the luminous masses of which develop from the centres of brush discharges resulting from a preceding lightning stroke. Such strokes are seen very infrequently.

Photographs have been taken with still cameras which show that the wind may blow the path of the lightning discharge along for distances of the order of 40 ft. or more. Such a stroke with several successive components gives an appearance in the photograph, or as observed visually, which has been called ribbon lightning.

Forked lightning is an apparent subdivision of the lightning into two or more simultaneous paths at the earth end. It is quite certain that in many such cases a change in path takes place between successive current peaks. This has been demonstrated photographically.

Heat lightning is the name often applied to streak lightning far enough away so that no thunder is heard.

Globular, or ball, lightning has been the subject of much discussion for many years. some maintaining that it was an optical illusion resulting from the retention of vision in the eye or the result of faulty observation; while others maintained that the rather considerable evidence on the part of many observers, some of whom certainly appeared to be well qualified, left no doubt as to the existence of ball lightning.

In 1924 and again in 1931 W. J. Humphreys published a request to those who had seen ball lightning to provide him with a detailed account of what they had seen. A total of 280 replies were received and studied by Humphreys, who stated in 1936 that not one was unmistakably "ball" lightning; *i.e.*, a slowly moving, more-or-less globular luminous mass, luminous because of its electrified condition. On the other hand, Walter Brand. in Germany. from 600 accounts of ball lightning selected 21 j which appeared to substantiate its existence. Ball lightning may be described as a luminous ball. often blood-red in colour. with an average diameter of 20 cm. When it emerges from the cloud traveling toward the earth, its velocity may he as high as roo m per second, while near the earth its velocity is much slower. being one to two metres per second. Usually. the ball explodes after an average life of 3 to 5 sec. F. Wolf suggested the possibility that ball lightning is the result of incomplete bead lightning associated with very small values of current.

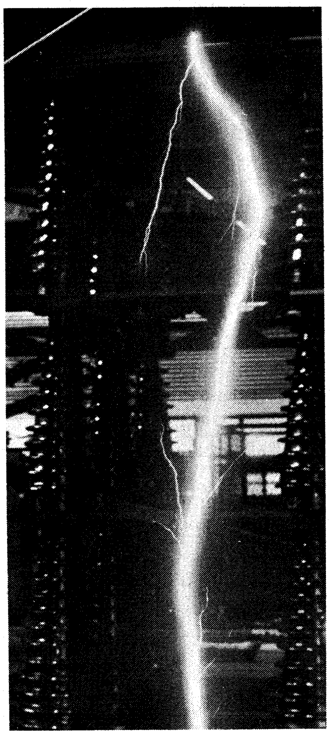
However, Wolf closed his discussion with the thought that the phenomenon is obscure and no really reliable explanation has been developed.

II. EFFECTS OF LIGHTNING

1. Thunder. — It is probable that thunder is caused largely, if not entirely, by a sudden increase in pressure as a result of heating, disassociation and ionization along the path of the lightning stroke. These pressure effects are well demonstrated in the blowing out of windows in buildings in which heavy discharges resulting from lightning take place. These pressure effects are commonly observed in connection with lightning damage to nonconductors. The multiplicity of current peaks, each producing its own pressure wave, coupled with the effect of length of stroke and reflections, all combine to produce the various sounds associated with thunder.

Several strokes of lightning were observed to the Washington monument, Washington, D.C., in April 1885, but no sound of thunder was heard. The same condition was observed in connection with strokes of lightning to the Empire State building in New York city, and it was concluded that with an upward initial leader stroke, not followed by downward leader current peaks, the rate of rise and decay of current may be slow enough so that the sound of thunder is not heard. On this basis thunderless strokes would occur only to tall structures.

Thunder is ordinarily heard only for distances of the order of about 15 to 18 mi. Gunfire can, of course, be heard under favourable conditions for much greater distances.



BY COURTESY OF GENERAL ELECTRIC COMPANY

ARTIFICIAL LIGHTNING PRODUCED IN A LABORATORY BY A DISCHARGE OF ABOUT 2,000,000 V.

2. Effect on Persons. — Persons struck by lightning have been revived by artificial respiration. It is worth pointing out that a person struck does not carry a charge, as many persons have thought, making it unsafe to touch him after he is struck by lightning. The usual result of being struck is electric shock or burns or both, and the usual first-aid measures should be applied. In the United States approximately 400 persons are killed each year by lightning, and an estimated 1,000 injured. The majority of these casualties are in the rural areas and small towns.

At times there have been reports of markings on the skin of persons struck which resemble trees or other objects. That the markings take such forms is the result of chance, and they merely represent the flow of current. That treelike burns are observed is not surprising, since it can be demonstrated in the laboratory that impulses similar to the wave shape of lightning currents will produce similar markings on sheets of insulating material over conducting material. To some degree this corresponds to the insulating properties of the skin over the conducting flesh underneath.

3. Effect on Aircraft. — The burns on planes indicate a preference for the flow of lightning current from wing tip to wing tip or from nose to tail. At times a stroke to a plane is preceded by long streamers from the nose. and fields have been sufficiently intense so that streamers have been observed across the windshield.

Based on evidence obtained from holes burned in the skin of planes it seems quite certain that strokes to planes are at times carried along by the plane for distances of the order of 200 to 300 ft. or even more. this being the distance the plane traveled while the stroke was in contact with the plane.

Aside from minor damage to the skin of metal planes, lightning may blind pilots for a brief period; magnetic effects may upset the compensation of magnetic compasses; and radio equipment may be damaged if not properly protected. Occupants of metal planes struck by lightning are seldom aware that the plane has been struck, and occasionally even pilots do not know the plane has been struck until ground inspection discloses the presence of surface burns. Strokes to planes are almost unknown at temperatures below 0° F., although E. J. Minser presented data which showed increased susceptibility to strokes at freezing temperatures and a few degrees above.

There is some accumulated evidence to indicate that as planes become larger and/or fly faster, the susceptibility to lightning strokes increases. Trailing antennas are sometimes destroyed by lightning, and their presence tends to increase the likelihood of a lightning stroke to the plane.

4. Damage Resulting from Lightning. — Lightning has a dual character since. as a rule, it consists of current peaks which may have a very high rate of current rise and current magnitude up to the order of 200,000 amp. (see *Occurrence* of *Lightning,* below); and, in the same stroke, currents as high as 500 amp. which may flow for fractional parts of seconds. The current peaks give rise to the explosive and magnetic effects, while the continuing current is largely responsible for the thermal effects. When conductors are carrying electricity, forces are developed because of the magnetic field which tend to crush the conductor. This has been termed the "pinch" effect. Lightning currents are often great enough to crush tubular conductors because of this effect.

Small conductors, such as radio aerials, may be completely destroyed by high lightning currents. In fact, no. 14 (American wire gauge) rubber-covered copper conductors have been changed into rubber tubes by the elimination of the conductor by a lightning discharge, without burning the rubber appreciably. These effects have been duplicated in the laboratory using high-current discharges of but a few microseconds duration.

Lightning current through nonconducting or semiconducting materials, such as stonemasonry or wood, gives rise to explosive effects.

The continuing current part of the stroke is normally responsible for fires caused by lightning, although of course if the material in the path of the stroke is highly combustible, fire may be caused by current peaks alone.

III. OCCURRENCE OF LIGHTNING

Nearly all theories of thunderstorms invoke some mechanism by which falling raindrops, snow or hail become charged in some manner with one sign of electricity. while the air and the smaller drops capable of being carried up by the rising columns of air associated with the storm are charged in the opposite sense. The separation of electricity proceeds until differences of potential are produced sufficient to result in a lightning stroke. *(See* ELECTRICITY. ATMOSPHERIC.)

Several theories have been advanced to account for the manner in which charges arise in thunderclouds. Perhaps the two most important were by C. T. R. Wilson and G. C. Simpson. Wilson's theory is based on the presence of large numbers of ions in the atmosphere coming in contact with drops of water polarized by the earth's electric field and in combination with the upward movement of air currents.

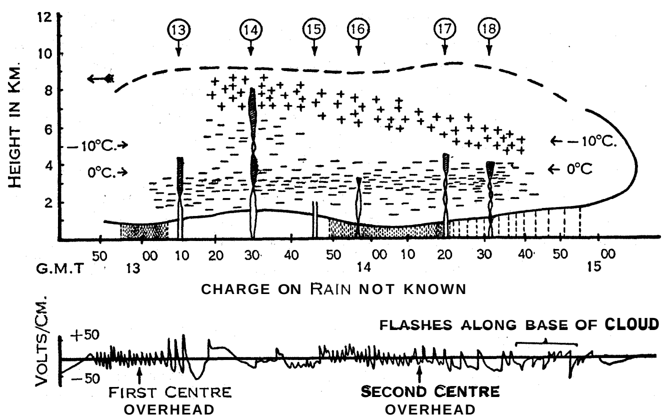
1. Wilson's Theory. — In each cubic centimetre of the atmosphere there are normally present about 1,000 positive and 800 negative small ions which have a mobility of about 1 cm. per second in a field of 1 v. per centimetre, together with 1,000 to 80,000 large ions of smaller mobility. According to Wilson, these ions are greatly increased in number by the strong electric fields attending a thunderstorm. The positive ions move toward the earth and the negative ions away from the earth, the velocities being dependent upon the field strength through which they are passing. For the electrification process to start, Wilson considered that the action of the earth's normal electric field polarizes the raindrops by induction, the lower side having a positive charge and the upper side a negative charge.

Drops falling toward the earth faster than the positive ions cannot be overtaken by them, and positive ions overtaken by the falling drops will be repelled from the lower surface. Such falling drops, however, will overtake and attract negative ions to the lower surface so that eventually the larger falling drops become negatively charged. The presence of these negatively charged drops in the lower regions of the cloud will add to the earth's field above them, increasing the polarization of drops above them and thus hastening the building up of electrical charges in the cloud. At the same time, drops moving more slowly than the positive ions will be overtaken by them, with the result that the drops become positively charged. Wilson suggested that the preponderance of positive rain may be explained on a similar basis, since the drop leaving the cloud would be in a more intense field because of the cloud, with the result that the lower side of the drop would be negative and would attract to itself positive ions, thus giving an indication of positive rain on the earth's surface.

2. Charges on Rain. — The first observations on the charge carried down by the rain were made by J. Elster and H. Geitel (1899) and by H. Gerdien (1903) and led to the coriclusion that more negative than positive electricity was precipitated by this cause. However, Simpson (1909) in a long series of measurements made at Simla, India, concluded that a much larger precipitation of positive than of negative occurs; and his conclusions were supported by many observers in various parts of the world. The currents carried to the ground by the rain are usually of the order of 10^{-12} amp. per square centimetre; and the amount of electricity per cubic centimetre of the precipitated water is usually less than one electrostatic unit.

3. Simpson's Theory. — Simpson's theory rests on the experimental fact that when falling drops of water are caused to break on a rising current of air, the water drops become positively charged, while the air becomes negatively charged. The negative charges are carried away by the velocity of the air current. The positively charged drops of water do not move away so easily, and the small drops recombine and fall back, only to be broken up again with a still higher positive charge. The air with its negative charges passes out into the main body of the cloud, which becomes negatively charged. In regions of the cloud where the vertical velocity exceeds 8 m. per second, no drops can fall and there will be no accumulation of electrical charge. This condition is presumed to exist in the front of the cloud.

Since many data have been obtained from many sources which agree that about 90% of the direct (cloud-to-ground) strokes are



SIMPSON AND SCRASE, "PROCEEDINGS," ROYAL SOCIETY OF LONDON (1937)

FIG. 1. — DISTRIBUTION OF CHARGES IN A THUNDERCLOUD AND ON RAIN WITH GRADIENTS AT GROUND SURFACE

Charts represent data collected during a violent thunderstorm which lasted nearly 2 hr. In the upper chart are shown the results of soundings numbered 13 to 18 made with balloons released at a fixed point. Records were obtained by using suitable instrumentation lowered to the earth by parachutes. Measurements of ground gradient shown in the lower chart began at 12:40 G.M.T. The large arrow (upper left) indicates the storm's travel past the observation point

from a negative cloud, Simpson and F. J. Scrase undertook to investigate the distribution of charge, using free balloons equipped to measure electrical gradient, relative humidity and atmospheric pressure. Temperatures were calculated from surface measurements. The results indicated that, typically, the thundercloud has most of its lower side negatively charged, the upper regions being positively charged, as shown in fig. 1.

Simpson and Scrase finally came to the conclusion that the boundary between the positive charge in the upper portion of the cloud and the negative in the lower portion is well below the freezing point and generally below $-10°$ C. In this part of the cloud would be ice crystals, to which Wilson's theory could not apply, according to Simpson and Scrase. As an example of somewhat similar conditions they pointed out that strong electrical fields had been found in polar regions resulting from blown snow; and Simpson suggested that the ice crystals become negatively charged and the air positively charged. Returning now to the cloud, the falling crystals leave the upper part positively charged, and the lower part negative. It is pointed out, however, that this theory has not been confirmed by satisfactory laboratory experiments. Simpson and Scrase suggested that there may be two mechanisms, one for the ice crystals and another for the part of a cloud where water drops are present.

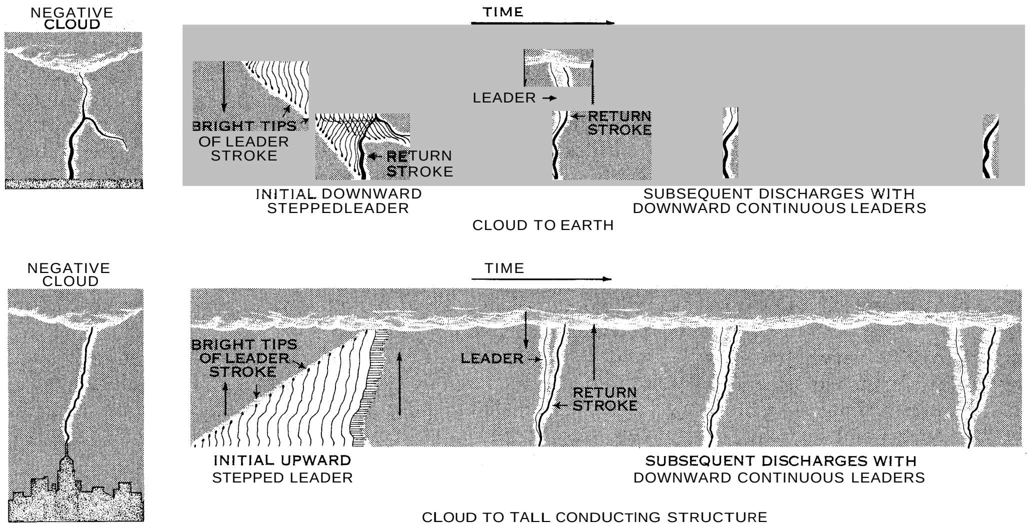
4. Mechanism of Lightning Discharge. — As the negative charge builds up in the lower portion of the cloud, positive charges appear on the earth's surface underneath by induction. As the charged clouds are blown along by the wind, the positive charges on the earth's surface move along in similar fashion. Since these positive charges are attracted to the negative charges in the cloud, they will move up any conducting or semiconducting object on the earth's surface, such as, for instance, transmission line towers, church steeples or trees, producing a corona discharge called St. Elmo's fire, providing the gradient is sufficiently high. However, St. Elmo's fire may be observed when thunderstorms are not present.

Cloud-to-Cloud Strokes. — Relatively little is known about cloud-to-cloud strokes since they result in very little damage to structures on the earth, although they also cause radio disturbance and may produce disturbances by induction in low-tension electrical systems because of the release of the so-called bound charge. Cloud-to-cloud strokes seem to have the same initial step leader mechanism but no return stroke. B. F. J. Schonland, S. J. Malan and H. Collens (1935), working in South Africa with the Boys camera (in which the film is moved rapidly with respect to the lens system), showed that cloud discharges to air which did not reach the earth took place; in which, in some cases, step-type leaders were photographed, while in others the continuous or dart-type leaders were observed. In neither case was a return stroke observed. In a study of cloud field changes reported in 1938, Schonland, Hodges and Collens identified pulsations of the same kind as found for step leaders with similar time intervals, the change of cloud field being a simple slow rise to its maximum value. Presumably these were air discharges or discharges within a cloud.

There is no reason to believe that cloud-to-cloud strokes will not have the same general mechanism. The progressive nature of cloud-to-cloud strokes is often slow enough to be plainly discernible to the eye.

There is no evidence to indicate that cloud-to-cloud strokes produce the high rates of current rise associated with cloud-to-earth strokes. The existence of thunder, however, indicates a rapid rate of rise, though no doubt one much slower than that found for current peaks in cloud-to-earth strokes. It is quite certain that airplanes are struck more often by cloud-to-cloud than cloud-to-earth strokes; and the nature of the burns on the metal skin of planes indicates the presence of the low-current-magnitude, long-time type of discharge. The maximum number of coulombs from such burns was estimated to be at least 300.

Cloud-to-Enrtlz Strokes.——Schonland and his associates found that the lightning stroke was initiated by a streamer which proceeded toward the earth in a series of steps. The process is illustrated in the upper part of fig. 2. The steps were about 50 m.



BY COURTESY OF GENERAL ELECTRIC COMPANY

FIG. 2.— MECHANISM OF TWO LIGHTNING DISCHARGES

From photographs by (left) still cameras and (right) high-speed Boys camera

in length with an average travel velocity of about 50 m. per microsecond (μ sec.). The average interval between each step was of the order of 50 μ sec., although a tendency for longer intervals was observed as the step leader approached the earth. The time required for this initial leader to reach the earth may be as great as 0.01 sec., although the time is usually much shorter, perhaps .002 sec.

The presence of a very brilliant illumination moving from the earth toward the cloud, through the channel established by the step leader, at a velocity of about 30 m. per microsecond. was shown on the photographic film as the lightning stroke reached the earth. A tendency was observed by Schonland for the illumination to decrease as the so-called return stroke approached the cloud. Successive current peaks, called a multiple stroke, may follow in the same path. These, however, are preceded by a continuous downward leader having a velocity of propagation of 1 to 23 m. per microsecond. These continuous leaders, upon making contact with the earth, are also followed by a return stroke having a velocity from 20 to 140 m. per microsecond. As many as 40 successive current peaks in one lightning stroke have been photographed.

Many strokes show branching, or what are sometimes called streamers. The Boys camera photographs show that such streamers are in general a part of the initial mechanism of choosing a path which is most attractive as viewed from the tip of the downward-moving leader; and that frequently more than one path appears sufficiently attractive to give rise to streamers. The successive current peaks, if-present, do not generally show the existence of the streamers, since the conduction established between the cloud and earth by the time the first successive current peak occurs is sufficient to preclude the continuance of such streamers.

By reference to the upper part of fig. 2 it will be noted that the streamer appearing in the still-camera photograph is not found to be associated with any of the current peaks except the first.

It has been suggested that the initial step leader is accompanied by a "pilot streamer" having a velocity of about 0.5 m. per microsecond. Its existence has not been shown photographically, the conclusion being held that the luminosity was too low to record its existence.

Earth-to-Cloud Strokes.— K. B. McEachron showed that approximately 80% of the lightning strokes to the Empire State building (1.250 ft. high) in New York city, were initiated by the building. as indicated in the lower part of fig. 2. The same step mechanism was photographed as already described, except that it began at the building and progressed to the cloud. with about the same velocities as already given for the cloud-initiated stroke. The upward leader stroke was not followed by a return stroke from the cloud, probably as the result of the low mobility of charges in the cloud compared to the conducting earth. which does produce the return stroke following contact by a downward leader. Instead, current of a low magnitude, perhaps a few hundred amperes. continues to flow; this may die out but is more often followed by one or more successive current peaks, as shown in fig. 2. These succeeding current peaks, as in the case of the cloud-initiated stroke, are preceded by the continuous downward leader and followed by the return stroke.

Continuing Current.— In many cases McEachron was able to obtain cathode-ray oscillograms of the current peaks in photographed strokes, as well as slow-speed oscillograms calibrated to record the continuing current between current peaks. For strokes to the Empire State building, the results indicate that current peaks are always connected with continuing current. G. D. McCann and J. J. Clark, on the other hand, indicate the possibility of the current's falling to zero between current peaks, the maximum time interval they recorded being 23,000 μ sec.

Stroke *Path*.—The path of the lightning stroke seems to be determined by conditions existing between the end of the downcoming initial leader at the end of each step and the surrounding atmosphere. The electrostatic field between the end of the leader and the earth follows smooth lines, but the path of the lightning stroke is very often crooked. The same observation may be made concerning man-made lightning discharges in the laboratory.

The lightning stroke mechanism is different from that in the laboratory, where a substantially uniform field may be obtained between spheres, or even with the nonuniform field between pointed electrodes spaced 1j or 20 ft. apart. However, under certain conditions it is possible to produce the leader mechanism with laboratory discharges of even shorter lengths than indicated.

Direction of Propagation— Clayden Effect.— The direction of branching of a lightning stroke is the direction of propagation of the initial step leader which makes possible the determination of direction of propagation from still-camera photographs of lightning. The evidence seems quite clear that with structures up to 200–300 ft. in height all strokes are cloud-initiated: but as the structure height increases the percentage of earth-initiated strokes will increase. Occasionally, photographs are taken in which the streatners or branches may appear black while the stroke itself appears normal. 'This is a photographic reversal called the Clayden effect and results from the different conditions of exposure for the main stroke compared to the streamers.

Source of Peak *Currents*.—Oscillographic data show that current peaks may rise to crest in times as short as one microsecond, nhich precludes the possibility of the sudden increase in current coming from the cloud because this time is much too short; rather the evidence, largely photographic. indicates that the downward initial leader from a negative cloud lays down a negative charge in the space surrounding the discharge channel as the leader approaches the earth.

The evidence further indicates that the stroke current builds up rapidly at the earth end because of the neutralization of the space charge surrounding the stroke channel when contact is made with the earth. Beginning at the ground end first. the space charge is neutralized progressively backward toward the cloud, giving rise to an increased luminosity traveling from the earth to the cloud, called the return stroke. It is believed that the return stroke constitutes the decreasing portion, or tail, of the current peak. The average time to decay to one-half of crest current is of the order of 40 μ sec., which is comparable to the time taken for the increase in luminosity to reach the cloud in many cases.

Just when the crest of a current peak is reached with relation to its life history in space is not known, but McEachron and W. A. McMorris suggested that it occurs at the moment of contact of downward leader and the earth, the front or rise of the current peak being the result of the flow of negative charges away from the point to be struck as the leader traverses the last few hundred feet of travel to the earth. However, C. E. R. Bruce and R. H. Golde believe that the peak current is too large to be accounted for in this manner and suggest that the crest current is not reached until after the return stroke has progressed a few hundred feet on its way toward the cloud.

The electric field at the earth's surface may be very intense, as shown by photographs taken showing upward-branched streamers from the earth's surface. That such streamers are not seen more frequently is not surprising, because the ground end of lightning strokes is seldom seen and much less frequently photographed; and in most cases the observer is too far away to obtain a proper record.

Cloud *Potential.*—It was suggested by C. F. Wagner and McCann that cloud potentials are of the order of 20,000,000 v., based on a gradient of 50 to 100 v. per centimetre shown by Simpson and Scrase in fig. 1, the calculation being made for a cloud height of 10,000 ft. Bruce suggested that no well-defined potential is necessary to initiate the self-propagating discharge; and indicated that in the case of lightning flashes to the Empire State building the average cloud-to-earth field is probably only of the order of 50 v. per centimetre.

5. Wave Shape of the Lightning **Stroke.**—Two methods of recording lightning current wave shapes have been used: (1) measuring the current directly as it flows through a structure struck by lightning using current- and time-recording equipment; and (2) measuring the current indirectly at a distance from the stroke through electromagnetic effects or optically. Practically all of the reliable data available have been obtained by the first method, although some work has been done using the second. Data concerning magnitude and polarity as functions of frequency of occurrence of strokes to transmission towers and conductors have been obtained in several locations throughout the world.

Direct measurements of the wave shape of the current peaks have been made using either a cathode-ray oscillograph or the fulchronograph (see below). In connection with the determination of electrical stresses within transformers because of lightning, it is generally necessary to be able to determine the rate of rise of current for times at least as short as one microsecond and to record the current flow for times at least as long as 70–100 μ sec., or at least to half current value for most strokes.

This mas accomplished by McEachron for strokes to the Empire State building and by I. S. Stekolnikov and C. Valeev for strokes to captive balloons in the U.S.S.R., using cathode-ray oscillographs. In addition, McEachron provided a "crater lamp" oscillograph capable of being initiated within 20 μ sec. and of recording over a second of time or even longer. Such dual recording is necessary because of the nature of the lightning stroke; *i.e.,* because it consists of long-time low-current components and short-time current peaks which may have a high magnitude. Using a special nonlinear resistance shunt, a current range from 50 to 100,000 amp. could be recorded.

The fulchronograph described by Wagner, McCann and E. Beck depends for its operation upon permanently magnetizing a series of small steel strips to a degree proportional to the lightning current flowing at the instant the particular strip is rotated into the field of the magnetizing coils. As used, 408 steel strips mounted in the periphery of an aluminum wheel are rotated between narrow coils through which the lightning current to be measured is passed. The "high speed" and "low speed" fulchronographs, with wheels revolving at 3,450 r.p.m. and 60 r.p.m., respectively, give values of current based on measurement of the residual flux, thus giving current values at time intervals of 43 μ sec. and .0025 sec., respectively. Such a measuring means is too slow to record the rapid rise of current in the front of a current peak; and thus the fulchronograph is supplemented by making use of circuits in which inductance or capacitance is used in combination with resistance, so that the maximum current flowing in the circuit bears a calculable relation to the rate of current rise of the lightning current peak. This maximum current leaves a record of its magnitude by the degree of magnetization remaining in cobalt steel strips properly associated with the current-carrying conductors.

Such steel strips with proper mounting are frequently called magnetic links. Although the fulchronograph does not give such complete information as the cathode-ray oscillograph, it has the advantage of much lower cost; so a much greater volume of data may be obtained in a given period of time for a given cost of instrumentation.

6. Crest Current.—Typical of the data obtained using the magnetic link described by C. M. Foust and J. T. Henderson is the group of curves shown in fig. 3. The magnetic links are arranged on the electric power transmission towers in such fashion that

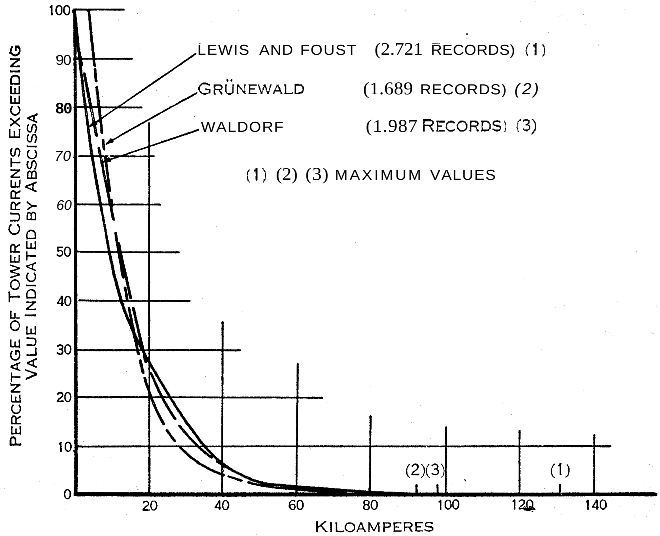


FIG. 3.— LIGHTNINGCURRENTS IN TRANSMISSION LINE TOWERS AS MEASURED WITH MAGNETIC LINKS

they are permanently magnetized by the passage of the lightning current through the associated tower leg or legs.

Although the results obtained between 1936 and 1944 indicated close agreement, lightning investigations conducted after 1954 indicate that they may be in error and probably are on the low side.

The curves showing tower currents which may be expected are very essential data to be used in connection nith the design of electric power transmission lines. in determining the number of insulators and the tower footing resistance, if overhead ground wires are to be used for the protection of the line against lightning. To determine the stroke current from the tower leg measurements, the tower currents nhich are believed to have occurred in the various towers during the same stroke are added together to secure a value for the stroke current.

The magnetic link data cannot give any information concerning individual current peaks making up the entire stroke except to indicate the maximum peak; however, the cathode-ray oscillograph and the fulchronograph do give detailed data concerning the current peaks and the entire stroke. In general, the values obtained by oscillograph and fulchronograph for peak currents to high structures are less than the transmission line tower data of fig. 3. The differences may be accountable partly to the effect of the taller structures and partly to the relatively small amount of oscillograph and fulchronograph data.

IV. DATA ON LIGHTNING DISCHARGES

1. Duration of the **Total** Stroke.—There is wide variation in the results given in fig. 4 by the various investigators, which is no doubt partly explained by differences in equipment used. Most of the data were obtained photographically, such results being

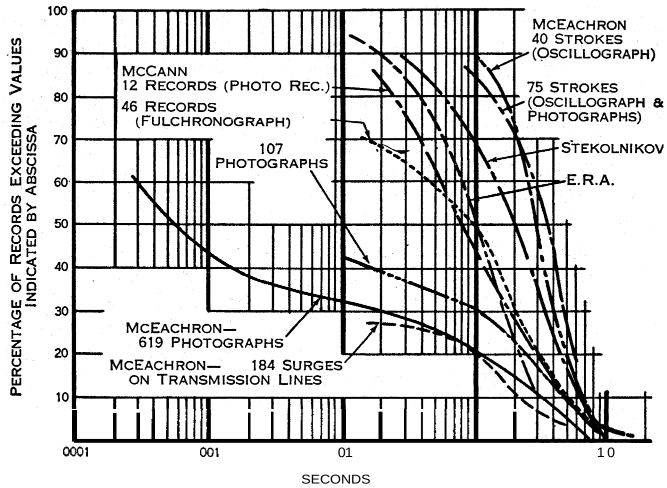

FIG. 4.— TOTAL DURATION OF LIGHTNING STROKES TO GROUND
(All photographs are of strokes to open ground)

greatly affected by lens and film speed, distance to the stroke and visibility. The Empire State building data (McEachron), taken oscillographically, showed a minimum duration of 0.1 sec. and a maximum of 1.6 sec.

The shortest duration was .0003 sec. which was obtained photographically at Pittsfield, Mass. The bulk of the data seemed to indicate an average duration of perhaps .01 sec.

2. Charge of the Total Stroke.— The data presented in fig. 5 are confined to measurements made on the stroke itself, the current and time being measured by fulchronograph or oscillograph. The maximum number of coulombs measured was 165, with an indicatedaverage of about 18 coulombs. It should be remembered that these values were measured in strokes to relatively tall structures and indicate the charge at the ground end of the stroke. Bruce and Golde pointed out that for the upward leader type of stroke the space charge neutralized by the current in the stroke is added to the charge in the cloud; while with the downward leader type the neutralized space charge is subtracted from the cloud charge. This is of some importance when considering the change in cloud charge as the result of direct strokes. However, the difference occurs only on the initial leader, since, as can be noted from fig. z, all leaders after the initial one are downward, whether to a tall structure or to ordinary terrain. Wagner and McCann suggested that lower coulomb values may be found to structures of lower height, which in general agrees with Bruce and Golde. However, as pointed out by the latter, the upward initial leaders

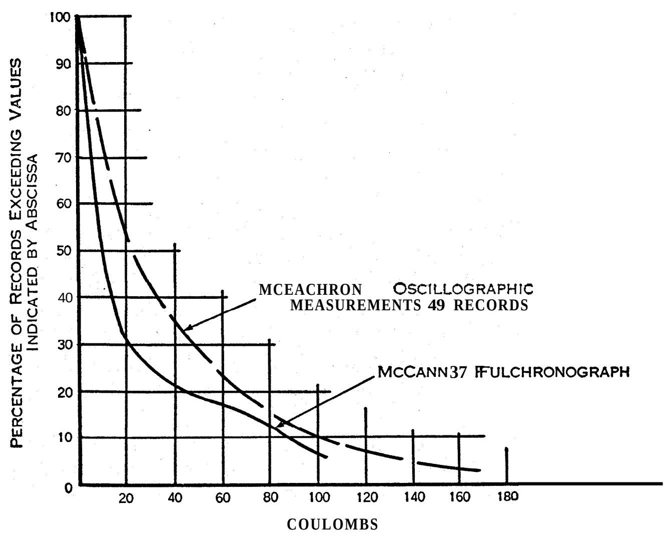

FIG. 5.— TOTAL STROKE CHARGES MEASURED AT THE GROUND TERMINAL OF LIGHTNING STROKES

for strokes to the Empire State building suggest that the distortion of the field caused by the building was sufficient to trip off the flash before it would have occurred to ordinary terrain, so that the charge might be expected to be smaller and not greater than in the normal case.

3. Polarity.— It has already been pointed out that strokes predominantly bring down negative charges to the earth. W. W. Lewis and Foust found that 93% of their records of strokes to transmission lines were negative polarity, while S. K. Waldorf and H. Grunewald found in transmission towers 82% and 86%, respectively. McEachron and McMorris found 63% of distribution lightning arrester current negative; and I. W. Gross and McMorris reported 88% negative for station lightning arresters applied to transmission lines. These results seemed to indicate a higher percentage of positive polarity as the current values became smaller, which might not be entirely an indication of positive current peaks in the stroke, but rather of induced currents resulting from the release of bound charges on the lines resulting from sudden changes of negative cloud fields. Thus, a negative stroke to some other point than the line involved would be registered as a positive record on the line being studied. This means that the percentage of negative strokes was probably higher than the direct measurements indicated.

Since all of the data on which the preceding statement was based were taken with the magnetic link, the presence of more than one polarity in the current would not necessarily be recorded.

Of the 49 strokes recorded oscillographically to the Empire State building during the years 1937–40, 84% were entirely negative; but no stroke was entirely positive. Of the eight strokes having positive current peaks, four are known to have begun negative; two others probably did; and of the remaining two, one, which had a positive peak of 58,000 amp. followed by three negative peaks, lacked definite information as to the beginning polarity. Wagner, McCann and Beck, using the fulchronograph, recorded 12 direct strokes, all initiated by negative discharges, but two had subsequent positive current peaks. Thus, current peaks of both polarities are occasionally present with a strong tendency for such strokes to begin negative.

As the stroke progresses backward into the cloud, successive centres of charge are tapped. As a rule these are all negative, but the data just presented show that occasionally positive centres of charge are reached, as indicated by the polarity changes recorded. Thus, the current-time record supplies data concerning the electrical structure of the cloud.

4. Diameter of the Lightning Channel.— Data on the diameter of the stroke channel have been obtained photographically and by measuring holes made in paper under controlled conditions. Data of this type have been obtained in the field with natural lightning and in the laboratory.

According to J. W. Flowers the light emitted and the current flow may not necessarily coincide in time, and the light may persist for times of the order of 10 μ sec. The start of light emission and the start of current flow are not separated by more than a few one-hundredths of a microsecond. Thus, for discharge currents in sparks or lightning channels which do not vary too rapidly, the distribution of the radiated light reveals the discharge channel. Flowers further states that the light radiation is proportional to the current in the channel; and suitable photographic methods of determining channel boundary indicate that the channel attempts to attain a constant value of about 1,000 amp. per square centimetre, provided the current is maintained for a sufficient time. According to Flowers, when the current is increasing rapidly the current density is greater and the channel expands at an explosive rate.

On this basis, if the current persists at 10,000 amp. for 100 μ sec. the channel diameter would be about 3 cm. Flowers suggested that 3–5 cm. may be about the maximum diameter attained.

From an analysis of a photograph of a multiple-lightning stroke, Schonland measured the diameter for 11 components and obtained an average of about 16-cm. diameter, with a range from 11 to 23 cm. P. L. Bellaschi, on the other hand, measured in the laboratory a column of 10 to 15 cm. in diameter for a 140,000-amp.

discharge. This checks Flowers' value of 1,000 amp. per square centimetre assuming that the discharge lasted long enough. However, this is not likely for such a high current peak in a natural lightning discharge.

V. PROTECTION AGAINST LIGHTNING

A. Protection of Structures

Protection of ordinary buildings from direct strokes of lightning is generally accomplished through the use of the lightning rod system originally developed by Benjamin Franklin. Essentially, such a system consists of pointed air terminals mounted on the ridge of gable roofs or around the edge of flat roofs and on chimneys and other elevated places likely to be struck, and connected together and grounded (in British usage, earthed) in such a fashion that lightning making contact with any of the air terminals will be safely conducted to the earth without damage to the structure.

Contrary to popular belief, lightning rods do not act to prevent lightning strokes but rather exert a local influence to direct strokes to the air terminals and thence safely to the earth. The "Code for Protection Against Lightning" (which is the United States bureau of standards *Handbook H-46* and which will hereinafter be referred to as the U.S. code) states that the separation between air terminals should not be more than 25 ft. and that the height of the air terminal need not be more than 10 in. above the object to be protected. The air terminals may be somewhat higher in the case of the flat roof.

The U.S. code also specifies that not less than two down conductors should be used, and that they should be connected to the earth at points as widely spaced as possible. If the building is longer than 110 ft., an additional down conductor is to be used for each additional 50 ft, in length.

The U.S. code states that lightning rods may be made of copper, corrosion-resistant alloys, copper-clad steel and galvanized steel. Conductors may be in the form of cable, tube, strip, rod or other shape of solid cross section. As to size, copper cable conductors should weigh not less than 187.j lb. per 1,000 ft., no wire of the cable being less than no. 17 (American wire gauge); if copper tubing is used, the wall thickness should not be less than no. 20. If galvanized steel is used, the net weight of steel is not to be less than 320 lb. per 1,000 ft.

It is important that all fastenings be secure and permanent in character. It is not necessary that lightning conductors be insulated from the building to which they are attached; in fact, lightning conductors are sometimes carried through walls or partitions; however, from the point of view of inspection there is advantage in having such conductors exposed.

Joints are of particular importance since they need to be made mechanically and electrically secure. Poor joints can be a source of sparks, and occasional inspection of the entire system is desirable to be sure that it is in good condition. Suitable precautions should be used, such as lead covering, where conductors or air terminals are likely to be subject to corrosion because of local conditions.

Ground connections should be provided for each of the down conductors, either through the use of driven rods or buried plates, or by conductors in trenches, the choice to be determined largely by local conditions. If a water pipe enters the building, at least one down conductor should be connected to it at a point just outside the entrance to the building. The importance of proper attention to good ground connections cannot be overemphasized. If the structure is located on rock where a good ground connection is not attainable, the use of a network of wires, called a mat, underneath and surrounding the structure is effective. This mat should be connected to the down wires in lieu of a ground connection, the desired result being to keep all parts of the structure and surrounding earth at substantially the same potential in the event of a stroke to the lightning rod system. Such a mat should be connected to the best ground connection available.

It is important that the various ground connections required for radio, telephone and power circuits, as specified by the various codes which apply, be followed. Large metal objects which are situated within a protected structure and which come within six feet of a conductor of the lightning rod system should be connected to it, and if farther away should in general be independently grounded.

British practice, as described in the British *Code* of *Practice* entitled "Protection of Structures Against Lightning" (published by the British Standards institution), is not materially different in principle from that described, but does vary in detail. More emphasis is given to the use of masts or single vertical conductors for the protection of both buildings and areas. Surrounding such a vertical conductor is a cone of protection described in terms of the ratio of the base radius of such a cone to its vertical conductor height. The U.S. code states that a ratio of 1:1 has been found satisfactory in important installations and up to a ratio of 2:1 in less important cases. The British code considers only the 1:1 ratio In providing a protection plan for structures of different heights using masts, it is desirable to work out the various intersecting cones to be sure that no object to be protected projects out through the cone.

In some situations more efficient use can be made of material by connecting the tops of masts together with overhead wires, in ahich case a wedge or tent of protection results. This method makes possible lower masts, thus reducing hazards to aircraft.

The question is often asked: "Do nearby trees offer lightning protection?" In general they represent a hazard, because the tree if struck would probably side-flash to the structure, the tree not being a good conductor. A lightning rod in the tree properly grounded would give the expected protection, interconnection being made between ground terminations at tree and structure. Isolated buildings, such as farm buildings, are more likely to be struck than buildings of similar size in towns or cities; and, of course, assistance in case of trouble is much less adequate, thus making lightning protection more necessary.

Steel-frame buildings do not need special lightning protection for their occupants or contents of the buildings. When considerable masonry extends above the steel frame of the building, damage may occur because of lightning. resulting in debris being thrown into the streets below. Protection in the form of air terminals or metal copings connected to the building steel would prevent lightning damage to the top of such structures.

B. Protection of Electrical Apparatus

In general, the electrical apparatus to be protected from the effects of lightning is connected to overhead circuits directly or through cable. Such apparatus usually consists of insulated electrical conductors wound around cores of magnetic steel which are usually grounded. To prevent the failure of such apparatus because of lightning it is necessary to limit the voltage applied to the insulation between conductors and also to that between conductors and those parts connected to the earth.

In the case of rotating apparatus (motors, generators) the nature of the construction is such that it is necessary to limit the rate of voltage rise between terminals and ground to prevent the overstressing of between-conductor insulation. This is accomplished by connecting suitable capacitors between the terminals and ground. The insulation between conductors and ground is protected by limiting the crest value of the lightning surge with lightning arresters.

Transformers may be designed in such a manner that the stresses between conductors and those between conductors and ground are co-ordinated so that limiting the crest value of the surge is all that is required.

Other station apparatus may also be protected by a voltage limiter, which is usually a lightning arrester or a gap. Perhaps the most serious disadvantage in the use of the gap is that circuit breakers must operate to interrupt any power current to ground following a lightning flashover. Such operation usually means an interruption to service.

1. Lightning Arresters.—A lightning arrester is a device nhich has the property of reducing the voltage of an impulse applied to its terminals; is capable of interrupting any system power current (follow current) which may flow through the arrester immediately following the lightning discharge; and which restores itself to its original condition. The arrester usually consists of a gap arrangement in series with a resistor which has the property of decreasing its resistance exponentially as the current through it increases. This nonlinear resistor and associated gap device are usually assembled in a suitable porcelain housing and provided with means for mounting. The gap device keeps the nonlinear resistor substantially disconnected from the A.C. power circuit except at the time when potentials appear having a magnitude sufficient to cause the gap device to become conducting, thus allowing the lightning current to flow to ground.

Since the system current would continue to flow through the arrester following such a lightning discharge, means must be provided to interrupt the flow of such system follow current; this is accomplished through the use of the gap device. The nonlinear resistor must have a sufficient resistance at normal system potential to limit power follow current to a value which can be interrupted by the gap device; and yet this resistance must become low enough to permit lightning currents of 20.000 amp. or more to flow without the voltage drop becoming so great that protection is not afforded to associated apparatus with an adeauate margin of safety. Such nonlinear resistors have the property of decreasing their resistance so that each time the applied voltage is doubled the current flow will be increased on the order of 12 or more times. All of them depend to a degree upon carborundum for their nonlinear resistance properties.

FIG. 6.—CUTAWAY DRAWING OF 11.5-KV. THYRITE ARRESTER UNIT

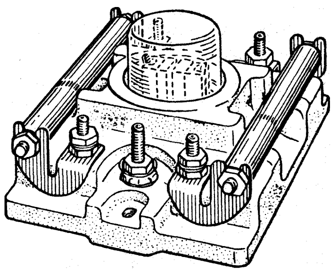
Arresters for high-voltage circuits usually consist of a series of arrester units stacked vertically above one another. The construction of a single 11.5-kv. unit is given inrthe cutaway section shown in fig. 6. The Thyrite disks taken together represent the nonlinear resistor, shown in the upper part of the porcelain container. The gap unit, within its own sealed container, consists of an assembly of several small gaps, the voltage distribution of which is controlled by parallel-connected resistors having special characteristics. Such gap devices are designed to divide the applied potential proportionately under normal power conditions, but to upset the voltage distribution between gaps when subjected to overvoltages because of lightning, thus resulting in breakdown of the gap device at lower levels of lightning voltage than would otherwise occur.

2. Protection of A.C. Rotating Apparatus.—The protection of A.C. rotating apparatus connected to circuits exposed to lightning constitutes a special problem because of the relatively low dielectric strength of the windings. To reduce the electrical stresses between adjacent turns of conductors, a reduction in the rate of rise of applied voltage, and consequently in the turn-to-turn stress, is secured by using capacitors connected line-to-ground. The voltage applied to the terminals is limited by a lightning arrester. In addition, the use of an auxiliary arrester on the incoming circuit at a distance of 1,500 ft. will result in a still lower potential at the generator or motor terminals.

3. Protection of Miscellaneous Electrical Equipment.—Lightning arresters are available for the protection of other equipment such as watt-hour meters, railway apparatus and other applications of a special nature. Power cables are generally protected by distribution-type arresters, but if long enough or if a sufficient number are connected in parallel, they may not need arrester protection.

The protection of D.C. motors is accomplished through the use of low impedance capacitors of four microfarads connected line-to-ground. There are also in use many aluminum-cell arresters consisting of aluminum plates, the surface of which is coated with a thin film of aluminum hydroxide, immersed in an electrolyte.

4. Protection of Communication Circuits and Apparatus.—Communication circuits: both telephone and telegraph, may have lightning potentials greatly in excess of their normal potentials impressed upon them either by induction or through contact by direct strokes. Without protection, damage to circuits or connected apparatus may occur, resulting in interference to service over the circuits. Conductors in metal-sheathed cables, particularly those which have no connection with overhead wire, are well shielded against lightning effects and are less subject to lightning effects than exposed overhead wires. In areas subject to lightning it is general practice to install protective devices on communication circuits to minimize lightning effects.



BY COURTESY OF BELL TELEPHONE LABORATORIES, INC.

FIG. 7.—PROTECTOR BLOCK WITH FUSES FOR COMMUNICATIONS CIRCUITS

Protectors are usually located at or near the communication apparatus and the customer's premises, at the junction of overhead wire and metal-sheathed cable, and in central offices on the line side of the apparatus.

Most lightning protective devices are constructed on the principle of providing a path to ground in the case of abnormal potentiais on the circuit, but no path to ground for the normal communication potentials. A higher potential, such as might occur from lightning, causes the devices to discharge the overvoltage harmlessly to ground. The insulation being protected is designed to withstand adequately potentials up to that at which the protective device discharges.

Fig. 7 shows a type of protector commonly used at telephone subscribers' stations. It consists of fuses and carbon protector blocks suitably assembled on a porcelain base. The protector blocks consist of two parts, one a carbon block which is connected to the earth, and the other a porcelain part which has a carbon insert connected to the line wire. When paired, a gap of a few one-thousandths of an inch exists between the carbon parts, and discharge across the gap will begin when the potential exceeds about 400-v. crest. Other materials and forms of gaps are also used. including the use of gaps enclosed in a partial vacuum.

The fuses are used to disconnect the subscribers' equipment in the event that a power wire comes in contact with the communication circuit. In such an event the carbon-block gap will discharge to earth, causing the power current to blow the fuse connected between the protector block and the incoming circuit.

Protection used at the junction of overhead wire and metal-sheathed cable is frequently installed in a weatherproof housing containing protective gaps for ten communication circuits or one cross arm of the overhead line. In this case fuses are not generally used.

For radio and television receivers equipped with outdoor antennas, protection is commonly afforded by a simple form of lightning arrester with an air gap that provides a path between antenna and ground in the event of high voltage on the antenna.

C. Protection of Power Transmission Lines

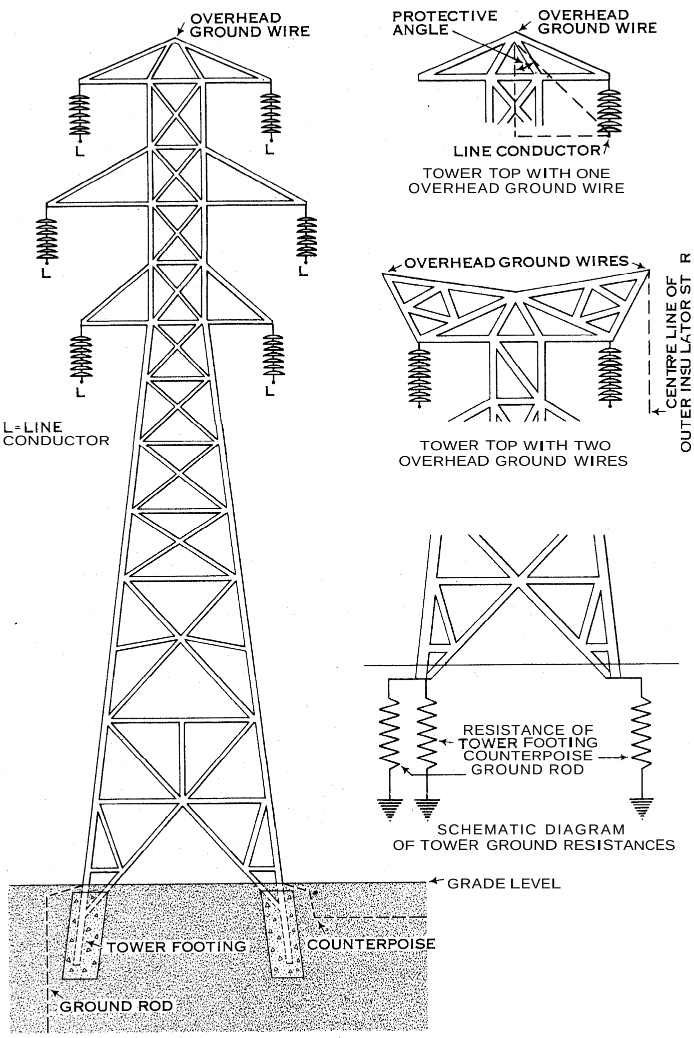
Overhead transmission lines depend for their successful operation on the electrical strength of the air. At supporting structures, such as steel towers or wood poles, the conductors are supported by porcelain or glass insulators of either the suspension or pin type. The design of these insulators is such that in the event of the application of high transient voltage, such as results from lightning, the insulator will arc over externally rather than puncture.

Such a flashover may allow system current to flow, since the electrical strength of the air has been momentarily greatly reduced; and such poner current flow. if continued long enough, will result in an interruption to service and may burn the conductors involved and perhaps damage insulators externally so they may have to be replaced.

Lightning may strike the suspended conductors of the transmission line at any point and may involve more than one conductor. There are two general methods of protection in use. The most common, especially for high-voltage lines, uses overhead ground wires arranged to shield the line conductors from lightning strokes. The second method employs means to prevent the flow of system current, which might follow a lightning flashover, from causing a trip-out or interruption to service; this is done by limiting the power current as to time or magnitude or both.

1. Overhead Ground Wires.—The purpose of the overhead ground wire is to divert the lightning stroke to itself, thus preventing contact with a line conductor, and also to conduct the current of the stroke to the earth. This is not sufficient, however, since the current of the stroke must get to the earth through the resistance of the tower footing; and this resistance may be high enough to cause the tower to rise in potential to such a degree that a flashover may take place between the tower and the line conductors. Thus, the location of the ground wires, the flashover values at the tower and in the span, and the tower footing resistance are all important in determining the proper performance of the line under lightning conditions when using overhead ground wires.

For double-circuit lines with vertically arranged conductors on either side of the tower, two overhead ground wires can be used, one above each of the outermost conductors at a distance approximately equal to the spacing between the conductors. For single-circuit, horizontally arranged lines, two overhead ground wires can be placed above and about midway between vertical planes through the outside and middle conductors, and above the plane of the conductors at a height of about two-thirds the spacing between them.



BY COURTESY OF GENERAL ELECTRIC COMPANY

FIG. 8.—DOUBLE CIRCUIT TOWER SHOWING SUGGESTED GROUND WIRE LOCATIONS, USE OF DRIVEN GROUND AND COUNTERPOISE

In tests on models, it was found that with a protective angle of 50° to 60° and a cloud height 10 times that of the ground wires, the strokes to line conductors would be limited to 1% of the strokes to the ground wire. To take into account such factors as wind, earth resistivity: variable cloud height and topography, a tolerance of 20° is suggested, which would indicate a protective angle of about 30°. An angle of 45° has been used on many transmission lines with satisfactory results (fig. 8).

At the tower there should be proper co-ordination between flashover of the supporting insulator and clearances to the steel, or down wires from the ground wires if wood structure is used. In some designs where use is made of wood to increase the insulation strength of the supporting structure, means are provided for bringing down the connection from the ground wire in such fashion that the wood is not short-circuited.

2. Tower Footing Resistance.—The voltage across an insulator string is $E = IR(1 - C)$, where I is the lightning current in the tower, R is the tower footing resistance and C is the coupling factor between the overhead ground wires and the conductors. The coupling factor, usually between 0.2 and 0.4, is dependent upon the number, configuration and spacing of the conductors and is influenced by the presence of corona. As a rule the designer does not have much opportunity to increase the coupling and thus reduce the voltage across the insulator, since such factors as electrical clearance, tower height and conductor size are determined largely by other considerations.

The designer may increase the flashover voltage between the line conductors and the ground wire and tower, which usually means more insulators and larger and higher towers; and/or he may reduce the tower footing resistance. The latter may be accomplished by connecting the tower base to ground rods driven into the earth, and/or to conductors buried approximately 18 in. under the surface of the earth. Such a buried conductor is called a counterpoise and may be continuous between towers, or may be less than a half span in length and arranged either parallel to the line or radial with respect to the tower.

3. **Wood Pole** Lines.—Many wood pole lines in all voltage classes up to 161 kv. have been in successful operation. If equipped with overhead ground wires and bonded and grounded hardware and down wires on the poles, they may be treated as steel towers from the lightning point of view. Many operators have used the insulation value of the wood cross arms, in which case the minimum insulation strength may be designed to be the air flashover between the conductor and nearest down wire. To prevent shattering as a result of direct strokes of lightning, the wood is often bridged by air gaps, using a ratio of about three feet of wood to each foot of parallel air gap.

LIGHTNING, FOLKLORE OF. Lightning, which is usually feared in primitive cultures, has been generally associated with the appearance of a god or considered a manifestation of the god's power or wrath.

God's control over lightning is frequently mentioned in the Old Testament. Job is asked the rhetorical questions: "Who hath divided a watercourse for the overflowing of waters, or a way for the lightning of thunder" and "Canst thou send lightnings, that they may go, and say unto thee, Here we are?" (Job xxxviii, 25, 35). Before God commanded Moses to climb to the top of

Mount Sinai, according to Exodus, chapter 19 "there were thunders and lightnings, and a thick cloud upon the mount. . . ."

In ancient Greece, thunder and lightning were considered omens of Zeus. The thunderbolt was said to have been cast by him, and any place which lightning struck was sacred. Salmoneus (*q.v.*), legendary king of Elis, often attempted to imitate Zeus by driving his chariot at full speed to imitate thunder while he burned torches to represent lightning. To hear thunder on the right before a battle was a favourable omen.

The Romans, however, considered thunder heard on the left the favourable omen. They also associated their god Jupiter with lightning and thunder. Good or evil fortune was predicted by thunder heard before an undertaking, and there was also a class of "neutral" lightning which did not predict success or failure.

To the Persians, lightning was an indication of divine wrath. Herodotus reports this view: "Said Artabanus, the adviser of Xerxes, 'Thou seest how the Deity strikes with thunderbolt those beasts that tower above their fellows, but the little ones worry him not; and thou seest also how his missiles always smite the largest buildings and trees of such kind; for God loves to truncate all those things that rise too high. Thus, too, a large army may be ruined by a small one, when God in his jealousy hurls a panic or a thunderbolt, through which they are shockingly destroyed; for God permits none but himself to entertain grand ideas.'"

Sir James Frazer (*q.v.*) in his Golden Bough tells of many superstitions in various cultures concerning trees which have been struck by lightning. The Thompson Indians of British Columbia used wood from a tree that had been struck by lightning to make incendiary arrows, or they attached splinters of such wood to their arrows. The Wendish peasants of Saxony and the Thonga of South Africa refused to use wood from such a tree as fuel, but the fire from a tree that had been struck by lightning was welcomed by the Winamwanga of Northern Rhodesia. Like the Maidu Indians of California, they believed that lightning was the personification of their god, and they revered it.

Myths concerning thunderbirds or persons are common among some North American Indians. The Tlingit, on the northwest Pacific coast of North America, believe that lightning is caused by the flash of the thunderbird's eye as he winks; other groups explain that lightning is the weapon of such a bird or person.

In general folklore, lightning never strikes the same place twice. The sound of thunder, according to natives in some parts of Australia, brings turtles out of the water to lay eggs.

In some parts of Germany it became customary during the Easter season for the people to char in a consecrated bonfire sticks of beech, walnut and oak, which were throughout the year burned during thunderstorms or placed on the roof of the house to protect it from being struck by lightning. It was also believed in several provinces of France that a charred Yule log, or *tréfoir,* which had been lit on Christmas Eve and burned daily until Twelfth-night, could, if stored under a bed, protect the house from lightning and a number of other misfortunes.

LIGHTNING BUG, the name often given in the United States to the firefly (*q.v.*).

LIGHTNING INSURANCE: see FIRE INSURANCE.

LIGHTSHIP: see LIGHTHOUSES.

LIGHT-YEAR, an astronomical unit of length, the distance traveled by light in the course of one year, being equivalent to about six million million (6×10^{12}) miles. The distance of stars may be measured in terms of this unit or in terms of the parsec (*q.v.*), which is about 3.26 light-years.

EIGNE, CHARLES JOSEPH, PRINCE DE (1735–1814), soldier and writer, came of a princely family of Hainaut, and was born at Brussels in 1735. He distinguished himself at Breslau, Leuthen, Hochkirch and Maxen, and after the Seven Years' War rose to the rank of lieutenant field marshal. An intimate friend and counselor of Emperor Joseph II, he lived luxuriously on his estates! returning to his military duties during the War of the Bavarian Succession, and again in 1784. During his travels in Europe he was a prominent figure both in society 'and in scholastic circles. In 1787 he was with Catherine II in Russia, accompanied her in her journey to the Crimea, and was made a Russian field marshal by the empress. In 1788 he was present at the siege of Belgrade. Shortly after this he was invited to place himself at the head of the Belgian revolutionary movement, in which many of his relatives took part, but he declined. He was given the rank of field marshal (1809) and an honorary command at court, where he lived in comparative luxury devoting himself to literary work. He lived long enough to characterize the proceedings of the congress of Vienna with the famous mot: "Les *Congrès* danse *mais* ne *marche* pas." He died at Vienna on Dec. 13, 1814.

His collected works appeared in 34 volumes at Vienna during the last years of his life (*Mélanges militaires, littéraires, sentimentaires*), and selections were published in French and German, and in English (1927).

Ligne's grandson, EUGENE LAMORAL DE LIGNE (1804–1880), was a distinguished Belgian statesman.

LIGNITE. In North America, coals having a moist mineral-matter-free heat content of less than 8,300 B.T.U. per pound are called lignite. Moisture content (as received) varies from 20% up to 60%. The classifications of other countries are overlapping. Some European lignite would be classified "subbituminous" in the U S Most brown coals in Europe would be classified as lignite. Lignite is generally younger geologically than higher-rank coal.

Approximately 4,000,000 tons of lignite are mined annually in the United States, largely by open-pit methods. North Dakota and Texas are the largest producers. Assured U.S. reserves total more than 463,000,000,000 tons, about 15% of the nation's total solid fuels reserves on a B.T.U. basis. About 95% of total tonnage is located in North Dakota, South Dakota and Montana.

The fuel is used by local utility, industrial and domestic consumers fairly close to the mine site. It is adaptable to firing in stokers of the overfeed type, in pulverizers and in cyclone furnaces. It can be shipped and stored in the same manner as higher-rank coals. Because of its greater liability to oxidation and to spontaneous combustion, it requires more careful compaction in stockpiles than coals of higher rank. Crushed lignite can be stored for periods of two or three months without compaction when treated with small quantities of oil.

Lignite (brown coal) resources are a major factor in the development of eastern and southeastern Europe. About one-third of the output is briquetted for domestic and industrial heating. Another one-third is used for power generation. The remainder is used by chemical and carbonization processes. See also COAL AND COAL MINING. (W. A. McC.)

LIGONIER, JOHN (JEAN LOUIS) **LIGONIER,** EARL, cr. 1766 (1680–1770), British field marshal, came of a Huguenot family settled in England. He served throughout Marlborough's campaigns in Flanders (1702–10). In 1720 he became colonel of the "Black Horse" (later the 7th dragoon guards), a command which he retained for a period of 29 years. At Fontenoy Ligonier commanded the British foot, and acted throughout the battle as adviser to the duke of Cumberland. During the "Forty-Five" he was called home to command the British army in the Midlands, but in Jan. 1746 was placed at the head of the British and British-paid contingents of the Allied army in the Low Countries.

Ligonier was present at Roucoux (Oct. 11, 1746) and, as general of horse, at Val (July 1, 1747), where he led the charge of the British cavalry. His horse was killed and he himself taken prisoner, though exchanged in a few days. With the close of the campaign ended Ligonier's active career, but (with a brief interval in 1756–57) he occupied various high civil and military posts to the close of his life. In 1766 he became field marshal.

See Combes, *J. L. Ligonier, une étude (1866)* and the histories of the 7th dragoon guards and grenadier guards

LIGUORI, SAINT ALFONSO MARIA DE' (1696–1787), Italian doctor of the church, was born at Marianella, near Naples, on Sept. 27, 1696, the son of Giuseppe de' Liguori. He studied law. passed his examination for the doctor's degree at the age of 16 and practised law for eight years. Giving up the bar, he was ordained priest in 1726. In 1732 he founded the Congregation of the Most Holy Redeemer. commonly called the Redemptorists. In 1762 he became bishop of Sant' Agata de' Goti, about

30 mi. from Naples. He resigned this bishopric in 1775 and died on Aug. 1, 1787. He was canonized in 1839 and declared a doctor of the church in 1871. In 1950 he was named patron of moralists and confessors by Pope Pius XII. His feast is celebrated on Aug. 2.

Liguori wrote extensively. By 1953 his works had gone through about 18,000 editions and had been translated into 60 languages. They fall into three classes. (1) The first, in the field of moral theology, is headed by his *Tlteologia moralis*. This first appeared in 1748 and went through nine editions in his lifetime and more than 60 subsequently. He summarized it in *Praxis confessarii*. Another work in this class is *Homo apostolicus*. (2) The second class embraces his ascetical and devotional writings for priests, religious and lay persons. This includes *Visits to the Blessed Sacrament*, *The True Spouse of Christ* (for nuns) and *Selva* (for priests) and *The Glories* of *Mary*. The last is one of the most influential and widely used manuals of Marian devotion, and it helped to shape the Marian doctrine. (3) The third class contains his dogmatic writings, such as *The History of Heresies*, his works on the infallibility of the pope and those on the power of prayer. This last theme he stressed so constantly that he is sometimes called the "doctor of prayer."

Liguori was also a celebrated preacher, a musician and a poet. He composed and put to music many hymns which are still favourites among the Italian people. His Christmas hymn "Tu Scendi dalle Stelle" is as closely associated with Christmas in Italy as are "Adeste Fideles" and "Silent Night" in other countries.

In theology Liguori is known as the principal exponent of equiprobabilism, a system of principles designed to guide the conscience when one doubts whether he is free from, or bound by, a given law. The system is based on the legal axiom, "in doubt the presumption favours the possessor." Applying it to doubts of conscience, Liguori laid down these three principles: (1) In a doubt with equally probable reasons pro and con, a person is free from the obligation of the law if he has been free from it hitherto, for freedom is in possession and the presumption favours the possessor. (2) In a doubt with equally probable reasons pro and con, a person is bound to keep the law if he has been bound to it hitherto, for the law is in possession. (3) In a doubt when the reasons for the obligation of the law are considerably more probable than those for liberty, the law must be kept.

Collected editions of St. Alfonso Liguori's works have been published in Italian, French, German. Dutch and English. For bibliographies, *see* M. de Meulemeester, *Bibliographie générale des écrivains Rédemptoristes*, 3 vol. (1933–39) and *Histoire sommaire de la Congrégation du Très-Saint-Rédempteur* (1950); as well as A. Sampers, "Bibliographia Xlphonsiana," *Spicilegium Historicunt C. SS. R.*, pp. 248–271 (1953).

(RA. J. M.; F. J. C.)

LIGURES BAEBIANI, a settlement of Ligurians in Samnium. Italy. The towns of Taurasia and Cisauna in Samnium had been captured in 298 B.C. by the consul L. Cornelius Scipio Barbatus, and the territory of the former remained Roman state domain. In 180 B.C. 47,000 Ligurians from Luna (Ligures Xpuani), were transferred to this district. and two settlements were named after the consuls of 181 B.C., the Ligures Baebiani and the Ligures Corneliani.

The site of the former town lies 15 mi. N. of Beneventum, on the road to Saepinum and Aesernia. The site of the other settlement—that of the Ligures Corneliani—is unknown.

LIGURIA, a modern region of Italy containing the provinces of Genoa, Imperia, Savona and La Spezia. and once forming the republic of Genoa. It lies between the Ligurian Alps and the Apennines on the north. and the Mediterranean on the south, and extending from the frontier of France on the west to the Gulf of Spezia on the east. Its northern limits touch Piemonte and Lombardia, while Emilia and Tuscana fringe its eastern borders, the dividing line following as a rule the summits of the mountains.

The area of Liguria is 2.089 sq.mi. Pop. (1961) 1,717,630, as compared with 1,075,760 in 1901. The railway from Pisa skirts the entire coast of the territory, throwing off lines to Parma from Sarzana and Spezia, to Milan and Turin from Genoa and to Turin from Savona; there is also a line from Ventimiglia north to Cuneo and Turin by the Col di Tenda. Its sparsely peopled mountains slope gently northward toward the Po, descending, however, abruptly into the sea at several points; the narrow coast district is famous under the name of the Riviera (*q.v.*).

The principal products of Liguria are maize, wine, oranges. lemons, fruits, olives and potatoes, though the olive groves are being rapidly supplanted by flower gardens. In the mountains the forests are important and considerable hydraulic power is also derived from the streams and used for railway traction; etc.

Copper, manganese and iron pyrites are mined. Sardinian lead is smelted at Pertusola on the Gulf of Spezia. The principal industries are ironworks: foundries, iron shipbuilding, engineering and boilerworks (Genoa, Spezia,' Sampierdarena, Sestri Ponente, etc.), railway signals (Savona) and the manufacture of cottons and woolens.

The inhabitants have always been adventurous seamen—Columbus, for example, was Genoese—and the coast has several good harbours, Genoa, Spezia and Savona being the best. In educational and general development, Liguria stands high among the regions of Italy.

Archaeology and Philology.—In earlier times the Ligurians occupied a much more extensive area than the ninth Augustan region of Italy. For instance, Strabo gives earlier authorities for their possession of the land on which the Greek colony of Massalia (Marseille) was founded; and Thucydides speaks of a settlement of Ligurians in Spain who expelled the Sicani thence. Southward their domain extended as far as Pisa on the coast of Etruria and hrretium inland in the time of Polybius (ii, 6). Seneca (*Cons. ad Helv.* vii, 9), states that the population of Corsica mas partly Ligurian. (For the archaeological side of the question *see* GOLASECCA.) Archaeological evidence shows them to have been a part of the "Mediterranean race:" and confirms the tradition as to the area they occupied.

The Bronze Age rock engravings near Ventimiglia (*q.v.*) are interesting. Their culture was much modified in the Iron Age by a Celtic invasion, after which the two peoples mere inextricably mixed.

On the linguistic side some fairly certain conclusions have been reached. One may note the frequency of the suffix *-asco-* (and *-usco-*) both in ancient and in modern Ligurian districts, and as far north as *Caranusca* near Metz. and also in the eastern Alps and in Spain. Most of the Ligurian proper names (*e.g.*, the streams, *Vinelasca, Porcobera, Comberamea; mons Tuledo; Venascum*) have a definite Indo-European character, as have those preserved in Latin inscriptions of the Ligurian districts, such as the *Tabula Genuatium* (C.I.L. I, 584) of 117 B.C. A complete collection of Ligurian place and personal names combined with the inscriptions of the district is printed in *The Pre-Italic Dialects*, edited by *R.* S. Conway and J. Whatmough. There is strong evidence in these names that the language spoken before the Roman conquest was Indo-European, and belonged to those languages which preserved the original q as Latin did, and did not convert it into *p* as did the Umbro-Safine tribes. The same is probably true of Venetia (*see* VENETI) and of an Indo-European language preserved on inscriptions found at Coligny and commonly referred to the Sequani.

The "Lepontic" inscriptions found in a small area (50 mi. by 3j mi.) round the lakes of Como, Lugano. Maggiore and Orta, are also Ligurian, with Celtic affinities. The Ligurian ethnica show the prevailing use of the two suffixes *-co-* and *-ati-*, which there is reason to refer to the pre-Roman stratum of population in Italy. (*See* VOLSCI.)

The Ligurians were eventually restricted more and more to the county adjoining the Gulf of Genoa, and at last they occupied only an area bounded by the upper reaches of the Po and Ticino on the north, the Arno on the east. and the Alps and the Var on the west. They are described as thin and wiry, short of stature and dark complexioned, hardy and warlike people winning a difficult livelihood from the soil, but also interested in commerce, and some of them daring seafarers.

The Ligurian coast became gradually subject to the Romans, and the road along it must have been correspondingly prolonged: up to the end of the Hannibalic war the regular starting-point for Spain by sea was Pisae; in 195 B.C. it was the harbour of Luna (Gulf of Spezia), though Genua must have become Roman a little before this time! while, in 137 B.C. C. Hostilius Mancinus marched as far as Portus Herculis (Villafranca), and in 121 B.C. the province of Gallia Narbonensis was formed and the coast-road prolonged to the Pyrenees. In *14* B.C. Augustus restored the whole road from Placentia to Dertona (Via Postumia), and thence to Vada Sabatia (Via Aemilia) and the River Varus (Var), so that it thenceforth took the name of Via Julia Augusta. The other chief roads of Liguria were the portion of the Via Postumia from Dertona to Genua, a road from above Vada through Xugusta Bagiennorum and Pollentia to Xugusta Taurinorum, and another from Augusta Taurinorum to Hasta and Valentia. The names of the villages—Quarto, Quinto, etc.—on the south-east and Pontedecimo on the north of Genoa allude to their distance along the Roman roads. Even the Roman Liguria, forming the ninth region of Augustus, was thus far more extensive than the modern, including the country on the north slopes of the Apennines and Maritime Alps between the Trebia and the Po, and extending a little beyond Xlbintimilium. On the west Augustus formed the provinces of the Alpes Maritimae and the Alpes Cottiae. Towns of importance were few, owing to the nature of the country. Dertona was the only colony, and Alba Pompeia, Augusta Bagiennorum. Pollentia. Hasta, Aquae Statiellae. and Genua may also be mentioned; but the Ligurians dwelt entirely in villages, and were organized as tribes. The mountainous character of Liguria made the spread of culture difficult; it remained a forest district, producing timber, cattle, ponies. mules, sheep. etc. Oil and wine had to be imported, and when the cultivation of the olive began is not known.

The arrangement made by Augustus lasted until the time of Diocletian, when the two Alpine provinces were abolished, and the watershed became the boundary between Italy and Gaul. At this time we find the name of Liguria extended as far as Milan, while in the 6th century the old Liguria was separated from it, and under the Lombards formed the fifth Italian province under the name of Alpes Cottiae. In the middle ages the ancient Liguria north of the Apennines fell to Piedmont and Lombardp, while that to the south, with the coast strip, belonged to the republic of Genoa.

LI HUNG CHANG (1823–1901), Chinese soldier and statesman. was born on Feb. *16.* 1823 at Hofei, in Ngan-hui. In 1847 he became a Chin-shih, or graduate of the highest order, two years later entering Hanlin university. He raised a regiment of militia against the Taiping rebels, thus earning the good will of the commander-in-chief, Tseng Kuo-fan. In 1859 he was transferred to the province of Fu-kien, where he was given the rank of taotai, or intendant of circuit. But at Tseng's request Li was recalled to take part against the rebels. He found his cause supported by the "Ever Victorious Army," which, after having been raised by an American named Ward, was finally placed under the command of Charles George Gordon. With this support Li gained victories which led to the surrender of Suchow and the capture of Nanking. For these exploits he was made governor of Kiangsu, was decorated with the yellow jacket. and was created an earl. An incident connected with the surrender of Suchow left a lasting stain upon his character. By an arrangement with Gordon the rebel wangs, or princes, yielded Nanking on condition that their lives should be spared. In spite of the assurance given them by Gordon, Li ordered their instant execution. This breach of faith so enraged Gordon's indignation that he seized a rifle and would have shot Li if he had not saved himself by flight, On the suppression of the rebellion (1864) Li took up his duties as governor, but on the outbreak of the rebellion of the Nienfei, a remnant of the Taipings, in Ho-nan and Shan-tung (1866) he was ordered again to take the field, and suppressed the movement. A year later he was appointed viceroy of Hukwang, where he remained until *1870*, when the Tientsin massacre led to his transfer to the scene. He was appointed to the viceroyalty of the metropolitan province of Chihli, where he actively repressed anti-foreign sentiment. For his services he was made imperial tutor and member of the grand council of the empire, and was decorated with many-eyed peacocks' feathers.

To his duties as viceroy were added those of the superintendent of trade, and from that time until his death, with a few intervals of retirement, he practically conducted the foreign policy of China. He concluded the Chifu convention with Sir Thomas Wade (1876), and thus ended the difficulty caused by the murder of Mr. Margary in Yunnan; he arranged treaties with Peru and Japan, and he actively directed the Chinese policy in Korea. On the death of the emperor T'ungchi in 187j he effected the *coup d'état* by which the emperor Kwang Su was put on the throne under the tutelage of the two dowager empresses; and in *1886*, on the conclusion of the Franco-Chinese war, he arranged a treaty with France. When viceroy of Chihli he had raised a large, well-drilled and well-armed force: and spent vast sums both in fortifying Port Arthur and the Taku forts and in increasing the navy. For years he had watched the successful reforms effected in Japan, and he feared and hated a conflict. But in *1894* events forced his hand, and war broke out. Both on land and at sea the Chinese forces were ignominiously routed, and in 1895, on the fall of Wei-hai-wei, the emperor sued for peace. Li represented the emperor at the Shimonoseki conference.

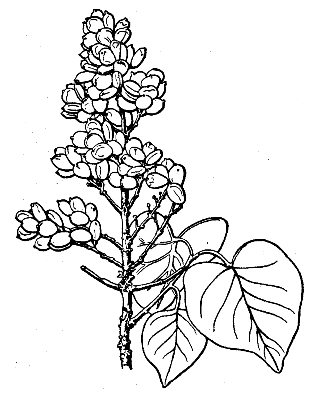
With great diplomatic skill Li pleaded the cause of his country, but finally had to agree to the cession of Formosa. the Pescadores, and the Liaotung peninsula to the conquerors, and to the payment of an indemnity of 200.000.000 taels. By a subsequent arrangement the Liaotung peninsula was restored to China, in exchange for an increased indemnity. During the peace discussions at Shimonoseki an attempt was made on his life. He was wounded, but soon recovered.

In 1896 Li represented the emperor at the coronation of the tsar. and visited Germany. Belgium. France, England and the Cnited States of America. For some time after his return to China he was virtually constituted minister for foreign affairs; but in 1900 he was transferred to Canton as viceroy of the two Kwangs.

The Boxer movement induced the emperor to recall him to the capital, and the peace of Sept. 1901 was largely secured by his efforts.

He died on Nov. 7, 1901. He left three sons and one daughter.

LILAC (*Syringa vulgaris*), a shrub of the family Oleaceae. The genus contains more than 25 species of ornamental hardy deciduous shrubs and trees, native in eastern Europe and temperate Asia. They have opposite, generally entire leaves and large panicles of small regular flowers, with a bell-shaped calyx and a four-lobed cylindrical corolla, with the two stamens characteristic of the family attached at the mouth of the tube.



FROM COOPER AND WESTELL, "TREES AND SHRUBS OF THE BRITISH ISLES" (DENT & SONS LTD.)

BRANCH OF THE LILAC (SYRINGA VULGARIS) SHOWING FRUIT

The common lilac is said to have come from Persia in the 16th century, but is doubtfully indigenous in Hungary. the borders of Moldavia. etc.

Two kinds of *Syringa*, viz. *alba* and *caerulea*, are figured and described by John Gerard (*Herball*, 1597), which he calls the white and the blue pipe privets. The white is the common privet, *Ligustrum vulgare*, which, with the ash tree, *Fraxinus excelsior*, are the only members of the family found wild in Great Britain.

The "blue pipe privet" is the lilac: as both figure and description agree accurately with it. It was carried by the European colonists to northeast America, and is still grown in gardens of the northern and middle states.

There are many fine varieties of lilac, both with single and double flowers; they are among the commonest and most beautiful of spring-flowering shrubs.

The Persian lilac' of gardens (S. *persica*), also known as the Chinese or Rouen lilac, a small shrub 4 to 6 ft. high with intense violet flowers appearing in May and June, is much cultivated for ornament.

FROM COOPER AND WESTELL, s AND SHRUBS OF THE BRITISH ISLES" (DENT & SONS, LTD.)

BRANCH OF THE LILAC (SYRINGA VULGARIS) SHOWING INFLORESCENCE

Of other species, *S. josikaea* from Transylvania, has scentless bluish-purple flowers; S. cmodi, a native of the Himalayas, is a handsome shrub with large ovate leaves and dense panicles of purple or white strongly scented flowers. Lilacs grow freely and flower profusely in almost any soil and situation, but when neglected are apt to become choked with suckers which shoot up in great numbers from the base.

They are readily propagated by means of these suckers. By far the most handsome lilacs, of which there are hundreds of varieties, are of hybrid, mostly French origin. Notable collections of these are found at Rochester, N.Y., and at the Arnold Arboretum, Jamaica Plain, Mass.

Syringa is also a common name for the mock orange, which are unrelated shrubs of the genus Philadelphus. (N. Tr.)

LILBURNE, JOHN (1614–1657), English democrat and republican, leader of the Levellers (*q.v.*). The younger son of a Durham gentleman, Lilburne was apprenticed to a London cloth merchant. At an early age he joined the underground opposition to Charles I's personal government, and helped to smuggle in and circulate pamphlets printed in the Dutch republic. For this he was in Feb. 1638 sentenced by the Star Chamber to be fined £500, whipped, pilloried and imprisoned until he submitted. He used the pillory as a rostrum, until Archbishop Laud had him gagged. He remained in prison until the Long parliament liberated him in Nov. 1640, Oliver Cromwell speaking on his behalf.

On the outbreak of civil war, Lilburne was commissioned as a captain. Taken prisoner at Brentford, he would have been condemned to death had not parliament forced his exchange by threatening reprisals. In April 1645, when he resigned his commission rather than take the covenant, Lilburne was a lieutenant colonel.

Henceforth his activities are inseparable from those of the Levellers. He wrote innumerable pamphlets. The special contribution of Lilburne ("Free-born John") was his vindication of the legal rights of Englishmen. He quoted Sir Edward Coke almost as often as the Bible, and was even criticized by his fellow Levellers William Walwyn and Richard Overton for attaching exaggerated importance to Magna Carta ("that mess of pottage"; "but a beggarly thing").

Lilburne ultimately came to agree that the existing constitution and law were inadequate to defend the birthright of the common man. He advocated manhood suffrage and extensive law reform, since "the poorest that lives hath as true a right to give a vote as well as the richest and greatest" (London's Liberty in Chains, 1646, p. 4). Past laws were justified only if they accorded with reason—*i.e.,* he abandoned the common-law appeal to precedent and custom.

Lilburne fiercely criticized first the Presbyterian parliament and then the Independent leaders of the army for not meeting the Levellers' demands. He was frequently arrested, but his popularity was such that juries invariably acquitted him. When on trial in Oct. 1649 he insisted that juries were judges of law as well as of fact, the judges being "but the Norman Conquerors intruders."

In 1650–52 Lilburne with John Wildman helped inhabitants of the Isle of Axholme to oppose a drainage scheme which impaired commoners' rights. Banished by parliament in 1652, Lilburne returned in 1653 after the dissolution of the Rump. He was put on trial, and his acquittal by a London jury was the occasion of a great demonstration which affected the troops and worried the government. So Lilburne was kept in prison until 1655. By then he had turned Quaker, and was prepared to give security for good behaviour.

Lilburne died at Eltham, Kent, on Aug. 29, 1657.

See M. A. Gibb, John Lilburne the Leveller (London, 1948); J. D. Hughes, "The Drainage Disputes in the Isle of Axholme," The *Lincolnshire Historian*, vol. ii (Lincoln, 1954). (J. E. C. H.)

LILIACEAE, in botany, a family of Monocotyledons belonging to the series Liliiflorae, and generally regarded as representing the typical order of Monocotyledons. The plants are generally perennial herbs growing from a bulb or rhizome, sometimes shrubby as in butcher's broom (*Ruscus*) or treelike as in species of Dracaena, Yucca or Aloe. The flowers are with few exceptions hermaphrodite, and regular with parts in threes, the perianth which is generally petaloid occupying the two outer whorls followed by two whorls of stamens, with a superior ovary of three carpels in the centre of the flower; the ovary is generally three-chambered with a number of anatropous ovules on axile placentas. The fruit is a capsule splitting along the septa (septicidal), or between them (loculicidal), or a berry; the seeds contain a small embryo in a copious fleshy or cartilaginous endosperm. Liliaceae is one of the larger families of flowering plants containing about 2,700 species in 233 genera being approximately one-eighth of the Monocotyledons; it is of world-wide distribution. It contains many useful plants (onion, leek, garlic) and garden plants (lily, tulip, hyacinth). The plants show great diversity in vegetative structure, which together with the character and mode of dehiscence of the fruit affords a basis for the subdivision of the family into tribes, eleven of which are recognized. The following are the most important tribes.

Melanthioideae.—The plants have a rhizome or corm, and the fruit is a capsule. Many are north temperate and three are represented in Britain, viz. Tofieldia, an arctic and alpine genus of small herbs with a slender scape springing from a tuft of narrow ensiform leaves and bearing a raceme of small green flowers; *Narthecium* (bog asphodel), herbs with a habit similar to *Tofieldia,* but with larger golden-yellow flowers; and Colchicum, a genus with about 30 species including the meadow saffron or autumn crocus (*C. autumnale*). Colchicum illustrates the corm-development which is rare in Liliaceae, though common in the allied family Iridaceae. Gloriosa, well known in cultivation, climbs by means of its tendril-like leaf-tips; it has handsome flowers with recurved orange-red or yellow petals; it is a native of tropical Asia and Africa. *Veratrum* is an alpine genus of the north temperate zone.

Asphodeloideae.—The plants generally have a rhizome bearing radical leaves, as in asphodel, rarely a stem with a tuft of leaves as in *Aloe,* very rarely a tuber (*Eriospermum*) or bulb (Bowiea). The flowers are borne in a terminal raceme, the anthers open introrsely and the fruit is a capsule, very rarely, as in Dianella, a berry. Asphodelus (asphodel) is a Mediterranean genus; Simethis, a slender herb with grassy radical leaves, is a native of west and southern Europe extending into south Ireland. Anthericum and *Chlorophytum,* herbs with radical often grass-like leaves and scapes bearing a more or less branched inflorescence of small generally white flowers, are widely spread in the tropics. Other genera are Hosta, native of China and Japan, cultivated in the open air in Britain; Hemerocallis, a small genus of central Europe and temperate Asia—*H. flava* is known in gardens as the day lily; *Phormium,* a Sew Zealand genus to which belongs New Zealand flax, *P. tenax,* a useful fibre-plant; *Kniphofia* (red-hot poker), South and East Africa, several species of which are cultivated; and Aloe. A small group of Australian genera closely approach the family Juncaceae in having small crowded flowers with a scarious or membranous perianth; they include Xanthorrhoea (grass-tree or black-boy) and Kingia.

Allioideae.—The plants grow from a bulb or short rhizome;

the inflorescence is an apparent umbel formed of several shortened monochasial cymes and subtended by a pair of large bracts. The largest genus *Allium* has about 325 species—7 are British. *Agapanthus* or African lily is a well-known garden plant; in Gagea, a genus of small bulbous herbs found in most parts of Europe, the inflorescence is reduced to a few flowers or a single flower; G. *lutea* is a local and rare British plant.

OM H. J. ELWES, "MONOGRAPH OF TH GENUS LILIUM"
LONG-FLOWERED WHITE LILY (LILIUM LONGIFLORUM). A, SCALY BULB, WITH TWO SMALL BULBS

Lilioideae.—Bulbous plants with a terminal racemose inflorescence; the anthers open introrsely and the capsule is loculicidal.

It contains about 30 genera, several represented in Britain. The typical genus *Lilium* and Fritillaria are widely distributed in the temperate regions of the northern hemisphere; *F. meleagris,* snake's head, is found in moist meadows in some of the southern and central English counties; *Tulipa* contains about 50 species in Europe and temperate Asia, and is specially abundant in the dry districts of central Asia; *Lloydia,* a small, slender alpine plant, widely distributed in the northern hemisphere, occurs on Snowdon in Wales; Scilla (squill) is a large genus, chiefly in Europe and Asia—*S. nutans* is the blue-bell or wild hyacinth; *Ornithogalum* (Europe, Africa and west Asia) is closely allied to *Scilla—O. umbellatum,* star of Bethlehem, is naturalized in Britain; *Hyacinthus* and *Muscari* are chiefly Mediterranean; *M.* racemosum, grape hyacinth, occurs in sandy pastures in the eastern counties of England. To this group belong a number of tropical and especially South African genera, such as *Albuca, Urginea, Drimia, Lachenalia* and others.

Dracaenoideae.—The plants generally have an erect stem with a crown of leaves which are often leathery; the anthers open introrsely and the fruit is a berry or capsule. It contains a small number of genera, several of which, such as *Yucca, Dracaena* and Cordyline include arborescent species in which the stem increases in thickness continually by a centrifugal formation of new tissue; an extreme case is afforded by Dracaena *Draco,* the dragon-tree of Teneriffe. *Yucca* and several allied genera are natives of the dry country of the southern and western United States and of Central America. Dracaena and the allied genus *Cordyline* occur in the warmer regions of the Old World.

Asparagoideae.—Plants growing from a rhizome; fruit a berry. Asparagus contains about 120 species in the dryer, warmer parts of the Old World; it has a short creeping rhizome, from which springs a slender, herbaceous or woody, often very much branched, erect or climbing stem, the ultimate branches of which are flattened or needle-like, leaf-like structures (cladodes), the true leaves being reduced to scales or, in the climbers, forming short, hard, more or less recurved spines. *Ruscus aculeatus* is butcher's broom, an evergreen shrub with flattened leaf-like cladodes, native of the southerly portion of England and Wales; the small flowers are unisexual and borne on the face of the cladode; the male contains three stamens, the filaments of which are united to form a short stout column on which are seated the diverging cells of the anthers; in the female the ovary is enveloped by a fleshy staminal tube on which are borne three barren anthers. Poly*gonatum* and Maianthemum are allied genera with a herbaceous leafy stem and, in the former axillary flowers, in the latter flowers in a terminal raceme; both occur rarely in woods in Britain; P. *multiflorum* is the well-known Solomon's seal of gardens, so called from the seal-like scars on the rhizome of stems of previous seasons, the hanging flowers of which contain no honey, but are visited by bees for the pollen. *Convallaria* is lily of the valley; Aspidistra, native of the Himalayas, China and Japan, is a well-known pot plant; its flowers depart from the normal arrangement of the family in having the parts in fours (tetramerous). Paris, including the British Herb Paris (P. quadrifolia), has solitary tetra- to poly-merous flowers terminating the short annual shoot which bears a whorl of four or more leaves below the flower; in this and in some species of the nearly allied genus Trillium (chiefly temperate North America) the flowers have a fetid smell, which together with the dark purple of the ovary and stigmas and frequently also of the stamens and petals, attracts carrion-loving flies, which alight on the stigma and then climb the anthers and become dusted with pollen; the pollen is then carried to the stigmas of another flower.

Luzuriagoideae are shrubs or undershrubs with erect or climbing branches and fruit a berry. Lapageria, a native of Chile, is a favourite greenhouse climber with fine bell-shaped flowers.

Smilacoideae are climbing shrubs with broad net-veined leaves and small dioecious flowers in umbels springing from the leaf-axils; the fruit is a berry. They climb by means of tendrils, which are stipular structures arising from the leaf-sheath. Smilax is a characteristic tropical genus containing about 210 species; the dried roots of some species are the drug sarsaparilla.

The two tribes Ophiopogonoideae and Aletroideae are sometimes removed from the Liliaceae and placed in the family, Haemodoraceae. The plants have a short rhizome and narrow or lanceolate basal leaves; and they are characterized by the ovary being often half-inferior. They contain a few genera chiefly old world tropical and subtropical. The leaves of species of *Sansevieria* yield a valuable fibre and the tubers of *Ophiopogon japonicus* are edible. *See* K. Krause in Engler and Prantl, *Die Natürlichen Pflanzenfamilien,* ed. 2, 15a:227–386, fig. 81–161 (1930).

LILIENCRON, DETLEV VON (1844–1909), German poet and novelist, was born at Kiel on June 3, 1844. He entered the army and took part in the campaigns of 1866 and 1870–71, in both of which he was wounded. He retired with the rank of captain, and spent some time in America. On his return (1882) he entered the civil administration at Kellinghusen in Holstein, where he remained till 1887. After some time at Munich, he settled in Altona and then at Altrahistedt, near Hamburg, where he died on July 22, 1909. He first attracted attention by the volume of poems *Adjutantenritte und andere* Gedichte (1883), which was followed by several dramas, a volume of short stories, *Eine Sommerschlacht* (1886), and a novel! *Breide Hummelsbüttel* (1887). In the collections of short stories which appeared under the titles *Unter flatternden Fahnen* (1888), *Der Mäcen* (1889) and *Krieg und Frieden* (1891), he gave powerful, realistic studies of war. Liliencron is one of the greatest of modern German lyric poets; his *Adjutantenritte,* with its fresh original note, broke with the well-worn literary conventions which had been handed down from the middle of the century. His other volumes of lyrics mere Der *Heidegänger* (1893), *Neue Gedichte* (1893), *Bunte Beute* (1903), and the posthumous Gute *Nacht* (1909). To this poetical work should be added the humorous epic in *Ottava rima, Poggfred* (1896; re-written and extended 1904). Liliencron's genius was essentially lyric. He has many exquisite lines, and many perfect stanzas, but few perfect long pieces. In much of his work the influence of the quiet landscape of Holstein is evident.

Liliencron's *Sämtliche Werke* were published in 14 vols. (1904–05), and edit. by R. Dehmel (8 vols., 1911–13). See studies by H. Spiero (Berlin and Leipzig, 1913, bibl.); H. Maynz (1920); I. Wichmann (1922). His published correspondence includes *Ausgewählte* Briefe (ed. Dehmel, 2 vols., 1910); *Liliencrons* Briefe an seinen *Verleger* (ed. W. Friedrich, 1910); *Unbegreiflich Herz,* letters to his first wife (ed. H. Spiero, 1925).

LILIENTHAL, OTTO (1848–1896), German inventor and aeronaut, was born at Auklam on May 23, 1848. With a view to studying the problem of equilibrium, Lilienthal made careful observations of the flight of birds, and succeeded in constructing an aeroplane in which a gliding flight could be maintained. Although his work was improved upon by Pilcher, to Lilienthal belongs the credit of demonstrating the superiority of arched over flat surfaces and of reducing gliding flight to regular practice. He made over 2,000 glides in safety, but on Aug. 9. 1896, his machine was upset by a sudden gust of wind, and he was killed near Rhinow. He was the author of a valuable book, Der *Vogelflug* als Grundlage der

Fliegekunst (1889).

LILITH, a female demon of Jewish folk-lore, equivalent to the English vampire. The personality and name ("night-monster") are derived from a Babylonian-Assyrian demon Lilit or Lilu. Lilith was believed to have a special power for evil over children. The superstition was extended to a cult surviving among some Jews even as late as the 7th century A.D. In the Rabbinical literature Lilith becomes the first wife of Adam, but flies away from him and becomes a demon.

LILLE, a city of northern France, capital of the Nord *département,* 154 mi. *N.* by E. of Paris on the Northern railway. Population (1954) 190,078. Lille lies in a rich agricultural and industrial plain on the right bank of the Deûle. In 1030, Count Baldwin IV of Flanders surrounded with walls a little town which had arisen around the castle of Buc. In the first half of the 13th century. the town obtained communal privileges. Destroyed by Philip Augustus in 1213, it was rebuilt by Joanna of Constantinople, countess of Flanders, but besieged and retaken by Philip the Fair in 1297. After having taken part with the Flemings against the king of France, it was ceded to the latter in 1312. In 1369 Charles V, king of France, gave it to Louis de Male, who transmitted his rights to his daughter Margaret, wife of Philip the Bold, duke of Burgundy. Under Burgundian rule Lille prospered and its merchants were at the head of the London Hansa. Philip the Good made it his residence. With Flanders it passed from the dukes of Burgundy to Austria and then to Spain. After the death of Philip IV of Spain, Louis XIV reclaimed the territory and besieged Lille in 1667. He forced it to capitulate, but preserved its liberties. In 1708, after an heroic resistance, it surrendered to Prince Eugène and the duke of Marlborough. The treaty of Ctrecht restored it to France.

In World War I Lille was first reached by advance German patrols in Aug., 1914. It was afterwards re-occupied by the French, but they retired again early in Oct., the serious defense of the city not being part of the general plan of campaign. After several days' bombardment the Germans entered on Oct. 12, 1914, and remained till Oct., 1918, when they were outflanked by the Allied capture of neighbouring towns. The deportation of a large number of citizens in 1916 was the culminating point of tyranny suffered by the people of Lille under war conditions.

The city was a favourite resort for German officers on leave, as it was not shelled by the Allies, although it was within range of the guns.

Lille is the headquarters of the I army corps, and has an enceinte and a pentagonal citadel, one of \-auban's finest works, west of the town, across the Defile. Before 1858 the town, fortified by Vauban about 1668, occupied an elliptical area of about 2,500 yd. by 1,300, with the church of Notre Dame de la Treille in the centre. but the southern ramparts and ditches were replaced by the Boulevard de la Liberte, a straight line from the goods railway station to the citadel. The new enceinte encloses the old communes of Esquermes, Wazemmes and Moulins-Lille, the area of the town being thus more than doubled and boulevards and squares added. The district of St. André to the north is the only elegant part of the old town. Outside the enceinte populous suburbs surround the city and on the north and east demolition of fortifications and rapid building are making Lille expand towards Roubaix and Tourcoing. At the demolition of the southern fortifications, the Paris gate, erected in 1682 in honour of Louis XIV, after the conquest of Flanders, was preserved. On the east are the Ghent (1617) and Roubaix (1622) gates, in Renaissance style, in bricks of different colours. On the same side the Noble-Tour is a relic of the mediaeval ramparts. There are water gates for the canal of the Defile and for the Arbonnoise, which extends into a marsh in the southwest. The citadel, with barracks and arsenal, is surrounded by public gardens. The churches possess valuable pictures and the modern cathedral of Notre Dame de la Treille has an ancient statue of the virgin, an object of pilgrimage. Lille was made a bishopric in 1913. The Bourse (17th century) is built round a courtyard; the Hôtel d'Aigremont, the HBtel Gentil and other houses are in the Flemish style; the HBtel de Ville was destroyed in the explosion of a munition dump in 1916 but a part of an old palace of Philip the Good (15th cent.) near to it still remains. The Palais des Beaux-Arts contains a museum and picture galleries including a unique collection of original designs of the great masters and a celebrated wax model of a girl's head usually attributed to some Italian artist of the 16th century. Many pictures were removed before the French evacuated Lille in 1914 and the galleries were largely restored after the end of the war in 1918. The large military hospital was once a Jesuit college.

Lille is the seat of a prefect and has tribunals of first instance and of commerce, a board of trade arbitrators, a chamber of commerce and a branch of the Bank of France. It is the centre of an académie (educational division) and has a university with faculties of laws, letters, science and medicine and pharmacy, together with a Catholic institute comprising faculties of theology, law, medicine and pharmacy, letters, science, a technical school, and a department of social and political science. There are also a higher school of commerce, a national technical school. schools of music and fine arts, and the industrial and Pasteur institutes.

The chief industries are the spinning of flax and the weaving of cloth, table-linen, damask, ticking and flax velvet. The spinning of flax thread for sewing and lace-making is specially connected with Lille. The manufacture of woollen fabrics and cotton-spinning and the making of cotton-twist of fine quality are also carried on. There are important printing establishments, state factories for the manufacture of tobacco and the refining of saltpetre and very numerous breweries, chemical, oil. white lead and sugar-works, distilleries, bleaching-grounds, dye-works, machinery and boiler works. Plant for sugar-works and distilleries, military stores, steam-engines. locomotives, and bridges of all kinds are produced by the company of Fives-Lille. Lille is one of the most important junctions of the Northern railway, and the Deûl canal affords communication with neighbouring ports and with Belgium. Trade is chiefly in the raw material and machinery for its industries, in the products thereof, and in the wheat and other agricultural products of the surrounding district.

LILLEBONNE, a town of France in the Seine-Maritime *département,* $3\frac{1}{2}$ mi. *N.* of the Seine and 24 mi. E. of Le Havre by the Western railway. Pop. (1954) 5,396. It lies in the valley of the Bolbec at the foot of wooded hills. Lillebonne—under the Romans, Zuliobona—was the capital of the Caletes in the time of Caesar. by whom it was destroyed. Rebuilt by Augustus, it became an important focus of Roman roads, but was later ruined by barbarian invasion. The remains of ancient baths and of a great theatre have been brought to light, and many Roman and Gallic relics found. The medieval fortifications were built of materials from the theatre. The church of Notre-Dame has a 16th century tower and portal; the donjon of a 13th century castle stands in the park. The principal industries are cotton-spinning and the manufacture of calico and candles.

LILLIBULLERO or LILLIBURLERO, the name given to a song popular at the end of the 17th century, especially among the army and supporters of William III in the war in Ireland during the revolution of 1688. The tune appears to have been much older, and was sung to an Irish nursery song at the beginning of the 17th century. The attribution to Henry Purcell is based on the very slight ground that it was published in *Music's Handmaid,* 1689, as "A new Irish Tune" by Henry Purcell.

The doggerel verses have generally been assigned to Thomas Wharton, and deal with the administration of Talbot. earl of Tyrconnel, appointed by James as his lieutenant in Ireland in 1687. The refrain of the song *Lilliburlero bullen* a *la* gave the title of the song. Wharton claimed he had "sung a king out of three kingdoms" and Burnet says "perhaps never had so slight a thing so great an effect." The air was introduced uith success by Gay (*q.v.*) into *The Beggar's Opera.*

LILLIE, FRANK RATTRAY (1870–1947), **U.S.** zoologist who demonstrated that fertilization involves the interaction of specific substances borne by the egg and sperm (fertilizin theory), and that embryonic sex differentiation is controlled by sex hormones circulating in the blood between fetal cattle tains (freemartin theory). Born in Toronto, Ont. on June 27. 1870. he nas educated at the University of Toronto and The University of Chicago (Ph.D., 1894). Returning to The University of Chicago in 1900, he became professor of embryology in 1906 and distinguished service professor in 1931. He served as chairman of the department of zoology (1910–31) and dean of the division of biological sciences (1931–35). Through his leadership (1908–42) the Marine Biological laboratory (Woods Hole, Mass) was built into a research institution of international distinction.

Lillie was founder and first president of the Woods Hole Oceanographic institution. He served as president of the National Academy of Sciences (1935–39) and was anarded its Agassiz medal in 1940. His books include Development of the Chick (1908, 1919), Problents of Fertilization (1919) and The *Woods* Hole Marine Bzological Laboratory (1944). He died in Chicago on Nov 5, 1947.

For a full account of Lillie's career see Biological *Memoirs,* National Academy of Sciences, vol. 30 (1957). (B. H. W.)

LILLO, GEORGE (1693–1739), English dramatist whose tragedy The London *Merchant,* or *the* History of George *Barnwell* (1731) revived an interest in domestic themes and influenced the sentimental drama of France and Germany, was born in London. Feb. 4, 1693. the son of a Dutch jeweler. He was for many years a partner in his father's business. His first piece *Silvia,* or the *Country Burial* (1730), a ballad opera, was produced at Lincoln's Inn Fields. The London Merchant, produced by Colley Cibber at Drury Lane, is founded on "an excellent ballad of George Barnwell, an apprentice of London who . . . thrice robbed his master, and murdered his uncle in Ludlow." Lillo had gone back to the Elizabethan domestic drama of passion of which the anonymous *Yorkshire* Tragedy is a type. Scoffing critics called it, with reason, a "Newgate tragedy" but it was regularly acted for many years at holiday seasons for the moral benefit of the apprentices. The last act contained a scene generally omitted on the London stage, in which the gallows actually figured. In 1734 Lillo celebrated the marriage of the Princess Anne with William IV of Orange in Britannia and Bataaia, a masque.

His other dramas were: *The Christian* Hero (1735); Fatal Curiosity (1736); an adaptation of *Pericles, Prince of* Tyre entitled *Marina* (1738); and *Elmerick,* or Justice *Triumphant* (1740).

Lillo died in London. Sept. 3. 1739. His unfinished version of the anonymous Elizabethan tragedy Arden of *Feversham* was completed by Dr. J. Hoadly and produced in 1759. His *Dramatic Works,* with *Memoirs* of the *Author* by *Thomas* Dacies were published in 2 vol., 2nd ed. (1810).

See E. Bernbaum, The Dranza of Sensibility (1915).

LILLY, WILLIAM (1602–1681), English astrologer immortalized as Sidrophel in Samuel Butler's Hudibras, was born on Mav 1. 1602. at Diseworth in Leicestershire, and was educated at the school of Ashby-de-la-Zouch. In April 1644. he began publishing his astrological almanacs. which received serious attention from some of the most prominent members of the Long Parliament. Like all successful astrologers. he tempered the indications given by the aspects of the heavens with his knowledge of current events, with the result that his predictions often showed a sympathy with the parliament. For this reason, and because he misjudged the scientific revolution that spread so rapidly in England during the 17th century. Lilly fell into disrepute after the Restoration.

He died at Hersham Surrey, on June 9. 1681. (0. J. E)

LILY, WILLIAM (1468?–1522), English Renaissance scholar and classical grammarian, was born at Odiham Hampshire. about 1468. After graduating at Oxford university he traveled in the south and east of Europe, during which time he studied Greek. He became the personal friend of William Grocyn. Thomas Linacre and Sir Thomas More. After teaching privately in London he was appointed high master of Dean Colet's refoundation of St. Paul's school (1512–22). He died in 1522.

Lily was a pioneer of Greek learning in England and one of the authors of the Latin grammar which bears his name. In 1540 Henry VIII ordered it to be used in all English grammar schools. In the Anglican canons of 1604 the bishop. when visiting a school, was directed to ask if the "Royal Grammar" was used.

Lily's *Grammar* was severely criticized by schoolmasters, and numerous revisions were made which corrected errors, eliminated needless complications and contributed useful additions. The most important criticism concerned the Latin syntax "by which children have been usually put upon learning the construction of a language, they were unacquainted with, from rules given them in that very language." Thus English translations of the rules and the syntax were made by William Haine of Merchant Taylors' school (1637). Richard Busby (1659) and many others. Charles Hoole published an edition in 1651 with an English translation on the left-hand pages.

Editions incorporating recognized emendations were also published at Cambridge (1634 and 1630) and at Oxford (1636 and 1687). John Ward's edition (1732) was commonly used in 18th-century English schools. Revised in 1758 and appropriated by Eton college as the Eton *Latin Grammar,* it was finally superseded ten years later by the *Public School* Latin *Grammar.*

Curtis, History *of Education in Great Britain,* 4th ed. (1957); Watson Foster, The English *Grammar* Schools to 1660: their Curriculum and *Practice,* ch. xv–xviii (1908). (S. J. C.)

LILY (Lilium), the typical genus of the family Liliaceae, embracing about 80 species, all confined to the northern hemisphere and widely distributed throughout the north temperate zone. The earliest in cultivation were described in 1597 by John Gerard, who figured eight kinds of true lilies, including L. *candidum* and a variety. *bizantinum;* two umbellate forms of the type L. *bulbiferum,* named L. *aureum* and L. *cruentum latifolium;* and three with pendulous flowers, apparently forms of the martagon lily. Parkinson. in his Paradisus (1629), described five varieties of martagon. six of umbellate kinds. together nith one American. L *canadense.*

MADONNA LILY (LILIUM CANDIDUM), KNOWN FROM ANTIQUITY

The Madonna lily. L. candi*dum,* was one of the commonest garden flowers of antiquity, appearing in the poets from Homer on, sharing popularity with the rose and the violet. Roses and lilies are thought to have entered Greece from the east by nay of Phrygia, Thrdce and Macedonia Mythologically the white lily Rosa *junonis* (called Madonna in the late 19th century) was fabled to have sprung from the milk of Hera. As the plant of purity it was contrasted with the rose of Aphrodite.

The word krinon (lily), on the other hand, included red and purple lilies. The red lily was that best known in Syria and Judaea, and the lily of the Old Testament may be conjectured to be a red lily from the simile used in Song of Solomon v, 13 ("His lips are lilies!') unless the allusion is to the fragrance rather than to the colour. The "lilies of the field" (Matt. vi, 28) are quite certainly Anemone coronaria, the poppy anemone, which is common in Palestine where lilies are not.

In North America about 20 native species of lily occur. In the eastern half of the continent the best-known are the wood lily (L. *philadelphicum*), the meadow lily (L. *canadense*), the Turk's-cap lily (*L. superbum*) and the bell lily (L. *grayi*). Noteworthy among the ten native lilies found in the Pacific states are the Washington lily (L. *washingtonianum*), the Columbia lily (L. *columbianum*) and the Humboldt lily (L. *humboldtii*). None of these American lilies compares with those from the Himalayas, Korea, China and Japan as garden plants. But many magnificent hybrid lilies were developed after 1930 on the Pacific coast. The North American Lily society at a meeting held at Cornell university awarded trophies for some of these outstanding hybrids to E. F. Palmer and Jan de Graaff. No true lily is found native in Great Britain.

The structure of the flower represents the simple type of monocotyledons, consisting of two whorls of petallike perianth lobes, of three free parts each: six free stamens: and a consolidated pistil of three carpels, ripening into a three-valved capsule containing many winged seeds. In form, the flower assumes three types: trumpet-shaped, with a more or less elongated tube (*e.g., L. longiflorum,* the white trumpet lily, and L. *candidum,* the Madonna lily); an open form with spreading perianth leaves (*e.g.,* L. *auratum*); or assuming a pendulous habit, with the tips strongly reflexed (*e.g.,* the martagon type). All have scaly bulbs which. in three western American species such as L. *humboldtii,* are remarkable for being somewhat intermediate between a bulb and a creeping rhizome. L. *bulbiferum* and its allies produce aerial reproductive bulbils in the axils of the leaves.

The bulbs of several species are eaten in some areas of the world. Medicinal uses were once ascribed to the species, but none appears to have any marked properties in this respect. From L. *longiflorum* was developed in Oregon the Croft lily, the commonest Easter lily in the United States.

The noble L. *auratum,* with its large white flowers, having a yellow band and numerous red or purple spots, is a magnificent plant when grown to perfection; and so are the varieties called *rubrovittatum* and Crimson Queen, which have the central band crimson instead of yellow, and the broad-petaled *platyphyllum* and its almost pure white subvariety called *virginale.* Of *L. speciosum,* the Japanese lily (well known to most gardeners as *lancifolium*), the true typical form and the red-spotted and white varieties are impressive plants for late summer blooming.

The tiger lily. L. *tigrinum,* and its varieties *fortunei, splendens* and *plenescens* are among the best species for the flower garden.

The pretty L. *leichtlinii* and *L. monadelphum,* with drooping yellow flowers, and the scarlet droop-flowered *L. tenuifolium* comprise, with those already mentioned, a series of the finest hardy flowers of the summer garden. The Indian L. *giganteum* is distinct in character, having broad heart-shaped leaves and a noble stem 10 to 14 ft. high and bearing a dozen or more large, deflexed, funnel-shaped, purple-stained white flowers; L. *cordatum* (China and Japan) is similar in character, but shorter stemmed.

The cultivation of lilies is not difficult if the gardener keeps in mind a few essentials. Nearly all of them tend to die out in a few years and should therefore be replaced by fresh plantings. They are rich feeders and should only be planted in rich garden loam, with a layer of well-rotted manure well below the bulb but never touching it. Many species, notably *L. hansonii* and *L. henryi,* prefer partial shade to full sun. Drainage must be perfect because they will not stand stagnant water over the winter. If rodents (which eat the bulbs) are a pest, bulbs should be planted in underground wire cages.

In planting (except for *L. candidum,* which should be planted shallowly) the bulbs should be planted at least three times their height below the surface, so that stem roots which develop above the bulb will be in the soil. If a bulb is 3 in. high, its base. when planted, should be 9 in. below the surface. All lilies respond to a winter mulch of manure about $1\frac{1}{2}$ in. thick. Tall sorts must be staked if the site is windy.

The word "lilv" is looselv used in connection with many plants which are not really members of the genus *Lilium,* but belong to genera which are quite distinct botanically.

Thus the Lent lily is a *Narcissus;* the African lily is *Agapanthus africanus;* the Belladonna lily is *Amaryllis belladonna (see* AMARYLLIS); the Jacobaea lily is *Sprekelia formosissima;* the Mariposa lily is *Calochortus;* the Peruvian lily is *Alstroemeria;* St. Bernard's lily is *Anthericum liliago;* St. Bruno's lily is *Pnradisea liliastrum;* the water lily is *Nymphaea;* the giant water lily of the Amazon is *Victoria regia* (*q.v.*); the arum lily is *Zantedeschia aethiopica;* and there are many others, among them the day lilies (*Hemerocallis*). *See* references under "Lily" in the Index volume.

BIBLIOGRAPHY.—For the ancient and medieval history of the lily *see* M. de Cannart d'Hamale, *Monographie historique et littéraire des lis* (1870). Authorities ior description and classification of the genus are J. G. Baker, "Revision of the Genera and Species of Tulipeae," *Journ. of Linn. Soc.,* 14:211 (1874), and H. J. Elwes, *Monograph of the Genus Lilium* (1880). The best sources on cultivation and varieties are H. M. Fox, *Garden Cinderellas* (1930); H. B. D. Woodcock and J. Coutts, *Lilies: Their Culture and Management* (1935); H. B. D. Woodcock and W. T. Stearn *Lilies of the World* (1950); M. E. Leeburn, *Lilies and Their Cultivation* (1955). *See* also the Royal Horticultural society's *Lily Year Book* (1947–58).

(N. TR.)

LILY OF THE VALLEY (CONVALLARIA MAJALIS)

LILY OF THE VALLEY (*Convallaria majalis*), a beautiful plant of the lily family (Liliaceae), native to moods in some parts of England. Europe, northern Asia and possibly in the higher Allegheny mountains from Virginia to Tennessee, although the American plant is thought by some to be C. *montana,* an endemic species.

It is widely cultivated for its dainty, white, nodding, fragrant flowers. borne in spring on slender stalks, which, like the two oblong basal leaves, rise from an underground creeping stem, or rootstock. On these underground stems arise small detachable buds, commonly called pips. These. if planted about $1\frac{1}{2}$ in. deep preferably in the shade, represent the easiest way to start a planting. There are also doubleflonered and pink horticultural varieties. (N. TR.)

LIMA, a department in central Peru bounded on the southwest by the Pacific ocean, on the northwest by Ancash on the northeast by Huánuco. Pasco, Junin and Huancavelica and on the southeast by Ica. The northeastern border of the department is drawn along the westernmost range of the Andes, which forms the continental divide. Area 13,087 sq.mi. Pop. (1958 est.) 1,625,848. The capital is the city of Lima, pop. 1.186~212.

FOTO BOOZ FROM ANDEAN AIR MAIL AND PERUVIAN TIMES

MINISTRY OF EDUCATION BUILDING
One of the tallest structures in Lima

Along the coast there is seldom any rain at all. At Lima the average annual rainfall is 1.8 in., yet many years pass with no recorded rainfall. Temperatures along the coast are low, averaging between 61° F. in August and 74.3° in February. Only where rivers descend from the Andes can there be· irrigation. The five chief rivers—the Chancay. Huaura, Mala, Rimac and Cafiete—are all short and only the last two, which rise in snow fields among the highest peaks, have a vear-round flow of water to the ocean.

The coast is peculiar in that a thick cloud rests over it, especially from June to October. This cloud is in contact with the mountain slopes from about 2.500 ft. to 4,000 ft above sea level and there, in the fog zone, is a lush growth of herbaceous annuals known as *loma,* on which cattle can be fed. Above the zone of lomas there is a regular rainy season from October to April.

Outside the great urban concentration of Lima and Callao (*qq.v.*) most of the people work as farmers and herders. Cattle destined for the market in Lima are driven up and down the mountain slopes to feed on the vegetation as it turns green with the rainy season or the fog season. The lomas provide pasture from June to October and the high mountain grasslands are green irom October to April. From April to June cattle are fed on hay grown under irrigation. Other crops of the irrigated lowlands include sugar cane, cotton and a variety of vegetables.

There is some fishing off Callao and Huacho, but not nearly so much as the wealth of fish life would support. Salt is produced from the evaporation of sea water at Huacho and Chilca. In the mountains there are copper mines at Casapalca, and coal mines at Oyon. The department is crossed from northwest to southeast by the Inter-American highway and is connected with the highland centres by both rail and highway.

(P. E. J.)

LIMA (a corruption of Rimac), capital of Peru and of the department of Lima (12° 3′ 3″ S., 77° 2′ 14″ W.), on the Rimac. a river in summer, a rivulet in winter, is $8\frac{1}{2}$ mi, from its seaport, Callao (*q.v.*).

In the desert coast zone, nearly 500 ft. above sea level, the city is surrounded by an irrigated plain, out of which rise, here and there. rugged hills, among them San Cristobal (1,343 ft.) just north of the city. Pop (1958 est.) 1,186,212.

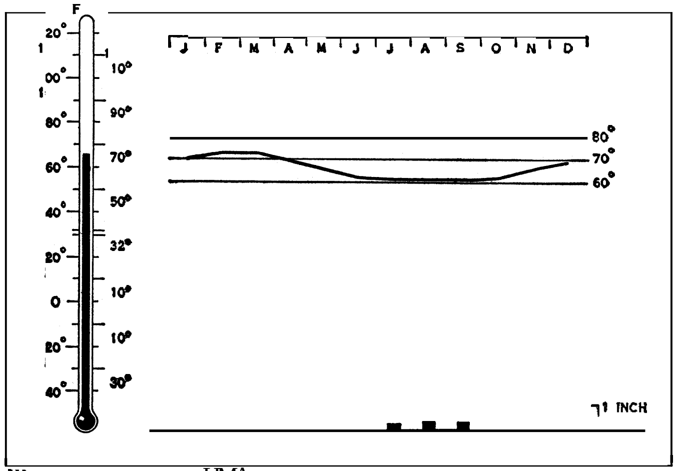
The climate is moderate, the mean annual temperature being 66° F.; it seldom drops below 54° or rises above 80°. Though there is almost no precipitation, the sky is overcast during the winter, when fogs and high relative humidity make it seem colder than it is.

History.—Lima was founded as the City of the Kings by Francisco Pizarro on Jan. 18, 1535, on the left bank of the Rimac. He traced the outlines of the chief plaza (Plaza de *Armas*) and the checkerboard of streets enclosing square areas (*manzanas*) with open plazas at intervals, a pattern which still survives. On the same day he laid the cornerstone of the cathedral, consecrated in 1625, where his remains are still preserved. Lima became the luxurious capital of the viceroys, the first of whom arrived in 1544. The obligatory centre of Spanish trade on the entire continent, it was the focus of Spanish colonization in South America. By a grant from Charles V, the Universidad Mayor de San Marcos was founded in 1551 under Dominican direction and secularized in 1571. The first archbishop was appointed in 1545. In 1570 the Inquisition was established. As vast wealth from the mines accumulated, the city was embellished with elaborate balconies and carved stone portals, while churches and monasteries glittered with gold and silver. Stone bridges were built across the Rimac; that of 1610 is still standing. Meanwhile, for protection against attacks of foreign pirates, the Duke of La Palata (viceroy 1681–89), built the city walls which stood until 1870, when they were razed and replaced by the present boulevards. This metropolis of a colonial empire was destroyed by earthquake on Oct. 28, 1746, and little in the present city antedates that catastrophe.

During Peru's struggle for independence Lima was the centre of Spanish resistance, and even after independence was declared (1821), it remained rigidly conservative. The era of reconstruction was followed by a vast influx of money from guano deposits, which resulted in some public improvements, such as the railway to Callao (1851), lighting and water systems. The city suffered from all the revolutions which convulsed Peru under the republic, but the greatest calamity was its occupation by a Chilean army from Jan. 17, 1881, to Oct. 22, 1883. During that time public buildings and scientific, literary and artistic collections were systematically pillaged. The spirit, as well as much of the history of Lima, is embodied in the six volumes of *Tradiciones* Peruanas by Ricardo Palma.

Streets, Buildings and Public Utilities.—The present city is a curious blend of old and new. The streets, about 30 ft. wide, are paved with stone or asphalt. Most of them have a different name on every block. The houses are usually one story in height, of adobe covered with plaster, built about a patio with plants and flowers, and barred outer windows. The better ones are two storys high, with balconies overlooking the street. The Torre Tagle mansion, now the foreign office, is the best remaining example of secular colonial architecture. The Plaza ***de Armas*** is still the centre of Lima, from which tram and omnibus lines radiate. It is surrounded by the cathedral on the east, the archbishop's palace, municipal building, government palace (Palace of the Viceroys), rebuilt and enlarged in 1938, and numerous shops and arcades. On the Plaza de la *Inquisición* is the ancient Inquisition building, now the senate house, with the chamber of deputies near by. In addition to the government palace, the National Palace of Justice (1939) and the Municipal palace (1944) are outstanding among later government edifices.

All the plazas have fountains, shrubs. and flowers. Some of them have statues of national heroes, such as Manco Capac, Bolívar, San Martin and Bolognesi. Many wide avenues, paved with concrete, are favourite promenades. The Paseo *Colón*, 1 mi. long, 150 ft. wide, with a statue of Columbus, is bordered by trees, flowers and beautiful residences. At one end is the Exposition park, 30 ac. of gardens, walks, artificial lakes, the national museum, mining and metallurgy exposition building and a zoological garden. A favourite promenade for the poorer classes is the Alameda de *los* Descalzos, north of the river, a shady avenue with statues and marble benches, leading to the monastery of the barefoot friars. Several concrete or asphalt highways have been built to neighbouring towns and suburbs. such as the Avenida *del* Progreso to Callao and Avenida *Leguía* to Miraflores, five miles to the south. Electric tramways and buses run to Miraflores, Barranco and Chorrillos, to Magdalena and through Callao to La Punta, all of which are bathing and yachting resorts. In and about Lima there are more than 90 mi. of street railways.



WEATHER GRAPH OF LIMA. THE THERMOMETER INDICATES THE ANNUAL MEAN TEMPERATURE. THE CURVE SHOWS THE NORMAL MONTHLY TEMPERATURE. AND THE COLUMNS, THE NORMAL MONTHLY PRECIPITATION. MONTHS NOT ACCOUNTED **FOR** IN COLUMN HAVE **A** "TRACE" OF PRECIPITATION. LESS THAN 0.1 INCH

During winter, the favourite resort is Chosica, 30 mi, east of Lima on the Central railway, with a sunny climate above the fogs. Chosica may also be reached by the Central highway. Peruvians are fond of sports, especially association football. There is a modern country club with tennis courts, golf links and polo field. The Jockey club has a racecourse with large grandstand, but the best races are held at the San Felipe hippodrome. The bull ring, the Plaza de Toros in Alameda de Acho, built in 1768, accommodates 8,000 spectators. There are several excellent theatres and numerous cinemas. Many parts of the ancient City of the Kings present a quite modern appearance, with tall office buildings, banks. schools, mid-20th century style homes. excellent hotels and a large two-story central market building which covers an entire block.

An enlarged water supply involved building two reservoirs of reinforced concrete. of 26,000,000 l. and 13,000,000 l. capacity, additional collecting galleries, a new aqueduct and renewing 62 mi. of pipe. A 16-in. main was also built to Miraflores.

Churches and Other **Institutions.**—In spite of these modern improvements, the past still presides over Lima. More than 50 Spanish colonial churches are scattered throughout the city, among which are Santo Domingo, San Francisco, La Merced, San Agustin and the Sanctuary of Santa Rosa de Lima, built on the site of the house where she was born in 1586, besides monasteries and convents of which that of San Francisco is the largest. Freedom of worship was granted to Protestants in 1915, and there are several Protestant churches. Among the clubs, some of which are located on the *Plaza de Armas*, should be mentioned the National, founded 1855, Union, 1868, and many foreign clubs such as the Phoenix (British) club. Learned societies include the Athenaeum, founded (1877) as a literary organization, the Historical institute (1905) and the Geographical society (1888), with a library of 10,000 volumes, 2,000 maps and a small museum as well as a seismological observatory. Its bulletins are a treasure house of information. The Corps of Mining and Hydraulic Engineers (1902) also issues bulletins indispensable to a student of the field. There is a national academy of medicine (1885), an outgrowth of that established by Dr. Unánue in 1787, engineers' and lawyers' clubs, a geological society and many more.

Education. — The University of San Marcos (1551) has faculties of theology, jurisprudence, medicine, political and economic science, philosophy, history and letters. mathematical, physical and natural sciences, and institutes of pharmacy and dentistry. It has a library, two museums, a department of physical education, a gymnasium and a meteorological observatory. The Catholic university has faculties of letters, jurisprudence and political science. A school of engineering was established in 1876 with departments of mines, civil engineering and architecture. There is a school of scientific agriculture, a military school in Chorrillos, a naval academy in La Punta, a school of arts and crafts, a popular university, established in 1921, a school of fine arts (1918), a teachers' college (1905), normal schools, a reform school for boys, the Jorge Chávez school of aviation, a national academy of music and conservatory, business and language schools, numerous secondary schools for boys, the largest of which is Guadalupe (1841), and some for girls, though the majority of schools for girls are convents or private schools. There are in all ten museums, which include collections of Peruvian antiquities, arts, costumes and paintings of scenes and characters in national history. The Lima charity organization maintains public hospitals, including the Arzobispo Loayza, modern in design and equipment. There are many private hospitals, eight volunteer fire companies, five large markets and a modern prison. The National library, founded in 1821 and destroyed by the Chileans in 1881, was razed by fire on May 10, 1943, destroying the library's valuable collection of some 120,000 volumes. A new building on the same site was completed in 1945. There is postal and telegraphic service with cable connection at Callao, and wireless communication from a high-power station near Lima. Lima's airport, 3 mi. from the city at Limatambo, is one of South America's best. There are many newspapers, chief among them *El Comercio* (1839), and periodicals devoted to various interests, some illustrated, some published in foreign languages.

Trade, Industry and Finance. — Hydroelectric power for city lighting and tramways, as well as for industrial purposes, is furnished by the Lima Light, Power and Tramways company, transferred by high-tension wires from Chosica and Yanacoto. Business is chiefly in the hands of wholesale houses, both native and foreign, which export raw products and import manufactured goods. They have chains of branch houses throughout the republic.

The most important manufacturing industry is textiles; eight cotton and two woollen mills have a total production of more than 30,000,000 yd. a year. Other industries are tanneries, factories for making shoes and leather articles, hats, furniture, chocolate and biscuits, tile, candles, soap and powder; also oil refineries, coke ovens, railway shops, flour mills, distilleries and breweries.

The *Estanco del Tabaco,* subsidiary of the National Tax Collecting company, has a factory in Lima which produces cigarettes and cigars. Other industries include factories for making glass, portland cement, aluminum articles for household use, rubber goods, hosiery and chemicals (caustic soda and chloride of lime).

The principal banks, with branches in other cities, are the Bank of London and South America; Italian bank (1889), now the Credit Bank of Peru; Popular bank (1899); Royal Bank of Canada (1916); National City bank (1920). The *Caja de Ahorros* (Savings bank) was established in 1868, the *Caja* de *Depdsitos y Consignaciones* (a depository for government trust funds such as customs receipts, internal taxes, tobacco revenues) in 1905 and the Reserve bank in 1922 (*see* also PERU).

BIBLIOGRAPHY.—J. Bromley and J. Barbagelata, ***Evolución urbana** de la ciudad de Lima* (Lima, 1945); Blue *Guide: Peru Ancient and Modern,* vol. ii (Lima) (Lima, 1946). (M. T. BI.; X.)

LIMA, a city of northwest Ohio, U.S., is located on the Ottawa river (Hog creek), 79 mi. S.S.W. of Toledo; the seat of Allen county. The site was designated by state law in 1831, and its name was chosen by lot, the last to be drawn from a hat. It was incorporated in 1832.

Lima became the centre of the northwest Ohio oil fields in the 1880s and 1890s, especially after scientists discovered a commercially profitable method of removing the oil's sulfur content. and peak annual output once surpassed 20.000.000 bbl. As production diminished in the 20th century. Lima became the centre of a pipeline system operated by six major oil companies from fields in Wyoming, Texas and Oklahoma and supplying the Great Lakes and east coast.

Lima's factories manufacture machine tools, automotive engines, aircraft parts, power shovels and cranes, quarry and road-building equipment, cigars. electric and neon signs, enamelware, steel castings, school and highway buses, hearses, electric motors, rubber, petroleum products and chemicals. It is also the centre of a diversified agricultural area producing grain. soybeans, sugar beets, potatoes, and dairy, poultry and meat products.

Nearby are Indian Lake, Lake St. Mary's and Ft. Amanda State parks.

The population in 1960 was 51,037; for comparative population figures see table in OHIO: *Population.* (R. C. Do.)

LIMAÇON: *see* CURVES, SPECIAL.

LIMAN VON SANDERS, OTTO (1855–1929), German soldier, was born in Stolp, Prussia, Feb. 18, 1855. Entering the German army in 1874 he held various posts in the cavalry, and in 1913 was sent to Turkey as leader of a German military mission. His appointment as commander of the 1st Turkish army was annulled because of Russian protests, but he remained inspector of the Turkish army. Made a Prussian general in Jan. 1914, in November he was given the chief command of the Turkish troops in the Caucasus. In March 1915, as commander of the 5th Turkish army, he successfully opposed the British and French attacks on the Dardanelles and Gallipoli. In 1918 Von Sanders succeeded Freiherr von der Goltz as leader of the Turkish forces in the middle east, and was in command in Syria and Palestine when Viscount Allenby was victorious there. Von Sanders escaped capture, but after the Armistice gave himself up to the Allies and was interned until Aug. 1919. He gave an account of his experience in Turkey in *Fünf Jahre Türkei* (1920; Eng. trans. 1928), which throws much light on the Dardanelles campaign and on Turkish politics. He died at Munich on Aug. 23, 1929.

LIMASOL (anc. LEMESSUS), a seaport on the south coast of Cyprus, in Akrotiri Bay with a considerable trade in wine and carobs. Pop. (1946) 22,799. Only a fort attributed to the 13th century has survived many earthquakes and much warfare. In the neighbourhood are the ancient sites of Amathus and Curium. Limasol was the scene of the marriage of Richard I, king of England, with Berengaria of Navarre, in 1191.

LIMB. (1) A word of Teutonic origin, meaning any member of the body, but now restricted to the legs and arms or the lower (pelvic) and the upper (thoracic) limbs. The word is also used of the main branches of a tree, of the projecting spurs of a range of mountains, of the arms of a cross, etc. "Limb" was used by ecclesiastical writers of the 16th and 17th centuries of a person as being a component part of the church or other corporate body; *cf.* such expressions as "limb of the law," etc.

It is also a term for an estate dependent on another, or for the subordinate members of the Cinque Ports, attached to one of the principal towns; Pevensey was thus a "limb" of Hastings. (2) An edge or border, frequently used in scientific language for the boundary of a surface; *e.g.,* the edge of the disk of the sun or moon, or of the expanded part of a petal or sepal in botany. This word is a shortened form of *limbo* or *limbus,* Lat. for "edge," for the theological use of which *see* LIMBUS.

LIMBA, a small group of intelligent, dark-skinned people of medium stature, living in the valleys of the upper Little Skarcies and Kakuna rivers in Sierra Leone, skilled traders, speaking an ancient language related to Landuman and Timne. They are grouped in confederated villages under a paramount chief. The paternal nephew marries the widow of his paternal uncle. The Limba are organized in clans and have secret societies and age classes. They are engaged in cultivation, arboriculture and cattle-raising. Their religion is animist in type, and there are traces of totemism.

See N. W. Thomas, *Anthropological Report on Sierra Leone* (1916).

LIMBACH, a town in the district of Karl-Marx-Stadt, Ger., in a manufacturing area 6 mi. W.N.W. from the city of Karl-Marx-Stadt. Combined with the town of Oberfrohna to form Limbach-Oberfrohna. Pop. (1950) 28,493. Its industries include the making of hosiery, gloves, cloth, silk and sewing machines, and dyeing and bleaching.

LIMBORCH, HENDRICK VAN (1680–1758), Dutch painter, was born at The Hague, Holland. He studied painting under Adriaan van der Werff, whose style he imitated rather successfully, although he never acquired the skill of his master. Limborch is known for landscapes, portraits and historical paintings. His extant works include "The Repose in Egypt" and "The Golden Age," both of which hang in the Louvre, "Venus and Cupid" and "Cupid and Psyche."

LIMBORCH, PHILIPP VAN (1633–1712), Dutch Remonstrant theologian, was born on June 19, 1633, at Amsterdam, where his father was a lawyer. He received his education at Utrecht, at Leyden, in his native city and finally at Utrecht university, which he entered in 1652. In 1657 he became a Remonstrant pastor at Gouda, and in 1667 he was transferred to Amsterdam, where, in the following year, the office of professor of theology in the Remonstrant seminary was added to his pastoral charge. He was a friend of John Locke. He died at Amsterdam, April 30, 1712.

His most important work, *Institutiones theologiae christianae, ad praxin pietatis et promotionem pacis christianae unice directae* (Amsterdam, 1686, 5th ed., 1735, Eng. trans. 1702), is a full and clear exposition of the system of Simon Episcopius and Stephan Curcellaeus. The fourth edition (1715) included a posthumous "Relatio historica de origine et progressu controversiarum in foederato Belgio de praedestinatione." Limborch also wrote *De veritate religionis Christianae amica collatio cum erudito Judaeo* (Gouda, 1687); *Historia Inquisitionis* (1692), in four books prefixed to the "Liber Sententiarum Inquisitionis Tolosanae" (1307–23) and *Commentarius* in *Acta Apostolorum et in Epistolas ad Romanos et ad Hebraeos* (Rotterdam, 1711). His editorial labours included the publication of various works of his predecessors and of *Epistolae ecclesiasticae praestantium ac eruditorum virorum* (Amsterdam, 1684), chiefly by Jakobus Arminius, Joannes Uytenbogardus, Konrad Vorstius (1569-1622), Gerhard Vossius (1577–1649), Hugo Grotius, Simon Episcopius (his granduncle) and Gaspar Barlaeus; they are of great value for the history of Arminianism. An English translation of the *Theologia* was published in 1702 by William Jones (*A Complete System or Body of Divinity, Both Speculative and Practical, Founded on Scripture and Reason,* London, 1702); and a translation of the *Historia Inquisitionis,* by Samuel Chandler, with "a large introduction concerning the rise and progress of persecution and the real and pretended causes of it" prefixed, appeared in 1731.

LIMBURG (LIMBOURG), **POL** (fl. *c.* 1400), Flemish miniature painter was the most famous of three brothers whose family name was Malouel, all of whom followed the same profession. At one time Pol traveled to Italy to study at first hand the works of contemporary Italian artists, whose influence is clearly evident in his later work, but little else is known of the details of his early life. Any records there may have been have disappeared, probably destroyed by the wars which ravaged the Netherlands during his lifetime.

For a time he and his two brothers, Hermann and Janneken, worked for Philip the Bold, duke of Burgundy, beginning for him the illustration of the *Bible historike.* This manuscript was later finished by other hands after Philip's death in 1404. Not long after, probably about 1411, the brothers entered the service of Philip's brother, John, duke of Berry, and it was under his patronage that Pol did his best work, the illuminating of the two prayer books *Les Très riches Heures du duc de Berry* and *Les Heures d'Ailly* (also known as the *Belles Heures).*

Although Pol did not finish the first manuscript in his lifetime, he and his brothers are thought to be responsible for nearly half of it, and it may have been partially completed after Pol's death by Hubert and Jan van Eyck, whose style Pol was one of the first of the Flemish painters to foreshadow.

See The Metropolitan Museum of Art, *The Belles Heures of Jean, Duke of Berry, Prince of France* (1958).

LIMBURG, one of the many small feudal states into which the duchy of Lower Lorraine was split up in the second half of the 11th century. The first count was Walram of Arlon, who married Judith, the daughter of Frederick of Luxembourg, duke of Lower Lorraine (d. 1065), who bestowed upon him a portion of his possessions lying upon both sides of the river Meuse. It received its name from the strong castle built by Count Walram on the river Vesdre, where the town of Limburg now stands. Henry, Walram's son (d. 1119), was turbulent and ambitious. On the death of Godfrey of Bouillon (1089) he forced the emperor Henry IV to recognize him as duke of Lower Lorraine. He was afterwards deposed and imprisoned by Count Godfrey of Louvain, on whom the ducal title had been bestowed by the emperor Henry V (1106). For three generations the possession of the ducal title was disputed between the rival houses of Limburg and Louvain. At length a reconciliation took place (1155). The name of duke of Lower Lorraine thenceforth disappeared, the rulers of the territory on the Meuse becoming dukes of Limburg, those of the larger territory to the west, dukes of Brabant. With the death of Duke Walram IV (1280) the succession passed to his daughter, Irmingardis, who was married to Reinald I, count of Guelders. Irmingardis died without issue (1282); and her cousin, Count Adolph of Berg, laid claim to the duchy. His rights were disputed by Reinald, who was in possession and was recognized by the emperor. Too weak to assert his claim by force of arms Adolph sold his rights to John I, duke of Brabant (*q.v.*) in 1283. This led to a long and desolating war which lasted until 1288. At the end of that time, finding the power of Brabant superior to his own, Reinald in his turn sold his rights to Count Henry III of Luxembourg.

Henry and Reinald, supported by the archbishop of Cologne and other allies, now raised a great army. The rival forces met at Woeringen and John of Brabant gained a complete victory, after which the duchies of Limburg and Brabant passed under the rule of a common sovereign. The duchy comprised during this period the bailiwicks of Hervé, Montzen, Baelen, Sprimont and Wallhorn and the counties of Rolduc, Daelhem and Falkenberg, to which was added in 1530 the town of Maastricht. The provisions and privileges of the famous Charter of Brabant, the *Joyeuse Entrke* (*q.v.*), were from the 15th century extended to Limburg and remained in force until the French Revolution.

By the Treaty of Westphalia (1648) the duchy was divided into two portions, the counties of Daelhem and Falkenberg with the town of Maastricht being ceded by Spain to the United Provinces, where they formed what was known as a "Generality-Land." At the peace of Rastatt (1714) the southern portion passed under the dominion of the Austrian Habsburgs and formed part of the Austrian Netherlands until the French conquest in 1794. During the period of French rule (1794–1814) Limburg was included in the two French departments of Ourthe and Meuse Inférieure. In 1814 the old name of Limburg was restored to one of the provinces of the newly created kingdom of the Netherlands, but the new Limburg comprised, besides the ancient duchy, a piece of Gelderland and the county of Looz. At the revolution of 1830 Limburg, with the exception of Maastricht, threw in its lot with the Belgians, and during the nine years that King William refused to recognize the existence of the kingdom of Belgium, the Limburgers sent representatives to the legislature at Brussels and were treated as Belgians. When in 1839 the Dutch king suddenly announced his intention of accepting the terms of the settlement proposed by the treaty of London, as drawn up by representatives of the great powers in 1831, Belgium found herself compelled to relinquish portions of Limburg and Luxembourg. The part of Limburg that lay on the right bank of the Meuse, together with the town of Maastricht and a number of communes on the left bank of the river, became a sovereign duchy under the rule of the king of Holland. In exchange for the cession of the rights of the Germanic confederation over the portion of Luxembourg which was annexed by the treaty to Belgium, the duchy of Limburg (excepting the communes of Maastricht and Venloo) was declared to belong to the Germanic confederation. This somewhat unsatisfactory condition of affairs continued until 1866, when at a conference of the great powers, held in London to consider the Luxembourg question *(see* LUXEMBOURG), it was agreed that Limburg should be freed from every political tie with Germany. Limburg became henceforth an integral part of Dutch territory.

In Dec. 1918 indignation was expressed by Belgium at the authorization by the Dutch government of the passage of the retreating German army through Limburg, which enabled the Germans to save 70,000 to 120.000 men and to carry away the proceeds of their exactions in Belgium and a large quantity of war material. Feeling in Belgium was the more inflamed because the Dutch government had refused to liberate the Belgians interned in Holland until the consent of Germany had been obtained, an attitude which should have had its logical counterpart in the internment of the retreating Germans. It was felt that Holland had created a precedent affecting the security of Belgium. In 1918–19 a proposal was brought before the peace conference in Paris for the revision of the treaty of 1839, in order to place Dutch Limburg under Belgian rule. This was not favourably received in Paris and was strenuously opposed in Holland. It was finally vetoed. Limburg was occupied by Germany in 1940.

See P. S. Ernst, *Histoire du Limbourg* (1837–52); M. J. de Poully, *Histoire de Maastricht et de ses environs* (1850); *Diplomaticke bescheiden betreffends de Limburg-Luxemburgsche aangelegenheden 1866–67* (1868); C. J. Luzac, *De Landen van Overmuze in Zonderheid 1662 (1888)*; R. Fruin, *Geschied. der Staats-Instellingen in Nederland* (1901).

LIMBURG, the N.E. province of Belgium. part of the ancient duchy of Limburg. The part of the duchy east of the Mèuse was transferred to Holland by the London conference and a part including the old capital, now called Dolhain, was put into the province of Liége.

The Kempen, a wild heath district, has coal under it, workings on which began in 1906 and production in 1917. Towns include Hasselt (the capital), St. Trond. Tongres, Maeseyck and Looz. from the last of which an ancient ducal family takes its title. There are 3 administrative *arrondissements,* 13 cantons and 206 communes. Area 930 sq.mi. Pop. (1955 est.) 528,123, or 567.9 per square mile.

LIMBURG, the southeasternmost and third smallest province of the Netherlands. bounded north by Gelderland, northwest by Korth Brabant. southwest by the Belgian province of Lirnburg, south by that of Liége and east by Germany. Its area is 857 sq.mi. and its population (est. 1957) was 849.870, the density per square mile being 991.7. In the extreme southeast there are Cretaceous hills rising to over 300 ft. (the highest land in the Netherlands), while the rest of the province is formed of more recent deposits. It is watered by the Meuse (Maas), which forms part of its southwestern boundary (with Belgium) and then flows through its northern portion, and by such tributaries as the Roer. Its capital is Maastricht, at the ancient river crossing, giving its name to one of the two administrative districts into which it is divided, the other being Roermond. Venlo is a station on the railway from Crefeld to Breda which crosses the province. while subsidiary lines link it with Maastricht to the south and Nijmwegen to the north.

The richest part of the province is the southeast: on the loess deposits here there is a rich cultivation of wheat, rye, sugar beet and fruit. There is a coal field near Heerlen and Kerkrade, and among the industries of Maastricht are glass, porcelain and leather. The province was speedily overrun by German troops during the invasion of May 1940.

LIMBURG, a town in the *Land* of Hesse, Ger., on the Lahn, there crossed by a bridge dating from 1315, and on the main railway line from Coblenz to Lollar and Cassel. Pop. (19jo) 15,419. It is the seat of a Roman Catholic bishop and the small seven-towered cathedral, dedicated to St. George the Martyr, was founded early in the 10th century and consecrated in 1235. It was restored in 1872–78.

Limburg, which has a castle, was a flourishing place during the middle ages and had its own line of counts until 1414, when it was purchased by the elector of Trier. It passed to Nassau in 1803. Its industries include the manufacture of tobacco, soap, machinery of various kinds, paints and leather.

LIMBURG CHRONICLE or FESTI LIMPURGENSES, a German chronicle probably written by Tileman Elhen von Wolfhagen after 1402. It is a source for the history of the Rhineland between 1336 and 1398 but is more valuable philologically and for the folklore and pictures of manners which it contains.

First published by Faust in 1617, it was edited by Wyss for *Monumenta Germaniae historica. Deutsche Chroniken,* Band iv (1883).

See A. Wyss, *Die Limburger Chroizik untersucht* (18; 5).

LIMBURGITE, a dark-coloured volcanic rock resembling basalt in appearance. but containing normally no feldspar. The name is taken from Limburg (Germany): where it occurs in the well-known rock of the Kaiserstuhl. It consists essentially of olivine and augite with a brownish glassy ground mass, in which a second generation of small augites frequently occurs; more rarely olivine is present also as an ingredient of the matrix.

The principal accessory minerals are titaniferous iron oxides and apatite, and in some limburgites large phenocrysts of hornblende and biotite are found; in others large crystals of soda-orthoclase or anorthoclase. Hauynite, a variety of sodalite (*q.v.*), is an ingredient of some of the limburgites of the Cape Verde Islands. Rocks of this group occur in considerable numbers in Germany (Rhine district) and in Bohemia. also in Scotland (Whitelaw hill, Haddington), Auvergne, Spain. Kilimanjaro, Brazil, etc. They are associated principally with basalts, nepheline- and leucite-basalts and monchiquites. From the last-named rocks the limburgites are not easily separated a; the two classes bear a very close resemblance in structure and in mineral composition. The ground mass of the monchiquites is not a glass. however. but crystalline analcite (see LAMPROPHYRE). Limburgites may occur as flows, as sills or dikes. and are sometimes highly vesicular.

LIMBUS, a theological term denoting the border of hell. where dwell those who, while not condemned to torture, are deprived of the joy of heaven. The more common form in English is "limbo," which is used both in the technical theological sense and derivatively in the sense of "prison," or for the condition of being lost, deserted. obsolete.

In medieval theology there are (1) the *Limbus Infantum* and (2) the *Limbus Patrum.*

1. The *Limbus Infantum* or *Puerorum* is the abode to which human beings dying without actual sin, but with their original sin unwashed away by baptism, were held to be consigned; the category included, not unbaptized infants merely, but also idiots, cretins and the like. The word "limbus," in the theological application, occurs first in the *Summa* of Thomas Xquinas; for its extensive currency it is perhaps most indebted to the *Commedia* of Dante (*Inf.* c. 4). The question as to the destiny of infants dying unbaptized presented itself to theologians at a comparatively early period. Generally speaking it may be said that the Greek fathers inclined to a cheerful and the Latin fathers to a gloomy view. Thus Gregory of Nazianzus (*Orat.* 40) says "that such children as die unbaptized without their own fault shall neither he glorified nor punished by the righteous Judge, as having done no wickedness, though they die unbaptized, and

as rather suffering loss than being the authors of it." Similar opinions were expressed by Gregory of Nyassa, Severus of Antioch and others — opinions which it is almost impossible to distinguish from the Pelagian view that children dying unbaptized might be admitted to eternal life, though not to the kingdom of God. In his recoil from Pelagian heresy, Augustine was compelled to sharpen the antithesis between the state of the saved and that of the lost and taught that there are only two alternatives — to be with Christ or with the devil, to be with Him or against Him. Following up, as he thought, his master's teaching, Fulgentius declared that it is to be believed as an indubitable truth that "not only men who have come to the use of reason, but infants dying, whether in their mother's womb or after birth, without baptism in the name of the Father, Son and Holy Ghost, are punished with everlasting punishment in eternal fire." Later theologians and schoolmen followed Augustine in rejecting the notion of any final position intermediate between heaven and hell but otherwise inclined to take the mildest possible view of the destiny of the irresponsible and unbaptized. Thus the proposition of Innocent III that "the punishment of original sin is deprivation of the vision of God" is practically repeated by Aquinas, Scotus and all the other great theologians of the scholastic period, the only outstanding exception being that of Gregory of Rimini, who on this account was afterward called "tortor infantum."

The first authoritative declaration of the Latin Church upon this subject was that made by the second council of Lyons (1274) and confirmed by the council of Florence (1439), with the concurrence of the representatives of the Greek Church, to the effect that "the souls of those who die in mortal sin or in original sin only forthwith descend into hell, but to be punished with unequal punishments." Perrone remarks *(Prael. Theol.* pt. iii, chap. 6, art. 4) that the damnation of infants and also the comparative lightness of the punishment involved in this are thus *de fide;* but nothing is determined as to the place which they occupy in hell, as to what constitutes the disparity of their punishment or as to their condition after the day of judgment. In the council of Trent there was considerable difference of opinion as to what was implied in deprivation of the vision of God, and no definition was attempted, the Dominicans maintaining the severer view that the *Limbus Infantum* was a dark subterranean fireless chamber, while the Franciscans placed it in a region of light above the earth. Some theologians continue to maintain with Bellarmine that the infants "in limbo" are affected with some degree of sadness on account of a felt privation; others, following the *Nodus praedestinationis* of Celestine Sfrondati (1649–96), hold that they enjoy every kind of natural felicity, as regards their souls now and as regards their bodies after the resurrection, just as if Adam had not sinned. In the condemnation (1794) of the synod of Pistoia (1786) the 26th article declares it to be false, rash and injurious to treat as Pelagian the doctrine that those dying in original sin are not punished with fire, as if that meant that there is an intermediate place, free from fault and punishment, between the kingdom of God and everlasting damnation.

2. The *Limbus Patrurn* or *Sinus Abrahae* ("Abraham's Bosom") is defined in mediaeval theology as the place in the underworld where the saints of the Old Testament were confined until liberated by Christ on his "descent into hell." Regarding the locality and its pleasantness or painfulness nothing has been taught as *de fide.* It is sometimes regarded as having been closed and empty since Christ's descent, but other authors do not think of it as separate in place from the *Limbus Infanturn.* The whole idea, in the Latin Church, has been described as the mere *caput mortuum* of the old doctrine of Hades, which was gradually superseded in the west by that of purgatory.

LIME. The tree and fruit of the species *Citrus aurantifolia,* widely grown for its fruits throughout the tropical and subtropical areas of the world. The native home of the tree is believed to be the East Indian archipelago and perhaps the nearby mainland of Asia. The Arabs are believed to have taken limes, as well as lemons, from India to the eastern Mediterranean countries and Africa around 1000 A.D. or possibly earlier. Limes were introduced to the western Mediterranean countries by returning crusaders in the 12th and 13th centuries A.D. Columbus took citrus fruit seed, probably including limes, to the West Indies on his second voyage in 1493 and the trees soon became widely distributed and partially naturalized in the West Indies, Mexico and Florida.

The tree seldom grows more than 8 to 15 ft. high and if not pruned becomes shrublike. Its branches spread and are irregular, with short stiff twigs, small leaves and an abundance of small, sharp thorns. The leaves are pale green; the small white flowers are usually borne in clusters. The fruit is $1\frac{1}{4}$ to $1\frac{3}{4}$ in. in diameter, oval to nearly globular, often with a small apical nipple; the peel is thin, and greenish-yellow when the fruit is ripe. The pulp is tender, juicy, yellowish-green in colour and decidedly acid. As a group, limes somewhat exceed lemons in both acid and sugar content. There are, however, some varieties so lacking in citric acid that they are known as sweet limes. These are grown to some extent in Egypt and other tropical countries.

The two general groups of acid limes are the Mexican and the Tahiti. The Mexican group is characteristic of the species C. *aurantifolia,* described above. Several varieties, including Everglade and Yung, have been named but in general differ but little from each other. Numerous thornless strains of Mexican limes have arisen from seedlings and from bud sports.

The trees of the Tahiti group resemble the lemon and are larger and more vigorous than those of the Mexican group, with leaves larger and darker coloured. The fruit is larger and more elongated than the Mexican lime; the peel is thicker and the fruit nearly seedless.

The flavour of the fruit of the two groups is similar, but the Tahiti lime lacks some of the bouquet which is typical of the Mexican. The Tahiti lime so closely resembles a lemon that the fruit could easily be confused except for the colour of the pulp and the distinctive taste. From the appearance of the Tahiti group there seems to be a possibility that this fruit may be a hybrid between the lemon and the typical Mexican lime. Leading varieties of the Tahiti group are Bearss, Pond and Tahiti, also called Persian.

Mexico is a leading country in lime production, producing around 2,000,000 boxes per year. Egypt produces about 1,000,000 boxes annually, but some estimates are much higher. From 300,000 to 400.000 boxes per year are produced in the United States, mainly in southern Florida. Limes are grown throughout the West Indies and to a limited extent in practically all citrus-growing areas. The trees are a little less cold resistant than most kinds of citrus, so production is largely restricted to relatively frost-free locations.

The lime hybridizes readily with other species of citrus and some closely related genera. Some of these hybrids are grown as novelties and, to a limited extent, commercially. The Perrine lemon, a cross of Mexican lime and Genoa lemon, is grown locally in Florida and warmer parts of Louisiana and Texas. The limequats, crosses of limes and kumquats, are hardier and more disease resistant than limes and are grown in areas slightly too cold for limes or lemons. Hybrids of limes and mandarin oranges are acid fruits grown locally and also used to some extent as rootstocks for the propagation of other kinds of citrus.

Limes are used mainly for flavouring drinks, food and confections, much as are lemons. Limeade and other lime-flavoured drinks have a flavour and bouquet quite distinct from those made from lemons. The juice may be concentrated, frozen or canned in a manner similar to lemon juice.

The yield of fresh juice depends upon the variety and the condition of the fruit and varies from 60 to go gal. per ton of fruit. The small Mexican lime is less readily handled by machinery in the reaming process than are the larger varieties. Limes contain vitamin C (ascorbic acid) and were formerly used in the British navy to prevent scurvy (hence the nickname "Limey"). Lime oil is a by-product of the fruit, the chief centre for its production being the West Indies. Citrate of lime and citric acid are also prepared from it.

Methods of culture, propagation and pest control for limes are comparable to those used in other citrus orchards. *See* LEMON and ORANGE.

LIME. In the strict chemical sense lime refers only to calcium oxide (or quicklime) ; however, lime which is commercially manufactured from limestone is rarely produced in the pure state and the presence of other substances gives rise to different types of limes having commercial importance. High-calcium limes, chiefly used for various chemical and industrial purposes, are produced from calcareous materials (generally limestone but also chalk and oyster shells) containing 95% to 99% calcium carbonate. Limestones containing various proportions of magnesium carbonate are widely found and are also used to make lime. Magnesium limes are produced from stones containing magnesium carbonate in excess of 5%. One magnesium lime of special importance is dolomitic lime, produced from the mineral dolomite, a type of limestone containing from 30% to 45% magnesium carbonate (see CALCITE; DOLOMITE; LIMESTONE). In the U.S. only limes made from high calcium and dolomitic limestones have commercial significance.

In common usage the term lime includes the various chemical or physical forms of quicklime, hydrated lime and hydraulic lime. When limestone is heated under controlled calcination conditions, the carbonates decompose: producing quicklime. Commercially, quicklime is commonly produced by burning carefully graded limestone in rotary kilns, similar to those used in portland cement manufacture. and in large stationary vertical kilns. The by-product carbon-dioxide gas is generally permitted to escape from the kilns, though sometimes it is collected and used to manufacture precipitated calcium carbonate, dry ice, etc. Quicklime, as it is normally manufactured, is highly reactive; however, when calcined for a prolonged time at elevated kiln temperatures, the porous structure contracts. The material loses its chemical reactivity and the lime is said to be "dead burned." Some dolomitic limestone is commercially processed in this manner; it is known as dead-burned dolomite and is widely used as a lining for basic open-hearth steel furnaces.

When quicklime reacts with water the process is called slaking; the reaction is exothermic, and proceeds at times with almost explosive violence. Dry hydrated lime is produced when quicklime is reacted with just sufficient water to satisfy its chemical affinity for moisture under the conditions of hydration. High calcium quicklimes react readily with water; on the other hand, dolomitic quicklimes, due to the less reactive magnesium oxide component, do not hydrate completely in ordinary processing equipment.

Dolomitic limes hydrated in equipment operated at atmospheric pressures and low retention times are known as dolomitic normal hydrated limes and essentially consist of calcium hydroxide, magnesium oxide with a small quantity of magnesium hydroxide. The magnesium oxide portion of dolomitic lime along with the calcium oxide can be hydrated completely in special equipment using longer retention periods or elevated pressures and temperatures. These "pressure hydrated" or highly hydrated limes are commercially known as dolomitic special hydrated lime.

Hydraulic lime is a type of cementitious lime that will set and harden under water in a manner similar to portland cement. It is obtained by calcining an impure limestone containing large quantities of silica and alumina so that sufficient calcium silicates and aluminates are formed to give the lime its characteristic hydraulic properties. Hydraulic limes are widely used in Europe for mortars in masonry construction; use in the United States, however, is limited.

Limes vary considerably in chemical and physical properties. In part this is due to differences in geology and chemical analyses of the raw limestone. More markedly, however, the degree of overcalcination and other processing variables and conditions affect the rate of slaking, plasticity, density and chemical reactivity of the limes produced. Both quick and hydrated limes are usually white in colour, though some grayish impure limes are known. Calcium and magnesium hydroxides are only slightly soluble in water; nevertheless, the term lime water denotes a weak aqueous solution. Milk-of-lime is a suspension of lime solids in water.

Lime is widely used to neutralize acids; on the basis of neutralizing values, quick and hydrated limes are stronger bases than sodium hydroxide and sodium carbonate.

Uses.--Next to sulfuric acid, lime was the most widely used chemical in industry in the second half of the 20th century, and mas the leading alkali in tonnage consumed. Both quick and hydrated lime products find extensive application in the agricultural, building and chemical industries. Formerly lime was considered primarily a building and agricultural material, and in many undeveloped parts of the world applications for lime are still largely confined to these fields. However, lime is employed basically as a chemical in industry. In the U.S. alone three-fourths of the annual lime tonnage is consumed industrially. Chemical lime is consumed in large quantities by the metallurgical industry in the manufacture of open-hearth and electric-furnace steel, production of magnesium, treatment of aluminum, gold and silver ores, and the smelting and refining of copper, zinc and other metals. Dead-burned dolomite is extensively used as a refractory material to line high-temperature kilns and furnaces. Large quantities of lime are required in the manufacture of paper, calcium carbide and glass, as well as in the purification of water supplies and in the treatment of sewage and industrial wastes. Other chemical applications are in sugar and petroleum refining and in the manufacture of sand-lime brick and concrete products. insecticides, leather goods, bleaching powder, sodium hydroxide, varnish and paints, grease and other products. A market for lime was also developed as a soil-stabilizing agent in the construction of base courses for modern highways and airport runways.

In agriculture, lime—not to be confused with pulverized limestone—is one of several soil liming materials used for promoting crop production by correcting soil acidity and furnishing important plant nutrients.

History.—Lime is one of the oldest products known to man, dating possibly as far back as the cave-man era and the discovery of fire. Primitive kilns which are believed to have been used for preparing lime during the Stone Age have been excavated. It is certain that lime was the first manufactured chemical used by mankind, probably the first agricultural material employed for soil fertility, and certainly one of the oldest mortar and plastering building materials known. Virtually every civilization has utilized lime. Lime plaster, still in good condition, has been found in some pyramids built more than 4,500 years ago in Egypt. The Old and New Testaments of the Bible mention lime several times. Lime was extensively used in mortars and plasters by the Greeks, Romans, Arabians, Moors and other Mediterranean cultures. It was also used by the Incas and Aztecs in South and Central America and by the Chinese in constructing their Great Wall. The first mention of lime as a chemical reagent was by the Roman, Xenophon, who recorded that ships carrying a cargo of linen and lime (for its bleaching) were wrecked in 350 B.C. near Marseilles. And another Roman, Vitruvius, an architect under Augustus, wrote the first detailed lime specification. The Romans also used lime in building the road base of the famous Appian way. The Romans originated cement (hydraulic lime), which they prepared from mixtures of lime putty and volcanic ash. Old relics and records in England indicate that lime was used as a mortar material during the Roman occupation. Lime plastering and stuccoing reached their peak during the Italian Renaissance; and during the same period Michelangelo, Raphael and other famous artists created their mural and fresco masterpieces using lime putties extensively. (See also FRESCO PAINTING.)

In North America lime was probably first used by the Spaniards in Florida in the 16th century. "Tabby" construction consisting of oyster shell lime, sand and crushed shells was employed for building walls. Early Spanish missions in California and the southwest were invariably constructed of lime stucco. As early as 1635 in Rhode Island quicklime was produced from limestone; however, the Pilgrims probably burned lime from shells at an earlier date shortly after settling at Plymouth, Mass. Lime manufacturing first became a significant industry in commerce about 1733, when boats were used to ship lime from Rockland, Me., to Boston Mass.

Technical progress since the beginning of the 20th century markedly advanced lime manufacturing to its modern important industrial position.

LIMEHOUSE, a parish in the metropolitan borough of Stepney on the north bank of the Thames and in the East End of London. Eng. It is said to take its name from the limekilns which were demolished in 1935. Running through Limehouse from the Lea to the Thames are (north to south) the Regent's canal and (northeast to southwest) the Limehouse Cut (built in 1769). Most of its associations are maritime and among the many buildings for seamen are the British Sailors' society, formerly the home of Nelson's family and dating from about 1650; the Empire Memorial hostel, a residential club opened in 1924; and the Ocean Library stores, the headquarters of more than 5,300 libraries for the merchant navy afloat. St. Anne's parish church (founded 1712. consecrated 1730) was designed by Nicholas Hawksmoor and is a landmark for ships coming up the river. The town hall dates from 1879 and the public library was opened in 1901 and enlarged in 1931.

LIMERICK, THOMAS DONGAN, SECOND EARL OF (1634–1715), governor of New York, was born in Castletown, Ire He began his career in the army, serving first in England and later under Louis XIV in France in an Irish regiment. He abandoned the army. however. to accept the position of lieutenant governor of Tangiers, an office he resigned in 1680. Two years later the duke of York named him governor of New York, which included, at that time, a portion of New England.

Dongan was responsible for a number of important developments in the history not only of New York but of the entire group of American colonies. The so-called "Charter of Liberties," drawn up by the New York assembly, nhich he convened shortly after he arrived in the colony, served as the basis of New York's later constitution and of the constitution of the entire Cnited States in many of its provisions. It was, however. never put into effect in New York, since the duke of York, although he signed it. failed to return the charter to the colony, probably because of its extreme liberalism. Dongan helped to fix the boundaries of New York by treaty with the Indians and by agreement with the surrounding colonies and Canada. His charters for the cities of New York and Albany both remained in effect for many years after they were drawn up, New York's for more than 100 years and Albany's for nearly 200. He was responsible for convincing the king of England that French power in America should not be allowed to increase if the English were to maintain their supremacy, especially with regard to the Indians of the Five Nations, and his Indian policy set the example for English colonial governors thereafter.

In 1638 Dongan was relieved of his governorship hut remained in New York until 1689. when he was forced to take refuge in New England because of the persecution of Roman Catholics which followed the fall from power of James II. He returned to England in 1691 and seven years later succeeded his brother as earl of Limerick. His family's lands had been seized even before he received the title, and he never recovered them. He died in London. a poor man. on Dec. 14, 171j.

LIMERICK, a western county of Ireland. province of Munster. bounded north by the Shannon estuary and the counties of Clare and Tipperary, east by Tipperary. south by Cork and west by Rerry. The land area is 1,036.9 sq.mi. Population (1961) 133,025.

Limerick is mainly a Carboniferous Limestone county! with fairly level land, broken by ridges of Old Red Sandstone. On the northeast, the latter rock rises on Slieve Felim, around a Silurian core, to 1,411 ft. In the south. Old Red Sandstone rises above an enclosed area of Silurian shales at Ballylanders, the opposite scarp of Old Red Sandstone forming the Ballyhoura hills on the Cork border. The Galtee mountains, which extend into Tipperary, attain in Galtymore a height of 3,018 ft. Volcanic ashes, andesites, basalts and intrusive sheets of basic rocks are well seen under Carrigogunnell castle and in a ring of hills around Ballybrood. The coals in the west are not of commercial value. Lead ore has been worked in places in the limestone.

The Shannon is navigable for large vessels to Limerick, above which are the rapids of Doonas and Castleroy and a canal. Castleconnell is a fishing centre. The Maigue, which rises in the Galtees and Aows into the Shannon, is navigable as far as Adare

Limerick was included in the kingdom of Thomond. Afterward it had a separate existence under the name of Aine-Cliach. From the 8th to the 11th century it was partly occupied by the Danes. (*See* LIMERICK. City.) Limerick is one of the 12 counties generally considered to owe their formation to Ring John who, at his accession installed Willam de Burgh as governor. About 100,000 ac. of the estates of the earl of Desmond, which were forfeited in 1j86. were situated in the county. and other extensive confiscations took place after the Cromtvellian wars. In 1709 a German colony from the Palatinate was settled by Lord Southwell near Bruff. Rathkeale and Adare.

There are remains of round towers at Ardpatrick and at Dysert, and of stone circles. pillar stones and altars at Loch Gur where important excavations have been made. Besides the monasteries in the city of Limerick, the most important monastic ruins are those of Adare abbey. Askeaton abbey, Galbally friary, Kilflin monastery. Kilmallock and Monaster-Kenagh abbey.

Limerick includes the greater part of the Golden vale, the most fertile district of Ireland. which stretches from Cashel in Tipperary nearly to the town of Limerick. Along the banks of the Shannon there are fertile tracts of meadowland formed of deposits of calcareous and peaty matter. The soil in the mountainous districts is mostly thin and poor and incapable of improvement The large farms nere chiefly devoted to grazing. until Limerick became one of the most active centres of the agricultural co-operative movement, organized by Sir Horace Plunkett. which produced a great advance in agricultural methods and organization. especially in co-operative creameries. The principal crops are oats, potatoes and wheat. The county benefited widely from the Shannon hydroelectric scheme, nith its main power station close to Limerick city, and also from the rapid development of the Shannon airport. close to the borders of Clare and Limerick, as an international centre of air traffic. Limerick junction, which lies on the main railway from Dublin to Cork and Rerry, is also close to the borders of the county. Its large racecourse is one of the principal attractions of the popular hunting country around Limerick. Important salmon fishing on the Shannon also has its headquarters at Limerick.

The western and eastern divisions of Limerick, which include the county borough, together return seven members to *dail* eirennn

LIMERICK, a county borough, port and the chief town of County Limerick, Ire.. occupying both banks and an island (King's Island) of the River Shannon, at the head of its estuary, 129 mi. W S.W. of Dublin by rail. Pop (1961) 50.497.

Lrmerick is said to have been the *Regia* of Ptolemy and the *Rosse-de-Nailleagh* of the Annals of Multifernan. There is a tradition that it was visited by St. Patrick in the jth century, but it is first authentically known as a settlement of the Danes, who sacked it in 812 and afterward made it the principal town of their krngdom of Limerick but were expelled from it toward the close of the 10th century by Brian Boroimhe. From 1106 till its conquest by the English in 1174 it was the seat of the kings of Thomond or North Munster. and, although in 1177 the kingdom of Limerick was given by Henry II to Philip de Braose. the city was frequently in the possession of the Irish chieftains till 1195 Richard I granted it a charter in 1197.

By King John it was committed to the care of William de Burgh, who founded English Town, and for its defense erected a strong castle. The city was frequently besieged in the 13th and 14th centuries. In the 15th century its fortifications were extended to include Irish Town, and until their demolition in 1760 it was one of the strongest fortresses of the kingdom. In 1651 it was taken by Gen. Henry Ireton, and after an unsuccessful siege by William III its resistance was terminated in 1691 by the treaty of Limerick. The dismantling of its fortifications began in 1760, but fragments of the old walls remain. In 1609 it received a charter constituting it a county of a city and also incorporating a society of merchants of the staple, with the same privileges as the merchants of the staple of Dublin and Waterford.

The prosperity of the city dates chiefly from the foundation of Newtown Pery in 1769 by Edmund Sexton Pery (d. 1806), speaker of the Irish house of commons. Under the Local Government act of 1898 Limerick became one of the six county boroughs having a separate county council. The city is divided into English Town (on King's Island), Irish Town and Newtown Pery, the first including the ancient nucleus of the city, and the last the principal modern streets. The main stream of the Shannon is crossed by Thomond bridge and Sarsfield or Wellesley bridge. The first is commanded by King John's castle, on King's Island, a Norman fortress fronting the river. At the west end of the bridge is preserved the Treaty stone, on which the treaty of Limerick was signed in 1691. The cathedral of St. Mary, also on King's Island, was originally built in 1142–80 and exhibits some Early English work. The modern Roman Catholic cathedral of St. John is in early pointed style. The churches of St. Munchin (to whom is attributed the foundation of the see in the 6th century) and St. John, Whitamore's castle and a Dominican priory, are of interest.

Communication with the Atlantic ocean is open. while inland navigation is facilitated by a canal which avoids the rapids above the city. Quays extend on each side of the river, and vessels of 600 tons can moor alongside at spring tides. There is a graving dock and a wet dock. The principal imports are grain, timber, oil and coal. The exports consist mainly of fish and agricultural produce. The principal industrial establishments include flour mills (Limerick supplying most of the west of Ireland with flour), factories for bacon curing and for condensed milk and creameries. Some brewing, distilling and tanning are carried on, and the manufacture of lace is maintained at the Convent of the Good Shepherd. The salmon fisheries of the Shannon, for which Limerick is the headquarters of a district, are the most valuable in Ireland. The city benefited greatly from the establishment of the Shannon hydroelectric power station close by (see SHANNON) and from the proximity of Shannon airport. about 20 mi. to the west.

LIMERICKS. The origin of this very popular type of nonsense verse is lost in obscurity, and recent research work has done little to pierce the gloom. Nor is it known for what reason the name "limerick" is attached to it. The theory that the title derives from the chorus "Will you come up to Limerick?" sung after impromptu verses composed at convivial parties, helps us not at all. since there is no record of this kind of verse being used at such parties. Rather is the limerick a kind of ribald epigram, passed on by word of mouth, and more often whispered than sung.

Langford Reed, the only collector of limericks who has toiled valiantly with their history, suggests that "this peculiar form of verse was brought direct to Limerick by the returned veterans of the Irish Brigade, who were attached to the French army for a period of nearly 100 years from 1691." The brigade was organized in Limerick, and when disbanded was no doubt responsible for giving currency to many rude barrack-room songs; but the evidence of a French origin for the five-lined metrical scheme of the limerick rests upon very feeble foundations. Langford Reed quotes from Boswell's Life of Johnson:

On s'étonne ici que Caliste
Ait pris l'habit de Moliniste;
Puisque cette jeune beaut6
Ote à chacun sa liberté
N'est-ce pas une Janseniste?

—an epigram in The Menagiana (1716) on a young lady who appeared at a masquerade dressed as a Jesuit during the fierce contentions of the followers of Molinos and Jansenius. But Reed also quotes:

Digerie, Digerie, Doge,
La souris ascend l'horloge;
L'horloge frappe
La souris s'échappe,
Digerie, Digerie, Doge,

and appears to consider this a true limerick form, thus permitting the verse form almost as wide a licence in metre as it has latterly attained in morals.

It may be sufficient to suppose that the limerick satisfies some natural instinct of the ear in rhymed verse, the prefatory couplet demanding a third line as complement, and staving this off, for the sake of surer effect, by the interposed short lines. But this would not account for the famous limericks of Edward Lear, in his Book of Nonsense (1846), where the last line is merely a choric repetition, employing one of the previous rhymes, and adding little or nothing to the sense. In spite of this defect, Lear certainly gave to what is now known as the limerick its modem popularity—some even assert that "learick" is the proper form of the word—and established at once its insistence on topography and its attention to varieties of personal behaviour.

There was a young girl of Majorca
Whose aunt was a very fast walker;
She walked sixty miles
And leaped fifteen stiles,
Which astonished that girl of Majorca.

Or again,

There was an old person of Anerly
Whose conduct was strange and unmannerly:
He rushed down the Strand
With a pig in each hand,
But returned in the evening to Anerly.

Lear, however, did previsage the now usually accepted formula:

There was an old man at the Cape
Who made himself garments of crape;
When asked "Will they tear?"
He replied "Here and there,
But they keep such a beautiful shape!"

Limericks have been composed upon every conceivable topic, not excluding philosophy and religion—

There was a young man who said "Damn!
It is borne upon me that I am
An engine which moves
In predestinate grooves,
I'm not even a bus: I'm a tram!"

but their usual themes became similar to those of the epigrams of Martial, and would doubtless so have remained, milder variants being substituted when blushes were to be spared, had it not been for their sudden vogue at the beginning of the present century as a subject for prize competitions in the newspapers, which gave large sums of money to readers for supplying the cleverest last line. The judges in these competitions must have had poor ears for scarcely any of the winning lines contained the correct number of feet. A good limerick should have the consecutive fluency of conversational prose, the metre remaining faultlessly dactylic throughout. No better example can be given than

There was an old man of Khartoum
Who kept two tame sheep in his room:
"For," he said, "they remind me
Of one left behind me,
But I cannot remember of whom!"

Fantastic rhyme schemes to the limerick are innumerable. As for instance,

The lifeboat that's kept at Torquay
Is intended to float in the suay:
The crew and the coxswain
Are sturdy as oxswain,
And as smart and as brave as can buay.

Limericks have been translated into all languages, and the globe has been ransacked for rhymable towns. The best verses contain the largest amount of improbable incident or of subtle innuendo that can be crowded into the available space, and they may be regarded as the fixed English form for light or indelicate epigrammatic satire, as opposed to the ordinary rhyming quatrains which are used on more dignified occasions. (E. V. K.)

LIMES GERMANICUS. The Latin limes denoted a path, a boundary path, or boundary; hence it was utilized to denote frontiers marked in some distinct fashion. In the sense of frontiers, the term has been extended by modern historians. Thus the Wall of Hadrian in North England (see BRITAIN: Roman) is now sometimes styled the Limes Britannicus, and so forth. In particular the frontier lines which bounded the Roman provinces of upper (southern) Germany and Rhaetia, stretching from near Bonn on the Rhine to near Regensburg on the Danube, are called the Limes Germanicus. The history of these lines is the subject of the following paragraphs. They have become much better known through systematic excavations and other researches, and though many details are still doubtful, their general development can be traced.

From the death of Augustus (A.D. 14) until after A.D. 70, Rome accepted as its German frontier the water boundary of the Rhine and upper Danube. Beyond these rivers Rome held only the fertile plain of Frankfiirt, opposite the Roman border fortress of Moguntiacum (Mainz), the southernmost slopes of the Black Forest and a few scattered têtes-du-pont. The northern section of this frontier, where the Rhine is deep and broad, remained the Roman boundary until the empire fell. The southern part was different. The upper Rhine and upper Danube are easily crossed. The frontier which they form is inconveniently long, enclosing an acute-angled wedge of foreign territory — the modem Baden and Wdrttemberg. Geographical convenience and movements of Roman subjects across the Rhine combined to urge a forward policy at Rome. and Vespasian began a series of advances which gradually closed up the acute angle, or at least rendered it obtuse.

The first advance came about A.D. 74, when what is now Baden was invaded and roads carried from the Roman bases on the upper Rhine, Strassburg (Argentoratum) and Windisch (Vindonissa) to Rottweil (Arae Fluviae). This road was subsequently extended to Cannstadt, meeting a road from Mainz, and was then probably extended to reach the Danube at Faimingen below Ulm. The point of the angle was broken off. The second advance was made by Domitian about A.D. 83. He pushed out from Moguntiacum, extended the Roman territory east of it, and enclosed the whole within a systematically defended frontier with numerous blockhouses along it and larger forts in the rear.

Among the blockhouses was one which by various enlargements grew into Saalburg fort, near Homburg. This advance necessitated a third movement, the construction of a frontier, connecting the annexations of A.D. 74 and 83. The line of this frontier ran from the Main to the upper waters of the Neckar, and was defended by a chain of forts. The whole was reorganized, probably by Hadrian, with a continuous wooden palisade reaching from the Rhine to the Danube. Either Hadrian or Pius marked out a new frontier roughly parallel to, but in advance of, these two lines.

This is the frontier which is now visible and visited by the curious. It consists of two distinct frontier works; one, known as the Pfahlgraben (or "Pale"), is an earthen mound and ditch, best seen in the neighbourhood of the Saalburg, but which once extended from the Rhine southward into southern Germany. The other, which begins where the earthwork stops, is a stone wall, though not very formidable, the Teufelsmauer ("Devil's Wall"); it runs roughly east and west parallel to the Danube, which it finally joins at Hienheim near Regensburg. The Pfahlgraben is extraordinarily direct in its southern part, which for more than 50 mi. runs mathematically straight and points almost absolutely true to the Polar star. It is an ancient frontier laid out in American fashion. This frontier remained for about 100 years, and no doubt in that long period much was done to it. The exact date even of the Pfahlgraben and Teufelsmauer is uncertain. But the pressure of the barbarians began to be felt seriously in the latter part of the 2nd century A.D., and the whole or almost the whole district east of the Rhine and north of the Danube was lost about A.D. 250.

BIBLIOGRAPHY.—The best English account is in H. F. Pelham's, essay in *Trans. of the Royal Hist. Soc.*, vol. XX, reprinted in his *Essays on Roman History*, p. 179–211 (1911), where the German authorities are fully cited. *Cf.* J. E. Sandys, *Companion to Latin Studies* (1921).

LIMESTONE, a rock containing at least 50% calcium carbonate, $CaCO_3$, but generally not including such rocks that have been recrystallized and chemically altered by metamorphism (see MARBLE). Limestones are typically soluble in cold dilute acids and have a specific gravity of 2.6 to 2.8. They are soft, for calcite, the most abundant mineral constituent, has a hardness of only 3, and are white to cream-coloured unless stained yellow or brown by iron oxides or rendered bluish to black by included organic matter and iron disulfide. Limestones are typically well cemented and without large amounts of intergranular porosity, although chalk and calcareous sinter are incoherent and earthy.

Limestone is appreciably soluble in water enriched in organic acids and carbonic acid. such as ground water which has passed through soil. Terrain which is underlain by limestone in humid regions develops underground drainage and the characteristic karst topography, and abounds in caves and sinkholes (see CAVE). Limestones are noteworthy in that extensive solution and reprecipitation may take place in them after formation, sufficient in some cases to obscure fossils and other evidence of their manner of formation.

Formation and Composition. — The carbonate portion of limestones consists of mixtures in yarious proportions of land-derived detrital particles, or debris, of older limestone, fecal pellets of invertebrates. fossils and fragments of partly consolidated limestone torn loose by waves in the depositional environment. These materials are cemented by microcrystalline carbonate ooze and coarser-grained pore-filling calcite cement. With increasing numbers of dolomite (*q.v.*) crystals replacing the calcium carbonate of the rock, limestones grade into dolomitic (*i.e.,* rich in magnesium carbonate) limestones and dolomites. The noncarbonate minerals include detrital quartz and feldspar and resistant minerals such as zircon, garnet, and tourmaline. Calcium phosphate and silica are contributed by the shells of some organisms. Well-formed crystals of albite and monoclinic potash feldspar, quartz, pyrite, and other minerals which grew in the rock during or after its formation are said to be authigenic. The nodules and bands of chert (flint) which replace limestones can be shown in some cases to have resulted from concentration of silica originally present in organic spicules and tests.

Most limestones are partly or entirely of organic origin. The soft, whitish limestones known as coquinas are composed almost entirely of shells and shell fragments, and were formed in warm shallow water like that around the Bahamas today, where organisms grew abundantly and the waves were able to wash away finer-grained material. Some chalks are largely composed of foraminifera such as Globigerina. Another foraminifera1 limestone, that made by the disc-shaped Nummulites, is famous as the rock from which the pyramids of Egypt were built. Crinoidal limestones are frequently found in older rocks such as the Carboniferous.

Reef limestones were formed by organisms that were able to erect rigid wave-resistant structures in relatively shallow water near upwelling currents rich in nutrients. Corals and calcareous algae are the principal frame builders today in places such as the Pacific atolls and the Great Barrier reef of Australia, but other organisms played this role in the past. Reef limestones are very pure carbonate rocks, and are often dolomitized.

The oolites in oolitic limestones are composed of $CaCO_3$ chemically deposited about nuclei of various kinds. The purer oolitic limestones contain very little fine-grained material and were formed in agitated water like that overlying the underwater oolite dunes near the edge of the Bahaman platform.

The origin of fine-grained limestones is frequently in doubt because of recrystallization of original features. Some probably were formed from the minute remains of primitive unicellular organisms (coccolithophores and rhabdoliths) others from tiny aragonite (*q.v.*) needles like those resulting from chemical precipitation and from the disarticulation of algal remains in the drewite muds of the Bahamas. Fine grained limestones containing appreciable amounts of clay minerals, pyrite and organic matter were formed below the level of wave action where tiny detrital particles could settle out, in a stagnant, oxygen-poor environment suitable for the preservation of organic matter and the formation of pyrite.

Limestones and dolomites associated with beds of anhydrite and salt, as in the rocks of Permian Age west of the great Capitan reef in west Texas and New Mexico, contain very few fossils and are believed to be chemical precipitates from saline waters concentrated by evaporation. The solubility of these carbonates is such that they should precipitate before anhydrite and salt. This sequence of precipitation is observed today in a long narrow inlet on the arid Peruvian coast.

Limestones formed from accumulations of carbonate rock particles carried by streams are found in the Arbuckle mountains of Oklahoma and in the region north of the Alps. Such rocks are uncommon and formed only in regions of high relief and abundant limestone outcrops, for limestone particles are quickly reduced in streams by abrasion and solution. Relatively common along tropical coasts, however, are limestones formed by the cementation of calcareous beach deposits and dunes.

Lakes in regions such as the north central part of the United States, where ground waters contain large amounts of calcium carbonate dissolved from glacial drift, contain fine-grained carbonate-rich deposits precipitated in large part by the activity of fresh-water algae. The deposits in Lake Zurich are made up of seasonal layers or varves which are alternately rich in carbonates and in organic matter. The dolomitic lake deposits of Eocene Age in Wyoming and Utah are also varved but the varied and unusual suite of authigenic minerals here indicates that the lake waters became highly concentrated.

Occurrences of limestone are discussed in articles on the various geologic systems and epochs, as CRETACEOUS SYSTEM; EOCENE AND PALEOCENE, etc., and on states and countries, as INDIANA; JAPAN. See also GEOLOGY; OCEAN AND OCEANOGRAPHY: Marine Sediments; SEDIMENTARY ROCKS.

Uses.—Limestone has a large variety of economic uses. High purity calcium carbonate rock is used in the production of sodium carbonate from sodium chloride (salt) by the Solvay process, the manufacture of aluminum oxide (alumina) by the Bayer process, production of synthetic phenol, calcium nitrate, dyestuffs and intermediates, and the refining of beet sugar by the carbonation process.

It is a food supplement for livestock and poultry and is used in whiting (see also CHALK) and as a reactant in the refining of salt brines and the manufacture of glass. The calcination of limestone at temperatures high enough to dissociate calcium carbonate yields both carbon dioxide and lime for commercial use. The latter is used in the construction industries and in manufacturing chemicals including calcium carbide, which is produced by fusing lime with coke in the electric-arc furnace.

Limestones containing impurities of the proper kind and amount are desired for some purposes, although other materials can be mixed with high purity limestone to achieve the same result. The manufacture of portland cement requires one part of shale or clay to three or four parts of limestone. Natural cement is made from rock containing 10% to 22% silica and 4% to 16% aluminum oxide and iron oxide. Rock wool manufacture requires 45% to 65% calcium carbonate (or magnesium carbonate), with the remainder of the rock principally silica.

Limestones may be phosphatic because of original concentrations of phosphatic shells or pellets. On some Pacific islands they become phosphatized from the replacement of carbonate by phosphates removed by ground water from guano. Such rock-phosphate is used for artificial fertilizers. Limestones, because of their susceptibility to attack by acid hydrothermal solutions, are also hosts for deposits of many valuable metals. Like other sedimentary rocks, they may contain accumulations of petroleum and natural gas.

Rocks high in dolomite are used for the manufacture of Epsom salts, of basic magnesium carbonate, which is mixed with asbestos for an insulating material, and of high-magnesium lime which is used in the building industry and in the production of certain chemicals such as magnesia. Dead-burned dolomite is used for patching and repair of basic open-hearth furnaces and for electric furnace bottoms.

There are many applications for which either limestone or dolomite may be used. These include monuments, exterior and interior facings and floors in buildings, flagstone for walks, and chips for roofing, stucco, etc. Crushed rock is used for railroad ballast, riprap fill around the base of dams, piers, etc., filter beds in sewage treatment and surfacing for airports, playground, tennis courts, etc. It is employed extensively in road construction, either alone or mixed with cement or bitumen, and as aggregate in making concrete for buildings and other structures. Agstone (crushed limestone for agricultural and other uses) is employed to regulate soil acidity, to improve soil structure, and to furnish nutrients. Used as fluxes in blast furnaces producing pig iron, during the manufacture of steel in basic open-hearths, and in nonferrous metal smelters, limestone and dolomite combine with impurities to form a slag which can be removed. More finely ground material is added as a filler and conditioner in fertilizers and is employed in the manufacture of paper by various processes.

The specifications for carbonate rock vary greatly with the particular application. Colour is particularly important for many uses of whiting substitutes. Poultry grit should contain less than 0.1% fluorine. A low iron oxide content is particularly important in glassmaking, and building stone used on exterior surfaces should not contain pyrite or marcasite which would yield iron oxide stains on weathering. The total carbonate content is of cardinal importance for agstone. Resistance to repeated freezing and thawing is important for flagstone, for concrete aggregate, and for crushed rock in riprap and railroad ballast. Resistance to abrasion is a required quality of limestone for floors and for road surfaces. Limestones are preferred to dolomite for use in the neutralization of acidic sewage and industrial wastes because of higher reaction rate.

LIMICOLAE, shore or wading birds, now known as suborder Charadrii, including jaçanas, snipes, oyster catchers, lapwings, plovers, woodcock, sandpipers, stilts, avocets, phalaropes, pratincoles and sheathbills (qq v.).

LIMINA APOSTOLORUM (literally, "The Thresholds of the Apostles"), an ecclesiastical term used to denote Rome and especially the church of St. Peter and St. Paul. A Visitatio *Liminum* might be undertaken ex voto (in accordance with a vow) or ex lege (in accordance with a law). In 743 a Roman synod decreed that all bishops subject to the metropolitan see of Rome should meet personally every year in that city to give an account of the state of their dioceses. Gregory VII and Sixtus V greatly enlarged the number of bishops subject to this law and Benedict XIV in 1740 extended the summons to all abbots, provosts and others who held territorial jurisdiction. Under the regulation of Pius X established in 1909, the Visitatio ad Limina Apostolorum must be made, either personally or by representative, by all ordinaries and vicars apostalic who have jurisdiction; the periods are five years for those whose dioceses are in Europe and ten for those outside Europe. During the middle ages ex voto pilgrimages ad Limina Apostolorum were popular among laymen.

LIMING is the applying of lime (calcium) materials to cropland soils to improve productivity. The principal effects are: (1) to supply needed calcium and (2) to reduce soil acidity. This practice was known long before the Christian era and has been used since the beginnings of agricultural history (see LIME: History). It was not, however, until the early years of the 20th century that the underlying chemical principles began to emerge. By mid-20th century, the liming of noncalcareous soils in the humid regions of the world had become a most important land-use practice.

Chemically, liming materials are chiefly carbonates of calcium. They are found abundantly in nature as limestone, dolomite, chalk, marl (*qq.v*) and shell, as well as in other forms. The soft forms, as chalk, can be prepared readily for applying and mixing with soils. The stone forms are of little use until reduced to suitable particle sizes. At one time this was done by burning and slaking. The development of rock crushing, screening and applying equipment in the first half of the 20th century quickly expanded the use of liming materials. With these developments, the amount applied to U.S. soils, to take one example, reached 25,000,000 tons annually.

Both crops and soils are involved in the need for and usefulness of liming materials. Crops require soil-derived calcium in various amounts and vary in their ability to obtain the supplies they need from different soils. For instance, buckwheat, a high-calcium requiring crop, can obtain its supplies from soils of low-supplying powers, while sweet clover, with a moderate requirement, does best on soils of high-supplying powers. Some reasons for such behaviour are: differences in feeding capacities; in ratio balances between basic and acidic soil components; and symbiotic effects which bring atmospheric nitrogen into the plant without accompanying basic components. Soils vary in their supply of calcium and in ability to release it, largely according to the variable amounts of clay-mineral complexes developed in the soil by soil-forming processes. These clays are characterized by various capacities for holding and exchanging basic chemical substances in which calcium and hydrogen are dominant. In productive soils a large proportion of calcium is released to crops and drainage waters.

Liming materials, if present, provide replacements; if not present, hydrogen is substituted and acidity begins to develop. As the acidity intensifies soils become less favourable for crop production: nutrient availabilities decline, soil micro-organisms are handicapped in their activities, substances toxic to plants may develop and physical conditions appear that lead to tillage, drainage and erosion difficulties. Well-planned liming practices will do much to correct these difficulties and to prevent their recurrence.

Liming practices are based chiefly on the principle of correcting acidity by supplying sufficient calcium to satisfy the base exchange requirements of soils for high productivity. Soil tests for acidity (pH) provide guiding information Where low-cost limestones are abundant. a product with particle sizes ranging downward from an eighth of an inch to dust may be applied in larger amounts for immediate and long-time efficiency. Subsequent applications may not be needed for periods ranging upward from 4 years to as much as 12 or more years. Used in this manner. liming practices will do much to keep soils physically fit. chemically balanced and biologically active for continuing high productivity. ***See*** also FERTILIZERS *AND* MANURES; SOIL; SOIL TESTING AND ANALYSIS (F. C. BR.)

LIMIT, a concept fundamental in mathematical analysis, occurs in so many contexts that its general definition can only be given in the setting of general topology. Here will be given a sketch of its origin and principal occurrences. Among the ancients the "method of exhaustion" (so-named in modern times) was the precursor of the theory of limits; it was employed by Euclid and Archimedes in proofs of theorems concerning figures with curved boundaries. A circle, for example, may be approximated by a sequence of inscribed regular polygons (fig. 1), beginning with the square ABCD and the octagon AEBFCGDH and so on, each figure having twice as many vertices as the preceding. If each polygon is regarded as having removed its area from that of the circle, it seems clear that the latter is progressively exhausted, in the sense that the remaining area becomes smaller than any previously assigned amount, however small. If p_1 is the perimeter of ABCD, then $\left(\frac{p_1}{2}\right)a_1$ is the area of ABCD;

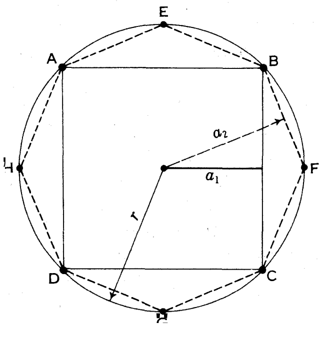

FIG. 1.— METHOD OF EXHAUSTION: POLYGONS APPROXIMATING THE CIRCLE

if p_2 is the perimeter of the octagon, then $\left(\frac{p_2}{2}\right)a_2$ is its area; and in general, $\left(\frac{p_n}{2}\right)a_n$ is the area of the nth approximating polygon. In modern language one would say that a_n becomes arbitrarily close to r, the radius of the circle, and p_n becomes arbitrarily close to $2\pi r$, the perimeter of the circle, as n increases. Thus $\left(\frac{p_n}{2}\right)a_n$ approaches $\left(\frac{2\pi r}{2}\right)r$ or πr^2, which must therefore be the area of the limiting configuration, the circle.

This sort of argument was characteristic of the 18th century; actually, the ancients argued more closely: To prove the area of the circle could not be ***less than*** πr^2 they would imagine by way of contradiction that it was, say, πs^2, with s less than r. Then an approximating polygon could be shown to exist whose area exceeded this amount. The part being less than the whole (for the polygon lay within the circle), this was impossible. That the area could not be ***greater than*** πr^2 could then be proved using circumscribed polygons, which exhausted the exterior of the circle. In the argument sketched here, there is not the slightest appeal made to notions of the infinite. The construction of polygons need not be pushed "to the limit"; some one finite polygon can be shown to produce the desired contradiction ***(see*** SCIENCE: *Alexandrian* **Science: First Period,** *300–30* B.C.).

Something, if not most, of the finite flavour of such rigorous argument was lost when, in the 17th century, the notion of limit appeared in the work of Newton, Leibniz and their successors in the development of the calculus. It seemed convenient, for example, sometimes to regard a curve (such as a circle) as a polygon of an infinite number of sides, each of infinitesimal length. Arguments based on such apparently nonsensical notions yielded results of such richness and scope that the ideas of the "infinitesimal calculus" survived the most devastating (and just) philosophical attacks. Yet errors and paradoxes occurred which were the work of a later era to resolve.

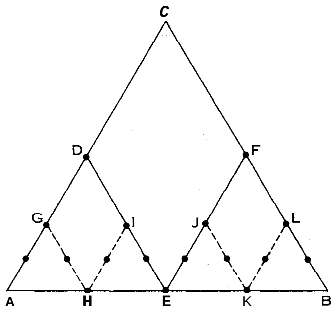

FIG. 2.— LIMIT PARADOX: THE POLYGONS APPROXIMATING STRAIGHT LINE AB ARE ALL TOO LONG

For example (fig. 2) the broken line ACB has twice the length of AB. So does ADEFB. So does AGHIEJKLB. If this process is continued, the area between the broken lines and AB diminishes to zero, and AB is clearly the limiting configuration. It might be argued that AB should therefore have twice its own length, because all the approximations do. This paradox is the result of the mistaken idea that the limiting configuration must have properties which are the limiting cases of the corresponding properties of the approximating configurations. By such reasoning, however, one would have also to claim that AB had an infinite number of corners, each a 60° angle.

Beginning with the work of Augustin Cauchy on the convergence of infinite series the 19th century carried to completion the work of arithmetizing analysis. The notion of limit, previously quasi-geometrical, was put into numerical language and divested of all trace of the language of "ultimate behaviour."

Arithmetical Theory of Limits.—If $a_1, a_2, a_3, \ldots, a_n, \ldots$ is a number sequence, we say it has the limit L if the following statement is true: For every positive number ϵ, however small, there corresponds an index p such that if $n > p$ (n greater than p), then $a_n - L$ is less than ϵ in absolute value. Thus, for example, if $a_n = \frac{n}{n+1}$, *i.e.*, if the sequence is $\frac{1}{2}, \frac{2}{3}, \frac{3}{4}, \ldots$, the limit L is clearly 1 because $a_n - L = \left(\frac{n}{n+1}\right) - 1 = \left(\frac{-1}{n+1}\right)$, whose absolute value is surely as small as any ϵ that might be named, once n is chosen answeringly large. In symbols, one writes

$$\lim_{n \to \infty} \left(\frac{n}{n+1}\right) = 1.$$

Other sequences do not have so obvious a limit; a famous example is where $a_n = \left(1 + \frac{1}{n}\right)^n$. Here the limit is conventionally named e, and is approximately 2.71828. The proof, in this case as in many others, that a limit does exist makes use of the criterion of Cauchy: A sequence a_n has a limit if and only if to each positive ϵ there corresponds an index p such that $a_m - a_n$ is less than ϵ in absolute value whenever m and n both exceed p. Georg Cantor (about 1880) made this criterion a part of the definition of real number. If f is a real function, that is. if for each real number x there corresponds a real value $f(x)$, we say

$$\lim_{x \to a} f(x) = L$$

if the following statement holds: for every positive number ϵ, there is an interval I surrounding a (say all real numbers between $a - \alpha$ and $a + \alpha$) such that if x is in I, but x is not a itself. then $f(x) - L$ has absolute value less than ϵ. This definition gives precision to the intuitive notion "$f(x)$ is near L when x is near a" and makes possible the rigorous proof of the theorems connecting the limit-taking operation with the more usual arithmetic procedures. These theorems are at the root of the utility of the calculus.

Generalizations.—The statements "$f(x)$ is near L when x is near a," and "a_n is near L when n is far out," whose precise definitions are given above, continue to have meaning even when the quantities involved are not real numbers or integers but instead are members of more general structures in which appropriate notions of nearness and far-outness have been defined. Nearness takes on meaning in all topological spaces, of which the real numbers, the complex numbers, and most geometric configurations are examples; and far-outness takes on a useful meaning in many ordered sets; of which the integers form an example.

LIMITATION, STATUTES OF, the name given to Acts of parliament by which rights of action are limited in England, Wales and the north of Ireland to a fixed period after the occurrence of the events which give rise to the cause of action. This is one of the devices by which lapse of time is employed to settle disputed claims. The principle was first adopted in English law in connection with actions for the recovery of real property. At first a fixed date was taken, and no action could be brought of which the cause had arisen before that date. By the Statute of Westminster the First (3 Edward I. c 39), the beginning of the reign of Richard I. was fixed as the date of limitation for such actions. Possession of rights in *alieno solo* from time immemorial was held to be an indefeasible title, and the courts held time immemorial to begin with the first year of Richard I.

A large number of statutes since that time have established periods of limitation for different kinds of actions, Of those now in force the most important are the Limitation Act 1623 for personal actions in general, and the Real Property Limitation Act 1833 relating to actions for the recovery of land. The latter statute has been much amended by the Real Property Limitations Act 1874.

By s 14 of the Act of 1833, when any acknowledgment of the title of the person entitled has been given to him, the statute begins to run from that fact. By s. 15, persons under the disability of infancy, lunacy or coverture, or beyond seas, and their representatives, are to be allowed ten years from the termination of this disability, or death (which shall have first happened), notwithstanding that the ordinary period of limitation shall have expired.

By the Act of 1623 actions of trespass, detinue, trover, replevin or account, actions on the case (except for slander), actions of debt arising out of a simple contract and actions for arrears of rent not due upon specialty shall be limited to six years from the date of the cause of action. Actions for assault, menace, battery, wounds and imprisonment are limited to four years, and actions for slander to two years. Persons labouring under the disabilities of infancy, lunacy or unsoundness of mind are allowed the same time after the removal of the disability. When the defendant was "beyond seas" (*i.e.*, outside the United Kingdom and the adjacent islands) an extension of time was allowed, but by the Real Property Limitation Act of 1874 such an allowance is excluded as to real property, and as to other matters by the Mercantile Law Amendment Act 1856.

An acknowledgment, whether by payment on account or by mere spoken words, was formerly sufficient to take the case out of the statute. The Act 9 Geo. IV. c. 14 (Lord Tenterden's Act) requires any promise or admission of liability to be in writing and signed by the party to be charged, otherwise it will not bar the statute.

Contracts under seal are governed as to limitation by the Act of 1883, which provides that actions for rent upon any indenture of demise, or of covenant, or debt or any bond or other specialty, and on recognizances, must be brought within 20 years after cause of action. Actions of debt on an award (the submission being not under seal), or for a copyhold fine, or for money levied on a writ of *fieri facias,* must be brought within six years. With regard to the rights of the Crown, the principle obtains that *nullum tempus occurrit regi,* so that no statute of limitation affects the Crown without express mention. But by the Crown Suits Act 1769, as amended by the Crown Suits Act 1861, in suits relating to land, the claims of the Crown to recover are barred after the lapse of 60 years. For the prosecution of criminal offences generally there is no period of limitation, except where they are punishable on summary conviction. In such case the period is six months by the Summary Jurisdiction Act 1848. Suits and indictments under penal statutes are limited to two years if the forfeiture is to the Crown, to one year if the forfeiture is to the common informer. Penal actions by persons aggrieved are limited to two years by the Act of 1833. Prosecutions under the Riot Act can only be sued upon within 12 months after the offence, and offences against the Customs Acts within three years. By the Public Authorities Protection Act, 1893, a prosecution against any person acting in execution of statutory or other public duty must be commenced within six months

Trustees are expressly empowered to plead statutes of limitation by the Trustees Act 1888. For further information *see* the Crown Suits Acts 1769 and 1861, Summary Jurisdiction Acts 1848 and 1925, the Riot Act, the Customs Acts, the Public Authorities Protection Act 1893, the Criminal Law Amendment Acts 1885 and 1922, and the Trustees Act 1888. (*See* PRESCRIPTION, LACHES.)

As regards the application and adoption of the English statutes in the colonies, *see* W. Burge, *Commentaries on Colonial and Foreign Laws* (new ed., 1907–27), vol. iv., pt ii.

United States.—The various States possess their own statutes of limitation which are modelled in the main upon the English statutes but differ widely in their minor details. Real actions are usually not barred for twenty years, whereas personal actions survive only for six years. Numerous distinctions exist with reference to personal actions, a distinction generally being drawn between actions sounding in contract and those sounding in tort, the latter having a shorter period ranging from two to six years. About half the States have copied the provisions of the English statute of 1833 known as Lord Tenterden's Act requiring any promise or acknowledgment of liability to be in writing in order to revive a debt barred by the period of limitation. Separate statutes prescribe varying periods of limitation for the prosecution of criminal offenses. A difference of opinion exists in the State courts as to whether the statute of limitations must be specially pleaded in order to be available as a defense. A few States take judicial notice of the running of the period but most States insist that the defendant must expressly claim the benefit of the statute.

LIMOGES, a town of west-central France, capital of the *département* of Haute-Vienne, formerly capital of the old province of Limousin, 176 mi. S. by W. of Orléans on the railway to Toulouse and a junction for Poitiers, Angoulême, Périgueux and Clermont Ferrand. Pop. (1954) 98,405.

Limoges sent a large force to the defense of Alesia.. In 11 B.C.

it took the name of Augustus *(Augustoritum)*; but in the 4th century it was called anew by the name of the *Lentovices*, whose capital it was. It then contained palaces and baths, had its own senate and the right of coinage. Christianity was introduced by St. Martial. From the 5th century onwards Limoges suffered greatly through wars. Upder the Merovingians Limoges was celebrated for its mints and its goldsmiths' work. In the middle ages and until 1792 the town was divided into two distinct parts, each surrounded by walls. The chbteau, which grew up around the tomb of St. Martial in the 9th century, and was surrounded with walls in the 10th and again in the 12th, was under the jurisdiction of the viscounts of Limoges, and contained their castle and the monastery of St. Martial; the *cite'*, under the jurisdiction of the bishop, had but a sparse population, the habitable ground being practically covered by the cathedral, the episcopal palace and other churches and religious buildings. In the Hundred Years' War the bishops sided with the French, while the viscounts were unwilling vassals of the English. In 1370 the *cite'*, which had opened its gates to the French, was taken by the Black Prince and given over to fire and sword. The religious wars, pestilence and famine desolated Limoges in turn but Henri d'Aguesseau and Turgot helped it to recover. Limoges celebrates every seven years the Fête d'Ostension, during which the relics of St. Martial are exposed for seven weeks, attracting large numbers of visitors. It dates from the 10th century, and commemorates a pestilence believed to have been stayed by the saint.

The town, on a hill on the right bank of the Vienne, comprises two parts originally distinct, the *cite'* with narrow streets and old houses occupying the lower slope, and the town proper the summit. In the latter a street known as the Rue de la Boucherie is occupied by a powerful and ancient corporation of butchers. Boulevards have replaced the ramparts, outside which are suburbs with wide streets and spacious squares. The cathedral was begun in 1273, in 1327 the choir was completed, and before the middle of the 16th century the transept, with its fine north portal and the first two bays of the nave; from 1875 to 1890 the construction of the nave was continued, and it was united with the west tower (203 ft. high), the base of which belongs to a previous Romanesque church. In the interior there is a magnificent rood loft of the Renaissance. St. Michel des Lions (14th and 15th centuries) and St. Pierre des Queyroix (12th and 13th centuries) contain interesting stained glass. An old basilica of St. Martial was pulled down after 1794. The Vienne is crossed by a railway viaduct and four bridges, two of which, the Pont St. Étienne and the Pont St. Martial, date from the 13th century. The museum includes a rich ceramic collection.

Limoges is the headquarters of the 22nd army corps and the seat of a bishop, a prefect, a court of appeal and a court of assizes, and has tribunals of first instance and of commerce, a board of trade, arbitrators and a chamber of commerce. The educational institutions include a national school of decorative art. The chief industry is that of making and decorating porcelain; others are enamelling, a mediaeval industry revived at the end of the 19th century, the making of shoes and clogs and skin gloves, cloth weaving, straw papermaking and printing. The Vienne is navigable for rafts above Limoges, and the logs brought down by the current are stopped at the entrance of the town by the inhabitants of the Naveix quarter, who form a special guild for this purpose.

LIMÓN (PUERTO LIMÓN) principal Caribbean port of the republic of Costa Rica. Pop. (1950) 11,310. Located in the vicinity of the land seen by Columbus in 1503, Limón was used alternately with other small ports by Spanish colonial merchants as well as smugglers and was the occasional target of pirate and Mosquito Indian attacks. It began to grow in importance after the end of the William Walker filibustering era *(see* WALKER, WILLIAM) and about 1867 the port was opened to foreign commerce. Under the leadership of Minor Keith, an American, a railroad through very difficult terrain finally joined Limón and San José in 1890. Construction cost 4.000 lives and about $8,000,000. Much of the construction was done by West Indian Negroes who, until the 1940s, were prohibited by law from migrating to other Costa Rican provinces. The banana industry was developed along the tracks to provide a cash cargo, and by 1900 the United Fruit company had taken the lead in this business.

The chief business of Limón is exporting and importing and it yearly handles more freight than any other port in Costa Rica. Limón is the capital of Limón province, area 3,629 sq.mi., pop. (1950) 41,360. The province is an area of heavy rainfall (about 100 in. annually) that produces sugar cane and two corn crops a year. The region suffered from Panama disease in the 1930s, banana production fell drastically and about 100.000 ac. of banana land were abandoned as the companies moved to the Pacific coast of Costa Rica. (T. L. K.)

LIMONITE or BROWN IRON ORE, a natural hydrated ferric oxide, is one of the major iron-bearing minerals. The name is from the Greek word for meadow, in allusion to its occurrence as bog ore in meadows and marshes. Limonite was originally considered to be one of a series of hydrated ferric oxides, some with specific names, including turgite, limonite, xanthosiderite and limnite. Investigation showed, however, that there is only one hydrated form, $Fe_2O_3.H_2O$ This compound is dimorphous, and occurs in two crystalline forms which differ in the nature of the hydrogen-oxygen bonds, and whose formulas may be written as follows, goethite, $HFeO_2$ and lepidocrocite $FeO(OH)$. It was then assumed that limonite was this monohydrate in an amorphous condition, but X-ray studies clearly established the fact that most of the so-called limonite, especially the type with a radial fibrous structure, is distinctly crystalline, and is actually goethite.

The name limonite should properly be restricted to impure hydrated iron oxide, with variable water content, and colloidal or amorphous in character. It is sometimes pitchlike or has a vitreous lustre, with a black colour, occurring in stalactitic or botryoidal forms; or more commonly as earthy or porous masses, brown to yellow in colour (yellow ochre). The streak is yellow-brown. The hardness may be as high as 5.5, but usually is apparently less. It is commonly mixed with clay, sand and manganese oxide. It is formed as an alteration product of other iron minerals, such as the hydration of hematite or the oxidation and hydration of siderite and pyrite. *See* also GOETHITE; IRON AND STEEL: *Iron Ore.* (L. S. RL.)

LIMOSIN (LIMOUSIN), **LÉONARD** (*c.* 1505–*c.* 1577), French painter best known for his fine portraits in enamel, the most famous of a family of seven enamel painters of Limoges, was the son of an innkeeper in that city. He was influenced at the beginning of his career by the German school; indeed, his earliest authenticated work, signed "L. L." and dated 1532, is a series of 18 plaques of the "Passion of the Lord," after Albrecht Diirer. But this influence was counterbalanced by that of the Italian masters of the school of Fontainebleau, Primaticcio, Rosso, Giulio Romano and Solario, from whom he acquired his taste for arabesque ornament and mythological subjects Nevertheless, the French tradition was sufficiently ingrained to save him from becoming an imitator. In 1530 he entered the service of Francis I as painter and *varlet de chambre,* a position which he retained under Henry II. For both these monarchs he executed many portraits in enamel—among them plaques depicting Diane de Poitiers in various characters—plates, vases, ewers and cups, besides decorative works for the royal palaces, for, though he is best known as an enameler distinguished for rich colour, and for graceful designs in grisaille on black or bright-blue backgrounds, he also enjoyed a great reputation as an oil painter. His last signed works bear the date 1574, but the date of his death is uncertain, though it could not have been later than the beginning of 1577. He executed nearly 2,000 enamels. He is best represented at the Louvre, which has his two famous votive tablets for the Sainte Chapelle, each consisting of 23 plaques, signed "L.L." and dated 1553; and many portraits. *See* also ENAMEL: *Origin and European Development.*

LIMOUSIN, a geographical region and former province of France. For the geographer, Limousin is the western part of the Massif Central, *i.e.,* the wide zone of Archaean and primary rocks that spreads westward from the upper valleys of the Cher and the Dordogne, over the three *de'partements* of Haute-Vienne, Corrèze and Creuse and the *arrondissements* of Confolens in Charente and Nontron in Dordogne. Far from the Alps, it was little affected by the Tertiary earth movements and consists mostly of peneplains or rolling plateaus and falls slowly from 3,000 ft. in the Montagne Limousine to 1,000 ft. in the low plateaus of the west; still it is a hilly country with deep river valleys. where communications were difficult till the railway age. The rough climate and the low fertility of the acid topsoils gave Limousin a reputation for poverty.

Originally a political unit (first the Gallic and Roman civitas of the Lemovices, then the Merovingian and Carolingian *pagus* Lemovicinus) coincided with these geographical limits. But since the 10th century the historical Limousin has been much smaller than the geographical. The Romans subdued the country in 49 B.C. and included it (27 B.C.) in the province of Aquitania. It was the object of endless contests between the Jlerovingian kings and later. from 760 to 768. the theatre of a fierce war between the Frankish king Pippin and the duke of Aquitaine. Waifer. In the 10th century it was divided between a number of feudal principalities: the northern part was cut off to form the county of Marche (*q.v.*), which later came to be considered a different province; some border districts (Confolens, Chabanais, Combrailles and Rochechouart) fell to the neighbouring principalities of Poitou. Auvergne and Angoumois; and the remnant was soon shared out between the viscountcies of Limoges, Comborn, Turenne and Ventadour.

From 866 these viscountcies mere vassals of the dukes of Aquitaine (*q.v.*) who used to be crowned in the cathedral of Limoges. Therefore, when Eleanor of Aquitaine married Henry Plantagenet, Limousin became part of the Angevin empire and a battlefield in the long struggle between Capetians and Plantagenets. After many risings against the latter, it fell to the French in 1214, but Henry III recovered some rights over the diocese of Limoges by the treaty of Paris (1259). At the beginning of the Hundred Years' War Limousin became again a battlefield. Overrun by the English after the battle of Poitiers. it was given over to them by the treaty of Brétigny (1360) but was reconquered by the French from 1370 to 1374. During those centuries Limousin had, however. been the centre of an original culture. connected with the civilization of southern France. In the 11th century the monastery of Saint Martial at Limoges was a place of learning, famous for its illuminated manuscripts; but the two main contributions of Limousin to the Occitanian culture are its enamelling industry (see ENAMEL), whose products were exported all over Europe, and its literature. It was the cradle of the lyric poetry of the troubadours, who used the Limousin dialect in their poems.

From the end of the 14th century this cultural autonomy declined as the centralizing policy of the kings made the country look increasingly northward rather than southward. In 1607 the viscountcy of Limoges, which from the houses of Comborn, Brittany and Blois had passed to that of Albret, was united to the crown by Henry IV. The gouvernement of Limousin was co-extensive with the four great feudal viscountcies, but the *généralité* of Limoges was much larger, since it included Angoumois and Basse Marche. In the 18th century its intendants, particularly the marquis de Tourny and the famous Turgot (who had there his political apprenticeship), tried hard to promote welfare and prosperity. But Limousin was one of the poorest French provinces in 1789, with its agriculture backward and its population politically inert (for example, during the French Revolution), and remained so, far into the 19th century. After 1850. however. the country underwent an economic revolution, owing" to the building of the railways, which made possible the import of fertilizers, lime and marl. The modernization of agriculture was quick, with the disappearance of waste and fallow and the extension of cattle breeding. Furthermore, the Limoges district became the main French producer of china and footwear. Under the third republic the evolution of political opinion toward the left went farther in Haute-Vienne and Corrèze than in any other French region, despite the predominance of agriculture and peasant ownership. In World War II Limousin was one of the main theatres of guerrilla warfare in France; on June 10, 1944, the whole population of the small town of Oradour-sur-Glane was murdered in retaliation by German troops of the S.S. division.

(F. CT.)

LIMPKIN, a single species of big, brown, raillike bird of the Americas. constituting the family Aramidae, closely related to the crane (*q.v.*). This bird (Aramus *scolopaceus*), 28 in., called courlan or crying bird from its loud. prolonged, wailing cry, and limpkin from its peculiar halting gait as it hunts along the ground, ranges lowlands from eastern Argentina north to southern Mexico. Puerto Rico and Hispaniola. One race (A. *s. pictus*) is resident in the Florida peninsula and southern Georgia (Okefinokee swamp). It is found along borders of wooded streams, bayous, sloughs or in open marshes, sometimes uplands, where it runs raillike through brush with long strides or perches on a small tree. The limpkin flies with short concave wings slowly flapping, neck extended and legs dangling. It feeds on mollusks, crustaceans, aquatic insects, frogs and worms. In the Everglades it feeds chiefly on large, greenish fresh-water snails (Ampullaria). These carried to its nest or favourite feeding perch and held firmly in one foot are struck several powerful blows with the 4-in. bill. The bill is then forced into the spiral opening of the shell to pull out the animal. The bulky nest of leaves, twigs and Spanish moss, it found among grasses or shrubs, or in a low tree over or near water; the eggs. four to six, rarely eight are buff splashed with brown and drab. (G. F. Ss.)

LIMPOPO or CROCODILE, a river of southeast Africa more than 1,000 mi. in length. next to the Zambezi the largest river of Africa entering the Indian ocean. Its head streams rise on the northern slopes of the Witwatersrand less than 300 mi. due W. of the sea, but the river makes a great semicircular sweep across the high plateau. For a great part of its course the Limpopo forms the northwest and north frontiers of the Transvaal. Its banks are well wooded and present many picturesque views. In descending the escarpment of the plateau the river passes through rocky ravines, piercing the Zoutpansberg near the northeast corner of the Transvaal at the Toli Azimé falls. In the low country it receives on the right bank its chief affluent, the Olifants river (450 mi. long), which shares with the main river the distinction of having cut back across the eastern escarpment, and of draining parts of the interior plateau. The Limpopo enters the ocean in 25° 15′ S. The mouth, about 1,000 ft. wide, is obstructed by sand banks. In the rainy season the Limpopo loses a good deal of its water in the swampy region along its lower course. High-water level is 24 ft. above low-water level, when the depth in the shallowest part does not cxcccd 3 ft. The river is navigable all the year round by shallow-draught vessels from its mouth for about 100 mi. to a spot known as Gungunyana's ford. In flood time there is water communication south with the river Komati (*q.v.*). At this season stretches of the Limpopo above Gungunyana's ford are navigable. The river valley is generally unhealthful.

The basin of the Limpopo includes the northern part of the Transvaal, the eastern portion of Bechuanaland, southern Matabeleland and a large area of Portuguese territory north of Delagoa bay. Its chief tributary, the Olifants, has been mentioned. Of its many other affluents, the Macloutsie, the Shashi and the Tuli are the most distant northwest feeders. Among the streams which, flowing north through the Transvaal, join the Limpopo is the Nylstroom, so named by Boers trekking from the south in the belief that they had reached the river Nile. In the coast region the river has one considerable affluent from the north, the Chengane, which is navigable for some distance.

The Limpopo is a river of many names. In its upper course it is called the Crocodile, and that name is also applied to the whole river. Though claiming the territory through which it ran, the Portuguese made no attempt to trace the river. This was first done by Capt. J. F. Elton, who in 1870, travelling from the Tati gold fields, sought to open a road to the sea via the Limpopo. He voyaged down the river from the Shashi confluence to the Toli Azimé falls, which he discovered, following the stream thence on foot to the low country. The lower course of the river had been explored 1868–69 by another British traveller. St. Vincent Whitshed Erskine.

LINACEAE, the flax family, comprising 22 genera and 320 species. mostly herbs and shrubs. The only important genus of this family of dicotyledons is *Linum*. See FLAX; LINSEED.

LINACRE, THOMAS (c. 1460–1524), English humanist and physician, founder (1518) and first president of the Royal College of Physicians, was probably born *c.* 1460 at Canterbury, Kent. Educated at the universities of Oxford and Padua, he was fully imbued with the "new learning" and c. 1501 was called to court as tutor to Prince Arthur. On the accession of Henry VIII he was appointed the king's physician and he also treated most of the great statesmen and prelates. He made benefactions to medical teaching at Oxford and Cambridge, wrote a Latin grammar and a work on Latin composition and published Latin translations of several of the works of the Greek physician Galen. He died in London on Oct. 20, 1524. An intimate friend of Erasmus, Sir Thomas More, John Colet, William Grocyn and others, Linacre is the prototype of the great scholar physicians of the Renaissance.

See J. N. Johnson, *Life of Thomas Linacre*, ed. by R. Graves (1835). (W. J. Bp.)

LINARES, inland province of central Chile. The province was separated from Maule province in 1873, reabsorbed in 1927 and recreated in 1936. Area (altered slightly in 1943) 3,791 sq.mi. Pop. (1952) 146,2j7. The province consists of central valley and Andean cordillera terrain, all lying within the Maule drainage system. In the rolling central valley soils are not outstanding, but the province is of major agricultural significance because there is an abundance of water for irrigation. It ranked high in wheat and in wine and flax production, in *chacareria* area (beans, corn, chick-peas, potatoes, peas and lentils), and in rice and sunflower acreage. The San Javier-Villalegre district is noted for its vineyards. Livestock raising (cattle and sheep) is general. Crops are processed and shipped through the market and administrative centres of San Javier (pop. (1952) 7,006), Parral (10,-717) and Linares (19,624), the provincial capital. The towns are served by the state railway; at Parral the Cauquenes (Arauco Province) branch line begins. The longitudinal highway also traverses the province, and lesser lateral roads lead to spas at Longaví, Panamávida, Catillo and Quinamávida. Although the city of Linares was founded as San Javier de Bella Isla (1755) and renamed Villa de San Ambrosio de Linares (1794), its present name became official in 1875. (J. T.)

LINARES, a town of southern Spain, in the province of Jaén, among the southern foothills of the Sierra Morena, 1,375 ft. above sea level and 3 mi. N.W. of Guadalimar river. Pop. (1950) 52,819 (mun.). It is connected by four branch railways with the argentiferous lead mines on the northwest, and with the main railways from Madrid to Seville. Granada and the principal ports on the south coast. Its population is chiefly engaged in the lead mines, and in the manufacture of powder, dynamite, match for blasting purposes, rope and the like. The mining plant is entirely imported, and smelting, desilverizing and the manufacture of lead sheets, pipes, etc.. are carried on. Linares lead is unsurpassed in quality. About 2 mi. S. is the village of Cazlona, with remains of the ancient *Castulo*. Linares remained in government hands until shortly before the close of the civil war of 1936–39.

LINCOLN, EARLS OF. The first earl of Lincoln was William d'Aubigny, created earl about 1139. He soon lost the title, becoming earl of Sussex, though more generally known as earl of Arundel. About 1141 King Stephen created William de Roumare (*c.* 1096–before 1161) earl of Lincoln; but about 1147–48 he granted the earldom to Gilbert de Gant (*c.* 1120–56). After Gilbert's death the earldom was dormant for about 60 years and although in Richard I's time William's grandson and heir was styled Earl William de Roumare. he was not apparently styled earl of Lincoln. In 1216 Louis of France gave it to another Gilbert de Gant; but on May 23, 1217, it was transferred to Ranulf de Blundeville, earl of Chester (d. 1232). From Ranulf the title to the earldom passed through his sister Hawise to the family of Lacy, John de Lacy (d. 1240) being made earl of Lincoln in 1232. He was a son of Roger de Lacy (d. 1212), justiciar of England and constable of Chester. It was held by the Lacys until the death of Henry, the 3rd earl (1251–1311).

Henry served Edward I in Wales, France and Scotland, both as a soldier and a diplomatist. He succeeded (1296) Edmund, earl of Lancaster. as commander of the English forces in Gascony. He fought at Falkirk in July 1298. He was then employed by Edward to negotiate successively with popes Boniface VIII and Clement V. and also with Philip IV of France; and was present at the death of the English king in July 1307. Under Edward II he joined Thomas, earl of Lancaster, and the baronial party. was one of the "ordainers" appointed in 1310 and was regent of the kingdom during the king's absence in Scotland in the same year. He died in London on Feb. 5, 1311, and was buried in St. Paul's cathedral. He married Margaret (d. 1309), granddaughter and heiress of William Longsword, 2nd earl of Salisbury, and his only surviving child, Alice (1281–1348), became the wife of Thomas, earl of Lancaster. who thus inherited his father-in-law's earldoms of Lincoln and Salisbury.

In 1349 Henry Plantagenet, earl (afterward duke) of Lancaster, a nephew of Earl Thomas, was created earl of Lincoln; and when his grandson Henry became king of England as Henry IV in 1399 the title merged in the crown. In 1467 John de la Pole (c. 1462–87), a nephew of Edward IV, was made earl of Lincoln. He joined Lambert Simnel and was killed at the battle of Stoke, leaving no children. The dignity was conferred in 1525 upon Henry Brandon (1516–34), son of Charles Brandon, duke of Suffolk, on whose death the earldom again became extinct. In 1572 Edward Fiennes Clinton, 9th Lord Clinton (1512–85), lord high admiral and the husband of Henry VIII's mistress, Elizabeth Blount, was created earl of Lincoln. The title is still held by Clinton's descendants. In 1768 Henry Clinton, the 9th earl (1720–94), succeeded his uncle Thomas Pelham as 2nd duke of Newcastle-under-Lyne, and since this date the title of earl of Lincoln has been the courtesy title of the eldest son of the duke of Newcastle.

See G. E. C(okayne), *Complete Peerage*, vol. vii (London, 1929).

LINCOLN, ABRAHAM (1809–1865), 16th president of the United States, was born on Feb. 12, 1809, in a backwoods cabin three miles south of Hodgenville, Ky. When he was two years old he was taken to a farm in the neighbouring valley of Knob Creek. His earliest memories were of this home and, in particular, of a flash flood that once washed away the corn and pumpkin seeds he had helped his father plant. The father, Thomas Lincoln, was descended from a weaver's apprentice who had migrated from England to Massachusetts in 1637. Though much less prosperous than some of his Lincoln forebears, Thomas was a sturdy pioneer. On June 12, 1806, he married Nancy Hanks. The Hanks genealogy is difficult to trace, but Nancy appears to have been of illegitimate birth. She has been described as "stoop-shouldered, thin-breasted, sad," and fervently religious. Thomas and Nancy Lincoln had three children: Sarah, Abraham and Thomas (died in infancy).

In Dec. 1816, faced with a lawsuit challenging the title to his Kentucky farm, Thomas Lincoln moved with his family to southeastern Indiana. There, as a "squatter" on public land, he hastily put up a "half-faced camp"—a crude structure of logs and boughs, with one side open to the weather—in which the family took shelter behind a blazing fire. Soon he built a permanent cabin, and later he bought the land on which it stood. Abraham helped to clear the fields and take care of the crops but early acquired a dislike for hunting and fishing. In after years he recalled the "panther's scream," the bears that "preyed on the swine," and the poverty of Indiana frontier life, which was "pretty pinching at times." The unhappiest period of his boyhood followed the death of his mother in the autumn of 1818. As a ragged nine-year-old, he saw her buried in the forest, then faced a winter without the warmth of a mother's love. Fortunately, before the onset of a second winter, Thomas Lincoln brought home from Kentucky a new wife for himself, a new mother for the children. Sarah Bush Johnston Lincoln, a widow with two boys and a girl of her own, had energy and affection to spare. She ran the household with an even hand, treating both sets of children as if she had borne them all, but she became especially fond of Abraham: and he of her. He afterward referred to her as his "angel mother."

This stepmother doubtless encouraged Lincoln's taste for reading, yet the original source of his desire to learn remains something of a mystery. Both of his parents were almost completely illiterate, and he himself received very little formal education. He once said that, as a boy, he had gone to school "by littles"—a little now and a little then—and his entire schooling amounted to no more than one year's attendance. His neighbours later recalled how he used to trudge for miles to borrow a book. According to his own statement. however, his early surroundings provided "absolutely nothing to excite ambition for education. Of course when I came of age I did not know much. Still somehow, I could read, write, and cipher to the Rule of Three; but that was all." Apparently the young Lincoln did not read a large number of books but thoroughly absorbed the few that he did read. These included Parson Weems's *Life of Washington* (with its story of the little hatchet and the cherry tree), *Robinson Crusoe, Pilgrim's Progress* and Aesop's *Fables*. From his earliest days he must have had some familiarity with the Bible, for it doubtless was the only book his family owned.

In March 1830 the Lincoln family undertook a second migration, this one to Illinois, with Lincoln himself driving an ox team. Having just reached the age of 21, he mas about to begin life on his own. Six feet four inches tall, he was rawboned and lanky but muscular and physically powerful. He was especially noted for the skill and strength with which he could wield an ax. He spoke with a backwoods twang and walked in the long-striding. flat-footed, cautious manner of a plowman. Good-natured though somewhat moody, talented as a mimic and storyteller, he readily attracted friends. He was yet to demonstrate what other abilities he possessed.

Prairie Lawyer.—After his arrival in Illinois, having no desire to be a farmer, Lincoln tried his hand at a variety of occupations. As a "rail splitter," he helped to clear and fence his father's new farm. As a flatboatman, he made a voyage down the Mississippi river to New Orleans (this mas his second visit to that city, his first having been made in 1828, while he still lived in Indiana). On his return he settled in New Salem, a village of about 25 families on the Sangamon river. There he worked from time to time as storekeeper, postmaster and surveyor. With the coming of the Black Hawk War (1832), he enlisted as a volunteer and was elected captain of his company. Afterward he joked that he had seen no "live, fighting Indians" during the war but had had "a good many bloody struggles with the mosquitoes." Meanwhile, aspiring to be a legislator, he was defeated in his first try and then repeatedly re-elected to the state assembly. He considered blacksmithing as a trade but finally decided in favour of the law. Already he had taught himself grammar and mathematics, and now he began to study lawbooks. In 1836, having passed the bar examination, he began to practice law.

The next year he moved to Springfield, the new state capital, which offered much larger opportunities for a lawyer than New Salem did. At first he was a partner of John T. Stuart, then of Stephen T. Logan, and finally, from 1844 on, of William H. Herndon. Nearly ten years younger than Lincoln, Herndon was more widely read, more emotional at the bar, and generally more extreme in his views. Yet this partnership seems to have been as nearly perfect as such human arrangements ever are. Lincoln and Herndon kept few records of their law business: and they split the cash between them whenever either of them was paid. It seems they had no money quarrels.

Within a few years after his removal to Springfield, Lincoln was earning from $1,200 to $1,500 annually, at a time when the governor of the state received a salary of $1,200 and circuit judges only $750. He had to work hard. To keep himself busy he found it necessary not only to practise in the capital but also to follow the court as it made the rounds of its circuit. Each spring and fall he would set out by horseback or buggy to travel hundreds of miles over the thinly settled prairie, from one little county seat to another. Most of the cases were petty and the fees small.

The coming of the railroads, especially after 1850, made travel easier and practice more remunerative. Lincoln served as a lobbyist for the Illinois Central to assist in getting a charter from the state, and thereafter he was retained as a regular attorney for that railroad. After successfully defending the company against the efforts of McLean county to tax its property, he received the largest single fee of his legal career—$5,000. (He had to sue the Illinois Central in order to collect the fee.) He also handled cases for other railroads and for banks, insurance companies, mercantile and manufacturing firms. In one of his finest performances before the bar, he saved the Rock Island bridge, the first to span the Mississippi river, from the threat of the river transportation interests who demanded the bridge's removal. His business included a number of patent suits and criminal trials. One of his most effective and famous pleas had to do with a murder case. A witness claimed that, by the light of the moon, he had seen Duff Armstrong, an acquaintance of Lincoln's, take part in a killing. Referring to an almanac for proof, Lincoln argued that the night had been too dark for the witness to have seen anything clearly, and with a sincere and moving appeal he won an acquittal.

By the time he began to be prominent in national politics, about twenty years after launching upon his legal career, Lincoln had made himself one of the most distinguished and successful lawyers in Illinois. He was noted not only for his shrewdness and practical common sense, which enabled him always to see to the "nub" of any legal case, but also for his invariable fairness and utter honesty.

Private Life.—While residing in New Salem, Lincoln was acquainted with Ann Rutledge. Apparently he was fond of her, and certainly he grieved with the entire community at her untimely death. in 1835, at the age of 19. Afterward stories were told of a grand romance between Abraham and Ann, but these stories lack the support of sound historical evidence. A year after the death of Miss Rutledge. Lincoln was carrying on a half-hearted courtship mith Mary Owens. Miss Owens concluded that Lincoln was "deficient in those little links that make up the chain of woman's happiness." She turned down his proposal.

So far as can be known, the first and only real love of Lincoln's life was Mary Todd. High-spirited, quick-witted, and well-educated. Miss Todd came from a rather distinguished Kentucky family, and her Springfield relatives belonged to the social aristocracy of the town. Some of them frowned upon her association uith Lincoln, and from time to time he too had doubts whether he ever could make her happy. Nevertheless, they became engaged. Then, on a day in 1841 that Lincoln recalled as the "fatal first of January" they broke the engagement, apparently on his initiative. For some time after that, he was overwhelmed by a mood of terrible depression and despondency. Finally the two were reconciled and, on Nov. 4, 1842, were married.

Four children, all boys, were born to the Lincolns. Robert Todd, the eldest and the only one to survive to adulthood, was never very close to his father. Edward Baker died at the age of 4 and William Wallace at 12. Thomas. affectionately known as "Tad," outlived his father; Tad, who had a cleft palate and a lisp. was Lincoln's favourite. Lincoln left the upbringing of his sons largely to their mother, who was alternately strict and lenient in her treatment of them.

The Lincolns had a mutual affectionate interest in the doings and welfare of their boys, were fond of one another's company, and missed each other when apart, as existing letters show. Like most married couples, the Lincolns also had their domestic quarrels. which sometimes were hectic but nhich undoubtedly were exaggerated by contemporary gossips. Mrs. Lincoln suffered from recurring headaches, fits of temper, and a sense of insecurity and loneliness that was intensified by her husband's long absences on the lawyer's circuit. After his election to the presidency, she was afflicted in spirit by the death of her son Willie, by the ironies of war that made enemies of Kentucky relatives and friends, and by the unfair public criticisms of her as mistress of the White House. She lost all money sense and ran up embarrassing bills. She also put on some painful scenes of wifely jealousy. At last, in 1875, she was officially declared insane, but that mas after she had undergone the further shock of seeing her husband murdered at her side. During their earlier married life, Mrs. Lincoln unquestionably encouraged her husband and served as a prod to his own ambition. During their later years together she probably strengthened and tested his innate qualities of tolerance and patience.

With his wife, Lincoln attended Presbyterian services in Springfield and in Washington, but he never joined any church. He once explained "When any church will inscribe over its altar the Saviour's condensed statement of law and gospel 'Thou shalt love the Lord thy God with all thy heart and with all thy soul and with all thy mind, and love thy neighbor as thyself,' that church will I join mith all my heart." Early in life he had been something of a skeptic and free thinker. His reputation had been such that, as he once complained. the "church influence" was used against him in politics. When running for congress in 1846, he issued a handbill to deny that he ever had "spoken with intentional disrespect of religion." He went on to explain that he had believed in the doctrine of necessity—"that is, that the human mind is impelled to action, or held in rest, by some power over which the mind itself has no control." Throughout his life he also believed in dreams and other enigmatic signs and portents. As he grew older. and especially after he became president and faced the soul-troubling responsibilities of the Civil War, he developed a profound religious sense. and he increasingly personified Necessity as God. He came to look upon himself quite humbly, as an "instrument of Providence," and to view all history as God's enterprise. "In the present civil war," he wrote in 1862. "it is quite possible that God's purpose is something different from the purpose of either party — and yet the human instrumentalities, working just as they do, are of the best adaptation to effect His purpose."

Lincoln was fond of the Bible and knew it well. He also was fond of Shakespeare. In private conversation he used many Shakespearean allusions, discussed problems of dramatic interpretation with considerable insight, and from memory recited long passages with rare feeling and understanding. He liked the essays of John Stuart Mill, particularly the famous one on liberty, but disliked heavy or metaphysical works.

Though he enjoyed the poems of Lord Byron and Robert Burns, his favourite piece of verse was the work of an obscure Scottish poet, William Knox. Lincoln often quoted Knox's lines beginning: "Oh! why should the spirit of mortal be proud?" He liked to relax with the comic writings of Petroleum V. Nasby, Orpheus C. Kerr, and Artemus Ward, or with a visit to the popular theatre.

To the Presidency. — When Lincoln first entered politics, Andrew Jackson was president. Lincoln shared the sympathies which the Jacksonians professed for the common man, but he disagreed with the Jacksonian view that the government should be divorced from economic enterprise. "The legitimate object of government," he was later to say, "is to do for a community of people whatever they need to have done, but cannot do at all, or cannot do so well for themselves, in their separate and individual capacities." He most admired Henry Clay and Daniel Webster among the prominent politicians of the time. Clay and Webster advocated using the powers of the federal government to encourage business and develop the country's resources by means of a national bank, a protective tariff, and a program of internal improvements for facilitating transportation. In Lincoln's view, Illinois and the west as a whole desperately needed such aid to economic development. From the outset, he associated himself with the Clay and Webster party, the Whigs.

As a Whig member of the Illinois state legislature, to which he was elected four times from 1834 to 1840, he devoted himself to a grandiose project for constructing with state funds a network of railroads, highways and canals. Whigs and Democrats joined in passing an omnibus bill for these undertakings, but the panic of 1837 and the ensuing business depression brought about the abandonment of most of them. While in the legislature he demonstrated that, though opposed to slavery, he was no abolitionist. Resolutions were introduced, in 1837, in response to the mob murder of Elijah Lovejoy, an antislavery newspaperman of Alton. Instead of denouncing lynch law, these resolutions condemned abolitionist societies and upheld slavery within the southern states as "sacred" by virtue of the federal constitution. Lincoln refused to vote for the resolutions. Together with a fellow member he drew up a protest against them. This maintained, on the one hand, that slavery was "founded on both injustice and bad policy" and, on the other, that "the promulgation of abolition doctrines tends rather to increase than to abate its evils."

During his single term in congress (1847–49), Lincoln as the lone Whig from Illinois gave little attention to legislative matters as such. He proposed a bill for the gradual and compensated emancipation of slaves in the District of Columbia, but the bill was to take effect only with the approval of the "free white citizens" of the district. It displeased abolitionists as well as slaveholders, and never was seriously considered.

Much of his time Lincoln devoted to presidential politics. to unmaking one president, a Democrat, and making another, a Whig. He found an issue and a candidate in the Mexican War. With his "spot resolutions" he challenged the statement of Pres. James K. Polk that Mexico had started the war by shedding American blood upon American soil. Along with other members of his party. Lincoln voted to condemn Polk and the war while voting supplies for carrying it on. At the same time he laboured for the nomination and election of the war hero Zachary Taylor. After Taylor's success at the polls, Lincoln expected to be named commissioner of the general land office as a reward for his campaign services, and he was bitterly disappointed when he failed to get the job. His criticisms of the war, meanwhile, had not been popular among the voters in his own congressional district. At the age of 40, frustrated in politics, he seemed to be at the end of his public career.

For about five years he took little part in politics, and then a new sectional crisis gave him a chance to re-emerge and rise to statesmanship. In 1854 his political rival Stephen A. Douglas maneuvered through congress a bill for reopening the, entire Louisiana purchase to slavery and allowing the settlers of Kansas and Nebraska (with "popular sovereignty") to decide for themselves whether to permit slaveholding in those territories. The Kansas-Nebraska act provoked violent opposition in Illinois and the other states of the old northwest. It gave rise to the Republican party while speeding the Whig party on the way to disintegration. Along with many thousands of other homeless Whigs, Lincoln soon became a Republican (1856). Before long, some prominent Republicans in the east talked of attracting Douglas to the Republican fold, and with him his Democratic following in the west. Lincoln would have none of it. He was determined that he, not Douglas, should be the Republican leader of his state and section. In their basic views he and Douglas were not quite so far apart as they seemed in the heat of political argument. Neither was an abolitionist, neither a proslavery man. But Lincoln, unlike Douglas, insisted that congress must exclude slavery from the territories. He disagreed with Douglas's belief that the territories were by nature unsuited to the slave economy and that no congressional legislation was needed to prevent the spread of slavery into them. He declared (1858): "'A house divided against itself cannot stand.' I believe this government cannot endure permanently half slave and half free." He predicted that the country eventually would become "all one thing, or all the other." Again and again he insisted that the civil liberties of every U.S. citizen, white as well as black, were at stake. The territories must be kept free, he further said, because "new free states" were "places for poor people to go and better their condition." He agreed with Thomas Jefferson and other founding fathers, however, that slavery should be merely contained, not directly attacked. In the Lincoln-Douglas debates of 1858, while contesting for Douglas's seat in the United States senate, he drove home the inconsistency between Douglas's "popular sovereignty" principle and the Dred Scott decision (1857), in which the U.S. supreme court held that congress could not constitutionally exclude slavery from the territories. Though he failed to obtain the senate seat, Lincoln gained national recognition and soon began to be mentioned as a presidential prospect for 1860.

On May 18, 1860, after Lincoln and his friends had made skillful preparations, he was nominated on the third ballot at the Republican convention in Chicago. He then put aside his law practice and, though making no stump speeches, gave his full time to the direction of his campaign. His "main object," he had written, was to "hedge against divisions in the Republican ranks," and he counseled party workers to "say nothing on points where it is probable we shall disagree." With the Republicans united, the Democrats divided, and a total of four candidates in the field. he carried the election on Nov. 6. No one in the deep south voted for him, and fewer than 40 out of 100 in the country as a whole. Still, the popular votes were so distributed that he won a clear and decisive majority in the electoral college.

The War Comes. — After Lincoln's election and before his inauguration, the state of South Carolina proclaimed its withdrawal from the Union. To forestall similar action by other southern states, various compromises were proposed in congress. The most important, the Crittenden compromise, included constitutional amendments (1) guaranteeing slavery forever in the states where it already existed and (2) dividing the territories between slavery and freedom. Though Lincoln had no objection to the first of these amendments, he was unalterably opposed to the second, and indeed to any scheme infringing in the slightest upon the free-soil plank of his party's platform. "I am inflexible," he privately wrote. He feared that a territorial division, by sanctioning the principle of slavery extension, would only encourage planter imperialists to seek new slave territory south of the American border and thus would "put us again on the highroad to a slave empire." From his home in Springfield he advised Republicans in congress to vote against a division of the territories. The proposal was killed in committee. Six additional states then seceded and, with South Carolina, combined to form the Confederate States of America.

So, before Lincoln took office, a disunion crisis was upon the country. Attention North and South focused in particular upon Fort Sumter, in Charleston harbour. This fort, still under construction, was garrisoned by U.S. troops under Naj. Robert Anderson. The Confederacy claimed it and, from other harbour fortifications: threatened it. Foreseeing trouble, Lincoln while still in Springfield confidentially requested Winfield Scott, general in chief of the U.S. army, to be prepared "to either hold, or retake, the forts, as the case may require, at, and after the inauguration." In his inaugural address (March 4. 1861), beside upholding the Union's indestructibility and appealing for sectional harmony, Lincoln restated his Sumter policy as follows: "The power confided in me, will be used to hold, occupy, and possess the property, and places belonging to the government, and to collect the duties and imposts; but beyond what may be necessary for these objects, there will be no invasion—no using of force against, or among the people anywhere." Then, near the end, addressing the absent southerners: "You can have no conflict, without being yourselves the aggressors."

No sooner was he in office than Lincoln received word that the Sumter garrison, unless supplied or withdrawn, would shortly be starved out. Still, for about a month, Lincoln delayed to act. He was beset by contradictory advice. On the one hand, General Scott. Secretary of State William H. Seward, and others urged him to abandon the fort, and Seward through a go-between gave a group of Confederate commissioners to understand that the fort would in fact be abandoned. On the other hand, many Republicans insisted that any show of weakness would bring disaster to their party and to the Union. Finally Lincoln ordered the preparation of two relief expeditions, one for Fort Sumter and the other for Fort Pickens, in Florida. (He afterward said he would have been willing to withdraw from Sumter if he could have been sure of holding Pickens.) Before the Sumter expedition got under way, he sent a messenger to tell the South Carolina governor: "I am directed by the President of the United States to notify you to expect an attempt will be made to supply Fort-Sumpter with provisions only; and that, if such attempt be not resisted, no effort to throw in men, arms: or ammunition, will be made, without further notice, or in case of an attack upon the Fort." Without waiting for the arrival of Lincoln's expedition, the Confederate authorities presented to Major Anderson a demand for Sumter's prompt evacuation, which he refused. On April 12, 1861, at dawn, the Confederate batteries in the harbour opened fire.

"Then, and thereby," Lincoln informed congress when it met on July 4, "the assailants of the Government began the conflict of arms." The Confederates, however, accused him of being the real aggressor. They said he had cleverly maneuvered them into firing the first shot so as to put upon them the onus of war guilt. Though some historians have repeated this charge, it appears to be a gross distortion of the facts. The facts apparently are these: Lincoln was determined to preserve the Union; to do so, he thought he must take a stand sooner or later against the pretensions of the Confederacy, and he concluded he might as well take this stand at Sumter.

Lincoln's primary aim was neither to provoke war nor to maintain peace. In preserving the Union, he would have been glad to preserve the peace also, but he was ready to risk a war, which he thought would be short.

Commander in Chief.—After the firing on Fort Sumter. Lincoln called upon the state governors for troops (Virginia and three other states of the upper south responded by joining the Confederacy). He then proclaimed a blockade of the southern ports. These steps—the Sumter expedition, the call for volunteers, and the blockade—mere the first important decisions of Lincoln as commander in chief of the army and navy. He still needed a strategic plan and a command system for carrying it out.

General Scott advised him to avoid battle with the Confederate forces in Virginia, to get control of the Mississippi river, and by tightening the blockade to hold the South in a gigantic squeeze. Lincoln had little confidence in Scott's comparatively passive and bloodless "Anaconda" plan. He believed the war must be actively fought if it ever was to be won. Overruling Scott. he ordered a direct advance on the Virginia front. which resulted in defeat and rout for the Union forces at Bull Run (July 21, 1861). After a succession of more or less sleepless nights, Lincoln produced a set of memoranda on military policy. His basic thought was this: the armies should advance concurrently on several fronts and should move in such directions as to hold and use the support of Unionists in Missouri, Kentucky, western Virginia, and eastern Tennessee. "I state my general idea of this war to be," he later explained. "that we have the greater numbers. and the enemy has the greater facility of concentrating forces upon points of collision; that we must fail, unless me can find some way of making our advantage an overmatch for his; and that this can only be done by menacing him nith superior forces at different points, at the same time." This, with the naval blockade, comprised the essence of Lincoln's strategy.

From 1861 to 1864, while hesitating to impose his ideas upon his generals, Lincoln experimented with command personnel and organization. Accepting the resignation of Scott (Nov. 1861) he put George B. McClellan in charge of the armies as a whole. After a few months, disgusted by the slowness of McClellan, he demoted him to the command of the army of the Potomac alone. He questioned the soundness of McClellan's plans for the peninsular campaign, repeatedly compelled McClellan to alter them, and after the Seven Days' battle before Richmond (June–July 1862) ordered him to give them up. Then he tried a succession of commanders for the army in Virginia—John Pope, McClellan again. Ambrose E. Burnside. Joseph Hooker and George Gordon Meade—but was disappointed with each of them in turn. Meanwhile he had in Henry W. Halleck a general in chief who gave advice and served as a liaison with field officers but who shrank from making important decisions. For nearly two years the Union armies had no very effective unity of command. President Lincoln, General Halleck and War Secretary Edwin M. Stanton acted as an informal council of war. Lincoln, beside transmitting official orders through Halleck, also communicated directly with the generals, sending personal suggestions in his own name. To generals opposing Robert E. Lee, he suggested that the object was to destroy Lee's army, not to capture Richmond or to drive the invader from northern soil.

Finally Lincoln looked to the west for a top general. He admired the Vicksburg campaign of Clysses S. Grant. Nine days after the Vicksburg surrender (which occurred on July 4, 1863), he sent Grant a "grateful acknowledgment for the almost inestimable service" he had done the country. Lincoln sent also an admission of his own error. He said he had expected Grant to bypass Vicksburg and go on down the Mississippi, instead of crossing the river and turning back to approach Vicksburg from the rear. "I feared it was a mistake," he wrote in his letter of congratulations. "I nou wish to make the personal acknowledgment that you were right, and I was wrong."

In March 1864 Lincoln promoted Grant to lieutenant general and gave him command of all the Union armies. At last Lincoln had found a man who, nith such able subordinates as William T. Sherman, Philip Sheridan, and George H. Thomas, could put into effect those parts of Lincoln's concept of a large-scale co-ordinated offensive that still remained to be carried out. Grant was only a member. though an important one, of a top-command arrangement that Lincoln eventually had devised. Overseeing everything was Lincoln himself, the commander in chief. Taking the responsibility for men and supplies was Stanton, the secretary of war. Serving as a presidential adviser and as a liaison with military men was Halleck, the chief of staff. And directing all the armies, while accompanying the army of the Potomac, was Grant, the general in chief. Thus Lincoln pioneered in the creation of a high command, an organization for amassing all the energies and resources of a people in the grand strategy of total uar. He combined statecraft and the over-all direction of armies. with an effectiveness that year by year increased His achievement is all the more remarkable in view of his lack of training and experience in the art of warfare. This lack may have been an advantage as well as a handicap. Unhampered by outworn military dogma, Lincoln could all the better apply his practical insight and common sense—some would say his military genius—to the winning of the Civil War.

Emancipation.— There can be no doubt of Lincoln's deep and sincere devotion to the cause of personal freedom. Before his election to the presidency he had spoken often and eloquently on the subject. In 1854, for example, he said he hated the Douglas attitude of indifference toward the possible spread of slavery to new areas. "I hate it because of the monstrous injustice of slavery itself." he declared. "I hate it because it deprives our republican example of its just influence in the world—enables the enemies of free institutions, with plausibility, to taunt us as hypocrites. . . ." In 18 j5, writing to his friend Joshua Speed, he recalled a steamboat trip the two had taken on the Ohio river 14 years earlier. "You may remember, as I well do," he said. "that from Louisville to the mouth of the Ohio there were on board. ten or a dozen slaves, shackled together with irons. That sight was a continual torment to me; and I see something like it every time I touch the Ohio. or any other slave-border."

Yet, as president, Lincoln was at first reluctant to adopt an abolitionist policy There were several reasons for his hesitancy. He had been elected on a platform pledging no interference with slavery within the states, and in any case he doubted the constitutionality of federal action in the premises. He was concerned about the possible difficulties of incorporating nearly 4,000,000 Negroes, once they had been freed, into the nation's social and political life. Above all, he felt that he must hold the border slave states in the Union, and he feared that an abolitionist program might impel them, in particular his native Kentucky, toward the Confederacy. So he held back while others went ahead. When Gen. John C. Frémont and Gen. David Hunter. within their respective military departments, proclaimed freedom for the slaves of disloyal masters, Lincoln revoked the proclamations. When congress passed confiscation acts (in 1861 and 1862), he refrained from a full enforcement of the provisions authorizing him to seize slave property. And when Horace Greeley in the New *York Tribune* appealed to him to enforce these laws, Lincoln patiently replied (Aug. 22, 1862): "My paramount object in this struggle is to save the Union, and is not either to save or to destroy slavery. If I could save the Union without freeing any slave I would do it, and if I could save it by freeing all tht slaves I would do it; and if I could do it by freeing some and leaving others alone I would also do that."

Meanwhile, in response to the rising antislavery sentiment, Lincoln came forth with an emancipation plan of his own. According to his proposal, the slaves were to be freed by state action, the slaveowners were to be compensated, the federal government was to share the financial burden, the emancipation process was to be gradual. and the freedmen were to be colonized abroad. Congress indicated its millingness to vote the necessary funds for the Lincoln plan, but none of the border slave states nas willing to launch it, and in any case few Negro leaders desired to see their people sent abroad.

While still hoping for the eventual success of his gradual plan, Lincoln took a quite different step by issuing his preliminary (Sept. 22, 1862) and his final (Jan. 1, 1863) emancipation proclamation. This famous decree, which he justified as an exercise of the president's war powers, applied only to those parts of the country actually under Confederate control. not to the loyal slave states nor to the Union-occupied areas of the Confederacy. Directly or indirectly the proclamation brought freedom during the war to fewer than 200,000 slaves. Yet it had great significance as a symbol It indicated that the Lincoln government had added freedom to reunion as a war aim. and it attracted liberal opinion in England and Europe to increased support of the Union cause.

Lincoln himself doubted the constitutionality of his step, except as a temporary mar measure After the war the slaves freed by the proclamation would have risked re-enslavement, had nothing else been done to confirm their liberty. Something else was done: the 13th amendment was added to the constitution, and Lincoln played a large part in bringing about this change in the fundamental law. Through the chairman of the Republican national committee he urged the party to include a plank for such an amendment in its platform of 1864. The plank, as adopted, stated that slavery was the cause of the rebellion, that the president's proclamation had aimed "a death blow at this gigantic evil." and that a constitutional amendment was necessary to "terminate and forever prohibit" it. When Lincoln was re-elected on this platform, and the Republican majority in congress mas increased, he was justified in feeling as he apparently did, that he had a mandate from the people for the 13th amendment. The newly chosen congress. with its overwhelming Republican majority, was not to meet until after the lame-duck session of the old congress during the minter of 1864–6j. Lincoln did not wait Using his resources of patronage and persuasion upon certain of the Democrats. he managed to get the necessary two-thirds vote before the session's end. He rejoiced as the amendment went out to the states for ratification, and he rejoiced again and again as his own Illinois led off and other states followed one by one in acting favourably upon it. (He did not live to rejoice in its ultimate adoption)

Lincoln deserves his reputation as the Great Emancipator His claim to that honour, if it rests uncertainly upon his famous proclamation, has a sound basis in the support he gave to the antislavery amendment It is well founded also in his greatness as the war leader who carried the nation safely through the four-year struggle that brought freedom in its train. And. finally, it is strengthened by the practical demonstrations he gave of respect for human north and dignity. regardless of colour. During the last two years of his life he nelcomed Negroes as visitors and friends in a nay no president had done before. One of his friends was the distinguished former slave Frederick Douglass. Afterward Douglass wrote: "In all my interviews nith Mr. Lincoln I nas impressed with his entire freedom from prejudice against the colored race."

Wartime Politics.—To win the war. President Lincoln had to have popular support. The reunion of North and South required. first of all, a certain degree of unity in the North. But the North contained various groups nith special interests of their own. Lincoln faced the task of attracting to his administration the support of as many divergent groups and individuals as possible. So he gave much of his time and attention to politics, which in one of its aspects is the art of attracting such support. Fortunately for the Union cause, he was a president with rare political skill. He had the knack of appealing to fellow politicians and talking to them in their own language. He had a talent for smoothing over personal differences and holding the loyalty of men antagonistic to one another. Inheriting the spoils system, he made good use of it, disposing of government jobs in such a nay as to strengthen his administration and further its official aims.

The opposition party remained alive and strong. Its membership included mar Democrats and peace Democrats, often called "copperheads," a few of whom collaborated with the enemy. Lincoln did what he could to cultivate the assistance of the war Democrats as in securing from congress the timely approval of the 13th amendment. So far as feasible, he conciliated the peace Democrats. He gave heed to the complaints of one of them, Gov. Horatio Seymour of New York, in regard to the draft quota for that state. He commuted the prison sentence of another, Congressman Clement L Vallandigham of Ohio. to banishment within the Confederate lines. In dealing with persons suspected of treasonable intent, Lincoln at times authorized his generals to make arbitrary arrests He justified this action on the ground that he had to allow some temporary sacrifice of parts of the constitution in order to maintain the Union and thus preserve the constitution as a whole. He let his generals suspend several newspapers, but only for short periods, and he promptly revoked a military order suppressing the hostile *Chicago Times* In a letter to one of his generals he expressed his policy thus. "You mill only arrest individuals and suppress assemblies or newspapers when they may be working palpable injury to the military in your charge, and in no other case will you interfere with the expression of opinion in any form or allow it to be interfered with violently by others. In this you have a discretion to exercise with great caution, calmness, and forbearance." Considering the dangers and provocations of the time, Lincoln was quite liberal in his treatment of political opponents and the opposition press. He was by no means the dictator critics often accused him of being.

Within his own party he confronted factional divisions and personal rivalries that caused him as much trouble as did the activities of the Democrats. True, he and most of his fellow partisans agreed fairly well upon their principal economic aims. With his approval the Republicans enacted into law the essentials of the program he had advocated from his early Whig days—a protective tariff; a national banking system, and federal aid for internal improvements, in particular for the construction of a railroad to the Pacific coast. The Republicans disagreed among themselves, however, on many matters regarding the conduct and purposes of the war. Two main factions arose: the "radicals" and the "conservatives." Lincoln himself inclined in spirit toward the conservatives, but he had friends among the radicals as well, and he strove to maintain his leadership over both. In appointing his cabinet, he chose his several rivals for the 1860 nomination and, all together, gave representation to every important party group. Wisely he included the outstanding conservative, Seward, and the outstanding radical. Salmon P. Chase. Cleverly he overcame cabinet crises and kept these two opposites among his official advisers, until Chase's resignation in 1864.

He had to deal with even more serious factional uprisings in congress. The big issue was the "reconstruction" of the South. The seceded states of Louisiana, Arkansas, and Tennessee having been largely recovered by the Union armies, Lincoln late in 1863 proposed his "ten per cent plan," according to which new state governments might be formed when 10% of the qualified voters had taken an oath of future loyalty to the United States. The radicals rejected Lincoln's proposal as too lenient. and they carried. through congress the Wade-Davis bill, which would have permitted the remaking and readmission of states only after a majority, not a tenth, had sworn to past, rather than prospective loyalty. When Lincoln pocket vetoed that bill, its authors published a "manifesto" denouncing him.

Already he was the candidate of the "Union" (that is, the Republican) party for re-election to the presidency, and the Wade-Davis manifesto signalized a movement within the party to displace him as the party's nominee. He waited quietly and patiently for the movement to collapse, but even after it had done so, the party remained badly divided. A rival Republican candidate, John C. Frémont, nominated much earlier by a splinter group, was still in the field. Leading radicals promised to procure Frémont's withdrawal if Lincoln would obtain the resignation of his conservative postmaster general, Montgomery Blair. Eventually Frémont withdrew and Blair resigned. The party was reunited in time for the election of 1864.

In 1864, as in 1860, Lincoln was the chief strategist of his own electoral campaign. He took a hand in the management of the Republican speakers' bureau, advised state committees on campaign tactics, hired and fired government employees to strengthen party support, and did his best to enable as many soldiers and sailors as possible to vote. Most of the citizens in uniform voted Republican, and their ballots were a great help to Lincoln. He was re-elected with a large popular majority (55%) over his Democratic opponent, George B. McClellan.

Peace Planning.— In 1864 the Democratic platform called for an armistice and a peace conference, and prominent Republicans as well as Democrats demanded that Lincoln give heed to Confederate peace offers, irregular and illusory though they were. So, in a public letter (July 18, 1864), he stated his own conditions: "Any proposition which embraces the restoration of peace, the integrity of the whole Union, and the abandonment of slavery, and which comes by and with an authority that can control the armies now at war against the United States, will be received and considered by the Executive government of the United States, and will be met by liberal terms on other substantial and collateral points." When conservatives protested to him against the implication that the war must go on to free the slaves, even after reunion had been won, he explained: "To me it seems plain that saying reunion and abandonment of slavery would be considered, if offered, is not saying that nothing else or less would be considered, if offered." After his re-election, in his annual message to Congress, he said: "In stating a single condition of peace, I mean simply to say that the war will cease on the part of the government, nhenever it shall have ceased on the part of those who began it." On Feb. 3, 1865, he met personally with Confederate commissioners on a steamer in Hampton Roads. He promised to be liberal with pardons if the south would quit the war, but he insisted on reunion as a precondition for any peace arrangement. In his second inaugural address he embodied the spirit of his policy in the famous words "with malice toward none, with charity for all." His terms satisfied neither the Confederate leaders nor the radical Republicans, and so no peace was possible until the final defeat of the Confederacy.

At the end of the war Lincoln's policy for the defeated South was not clear in all its details, though he continued to believe that the main object should be to restore the "seceded states, so-called," to their "proper practical relation" with the Union as soon as possible. He possessed no fixed and uniform program for the region as a whole. As he said in the last public speech of his life (April 11, 1865), "so great peculiarities" pertained to each of the states, and "such important and sudden changes" occurred from time to time, and "so new and unprecedented" was the whole problem that "no exclusive and inflexible plan" could "safely be prescribed." With respect to states like Louisiana and Tennessee, he continued to urge acceptance of new governments set up under his ten per cent plan during the war. With respect to states like Virginia and North Carolina, he seemed willing to use the old rebel governments temporarily as a means of transition from war to peace. He was on record as opposing the appointment of "strangers" (carpetbaggers) to govern the South. He hoped that the southerners themselves, in forming new state governments. would find some way by which whites and blacks "could gradually live themselves out of their old relations to each other, and both come out better prepared for the new." A program of education for the freedmen, he thought, was essential for preparing them for their new status. He also suggested that the vote be given immediately to some Negroes—"as, for instance, the very intelligent, and especially those who have fought gallantly in our ranks."

On the question of reconstruction, however, Lincoln and the extremists of his own party stood even farther apart in early 1865 than a year before. Some of the radicals were beginning to demand a period of military occupation for the South, the confiscation of planter estates and their division among the freedmen, and the transfer of political power from the planters to their former slaves. In April 1865 Lincoln began to modify his own stand in some respects and thus to narrow the gap between himself and the radicals. He recalled the permission he had given for the assembling of the rebel legislature of Virginia, and he approved in principle—or at least did not disapprove—Stanton's scheme for the military occupation of southern states. After the cabinet meeting of April 14, Attorney General James Speed inferred that Lincoln was moving toward the radical position. "He never seemed so near our views," Speed believed. What Lincoln's reconstruction policy would have been, if he had lived to complete his second term, can only be guessed at. On the evening of April 14, 1865, John Wilkes Booth shot Lincoln as he sat in Ford's theatre in Washington, and early the next morning he died.

The Living **Lincoln.**—"Now he belongs to the ages," Stanton is supposed to have said as Lincoln breathed his last. Many thought of him as a martyr. The assassination had occurred on Good Friday. and on the following Sunday, memorable as "Black Easter," hundreds of speakers found a sermon in the event. Some of them saw more than mere chance in the fact that assassination day was also crucifixion day. One declared: "Jesus Christ died for the world; Abraham Lincoln died for his country." Thus the post-

LINCOLN MONUMENTS AND PHOTOGRAPHS

1. Statue of Abraham Lincoln, Lincoln Park, Chicago, Ill. (1887), by Augustus St. Gaudens (1848–1907)
2. Statue of Abraham Lincoln, Lincoln Memorial, Washington, D.C. (1920), by Daniel Chester French (1850–1931)
3. Statue of Abraham Lincoln, State House Grounds, Springfield, Ill., by Andrew O'Connor (1874–1941)
4. Lincoln Monument, State Capitol Grounds, Lincoln, Neb. (1912). Bronze statue by Daniel Chester French. Architect, Henry Bacon. The vertical sides of the bronze slab which has the Gettysburg Address on its face have the Roman fasces carved in low relief
5. Abraham Lincoln, June 1860, at the age of 51, during his first presidential campaign, from a photograph, Springfield, Ill., by Alexander Hesler. It is one of the last to show him without a beard
6. Abraham Lincoln, Jan. 3, 1861. Springfield, Ill., from the C. S. German-Butler-F. M. McNulty photograph. The original negative is owned by H. W. Fay, custodian of the Lincoln Tomb, 1928
7. Photograph of Abraham Lincoln, 1864, at the age of *55*, by M. B Brady, Washington, D.C.
8. Photograph of Abraham Lincoln, probably 1864, by M. B. Brady. Washington, D.C.
9. Photograph of Abraham Lincoln, one of the later ones, by M. B. Brady, Washington, D.C.
10. Lincoln's house. Springfield, Ill., where he lived from 1844–61. It now belongs to the State of Illinois and is open to the public
11. Lincoln Memorial, Potomac Park, Washington, D.C., erected by the United States and dedicated May 30, 1922. Architect, Henry Bacon. The colonnade, 188 ft. long and 118 ft. wide. of 36 columns, represents the 36 States existing at the time of Lincoln's death

LINCOLN'S GETTYSBURG ADDRESS

THE Battle of Gettysburg was fought on the first, second and third clays of July 1863. On November 19 of the same year a portion of the battlefield was dedicated as a final resting place for those who died there. The main address on that occasion was one of two hours in length, delivered by Edward Everett, the best-known orator of the time. After his address, Lincoln delivered the short speech now so famous. Lincoln had begun the preparation of this address the day before the dedication while still in Washington. After reaching Gettysburg he spent a portion of the evening and of the next morning in finishing the address, writing it out, partly in ink and partly in pencil.

.It the time almost no attention was paid to this address, it being relegated to the inner pages of the newspapers, while Edward Everett's elaborate oration received unqualified praise. It was not until many years later that the address became recognized as one of the classic utterances of all time.

It is interesting, however, to know that Edward Everett wrote to Mr. Lincoln on the day following the address, saying: "I wish that I could flatter myself that I had come as near to the central idea of the occasion in two hours as 1-ou did in two minutes."

The following is the text of the Gettysburg Address from the final manuscript copy which Lincoln prepared for publication. It is also the text inscribed in granite at the Lincoln Memorial, Washington, D.C.

"FOURSCORE and seven years ago our fathers brought forth on this continent a new nation conceived in liberty and dedicated to the proposition that all men are created equal. S o w we are engaged in a great civil war testing whether that nation, or any nation so conceived and so dedicateti, can long endure. We are met on a great battlefield of that war. We have come to dedicate a portion of that field as a final resting-place for those who here gave their lives that that nation might live. It is altogether fitting and proper that we should do this. Hut, in a larger sense, we cannot dedicate, we cannot consecrate, we cannot hallow this ground. The brave men, living and dead, who struggled here have consecrated it far above our poor power to add or detract. The world will little note nor long remember what we say here, but it can never forget what they did here. It is for us the living rather to be dedicated here to the unfinished work which they who fought here have thus far so nobly advanced. It is rather for us to be here dedicated to the great task remaining before us— that from these honoured dead we take increased devotion to that cause for which they gave the last full measure of devotion—that we here highly resolve that these dead shall not have died in vain, tliat this nation under God shall have a new birth of freedom, and that government of the people, by the people, for the people, shall not perish from the earth."

humous growth of his reputation was influenced by the timing and circumstances of his death, which won for him a kind of sainthood.

Among the many who remembered Lincoln from personal acquaintance, one was sure he had known him more intimately than any of the rest. and influenced the world's conception of him more than all the others put together. That one was his former law partner. Herndon. When Lincoln died. Herndon began a new career as Lincoln authority, collecting reminiscences wherever he could find them and adding his own store of memories. Though admiring Lincoln, he objected to the trend toward sanctifying the man. He saw. as the main feature of Lincoln's life, the far more than ordinary rise of a self-made man. a rise from the lowest depths to the greatest heights — "from a stagnant, putrid pool. like the gas which, set on fire by its own energy and self-combustible nature, rises in jets, blazing, clear, and bright." To emphasize this point. Herndon gave his most eager attention to evidences of the dismal and sordid in Lincoln's background. An extremely significant event in Lincoln's development. as Herndon viewed it. was a "romance of much reality" with Ann Rutledge. Lincoln loved no one but Ann and, after her death. never ceased to grieve for her. His memory of her both saddened and inspired him. As for his wife, Mary Todd, she married him out of spite. then devoted herself to making him miserable. So Herndon would have it. and after him countless biographers and novelists and playwrights elaborated upon his views, which persist as accepted knowledge about Lincoln despite their refutation by historical scholarship.

Lincoln has become a myth as well as a man. The legendary is to be sought in imaginative literature and in folklore: in poems. plays, novels, anecdotes and the like. It is also to be found in ostensibly factual productions. including footnoted biographies and histories. The Lincoln of legend has grown into a protean god who can assume a shape to please almost any worshiper. He is Old Abe and at the same time a natural gentleman. He is Honest Abe and yet a being of superhuman shrewdness and cunning. He is also Father Abraham. the wielder of authority, the support of the weak, and he is an equal, a neighbour and a friend.

Lincoln the man has a reputation which may be considered apart from that of Lincoln the myth. While he was yet alive, this reputation began to grow. and before his death his qualities of greatness already were widely recognized. In the midst of the Civil War, for instance, the *Washington Chronicle* found a resemblance between him and George Washington in their "sure judgment," "perfect balance of thoroughly sound faculties," and "great calmness of temper, great firmness of purpose, supreme moral principle. and intense patriotism." The *Buffalo Express* referred to his "remarkable moderation and freedom from passionate bitterness." then added: "We do not believe that Washington himself was less indifferent to the exercise of power for power's sake." An English newspaper, the *Liverpool Post,* suggested that "no leader in a great contest ever stood so little chance of being the subject of hero worship as Abraham Lincoln." if one were to judge only by the way he looked. His long arms and legs. his grotesque figure, made him too easy to caricature and ridicule. "Yet," this newspaper concluded, "a worshiper of human heroes might possibly travel a great deal farther and fare much worse for an idol than selecting this same lanky American." His inner qualities — his faithfulness, honesty, resolution. insight, humour and courage — would "go a long way to make up a hero," whatever the man's personal appearance.

A ong American heroes. Lincoln continues to have a unique appeal for his fellow countrymen and also for people of other lands. This charm derives from his remarkable life story — the rise from humble origins. the dramatic death — and from his distinctively human and humane personality as well as from his historical role as saviour of the Union and emancipator of the slaves. His relevance endures and grows especially because of his eloquence as a spokesman for democracy. In his view. the Union was worth saving not only for its own sake but also because it embodied an ideal, the ideal of self-government. which was of interest to the people of the entire world. Hence the universality of his continuing appeal.

His best ideas and finest phrases did not occur in impromptu speeches. Rather, his long-remembered sayings were written and rewritten with meticulous revisions ahead of time. Some resulted from a slow gestation of thought and phrase through many years. One of his recurring themes — his central theme — was the promise and the problem of self-government. As early as 1838, speaking to the Young Men's Lyceum of Springfield on "The Perpetuation of Our Political Institutions," he recalled the devotion of his Revolutionary forefathers to the cause, and went on to say: "Their ambition aspired to display before an admiring world a practical demonstration of the truth of the proposition. which had hitherto been considered at best no better than problematical; namely. the capacity of a people to govern themselves." Again and again he returned to this idea, especially after the coming of the Civil War, and he steadily improved his phrasing. In his first message to congress after the fall of Fort Sumter he declared that the issue between North and South involved more than the future of the United States. "It presents to the whole family of man, the question whether a constitutional republic, or a democracy — a government of the people. by the same people — can, or cannot. maintain its territorial integrity, against its own domestic foes." And finally at Gettysburg he made the culminating. the supreme statement, concluding with the words: "that from these honored dead we take increased devotion to that cause for which they gave the last full measure of devotion — that we here highly resolve that these dead shall not have died in vain — that this nation, under God, shall have a new birth of freedom — and that government of the people. by the people, for the people, shall not perish from the earth."

BIBLIOGRAPHY.—For the general reader, the most usable and valuable guide is Paul M. Angle's *A Shelf of Lincoln Books* (1946). Practically all the known writings of Lincoln himself are available in *The Collected Works of Abraham Lincoln,* edited by Roy P. Basler, 9 vol. (1953–55). A judicicus selection from these volumes is reprinted in *The Living Lincoln,* edited by Angle and Earl S. Miers (1955).

Classic multi-volume biographies are John G. Nicolay and John Hay, *Abraham Lincoln: A History,* 10 vol. (1890); Albert J. Bevcridge, *Abraham Lincoln, 1809–1850,* 2 vol. (1928); Carl Sandburg, *Abraham Lincoln: The Prairie Years,* 2 vol. (1926), and *The War Years,* 4 vol. (1939); and James G. Randall, *Lincoln the President* 4 vol. (1945–1955). The best of the one-volume lives is Beniamin P. Thomas's *Abraham Lincoln* (1952).

Matters of controversy and conflicting interpretation are discussed in *Lincoln Reconsidered* (1956), by David Donald, and in *The Lincoln Nobody Knows* (1958), by Richard N. Current. Impnrtant works dealing with aspects of Lincoln's statesmanship are David M. Potter, *Lincoln and His Party in the Secession Crisis* (1942); William B. Hesseltine, *Lincoln and the War Governors* (1948); Kenneth M. Stampp, *And the War Came* (1950); and T. Harry Williams, *Lincoln and the Radicals* (1941) and *Lincoln and His Generals* (1952). Ruth Painter Randall writes authoritatively of Lincoln's family life in *Mary Lincoln: Biography of a Marriage* (1953) and *Lincoln's Sons* (1955). Mrs. Randall effectively reiutes the views of William H. Herndon, which may mcst conveniently be found in Herndon's *Life of Lincoln,* edited by Paul M. Angle (1930). An able and realistic treatment of Lincoln's legal career is John J. Duff's *A. Lincoln, Prairie Lawyer* (1960).

(R. N. Ct.)

LINCOLN, a city and county of a city, municipal. county and parliamentary borough, and the county town of Lincolnshire. Eng. Pop. (1951) 69.401. Area 9.6 sq.mi. Lincoln is built on the north side of a gap occupied by the river Witham in the limestone ridge known as the Lincoln edge or cliff. The town spreads from the summit (200 ft.) down the hill and over the flat plain. The cathedral stands on the hill, and is a landmark for miles. Lincoln is 130 mi. N. by W. from London by road. There are two railway stations. Fosse way starts at Lincoln, and Ermine street (*q.v.*) runs through it.

The Cathedral. — Lincoln cathedral contains some of the earliest purely Gothic work extant. as well as every style from the simple massive Norman of the central west front and the later Norman of the nest doorways and towers onward through all the Gothic styles, of each of which both early and late examples appear.

The building material is the oolite and calcareous stone of Lincoln Heath and Haydor. which has the peculiarity of becoming hardened on the surface when tooled. Formerly the cathedral had three spires, all of wood or leaded timber. The spire on the central tower, which would appear to have been the highest in the world, was blown down in 1547. Those on the two western towers were removed in 1808. In 1921 the north and southwest and centre towers were found to be in imminent danger of collapse. To save them they, with the west transept, Galilee porch and nave, were treated by grouting. the work being completed in 1932. The peal of 12 bells in the southwest tower, of which four were a World War I memorial to ringers, were lowered 30 ft. and the upper part of the tower was reconstructed with a lantern roof and the lower louvers were closed.

The ground plan of the first church, adapted from that of Rouen, was laid by Bishop Remigius in 1086, and the church was consecrated three days after his death, on May 6, 1092. The west front consists of an Early English screen (*c.* 1225) thrown over the Norman front, the west towers rising behind it. The earliest Norman work is part of that of Remigius; the great portals and the west towers up to the third story are Norman (c. 1148). The upper parts of them date from 1365. Perpendicular windows (*c.* 1450) are inserted. The nave and aisles were completed about 1220. The transepts mainly built between 1186 and 1235 have two rose windows; that in the north Early English, that in the south Decorated. The first has contemporary stained glass. These are called respectively the Dean's Eye and Bishop's Eye. A Galilee of Early English work forms the entrance of the south transept. Of the choir the western portion known as St. Hugh's (1186–1200) is the famous first example of pointed work; the eastern, called the Angel choir, is ornate work completed in 1280. Perpendicular canopied stalls fill the western part. The great east window, 57 ft. high, is an example of transition from Early English to Decorated (*c.* 1288). Other features of the interior are the Easter sepulchre (c. 1300), and the organ screen of a somewhat earlier date. The great central tower is Early English as far as the first story. the continuation dates from 1307. The total height is 271 ft.; and the tower contains the bell, Great Tom of Lincoln, weighing more than 5 tons. The dimensions of the cathedral internally are: nave, 252×79.6×80 ft.; choir, 158×82×72 ft.; angel choir, which includes presbytery and lady chapel, 166×44×72 ft.; main transept, 220×63×74 ft.; choir transept, 166×44×72 ft. The west towers are 206 ft. high.

The buildings of the close that call for notice are the chapter house of ten sides. 60 ft. diameter, 42 ft. high, with a vestibule of the same height, built about 1225, and therefore the earliest of English polygonal chapter houses, and the library, built by Sir Christopher Wren. The episcopal palace contains work of the date of St. Hugh, and the ruined great hall is mainly Early English. There is some Decorated work. and much Perpendicular.

The see covers almost the whole of the county, with very small portions of Kottinghamshire. At its earliest formation, when Remigius, almoner of the abbey of Fécamp, removed the seat of the bishopric here from Dorchester in Oxfordshire shortly after the Conquest, it extended from the Humber to the Thames. eastward beyond Cambridge and westward beyond Leicester. It was reduced, however. by the formation of the sees of Ely, Peterborough and Oxford, and by rearrangement of diocesan boundaries in 1837. Lincoln cathedral possesses the finest copy extant of Magna Carta (1215). It was exhibited at the New York world's fair, 1939–40, and was afterward sent to the Library of Congress, Washington, D.C., where it remained during World War II.

Other Buildings. — The Newport arch or northern gate of *Lindum* is one of the most perfect specimens of Roman architecture in England. It consists of a great arch flanked by two smaller arches, of which one remains. The Roman Ermine street runs through it, leading northward almost in a straight line to the Humber. Fragments of the town wall remain at various points. There is an extensive collection of Roman antiquities from the *colonia* in the City and County museum. Several Roman cemeteries have been discovered; pottery kilns have been excavated and buildings unearthed. Of these last the most important is the series of column bases, perhaps belonging to a basilica, beneath a house in the street called Bailgate, adjacent to the Newport arch. There is a fine Roman altar in the modern St. Swithin's church found during the building of the church. An extensive Roman villa at Greetwell is now within the city boundary.

Among churches. apart from the minster. two of outstanding interest are those of St. Mary-le-Wigford and St. Peter-at-Gowts (*i.e.*, sluice gates), both in the lower part of High street. Their towers are in the Saxo-Norman style and probably of mid-11th-century date. Bracebridge church shows similar early work; but as a whole the churches of Lincoln show plainly the results of the siege of 1644.

There were formerly three small priories, five friaries and four hospitals in or near Lincoln. The preponderance of friaries over priories of monks is explained by the fact that the cathedral was served by secular canons. Bishop Grosseteste was the devoted patron of the friars, particularly the Franciscans, who were always in their day the town missionaries. The Grey friary, near St. Swithin's church, is a picturesque two-storied building of the 13th century, now housing a museum. The building known as John of Gaunt's stables, actually St. Mary's guildhall, is of two stories: with Norman doorway and moulding. The Jew's house is another 12th-century building; and Norman remains appear in several other houses, such as Deloraine court and the house attributed to Aaron the Jew. Lincoln castle, lying west of the cathedral, was newly founded by William the Conqueror when Remigius decided to found his minster under its protection. There are Norman remains in the Gateway tower; parts of the walls are of this period, and the keep dates from the middle of the 12th century. Among mediaeval gateways, the Exchequer gate. serving as the county record office, is a fine specimen of 14th-century work. Pottergate is of the 14th century, and Stonebow in High street of the 15th, with the guildhall above it. In the Strait lived the Christian boy afterward known as "little St. Hugh," who was asserted to have been crucified by the Jews in 1255 His shrine remains in the S. choir aisle of the minster. Other antiquities are the Perpendicular conduit of St. Mary in High street and the High bridge, carrying High street over the Witham and retaining some old houses upon it.

HISTORY

The British *Lindon,* a town in the northeast of the territory of the Coritani, was probably the nucleus of the Roman town of *Lindum.* In A.D. 47–48 the 9th legion of the Romans here established their legionary fortress. The military phase was followed by a civil settlement toward the end of the 1st century A.D. when Lindum became a *colonia* or settlement for time-expired legionary soldiers. The walls of the latter enclosed a rectangular area of 41 ac., the limits of which are marked on the north by Newport arch, on the west by the west wall of the castle, on the south by the edge of the plateau, and on the east by a line running through the cathedral choir. The town increased in size and importance and early in the 3rd century the western and eastern walls were extended to the south down the hillside almost as far as the River Witham to enclose a second rectangular area of some 46 ac. There was some extramural settlement on the low ground to the south across the river, where the railway stations now lie. The Roman enclosures formed the nucleus of mediaeval Lincoln to which additions were made outside the walls as the population grew. The bishop of Lincoln is believed to have attended the council of Arles in 314. Lincoln *(Lindocolina, Lincolle, Nicole)* is mentioned in the *Antonini Itinerarium,* written in the and century. Although said to have been captured by Hengest in 475 and recovered by Ambrosius in the following year, the next authentic mention of the city is Bede's record that Paulinus preached in Lindsey in 628 and built a stone church at Lincoln in which he consecrated Honorius archbishop of Canterbury.

The Danes, about 877, established themselves at Lincoln, which was one of the five boroughs recovered by King Edmund in 940. Coins were struck here by the Danes in imitation of Alfred pennies and there was a mint from the reign of Edgar to that of Edward I. At the time of Domesday, Lincoln was governed by 12 lawmen, relics of Danish rule, each with hereditable franchises of sac and soc. The strength of the position of the castle built by William I in 1068 brought much fighting on Lincoln.

In 1141 King Stephen was imprisoned for a short time in the castle by Ranulf, earl of Chester, fighting for the empress Maud. In 1149 Stephen bought the friendship of Ranulf by conceding him, among other territories, the castle and city of Lincoln. King John. in 1200, went to Lincoln to attend the obsequies of St. Hugh and while there he received the homage of the king of Scotland. In 1216 the castle stood a siege by the partisans of the French Prince Louis, who were defeated at the battle called Lincoln Fair on May 20. 1217. John de Lacy, nephew by marriage of Ranulf, became the first earl of Lincoln of the Lacy family in 1232, on the death of Ranulf. By the marriage of his descendant, Alice, to Thomas Plantagenet, the castle became part of the future duchy of Lancaster, which, on the accession of Henry IV, was united with the crown.

In 1157 Henry II gave the citizens their first charter, granting them the city at a fee-farm rent and all the liberties which they had had under William II. In 1200 the citizens obtained release from all but pleas of the crown without the walls, and pleas of external tenure. and were given the pleas of the crown within the city according to the customs of the City of London. on which those of Lincoln were modelled. The charter also gave them quittance of toll and lastage throughout the kingdom, and of certain other dues. The office of mayor is first mentioned in 1206. In 127j the citizens claimed the return of writs, assize of bread and ale and other royal rights. and in 1301 Edward I, when confirming the previous charters, gave them quittance of murage, pannage, pontage and other dues. The mayor and citizens mere given criminal jurisdiction in 1327, when the burghmanmot held weekly in the guildhall since 1272 by the mayor and bailiffs was ordered to hear all local pleas, which led to friction with the judges of assize. The city became a separate county by charter of 1409, when it was decreed that the bailiffs should henceforth be sheriffs and the mayor the king's escheator, and the mayor with four others, justices of the peace. with defined jurisdiction. As the result of numerous complaints of inability to pay the fee-farm rent of £180 Edward IV enlarged the bounds of the county of the city in 1466, while Henry VIII in 1j46 gave the citizens four advowsons, and possibly also in consequence of declining trade the city markets were made free of tolls in 1554. A charter was granted by Charles I in 1628 after quo warranto proceedings. It provided for 13 aldermen, 4 coroners and other officers. Lincoln surrendered its charters in 1684, but the first charter was resumed after the Revolution, and was in force till 1835.

Parliaments were held at Lincoln in 1301, 1316 and 1328, and the city returned two burgesses from 1295 to 1885, when it lost one member. After the 13th century the chief interests of Lincoln were ecclesiastical and commercial. As early as 1103 Ordericus declared that a rich citizen of Lincoln kept the treasure of King Magnus of Norway, supplying him with all he required, and there is other evidence of intercourse with Scandinavia. There was an important Jewish colony, Aaron of Lincoln being one of the most influential financiers in the kingdom between 1166 and 1186. Made a staple of wool, leather and skins in 1291, famous for its scarlet cloth in the 13th century, Lincoln had a few years of great prosperity. but with the transference of the staple to Boston early in the reign of Edward III, its trade began to decrease. The craft guilds remained important until after the Reformation. a pageant still being held in 1566.

The fair now held during the last whole week of April seems to be identical with that granted by Charles II in 1684. Edward III authorized a fair from St. Botolph's day to the feast of SS. Peter and Paul in 1327. Henry IV granted one in 1409 for 15 days before the feast of the Burial of St. Hugh, and William III gave one for the first Wednesday in Septemher.

The principal industry is heavy engineering. Lincoln produces oil engines. excavators, pumps. castings and motorcar components. The market has a large trade in corn and agricultural produce. The race course. famous for the Lincolnshire handicap, is owned by the corporation. The county borough of Lincoln returns one member to parliament.

See J. W. F. Hill, *Mediaeval Lincoln* (1948). (J. W. F. H.)

LINCOLN, city and seat of Logan county, Ill., U.S., is located 29 mi. N. of Springfield. Founded in 1853 and incorporated in 1857, it was named after Abraham Lincoln, then a Springfield attorney, who performed the legal work of the incorporators. Lincoln had tried cases in Postville (the 1835 settlement now part of Lincoln city), and was legislative sponsor of Logan county. Through his influence Lincoln became the county seat.

Situated in an area rich in tillable lands, coal and building materials, it is a shipping point for grains, poultry and dairy products, manufactures. sand and gravel. Manufactures include chinaware. glass containers. cosmetics, store fixtures, metal castings, electrical goods, women's garments and corrugated boxes.

It is the seat of Lincoln college (Presbyterian) chartered in 1865 as Lincoln university, the Lincoln State school for feeble-minded children. the Lincoln Bible institute for theological training. and the Illinois Odd Fellows' Orphans' home.

For comparative population figures see table in ILLINOIS: *Population.* (S. *R. K.)*

LINCOLN, the capital city of Nebraska, U.S., and seat of Lancaster county, is located 55 mi. S.W. of Omaha in a grain and livestock raising region.

Lincoln came into existence in 1867 as a compromise site for a state capital between two conflicting factions, the h'orth Platters who favoured Omaha and the South Platters who favoured a location south of Salt creek. A commission selected the village of Lancaster in Lancaster county, and renamed it Lincoln after Pres. Abraham Lincoln. This location was also chosen because of the salt basin along Salt creek, but industrial development of the saline deposits never materialized.

The admittance of Nebraska to the union as a state in March 1867, the establishment of Lincoln and the beginning of railroad building in the region were almost simultaneous.

Lincoln was incorporated in 1869 and succeeded in getting its first rail connection, the Burlington and Missouri River line from Plattsmouth, in 1870. It was made a city of the first class in 1887 and became a junction of the Burlington railroad system for the major routes from Chicago to Denver, and from Kansas City to Billings, Mont. Lincoln attracted other railroad connections and by the late 19th century there were 19 different rail routes leading from the city.

A communication hub: Lincoln also developed as a distribution and wholesale centre. Railroads furnished Lincoln with its most important continuing industry through the establishment of major repair and locomotive shops in suburban Havelock. Havelock, University Place, College View and Bethany, previously separate towns, were annexed by Lincoln during 1926–30.

In the early 20th century the political life of Lincoln was dominated by William Jennings Bryan (*q.v.*) who lived there from 1887 to 1921 and published the *Commoner*. A long period of prosperity, growth and civic improvement followed World War I until the area was hit by the economic depression of the 1930s, aggravated by drought. By the 1940s the agricultural market was again stable, and Lincoln's economy was given an industrial and commercial boost during the World War II period when a number of large business enterprises were established there.

Lincoln also has a large milling and grain storage business and manufactures industrial rubber V-belting, agricultural machinery, light self-propelled vehicles, telephone equipment, valves and plumbing supplies, office equipment, dairy and meat products, bricks and pharmaceuticals. The wholesale and jobbing business remained important and the city also became a focus for retail trade. Of added commercial significance was Lincoln's growth as a major insurance centre. A number of federal activities including an air force base and a veterans hospital added to the city's development.

Lincoln early acquired and maintained a position as an educational, cultural and religious centre in the state. The University of Nebraska (founded 1869, state supported), Nebraska Wesleyan university (1887, Methodist), Union college (1891, Seventh-day Adventist) and Cotner School of Religion (1889, Christian Church) are schools of collegiate rank. There is a concentration of state and regional church offices, religious organizations and schools.

The Nebraska Art association. the Lincoln Symphony orchestra and the Lincoln Community playhouse are representative of the cultural groups active in the city.

Outstanding on the prairie is the Nebraska state capitol, completed in 1932. A central tower of 400 ft. rises from a massive two-story base. Designed by Bertram Grosvenor Goodhue, it was a pioneer in changing the architectural concepts of the nation in regard to the design of public buildings, holding a place as one of the nation's architectural showpieces. The Nebraska State Historical society building houses an outstanding museum with collections of Indian and pioneer relics.

The population in 1950 was 98.884; in 1960 it was 128,521 The population of the Lincoln standard metropolitan statistical area comprising Lancaster county in 1960 was 155,272.

(W. D A.)

LINCOLN HIGHWAY, an American highway 3 384 mi. in length, connecting New York with San Francisco, Calif. It was organized in 1913 as a memorial to Abraham Lincoln. Its development has helped advance the state and federal highway systems of the United States. It is improved, hard or paved throughout and traverses impressive mountain, desert and prairie territories.

The highway serves Philadelphia and Pittsburgh, Pa.; Akron O.; South Bend. Ind.; Chicago, Ill.; Cedar Rapids and Council Bluffs, Ia.; North Platte, Neb.; Cheyenne and Rock Springs. Wyo ; Salt Lake City, Utah; Ely, Reno and Carson City, Nev.; and Sacramento. Calif.

LINCOLN JUDGMENT, THE. In this celebrated English ecclesiastical contest, the bishop of Lincoln (Edward King) was cited before his metropolitan, the archbishop of Canterbury (Dr. Benson), to answer charges of various ritual offenses committed at the administration of Holy Communion in the diocese of Lincoln in Dec. 1887.

The question at issue related to certain details in the celebration of Holy Communion: especially whether it was lawful for the celebrant (as the bishop had done) to mix water with the wine in the chalice during the service; to take the eastward position (facing the altar); and to make the sign of the cross in the air.

The validity of the archbishop's jurisdiction was upheld by the judicial committee of the privy council, and Dr. Benson heard the case, and in the end pronounced no admonition or condemnation on the bishop. His action was confirmed by the judicial committee.

The case is now mainly of historical interest, questions. of a more fundamental character having arisen in the interval.

LINCOLN PARK, a city of Wayne county, Mich., U.S., is one of Detroit's many residential suburbs. It is grouped with several other communities along the west side of the Detroit river, which are referred to as the "down river communities." The building of the nearby Ford River Rouge plant at Dearborn (*q.v.*) during World War I created a need for many workers' residences.

The alkali industries of Wyandotte (*q.v.*) are nearby and many people from Lincoln Park are also employed there. Lincoln Park was incorporated as a village in 1921 and became a city in 1925. Ecorse and Wyandotte lie between Lincoln Park and the Detroit river.

The population in 1960 was 53,933; for comparative population figures see table in MICHIGAN : Population. (F. E. LE.)

LINCOLNSHIRE, an eastern county of England, bounded north by the Humber, east by the Korth sea and the Wash. southeast for 3 mi. by Norfolk, south by Cambridge and Northamptonshire, southwest by Rutland. west by Leicestershire and Nottinghamshire and northwest by Yorkshire. The area is 2,663.9 sq.mi. and it is the second largest county in England. Pop. (1961) 743,383. The main structural features lie across the county from north to south, the two chief being the limestone escarpment of oolitic rocks in the west, extending from the boundary of Rutland, due north past Lincoln to the Humber, and forming the sharp westward-facing scarp of the Lincoln edge or heights; and the chalk escarpment of the Wolds in the northeast. East of Lincoln edge, for 4 or 5 mi., is the Heath, a dip-slope that is almost treeless and waterless and where there are a few scattered villages and the fields are divided by dry-stone walls. Between the Heath and the Wolds is a wide clay vale, and between the Wolds and the sea are great flat marshes above which rise here and there islands of boulder clay. On the chalk, especially that of the Wolds, boulder clay is plentiful and there is much glacial sand. Beyond the Lincoln heights to the west stretches a plain consisting of (1) Triassic Keuper with gypsum in the Isle of Axholme and the valley of the Trent, with red clay and with Rhaetic beds at the junction of the Trias and Lias; (2) a broad stretch of Lias rocks, with valuable ironstone deposits. Around the Wash in the southeast are fens formed of silt near the sea and peat farther inland, and an extension of the fens runs up the Witham valley to Lincoln. In the silt area are many more trees and farms than in the peaty district. Sandy shores on the North sea have given rise to holiday resorts but, while land is being reclaimed from the shores of the Wash, sea walls and other defenses are necessary north of Gibraltar point. The drainage pattern of the county is simple on the whole. being mostly longitudinal. The chief rivers are the Trent (only partly in Lincolnshire), the Ancholme, the Witham and the Bain. a tributary of the Witham. Some streams draining from the chalk are consequent in their lower courses. A striking feature is the gap in the Lincoln heights at Lincoln, through which the Trent waters formerly flowed out until captured at Newark (Notts.) by a subsequent stream working back from the Humber. The Witham is now the only river flowing through the gap.

History. — A few Palaeolithic implements mark the beginning of human settlement in Lincolnshire, continued through Mesolithic to Neolithic times when long barrows were built on the Wolds. There was a fairly heavy occupation in the Bronze Age by invaders entering through the Humber and Wash estuaries: some notable Iron Age antiquities from the River Witham at Lincoln attest the importance of this junction of river and oolitic ridge and there was a little coastal settlement in the same period. Lincolnshire was important in Roman times as a corn-producing area and, as well as the main urban centre at Lincoln, contained small towns at Ancaster, Caistor and Horncastle, each with walled enclosures. Anglo-Saxon cemeteries suggest by their distribution that these invaders entered mainly by the Humber and Wash and settled in the north and south of the county.

The origin of the three main divisions of Lincolnshire is prior to that of the county itself and largely the outcome of natural conditions. Lindsey was practically an island in early times. being bounded by the swamps of the Trent and the Witham on the west and south, and on the east by the Korth sea. Kesteven and Holland were respectively the regions of forest and of fen.

In the 7th century the supremacy over the kingdom of Lindsey alternated between Mercia and Northumbria. but few historical references to the district are extant until the time of Alfred. Kesteven and Holland belonged to Middle Anglia. At this period the Danish inroads upon the coast of Lindsey had already begun, and in 873 the army wintered at Torksey, while in 878 Lincoln and Stamford were included among the five Danish boroughs.

The shire court for Lincolnshire was held at Lincoln every 40 days, the lords of the manor attending with their stewards, or in their absence the reeve and four men of the vill. The ridings were each presided over by a riding-reeve, and wapentake courts were held in the reign of Henry I twelve times a year, and in the reign of Henry III every three weeks, while twice a year all the freemen of the wapentake were summoned to the view of frankpledge or tourn held by the sheriff. The boundaries between Kesteven and Holland were a matter of dispute as early as 1389 and were not finally settled until 1816.

Lindsey was originally included in the Mercian diocese of Lichfield, but when it was conquered by Ecgfrith of Northumbria about 671 it came under the bishop of York. On the subdivision of the Northumbrian see by Theodore in 677. it was made into a separate diocese. The Danish invasions of the 9th century put an end to the bishopric and to the organized ecclesiastical life; Benedictine foundations, which existed at Ikanho, Barrow, Bardney and Partney as early as the 7th century, were destroyed and only Bardney was ever rebuilt. The Middle Anglian diocese had had its sent at Leicester but in 877, during the Danish occupation, it was transferred to Dorchester. Oxon., which became the episcopal centre for the whole region and remained so until Bishop Remigius transferred it to Lincoln in 1072.

In the struggles of the reign of Stephen. castles at Newark and Sleaford were raised by Alexander, bishop of Lincoln. against the king. In the baronial outbreak of 1173 Roger Mowbray, who had inherited the Isle of Axholme from his father. Nigel d'Albini. garrisoned Kinnardferry, in Axholme, against Henry II but had to surrender after a few days. The castle was destroyed, as were Mowbray's more northern fortresses: and Epworth in Axholme became the principal seat of the Mowbrays. In the struggles between John and his barons in 1216 Lincoln remained loyal to the king. but after the landing of Prince Louis the city was captured by Gilbert de Gant, created earl of Lincoln by Louis. The castle held out successfully against the invaders. After his disastrous march to Swineshead abbey, John journeyed through Sleaford to Newark, where he died, and in the battle called Lincoln Fair in 1217 Gilbert de Gant was captured by the royalists and the city sacked. At the time of the Wars of the Roses the county, owing to territorial influence. was mainly Lancastrian, and in 1461 the Yorkist strongholds of Grantham and Stamford were sacked to such effect that the latter never recovered. In the Civil War of the 17th century, Lindsey for the most part declared for the king. Lord Willoughby of Parham was a prominent parliamentary leader. and the Isle of Axholme and the Puritan yeomanry of Holland declared for parliament.

At the time of the Domesday survey there were between 400 and 500 mills in Lincolnshire; 2.1 11 fisheries producing large quantities of eels; 361 saltworks; and iron forges at Stow, St. Mary and Bytham. Lincoln and Stamford were flourishing centres of industry, and markets existed at Kirton-in-Lindsey. Louth. Old Bolingbroke. Spalding, Barton and Partney. The early manufactures of the county are all connected with the woollen trade, Lincoln being noted for its scarlet cloth in the 13th century, while an important export trade in the raw material sprang up at Boston. The deforestation of Kesteven in 1230 brought large areas under cultivation. and the same period is marked by the growth of the maritime and fishing towns, especially Boston (which had a famous fish market). Grimsby. Barton, Saltfleet, Wainfleet and Wrangle. The Lincolnshire towns suffered from the general decay of trade in the eastern counties which marked the 15th century, but agriculture was steadily improving, and with the gradual drainage of the fen districts culminating in the vast operations of the 17th century. more than 330,000 ac. in the county were brought under cultivation, including more than two-thirds of Holland. The fen drainage resulted in the extinction of many local industries, such as the trade in goose feathers and the export of wild fowl to the London markets. Other historic industries of Lincolnshire are the breeding of horses and dogs and rabbit snaring.

As early as 1295 two knights were returned to parliament for the shire of Lincoln, and two burgesses each for Lincoln. Grimsby and Stamford. In the 14th century Lincoln and Stamford were several times the meeting places of parliament or important councils, the most notable being the Lincoln parliament of 1301, while at Stamford in 1309 a truce was concluded between the barons, Piers Gaveston and the king. Stamford discontinued representation for about 150 years after the reign of Edward II; Grantham was enfranchised in 1463 and Boston in 1552. Under the act of 1832 the county was divided into a northern and southern division each returning two members, and Great Grimsby lost one member. Cnder the act of 1868 the county returned six members in three divisions and Stamford lost one member. Under the act of 1885 the county returned seven members in seven divisions; Lincoln, Boston and Grantham lost one member each and Stamford was disfranchised. In 1935 Lincolnshire and Rutland were together divided into seven: Brigg, Gainsborough, Grantham. Holland with Boston, Horncastle, Louth, and Rutland and Stamford.

Administration.—Lincolnshire is divided into three administrative counties called the Parts of Holland, the Parts of Kesteven and the Parts of Lindsey, each with a county council. Holland, the smallest. covers 418.j sq.mi. and contains one municipal borough (Boston), one urban and three rural districts. Its population in 1951 was 101,55j. Kesteven. in the southwest, covers 724.2 sq.mi. and within it are two municipal boroughs (Grantham and Stamford), two urban districts and four rural districts. Its population in 1951 was 130,717. Lindsey: covering 1j20.4 sq.mi. including the county boroughs of Lincoln and Grimsby, contains three municipal boroughs (Cleethorpes, Louth and Scunthorpe), nine urban and nine rural districts. Its population in 1951 was 473,550.

There are 605 rural parishes, the majority with fewer than 300 inhabitants, and the small rural community is typical of Lincolnshire. Apart from the industrial areas in the north and northwest, the seaside resorts and a number of market towns. Lindsey is mainly a county of small villages, 258 of its 404 parishes having fewer than 300 inhabitants. The provision of adequate schools, village halls, public transport and other amenities is therefore a special problem. Holland has fewer and larger parishes. only three of its 43 having less than 300 inhabitants: although some of the larger parishes contain more than one village. Kesteven with 154 parishes (just under half of them having fewer than 300 inhabitants) stands intermediate. By arrangement between the three administrative counties there is a single police force outside Lincoln and Grimsby.

For judicial purposes the county is variously divided. It lies in the midland circuit of the high court and the assize town is Lincoln. Separate commissions of the peace are issued for Holland, for Kesteven, for Lindsey (divided into 3, 6 and 17 petty sessional divisions respectively), for Grantham, for Grimsby and for Lincoln, and separate quarter sessions are held for each of these areas. Lincoln has its own assizes, being a county of a city.

The crown is represented by a lord lieutenant appointed for the entire geographical county and by a high sheriff for the entire county except Lincoln, which elects its own.

Architecture.—At the time of the suppression of the monasteries in the reign of Henry VIII there were upward of 100 religious houses; and among the fens rose some of the finest abbeys held by the Benedictines. The Gilbertines were a purely English order which took its rise in Lincolnshire. Sempringham, the chief house of the order, was founded by St. Gilbert of Gaunt in 1139. Barlings (Premonstratensian), northeast of Lincoln, was founded in 1154. The Benedictine Mitred abbey of Crowland (*q.v.*) existed in 1051. Thornton abbey (Black Canons) in the north near the Humber and Kirkstead abbey (Cistercian) were founded in 1139.

In the Parts of Lindsey fine examples of various styles are the churches of St. Peter, Barton-on-Humber, for Saxon work; Stow, for Norman of various dates; Bottesford and St. James. Grimsby, for Early English; Tattershall and Theddlethorpe for Perpendicular. In the Parts of Kesteven the churches are built of excellent local stone. The Decorated style is particularly well displayed in the churches of Heckington. Grantham, Caythorpe, Claypole, Navenby and Ewerby. Some of the finest churches are in the Parts of Holland although the district is composed wholly of marshland and is without stone of any kind: the churches of the south part of this district probably owe their origin to the munificence of the abbeys of Crowland and Spalding. The church of St. Botolph, Boston (*q.v.*), is famous for its magnificent lantern-crowned tower or "stump."

There are few remains of mediaeval castles. those of Lincoln and Tattershall being the most noteworthy. The city of Lincoln is remarkably rich in remains of domestic architecture from the Norman period onward and Stamford's lovely Georgian houses are built of local ironstone.

Agriculture.—Lincolnshire is one of the principal arable counties of England, 86% of the total area of nearly 1,700,000 ac. being cultivated. In 1951 wheat was the largest grain crop, covering 261,000 ac.; barley and oats together occupied 241,000 ac. Cattle and pigs are raised in large numbers (280,000 and 145,000 respectively in 1951). The Lincoln Red shorthorn has been bred in the county since the middle of the 19th century and a breed of pig favoured by farmers there is the Lincolnshire Curly Coat. On the wolds and heaths are flocks of the largest British sheep—the Lincoln Longwool—whose popularity outside the county has increased since World War II. It has been of great value for crossing with Merino in New Zealand. Australia and the Argentine. Lincolnshire agriculture is highly mechanized.

One-fifth of the vegetable acreage of England and Wales is in Lincolnshire and a sixth of the sugar beet. Horticultural crops are predominant in the south of the county round the Wash, where 145,000 ac. of potatoes are grown. The Spalding area is notable for its bulb-fields, and there 3,000 ac. are devoted to daffodil and tulip bulbs.

Industries.—In a county of such varied geological structure the surface extraction of minerals is a considerable industry. Ironstone is won from rich beds at several places. The Frodingham ironstone (Lower Lias) is quarried along 7 mi, of its outcrop near Scunthorpe, the Marlstone ironstone (Middle Lias) near Grantham, and the Northampton ironstone (Inferior Oolite) at Colsterworth; and there is mining of the Claxby ironstone (Lower Cretaceous) south of Caistor. Due to the dip of the strata, an increasing depth of overburden is having to be removed in opencast working! and underground mining must eventually supersede quarrying near Scunthorpe. The reserves of ore there are amply sufficient for more than 200 years. There are large cement works near Barton upon Humber (using chalk) and at Kirton-Lindsey (using the Lincolnshire limestone). Building stone from the Lincolnshire limestone has long been famous, the finest quarries being at Ancaster. Clay, sand and gravel are also worked.

At Scunthorpe are some of the largest and most up-to-date iron foundries and rolling mills in Europe, and between 1901 and 1952 the population of the town grew from 9,000 to 55,000 on account of its steel industry. Lincoln, Grantham and Gainsborough long enjoyed an international reputation for the manufacture of agricultural machinery; but the scope of their engineering and other industries has greatly extended and includes (at Lincoln) oil engines, pumps, winding gear, excavators, forged castings, steam boilers and heavy platework; (at Grantham) oil engines, cranes, boilers and road rollers; (at Gainsborough) tractors, automatic packing machinery, road rollers and flour milling. There are smaller but established industries such as milling, brewing, beet-sugar extraction, ropemaking. canning (especially at Boston) and oil-cake manufacture at Barton upon Humber, Brigg. Boston, Louth. Sleaford and elsewhere. At Immingham (*q.v.*) on the Humber a deep water dock was constructed in 1912 and has been extensively used for trading. chiefly in coal, iron, grain, timber and motor vehicles. With the development close by, since 1945, of large chemical and fertilizer factories and an oil refinery, the village is expanding into a small but prosperous town. At Keadby on the Trent a new electric power station was put into operation in 1952. Grimsby is the greatest deep-sea fishing port in England and has a numerous fleet (about 300) of steam trawlers. Boston is a port whose shipping trade with the European continent consists largely of the importation of timber and agricultural produce.

At Cranwell. 12 mi. N.E. of Grantham. is the Royal Air Force college originally set up in 1920 and officially opened in 1934. It is the training place for permanent commissioned officers. There is also a training station for short-service officers.

The Lincolnshire coast is a very popular holiday area for the industrial Midlands. The principal resorts (from north to south) are Cleethorpes. Mablethorpe and Sutton. Chapel St. Leonards, Ingoldmells (where there is a big holiday camp) and Skegness. Large sums were spent to restore the sea defenses after the storms of Jan. 1953. The Skegness and Gibraltar Point nature reserve has a very fine bird observatory.

Communications.—Lincoln was an important meeting place of Roman roads. and today it is a great railway centre. Canals are now little used, but the rivers Trent, Witham, Ancholme and the Roman Fossdyke are navigable by barge. A ferry crosses the Humber from New Holland to Kingston upon Hull in Yorkshire, but the county's ambition is the erection of a Humber bridge, 2 mi. long, between Barton in Lincolnshire and Hessle in Yorkshire.

LIND, JAMES (1716–1794), Scottish physician, who has been called the "founder of naval hygiene in England," took his M.D. at Edinburgh in 1748. He was physician to the Royal Naval hospital at Haslar (1758–83), and then physician to the royal household at Windsor. When Lind went to Haslar, scurvy was rife in the navy, and he had as many as 350 cases in a ten weeks' voyage. As early as 1593 Sir Richard Hawkins had discovered the utility of orange and lemon juice in the sailors' diet. Lind revived it; an admiralty order prescribed the use of lemon juice (179j), and scurvy disappeared from the navy. He also studied typhus (then known as jail fever), recommending disinfection by the smoke of wood; suggested the use of hospital ships for sick sailors in tropical ports; arranged (1761–62) for the distillation of sea water for drinking purposes; and secured many important and beneficial changes in life on board ship. Lind died on July 13, 1794. His three classical works are: *A Treatise* on *the Scurvy* (1754); *On the Most Effectual Means of Preserving the Health of Seamen* (1757); and *Essay on Diseases of Europeans in Hot Climates* (1768).

LIND, JENNY (1820–1887), the famous Swedish singer, was born at Stockholm, Swed., on Oct. 6, 1820, the daughter of a lace manufacturer. Mlle. Lundberg, an opera dancer, first discovered her musical gift, and induced the child's mother to have her educated for the stage; during the six or seven years in which she was what was called an "actress pupil," she occasionally appeared on the stage, but in plays, not operas, until 1836, when she made a first attempt in an opera by A. F. Lindblad. She was regularly engaged at the opera house in 1837. Her first great success was as Agathe, in Carl Maria von Weber's *Der Freischütz,* in 1838, and by 1841, when she started for Paris, she had already become identified with nearly all the parts in which she afterward became famous. But her celebrity in Sweden was due in great part to her histrionic ability, and her wonderful vocal art was attained only after a year's hard study under Manoel Garcia.

Her first appearance in England was as Alice in Giacomo Meyerbeer's *Robert le Diable* at Her Majesty's theatre (May 4, 1847). The furore she created was prodigious. She sang in several of her favourite characters, and in that of Susanna in Wolfgang Amadeus Mozart's *Figaro,* besides creating the part of Amalia in Giuseppe Verdi's I *Masnadieri,* written for England and performed on July 22. In the autumn she appeared in operas in Manchester and Liverpool and in concerts at many provincial centres. At Norwich began her acquaintance with the bishop, Edward Stanley (1779–1849), which was said to have led to her final determination to give up the stage as a career.

After four more appearances in Berlin, and a short visit to Stockholm, she appeared in London in the season of 1848, when she sang in Gaetano Donizetti's *L'Elisire d'amore* and Vincenzo Bellini's *I Puritani,* in addition to her older parts. At the beginning of the season of 1849 she intended to give up operatic singing, but a compromise was effected by which she was to sing the music of six operas, performed without action, at Her Majesty's theatre; but the first, a concert performance of Mozart's *Il Flauto magico,* was so coldly received that she felt bound, for the sake of the manager and the public, to give five more regular representations, and her last performance on the stage was on May 10, 1849, in *Robert le Diable.* In 1850, just before leaving for the U.S., she sang the soprano music in *The Messiah* at Liverpool with superb art. She remained in the U.S. for nearly two years, being for a great part of the time engaged by P. T. Barnum. In Boston, she married (1852) Otto Goldschmidt (1829–1907), whom she had met at Liibeck in 1850.

For some years after her return to England, her home for the rest of her life, she appeared in oratorios and concerts, and her dramatic instincts were as strongly and perhaps as advantageously displayed in these surroundings as they had been on the stage, for the grandeur of her conceptions in such things as the scene of the widow in *Elijah* and the religious fervour of "I know that my Redeemer liveth," could not have found a place in opera. In her later years she took an active interest in the Bach choir, conducted by her husband, and not only sang in the chorus, but gave the benefit of her training to the ladies of the society. For some years she was professor of singing at the Royal College of Music. Her last public appearance was at Düsseldorf on Jan. 20, 1870, when she sang in *Ruth*, an oratorio composed by her husband.

She died at Malvern on Nov. 2, 1887. The supreme position which she held so long in the operatic world was due not only to the glory of her voice and the complete musicianship which distinguished her above all her contemporaries, but also the naïve simplicity of her acting in her favourite parts, such as Amina, Alice or Agathe. In these and others she had the precious quality of conviction, and identified herself with the characters she represented with a thoroughness rare in her day. Unharmed by the perils of a stage career, she was a model of rectitude, generosity and straightforwardness, carrying the last quality into a certain blunt directness of manner that was sometimes rather startling.

LIND-AF-HAGEBY, EMELIE AUGUSTA LOUISE (1878–), British writer, born in Sweden on Sept. 20, 1878, was educated in Stockholm and at Cheltenham college, England. From 1896 onward she lived in England and in 1912 became a naturalized British subject. She worked actively for the movement toward the emancipation of women. She was a strong opponent of vivisection, and founded several societies, including the international federation of antivivisection and animal protection societies (1909). At the outbreak of World War I her three hospitals for wounded horses were authorized by the French government (the Purple Cross), and two years later she opened a sanatorium at Carqueiranne for French and Serbian soldiers, and children who had suffered through the war. She became a well-known public speaker, and wrote numerous books and pamphlets on humanitarian subjects. Her works include *August Strindberg* (1913), *Mountain Meditations* (1917), *Marriage and the New Woman* (1920), *Women's Right to Work* (1920), *Be Peacemakers* (1924), *The Great Fox-Trot* (1938).

LINDAU, PAUL (1839–1919), German dramatist and novelist, the son of a Protestant pastor, was born at Magdeburg, in the Prussian province of Saxony, on June 3, 1839. He was educated at the *Gymnasium* in Halle and then studied in Leipzig, Berlin and Paris, where he spent five years.

Lindau was one of the most brilliant journalists of his day, beginning as a foreign correspondent for the German press while he was a student in Paris and continuing after his return to Germany in 1863. In 1870 he founded *Das neue Blatt* at Leipzig, and from 1872 to 1881 he edited the Berlin weekly, *Die Gegenzvart.* Meanwhile, in 1878, he founded *Nord und Siid,* a famous monthly, which he continued to edit until 1904. Many of his contributions to the press were collected in a series of entertaining volumes.

Two books of travel, *Aus Venetien* (1864) and *Aus Paris* (1865), were followed by some volumes of critical studies written in a light satirical vein, which at once made him famous. These works include *Harmlose Briefe eines deutschen Kleinstädters,* in two volumes (1870), *Moderne Märchen für grosse Kinder* (1870) and *Literarische Rücksichtslosigkeiten* (1871).

In 1895 he was appointed intendant of the court theatre at Meiningen, but in 1899 he moved to Berlin, where he became manager of the Berliner Theater and subsequently, until 1905, of the Deutsches Theater. *Marion* (1868) was the first of a long series of plays in which Lindau showed a mastery of stage effects and a command of witty and lively dialogue. Among the more famous of his works for the stage were *Maria und Magdalena* (1872), *Tante Therese* (1876), *Gräfin Lea* (1879), *Die Erste* (1895), *Der Abend* (1896), *Der Herr im Hause* (1899) and *So ich dir* (1903). Five volumes of his plays were published (1873–88).

His work also includes some volumes of short stories, which acquired great popularity, especially *Herr und Frau Bewer* (1882) and *Toggenhurg und andere Geschichten* (1883). A novel sequence with the general title *Berlin* included *Der Zug nach dem Westen* (1886), *Arme Mädchen* (1887) and *Spitzen* (1888). Among his later novels were *Die Gehilfin* (1894), *Die Brüder* (1895) and *Der König von Sidon* (1898). Earlier books on Molière (1871) and Alfred de Musset (1877) were followed by some volumes of dramatic and literary criticism.

Lindau died in Berlin on Jan. 31, 1919.

LINDAU, a town and pleasure resort in the *Land* of Bavaria, Ger., central point of the transit trade between Bavaria and Switzerland, situated on two islands off the northeastern shore of Lake Constance. Pop. (1959 est.) 23,334. On the site now

occupied by the town there was a Roman camp, the castrum Tiberii, and the authentic records of Lindau date back to the end of the 9th century. In 1274, or earlier, it became a free imperial town. In 1804 it lost its imperial privileges and passed to Austria, being transferred to Bavaria in 1805.

LINDBERGH, CHARLES AUGUSTUS (1902–), U.S. aviator, probably the best-known but least understood figure in aeronautical history, the man whose dramatic solo flight across the Atlantic in May 1927 accelerated world-wide interest in aviation. That flight brought him fame, wealth and a great personal tragedy, but in retrospect it stands only as one episode in a career that greatly influenced the development of commercial and military flying.

Lindbergh was born in Detroit, Mich., on Feb. 4, 1902. His early years were spent mostly in Little Falls, Minn., and in Washington, D.C. (His father represented the 6th district of Minnesota in congress for ten years.) His formal education terminated during his second year at the University of Wisconsin, Madison, when his growing interest in aviation led to enrollment in a flying school in Lincoln, Neb., and the purchase of a World War I Curtiss "Jenny," which he flew on barnstorming tours through southern and midwestern states. After a year at the army flying schools in Texas (1924–25), he became an airmail pilot (1926), flying the route from St. Louis, Mo., to Chicago, Ill. During this period he obtained financial backing from a group of St. Louis businessmen to compete for the $25,000 prize offered by Raymond Orteig for the first nonstop flight between New York and Paris. In the Ryan monoplane "Spirit of St. Louis" he made the flight in 33½ hours on May 20–21, 1927. There followed a series of flights in Europe and America.

In Mexico, Lindbergh met Anne Morrow, daughter of the United States ambassador, Dwight Morrow. They were married on May 27, 1929, at the Morrow home in Englewood, N.J. Together they made fights that took them into many countries of the world. During this period Lindbergh acted as technical adviser to Transcontinental Air Transport and to Pan American Airways, personally pioneering many of their routes.

In March 1932 Lindbergh's two-year-old son, Charles Augustus, Jr., was kidnaped from their home near Hopewell, N.J., and murdered. Partly because of Lindbergh's world-wide popularity, this became the most celebrated crime of the 1930s, and it was a major subject of newspaper attention until April 1936, when Bruno Richard Hauptmann was executed after being convicted of the kidnap-murder. The publicity was so distasteful to the Lindberghs that they took refuge in Europe. After 1936, when he visited German centres of aviation, Lindbergh repeatedly warned against the growing air power of Germany. His decoration by the German government in 1938 led to considerable criticism, as did the neutrality speeches he made in 1940–41 after his return to the United States. Criticism of his public statements by Pres. Franklin D. Roosevelt led Lindbergh to resign his air corps reserve commission in April 1941.

When the United States entered World War II. however. Lindbergh, as a civilian, threw himself unobtrusively into the war effort. serving as a consultant to the Ford Motor company and to the United Aircraft corporation. In the latter capacity he flew 50 combat missions during a tour of duty in the Pacific. and later, after the end of the war in Europe, he accompanied a navy technical mission in Europe investigating German aviation developments.

Following World War II Lindbergh and his family lived quietly in Connecticut. He continued as consultant to Pan American World Airways and to the U.S. department of defense. He was a member of the National Advisory Committee for Aeronautics and served on a number of other aeronautical boards and committees. He received many honours and awards, including the medal of honor (by special act of congress, 1927), the Guggenheim medal and the Wright Brothers Memorial trophy. For his services to the government he was appointed brigadier general in the air force reserve by Pres. Dwight D. Eisenhower in 1954. His book *The Spirit of St. Louis,* describing the flight to Paris, was published in 1953 and gained him a Pulitzer prize. He was also the author of *We* (1929), *Of Flight and Life* (1948) and, with Alexis Carrel, *The Culture of Organs* (1938), concerning researches on which he and Carrel had collaborated.

ANNE MORROW LINDBERGH (1906–) wrote essays and poetry, in addition to accounts of her trips. Her books include *North to the Orient* (1935), *Listen! The Wind* (1938), *Gift From the Sea* (1955) and *Unicorn and Other Poems, 1935–1955* (1956).

(S. P. J.; X)

LINDE, CARL VON (1842–1934). German engineer. inventor of a process of liquefying gas that is basic to the science of refrigeration, was born at Berndorf, in Bavaria. on June 11, 1842. He attended the Polytechnikum at Zurich. Switz., during 1861–64 and then obtained employment at locomotive works. first in Berlin, then in Munich. In 1868 Linde became assistant professor of machine design at the newly established Technische Hochschule in Munich. A scientific paper published in 1870 dealing with the withdrawal of heat at low temperature by mechanical means decided his life work. Another paper relating to refrigeration followed: and brewers, taking note of the practical value of his studies, financed his development of a methyl-ether refrigerator in 1874. In 1876 he took out his first patent for an ammonia refrigerator. Other refrigeration machines had been in use, but Linde's was the first one based upon precise calculations of efficiency. In 1891 he established an experimental laboratory to study refrigeration and related matters more strictly scientifically. Utilizing the Joule-Thomson effect, he succeeded in producing liquid air in 1895. A rectifying column devised by Linde produced either fairly pure oxygen or fairly pure nitrogen in a single rectification. Many later developments in this field have used essentially Linde's methods, and modern research in the physics of low temperatures and also of very high vacuum have been made possible by his work. He was raised to the nobility in 1897 and died at Munich on Nov. 16, 1934.

LINDEMANN, (CARL LOUIS) FERDINAND VON (1852–1939), German mathematician. known particularly for his proof that the number π is transcendental. that is, does not satisfy any equation nith rational coefficients, was born at Hanover on April 12, 1852. Educated at the universities of Göttingen, Erlangen, Munich, Paris and London. he served as professor of mathematics at the universities at Freiburg im Breisgau, Königsberg and Munich. His mathematical papers were mainly on geometric topics. His famous proof establishes that the classical Greek construction problem of squaring the circle by compass and ruler is insoluble. He died in Munich, March 7, 1939. (O. OE.)

LINDEN, a city in Union county, N.J.. U.S.. 18 mi. S.W. of New York city. Because of its metropolitan location, many major companies operate plants there, and manufactures include chemicals, oil, metal products, cars and trucks, aircraft parts, furniture, clothing, and foods and beverages. The town was settled early in the 18th century on four village sites, which combined in 1861 to form the township of Linden, a name chosen to reflect the existence of many linden trees in the area. Incorporated as a city in 1924, it was largely a farming centre until local industrialization began around 1900.

For comparative population figures *see* table in NEW JERSEY: *Population.* (W. L. CA.)

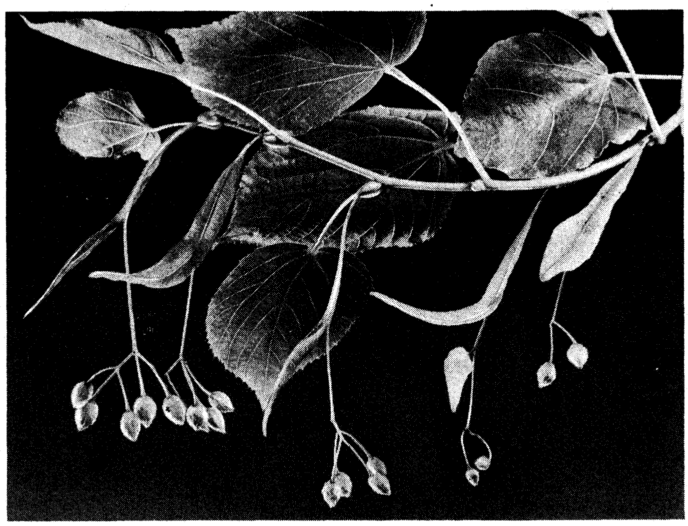
LINDEN (LIME, BASSWOOD) is a member of the genus *Tilia* of the family Tiliaceae. Lime and Linden both have their origin in the word *lind,* Old English for lime tree.

The genus *Tilia* includes about 30 species of deciduous trees widely distributed through the northern hemisphere. It also includes a number of natural and well-established hybrids. The lindens are readily recognized by their coarsely toothed, irregularly heart-shaped leaves and their flowers and fruits, borne in clusters at the termination of long stalks suspended from large, foliaceous, straplike bracts. Few trees exhale greater fragrance when in blossom and the cream and gold flowers, rich in nectar, attract the honeybee. Linden honey, light in colour, is highly regarded for its food value.

Linden wood, soft yet firm, has been a prime favourite with continental wood carvers for centuries. Many of the best expressions of their art are the exquisite frets and carvings of religious motifs to be found in churches of both the old and new worlds. The inner bark of the lindens is rich in fiber, and several species are still cultivated by the Russians for paper, cloth, and cordage fibers. The soft inner tissues were used by ancients as an antiseptic for binding and healing wounds.

Several of the lindens acquire great size; one is recorded in Norfolk. Eng.. as being 16 yd. in circumference. The famous linden tree which gave the town of Neuenstadt in Wurttemberg the name of Neuenstadt an der grossen Linden was nine feet in diameter. Among the many famous avenues of limes are the Unter den Linden, of Berlin, and the avenue at Trinity College, Cambridge.

The large-leaved lime, T. *platyphyllos,* a large tree often 100 ft. tall, is found over much of Europe, including France, Germany, Belgium. Poland, Spain and Italy, and extends eastward into Greece and the Crimea. The small-leaved linden, T. *cordata,*



JOHN MARKHAM

FRUIT AND FOLIAGE OF LINDEN OR EUROPEAN LIME (TILIA EUROPAEA) another tree of commercial proportions, occurs naturally in the Scandinavian countries thence south to Spain, the Balkans and east to the Crimea and Siberia.

The common and widespread European lime, *T. europaea*, is generally regarded by most taxonomists as being a natural hybrid between the two foregoing species. The Crimean lime. T. *ezrchlora*, is a well-established hybrid between *T. cordata* and *T. dasystyla*, the latter species a tree of southeastern Europe, the Caucasus and northern Iran. Two Asiatic species, the Japanese lime *(T. japonica)* and mongolian linden (T. *mongolica*), are locally important timber trees.

Most important of the four American species is American basswood (T. *americana*), a tree of modest proportions that occurs in mixed hardwood forests from New Brunswick to southern Manitoba, thence south to North Carolina and Missouri. Its moderately soft, straight-grained wood of light colour is used in manufacturing venetian blinds, piano keys, luggage, millwork and, especially, cabinets and excelsior. (E. S. Hr.)

LINDENTHAL, GUSTAV (1850–1935), U.S. engineer. was born at Brünn. Aus., May *21. 1850,* and was educated there and at Vienna. After some experience in railway and bridge work in Austria and Switzerland, he moved to the United States in 1871. He was engineer at the Centennial exposition, Philadelphia. Pa.. 1874–77, and then practised in Pittsburgh as consulting engineer in railway and bridge construction till 1890. when he moved to New York city. In *1902–03* he was commissioner of bridges for the city of New Tork.

Lindenthal designed and acted as consulting engineer for the steel-arch railway bridge spanning the East river at Hell Gate, which was opened for traffic in March *1917.* With its approaches. it is about 3½ mi. in length and at the date of completion contained the longest steel arch in the world (977 ft.). It remains one of the greatest arches of all time: its outline, framed between great masonry towers, produces a monumental composition. Lindenthal died July *31. 1935.*

LINDESAY, ROBERT, of Pitscottie *(c.* 1530–*c.* 1590), Scottish historian: of the family of the Lindesays of the Byres, was born at Pitscottie, in the parish of Ceres, Fifeshire, which he held in lease at a later period. His *Historie and Cronicles of Scotland,* covering the period from 1437 to 1456, the only work by which he is remembered, is described as a continuation of that of Hector Boece, translated by John Bellenden. Sir Walter Scott made use of it in *Marmion.*

The *Historie and Cronicles* was first published in *1728. A* complete edition of the text *(2* vol.). based on the Laing manuscript No. 218 in the University of Edinburgh. was published by the Scottish Text society in *18'39* under the editorship of Aeneas J. G. Mackay. The manuscript formerly in the possession of John Scott of Halkshill is fuller. and, though in a later hand, is, on the whole. a better representative of Lindesay's text.

LINDET, JEAN BAPTISTE ROBERT *(1749–1825),* French revolutionary. was born at Bernay (Eure), and was an *avocat* at Bernay. Appointed deputy to the legislative assembly and then to the Convention. he furnished a *Rapport sur les crimes imputés à Louis Capet* (Dec. 10, 1792), and voted for the death of Louis without appeal or respite. As member of the Committee of Public Safety he successfully organized the food supply of the army in the face of great difficulties. Without being formally opposed to Robespierre, he did not support him, and he was the only member of the Committee of Public Safety who did not sign the order for the execution of Danton and his friends. He opposed the Thermidorian reaction and defended Barère, Billaud-Varenne the Collot d'Herbois on March *22,* 1795. Himself denounced on May 20, 1795, he was defended by his brother Thomas (Constitutional bishop and member of the Convention) but escaped condemnation by the vote of amnesty of the 4th Brumaire, pear IV (Oct. *26.* 1795). He was minister of finance from June *18* to Nov. 9, 1799, but refused office under the consulate and the empire. In 1816 he was proscribed by the Restoration government as a regicide and left France until just before his death on Feb. *17, 1825.*

LINDGREN, WALDEMAR (1860–1939), U.S. economic geologist, was born near Kalmar, Sweden, on Feb. *14, 1860.* His father was a district judge and a member of the Swedish parliament. Lindgren was educated at Kalmar and at the Royal Academy of Mines at Freiberg, Ger., then Europe's foremost school of mining and geology, from which he graduated in *1883.* He went to the United States in the same pear and, in *1884,* began 28 years of continuous service with the United States geological survey (USGS), during which he acquired the varied firsthand familiarity with the ore deposits of the western states that became the cornerstone of his career. His acute observations during those years, interpreted with rare judgment and presented with clarity, made it possibie to diagnose from the mineralogy and textures of ores, with an accuracy not before attained, the physical and chemical conditions under which they formed. They established more firmly than before the igneous sources of many of the mineralizing solutions and clarified the methods by which ores were deposited, notably the method of replacement, the importance of which was not appreciated at the time.

Lindgren became chief geologist of the USGS in 1911, but a year later he resigned to become professor of economic geology and chairman of the department of geology at the Massachusetts Institute of Technology. There, during *27* years, he shared with his students his exceptional knowledge of the work of other geologists and the results of his own rich experience. During his last years in the USGS. he wrote *Mineral Deposits (4th* ed.. 1933) which became generally recognized as the leading advanced text in its field. Lindgren was the recipient of many honours, including membership in the National Academy of Sciences, the presidency (1924) and the Penrose gold medal of the Geological Society of America (1933), and the presidency of the International Geologic congress (1933), and many others. He died at Brighton. Mass.. on Nov. *3.* 1939. For further discussion of Lindgren's theories of mineralization and additional information about his classification of mineral deposits *see* ORE DEPOSITS: *Classification and Genesis.* (E. S. BA.)

LINDLEY, JOHN (1799–1865), English botanist, known for his attempts to formulate a natural system of plant classification and for his services to horticulture, was born Feb. 5. 1799, at Catton, near Korwich, where he was educated. On Lindley's going to London in *1819.* Sir William Jackson Hooker gave him an introduction to Sir Joseph Banks, who employed him as assistant librarian. In *1820* he published an original *Rosarum Monographia,* with descriptions of new species and drawings executed by himself, and in *1821 Digitalium Monographia.*

Shortly afterward, while writing the descriptive portion of the *Encyclopaedia of Plants,* he became convinced of the superiority of the "natural" system of plant classification of A. L. de Jussieu, as distinguished from the "artificial" system of Linnaeus followed in that encyclopaedia. This conviction found expression in Lindley's *A Synopsis of the British Flora; Arranged According to the Natural Orders (1829)* and *An Introduction to the Natural System of Botany (1830).*

In *1829* Lindley accepted the chair of botany in University college. London, which he retained till *1860.* He was also assistant secretary of the Royal Horticultural society in *1830* and secretary in *1858* and served on many government committees and commissions. He died at Acton, Middlesex, on Nov. *1, 1865.*

Lindley's works also include *The Fossil Flora of Great Britain* (with W. Hutton, 1831–37); *Flora Medica (1838)*; *Theory of Horticulture (1840); The Vegetable Kingdom (1846); Folia Orchidacea* (1852–59); and *Descriptive Botany (1858).* He was editor of the *Botanical Register* and *Gardeners' Chronicle.*

LINDLEY, NATHANIEL LINDLEY, BARON (1828–1921), English judge, son of John Lindley (*q.v.*), was born at Xcton. Middlesex. on Nov. *29, 1828,* and was educated at University college school and University college, London. Called to the bar at the Middle Temple in *1850,* he began practice in the court of chancery and became a Q.C. in *1872.* In *1875* he was appointed a justice of common pleas and, in pursuance of the changes made by the judicature acts. became a justice of the common pleas division of the high court of justice and, in *1880.* of the queen's bench division. In *1881* he was raised to the

Court of Appeal and made a privy councillor; in 1897 he succeeded Lord Esher as master of the rolls, and in 1900 was made a lord of appeal in ordinary, with a life peerage and the title of Baron Lindley. He resigned the judicial post in 1905, and died at East Carlton, near Norwich, on Dec 9, 1921. Lord Lindley was the last serjeant-at-law appointed. His reputation is mostly a professional one. He was at home throughout the law; a brilliant example of his judgments will be found in *Colls* v. *Home and Colonial Stores* (1904, AC. 179). He published *An Introduction to the Study of Jurisprudence* (1855), a translation of Thibaut's *System des Pandekten-Reckts: Treatise on the Law of Partnership* (2 vols., 1860). with a supplement in 1862. This work has since been developed into two text-books, *Lindley on Companies* and *Lindley on Partnership.*

See *The* Times (Dec. 12, 1921) ; *Law Journal* (Dec. *17,* 1921) ; *Dict. Nat. Biog.* (Supp: 1912–21).

LINDLEY, WILLIAM (1508- goo), English engineer, was born in London on Sept. 7, 1808. He was engaged for a time in railway work in various parts of Europe, and then settled in Hamburg, as engineer-in-chief to the Hamburg-Bergedorf railway. His first achievement was to drain the Hammerbrook marshes, and so add some 1,400 ac. to the available area of the city. His real opportunity, however, came with the great fire which broke out on May 5, 1842, and burned for three days. The strong measures he adopted to prevent the spread of the fire, including the blowing-up of the town hall, brought his life into danger with the mob, who professed to see in him an English agent charged with the destruction of the port of Hamburg. Lindley was then appointed consulting engineer to the senate and town council, to the Water Board and to the Board of Works. He constructed a complete sewerage system, and designed, between 1844 and 1848 the water-works of the city, the intake from the Elbe being at Rothenburgsort. In 1846 he erected the Hamburg gasworks; public baths; wash-houses were built, and large extensions to the port executed according to his plans in 1854; and he supervised the construction of the Altona gas and water-works in 1855. Among other services he rendered to the city were the trigonometrical survey executed between 1848 and 1860, and the conduct of the negotiations which in 1852 resulted in the sale of the "Steelyard" on the banks of the Thames belonging to Hamburg jointly with the two other Hanseatic towns, Bremen and Liibeck.

In 1860 he left Hamburg, and during the remaining 19 years of his professional practice he was responsible for many engineering works in various European cities, among them Frankfort-on-the-Main, Warsaw, Pesth, Diisseldorf, Galatz and Basel. In Frankfort he constructed sewerage works on the same principles as those he followed in Hainburg, and the system was widely imitated in Europe and America. He advised the New River Company of London on the adoption of the constant supply system in 1851; and he was commissioned by the British Government to carry out various works in Heligoland, including the big retaining wall "Am Falm." He died at Blackheath, London, on May 22, 1900.

LINDQ, MARK PRAGER (1819–1879), Dutch prose writer, of English-Jewish descent, was born in London on Sept. 18, 1819. He settled in Holland, taught English, studied at Utrecht, and made translations from the works of the classic English novelists. He also wrote humorous original sketches and novelettes in Dutch, which he published under the pseudonym of De Oude Herr Smits ("Old Mr. Smits"). Lindo's serious original Dutch writings he published under his own name, the principal one being *De Opkomst en Ontwikkeling van het Engelsche Volk* ("The Rise and Development of the British People," 2 vols, 1868–1874)—a valuable history. Lindo was appointed an inspector of primary schools in the province of South Holland in 1865, a post he held until his death at The Hague on March 9, 1879.

LINDSAY, the family name of the earls of Crawford. The family is one of great antiquity in Scotland, the earliest to settle in that country being Sir Walter de Lindesia, who attended David, earl of Huntingdon, afterwards King David I., in his colonization of the Lowlands early in the 12th century. His descendants divided into three branches, whose heads sat as barons in the Scottish parliament for more than 200 years before the elevation of the chief of the house to an earldom in 1398. The Lindsays held the great mountain district of Crawford in Clydesdale, from which the title of the earldom is derived, from the 12th century till the close of the 1 jth, when it passed to the Douglas earls of Angus. *See* CRAWFORD, EARLS OF.

See A. W. C. Lindsay, afterwards earl of Crawford, Lives *of* the *Lindsays, or a Memoir* of the *Houses of Crawford and Belcarres* (3 vols., 1843 and 1858).

LINDSAY, SIR COUTTS, 2ND BART. (1824–1913), English artist, was born on Feb. 2, 1824 and died at Kingston on May 7, 1913. He entered the army, where he commanded the 1st Regt. of the Italian Legion during the Crimean War. Between 1862 and 1874 he exhibited many pictures, and in 1877 founded the Grosvenor Gallery, London, which exhibited the works of the pre-Raphaelite group and other artists outside the academic circle.

LINDSAY, NORMAN ALFRED WILLIAM (1879–), Australian artist and novelist, was born at Creswick, Victoria, on Feb. 23, 1879. He began to draw for a Melbourne newspaper at 16, and in 1901 moved to New South Wales. He was for many years the chief cartoonist of the *Sydney Bulletin.* His chief characteristics of imaginative power. grim strength and a certain coarseness of style are apparent in his illustrations to Theocritus. Boccaccio, Casanova and Petronius, the best of which were collected in *The Pen Drawings of Norman Lindsay* (1918). Among his other published works are *Redheap* (1931), *Saturdee* (1933), *Pan in the Parlour* (1934), *Age of Consent* (1938) and *The Cousin from Fiji* (1945). He illustrated many books, including his own novel *The Cautious Amorist,* and was joint founder of the Endeavour press. (D. L. FR.)

LINDSAY, (NICHOLAS) VACHEL (1879–1931), U.S. writer, was born at Springfield, Ill., Nov. 10, 1879. In 1897 he entered Hiram college, in Ohio, but left after three years to study art in Chicago and New York city. He supported himself, in part, by lecturing for the Y.M.C.A. and the Anti-Saloon league. Meanwhile he had turned to the writing of poetry, and for several summers he wandered through the states, reciting his poems in return for food and shelter. His ambition was to convert America to his vision of beauty. "If I put my soul and body without reserve into the hands of the Lord," he wrote in his diary, "my part will be done. Then let them lead or kill or cure me as they will." (Quoted by Edgar Lee Masters in *Vachel Lindsay: A Poet of America,* Charles Scribner's Sons.)

Lindsay's fame began when *Poetry* published his "General Booth Enters Into Heaven" in its fourth issue (1913). His poems of this kind, based on the American rhythms of the crowd and the camp meeting, are his best. Audiences for years delighted to hear him perform them as a kind of "higher vaudeville." Much of Lindsay's poetry is visionary and "hieroglyphic," but he understood the leaders of American cults and causes, men like Alexander Campbell (founder of the Disciples of Christ), Johnny Appleseed, John Peter Altgeld and William Jennings Bryan. The 20 or so poems which audiences demanded so often that Lindsay grew weary of reciting them ("General William Booth," "The Congo," "Bryan, Bryan, Bryan, Bryan" and "The Santa Fe Trail," for example) became a part of the United States poetic heritage. His "Moon-Poems" and others of this phantasmic kind have been forgotten. Lindsay's best work was done by 1920. Of his later volumes of verse, only *The Candle in the Cabin* (1926) contains poems of distinction.

Lindsay's principal works are: *General William Booth Enters Into Heaven and Other Poems* (1913); *Adventures While Preaching the Gospel of Beauty* (1914), prose; *The Congo and Other Poems* (1914); *A Handy Guide for Beggars* (1916), prose; *The Chinese Nightingale and Other Poems* (1917); *The Golden Whales of California, end Other Rhymes in the American Language* (1920); *The Golden Book of Springfield* (1920), prose; *Going-to-the-Sun* (1923); *Going-to-the-Stars* (1926); *The Candle in the Cabin: A Weaving Together of Script and Singing* (1926). Lindsay took his life on Dec. 5, 1931.

Whipple, *Spokesnzen* (1928). For additional bibliography and a full listing of Lindsay's works *see* R. E. Spiller (ed.), *Literary History of the United States,* vol. iii (1948). (W. T.)

LINDSEY, BENJAMIN BARR (1869–1943), U.S. judge, a pioneer in juvenile court work and first judge of the conciliation court at Los Angeles, Calif., was born in Jackson, Tenn., on Nov. 25, 1869. At the age of 16 he moved to Denver, Colo., and in 1894 was admitted to the Colorado bar. He sponsored legislation establishing the juvenile court at Denver, served as its presiding judge from 1900 to 1927 and made it the model for similar courts throughout the country. His philosophy, now widely accepted, was that the juvenile offender should be under the protection of the state and a ward of the court, that equity rather than criminal procedure should be employed and that treatment of the juvenile's problem rather than punishment should be the objective. From 1939 until his death he served as judge of the conciliation court at Los Angeles, a special court he helped establish to deal with divorce cases where there was some chance to reconcile the parties. He was one of the first to propose a "family court" with integrated jurisdiction over delinquency and divorce. His ardent championship of "companionate marriage," by which he meant practising birth control to prevent parenthood until a marriage was solidly established, divorce by mutual consent where the marriage had failed and there were no children but no divorce as of right if children were involved, created great controversy and was confused by his critics with the "trial marriage" proposal of Bertrand Russell. Outspoken, at times contentious, he was an implacable foe of political machines and a leading reformer of archaic legal procedures concerning family social problems. He wrote *Problems of the Children* (1903); *The Beast and the Jungle* (with Harvey O'Higgins) (1910); *Children in Bondage* (with George Creel) (1914) ; *Pan-Germanisnz in America* (1919) ; *The Doughboy's Religion* (with Harvey O'Higgins) (1919); *The Revolt of Modern Youth* (with Wainwright Evans) (1925); *Childhood, Crime, and the Movies* (1926) ; *The Companionate Marriage* (with Wainwright Evans) (1927) ; *The Dangerous Life* (with Rube Borough) (1931), an autobiography; and many brochures on juvenile delinquency, domestic relations and crime. He died in Los Angeles. March 26, 1913. (H. H. F.)

LINDSEY, an Anglo-Saxon kingdom probably conterminous with the modern district of Lindsey, Lincolnshire, mas an area of early Anglian settlement. A genealogical list of its royal house, extending to Aldfrith, who can be identified with a king of this name who attests a charter of Offa of Mercia between 787 and 796, shows that it had kings of its own. One name in the list, Caedbaed, has a British first element, which may suggest some intermarriage with the Britons. About 631 it mas subject to Edwin of Northumbria, and Oswald of Northumbria also obtained control there, which was resented by the inhabitants. Before 674 Lindsey had become subject to Wulfhere of Mercia, who lost it to Ecgfrith of Northumbria in that year; but Wulfhere's brother: Aethelred of Mercia, recovered it after his victory at the Trent in 678, and it probably remained subject to Mercia until the Danish settlement.

The Danes raided Lindsey in 841 and wintered at Torksey in 873. When they settled in northeast Mercia in 877. Lincoln became one of the Five Boroughs *(see* DANELAW), and Lindsey was probably divided at that time into its three ridings. It seems to have submitted to Edward the Elder in 918. It was raided by the Danes in 993, accepted Sweyn I as king in 1013 and supported Canute when Sweyn died in 1014, thus calling down the vengeance of King Aethelred II. Place names show an intensive Danish settlement, which explains this incident.

After the conversion by Paulinus in about 631. nothing is heard of the church in Lindsey until 677, when Archbishop Theodore created a diocese, with its see at an unidentified Sidnaceaster. This ceased at the Danish settlement. and the religious history of Lindsey becomes obscure. A bishop Leofwine, first recorded in 953, is said by Florence of Worcester to have united the sees of Lindsey and Dorchester-on-Thames in Edgar's reign, and Lindsey remained part of the latter diocese except that it had a bishop of its own, Sigeferth, from about 997 to 1004. After the Norman conquest, the see was moved from Dorchester to Lincoln. Lindsey was claimed unsuccessfully by 11th-century archbishops of York as part of their diocese.

See F. M. Stenton, "Lindsey and Its Kings," in H. W. C. Davis (ed.), *Essays in History Presented to Reginald Lane Poole* (1927) and *Anglo-Saxon England,* 2nd ed. (1947). (D. WK.)

LINDSTROM, GUSTAF (1829–1901), Swedish paleontologist, was born at Visby in Gotland on Aug. 27, 1829. In 1848 he entered the university at Uppsala, and in 1854 he became interested in the zoology of the Baltic and published several papers on the invertebrate fauna and on the fishes. He described the fossils of the Silurian rocks in Gotland; also remains of the fish *Cyathaspis* from Wenlock beds, and (with T. Thorellj a scorpion *Palaeophonus* from Ludlow beds at Visby. He determined the true nature of the operculated coral *Calceola;* and while he described organic remains from other parts of northern Europe, he worked especially at the Paleozoic fossils of Sweden. In 1876 he was appointed keeper of the fossil Invertebrata in the State museum at Stockholm, where he died on May 16, 1901.

See obituary (with portrait) by F. A. Bather, *Geol. Mag.* (1901).

LINDUS, one of the three cities of Rhodes before their synoecism, was situated at Vroulia on the east coast, with a finely placed acropolis and good natural harbour. Danish excavators have discovered the early temple of Athena Lindia on the acropolis, splendid propylaea resembling those at Athens, other early temples, rock inscriptions, a theatre and rock tombs. The sculptors of Laocoon are among the priests of Athena Lindia. On the acropolis is a castle, built. like many houses in the town, by the Knights of St. John in the 14th century.

See Chr. Blinkenberg and K. F. Kinch, *Exploration archéologique de Rhodes* (1904–07); *Fouilles de Vroulia Lindiaca* (several memoirs).

LINE, in mathematics, is an abstraction to which the stroke of a pen only approximates. Euclid defines it as length without thickness and specifies that the boundaries of a line are points and that lines define the boundaries of a surface. Another classical definition (not in Euclid) regards the line as generated by the motion of a point and, similarly, a surface by the motion of a line. Starting from the other end, a surface can be defined as the boundary of a space *(see* SOLUTIONS: *Definitions*), a line as the intersection of two surfaces, and a point as the intersection of a line and a surface or of two lines on one surface.

In modern geometry (at least in English) the term line generally means a straight line (the more general curved line being called a curve) thought of as extended indefinitely both ways; if bounded at one end it is called a half line, if at both ends a segment. Some old-established phrases survive, such as line of force and line of striction, which do not imply straightness. Euclid defines a straight line as one that lies evenly with respect to the points on itself, a phrase that has called for a good deal of exegesis; for Archimedes it is the shortest distance between two points; and another definition, essentially due to Hero of Alexandria, is that a straight line does not change its position when rotated about its two ends. The properties of straight lines that are most fundamental for modern geometers are those that belong to the aggregate of straight lines, rather than to each one, and include the notions that any two points can be joined by a straight line, that no two straight lines can have more than one common point and that two straight lines in one plane either meet in a point or are parallel; all of which are among Euclid's axioms and postulates.

In analytic or algebraic geometry the straight line is represented by one or more equations uf the first degree. in plane geometry by a single equation and in solid geometry by two independent equations.

The special study of line geometry deals with the properties of families of straight lines in space that satisfy one or more conditions, such as passing through a given point, meeting or touching a given curve or touching a given surface. *See* ANALYTIC GEOMETRY; LIKE GEOMETRY; CURVES; CURVES, SPECIAL; *see* also references under "Line" in the Index volume. (P. DU V.)

LINEAR PROGRAMING: see MANAGEMENT SCIENCES.

LINE ENGRAVING: *see* ENGRAVING, LINE.

LINE GEOMETRY. In geometry, curves and other loci are frequently regarded as generated by a point, the position of which is defined by certain conditions. A straight line however may be thought of as the generating element, such as a tangent to a curve, or as a generator of a cone. That branch of geometry in which the line is regarded as the generating element is called line geometry.

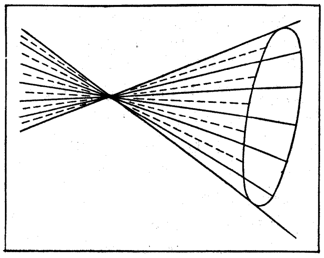


FIG. I

A point in space is determined by its distances from three planes which intersect in one point (*i.e.,* by its *co-ordinates),* and a plane is defined by the totality of the points the co-ordinates of which satisfy a linear equation. The coefficients of the co-ordinates in the equation are called *plane co-ordinates.* A point and a plane are in united position when their co-ordinates satisfy a certain bi-linear equation (*i.e.,* linear in the co-ordinates of the point, and also linear in the co-ordinates of the plane). The principle of duality (*q.v.*) asserts that for every theorem involving points, obtained from properties of point co-ordinates, there is another involving planes, and conversely. These properties remain true if each point co-ordinate is replaced by any linear fractional homogeneous expression in four numbers x_1, x_2, x_3, x_4 with common denominator and non-vanishing determinant. The numbers x_i are called *projective point co-ordinates.* Similarly, u_1, u_2, u_3, u_4 may be taken as *projective plane co-ordinates,* and the condition for united position may be expressed by the equation $\Sigma\ u_i x_i = o$.

In the plane, the projective co-ordinates, x_1, x_2, x_3, may be defined either as point co-ordinates or as line co-ordinates, thus giving rise to point-line duality in the plane. In space a straight line is self dual; it is uniquely determined by any two distinct points on it, or by any two distinct planes through it. The line itself may be regarded as an element; for many purposes in kinematics, in dynamics, and in optics this is more advantageous than to have it defined indirectly in terms of points or planes.

Line **Co-ordinates.**—Given two points $(x_1, x_2, x_3, x_4) = (x)$, $(y_1, y_2, y_3, y_4) = (y)$ on a line, the six expressions of the form $x_i y_k - x_k y_i$ are called its *homogeneous line co-ordinates* p_{ik}. Apart from a constant factor common to all, they are independent of what two distinct points are chosen. Among them there is a quadratic relation which is identically satisfied $P \equiv 0$. All the relations between two lines, such as distance, angle or condition for intersection, or any other relation, can be expressed in terms of their co-ordinates. A line meets two distinct planes each in one point, finite or infinite, and a point in each is determined when its two co-ordinates are fixed. Thus it follows that a line is determined by four independent co-ordinates, or there exist ∞^4 lines in space.

When the co-ordinates p_{ik} satisfy one equation, there are ∞^3 lines singled out, which constitute a *complex;* if they satisfy two such equations, the ∞^2 lines constitute a *congruence;* if they satisfy three, the ∞^3 lines belong to a *ruled surface;* if they satisfy four, there will be only a finite number of lines. The linear complex $\Sigma a_{ik} p_{ik} = 0$ can, by a proper choice of a system of co-ordinates, be reduced to the form $xy' - x'y + k(z - z') = 0$, in which x, y, z and x', y', z' are the cartesian co-ordinates of any two points on a line. If $k = 0$, the complex is special; it now consists of all the lines which meet the fixed line $x = 0$, $y = \sim$ the *axis.* If k is not zero, the line $x = 0$, $y = 0$ is still called the axis but not all the lines of the complex meet it. The complex can be visualized in various ways. It is identical with the null system of mechanics, *i.e.,* the totality of those axes of rotation with regard to which a system of forces in space have a moment of rotation zero. In a linear complex there is, associated with every point P (pole) (*see* POLE AND POLAR) a plane π (polar) passing through it which contains a pencil of lines with vertex at P. Dually, the lines of a linear complex lying in a plane pass through a point called the pole of the plane. As P describes a line 1, its polar plane as to a linear complex $A = 0$ describes a pencil with axis a line $1'$. Dually, every plane π' through 1 has a pole P' on $1'$. Two such lines l, l' are called *conjugate polars* as to $A = 0$. When 1 is a line of $A = o$, $1 = l'$. Any line of $A = 0$ which meets l will also meet $1'$ and every line which meets both l and l' is a line of $A = 0$. By this transformation a linear complex $B = 0$ is changed into a linear complex $B' = 0$. If A and B are in involution, $B = B'$. The six co-ordinate complexes $x_i = 0$ in the Klein system are mutually in involution.

A geometric picture can be obtained as follows: let a be the axis, and π any plane perpendicular to a. If the plane be moved parallel to itself, and rotated into itself about a, the translation and the tangent of the angle of rotation being in proportion, then every point P of a will describe a right circular helix. The lines of the complex are the normals to these ∞^2 helices.

The lines which belong to two linear complexes $A = 0$, $B = 0$ belong to every complex of the system $\lambda A + \mu B = 0$ for every value of λ and μ. Within this system are two special complexes $A' = 0$, $B' = 0$, and the linear congruence may be defined as the ∞^2 lines which meet two given lines, called the directrices of the congruence. They may be distinct, coincident or imaginary. When they are coincident, the congruence consists of ∞^1 pencils of lines with vertices P on the directrix d, and lying in planes a through d, such that P, π are projectively related.

Two complexes $A = o$, $B = o$ are in involution when on every line p of the complex, the poles of an arbitrary plane through p in $A = 0$, $B = 0$ are harmonic (*i.e.,* with cross ratio $= -1$; *see* PROJECTIVE GEOMETRY: *Cross-Ratio)* as to the intersections of p with the axes of the two special complexes $A' = 0$, $B' = 0$ in the system.

The lines which belong to three linear complexes $A = 0$, $B = 0$, $C = 0$ constitute the ∞^1 lines of a regulus, *i.e.,* one system of generators of a quadratic surface; if they are real, they form a hyperboloid of one sheet, or a hyperbolic paraboloid. These lines also belong to every linear complex of the form $\lambda A + \mu B + \nu C = 0$. The other system of generators belongs to three independent linear complexes, each of which is in involution with $A = 0$, $B = 0$, $C = 0$.

The lines belonging to four linear complexes are the two transversals of the axes of the four independent special linear complexes contained in the system. They may be distinct, co-incident or imaginary. These ideas had been recognized in part by various writers, but they were first put into systematic form in terms of co-ordinates by Arthur Cayley in 1860. The results attracted the attention of several mathematicians, in particular of Julius Plucker, who soon contributed a number of notes leading to their further development. Eight years later appeared the first part of Plucker's book on line geometry.

By means of a simple transformation of the line co-ordinates p_{ik}, the quadratic identity $P \equiv 0$ can be reduced to the sum of six squares, $\Sigma x_i^2 = 0$. These x_i are called *Klein co-ordinates;* they furnish one of the most striking examples in mathematics of the power and the ease of obtaining results in consequence of a proper notation.

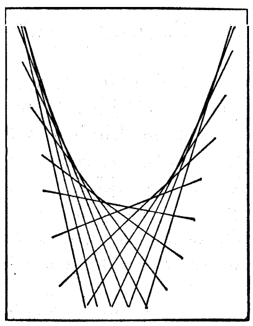

FIG. 2

The Line-sphere Transformation.—The p_{ik} or the x_i can also be interpreted as the co-ordinates of a sphere, since the co-ordinates of the centre and the length of the radius furnish four independent quantities which determine a sphere. By making the co-ordinates homogeneous, and by expressing the length of the radius in terms of the coefficients in the equation of the sphere, the quadratic identity appears. Two lines which intersect are thus transformed into two spheres which touch each other. The points of space (spheres of zero radius) are the images of the lines of a certain complex; the planes of space (spheres whose radii become infinite) are the images of the lines of a certain special linear complex. A linear equation in sphere co-ordinates (linear complex of spheres) defines the ∞^3 spheres which cut a fixed sphere at a constant angle.

The line-sphere transformation together with its projective generalizations, is a ponerful weapon in the study of certain curves and ruled surfaces. Thus, all the sextic ruled surfaces (120 types) and those of order seven having a straight line directrix (about 300 types) have been determined by this method.

Mapping on Hyperspace.—If the p_{ik} (or the x_i) are thought of as homogeneous point co-ordinates in space of five dimensions, the quadratic identity $P=0$ becomes the equation of a quadric variety, hence line geometry may be interpreted as the geometry on a quadric variety in five-way space. A linear complex is then the section of the quadric by a linear four-nay space, and hence it defines a three-dimensional quadratic variety in space of four dimensions. By stereographic projection this can be mapped on the points of three-nay space, hence there is a one-to-one correspondence betneen the points of ordinary space and the lines of any linear complex.

The **Cylindroid.**—The axes of the complexes of a pencil describe a ruled cubic surface. the cylindroid, which is of value in the application of line geometry to dynamics, as is shown in the treatise of Ball. It may be generated as follows: Given a line d, and on it two points P, P'. Through P draw any line p perpendicular to d, and through P' draw a line p' perpendicular to d and to p. Now as a variable point G moves along d from P to P', associate with it a line g always passing through G, perpendicular to d, and such that the distance from P is proportional to the cosine of double the angle that g makes mith the plane d, p. At P, g coinrides with p, at P', g coincicles nith p' and nhen G is in the middle of the segment PP', g makes an angle of 45° with rhe plane d, p. Then think of a second line g' doing the same thing, but winding in the other direction. The line d is a double line on the resulting surface. The planes containing the pairs of intersecting lines g, g' are all parallel to a fixed plane; they intersect in an ideal line d' which also lies on the surface.

By taking d for the z axis, $x-y=0$, $z=h$ for p, $x+y=0$, $z=-h$ for p', the equation has the form

$$z(x^2+y^2)=2hxy.$$

Every ruled cubic mith two distinct directrix lines can be projected into this form.

The General Complex.—An algebraic equation homogeneous and of order n in p_{ik}, together with the identity $P=0$ defines a complex of order n. By holding one point (y) fixed, the points (x) which satisfy the equation all lie on a cone of order n, having (y) as vertex. Similarly, the lines of the complex which lie in a fixed plane all touch a curve of class n. For an arbitrary point, the complex cone has no multiple or cuspidal generators, and in an arbitrary plane the complex curve has no double or inflexional tangents. A point (y) nhich is the vertex of a cone having a double generator is called a *singular point*. The locus of the singular points is a surface. Similarly, the plane (u) mhich contains a complex curve with a double or inflexional tangent is called a *singular plane*. The envelope of the singular planes is identical mith the locus of the singular points. It is called the *surface of singularities;* in particular cases it may be simply a curve.

A congruence may be the complete or partial intersection of two complexes. If it is algebraic the number of its lines passing through an arbitrary point is called its *order,* the number in an arbitrary plane is called its *class*. Let p be any line of a congruence, the distance from p to consecutive lines of the congruence is a certain differential expression of the first order. mhich vanishes to the third order for two points P, P' on p. These are called *foci,* and their locus, as p describes the given congruence, is the *focal surface,* to which p is a bitangent. P and P' may describe the same surface. or different surfaces, or either or both may describe a curve. In the last case the congruence consists of the lines which intersect both curves Congruences of lines are of particular importance in differential geometry (*q.v.*), both metric and projective, *e.g.,* that formed as lines of curvature, asymptotic lines, etc., and that formed by the tangents to one parameter systems of curves on a surface, as by the normals to a surface. They are also of importance in optics.

The complete or partial intersection of three complexes is a *ruled surface*. The number of its lines which meet a given line is its *order*, which is also its *class*. For every order greater than two, a con-conical ruled surface must have one or more double curves. Every plane section is either proper or, if composite, must consist of one proper curve and of straight lines, counted simply or multiply. All the plane section?, apart from straight-line components, are birationally equivalent (their points are in one-to-one correspondence), hence if the surface is algebraic all have the same genus, which may be called the genus of the ruled surface. These ruled surfaces of maximum genus for a given order are those contained in a linear congruence. If all the generators of a ruled surface are tangents to a curve C, the surface is called a *developable surface*. Then C appears on the surface as a cuspidal curve. The surface also contains double curves, if the order of the curve C is greater than 3.

Every generator of a non-developable ruled surface of order n meets $n-2$ other generators.

The Quadratic Complex.—If $\phi=0$ is the equation of the complex of order 2, then the lines belonging to it satisfy the equation $\phi+\lambda P=0$ for every value of λ. When the discriminant of this form has six distinct roots Xi, the equation can be reduced to $\phi=\Sigma\lambda_i x_i^2=0$ when $P=\Sigma x_i^2=0$. The surface of singularities is in this case the most general Kummer surface of order and class 4, with 16 double points and 16 singular planes, *i.e.,* planes which touch the surface at every point of a conic. Each conic passes through six double points, and each double point lies on six such conics. The same surface is also a complete focal surface for six congruences of order and class 2, namely those defined by $\phi=0$, $x_i=0$ $(i=1, 2, \ldots, 6)$.

The surface is invariant under the operation of interchanging the points of contact of the lines of each congruence; these generate a finite group of order 32, of which 16 are harmonic homologies, and 16 are involutorial correlations. For particular forms of ϕ, corresponding particularities exist in the Kummer surface. Thus, if $\phi=\Sigma a_{ik}p^2_{ik}=0$, the complex consists of lines mhich intersect two given quadrics harmonically. The surface of singularities is now the tetrahedroid. The six nodes on each conic are in involution. It is a projective generalization of the wave surface of Fresnel. This complex is known as Battaglini's complex. Another particularization is that in which the λ-discriminant is a square and each λ_i makes every first minor vanish. The complex consists of the lines which meet the faces of a fixed tetrahedron in projective tetrads. The surface of singularities consists of the faces of the tetrahedron. This complex is called the *tetrahedral complex.* The first systematic study of the quadratic complex was made by Battaglini, who assumed, erroneously, that the most general one could be expressed as a linear function of the squares of the p_{ik}.

The correction of this error led to the complete classification according to the form of the X-discriminant, thus affording one of the early applications to the theory of elementary divisors. The Kummer surface also furnished one of the first illustrations of a surface nhich remains invariant under an infinite number of distinct birational transformations, but this property is shared by the focal surface of many other congruences. Line geometry shows close connection among various branches of mathematics.

This important report of about 250 pages cites over 1,500 titles, practically all the bibliography, and brings the development of the subject down to the time at which it was uritten. (V. Sn.)

LINEN AND LINEN MANUFACTURES. Under the name of linen are included all the yarns spun and fabrics woven from flax fibre. (*See* FLAX.)

From the earliest periods of human history till almost the close of the 18th century linen manufacture was one of the most extensive and widely disseminated of the domestic industries of European countries. The industry was most largely developed in Russia, Austria, Germany, Holland, Belgium, the northern provinces of France, and certain parts of England, in the north of Ireland. and throughout Scotland; and in these countries its importance was generally recognized by the enactment of special laws, having for their object the protection and extension of the trade. The inventions of Arkwright, Hargreaves and Crompton in the later part of the 18th century, benefiting almost exclusively the art of cotton-spinning, and the unparalleled development of that branch of textile manufactures, largely due to the ingenuity of these inventors, gave the linen trade as it then existed a fatal blow. Domestic spinning, and with it hand-loom weaving, immediately began to shrink; the trade which had supported whole villages and provinces entirely disappeared, and the linen manufacture, in attenuated dimensions and changed conditions, took refuge in special localities, where it resisted, not unsuccessfully, the further assaults of cotton, and, with varying fortunes, rearranged its relations in the community of textile industries. The linen industries of the United Kingdom were the first to suffer from the aggression of cotton; more slowly the influence of the rival textile reached other countries.

In 1810 Napoleon I. offered a reward of 1,000,000 francs to any inventor who should devise the best machinery for the spinning of flax yarn. Within a few weeks thereafter Philippe de Girard patented in France important inventions for flax spinning by both dry and wet methods. His inventions, however, did not receive the promised reward and were neglected in his native country. In 181j he was invited by the Austrian Government to establish a spinning mill at Hirtenberg, near Vienna, which was run with his machinery for a number of years, but it failed to prove a commercial success. In the meantime English inventors had applied themselves to the task of adapting machines to the preparation and spinning of flax. The foundation of machine spinning of flax was laid by John Kendrew and Thomas Porthouse, of Darlington, who, in 1787, secured a patent for "a mill or machine upon new principles for spinning yarn from hemp, tow, flax or wool." By innumerable successive improvements and modifications, the invention of Kendrew and Porthouse developed into the perfect system of machinery with which, at the present day, spinning-mills are furnished; but progress in adapting flax fibres for mechanical spinning, and linen yarn for weaving cloth by power-loom was much slower than in the corresponding case of cotton.

Modern Methods of Manufacture.— The modern manufacture of linen divides itself into two branches, spinning and weaving, to which may be added the bleaching and various finishing processes, which, in the case of many linen textures, are laborious undertakings and important branches of industry. The flax fibre is received in bundles from the scutch mill, and, after having been classed into various grades according to the quality of the material, is labelled and placed in the store ready for the flax mill. The whole operations in yarn manufacture comprise (1) hackling, (2) preparing, and (3) spinning. For cominoner types of yarn, a process known as carding replaces that of hackling.

Hackling.— This first preparatory process consists not only in combing out, disentangling and laying smooth and parallel the separate fibres, but also serves to split up and separate the strands of fibre which, up to this point, have been agglutinated together. The hackling process was originally performed by hand. and it was one of fundamental importance, requiring the exercise of much dexterity and judgment. The broken, ravelled and short fibres, which separate out in the hackling process, form tow, an article of inferior value to the spinner. A good deal of hand-hackling is still practised, especially in Irish and continental mills; and it has not been found practicable, in any case, to dispense entirely with a rough preparation of the fibre by hand labour. In hackling by hand, the hackler takes a handful or "strick" of rough flax, winds the top end around his hands, and then, spreading out the root end as broad and flat as possible, by a swinging motion dashes the fibre into the hackle teeth or needles of the rougher or "ruffer." The rougher is a board plated with tin and studded with spikes or teeth of steel about jin. in length, which taper to a fine sharp point. The hackler draws his strick several times through this tool, working gradually up from the roots to near his hand, till in his judgment the fibres at the root end are sufficiently combed out and smoothed. He then seizes the root end and similarly treats the top end of the strick. The same process is again repeated on a similar tool, the teeth of which are jin. long and much more closely studded together, and for the finer counts of yarn a third and a fourth tool may be used, of still increasing fineness and closeness of teeth. In dealing uith certain varieties of the fibre, for fine spinning especially, the flax is, after roughing, broken or cut into three lengths—the top, middle and root ends. Of these the middle cut is most valuable, being uniform in length, strength and quality. The root end is more woody and harsh, while the top, though fine in quality, is uneven and variable in strength. From some flax of extra length it is possible to take two short middle cuts; and, again, the fibre is occasionally only broken into two cuts Flax so prepared is known as "cut line," in contradistinction to "long line" flax which is the fibre unbroken. The subsequent treatment of line, whether long or cut, does not present sufficient variation to require further reference to these distinctions.

In the case of hackling by machinery, the flax is first roughed and arranged in stricks, as above described under hand hackling. In the construction of hackling machines, the general principles of those now most commonly adopted are identical. The machines are known as vertical sheet hackling machines, their essential features being a set of endless leather bands or sheets revolving over a pair of rollers in a vertical direction. These sheets are crossed by iron bars, to which hackle stocks, furnished with teeth, are screwed. The hackle stocks on each separate sheet are of one size and gauge, but each successive sheet in the length of the machine is furnished with stocks of increasing fineness, so that the hackling tool at the end where the flax is entered is the coarsest, say about four pins per inch, whereas that to which the fibre is last submitted has the smallest and most closely set teeth. The finest tools may contain from 45 to 60 pins per inch. Thus the whole of the endless vertical revolving sheet presents continuous series of hackle teeth, and the machines are furnished with a double set of such sheets revolving face to face, so close together that the pins of one set of sheets intersect those on the opposite stocks. Overhead, and exactly centred between these revolving sheets, is the head or holder channel, from which the flax hangs down while it is undergoing the hackling process on both sides. The flax is fastened in a holder consisting of two heavy flat plates of iron, between which it is spread and tightly screwed up. The holder is 11in. in length, and the holder channel is fitted to contain a line of six, eight or 12 such holders, according to the number of separate bands of hackling stocks in the machine. Tbe head or holder channel has a falling and rising motion by which it first presents the ends and gradually more and more of the length of the fibre to the hackle teeth, and, after dipping down the full length of the fibre exposed, it slowly rises and lifts the flax clear of the hackle stocks. By a reciprocal motion all the holders are then moved forward one length; that at the last and finest srt of stocks is thrown out, and place is made for filling in an additional holder at the beginning of the series. Thus with a six-tool hackle, or set of stocks, each holder full of flax from beginning to end descends into, and rises from, the hackle teeth six times in travelling from end to end of the machine. The root ends being thus first hackled, the holders are shot back along an inclined plane, the iron plates unclamped, the flax reversed, and the top ends are then submitted to the same hackling operation The tow made during the hackling process is carried down by the pins of the sheet, and is stripped from them by means of a circular brush placed immediately under the bottom roller. The brush revolves in the same direction as, but quicker than the sheet, consequently the tow is withdrawn from the pins. The tow is then removed from the brush by a doffer roller, from which it is finally removed by a doffing knife. This material is then carded by a machine similar to, but finer than, the one described under **JUTE** (*q.v.*). The hackled flax, however, is taken direct to the preparing department. In the machine just described the work is usually performed by four operatives, who feed in the holders, remove them at the opposite end, and change the stricks of flax—end for end—in the holders. The automatic hackling machine does all this work except that of the first feed. The holders are removed, the nuts unscrewed, the flax turned, the nuts screwed tight and the furnished folder replaced in the machine by ingenious mechanism. Further, in some machines, the hackled stricks are mechanically fed into the spread-board—a type of drawing frame.

Preparing.—The various operations in this stage have for their object the proper assortment of dressed line into qualities fit for spinning, and the drawing out of the fibres to a perfectly level and uniform continuous ribbon or sliver, containing throughout an equal quantity of fibre in any given length. From the hackling the now smooth, glossy and clean stricks are taken to the sorting room, where they are assorted into different qualities by the "line sorter," who judges by both eye and touch the quality and capabilities of the fibre. So sorted, the material is passed to the spreading and drawing frames, a series or system of machines all similar in construction and effect. The essential features of the spreading frame are: (1) the feeding cloth or creeping sheet, which delivers the flax to (2) a pair of "feed and jockey" rollers, which pass it on to (3) the gill frame or fallers. The gill frame consists of a series of narrow hackle bars, with short closely studded teeth, which travel between the feed or retaining rollers and the drawing or "boss and pressing" rollers to be immediately attended to. The fallers are moved forward, at a slightly greater speed than that of the retaining rollers, by means of spiral screws, and the flax fibres are drawn out or attenuated by the drawing rollers; meanwhile the fibres are straightened between the gill pins of the fallers. When the fallers successively approach within a short distance of the drawing rollers, they are pushed downwards into a lower plane to be carried backwards by a similar but coarser spiral screw to a point near the retaining roller, when they are pushed upwards to repeat the cycle. They thus form a field of pins or an endless moving level toothed platform for carrying away the flax from the feed rollers. This is the machine in which the fibres are, for the first time, formed into a continuous length termed a sliver. In order to form this continuous sliver, it is necessary that the short lengths of flax should overlap each other on the spread sheet or creeping sheet. This sheet contains four or six divisions, so that four or six lots of overlapped flax are moving at the same time towards the first pair of rollers—the boss rollers or retaining rollers. The fibre passes between these rollers and is immediately caught by the rising gill pins which carry the fibre towards the drawing rollers. The pins of the gills should pass through the fibre so that they may have complete control over it. The fibre is thus carried forward to the drawing rollers, which have a surface speed of from ten to 30 times that of the retaining rollers. The great difference between the speeds of the retaining and drawing rollers results in each sliver being drawn out to a corresponding degree. Finally all the slivers are run into one and in this state are passed between the delivery rollers into the sliver cans. Each can should contain the same length of sliver, a common length being 1,000yd. A bell is automatically rung by the machine to warn the attendant that the desired length has been deposited into the can. From the spreading frame the cans of sliver pass to the drawing frames, where from four to 12 slivers combined are passed through feed rollers over gills, and drawn out by drawing rollers to the thickness of one. A third and fourth similar doubling and drawing may be embraced in a preparing system, so that the number of doublings the flax undergoes, before it arrives at the roving frame, may amount to from 1,000 to 100,000, according to the quality of yarn in progress. Thus, for example, the doublings on one preparing system may be $6 \times 12 \times 12 \times 12 \times 8 = 82,944$. The slivers delivered by the last drawing frame are taken to the roving frame, where they are passed singly through feed rollers and over gills, and, after drafting to sufficient tenuity, they are slightly twisted by flyers and wound on bobbins, in which condition the material—termed "rove" or "rovings"—is ready for the spinning frame.

The preparation of tow for spinning differs in essential features from the processes above described. Tow from different sources, such as scutching tow, hackle tow, etc., differs considerably in quality and value, some being very impure, filled with woody shives, etc., whereas other kinds are comparatively open and clean. A preliminary opening and cleaning is necessary for the dirty, much-matted tows, and in general thereafter they are passed through two carding engines called respectively the breaker and the finisher cards till the slivers from their processes are ready for the drawing and roving frames. In the case of fine clean tows, on the other hand, passing through a single carding engine may be sufficient. The processes which follow the carding do not differ materially from those followed in the preparation of rove from line flax.

Spinning.—The spinning operation, which follows the roving, is done in two principal ways, called respectively dry spinning and wet spinning; the first being used for the lower counts or heavier yarns, while the second is exclusively adopted in the preparation of fine yarns. There is also a demi-sec method of spinning employed in some mills. The spinning frame does not differ in principle from the throstle spinning machine used in cotton manufacture. The bobbins of flax rove are arranged in rows on each side of the frame (the spinning frames being all double) on pins in an inclined plane. The rove passes downwards through an eyelet or guide to a pair of nipping or retaining rollers between which and the final drawing rollers, placed in the case of dry spinning from 18in. to 22in. lower down, the fibre receives its final draft while passing over and under cylinders and guide-plate, and attains that degree of tenuity which the finished yarn must possess. From the last rollers the now attenuated material, in passing to the flyers, receives the degree of twist which compacts the fibres into the round hard cord which constitutes spun yarn; and from the flyers it is wound on the more slowly rotating spool within the flyer arms, centred on the top of the spindle. The amount of twist given to the thread at the spinning frame varies from 1·5 to 2 times the square root of the count. In wet spinning the general sequence of operations is the same, but the rove, as unwound from its bobbin, first passes through a trough of water heated to about 150° F.; and the interval between the two pairs of rollers in which the drawing out of the rove is accomplished is very much shorter. The influence of the hot water on the flax fibre appears to be that it softens the gummy substance which binds the ultimate fibres together, and thereby allows these fibres to a certain extent to be drawn out without breaking the continuity of the fibre; and further it makes a finer, smoother and more uniform strand than can be obtained by dry spinning. The extent to which the original strick of flax as laid on the feeding roller for (say) the production of a 50 lea yarn is by doublings and drawings extended, when it reaches the spinning spindle, may be stated thus: 35 times on spreading frame, 15 times on first drawing frame, 15 times on second drawing frame, 14 times on third drawing frame, 15 times on roving frame and 10 times on spinning frame, in all 16,537,500 times its original length, with $8 \times 12 \times 16 = 1,536$ doublings on the three drawing frames. That is to say, 1yd. of hackled line fed into the spreading frame is spread out, mixed with other fibres, to a length of about 9,400m. of yarn, when the above drafts obtain. The drafts are much shorter for the majority of yarns.

The next operation is reeling from the bobbins into hanks. By act of parliament, throughout the United Kingdom the standard measure of flax yard is the "lea," called also in Scotland the "cut" of 300 yards. The flax is wound or reeled on a reel having a circumference of 90in. ($2\frac{1}{2}$yd.) making "a thread," and 120 such threads form a lea. The grist or count of all fine yarns is estimated by the number of leas in 1lb.; thus "50 lea" indicates that there are 50 leas or cuts of 300yd. each in 1 lb. of the yarn so denominated. With the heavier yarns in Scotland the quality is indicated by their weight per "spyndle" of 48 cuts or leas; thus "3 lb. tow yarn" is such as weighs 3 lb. per spyndle, equivalent to "16 lea," because jute count $\times$ lea count $= 48 \therefore \frac{48}{16}$ lea $= 3$ lb. per spyndle.

The hanks of yarn from wet spinning are either dried in a loft with artificial heat in one of the many modern hank-drying machines or exposed over ropes in the open air. When dry they are twisted back and forward to take the wiry feeling out of the yarn, and made up in bundles for the market as "grey yarn." English spinners make up their yarns into "bundles" of 20 hanks, each hank containing 10 leas; Irish spinners make hanks of 12 leas, $16\frac{2}{3}$ of which form a bundle; Scottish manufacturers adhere to the spyndle containing 4 hanks of 12 cuts or leas.

Commercial qualities of yarn range from about 6 lb. tow yarns (8 lea) up to 160 lea line yarn. Very much finer yarn up even to 400 lea may be spun from the system of machines found in many mills; but these higher counts are only used for fine thread for sewing and for the making of lace. The highest counts of cut line flax are spun in Irish mills for the manufacture of fine cambrics and lawns which are characteristic features of the Ulster trade. Exceedingly high counts have sometimes been spun by hand, and for the preparation of the finest lace threads it is said the Belgian hand spinners must work in damp cellars, where the spinner is guided by the sense of touch alone, the filament being too fine to be seen by the eye. Such lace yarn is said to have been sold for as much as £240 per pound. In the Great Exhibition of 1851, yarn of 760 lea, equal to about 130m. per lb. was shown which had been spun by an Irish woman 84 years of age. In the same exhibition there was shown by a Cambray manufacturing firm hand-spun yarn equal to 1,200 warp and 1,600 weft or to more than 204 and 272m. per lb. respectively.

Bleaching. — A large proportion of the linen yarn of commerce undergoes a more or less thorough bleaching before it is handed over to the weaver. Linen yarns in the green condition contain such a large proportion of gummy and resinous matter, removable by bleaching, or by benzine previous to bleaching, that cloths which might present a firm close texture in their natural unbleached state would become thin and impoverished in a perfectly bleached condition. Nevertheless, in many cases it is much more satisfactory to weave the yarns in the green or natural colour, and to perform all bleaching operations in the piece. Many manufacturers allow about 20 to 25% of loss in weight of yarn in bleaching from the green to the fully bleached stage, but some bleachers can obtain the desired degree of whiteness with a much lower percentage of loss; and the intermediate stages of boiled, improved, duck, cream, half bleach and three-quarters bleach, all indicating a certain degree of bleaching, have corresponding degrees of loss in weight. The differences in colour resulting from different degrees of bleaching are taken advantage of for producing patterns in certain classes of linen fabrics.

Linen thread is prepared from the various counts of fine bleached line yarn by winding the hanks on large spools, and twisting the various strands, two, three, four or six cord, as the case may be, on a doubling spindle similar in principle to the yarn spinning frame, excepting, of course, the drawing rollers. A large trade in linen thread has been created by its use in the machine manufacture of boots and shoes, saddlery and other leather goods, and in heavy sewing-machine work generally. The thread industry is largely developed at Lisburn, near Belfast, at Johnstone, near Glasgow, Bridport, Dorsetshire, and at Paterson, N.J., United States. Fine cords, net twine and ropes are also twisted from flax.

Weaving. — The difficulties in the way of power-loom linen weaving, combined with the obstinate competition of hand-loom weavers, delayed the introduction of factory weaving of linen fabrics for many years after the system was fully applied to other textiles. The principal difficulty arose through the hardness and inelasticity of the linen yarns, owing to which the yarn frequently broke under the tension to which it was subjected. Competition with the hand-loom against the power-loom in certain classes of work is conceivable, although it is absolutely impossible for the work of the spinning wheel to stand against the rivalry of drawing, roving and spinning frames. To the present day, in Ireland especially, a great deal of fine weaving is done by hand-loom. Warden states that power was applied on a small scale to the weaving of canvas in London about 1812; that in 1821 power-looms were started for weaving linen at Kirkcaldy, Scotland; and that in 1824 Maberly and Company, of Aberdeen, had two hundred power-looms erected for linen manufacture. The power-loom has been in uninterrupted use in the Broadford factory, Aberdeen, which then belonged to Maberly and Company, down to the present day, and that firm may be credited with being the effective introducers of power-loom weaving in the linen trade.

The various operations connected with linen weaving, such as winding, warping, dressing, beaming and drawing-in, do not differ in essential features from the like processes in the case of cotton weaving, etc., neither is there any significant modification in the looms employed. (See WEAVING.) Dressing is a matter of importance in the preparation of linen warps for beaming. It consists in treating the spread yarn with flour or farina paste, applied to it by flannel-covered rollers, the lowermost of which revolves in a trough of paste. The paste is equalized on the yarn by brushes, and dried by passing the web over steam-heated cylinders before it is finally wound on the beam for weaving.

Fabrics. — Linen fabrics are numerous in variety and widely different in their qualities, appearance and applications, ranging from heavy sail-cloth and rough sacking to the most delicate cambrics, lawns and scrims. The heavier manufactures include as a principal item sail-cloth, with canvas, tarpaulin, sacking and carpeting. The principal seats of the manufacture of these linens are Dundee, Arbroath, Forfar, Kirkcaldy, Aberdeen and Barnsley. The medium weight linens, which are used for a great variety of purposes, such as tent-making, towelling, covers, outer garments for men, linings, upholstery work, etc., include duck, huckaback, crash, tick, dowlas, osnaburg, low sheetings and low brown linens. Plain bleached linens form a class by themselves, and include principally the materials for shirts and collars and for bed sheets. Under the head of twilled linens are included drills, diapers and dimity for household use; and damasks for table linen, of which two kinds are distinguished — so-called single or five-leaf damask, and double or eight-leaf damask, the pattern being formed by the intersection of warp and weft yarns at intervals of five and eight threads of yarn respectively. The fine linens are cambrics, lawns and handkerchiefs; and lastly, printed and dyed linen fabrics may be assigned to a special though not important class. In a general way it may be said regarding the British industry that the heavy linen trade centres in Dundee and the adjoining counties; medium goods are made in most linen manufacturing districts; damasks are chiefly produced in Belfast. Dunfermline and Perth; and the fine linen manufactures have their seat in Belfast and the north of Ireland Leeds and Barnsley are the centres of the linen trade in England.

Linen fabrics have several advantages over cotton, resulting principally from the microscopic structure and length of the flax fibre. The cloth is much smoother and more lustrous than cotton cloth; and, presenting a less "woolly" surface, it does not soil so readily, nor absorb and retain moisture so freely, as the more spongy cotton; and it is at once a cool, clean and healthful material for bed-sheeting and clothing. Bleached linen, starched and dressed, possesses that unequalled purity, gloss and smoothness which make it alone the material suitable for shirt-fronts, collars and wristbands; and the gossamer delicacy, yet strength, of the thread it may be spun into fits it for the fine lace-making to which it is devoted. Flax is a slightly heavier material than cotton, while its strength is about double. (T. W.)

LINEN FOLD, a panel decoration of the late Gothic period common in north Europe and England, especially used in woodwork, for wainscots, screens, chests. etc., and consisting of a representation of folded or pleated cloth or parchment, with the folds vertical. Certain 14th century French woodwork already shows panels thickened at the centre, with concave surfaces at each side; this thickness is terminated at top and bottom by curved lines. An additional scrolling or pleating of the surface developed this simple type into the elaborate linen fold decoration of the following century. Linen fold panels are especially common in the flamboyant work of France and in late Gothic in Flanders; it is probably through Flemish influence that they were introduced into England.

LINEN-PRESS, a contrivance, usually of oak, for pressing sheets, table napkins and other linen articles! resembling a modern office copying-press. Linen-presses were made chiefly in the 17th and 18th centuries, and are now chiefly interesting as curiosities of antique furniture.

LINER, a colloquial term used to describe large ocean-going passenger ships. *(See* SHIP.)

LINE SPECTRA: *see* SPECTROSCOPY.

LING, PER HENRIK (1776–1839), Swedish medical-gymnastic practitioner, was born at Ljuna. After taking his degree in divinity in 1797 he travelled abroad, earning a precarious living by teaching. In 1804 he returned to Sweden and became teacher of fencing at the University of Lund. He then took the medical course and elaborated a system of gymnastics, divided into four branches: (1) pedagogical, (2) medical. (3) military, (4) aesthetic. In 1813 Ling became principal of the Royal Gymnastic Central institute opened in Stockholm for the training of gymnastic instructors. In recognition of his introduction of gymnastics for therapeutic purposes, popularly known as the "movement cure" or Swedish massage, the Swedish General Medical association elected him a member in 1831.

Ling's collected works *(Samlade Arbeten)* were published in three volumes (1859–65).

LING (*Molva molva*), a food fish of the cod family, elongate in form: with terminal mouth. strong canines in the lower jaw, a short first dorsal fin, a long second dorsal and anal, and a rounded caudal.

It is a deep-water fish, ranging from Iceland and northern Europe to the Bay of Biscay; it is piscivorous, and reaches a length of 7 feet.

LING: *see* ERICACEAE; HEATH.

LINGARD, JOHN (1771–1851), English historian, mas born on Feb. 5. 1771, at Winchester. Educated at the English college at Douai, where he spent some time as tutor in the family of Ldrd Stourton, in Oct. 1794 he settled along with seven other former members of the old Douai college at Crook hall near Durham, where on the completion of his theological course he became vice-president of the reorganized seminary. In 1795 he was ordained priest, and soon afterward undertook the charge of, the chairs of natural and moral philosophy. In 1808 he accompanied the community of Crook hall to the new college at Ushaw. Durham, but in 1811, after declining the presidency of the college at Maynooth, he withdrew to the secluded mission at Hornby in Lancashire, where for the rest of his life he devoted himself to literary pursuits.

In 1817 he visited Rome, where he made researches in the Vatican library. In 1821 Pope Pius VII created him doctor of divinity and of canon and civil law; and in 1825 Leo XII is said to have made him cardinal *in petto*. He died at Hornby on July 17, 1851.

Lingard wrote *The Antiquities of the Anglo-Saxon Church* (1806), of which a third and greatly enlarged edition appeared in 1845 under the title *The History and Antiquities of the Anglo-Saxon Church; containing an account of its origin, government, doctrines, worship, revenues, and clerical and nzonastic institutions;* but the work with which his name is chiefly associated is *A History of England, from the first invasion by the Romans to the Commencement of the reign of William 111* (8 vols., 1819–30).

See the notice by Tierney prefixed to vol. x of the 6th ed. of the *History* (1854–55); and M. Haile and E. Bonney, *Life and Letters of John Lingard* (London. 1911).

LINGAYATS. An independent Saiva sect, or, indeed. the only strictly Saiva sect, are the *Vīra Saivas,* more commonly called *Lingayats* (popularly Lingaits) or *Lingavats*, from their practice of wearing on their person a phallic emblem of Siva, made of copper or silver, and usually enclosed in a case suspended from the neck by a string. Apparently from the movable nature of their badge, their *Gurus* are called *Jangamas* ("movable"). This sect counts numerous adherents in southern India. The reputed founder, or rather reformer, of the sect was Basava (or Basaba), a Brahmin of the Belgaum district who seems to have lived in the 11th or 12th century. According to the Basava-purana he early in life renounced his caste and went to reside at Kalyana, then the capital of the Chalukya kingdom, and later on at Sangamesvara near Ratnagiri, where he was initiated into the Vira Saiva faith which he subsequently made it his life's work to propagate.

Basava's doctrine, a kind of reaction against the severe sacerdotalism of Sankara, has spread over all classes of the southern community, most of the priests of Saiva temples there being adherents of it; while in northern India its votaries are only occasionally met with. and then mostly as mendicants, leading about a neatly caparisoned bull as representing Siva's sacred bull *Nandi.*

LINGAYEN, a municipality (with administrative centre and 23 *barrios* or districts) and capital of the province of Pangasinan, Luzon, Philippine Islands, about 110 mi. N. by W. of Manila, on the south shore of the Gulf of Lingayen, and on a low and fertile island in the delta of the Agno river. Pop. (1960) 45,039. Palay (rice) is the principal crop. Fishing is also a leading industry, and wine is made from the nipa palm.

The Pangasinan language is the vernacular. Lingayen was a principal landing point for Japanese troops in their drive southward to Manila in Dec. 1941.

LINGEH, a port town of Iran on the shores of the Persian gulf in 26" 33' N., 54° 53' E., about 300 mi. S.E. of Bushire in Fars *(ostan* 7).

The old port was at Kung, 7 mi. E. where the Portuguese had a "factory" and exercised political and commercial influence long after the loss of Hormuz (*q.v.*) until 1711. During the reign of the Zand dynasty, Lingeh was seized by Arabs from Ras-al-Khaimah who retained possession till 1887 when the Persian government re-established its authority. The population in 1956 was 4,920.

The town, comparatively well built and of pleasing appearance from the sea, extends for about a mile along the shore but, with the exception of an extensive belt of date palms, the surroundings are extraordinarily arid and the hills at the back of the town, which rise to 3,937 ft., render communications with Lar and the hinterland difficult. There is no harbour for larger vessels and the anchorage is about three-quarters of a mile offshore in 5 fathoms. Lingeh has a good reputation for boatbuilding and repairing. At one time it rivalled Bahrein as a centre for the collection and export of pearls; but the headquarters of the trade is on the Arabian coast.

Exports were fresh and dried fruits, carpets, skins, flax, tobacco, gum and assafoetida, chiefly to India. Steamers of the British India Steam Navigation company call fortnightly in each direction. There is a wireless station which communicates with the rest of the world through Henjam.

Brit. Hydrographic office, *Persian Gulf Pilot,* 9th ed. (London, 1942). (P. Z. C.; X.)

LINGEN, town of Lower Saxony, Federal Republic of Germany. on the Ems canal; 43 mi. N.N.W. of Münster. Pop. (1959 est.) 24,636. It has manufactures of paper, sausages and trade in cattle. Among other industries are weaving and ore mining. Lingen was the seat of a university from 1685 to 1819. The county of Lingen in 1508 was divided into an upper and a lower county, but the two were united in 1541. A little later Lingen was sold to the emperor Charles V, and passed in 1597 to Maurice. prince of Orange. After the death of the English king, William III. in 1702, it passed to the king of Prussia, and in 1815 the lower county was transferred to Hanover, only to be united again with

Prussia in 1866.

LINGUA FRANCA is an auxiliary or compromise language used between peoples speaking mutually incomprehensible vernaculars. It may be one of a number of native languages like Swahili in east Africa, Hausa in nest Africa. and Hindustani in India; or it may be a mixed jargon like the pidgin English of the western Pacific or the Sabir (a mixture of French, Italian. Spanish, Greek and Arabic) of the Mediterranean ports.

The term lingua franca was perhaps first applied to a jargon based on southern French and Italian which crusaders and traders developed in the eastern Mediterranean during the middle ages Extension of trade routes, overseas colonization and slavery during and after the Renaissance, gave rise to a number of mixed contact jargons like Indo-Portuguese (Ceylon), Annamito-French (Cochin China), Spanish Papiamento (Curaçāo) and several varieties of pidginized English—all based on the languages of the colonizing nations.

Origin.—Such jargons generally begin as a compromise between two groups, each desiring to communicate, but unwilling or unable to learn the language of the other. The European may try to make himself understood by imitating the native's effort to speak the European language. The native, taking this imperfect imitation as a model, tries to reproduce it as best he can with the pronunciation and some of the grammatical structure of his own language. thus giving the European further distortions to imitate—and so on until a new compromise language is developed. In plantations. slaves from mutually unintelligible tribes got their model from infrequent contacts with European masters and used their vague impressions of their masters' language as a basis of a lingua franca for communication among themselves.

Spread.—The more polyglot an area, the better the chance for a lingua franca to spread. Thus Beach-la-mar or Sandalwood English became an important language in Melanesia where neighbouring villages might speak distinctly different languages: but not so in Polynesia where many dialects are mutually intelligible. Linguistic diversity in the American northwest was largely responsible for the spread of the Chinook jargon, a lingua franca based on Chinook and other American Indian languages, with English admixture. It became the trade language used not only between white traders and Indians. but also between different Indian tribes; and for a time it was the native language of the offspring of Oregon squaws and French-Canadian *voyageurs.*

When such jargons supplant the mother tongue they become known as Creole languages. Examples of these are Haitian French Creole. Cape Verde Portuguese, and Taki-Taki, a language developed out of a jargonized English used by the African slaves of English and Portuguese landholders who settled in Dutch Guiana in the middle of the 17th century.

Some contact vernaculars may thus develop into written and standardized national languages. Malay. a compromise of various Malayo-Polynesian languages, was used as a lingua franca in Bntish Malaya and the Dutch East Indies and later became the national language of the Republic of Indonesia.

See also BILINGUALISM; PIDGIN. (W. F. MY.)

LINGUET, SIMON NICOLAS HENRI (1736-1794), French journalist and advocate, was born on July 14, 1736, at Rheims. He was admitted to the bar in 1764, where he became one of the most famous pleaders of his century. but was dismissed in 1775 on account of his bitter attacks against his fellow advocates, especially against Gerbier (1725–88). He then founded the *Journal de politique et de littérature,* but was compelled to resign and leave the country after the publication of a sarcastic article on the French academy. After some years as a free-lance abroad, publishing the *Annales politiques, civiles et littéraires* in London and Brussels, he attempted to return to France in 1780, and was imprisoned for two years for an attack on the duc de Duras (1715–89). After a further period abroad he returned to France in 1786 as an Austrian councillor of state, and obtained 24,000 livres from the duc d'Aiguillon for legal services rendered some 1j years earlier His fame at the time surpassed that of his rival Pierre Beaumarchais He then visited the emperor at Vienna to plead the case of Van der Noot and the rebels of Brabant. On his return to Paris in 1791 he defended the rights of San Domingo before the national assembly; his last work was written in defense of Louis XVI. He retired to Marnes, near Ville d'Avray to escape the Terror. but was captured and guillotined at Paris on June 27, 1794, on the charge of "having flattered the despots of Vienna and London."

Linguet's writings include *Histoire du siècle d'Alexandre le Grand* (1762); *Histoire impartiale des Jésuites* (1 768, condemned to be burned); *Fanatisme des philosophes* (1 764); *Histoire des révolutions de l'empire romain* (1766–68); *Théorie des lois civiles* (an attack on the politics of Montesquieu. 1767); *Mémoires sur la Bastille* (1789). His best legal treatise is *Mémoire pour le comte de Morangies* (1; 72).

LINGUISTICS is the science devoted to the study of language and languages in all their aspects—their structure, their interrelationship with the rest of human activity, their history and mutual relations. It is an analytical science, resembling mathematics in many of its procedures. and can be called a "natural science" because it deals with the observation of discreet behaviour events. It is a social science. a branch of anthropology, in that it examines a part of human behaviour and the relation of language to the totality of human culture. It also deals with and impinges upon the humanities, taking its source materials partly from literary and other artistic creations, and studying history as well as contemporary activity.

Linguistics as a scientific discipline can be treated in terms of the following topics: history and development of the subject from antiquity to modern times in various parts of the world; analytical methods and procedures for the study of the sounds and forms of language; relationships of languages; application to problems of pedagogy and education in general; model and example for the study of human behaviour as a whole, including human history.

For other aspects of linguistics, *see* the articles PHILOLOGY; PHONETICS; GRAMMAR; LAKGUAGE; TEXTUAL CRITICISM; FOLKLORE; ETYMOLOGY; SEMANTICS IK LINGUISTICS. Some of these subjects are independent disciplines, others part of the integrated science of linguistics. Linguistics also has a relation to communication as a whole, the use of mass communication media, the psychology of learning, and certain aspects of psychotherapy and mental health.

HISTORY OF LINGUISTICS

Like many sciences. linguistics developed from procedures and observational techniques which were begun in prescientific times and which often produced results that are still valid. Among many peoples there have been sacred texts and other materials which were supposed to be preserved unaltered. This seems to have led to an attitude of observation of the details of linguistic usage which could serve as the basis for the kind of generalizations that are called grammatical statements. One place where this happened was ancient India. Their sacred texts, the Vedas, were studied and learned with the greatest care, and a tradition of grammatical examination of them arose. This tradition has come down to modern times in the compilation attributed to one Pāṇini, and in the restatements of and commentaries on his work. Pāṇini was the first precursor of modern linguistics. He based his statements on the direct observation of the actual language material in the texts he analyzed. and he expressed them in quasi-mathematical symbols. In many aspects his methods have not been improved upon since.

In another time and place, ancient Greece, there was also extant a large literature which was constantly being studied and transmitted. There, however, the attitude was a general one of interest in the phenomena of the universe, and of trying to interpret them philosophically. The Greeks developed a grammatical tradition which described their language with reasonable accuracy, but couched the description in philosophical rather than scientific terms. This philosophical grammar was passed on to the Latins, who followed it with some uneasiness. as their language was sufficiently different from Greek to require differences in analysis. This classical Graeco-Roman tradition lingered on in mediaeval

Europe. and with the coming of the Renaissance this grammatical philosophy began to be applied to the modern languages of Europe. As they were quite diiferent in structure, the classical analysis did not fit. However. couched as it was in philosophical terms, it could be stretched to cover up almost any real structural difference. This happened. and a linguistic science became almost impossible because the traditional philosophical grammar became hallowed with approved authority of all kinds.

With the discovery of the new world the linguistic experience of the western peoples widened, but the grammatical tradition made it difficult to record and describe the newly found languages accurately. They were forced into Latin moulds almost everywhere. In the 18th century, however, Europeans became acquainted with the traditions of India, and began to learn Sanskrit. In doing so. they learned about the Indic grammatical school of Piinini and his followers. Immediately, a new view of languages and of grammatical description became possible. As the principles of Piinini's descriptive techniques became known, and more new languages were found in the world. the foundations of modern linguistic analysis became firmer. However. they did not come to full fruition until the end of the 19th century in the Americanist linguistic school (*see* below). The first direct result of the discovery of Sanskrit was to bring about the development of the comparative linguistics of the 19th century: the techniques thus developed were the first scientific linguistics in the western world.

COMPARATIVE LINGUISTICS

Among the 18th century Englishmen in India who learned Sanskrit and began to study Indic literature was Sir William Jones. In 1786 he stated, in an address to a learned society, that the resemblance of Sanskrit to Greek and Latin is too close to be due to chance, and shows that all three "have sprung from some common source which. perhaps, no longer exists," and that Germanic and Celtic probably had the same origin. This is the first recorded recognition of what constitutes language relationship as recognized by modern linguistics. and may thus be counted as the beginning of comparative linguistics.

Before this time, there had been many instances of recognition that certain languages resembled each other, but very little had been done to state the resemblances systematically. In fact, it was simply not realized that the resemblances had to be systematic. Where it was apparent that a language like Italian was somehow a later form of Latin, the attitude was that it was a corruption of a perfect original, and as such hardly to be expected to show regularity and system. The thinking started by Jones led to the giving up of this sort of attitude by all serious scholars in the field. It was recognized that languages change constantly, that the changes are systematic and regular. and that only by careful examination of the changes within a language and comparison of the differences between languages could origins and relationships be established.

For the Indo-European languages, the beginning of systematic comparison was a treatise on verb inflection in Sanskrit. Greek, Latin. Persian and Germanic, published in *1816* by Franz Bopp. In 1818 Rasumus Rask, and in 1819 Jacob Grimm examined the relationships of the Germanic languages to each other. In 1833–36 August Friedrich Pott published his etymological studies of Indo-European. August Schleicher. in 1861, published a comparative grammar of the Indo-European languages, and in *1886* Karl Brugmann and Berthold Delbrück began to publish their *Outline of the Comparative Grammar of the Indo-European Languages*, which remained the standard work of reference in the field. Friedrich Diez studied the Romanic languages in a comparative grammar (1836–44), Johann Kaspar Zeuss began the study of Celtic (1853), and Franz von Miklosich wrote a comparative grammar of the Slavic languages (1852–74).

The interest in comparative linguistics led to the investigation of other language families (Finno-Ugric and Semitic at first), and also to the beginning of the descriptive treatment of contemporary languages without regard to history. That is. 19th century comparative linguistics was actually the beginning of all modern linguistic science, and from it grew what we now call linguistics, so that comparative and historical studies are based on the results of the descriptive method.

It is of interest to show how linguistic comparison of this kind is done and what its results are. If we look at French. Spanish and Italian we see immediately that they show great resemblances to each other. Suppose that these were the only languages of this kind in existence, and that they were known only in their modern forms. with no old texts. We might begin their comparison by making a list of several hundred words in each — numerals, kinship terms, words for parts of the body and for common artifacts, words for people, and so on. For the present purpose Table I gives a short list of this kind. In the listing of words in Table I

TABLE I.—*Examples of Linguistic Comparison*

Meaning	French		Spanish		Italian	
	Word	Pronunciation	Word	Pronunciation	Word	Pronunciation
one	un	øn	un(o)	ún[o]	un(o)	ún[o]
two	deux	dø[z]	dos	dós	due	dúe
three	trois	trua[z]	tres	trés	tre	tré
four	quatre	hatra	cuatro	kwátro	quattro	kwáttro
five	cinq	senk	cinco	θínko	cinque	čínkwe
six	six	sis	seis	séys	sei	séi
seven	sept	set	siete	syéte	sette	sέtte
eight	huit	üit	ocho	óčo	otto	ɔ́tta
nine	neuf	nof	nueve	nwébe	nove	nɔ́ve
ten	dix	dis	diez	dyéθ	dieci	dyέči
father	père	pe·r	padre	pádre	padre	pádre
mother	mère	me·r	madre	mádre	madre	mádre
brother	frère	fre·r	hermano	ermáno	fratello	fratέllo
sister	soeur	sdr	hermana	ermána	sorella	sorέlla
man	homme	oma	hombre	ómbre	uomo	wɔ́mo
woman	femme	fama	mujer	musér	donna	dónna
hand	main	men	mano	máno	mano	máno
foot	pied	pie	pie	pyé	piede	py Ede
head	tête	te·ta	cabeza	kabéθa	testa	tέsta
heart	coeur	kør	corazón	koraθón	cuore	kwɔ́re

a phonemic transcription is given, since it is the sounds that are being compared.

In the pronunciation, [*z*] means that the item appears with a *z* sound if a vowel follows. but otherwise does not have it; ϕ is a symbol for the front-rounded vowel usually spelled eu in French (*ö* in German); a indicates the release of the final consonant, varying from a full vowel of the character of the *a* in *sofa* to a mere audible ending of the consonant sound; n after a vowel in French means nasalization of the vowel; e· means a long vowel, something like the English sound in *pair;* ˈ indicates primary stress; [ ] means that the vowel is not always present; *θ* is a symbol representing the Castillian sound, like English *th* in *think*, but in Latin America pronounced like *s;* č is like *ch* in *church;* ε in Italian is the open vowel (more like English e in *set*), while e is a closer vowel (something like *a* in *rate*); ɔ is open, something like *o* in *or*, while o is close, like *o* in *note*.

When these lists are compared and we speculate. from a knowledge of phonetics (*see* below), on what original sounds might have given rise to the present sounds. the original forms can be reconstructed hypothetically. To exemplify the process, each form will be taken up separately.

The word for 'one' shows /ún[o]/ in two languages, /ϕn/ in the third; original /u/ could become/ϕ/—and other material in French confirms this; the final vowel is sometimes not present in Spanish and Italian; it was lost in French, and the /n/ then nasalized the vowel. We reconstruct */úno/ (the asterisk means the form is hypothetical). It will be seen later what this means in the light of the known Latin form *ūnum*.

For 'two' we have /dϕ[z]/ and /dós/ reconstructible to */dós/, but /dúe/ is clearly from some other form.

'Three' reconstructs to */trés/.

'Four' reconstructs to */kwátro/ or */kwáttro/—there is no way to know from this small amount of evidence which one it was.

For 'five' we must postulate an initial sound that could give rise to /č/, /s/, and /θ/—say /č/; the final /we/ in Italian and /o/ in Spanish might go back to an original /o/; we reconstruct */čínko/.

For 'six' we reconstruct */séys/, reserving judgment about the vowel because it has become /i/ in French.

For 'seven' we postulate */sétte/.

Were it not for the Spanish /č/, 'eight' might be */ótto/; but the /č/ suggests */ótyo/ or */óyto/.

For 'nine' we have */nóve/.

'Ten' shows a vowel like 'six' in French. like 'seven' in Spanish and the last consonant is like the initial one in 'five'. We reconstruct */déči/.

The words for 'father' and 'mother' seem to reconstruct to */pádre/ and */mádre/. The French form for 'brother' ought then to go back to */frádre/; but Spanish bas an entirely different form, and Italian shows /frat-/. with what n-e can later establish as a diminutive ending. This suggests that we reconstruct */frátre/ rather than */frádre/; then we extrapolate this result to the two preceding cases. and get */pátre/ and */mátre/. Then. if we say that an original single /t/ became /d/ in Spanish and Italian in this position (after /a/ and before /r/), and disappeared in French with preceding vowel change. we can go back to 'four' and decide that its original form had a double /t/, which remained in Italian, and became single in French and Spanish—*/kwáttro/.

The word for 'sister' can give us only */sor-/ at this stage, since Spanish does not help to establish the form.

'Man' is difficult to reconstruct. When we consider the Italian plural /wómini/ (*uomini*), it becomes possible to set up an original */ómini/ or */ómine/ for the singular, and a plural */ómines/. The Italian singular must be from a form */ómo/.

The words for 'woman' are all different, and cannot be reconstructed.

'Hand' goes hack easily to /máno/, while 'foot' seems to call for an original */pyéde/ or */pede/.

'Head' in French and Italian comes from */tésta/, but Spanish has a different word.

'Heart' must he from */kóre/. Spanish having an added suffix.

As was the case with the */tt/ of 'four' and the */t/ of 'father,' the addition of further material can refine and correct the reconstructions. The final reconstructions. based on all the available linguistic material. look thus: */úno/. */dós/ alternating with */due/. */trés/, */kwáttro/, */čínko/ alternating with /čínkwe/ (*i.e.*, here /o/ and /we/ cannot be from the same source), */séys/, */sέtte/, */óyto/, */nɔ́ve/, */dέči/, */pátre/, */mátre/, */frátre/ for *frère* (*/germáno/ for *hermano*, */fratéllo/ for the Italian form), */sór/ (*/germána/, */sorélla/), */ɔ́mine/ (*/ɔ́mo/), */fémma/ (*molyér/—the Italian has a form *moglie* /mólʸe/ 'wife'), */máno/, */pέde/, *tέsta/ (*/kapétya/), */kɔ́re/ (*/koratyóne/).

When knowledge of Latin is brought in. it is found that the forms differ in some respects from those that gave rise to the modern ones. The classical Latin forms are: *ūnum* (this is the masculine accusative form, which is at the base of the Romanic masculine forms). *duōs* (also acc.), *trēs, quattuor, quīnque, sex, septem, octō, novem decem, patrem* (acc.), *mātrem, frātrem, sorōrem, hominem, fēminam, manum, pedem, caput, cor*. This means that in the spoken Latin that is at the base of the Romanic forms certain words were changed or replaced. or were used differently from classical usage: *duae,* originally the feminine nominative of the numeral 'two,' came to be the only form used in central Italy, and became *due,* while *duōs,* the masculine acc., became */dóos/ and gave rise to *deux, dos; quattuor* was everywhere made more "regular" by becoming */kwáttrum/, *quīnque* became */kínkwe/ in Italy, but */kinko/ in Spain (the French *cinq* could be from either form); in Spain *fratrem* went out of use, to be replaced by *germanus,* originally meaning 'cousin, kinsman,' and the feminine *germana* replaced sorōrem. while in Italy diminutive forms *fratel-121s* and *sorella* came into being; *sorōrem* became */sórem/ and gave rise to *soeur* and *sor(ella); homō,* the nominative. persisted in Italy. becoming *uomo* (it also remained in France, but there came to he the indefinite pronoun *on*), while *hominem* became *homme* and *hombre; fēmina* continued in use in France, but was replaced in Spain by *mulierem* 'wife' (though Spanish also has *hembra* 'female.' from *fēmina*); *caput* was extended to */kapétya/ in Spanish. but replaced by *testu,* originally meaning 'beanpot,' in France and Italy.

From this demonstration the following results of the comparative method in linguistics can he seen. The changes in form in a language must be regular and consistent; where there are inconsistencies they must be explained by postulating replacement forms for those otherwise known. or by postulating more than one original form. The more that" is knon-n about a modern language or about an older one. the better and more complete can be the statements of relationship and of development. Whether we have written records of an ancestral language or not. we can reconstruct from modern languages with successively greater accuracy as we learn more about them and as we have more languages to compare. All kinds of detailed phonological information can be gleaned from the method: in the examples above, we see Latin *h* disappearing, /k/ becoming /č/ or /s/ in certain positions, vowels changing their quality, final consonants being lost. Grammatical changes can be seen in the loss of case distinctions in the modern Romanic languages. Meaning changes are seen in the word replacements.

But from the comparative method only what is still left in the languages can be reconstructed to an original form. Some things get lost irretrievably. So the Latin final *m* of *septem* and *decem* has left no traces and if we didn't have the classical forms we could not even guess at its presence. Similarly, the *p* of *septem* cannot be reconstructed as anything but a *t;* and while the *c* of *octō* has left traces leading to a reconstructed /y/, its original nature is unrecognizable.

On the basis of such reconstructions, language families have been arrived at. The members of such a family, the related languages, are the end products of change from a single original language. (*See* also LANGUAGE.)

DESCRIPTIVE LINGUISTICS

American Anthropological **Linguistics.**—While in Europe during the 19th century there was being elaborated the coniparative method in linguistics. and the interest was largely in historical matters. in America there developed a tradition of studying. in and of themselves. languages whose history and relationships were unknown. Traditional grammatical categories were inapplicable, there were no n-ritten records. apd even in cases of clear relationship. too little n-as known about the related languages to make reconstruction possible.

As early as the 17th century Roger Williams in Rhode Island was describing an Algonkian language under the title of "the language of America." When the American Philosophical society mas founded under the leadership of Benjamin Franklin, a number of its members, including Thomas Jefferson, showed a real interest in American Indian languages and their description.

With the westward expansion of the United States, many American Indian tribes became known to white settlers. and their movements and habits became matters of concern to the United States government. Various government agencies were established to deal with these matters, and some of the persons engaged in the work became interested in the languages of the Indians. Thus began the anthropological tradition in Americanist linguistics.

In 1842 the American Ethnological society n-as founded; one of its principal aims n-as the study of American Indian languages. Some 30 years later the Bureau of American Ethnology was started, as a part of the Smithsonian institution. The first director of the bureau. J. W. Powell. made it his principal interest to describe or at least identify the various languages of the Indians of the country. In 1891 there was published, in the 7th annual report of the bureau for 1885–86. Powell's "Linguistic Families of North America" (pp. 1–142). This work used the already established principles of comparative linguistics to make preliminary classifications of the languages of the Indians of the United States and Canada. Some 55 families were established. so soundly that not one error has been found since. though some of the families have been subsequently combined into larger groups with others. The result of this work was, however, not to lead to immediate further comparative work, but to spur on the study of the individual languages.

In the 1880s Franz Boas began to teach anthropology at Columbia university. Boas was originally trained as a natural scientist. This gave him an attitude that led to his approaching linguistic study as a matter of description and not history. Boas accompanied all his anthropological researches by extensive study of the languages of the people observed. He made all his students do the same. Anthropological linguistics. examining languages in terms of their own structure and regardless of historical considerations, thus became the principal kind of scientific language study in the United States.

While Boas was founding and fostering American anthropology and anthropological linguistics, work was also being done in the United States in the more traditional fields of Indo-European comparative linguistics. Even here, however, an insistence on full and exact description regardless of history was to be found. William Dwight Whitney, professor of Sanskrit at Yale in the 1880s, wrote a Sanskrit grammar that was, in effect, a modern version of Pāṇini's, without the esoteric symbolism. Whitney also wrote hooks on general linguistics.

The students of Whitney and Boas and their associates were thus all imbued with an interest in language description and language structure. The most noted of these were Edward Sapir (1884–1939) and Leonard Bloomfield (1887–1949). Sapir studied under Boas, and was his most brilliant student. He became the leading theoretical linguist in the field of American Indian languages, producing many important studies. In 1916 he published a paper showing the relationship of historical linguistic information to anthropological time perspective. In 1921 he published his *Language*, a general work in linguistic science that is still valued and usable. Sapir also produced, in 1925, a study that was the forerunner of modern phonemics (*see* below), and in the last years of his life, as professor of linguistics and anthropology at Yale, contributed much of great importance to the development of Indo-European comparative studies.

Bloomfield began his career as a traditional comparativist linguist in Indo-European and Germanic studies. He soon began to take an interest in American Indian languages, and in the whole Americanist descriptive tradition. In 1914 he published a general work on linguistics, and in 1933 rewrote it into a new work, entitled *Language*. Bloomfield's *Language* remained the best general introduction to linguistic science and the methods of analysis. Both Bloomfield and Sapir in their years at Yale produced a number of students who became leaders in their field.

The kind of linguistic work done by the Americanists was comparatively rare in other parts of the world. In African languages, there were linguistic studies with theoretical approaches that were similar in many respects to those used in America, and some work of the same kind was done in India, the far east, and with the languages of the Pacific area.

European Structuralist Linguistics.— The great interest in comparative linguistic studies in Europe did not exclude much descriptive work also. In fact, as soon as comparative interests were extended to the lesser known languages, it became clear that extensive descriptive studies would he needed to provide a base for reconstruction. In the fields of the languages of Asia, and for the dialects of the standard languages of Europe, it was necessary to work along many of the same lines as the Americanists employed.

In various countries there were started dialect studies which resulted in dialect atlases. Questionnaires and word lists were compiled, and the ways in which the items were said in different regions were recorded. Dialect atlas work also began in the United States about 1925.

As both descriptive and comparative studies of the kinds mentioned developed, an interest in a number of theoretical problems arose. There was the question of the relation of the language to the things talked about. This was approached in terms of the meaning or content of linguistic forms. The attempt to investigate these matters necessarily required increasing attention to language as a systematic structure, rather than as an aggregate of isolated forms. Ferdinand de Saussure, in his teaching at Geneva, developed a theory of linguistic structure that dealt with these problems. De Saussure as a young man had already exercised his structural bent by suggesting (in 1875) a theoretical approach to the phonological structure of Indo-European that differed markedly from the accepted doctrine as found in the work of Karl Brugmann and his predecessors. De Saussure postulated a relationship between the apparent short and long vowels of proto-Indo-European in which the short vowels were basic, and the long vowels were reconstructed as original sequences of a short vowel and a lengthening element which was described as some kind of h-like consonant. When Hittite was discovered in 1907 and later analyzed it was found that several such consonants had actually existed, and that De Saussure's structural extrapolation had actually been a correct picture of the situation. The theoretical basis of Indo-European studies was greatly reoriented by the developments after this confirmation.

In Russia, working with the structure of the Slavic languages, Jan Baudouin de Courtenay in 1894 produced a study of the phonological structure of these languages in which the modern concepts of phonemes and morphophonemic relationships (*see* below) were set forth for the first time. Various Russian and other European scholars were influenced by Baudouin de Courtenay's ideas, and this resulted in the development, under the leadership of Nicholas Trubetskoy (of Vienna) of the so-called Prague school of phonology. Trubetskoy and his colleagues formulated their principles at a congress of Slavic scholars in Prague in *1929*. The results were published in the first volume of the series known as *Travaux du Cercle Linguistique de Prague*. Modern phonemic analysis as a widespread activity took its start from this set of principles. But, as was noted, Sapir had already, in 1925, put forth ideas that anticipated these principles, and others of the Americanist group of linguists had worked along the same lines.

De Saussure's and Baudouin de Courtenay's theoretical approaches have also guided the work of linguists in Norway and Denmark: and to a lesser degree in France. These came to be known as structuralist studies, though much of the comparative work of the 19th century and most of the anthropological linguistic work has also explicitly dealt with systematic structure.

Fields of Linguistic **Analysis.**—After the end of World War II, with the resumption of international scholarly intercourse and activity, the various groups of linguists were able to exchange ideas and examine each other's theories and practices. It became clear that in general there was much fundamental agreement. A statement of what linguistic analysis is concerned with and how it operates is thus possible.

Difierences in terminology and in the philosophical bases of linguistics exist, but the actual work is seen to be along much the same lines everywhere.

As has been said, linguistics is a science; it involves the making of preliminary observations about a set of occurrences; the formulation of a working hypothesis about the events — their cause, relation, effects, and so on; further and detailed observations in terms of the frame of reference provided by the hypothesis; making statements about the events and their interrelation and function as parts of a system; testing the validity of the statements, with reformulation if necessary. As a social science, linguistics must observe events in statistically or otherwise valid samples, and must test its statements by comparing the events in different observational sets: that is, in different languages.

The field of linguistics in its largest aspects — those including all the studies associated with language—may be called macrolinguistics. This total field may be divided into three parts: prelinguistics, microlinguistics and metalinguistics (*see* Table II).

Prelinguistics is concerned with the study of the physical and biological events which enter into the act of speech (and hearing), and with the organization of the statements about these events in a form usable by the linguist. The linguist must have a body of knowledge about that part of the physical and physiological activity of speakers and hearers that produces language. He must know something about acoustics, and about the movements of the speech-articulating organs. This involves also some knowledge of the neural activity in the brain of the user of language. This information must be classified and arranged for the linguist by the physiologists and psychologists working with the material, and it must be classified in terms of the linguistic goal sought. That is, in physiology as such there are no organs of speech. But certain organs of the body are concerned with speech, and the linguist wants to know what these organs do and how they function. This aspect of prelinguistics calls for a description of the organs concerned, first in terms of their size, shape, and relation to each other, and then by the kinds of movements they are capable of and the sounds that are thus produced. Further, there is then needed a description of the ear and its sound-receiving mechanism, and of how this mechanism works. The linguist also asks the physiological psychologist to tell him about the parts of the brain that seem to be concerned with speech production and reception, and to indicate their function. This latter information was still largely unavailable in the later 1950s.

With a knowledge of prelinguistics, the linguist then begins microlinguistics, or linguistics proper. When the term linguistics is used generally, it refers to microlinguistic analysis unless specifically extended. In microlinguistics there are three main fields of interest: the analysis of the sounds of language, the analysis of the grammatical forms, and the analysis of the reference of these forms (their meaning). The analysis of sounds has several aspects: it deals first with the articulation and perception of sounds (based directly on the prelinguistic data alluded to above), then with their classification as speech sounds; this makes up the broad field of phonetics — subdivided into articulatory phonetics, acoustic phonetics and phonetics proper. Phonetics is then used to determine the varieties of sounds occurring in a language, and to classify them into significant contrasting units, called phonemes; below under *Phonology* details of phonetic classification and the principles of phonemics will be presented.

The analysis of sounds is involved in one further step, the study of the functioning of phonemes in the actual grammatical forms; the usual term for this aspect of the analysis is morphophonemics, which will be discussed below, under *Morphology*. The analysis of the forms of language begins with consideration of the morphophonemics, which is based directly on the phonemic analysis. It goes on to establish the units of form, the morphemes, in morphemics; this constitutes the morphology. A further and partially overlapping aspect of form analysis is the examination of the mords of a language as such; this starts from the morphemes composing the words and ends with the description of the kinds of words and their structure.

This leads then into the study of syntax (see below), where words as parts of constructions are examined: and the kinds of constructions they enter into are determined. There are several levels of syntactic analysis, involving successively larger combinations — words into phrases, phrases into clauses, clauses into sentences. At this point the microlinguist reaches his final and highest analytical level, the one where he begins to examine the references of linguistic forms. As microlinguist, however, he still limits himself to the linguistic system: he studies the restrictions on the distributions of words and constructions in terms of what precedes and follows them. This level of analysis has been investigated only slightly, and the necessary techniques can only be guessed at.

After the microlinguist has taken his analysis as far as he can, the metalinguistic examination of language is ready to be begun. At this level the distributional facts of the linguistic forms are taken as known, though in actual fact no such completeness of data has yet been achieved for any language. The known forms are now examined in relation to other cultural systems. The accompanying vocalizations and gestures (see LANGUAGE) may be studied in terms of the words and constructions they go with. Then the relationship of language usage to all other cultural systems — society, economic practices, the relations of men and women, the material resources of a people, and so on, may be examined systematically. This will be further discussed below.

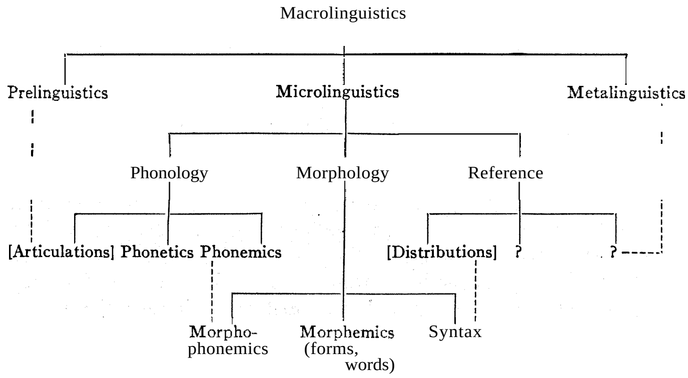
PHONOLOGY

The linguistic analysis of the sounds of language as a whole and of specific languages can be considered under three headings: (1) the study of the articulation of speech sounds; (2) the classification and description of speech sounds (phonetics); and (3) the functioning of speech sounds in the language structure (phonemics).

Articulation of Speech Sounds.—From the very beginning of the study of language there has existed a series of observations of the articulatory movements that produce speech sounds. Certain sounds have been described as produced by movements of the lips, others by the tongue, some as coming through the nasal passage, others as purely oral, and so on. These descriptions were the basis of the classification of sounds arrived at in phonetics.

Before modern times, the descriptions were at times fanciful or incorrect, and in any case were often incomplete because of the impossibility of observing internal activity in the mouth or elsewhere. During the 19th century there were developed various kinds of apparatus which enabled more accurate descriptions to be made of the movements of the articulatory organs. In the first half of the 20th century there were developed techniques for takin X-ray pictures of speech in action, and for analyzing the acoustic components of sounds. Thus arose the special fields of articulatory and acoustic phonetics (often referred to together as instrumental or experimental phonetics). In these fields much of the actual work is prelinguistic, being concerned with physics and physiology, but it goes over into the microlinguistic field of phonology as soon as it restricts itself to the actual descriptive bases for the classification of speech sounds as such. The descriptions of articulations on which most phonetic classification is based are found to be confirmed by modern acoustic analyses. The latter have been made principally with the help of such machines as the sound spectrograph.

TABLE *11.—Summary of Divisions of the Total Field of Linguistics**



*The terms in brackets above are the words for the subject matter of fields for which no common appellation exists. The question marks indicate lack of agreement as to what might be placed at those points. Dotted lines show interconnections other than those of direct subdivision.

Phonetics. — On the basis of observation of what happens when speech is produced, students of language, whether prescientific or scientific observers, have classified the resulting noises into various kinds of sounds. Phonetic description and classification, as has been said, have existed for a long time. In modern times there have been many studies of speech sounds in general and of the sounds of specific languages, and overall and basic classifications exist that are generally acceptable to workers in the field.

Speech sounds can be classified first into vowels and consonants. Vowels may be described as sounds produced in a resonance chamber (the oral passage, with or without the addition of the nasal passage) such that there is a minimum of interference with the freely and regularly vibrating air as it passes out from the throat passage Consonants, on the other hand, are produced so that there are various obstacles to the freely vibrating or moving air, with resultant noise or irregular vibrations introduced into the total sound. The position of the tongue in relation to the roof of the mouth and to the teeth, and the degree of spreading or rounding of the lips affect the kind of sound produced. Vowels are generally produced with the accompanying vibration of the vocal chords which is called voice, though voiceless vowels also occur. Consonants may be voiced or voiceless.

In articulatory phonetics vowels are classified by three criteria: tongue height, tongue advancement or retraction, and lip spreading or rounding. The usual practice is to show the classification as in Table III.

After the sounds have been classified, it is convenient to have symbols to represent them; such symbols are the letters of the alphabet, with additions and modifications as needed. A set of such symbols is called a phonetic alphabet. All phonetic alphabets are more or less alike, though differing in detail. It is not important what symbols are used, as long as they are carefully defined in terms of a table like that below. Such a table has predictive value also; until about 1950 the vowel sounds in the higher low and low front rounded positions had never been reported in any language: though any phonetician could make them; then a Mongolian dialect was found in which they were present, and it was perfectly easy to identify the sounds when they were heard. Using the initials F, C, B, U, R, H, Lh, Hm, M, Lm, Hl, L, we can exemplify some of the sounds in the table: HFU like French i in

TABLE III.—Table Used in Classifying Vowels

	Front		Central		Back	
	Unrounded	Rounded	Unrounded	Rounded	Unrounded	Rounded
High						
Lower high						
Higher mid						
Mid						
Lover mid						
Higher low						
Low						

si, LhFU like English *i* in *hit*, HmFU like French *é* in *café*, MFU like English *e* in *met*, LmFU like French e in *nette*, HlFU like English a in *hat*, LFU like French *a* in *patte*, HFR like French *u* in *tu*, MCU like English a in *sofa*, LBU like American English o in *hot*, HlBR like Southern British *o* in *hot*, etc. Sounds that are slightly different from the standard as defined by the table can be described by modifying terms and denoted by symbols with added diacritics; thus Spanish *i* in *si* is lower and less tense than French *i* in *si*; if the symbol [i] is used for the French sound, the Spanish one can be denoted by [i̫ˇ], where ˇ means lower, and ˬ means relaxed. It is customary to put phonetic symbols in brackets.

Consonants are classified in a table showing place of articulation and manner of articulation as in Table IV.

Bilabials are made with the two lips, as *p* in *pit*, *b* in *hid* (voiceless and voiced bilabial stops respectively), *m* in *mid* (voiced nasal). Labiodentals are the *f* and *v* sounds (voiceless and voiced spirants). Apical sounds are made by the tip of the tongue against the teeth (dental—as *th* in *thin*, a voiceless spirant). the upper gums back of the teeth (alveolar—as English *t* in ***tin***, a voiceless stop), or slightly raised or curled back of the gums (cacuminal—as American English *t* after *r* as in *hurt*, a voiceless stopj. Frontals or palatals are made by the middle portion of the tongue (the "front" technically) against the roof of the mouth; English *sh* in *shoe* is for most speakers a midpalatal voiceless spirant. Dorsals are made by the back of the tongue against the roof of the mouth: English *c* in *car* represents the midvelar voiceless stop. A glottal spirant is English *h* in *hot*. Stops are made by closing the passage and then releasing it. Nasals are stops with accompanying opening of the nasal passage. Spirants are sounds made by approaching the articulating organs but leaving part of the passage open. Laterals are made by leaving a passage open at one or both sides of the articulator (as 1 in English *low*). Vibrants are made by rapidly striking the articulating organs together; the sound represented by *brrr*, indicative of cold. is usually a bilabial voiced vibrant; the heavily trilled *r* of Spanish *rcy* is an alveolar voiced vibrant; some speakers of Parisian French use a postvelar voiced vibrant for *r* in *rouge*. As in the case of vowels, symbols can be devised for all the sounds in the table. and various other symbols and modifiers added for sounds not shown in the table as here given.

In addition to vowels and consonants. various other sound phenomena can be recorded, such as pitch (high, mid, low, falling, rising. etc.), stress (loud. medial, soft, etc.), quantity (short, long, extra-long, etc.), and various kinds of voice qualities and other modifications (nasal twang, whisper, etc.) There is less agreement on these phonetic phenomena than on vowel and consonant analysis.

Phonemics. — In every language the number of different sounds is often quite large, but the number of significant differences is smaller. For instance; in English the word *pit* begins with a voiceless bilabial fortis (tense) stop, with aspirated release; in *spit* the *p* represents a voiceless bilabial lenis (lax) stop, with smooth release into the vowel; in *upper* the internal consonant sound is a voiceless bilabial fortis stop with smooth release; in *up* the final consonant is usually a voiceless bilabial fortis stop without release. The phonetically untrained speaker of the language is unaware of these details, and to him these are all the "same" sound. On the other hand, the difference between the voiceless bilabial sounds in *pit, ripping, rip* and the voiced bilabial lenis stop in *bit, ribbing, rib* is heard and noted by the speaker of English. In the latter case he does not note, however, that *b* in *bit* begins without voice, *b* in *ribbing* is fully voiced, and *b* in *rib* ends voiceless.

The various *p* sounds discussed are said to be the members of a class of sounds which, as a whole, makes a significant difference from (is in contrast with) other such classes. Such a class of sounds is called a phoneme. It is customary to represent phonemes by symbols chosen from among the symbols used for the various members of the class. and to enclose them in slant lines; *i.e.*, the phoneme /p/, the phoneme /b/, etc. The members of a phoneme are called its allophones. The allophones of a phoneme are said to be in complementary distribution: that is, each occurs in statable positions in relation to the beginning or end of the item examined, or to other sounds, and no two allophones occur in the same positions: thus aspirated *p* is an initial allophone of /p/, lenis *p* is the allophone after *s*, fortis with smooth release is the allophone between vowels if the following vowel is weak. unreleased is the allophone in final position. Another criterion for phoneme membership is phonetic similarity: all the allophones of English /p/ are voiceless bilabial stops, but the /b/ allophones are also bilabial stops, so that mere phonetic similarity is not enough to decide whether one has only one phoneme or more than one. The criterion of complementary versus contrasting distribution is first. then that of phonetic similarity.

By the methods sketched. with additional refinements of detail, all the sounds of a language are grouped into a limited number of phonemes. Some languages have relatively few phonemes—say about 1 j, others have as many as jo or even more. The phonemes are of several classes: some vowels, a number of consonants, possibly several stresses and/or pitches. and some juncture (or transition) phonemes. One analysis of English establishes an overall pattern for the language as a whole of 45 phonemes: nine vowels, three semivowels, 21 consonants, four stresses, four pitches and four junctures. The vowels are as in *pit, pet, pat;* the adverb *just* as pronounced in most American English—often jokingly spelled *jist; cut;* American English *cot; put;* eastern New England *coat;* British or New England *cot.* The semivowels are: the y-like off-glide in the so-called long vowels and diphthongs in *see, say, sigh, soy* (and others, as any of the nine vowels can be followed by this off-glide); the *w*-like off-glide in *do, go, now* (and others), the centring off-glide in the usual eastern and southern American and British *dear, dare, cur, car, poor, core, war* (whether the *r* is fully heard or not) The

TABLE IV.—Consonant Table Showing Place and Manner of Articulation

Spirants													
Lateral,													
Vibrants													

consonants are as in the initials of *pit, tip, kick, bid, dig, go, chap, jet, fit, thin, sin, shin, vat, then, zone,* the internal consonant in *azure,* the initials of me, *now,* the final in *sing, low, row;* the consonants *w, y,* and *h* in *wet, yet, hot* are prevocalic allophones of the three semivowels mentioned before. The stresses are as in *elevator-operator* where *el-* has primary, *op-* has secondary, *-va-* and *-ra-* have tertiary, and the other syllables have weak stresses. The pitches are as in ^{2}*I* ^{3}*saw him*^{1}—beginning with middle pitch, rising to high on *saw,* and falling to low at the end; if *saw* is emphasized it has pitch 4, extra high. The junctures are: internal open, as in *night rate* contrasted nith *nitrate;* clause-terminal sustained as after the first *him* in *The first time I saw him I didn't like him;* rising as at the end of the sentence *Do you mean it?;* fading as at the end of the usual declarative sentence in English.

The phonemes constitute the basic structure of the material of the language, and it is out of them that the grammatical forms, to be considered next, are formed.

MORPHOLOGY

The material of a language alluded to above is generally taken to be its words. This layman's approach is confirmed by linguistic analysis. When a child learns its native language, or anyone learns a foreign language, it is the words that are first apprehended as more or less indivisible units. Of course, as accuracy increases, one specifically learns the sounds as recurring units, and in this sense phonology is basic to the further analysis of a language. However, morphological study is possible even when the phonology of a language is imperfectly known.

As was the case for phonology, the overall term morphology can be considered under three headings: (1) the study of the phonemic structure of grammatical forms and words (morphophonemics) ; (2) the analysis of the forms themselves and of how they enter into words (morphemics and the lexicon) ; and (3) the arrangement of the words in larger units such as phrases, clauses and sentences (syntax).

Morphophonemics.—This part of morphology can be done only for languages whose phonology is rather well known. If the records of an extinct language are in a writing system that uses unit symbols for whole words—as was the case for ancient Egyptian and for Sumerian—then it is obviously not possible to know much about the phonemes of which the words were composed. In the case of existing languages, if only some conventional written form of the language is known, there are likely to be parts of the phonology that are not represented in the writing, and thus the phonemic make-up of some of the morphemes may be in doubt or unknown. Even for those languages that have been most studied and analyzed. linguists still have doubts about some aspects of the phonology, so that morphophonemic statements cannot be complete.

For English the kinds of morphophonemic statements that can be made may be illustrated. It is observed that English words may begin with a vowel; of the nine simple vowels indicated above, five are common as initials—those in *it, elder, at, up, otter;* in weak-stressed syllables, a sixth vowel occurs frequently, that used in *exception, event,* and other words by people who use the *cut* vowel in *above, allow,* but the *"jist"* vowel in *exception,* etc. The vowel of *put* occurs initially for some speakers only in the exclamation *oops* (others use the vowel-plus-semivowel of *food* in this word) ; in *obey* and other words spelled with *o* there may be instances of the short vowel also found in New England *coat;* in *already* as pronounced by some the ninth vowel is found. English words may also begin with one of the vowel-plus-semivowel combinations; the actual occurrences vary in different parts of the English-speaking world. An English word may begin with any of the single consonants except the *ng* of *sing.* Also found initially are groups of two or three consonants; the two-consonant clusters are numerous but of certain kinds only—tr- exists but not *tl-,* while both *pr-* and *pl-* are found; there are only a few three-consonant clusters—spl-, *spr-, str-,* /skl/ spelled *scl-,* /skr/ spelled *scr-,* /skw/ spelled *squ-,* /spy/ in words spelled *sp* before *u* or *eu* or *ew,* /sty/ in words spelled *st* before *u* or *eu* or *ew* (but many speakers of English do not use the /y/ in these words). English words may end in a weak-stressed short vowel, or in a vowel-semivowel combination with any stress, or in any single consonant, and in clusters of two, three, or four consonants—the last two kinds being few in number. Every English word has at least one vowel, and when said by itself has one (and only one) primary stress. English words may be of one syllable (*i.e.,* with one vowel). or of many syllables, though most are of one, two or three syllables. Various stress patterns are noted in English words: *upper, above, animal, allowing, entertain,* etc. All English utterances, whether long or short, are said with a sequence of pitches of some kind, the most usual (declarative sentence) being 2-3-1, the 3 falling on the syllable with the primary stress.

In addition to the kinds of statements just made, it can also be said about English that there are many instances of addition of one or two (or occasionally more), sounds to a word to form related words: *cat, cats; bed, beds; rose, roses; go, going; nice, niceness; starve, starvation.* In some cases there are noted changes in the original form: *knife, knives; tuke, took; vain, vanity.*

A complete morphophonemic analysis has not been made for English or any other language. But Pāṇini for Sanskrit made a very extensive analysis of the morphophonemic relations.

Morphemics.—The examination of the kinds of phenomena discussed under morphophonemics makes possible the segmentation of the material of a language into various kinds of structural grammatical units. This is done by noting what may be called recurrent partials. Thus in observing the English forms *boy, boys, girl, girls,* one sees immediately the recurrent partials *boy, girl* and *-s.* In comparing *boy, boiling* to *prince, princeling* one might be tempted to set up the partials *boy (boi-), prince, -ling,* but a further look at the situations in which the forms are found shows that *boiling* does not relate to *boy,* but is rather connected with *boil* as *doing* is with *do,* giving the segmentation *boil* and *-ing.* The recurrent partials that are established are then grouped together by the principle of complementary distribution (parallel to the grouping of allophones into phonemes); they are allomorphs of morphemes. In most morpheme analysis the short cut is taken of grouping allomorphs by finding their meaning; similar meaning is taken to mean that the forms belong to the same morphemes. But this can lead to all kinds of structural misapprehensions; if *subscript* and *underwritten* have similar meanings when the parts are separated, does this mean that *sub-* and *under-* are the same morpheme, and that *-script* belongs with *written (write)?* The answer is clear: criteria of distributional position must be used in morphemics as in phonemics, and meaning can at best be a guide to what to look for.

The morpheme structures of languages are extremely varied. In English it is possible to distinguish inflectional morphemes, derivational morphemes and base morphemes. Inflectional and derivational morphemes in English are suffixes—they come after the base, inflectional suffixes being last. In addition to bases and suffixes, it is found that we must recognize superfix morphemes in English: these are the patterns of stress (with or without one or more internal junctures), that close, as it were, the formational process of a word. Thus *boy, boys, boyish, boyishness, boyishnesses* are analyzed morphemically as follows: base *boy-;* inflectional suffix *-s* (pronounced /z/); derivational suffixes *-ish* and *-ness;* inflectional suffix *-es* (pronounced /ïz/ —ï being the high mid vowel of the first syllable of *event, see* above) ; superfixes "primary stress" on *boy* and *boys,* "primary-weak" on *boyish,* "primary-weak-weak" on *boyishness,* "primary-weak-weak-weak" on *boyishnesses.* English also has some morphemes like *pre-, in-,* a-, *be-, re-,* that precede the base; these function like special kinds of bases, and are best labelled pre-bases.

In some languages there are real prefixes that function like suffixes in inflection or derivation. Classical Arabic has forms like *katabat* "she wrote," with *-t* for feminine third person subject, but *taktubu* "she is writing," where the prefix *t-* is the sign of the feminine. In the language of Taos Pueblo, New Mexico, most subject and object relations of verbs, and the indications of possession for nouns are shown by prefixes: *tik'ôlą* "I ate it." where *ti-* means first person subject and third person singular object of one of five classes; *kikána* "our mother." where *ki-* means "our" (we being more than two). Some languages also have infix morphemes: Latin *relinquō* as compared with *relictus* shows an old *-n-* infix that originally functioned freely in proto-Indo-Hittite. Another kind of morpheme may be called pattern morphemes: in Arabic *kataba* the base (or "root") is *k-t-b* "to write" and the pattern *-a-a-a* indicates suffix tense (perfect); in *taktuba* we have the same base, but the pattern is *a--u-a* indicating the prefix tense (imperfect).

The inflectional morphemes of a language occur in sets that are labelled paradigmatic, and form paradigms of inflection. The paradigms are the basis for determining the kinds of words ("parts of speech") a language has. English has paradigms like the following: *boy, boy's, boys,' boys'; man, man's, men, men's;* these establish the class of words that may be labelled nouns; nouns are then defined as words that have inflection for plural and for possessive (or for one of these). The paradigms *go, goes, going, went, gone; talk, talks, talking, talked, talked,* etc., establish the word class of verbs, defined as words inflected for past and, in most cases, also for gender-indicated subject in the nonpast (*he, she,* it *talks),* present participle, and past participle. English also has the personal pronouns **I,** *you, we, he, she, it, they, who* (and *thou*), with an irregular inflectional pattern (**I,** *me, my, mine,* etc.). All other English words are uninflected (including adjectives with derived comparative and superlative), and their further classification as adverbs, prepositions and so on is made by syntactic criteria *(see* below).

Each language has its own patterns of inflection and its own set of parts of speech, with definitions specific to the language. In French, adjectives are defined as words inflected for gender (feminine *bonne,* masculine *bon)* as well as for plural (*bonnes, bons*), while nouns have only plural inflection (*homme, hommes*). Latin nouns are defined by inflection for five cases (a few have six) in the singular and four in the plural. The Nootka language of the Indians of Vancouver Island has only noninflected words (a few) and inflected words. All the inflected words have a complex inflectional system. some of the forms being translatable as nouns, some as adjectives, and so on; thus the base meaning "human" can have a nounlike form meaning "a man" and a verblike form meaning "he is a man." If a language has no inflection, and also no derivation by suffixes. as is the case in modern Chinese, then its words can be classified only by syntactic means, and not by morphemic ones.

Syntax. — The words of a language having been analyzed and their constituent morphemes determined, the next step in analysis is to find out the kinds of constructions in which they occur. In most, if not all, languages it appears that there exist morphemes of a special type which determine some of the constructions. In addition to these there are also factors of order and arrangement which constitute a higher analytical level than that of morphemes. In syntax, as in the other subdivisions of morphology, it has been traditional to establish the limits of constructions and to designate their functions in terms of meaning. But it is possible to make the analysis entirely in terms of the special morphemes mentioned and the higher-order arrangements; when this is done, it is seen that the linguistic material. here as elsewhere, furnishes its own analysis, and that this analysis can then serve as the basis for beginning the study of meanings and other metalinguistic matters.

In English the first level of syntax involves combining words into phrases. This is accomplished by morphemes of a special type, the phrase superfixes. Phrase superfixes consist of arrangements of stresses such that there are one primary stress and one or more other stresses, and there may be one or more internal junctures. This description sounds like that of word superfixes (above), but while there are as many word superfixes as there are different stress patterns in English words, there are only relatively few phrase superfixes. Moreover, the stresses of the phrase superfixes are dependent on and supersede the word stresses in stated ways. The word *writing* has the word superfix primary-weak, as does the word *paper;* there is a phrase superfix primary-internal juncture-tertiary, which, when applied to these two words in sequence, results in the phrase *writing paper* with stress pattern primary-weak-internal juncture-tertiary-weak; that is, the primary of the phrase superfix replaces the primary of the first word, while its tertiary replaces the primary of the second. To illustrate other phrase superfixes we shall use the marks ′ for primary, ^ for secondary, ˋ for tertiary, ◡ for weak, + for internal juncture. Examples are ˋ+′ *get up* (verbal) — but cf. ′+ˋ*get-zip* (a nominal phrase); ′+^ on *white house* in the sentence "I mean the *white* house, not the brown one"—*cf.* ′+ˋ in *White House;* ^+′ on *white house* in "We live in the white house you see down the street"; ′◡ (without juncture) in "Do it"; ◡(+)′ (with or without juncture) in "the man"; etc.

Larger units than the phrases illustrated are clauses. A clause is determined by an intonation pattern, which is a morpheme consisting of three or four pitch phonemes, and a terminal juncture. In the sentence "He said he'd like to see you before you leave," there are two clauses in this sense "^{2}He said he'd like to ^{3}see you^{2}" with sustained terminal pitch. and "^{2}before you ^{3}leave^{1}" with fading terminal pitch. The intonation patterns are *2–3–2-* sustained and 2–3–1-fading.

In syntactic analysis in a language like English, the first task is to determine the clauses and their intonation patterns. Then the clause is separated into its phrases, which often overlap; in the sentence illustrated just above the first clause has the phrases "he said" with ˋ+′, "he'd like" with ˋ+′, "to see" with ◡+′, "see you" with ′+ˋ; these combine so that only one primary (′) remains (on "see"). and the others are reduced to secondaries (^), giving ˋ+^+ˋ+^+◡+′+ˋ; in the second clause we have "before" as a separate construction, with primary here reduced to secondary, and "you leave" with ˋ+′. The various phrases can be given labels in terms of the kinds of functions they have: "he said" is a pronoun-plus-verb phrase and has a subject "he" and a predicate "said"; "he'd like to see you" is a complement of the verb "said" and as such is like a simple noun; we use the term nominal for it; it is divided into a subject-predicate part "he'd like" and complement "to see you" (a nominal, usually called the infinitive), and this latter has the verbal "to see" and the pronoun complement "you." Further statements can be made about the order of the items; what precedes a verb or verbal phrase is the subject; the complement follows.

Other constructions also have their rules of order—as the adjective preceding the noun in *good book,* the auxiliary preceding the participle in *is going,* the negative following the inflected verb in *do not.* Associated with rules of order are common superfix and intonation structures: the complement, whether nominal or adverbial has primary stress, unless it is a pronoun object, in which case it is weak or tertiary; prepositions have weak or tertiary stress before a noun *(in bed* ◡+′, *over water* ˋ◡+′◡), and tertiary stress when clause-final ("that rug is pleasant to walk on" ^+^+◡+^◡+◡+′+ˋ).

The syntax of any language can be arrived at in analogous ways. The phonologically determined parts of a discourse are found, and their constituent phrases separated out; then the make-up of the phrases in terms of inflected words is discovered and equivalents of inflected-word functions are determined. Then other words can be labeled with appropriate terms. Similar terms may be used in many languages, but the definitions and rules are determined by the actual usage and structure, not by philosophical speculation on meaning.

ANALYSIS OF MEANING; APPLICATIONS

Distributional Meaning. — When the syntactic analysis of a language is well advanced, it is then possible to begin determinations of the distribution of classes of words and of individual words and also morphemes, to find the limitations on their use which will indicate the metalinguistic structure (referential meaning—see below). Thus we find in English that we use *beautiful* with such words as *house, grass, woman* but more rarely and for special effect with *shack, weeds, man;* we find that *handsome* before *man* is apparently equivalent to *beautiful* before *woman,* but with *shack* and *weeds* no equivalent seems to occur. When the verb *massacre* is used, the object must be plural or collective;

when *mill around* occurs, the subject is plural or collective. By such observations, it is possible to establish all kinds of subdivisions of the different parts of speech and of constructions on the basis of what other kinds of words they go with, thus determining their distributional limitations. This sort of examination of distribution has not been done for any language except occasionally in studies of special literary works and of small sections of the total vocabulary.

Another aspect of distributional studies is one illustrated by the phrases *awe-struck* and *grief-stricken*. Both *struck* and *stricken* are morphemically past participles of the verb *strike*, and each has the syntactic function of an adjectival word in the two expressions. But one never says *awe-stricken* or *grief-struck*, nor does one say He *was stricken by a car*, though one can be *stricken by affliction*.

Distributional studies can be extended from individual words and constructions to whole discourses. That is, examining a speech, for instance, one can observe how one part of it follows another and establish relationships and predictable sequences. This leads directly to the analysis of what may be called congruence. In a legal text one must necessarily use words different from those in a popular lecture; a professor speaking to his class uses different words than when he speaks to his family; or if he does not, he becomes an object of ridicule. This brings us finally to the whole matter of the analysis of style, and of the criteria that constitute different styles. Discourse analysis, congruence analysis, and studies of style are microlinguistic disciplines that have been hinted at by linguists but only barely begun.

Referential Meaning.—All users of language since the dawn of mankind have of course been concerned with the reference of the linguistic forms they use to the rest of their behaviour and to the universe about them. In a practical way all speakers know the "real" meaning of what they say. But this "real" or referential meaning can be scientifically studied only by having extensive analyses of the linguistic structure and of the rest of the behaviour. That is, the child, in learning his language, points to objects and asks questions; when he encounters abstractions, he learns their meaning by observing the accompanying behaviour. He learns his total culture as he grows up and learns the accompanying language behaviour. The macrolinguist, in extending his interest from the highest levels of microlinguistics—those just discussed under the heading of distributional meaning—to referential meaning, extends his activity to what we are calling metalinguistics. He seeks to analyze or have analyzed for him all other cultural systems along lines analogous to those used in linguistic analysis. He suggests that analysts of culture should determine for their various fields units comparable to the phonemes, morphemes and distribution patterns of language. When such studies are available, then he believes it will be possible to establish point-by-point relations between language, as linguistically analyzed, and the other analyses.

In the meantime, meanings continue to be established by description, discursive speculations, and exposition of concrete objects and behaviour.

Translation.—In the light of what linguistic analysis holds theoretically desirable for ascertaining meaning, it is seen that translation can at best be approximate until more extensive metalinguistic studies have been made. When translation is between two languages that are structurally similar and whose speakers are culturally related as a whole, as between English and French, it is possible for the skilful translator to convey real equivalences of meaning in all or nearly all cases. Furthermore, if the material being translated is technical in nature, and speakers of both languages practise the particular technology, direct and exact translation is often possible. But if the languages in question are dissimilar structurally, as are English and Vietnamese, and the cultures as a whole are different, as are those of America and of Vietnam, then the problem of translation becomes very great; one really has to have full microlinguistic analyses of both languages and extensive general cultural knowledge and analysis.

A problem that has interested some researchers, especially since the development of electronic calculators, is that of a machine to do translation. That such a machine is theoretically possible is beyond doubt. and in 1953 a mechanical translator was actually demonstrated for a short and specialized text translated from English to Russian. The further development of such machines will call for the most extensive kind of microlinguistic studies, especially of morphemics and syntax, and very searching investigations into at least the general outlines of other cultural systems. The number of relationships that will have to be coded into a mechanical translator may be very large, but it will be finite and thus subject to such treatment.

Linguistics and **Education.**—A large aspect of education in all countries is the teaching of the use of the native language and, at higher age levels, the teaching of foreign languages. Both of these activities can increase their effectiveness by use of the results of linguistic knowledge. The native language is usually taught as an accumulation of traditional lore about sounds and their representation in spelling, "correct" and "incorrect" grammar, style, and so on. These are all matters to which the science of linguistics, as described above, can bring useful and usable findings. When the phonology of a language has been properly analyzed, the teaching of the writing system, no matter how complex it may be, is facilitated and regularized. The teaching of the use of a standard or literary language is maximally effective when the structures of that language and of all other languages or dialects involved are well known. The teaching of effective writing and good style depends on having objective criteria for measuring the goals.

In addition to these direct kinds of assistance, linguistics can also help in the total process of education. Most teaching, and especially most schooling, is in terms of linguistic interaction. Knowledge of the structure of the language material, of the prelinguistic facts about it, and of the metalinguistic relations of the language to the rest of the culture (which is the content of the school curriculum) can obviously help in imparting the desired material to the learner.

As a social science, then, linguistics is based on the physical and biological sciences, its analytic procedures may serve as a model for the other social sciences, and its results can be embodied in practical applications to education and the various humanities.

LINKAGES, in mechanics, are combinations of links or bars, in general connected by pins, slides, rollers or screws. If the combination is such that no relative motion can exist between the parts a structure results. If the links can move relative to each other the linkage becomes a kinematic chain. Specific forms of kinematic chains are useful when the motions of the links are controlled so that constrained relative motion results. Such linkages are commonly referred to as mechanisms when the transmission of energy is not important.

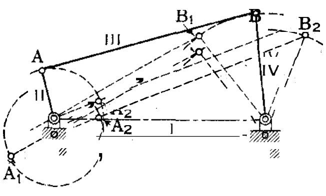

FIG. 1.—FOUR-BAR LINKAGE

Many linkages, or mechanisms, are used to obtain specific motions with little regard to the performance of work. Such devices as watches, typewriters, record changers, mechanical computers and working models are of interest for the relative movements of the parts, not the energy involved. Machines, however, commonly involve the performance of work or the transmission of power to some useful end.

Thus, practically all machines may be thought of as being mechanisms or linkages in various combinations in which work or energy is significant. The automobile, for example, is made up of many linkages, some of which—parts of the engine and transmission—function as machines, while others—steering and throttle linkages—are present primarily to provide certain desired motions of the parts.

Historical Background. — Many linkages in common usage, have had their origin in centuries past. From the time of the great early Egyptian civilizations, the minds of men have sought means to produce motions not obtainable with the human hand alone. Multiplication of effort, faster speeds, more complex motions over greater distances or in smaller spaces have been the goals of such men as Archimedes, Hero of Alexandria. Leonardo da Vinci, James Watt and others.

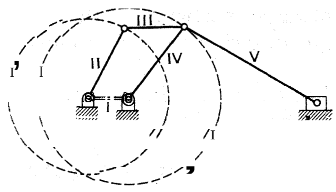

FIG. 2. — DRAGLINK MECHANISM

Hinged tongs were in use as early as the 6th century B.C. The screw of the Archimedean screw was invented. according to some authorities. around 400 B.C., and was in use in Egypt before Archimedes' time. By the 1st century A.D. the lever and the screw press were in use for crushing grapes. The ratchet and pawl (see RATCHET AND PAWL) were shown in types of crossbows described by Hero and Philo in the same century. A linkage for operating a fascinating hydraulic organ also was described by Hero. But for nearly 1.000 years, from about A.D. 400 to 1400, little advance was made in the use of mechanisms and linkages.

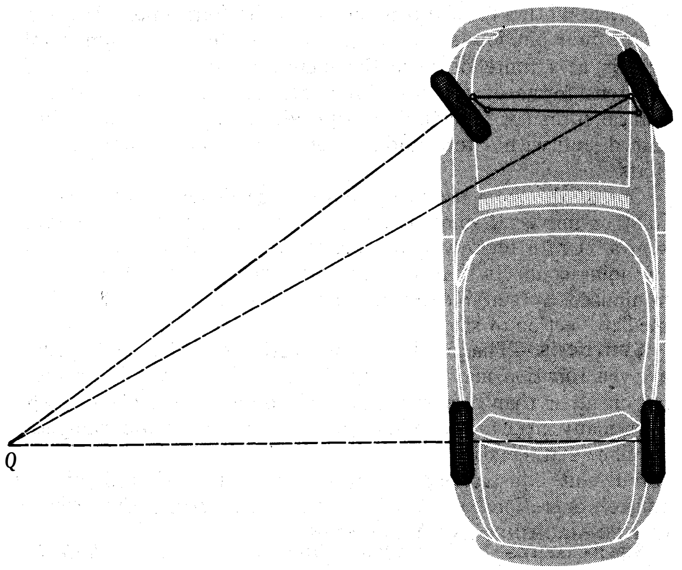

FIG. 3. — IDEAL RELATION OF AUTOMOBILE WHEELS WHEN TURNING A CORNER

Then the gradual awakening of western civilization and development of the industrial age stimulated many new and improved devices. Weaving and spinning machines and machines of war occupied Da Vinci's thoughts with ingenious and far-reaching results. Stamp mills and water-driven bellows used crude linkwork in the 16th century, the joints being constructed of interlocking eyes, as are the links of a chain. The Industrial Revolution saw the rise of many new linkages and led into the development of complex devices such as the Stephenson, Walschaert and Joy locomotive valve arrangements. Better methods of analysis and precision of manufacture in the 20th century gave rise to increasingly precise and complex linkages in typewriters, computing devices. packaging equipment and manipulating mechanisms used to position, hold and transfer products of industry.

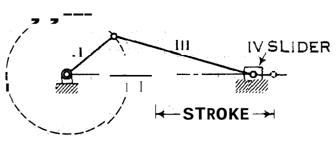

FIG. 4. — SLIDER-CRANKLINKAGE

Some giant linkages have been created, such as in some of the mining equipment of the 19th century. A mine pump in Germany is said to have had a connecting rod over 7,200 ft. long. In 1682 a French fountain display incorporated a linkage 2,000 ft. long, In existence in the mid-20th century was a water wheel 72 ft. in diameter that drove a mine pump on the Isle of Man. The 600-ft. long connecting rod was disconnected during the 1930s, but the wheel remained in operating condition. Some of the largest linkages continue to be employed in mining, as in the giant shovels used for removing overburden in strip mines.

FIG. 5.—HAND PUMP LINK MECHANISM

Classification. — Attempts have been made at classification of linkages using rules such as the number of degrees of freedom of the chain. A link with unrestricted motion is said to have six degrees of freedom since it can move in any one of three mutually perpendicular directions in space and can rotate in any one of three mutually perpendicular planes. Such criteria, however, can distinguish between structures and mechanisms in general but may fail for special cases where a point-by-point analysis will be required.

Basic to all linkages are the types of joints or pairs employed. Such pairs may be classified as higher pairs when line or point contact between the members is indicated. Examples of such pairs are ball bearings, cams and flatface followers. pins in slots and gear teeth. Lower pairs are pairs with geometrically similar areas in contact, such as plain bearings, a piston in a cylinder, and ball and socket joints.

FIG. 6. — WHITWORTHQUICK-RETURN MECHANISM

A further description is provided by the terms turning pairs (pin joints, sleeve bearings); sliding pairs (piston in cylinder, gears); and rolling pairs (balls and races in ball bearings, railroad car wheel on rail). A special pair having relative helical motion is known as a screw pair, as exemplified by the common bolt and nut.

Common Linkages. — The study of linkages generally begins with the analysis of some of the more common types and progresses to the more difficult problems of synthesis. One basic linkage is the four-bar linkage or quadric-crank mechanism (see fig. 1). This consists of four links connected by pin joints with one link (I) generally stationary. Link II is usually called a crank. link IV a lever, and link III a coupler. By varying the proportions of the links. various motions are transmitted to link IV as well as to points on link III. Thus, in fig. 1 the crank can make a complete revolution while the lever oscillates as shown by the dotted lines. This linkage can be used as a simple device to translate rotation into oscillation which. with a ratchet linkage. will produce an intermittent motion.

By altering the proportions the drag link mechanism, fig. 2, may be created. Here links II and IV both rotate completely, II at constant speed and IV with varying speed. This mechanism. when coupled with an additional link V, creates a type of quick-return mechanism commonly used in a Dill slotter, a machine for cutting keyways in shafts. If the links are paired with opposite links of equal length, a parallel linkage is formed such as is used in the cranks and parallel rod of a locomotive or in the Universal drafting machine, which is widely used in place of T squares and triangles. The automobile steering mechanism has generally employed a four-bar linkage to obtain the necessary differential motion of the two front wheels. Ideal performance dictates that the two wheels should operate as in fig. 3 in making a turn. Practically, a compromise usually is reached that provides for turning the wheels through unequal angles but does not attain a common centre of curvature at Q for the paths of all four wheels.

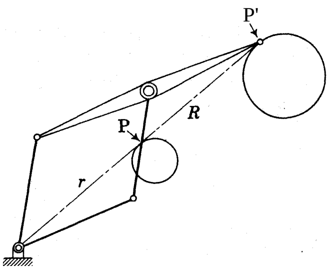
FIG. 7.—TOGGLE LINKAGE

The idea of inversion is very important in the study of linkages. A mechanism or linkage is said to be inverted when the originally fixed or reference link is permitted to move and a different link is held fast, without changing the basic proportions of the linkage. Such inversion changes the motions of all links relative to a fixed reference system but does not change the motions of the links relative to each other.

A quadric-crank linkage in which the lever, link IV, is permitted to become infinitely long is represented by the slider-crank mechanism, fig. 4. One of the pin joints has thus been replaced by the rectilinear sliding pair. In this form it is the familiar crankshaft, connecting rod, piston and cylinder of the internal combustion engine, air compressor or refrigerator compressor. Mathematical and graphical techniques have been developed to analyze the motions of this mechanism quickly and accurately.



FROM J. S. BEGGS, "MECHANISM"; REPRODUCED BY PERMISSION OF MCGRAW-HILL BOOK CO., INC.

FIG. 8.— PANTOGRAPH

Several inversions of this interesting and versatile linkage have been put to use. With link IV fixed, the common hand pump, fig. 5, results. By holding stationary the connecting rod, an oscillating piston and cylinder mechanism may be obtained, such as has been used in marine engines. Radial aircraft engines in which the cylinders rotated about a fixed crank were obtained from a fourth inversion of the basic slider-crank linkage at the time of World War I.

Inversiohs of the slider crank are frequently combined with additional linkage in modem machinery. The crank shaper, and the Whitworth quick-return mechanism, fig. 6, are devices used in machine tools where a reciprocating motion with controllable unequal times for advance and return strokes of the slider C are desired.

One quite useful variation is the toggle linkage, fig. 7. As the slider C approaches the end of its stroke it is capable of exerting a very large force F with a relatively low force P. By making AB = BC and having F act perpendicular to F, then

$$\frac{F}{P} = \frac{1}{2 \tan \alpha}$$

FIG. 9.— UNIVERSAL (HOOKE'S) JOINT

Stone crushers, presses, clutches, pneumatic riveters use forms of this device.

Straight-Line Linkages.—The production of a straight-line motion in a plane has intrigued the minds of many scientists and engineers in times past. Exact straight-line motions may be obtained by the Scott Russel linkage, Hart's straight-line motion, Peaucellier's movement and the pantograph, fig. 8. However, these devices are not widely used since straight-line motions are generally obtained with slides. In special cases where the slide cannot be mounted at the point that is to move in a straight line, these linkages, particularly the Scott Russel, or some type of approximate straight-line motion linkage, are used.

The classical approximate straight-line motion linkages are generally special cases of the four-bar linkage. The best known of these are Watt's, Roberts' and Chebichev's mechanisms. Some giant dock cranes employed for loading ships are examples of the use of the Roberts approximate straight-line motion.

The pantograph is useful in the redrawing of maps or other figures to a different scale, several arrangements of this linkage being possible. In fig. 8 point P′ will trace the same figure traced by P, but R/r times as large. By joining several such linkages together the common lazy tongs is achieved, a device much used as a telephone support, in toys and in a railroad freight car unloader.

Steam engine valve gears, rather complex linkages involving straight-line motions, were developed as the reciprocating steam engine came into use during the 19th century. The Baker valve gear became one of the most popular of these linkages for the steam locomotive.

Space Linkages.—The conic four-bar linkage enables relative spherical motion to take place between the four links. If the axes of the four pin joints are not parallel but have a common intersection at a finite distance the members remain movable. The different forms of the plane linkages can be reproduced in the conical form (or space linkage) provided the above rule is maintained, and with a few modifications to eliminate interference of parts.

One of the most useful of these space linkages is the Hooke's joint or universal joint, fig. 9, used for joining two intersecting shafts. Unfortunately, a varying angular speed ratio results when the joint connects shafts at an angle, though this defect can be minimized by suitable arrangement of two joints and an intermediate section of shafting.

Synthesis.—The problem of proportioning a linkage to perform a given function may be relatively difficult when using a combination other than a simple cam and follower (see CAM). However, many mechanical computing devices have been developed for specific mathematical operations and are in widespread use throughout industry, performing a great variety of production and control operations. See COMPUTING MACHINES, ELECTRONIC; OFFICE MACHINES AND APPLIANCES.

LINKÖPING, a city of Sweden, the chief town of the *län* (county) of Östergötland, situated on the Stang river near its outflow into Lake Rox, 100 mi. S.W. of Stockholm. Pop. (1960) 65,082.

A bishop's see was established about 1100. At a synod held in 1153 payment of Peter's pence (expenses toward the Holy See) was agreed upon at the instigation of the English legate Nicholas Breakspear, afterward Pope Adrian IV. The coronation of Valdemar, the son of Birger Jarl, took place in the cathedral in 1251. In the reign of Gustavus I Vasa several important diets were held in the town. In 1598 it was the scene of the battle against the Catholic king Sigismund III of Poland, which guarded the Evangelic Lutheran Church in Sweden and secured the Swedish throne for the Vasa dynasty.

The cathedral (c. 1100–1499 and restored in the late 19th century) is a great romanesque and Swedish Gothic building with a magnificent south portal and late Gothic choir; it has an altarpiece by Maerten van Heemskerck (1543) and a modern one by the Norwegian artist Henrik Sorensen (1931). In the church of St. Lars are some paintings by Pehr Hoerberg (1746–1816), the Swedish peasant artist; the remains of an older Roman church are preserved under the church floor.

Other buildings of note are the 13th-century castle (once the episcopal palace, afterward a royal palace rebuilt in the 16th century but now the residence of the governor of the county) and the old gymnasium founded by Gustavus II Adolphus in 1627 The Lutheran bishop's palace was erected in 1734 on the old site of a Franciscan monastery. There are also noted diocesan and city libraries and a modern museum (1939) with a picture gallery and collections of prehistoric art. Other museums are the Krogsfallsgården with two peasant houses, "Uncle Adam's House" with late 19th-century interiors and the Valla open-air museum with houses from the old city. The Fountain of the Folkungs by Carl Milles (1927), with an equestrian statue of Folke Filbyter, the mythical ancestor of the famous family, is in the Stora Torget (the principal square).

Industrial development came with the building of the Gota and Kinda canals and the Stockholm-Malmo railway. The town is a rail junction nith aircraft, freight car and automobile industries. Rope, textiles, tobacco and beer are produced. (B. J. C.)

LINLEY, THOMAS (1733–1795), English musician and father of a large family of musicians, was born at Badminton on Jan. 17, 1733. He studied music at Bath, and afterwards settled there as a singing-master and conductor. From 1774 he was engaged in the management of the oratorios performed at Drury Lane theatre, London. He composed or compiled the music for many of the dramatic pieces played there, including *The Duenna,* by his son-in-law Richard Brinsley Sheridan. In 1777 he was elected a member of the Royal Society of Musicians. He died in London on Nov. 19, 1795.

LINLITHGOW, a royal burgh and the county town of West Lothian, Scot. It lies on the south side of a loch. 18 mi. W. of Edinburgh by road. Pop. (1961) 4,327. In the 19th century its old-world appearance was much changed by rebuilding, and thereafter by the demolition of other buildings of local architectural merit. The outstanding feature of Linlithgow is the roofless royal palace (the birthplace of Mary, queen of Scots) and the parish kirk of St. Michael, standing together on the rising ground of the promontory which divides the loch into two nearly equal parts. The palace, a favourite abode of the kings of Scotland, is square in plan, enclosing an inner close in the centre of which stand the remains of the King's fountain erected by James V. At each corner is a tower provided with a turnpike turret. The north-western tower is crowned by a little octagonal cap-house known as Queen Margaret's bower from the tradition that it was from there that the consort of James IV watched for his return from Flodden. The original entrance, an imposing architectural feature, is in the eastern quarter, built in the first half of the 15th century; James V closed this entry and provided one in the south quarter. The north quarter, which contained the queen's suite, having become ruinous, was rebuilt for the "homecoming" of James VI in 1617. The royal apartments, the chapel and the Great hall, otherwise known as the Lyon chamber, were situated on the first floor. By the burning of the palace in 1746 by Gen. Henry Hawley's dragoons, Scotland lost a very historic and interesting architectural crown building.

Standing on the high ground southward of the palace is the mediaeval kirk of St. Michael the Archangel. In the early part of the 19th century the open crown spire was removed from the head of the tower, and thus the building was robbed of a typical Scottish feature. In front of the town hall (1662) is the Cross well, erected in 1807 by a one-handed mason. It is a copy of one made at the Restoration by Robert Myme, the king's master mason, who based his design on the King's fountain within the palace.

About 4 mi. S. by W. lies Torpichen, where the knights of St. John of Jerusalem had the chief Scottish preceptory. (J. S. Rn.)

LINNAEUS, CAROLUS (Carl Von Linné) (1707–1778), Swedish botanist after whom the world's system of classification of plants and animals is named. He was born on May 23 (N.S.) at South Rashult, where his father was a curate. His love of flowers developed at an early age. and it is recorded that when only eight years old he was nicknamed "the little botanist." He was educated at Wexio and at the universities of Lund and Uppsala, at which latter he qualified in medicine. It was when he visited Uppsala that he met the veteran botanist Olaf Celsius, an event that had a profound influence on his subsequent career. He was appointed lecturer in botany in 1730 and two years later explored in Lapland for the Academy of Sciences, the results of his journeyings being published in Amsterdam in 1737 as the *Flora Lapponica* and in English by Sir J. E. Smith as *Lachesis Lapponica* (1811). His reputation was established by this and, even more, by the appearance in 1735 of his *Systema naturae* and of the *Genera Plantarum* two years later. while the *Species Plantarum* did not appear till 1753. For purposes of nomenclature of flowering plants and ferns the first edition of the *Species Plantarum* has been internationally agreed as the starting point together with the fifth edition of the *Genera Plantarum* published in 1754. The *Systema naturae,* which Linnaeus had shown to Jan Fredrik Gronovius in manuscript, so impressed the latter that he published it at his own expense. This system was based mainly on the number of stamens and the number of pistils in the flower and the manner in which, if not free, they were joined together. Although artificial, as Linnaeus himself recognized, such a system had the supreme merit of enabling students rapidly to place a plant in a named category, and that at a period when the richness of the world's flora was being discovered at a rate which outstripped more leisurely methods of investigation. So successful was it in practice that its facile application was the greatest obstacle to its replacement by the so-called natural systems that superseded it. Linnaeus visited England in 1736 where he met Sir Hans Sloane in London, Phillip Miller at Chelsea Physic garden and Dillenius (Johann Jakob Dillen; *q.v.*) at Oxford. He returned to Holland to complete his work on the famous *Hortus Cliffortianus* and visited the Jussieu (*q.v.*) family in Paris with whom he became a close friend. A month later he was once again in Sweden and in 1738 settled in Stockholm as a practising physician, in which he attained considerable success. In 1739 he married the daughter of a physician, Sara Moraea, to whom he had been betrothed four years earlier. Two years after his marriage Linnaeus was appointed to the chair of medicine at Uppsala but a year later exchanged this for the chair of botany.

Henceforward his time was taken up by teaching and the preparation of other works. He issued his *Flora Suecica* in 1745 and *Fauna Suecica* in 1746; his two volumes of observations made during journeys in Sweden, *Wastgota resa* (1747) and *Skanska resa* (1751); his *Hortus Upsaliensis* (1748); his *Philosophia Botanica* (1751) and his important *Species Plantarum* (1753), in which the specific names are fully set forth. In 1755 he declined an invitation from the king of Spain to settle in that country with a liberal salary and full liberty of conscience. In 1761 he was granted a patent of nobility, antedated to 1757, from which time he was styled Carl von Linné. To his delight the tea plant was introduced alive into Europe in 1763. An apoplectic attack in 1774 greatly weakened him, and he died on Jan. 10, 1778, at Uppsala, in the cathedral in which he was buried.

Linnaeus delighted in devising classifications, and not only systematized the two kingdoms of living things, but even classified the mineral kingdom and drew up a treatise on the kinds of diseases. He was the first to enunciate the principles for defining genera and species and to adhere to a uniform use of specific names.

Of his 180-odd works those published during his lifetime were enumerated in R. Pulteney's *General View of the Writings of Linnaeus* (1781). His *epistolae ineditae* appeared at Groningen in 1830. His widow sold his collections and books to Sir J. E. Smith. the first president of the Linnean society of London. When Smith died in 1828 a subscription was raised to purchase the herbarium and library for the society, whose property they remain.

Bibliography. — T. M. Fries, *Linné, Lefnadsteckning,* 3 pt. (1903), Eng. version, *Linnaeus,* with full bibliography (1923); O. Levertin, *Carl von Linné* (1907); J. M. Hulth, *Bibliographia Linnaeana* (1907); O. Hjelt, *Carl von Linnés betydelse sasom naturforskare och iakare* (1907; German tr., 1908); and W. Junk, *Linné im Lichte neuerer Forschung* (1925).

LINNET, *Carduelis cannabina,* a common songbird, frequenting almost the whole of Europe south of lat. 64°, and in Asia extending to Turkestan. It is a winter migrant to Egypt and Ethiopia, and is abundant at all seasons in Barbary, as well as in the Canaries and Madeira. Though the fondness of this species for the seeds of flax (*Linum*) has given it its common name in many European languages, it feeds chiefly on the seeds of Compositae (ragweed, sunflower, etc.). The males in spring have a handsome crimson-red breast and crown. The song is pleasant but apt to be monotonous. The linnet begins to breed in April, the nest being generally placed in a low bush. It is a neat structure of fine twigs. roots or bents. lined with wool or hair. The eggs, four to seven in number, are of a very pale blue marked with reddish or purplish brown. Two broods are raised in a season.

JOHN MARKHAM

LINNET (CARDUELIS CANNABINA) AT NEST WITH YOUNG

The plumage of this small finch varies much with age, sex and season; each phase may have a different common name, such as red linnet. gray linnet. The name mountain linnet is applied to the yellow-billed C. *flavirostris,* which never has crimson on crown or breast. Green linnet is a common name for the greenfinch (*q.v.*).

In the southwestern United States linnet is a name for the house finch (*Carpodacus mexicanus* frontalis), familiar, nesting about houses and a good singer; and to the desert house finch (C. *m. solitudinis*), British Columbia to Nevada and eastern California.

(G. F. Ss.)

LINOLEUM: see FLOOR COVERINGS.

LINOTYPE, U.S. trade name for a hot-metal composition typesetting machine that casts printing type in lines (slugs). Basic operations of the machine are the assembly of matrices from a multichanneled magazine in which they are stored; justification of the assembled line of matrices by spacebands (adjustable spacing devices); forcing of quick-cooling molten type metal against the assembled and justified matrices; trimming and delivery of the cooling slug of type; and distribution of each matrix to its proper channel in the magazine, ready for re-use. Invented by Ottmar Mergenthaler (*q.v.*) in the 1880s, the Linotype revolutionized the printing industry, making possible more rapid typesetting, with one Linotype operator being able to set the same amount of type as several hand compositors. *See* also PRINTING TYPE; TYPESETTING.

LINSANG, a civetlike carnivorous mammal (Prionodon *linsang*), found from upper Burma through the Malay peninsula to Borneo and Java. Linsangs are slender in build, with short legs and long, banded tail. Their general colour is pale buff, the forehead and muzzle are brown and five broad black or brown transverse bands cross the back. Other longitudinal markings occur on neck and sides. This species is about 30 in. long. See CARNIVORE.

(J. E. HL.)

LINSEED AND LINSEED OIL. Linseed, an oilseed known also as flaxseed, is the seed of a variety of the common flax. *Linum usitatissimum*, which is cultivated principally in the United States. Canada. the U.S.S.R., India and Argentina for its yield of linseed oil and linseed oil meal. This variety of flax has shorter straw, more branches and more seeds than other varieties that are grown primarily for fibre to be woven into linen. World production of linseed is about 140,000,000 bu. per year; the United States, the Soviet Union and Argentina rank among the leading producers. (*See* also FLAX.)

Linseed is borne in globular capsules, each containing ten long, flat elliptical seeds with slight projections at one end. Sizes vary considerably; typical seeds are about 3–4 mm. long, 2–3 mm. wide and 0.5 mm. thick. Average weights range from 3 to 9 mg. The seeds, usually brown, are smooth and shiny and contain a mucilaginous substance in their outer layer that makes them sticky when wet. Beneath the seed coat is a thick layer of endosperm, inside which the main volume of the seed is occupied by the two cotyledons. Unlike most grasses, mature linseed is devoid of starch granules.

The oil content of the whole seed depends upon several factors, including the type of the linseed: maturity of the seed, locality. soil, temperature, rainfall and other conditions of climate and weather under which the seed is grown. The oil content usually ranges from 33% to 43% in air-dried seed having a moisture content of about 6%.

Linseed oil has a high iodine number (value), which reflects the high degree of unsaturation of its fatty acid radical. The oil is a mixture of the glycerides of linolenic. linoleic. oleic, stearic and palmitic acids. Its high iodine number (usually between 175 and 205, depending on the grade) is due mainly to the linolenic and linoleic acid components. Linseed oil is a golden-yellow, amber or brown liquid that is classified as a drying oil because it thickens and hardens on exposure to air (see also OILS. FATS AND WAXES). It has a low melting point (about −20° C.) and is a little more viscous than most vegetable oils. It is used in the manufacture of paints, printing inks, linoleum, varnish and oilcloth.

Linseed oil is prepared commercially in several grades, including raw, refined, boiled and blown. Raw oil is the slowest drying of all the grades. The refined grade is raw oil from which solid fats, fragments of seeds and other undesirable materials have been removed. Boiled linseed oil dries in less time than either raw or refined oil and exhibits improved drying qualities (*i.e.*, it becomes thicker, denser and darker when dry) as a result of having materials called driers, such as manganese oxide, added while the oil is hot; the name is inaccurate, since the oil is not boiled. The blown grade dries to an even harder film as a result of having air blown through the oil while it is heated to about 125° C.; this grade is used in enamels and interior paints.

Although exposure to air causes the flavour of the seed to deteriorate rapidly, especially if it has been refined and deodorized, linseed was used as food by the ancient Greeks and Romans, and it continues to be used as such in parts of central Europe. In modern times, however, its main food use is as a livestock feed. After the oil is removed from linseed by compression, the remaining meal is heated and pressed into cakes for livestock. Linseed meal contains about 33% protein and is high in minerals. especially calcium and phosphorus. See FEEDS, ANIMAL: *Important* Concentrate Feeds; see also references under "Linseed and Linseed Oil" in the Index volume.

See U.S. Tariff Commission, *Flaxseed and Linseed Oil,* "Industrial Material Series," Report no. M-7 (Nov. 1952); E. W. Eckey, *Vegetable Fats and Oils* (1954).

(P HE.)

LINSINGEN, ALEXANDER VON (1850–1935), Prussian general, who commanded large German forces on the eastern front during World War I and who was responsible for the disposition of troops in and around Berlin at the time of the revolution in Nov. 1918. Born on Feb. 10, 1850. at Hildesheim. Hanover, Linsingen entered the Prussian army in 1868. He was commissioned a lieutenant in the infantry a year later, and in the Franco-German War he was awarded the Iron Cross. From 1909 to 1914 he was in command of the army II corps at Stettin (now

Szczecin), holding the rank of lieutenant general. During World War I he served first on the western front. holding commands at the early battles of Mons. the Marne and Ypres. He was later transferred to the eastern front, and in Jan. 1915 he was given command of the German southern army. which he exchanged in July for the command of the army of the Bug.

In September. after his army had taken Brest-Litovsk (now Brest), the German-Austrian southeastern group (army group L) was placed under his command. With these troops he pursued the retreating Russians, established a defensive line near Pinsk and foiled all Russian attempts to break through from 1915 to 1918. In March 1918 Linsingen led the advance into the Ckraine. and in June he mas appointed chief in command in the hlark (the province of Brandenburg, including Berlin!. In this capacity he was responsible for placing the troops who had been left in Berlin and neighbouring garrisons for the purpose of preserving order. On the eve of the revolution he and his officers in command under him failed to maintain their authority. and on Nov. 9. 1918. the troops made common cause with the revolutionaries who overthrew the imperial and royal regime and secured the proclamation of the German republic. A plan by Linsingen to put down the revolution with bombing planes was rejected by the war ministry, whereupon he retired to Stettin. He later moved to Hanover, where he died on June 5, 1935.

LINTH, a river of Switzerland. is one of the tributaries of the Aare (*q.v.*). It rises in the glaciers of the Tödi range and has eroded a deep bed that forms the Linthtal, which comprises the greater part of the canton of Glarus. A little below the town of Glarus the river, keeping its northerly direction, flows across the alluvial plain that it has formed toward the lake of Zurich. In order to regulate the flow of the river over this plain it has been canalized. and dikes protect the riparian lands. These works were begun in 1807, and the first portion of the undertaking was completed in 1811. when it received the name of the Escher canal. the river being thus diverted into the Walensee or lake of Walenstadt. The Walensee is 9 mi. long with an area of 9 sq.mi., an altitude of 1.375 ft. and a maximum depth of 492 ft. The Churfirsten range dominates the northern shore, which is less populated than the southern. The Seez river enters the lake from the east. Walenstadt is the main town on the lake. The second portion of the Linth. known as the Linth canal, regulated the course of the river between the Walensee and the lake of Ziirich and was completed in 1816. Many improvements and extra protective works were carried out after 1816, the date of the completion of the work being 1911. The Linth emerges from the lake of Ziirich as the Limmat and, keeping the northwesterly direction, joins the Aare a little way below Brugg and just below the junction of the Reuss with the Aare. The combined length of the Linth-Limmat is 87 mi. (A. F. A. M.)

LINTON, RALPH (1893–1953), U.S. anthropologist, an influential contributor to the development of cultural anthropology, was born into a Quaker family in Philadelphia. Pa.. on Feb. 27, 1893. While a student at Swarthmore college (B.A., 1915). he participated in archaeological expeditions to New Mexico, Colorado and Guatemala. Thereafter, he studied at the University of Pennsylvania (M.A., 1916). After serving in the American expeditionary forces as a corporal during World War I. Linton studied briefly at Columbia university and then at Harvard university (Ph.D., 1925). During these student years he continued to engage in archaeological research in New hlexico. Colorado. Ohio and the Marquesas Islands. Linton's experience in the Marquesas Islands turned his attention to ethnology and, during his association with the Field Museum of Natural History (later the Chicago Natural History museum) from 1922 to 1928. he led an expedition to Madagascar (1926) that resulted in his major ethnographic work, The *Tanala,* a Hill Tribe of *Madagascar* (1933).

Linton was professor at the University of Wisconsin (1928–37), Columbia (1937–46) and Yale (1946–53). His most important theoretical work, *The* Study of *Man* (1936). was a widely influential synthesis of theories from anthropology, psychology and sociology concerning the nature of human culture. Other major works were *The Cultural* Background *of* Personality (1945); and *The Tree of Culture* (1955), the fruition of his stimulating lectures on world ethnology at Yale university. His professional honours included the presidency of the American Anthropological association (1946), membership in the National Academy of Sciences Viking fund medallist (1951) and winning the Huxley memorial medal of the Royal Anthropological institute (1954). He died on Dec. 24, 1953, in New Haven, Conn. (D B St)

LINTON, WILLIAM JAMES (1812–1898), English wood engraver, author and active Chartist, was born in London on Dec. 7, 1812. He was apprenticed to the engraver. G. W. Bonner, and from an early age contributed engravings to the R. A. summer exhibitions and to books and periodicals. working both from his own designs and from those of other artists. He was noted for his skillful exploitation of the "white line." An ardent republican, Linton was politically active in the 1840s and early 1850s, founding a political party and editing a number of radical papers. His second wife. whom he married in 1858, was Eliza Lynn, the novelist, but the marriage was not a success. In 1866 Linton emigrated with his family to the United States. He set up a printing press at New Haven. Conn., where he died on Jan. 1, 1898. Linton wrote poetry, an autobiography (*Memories,* 1895) and books on his craft, among them The *Masters* of *Wood-Engraving* (1890). (A. Bs.)

LINTOT, BARNABY BERNARD (1675–1736), English publisher. was born at Southwater. Sussex, on Dec. 1. 1675, and started business as a publisher in London about 1698. He published for many of the leading writers of the day, notably Vanbrugh Steele. Gay and Pope. The latter's Rape of *the* Lock in its original form was first published in Lintot's *Miscellanies,* and Lintot subsequently issued Pope's translation of the *Iliad* and the joint translation of the Odysrey by Pope. Fenton and Broome. Pope, having quarreled with Lintot with regard to the supply of free copies of the Odyssey to the author's subscribers, in 1728 satirized the publisher in the *Dunciad* and in 1735 in the Prologue to the Satires.

Lintot died on Feb. 3. 1736.

LINUM is a genus of the family Linaceae. There are about 200 species of plants found in temperate and subtropical regions, especially the Mediterranean. About 30 species are native to North America. Among these are *Linum virginianum* (slender yellow flax'), of the eastern states; L. *floridanum* (Florida yellow flax). of the southeastern states; L. *rigidum* (large-flowered yellow flax), of the interior prairie region; L. *lewisii* (wild blue flax). widely distributed from Wisconsin to Alaska and southward to California and Texas; and L. *californicum* (white-flowered flax), of the coast ranges.

L. *grandiflorum* (flowering flax), a native of North Africa, with large red flowers, and L. *flavum,* with golden-yellow flowers native to Europe, are grown as ornamental plants. There are four species in the British flora: L. *catharticum* (purging flax), with white flowers. which is common; L. perenne (perennial flax); L. *angustifolium* (narrow-leaved flax); and L. *usitatissimum* (flax or linseed), which has been introduced and is cultivated especially in Ireland. Flax. the fibre of the last-named species, is obtained by the removal of the softer tissues by retting; the shorter fibres form tow. The seeds (linseed) yield an oil by pressure, and the cake left is a cattle food. See FLAX.

LINUS, SAINT was, according to Irenaeus, the immediate successor of St. Peter as bishop of Rome. Irenaeus says (in Against Heresies) "the blessed Apostles passed on the sacred ministry of the episcopacy to Linus." Linus was in all probability also attested by Hegesippus' list and is mentioned by Eusebius of Caesarea (*Church* History). In the Book of Popes (Liber *Pontificalis,* Duchesne edition) Linus comes immediately after St. Peter. This list dates back to primitive Christianity. His feast day is Sept. 23.

See L. R. Loomis and J. T. Shotwell, *Book of the Popes,* Eng. trans. based on Duchesne's work, in "Record of Civilization Series" (1916). (J. M. F. M.)

LINUS. A name abstracted from the ancient ritual cry ailinos, the refrain of a dirge, supposed Phrygian by Euripides[1]

[1]Eurip., *Orest.*, 1395.

but probably of Semitic origin (ai *lanu,* "woe to us"). It is as old as Homer,[2] and how much older is not known. To account for this lament for Linus (Gr. Linos), as it was supposed to be, two principal stories were told: (1) *Argive.*—Linus, child of Apollo and Psamathe, was exposed at birth and was torn in pieces by dogs. In revenge, Apollo sent a *Poine* or avenging spirit. which destroyed the Argive children. The hero Coroebus killed her. and a festival, Arnis, otherwise called Dog-killing day (*kunophontis*), was instituted, in which stray dogs were killed, sacrifice made, and Linus and Psamathe mourned for.[3] (2) *Theban.*—Linus was the son of Crania and Amphimarus, and a great musician. He invented the Linus song but was put to death by Apollo for setting up as his rival.[4] A later, half-burlesque story says that he was Hercules' music master and was killed by his pupil, whom he tried to correct.[5] He had a cult on Mt. Helicon. Later tradition rationalized him into an ancient poet, prophet or the like.

This and similar figures (Adonis, Maneros, Narcissus) are plausibly explained as originating ultimately in the ceremonial laments for the dead corn spirit.

BIBLIOGRAPHY.—Greve in Roscher's *Lexikon* (bibl.); Sir J. G. Frazer, Golden *Bough,* vii, 257.

LINZ, the provincial capital of Upper Austria (Oberösterreich), lies on the Danube 100 mi. W. of Vienna. Pop. (1961) 197,121. The see of a bishop since 1785, it is a cultural centre with schools of art and music, a technical college, a religious seminary, scientific institutes, museums and art galleries, libraries, archives, an opera and theatres. Historic buildings include the castle; the Romanesque church of St. Martin (first mentioned 799); the early baroque town hall; the rectangular architecturally homogeneous main square (13th century) with a monument to the Holy Trinity; the City Parish church (built in the 13th century, remodeled baroque in the 17th century); the old cathedral (late 17th century); and the church of the Minorites (Franciscans) (13th century, remodeled 18th century). Other notable buildings are the 16th-century Landhaus (building of the provincial diet) and monastic churches (Capuchin, Ursuline, Carmelite). In the 19th century Archduke Maximilian d'Este fortified the town with a belt of towers, and the main fort on the Postlingberg (1,765 ft.) can be reached by mountain railway (the steepest without rack and pinion in Europe).

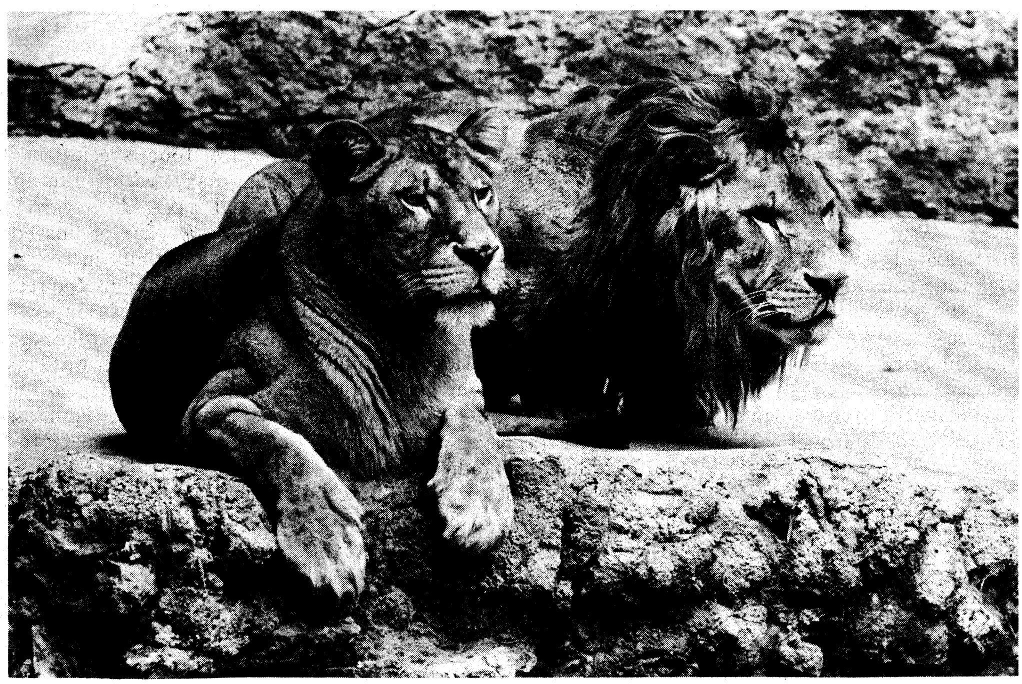
The most direct rail route between the Baltic sea and the Adriatic runs through Linz. and the town's position on the Danube makes possible a flourishing river transit trade. Urfahr, a large suburb on the left bank. is connected with the city by two bridges. After 1938 Linz developed into an important industrial centre with blast furnaces, smelting works, steel factories and a nitrogen fixation plant. War damage necessitated their reconstruction after 1945. The Linz-Donawitz (LD) oxygen-injection steel process is well knoan. The manufacture of machinery, electrical equipment, textiles and tobacco is also considerable.

Linz grew out of the Roman castle of Lentia (1st century A.D.) and it became an important medieval trading centre. By the 13th century it had all the outward characteristics of a regular city, but no civic rights. It achieved the status of provincial capital during the residence of the emperor Frederick III and was noted for its fairs. By the 18th century it was a city of the nobility, but it temporarily declined in the 19th century. The astronomer Johannes Kepler, the poet Adalbert Stifter and the composer Anton Bruckner all spent part of their working lives in Linz. (If'. F. RA.)

LION, since the earliest times one of the best-known wild animals. During the Pleistocene period the lion (*Panthera* leo) was distributed over the greater part of Europe, and within the historical period it inhabited north Africa, western Asia and probably Greece. It is now found in most parts of Africa south of the Sahara desert and in Kathiawar in Gujarat state, northwestern India, but is now extinct in Iran and Iraq. The lion. tiger, leopard, jaguar, and snow and clouded leopards, generally known as the big cats, make up the genus *Panthera* of the family Felidae, order Carnivora (see CARNIVORE).

The lion is a powerfully built beast of prey with long body, short legs and large, well-developed muscles. It varies considerably in size but averages about 9 ft. 6 in. (including the tail), stands about 3 ft. at the shoulder and weighs 400 to 500 lb. The hair is short and varies greatly in colour from pale sandy to dark tawny; the tuft at the end of the tail is usually darker. The outstanding characteristic of the male, the mane, varies greatly in its development from the entirely maneless condition through a mere fringe of longer hair round the face to the splendid full mane. At its most luxuriant it covers the back of the head, neck and shoulders and is continued on to the throat and chest, where it joins a fringe along the underside of the belly. In some lions the whole of the mane and fringe are very dark, almost black, so that the animal has a majestic and impressive appearance; in others it is lighter, often no darker than the rest of the coat. The reasons for the variation in mane development are unknown; they may be heritable, like the differences in hairiness among human beings. But it has also been suggested that lions living in dense bush country have their manes so thoroughly combed while penetrating among thick thorn scrub that most of the long hair is pulled out. The fact that lions in captivity generally grow much longer and fuller manes than wild lions is quoted in support of this supposition. A newborn lion cub is covered with dark spots on a pale ground colour, but these markings are generally lost with approaching maturity; in some lions, however, the spots are retained on the limbs, under parts and flanks throughout life.

The lion has no definite breeding season, and cubs may be born at any time of the year; the litter varies from two to four, rarely six (in captivity). In captivity lions often breed every year,



H. ARMSTRONG ROBERTS

FEMALE AND MALE LIONS (PANTHERA LEO)

[2]Hom., *Il.*, xviii, 570.

[4]Paus., ix, 20, 6.
[5]Apollodorus, ii, 63.

but in the wild it is probable that they do not breed more frequently than once in two years. The young are born blind, the eyes opening at the age of about a week; they do not become adult until the permanent canines replace the .milk teeth, at the ape of about one year. In the wild the lion reaches its prime at about five or six years of age. The life span is not known for lions in the wild, but in captivity they may live 25 years or more.

The well-known roar of the lion is generally given forth when the animals arouse themselves in the evening before a night's hunting and again before lying up at dawn. The old story that the lion lashes himself into fury with the "claw" on his tail before making an attack is only a legend; the claw is usually no more than a small horny scale or spur attached to the skin at the tip of the last vertebra. In addition to the roar, the lion utters many other sounds: coughs. grunts, growls and deep purring noises.

Lions tend to be sociable animals and often live together in parties of a dozen or more, generally comprising several lionesses with their partly grown cubs. A lioness with cubs is often accompanied by a cubless one. The lion hunts by night and spends the day lying up in cover or under the shade of trees or rocks. After patiently stalking its prep. the lion makes a lightning-fast charge for the kill. Lions have frequently been seen hunting in company. and it is stated that some mill lie in ambush while others of the party drive prey toward them. In Africa lions feed on any animals they can pull down. from the smaller antelopes to the giraffe, although it takes several working together to overcome the larger animals. In the neighbourhood of human settlements lions are sometimes very destructive to stock, showing great cunning in breaking into enclosures and enormous strength in jumping over thick fences with their prey in their jaws.

Lions, like most other potentially dangerous animals, generally avoid man. but they sometimes take to man eating and may kill large numbers of natives if they are not promptly sought out and killed before man eating becomes a habit. When brought to bay a lion will often charge his attacker, rushing upon him with great speed. The lion can inhabit open country with only sparse cover. See also TIGER.

(L. H. M.)

LION FISH (TURKEY FISH), a tropical marine fish (*Pterois volitans*), somewhat poisonous. of very striking appearance: its very high dorsal and large pectoral fins are more or less divided into long, wide-spreading strands that stand out from the body. In each strand is a spine and an associated venom gland. Its body, up to one foot long, and its fins are patterned with light and dark stripes.

Like the rest of the scorpion fish or rockfish family (Scorpaenidae), the lion fish is sluggish. spending most of its time on the bottom. It is found in the Indian ocean and in the Pacific from the East Indies eastward to Polynesia. Contact with the spines results in a painful wound in man; however, the toxin is not so virulent as that of the related stonefish or poison fish (*q.v.*). See also SCORPION FISH; FISHES. (J. T. N.; X.)

LIONNE, HUGUES DE (1611–1671), French statesman, was born at Grenoble on Oct. 11, 1611, of an old family of Dauphini.. Early trained for diplomacy, his abilities attracted the notice of Cardinal Mazarin, who sent him as secretary of the French embassy to the congress of Münster and, in 1642, on a mission to the pope. From that time he filled high offices. He helped to negotiate the peace of the Pyrenees (1659), which secured the marriage of Louis XIV to the infanta Maria Theresa. At Mazarin's dying request he was appointed his successor in foreign affairs and, for the next ten years, continued to direct French foreign policy. Among his most important diplomatic successes were the treaty of Breda (1667), the treaty of Aix-la-Chapelle (1668) and the sale of Dunkirk. He died in Paris on Sept. 1. 1671. leaving memoirs.

See U. Chevalier, *Lettres inédites* de *Hugues de Lionne,* (1879); J. Valfrey, *La diplomatie française au XVIII^e siècle: Hugues de Liotzne, ses ambassadeurs* (2 vol., 1877–81). For further works *see* Rochas, *Biogr. du Dauphiné,* tome ii, p. 87 (1860).

LIOTARD, JEAN ÉTIENNE (1702–1789), Swiss painter noted for his pastel portraits, was born at Geneva. He began his studies under Gardelle and Petitot. He went to Paris about 1723, studying under J. B. Massé and F. le Moyne on whose recommendation he was taken to Naples by the Marquis Puysieux. In

1735 he was in Rome. painting the portraits of Pope Clement XII and several cardinals. Three years later he accompanied Lord Duncannon to Constantinople; from there he went to Vienna in 1743 to paint the portraits of Empress Maria Theresa and her family. His eccentric adoption of oriental costume secured him the nickname of "the Turkish painter." He visited England. where he painted the princess of Wales in 1753, and went to Holland in 1756, where, in the following year, he married Marie Fargues. Another visit to England followed in 1772, and in the next two years his name figures among the Royal Academy exhibitors. He returned to his native town in 1776 and died there in 1789.

Liotard was an artist of great versatility, and though his fame depends largely on his graceful and delicate pastel drawings, of which "La Liseuse." the "Chocolate Girl" and "La Belle Lyonnaise" at the Dresden gallery are delightful examples. he achieved distinction by his enamels, copperplate engravings and glass painting. He wrote *Treutise on the Art of Painting,* and was an expert collector of paintings by the old masters. A portrait of the artist is in the Uffizi gallery, Florence: Italy.

LIOUVILLE, JOSEPH (1809–1882), French mathematician known for his work in analysis, the theory of numbers and differential geometry. was born at St. Omer and died at Paris. He graduated in 182; from l'École Polytechnique where, in 1833. he became professor. At the early age of 30 he was elected to the Académie des Sciences (Paris). and presently was appointed professor at the Sorbonne and the Collège de France. He founded (1836) and edited the *Journal* des *Mathématiques Pures et Appliquées,* which did much to raise and maintain the standard of French mathematics throughout the 19th century.

Liouville was a boldly original mathematician. His works. never collected, comprise about 400 memoirs and notes, more than 200 on the theory of numbers alone. In 1832–33, he investigated criteria for the analytic character of integrals of algebraic functions. Liouville was the first. in 1844, to prove the existence of transcendental numbers. and he constructed an infinite class of such numbers. He worked also in differential equations and boundary-value problems. His methods in this department became of capital importance in 20th-century mathematical physics, as well as in the theory of integral equations. In differential geometry, he contributed notably to the theories of applicability of surfaces and conformal transformations. The concept of geodesic curvature was introduced by Liouville. Nearly all of his work on the theory of numbers (1857–82) was published without indication of the means by which he had obtained his striking results, relating mostly to numerical functions, representation in quadratic forms and general formulas in parity functions. All have since been proved. In analysis, Liouville was the first to deduce the theory of doubly periodic functions from general theorems, including his own. in the theory of analytic functions of a complex variable. (E. T. B.; O. OE.)

LIPA, a municipality (with administrative centre and 45 *barrios* or districts), of the province of Batangas, Luzon, Philippines, about 90 mi. S. by E. of Manila, on high ground at the intersection of old Spanish military roads, east of the lake of Taal and near the railway running to Batangas. Pop. (1960) 69.342. It is one of the largest and wealthiest inland municipalities of the archipelago. Sugar, corn, cacao and tobacco are among the principal products. Coffee was formerly produced in considerable quantity, but many of the trees were destroyed during the insurrection of 1899–1902; others were destroyed by insects. Jusi cloth is woven in Lipa, and tied abacá (Manila hemp) is marketed in considerable volume. Tagalog is the vernacular.

LIPARI ISLANDS (ISOLE EOLIE; AEOLIAN ISLANDS), a group of volcanic islands located off the north shore of Sicily, in Messina province. They have a general "Y" shape, the base of the "Y" being the westernmost island, Alicudi, the northern tip being Stromboli and the southern tip being Vulcano. The other major islands are Lipari, Salina, Filicudi and Panarea. They have a total land area of 44 sq.mi. and a population (1951) of 14,782. Seismic and volcanic activity has been known since ancient times, and the Greeks believed the islands to be the home of Aeolus, king of the winds, hence the alternate name of the group. There are fumaroles on Lipari and Panarea; Vulcano and Stromboli are active. Pumice is exported from the islands, and the principal agricultural product is heavy malmsey-type wine from Lipari. There is regular steamer service to Milazzo, Messina and Naples.

Excavations in the 20th century have established an uninterrupted archaeological record from the Neolithic period. Ceramics and artifacts have been found, while the volcanic obsidian of the islands has been detected as far as Crete. 4 feature of archaeological research was substantiation of the legend that Aeolus came from Magna Graecia along the coast of south Italy rather than Sicily. Lipari (pop. [1957 est.] 3,731 [commune]) is the chief town, with the important Aeolian archaeological museum. Panarea has a Bronze Age village; Stromboli's spectacular volcano is a noted tourist attraction.

The Greeks established themselves in the islands in the 6th century B.C. Later there was a Carthaginian naval station. until the Romans took over in 252 B.C. In Roman days, as in the Fascist era, the islands served as a place of banishment for political prisoners. In medieval times they were conquered by the Saracens, who were expelled by the Normans in the 11th century. The islands frequently changed hands during the wars between the Angevins of Naples and the Sicilian kings in the 14th century. Alfonso V of Aragon annexed them to Naples. but Ferdinand II of Aragon finally united them to Sicily in the late 15th century. (G. KH.)

LIPCHITZ, JACQUES (1891–), one of the early revolutionaries of modern sculpture because of his participation in Cubism (*q.v.*) and his development of a new language for sculpture that was not based upon anatomy or the outward form of the human body. Born in Druskieniki. Latvia. Aug 22. 1891. Lipchitz studied and worked in Paris after 1909; by 1941, when he moved to New York, his international reputation was established. His new means of interpreting the human body esthetically and psychologically can be seen in "Man With a Guitar" (1915) and "Prodigal Son" (1931). In his "transparencies" of the 1920s Lipchitz was one of the first sculptors to introduce voids within his sculptured figures. His strongest art deals with tension, as in "Figure" (1926–30), and man's spiritual history, as in "The Virgin of Assy" (1948–54). Lipchitz always stressed the sculptor's transforming manipulation and shaping power.

There is a well-known portrait of Lipchitz and his wife by Amedeo Modigliani (*see* PORTRAIT PAINTING: *The 20th Century*).

See Henry R. Hope, The *Sculpture* of Jacques Lipchitz (1958); Robert Goldwater, *Lipchitz* (1959). (A E. EL)

LIPETSK, a town in the Lipetsk *oblast,* Russian Soviet Federated Socialist Republic. Pop. (1959) 156,000. The region was formed on Jan. 6. 1954, out of districts detached from the regions of Voronezh. Orel, Ryazan and Kursk. The city, on the right bank of the Voronezh river. was founded in the 13th century and razed to the ground by the Tatars a few decades later It was founded again in 1779. There are deposits of iron ore in the area. and Lipetsk is a centre for pig-iron production and related heavy industries.

LIPKA, JOSEPH (1883–1924), U.S. mathematician, was born at Briessin, Poland, in 1883. He emigrated to the U.S. as a child and was educated at Columbia university (Ph.D., 1912). A member of the faculty of the Massachusetts Institute of Technology, his earlier work, from 1908, was chiefly in applying differential geometry to dynamics and developing in Euclidean spaces of two or three dimensions the geometric properties of dynamical trajectories and related systems of curves. In 1921 he went abroad for study, especially with Tullio Levi-Civita of Italy. He subsequently published papers revolving about Levi-Civita's notion of parallelism. He generalized this notion by replacing the geodesics at the basis of it by the trajectories of a natural family, which suggested a new type of parallelism called "conformal parallelism." an idea of great value in problems in dynamics, and from it developed a new set of invariants that yield corresponding results bearing on trajectories. He died at Boston, Mass., on Jan. 24, 1924.

LIPMANN, FRITZ ALBERT (1899–), U.S. biochemist, received (with H. A. Krebs) the 1953 Nobel prize in medicine and physiology. Born in Konigsberg. Ger., on June 12, 1899, he studied medicine at the universities of Konigsberg, Munich and Berlin (M.D., 1922) and later studied chemistry (Ph.D., Berlin, 1927). He did early research in the laboratory of Otto Meyerhof (1927–30). After a short period with Albert Fischer at the Kaiser Wilhelm institute, Berlin, he followed him to Copenhagen to the newly established Biological Institute of the Carlsberg foundation (1932–39). Lipmann had earlier spent a year as a Rockefeller Foundation fellow at the Rockefeller institute (1931–32), and in 1939 joined the faculty of Cornell Medical school (New York city). He became a U.S. citizen in 1944. He was head of the Biochemical Research department, Massachusetts General hospital, Boston (1941–57), and after 1949 was professor of biological chemistry, Harvard Medical school, until he returned to the Rockefeller institute in 1957. His work influenced and developed understanding of biological energy transfer. He discovered vital metabolic catalysts. (G. E. Pn.)

LI PO or **LI TAI** PO (李白,李太白, 701–762), considered by many critics as China's greatest poet, was born in Pa-hsi (巴西) in Szechwan. He was a descendant, in the ninth generation, of the emperor Hsing-Sheng. At his birth, his mother had a dream in which she saw the planet, Chang-kêng (長庚星, Venus) and because of this omen he was named Po or "The Bright." At ten, he learned the *Book of* Odes and the *Book of History*. He was fond of fencing and developed a taste for drink, a passion for poetry, and a desire for adventure. After the age of 20, he wandered as far as Shantung, and then retired to the Min mountains (岷山) living the life of a *hsien* (仙, an immortal endowed with divine powers as an angelic man) together with five other sympathetic companions, King Chao, Han Chun, Pei Chêng, Chang Shuming and Tao Mien. Their coterie was known as the Six Idlers of the Bamboo Streams (竹溪六逸). Li Po was then summoned by the provincial examination board, who wished to award him governmental preferment, but he made no response. When Su Ting, the governor of Ichou, was introduced to him, he was struck by the poet's genius and said, "This man has conspicuous natural talents. If he had more learning, he would become a second Ssuma Hsiangju" (司馬相如, 126 B.C., the greatest poet of the Han dynasty).

About 742, he reached the capital, Changan (長安), where his poetry aroused the admiration of Ho Chihchang (賀知章), the minister of the emperor and the president of the Hanlin academy (翰林學院). About this time, there was a Korean messenger with an imperial document written in Korean. This nobody could read but Li Po. After being many times summoned by the emperor Ming Huang, Li Po appeared before him to receive promotion. At one time, while Li Po was drinking in low taverns, the emperor sent for him to compose a song; but Li Po was so drunk that his head and face had to be washed repeatedly with cold water before he could go to the pavilion. While the emperor played the flute, Yang Kueifei (楊貴妃), the court mistress, accompanied him on the guitar and Li Po drank and wrote verses, not returning to the Hanlin academy until after midnight.

Once, when Li Po was very drunk the emperor ordered Kao Lishih to take off the poet's shoes; Kao felt humiliated and persuaded Yang Kueifei that some of Li Po's poems were derogatory to her. She therefore dissuaded the emperor whenever he wanted to give high rank to the poet. His official failure was thus brought about. Finally the poet petitioned the emperor that he be allowed to go away, and he was given money and an imperial edict which enabled him to obtain wine free of charge wherever he should go. Li Po, together with Ho Chihchang, Li Shihchih, Li Chin, Tsui Tsungchih, Chu Chin, Chang Hsu and Chio Sui then went away, forming a new coterie called the Eight Immortals of the Wine Cup (酒中八仙).

Afterward Li Po drifted into the service of Prince Lin of Yung who, when he failed in certain of his designs, blamed Li Po. But he forgave him and the poet set out to go to his kinsman, Li Yanping. On his way he fell from the boat in which he was travelling while trying to kiss the reflection of moonlight in the water, and was drowned.

Li Po's style is unmatched for purity. He deals mainly with the themes, wine and women, and where emotions enter his verse they go deep into the heart of the reader. His work has strong imaginative and aesthetic appeal with an exquisite exactness of touch and extreme dexterity. Philosophy, religious or social, has no place in his work; to him the poet is no teacher or prophet, but a creator revealing beauty for its own sake.

LIPPE, a former *Land* of the German Reich. bounded northwest, west and south by the Prussian province of Westphalia and northeast and east by the Prussian provinces of Hanover and Hesse-Nassau, and Waldeck-Pyrmont. It also possessed three small enclaves—Kappel, Lipperode and Grevenhagen in Westphalia. The area was 469 sq.mi., and the population (1939) 188,596, showed a density of 404 to the sq.mi. The area is hilly and consists chiefly of the basin of the Werre. which from Lage northward flows in a wide valley. From there the land rises to the higher hills which encircle it on the east. south and west (the Teutoburger Wald) borders. The forests of Lippe produce abundance of excellent timber, and consist mostly of deciduous trees, beech preponderating. The valleys contain good arable land, the tillage of which employs the greater part of the inhabitants. Small farms, the larger proportion of which are under $2\frac{1}{2}$ ac., are numerous, and their yield shows a high degree of prosperity among the peasant farmers. The principal crops are potatoes. beetroot (for sugar), hay, rye. oats, wheat and barley. Cattle, horses, sheep and swine are also reared. The industries are small and consist mainly in the manufacture of starch, paper, sugar. tobacco, meerschaum wares. and in weaving and brewing. Salzuflen is famous for its brine-springs. Each year, in spring, brickmakers leave the principality to return home in the late autumn. The roads are good. A railway intersects the country from Herford (on the Cologne-Hanover main line) to Altenbeken; and another from Bielefeld to Hameln traverses it from west to east. The constitution was drawn up in 1920. It provided for a representative chamber (*Landtag*) of 21 members. and an executive chamber (Landes prasidium) of 3. The courts of law were centred at Detmold. After 1933 the constitution was superseded by the administration of a National Socialist district leader (*Gauleiter*) appointed by Hitler.

History.—Lippe was inhabited in early times by the Cherusii, whose leader Arminius (Hermann) annihilated in A.D. 9 the legions of Varus in the Teutoburger Wald. It was afterward occupied by the Saxons and was subdued by Charlemagne. The founder of the princely family, one of the most ancient in Germany, was Bernard I (1113–1144), who received a grant of the territory from the emperor Lothiar, and assumed the title of lord of Lippe (cdler Herr *von* Lippe). From Count Simon VI (1555–1613) descended the Counts of Lippe-Biesterfeld and Lippe-R'eissenfeld, and the Princes of Schaumburg-Lippe. On the death of Prince Woldemar of Lippe in 1895, a dispute arose as to the succession between the various branches of the Lippe family, which was only definitely settled in 1905, when Count Leopold of Lippe-Biesterfeld became Prince of Lippe. Lippe, which had been made a principality in 1720 (confirmed in 1789) became a republic in common with the rest of Germany in Nov. 1918. In 1945, Lippe was incorporated into North Rhine-Westphalia.

LIPPE, a river of Westphalia, Ger., a right-bank tributary of the Rhine, rises near Bad Lippspringe under the western slope of the Teutoburger Wald and. after a course of 147 mi.. flows into the Rhine near Wesel. It is navigable, by the aid of 12 locks, downstream from Lippstadt. for boats and barges drawing less than four feet. The Lippe was once used for the transport of coal, timber and agricultural produce to and from Westphalia, but in 1930 it was replaced by a canal that follows its course from the Dortmund-Ems canal to the Rhine. The Lippe supplies water to the canal system of the Ruhr. The canal! which carries 6.000.000 tons of cargo annually, takes the largest barges that use the Dortmund-Ems canal. During the 1960s it was extended beyond the Dortmund-Ems canal toward Hamm. (R. E. Di.)

LIPPI, FILIPPINO (Filippo) (*c.* 1457–1504), Italian painter, son of Fra Filippo Lippi (*q.v.*) and the nun Lucrezia Buti, was a follower of his father and of Botticelli. He was born at Prato, probably in 1457. After Fra Filippo Lippi's death, Filippino entered the workshop of Botticelli. By 1473 he had finished his apprenticeship. The style of Filippino's earliest works stems from that of Botticelli; they include Madonnas at Budapest. Berlin and in the National gallery, London. where there is also an "Adoration of the Magi." Filippino's use of line throughout these panels is less sensitive and subtle than Botticelli's. In a group of paintings executed about 1480–8j he develops a harder and more individual style. The most notable of these are altarpieces in S. Michele at Lucca and the Museo di Capodimonte in Naples, and a panel of the "Journey of Tobias" in the Pinacoteca Sabauda. Turin. Despite the lack of dated or documented works, it is clear that by this time Filippino enjoyed a considerable reputation, since he is known to have been employed, along with Botticelli. Perugino and Ghirlandajo, on the frescoed decoration of Lorenzo de' Medici's villa at Spedaletto near Volterra, and at the end of 1482 was commissioned to complete work left unfinished by Perugino in the Palazzo della Signoria in Florence. No trace of either work survives. Soon after (probably 1483–84) he was entrusted with the completion of the frescoes in the Brancacci chapel in the Carmine, which had been left unfinished on Masaccio's death in 1428.

His most popular picture, the beautiful altarpiece of the "Virgin appearing to St. Bernard" (Badia. Florence), has been variously assigned to the years 1480 and 1486. In April 1487 Filippino Lippi signed a contract for the frescoed decoration of the chapel of Filippo Strozzi in Sta. Maria Novella, Florence. Work on this was delayed by a second commission for a fresco cycle. this time in Rome, where, on the recommendation of Lorenzo de' Medici, Filippino was invited to decorate the Caraffa chapel in Sta. Maria sopra Minerva. Nothing in Filippino's earlier works prepares for the vein of inspiration which he struck in the Caraffa chapel. where the roof is filled with four figures of sibyls, the right wall with frescoes of the "Miracle of the Speaking Crucihx" and the "Triumph of St. Thomas," and the altar wall with a fresco of the "Assumption."

On his return from Rome (probably 1491) Filippino Lippi executed a fresco of the "Sacrifice of Laocoon" for the villa of Lorenzo de' Medici at Poggio a Cajano, in which some of the decorative expedients used in the Caraffa chapel are again employed, and resumed work in the Strozzi chapel (completed 1502), the frescoes which look forward to the Tuscan Mannerism of the 16th century. Of the large number of panel paintings produced in this. Filippino's final phase, the most remarkable are an "Adoration of the Magi" in the Uffizi (painted for S. Donato a Scopeto in 1496) and an altarpiece of the "Deposition" commissioned for the high altar of SS. Annunziata in Florence and completed after Filippino's death by Perugino (Uffizi, Florence). Filippino died on April 18. 1504.

See A. Scharf, *Filippino Lippi* (1935); K. Neilson, *Filippino Lippi* (1938). (J. W. P.-H.)

LIPPI, FRA FILIPPO (Lippo) (1406–1469), one of the best-knonn and most influential Tuscan painters of the 1jth century, was born in Florence in 1406. His father, a butcher, died during Lippi's boyhood, and the boy was given over by his mother to the Carmelite friars of Sta Maria del Carmine in Florence. where on June 18, 1421, he took his first vows. He is mentioned in 1430 as a painter in the community records. where his name appears in Jan. 1432 for the last time. Filippo Lippi was thus trained a5 a painter under the shadow of Masaccio's and Masolino's frescoes in the Brancacci chapel in the Carmine. These influences are reflected in what is probably his earliest work.

NATIONAL GALLERY OF ART, WASHINGTON, D.C., SAMUEL H. KRESS COLLECTION

"MADONNA AND CHILD." BY FRA FILIPPO LIPPI, ABOUT 1406–1469. IN THE NATIONAL GALLERY OF ART. WASHINGTON

a fresco formerly in the cloister (now transferred to canvas) commemorating the reform of the Carmelite order by Pope Eugenius IV in Feb. 1432. In the massive forms of the figures in this fresco and in its solidly constructed architecture Lippi reveals his study of Masaccio, though a latent decorative tendency (later to dominate his work) is already evident in the delicate palette and light tonality. At this point Lippi appears to have left Florence, and in the summer of 1434 was employed in S. Antonio at Padua.

His first dated work, a "Madonna" from Tarquinia Corneto, now in the Galleria Nazionale in Rome, belongs to the year 1437. Like the Carmine fresco, the "Madonna" of 1437 is a powerful and uncompromising work. Immediately after it. Lippi seems to have executed what is perhaps his finest and most characteristic panel painting, an altarpiece of the Annunciation in S. Lorenzo in Florence. This combines space structure of great sophistication with the simple emotionalism that ensured him lifelong popularity. On March 8, 1437, Lippi received the commission for an altarpiece for the Barbadori chapel in S. Spirito (now in the Louvre, Paris). Between 1441 and 1447 Lippi painted for the high altar of S. Ambrogio the great altarpiece of the "Coronation of the Virgin," now in the Uffizi. This includes on the right a self-portrait of the painter designated by the words, Is *perfecit* opus.

After about 1445 Lippi seems to have fallen under the influence of Fra Angelico, which is manifest in the relatively simple scheme of a second altarpiece of the "Coronation of the Virgin" painted for the convent of Monte Oliveto at Arezzo after 1444 (,Vatican gallery), as well as in a masterly *tondo* of the "Adoration of the

Magi" now in the National gallery. R'ashington. A second circular painting of somewhat later date (probably 1452), showing the Virgin and Child with scenes from the life of St. Anne in the background. exists in the Palazzo Pitti, Florence; in this too the problem of the circular field is solved with consummate mastery. Thereafter Lippi began work on his most ambitious project. the frescoed decoration of the choir of the cathedral at Prato illustrating the life of St. Stephen and that of John the Baptist. The commission for these important frescoes was first offered to Fra Xngelico and subsequently (1452) to Fra Filippo Lippi. Work on them appears to have continued until 1364. The bottom frescoes on each side of the choir are works of great solemnity and power. In 1466 Lippi commenced his last major work, the frescoes in the apse of the cathedral at Spoleto. Owing to the master's ill health these weak works were executed almost exclusively by members of his studio.

While in Prato Fra Filippo Lippi abducted from the convent of Sta. Margherita (of which he mas chaplainj a nun, Lucrezia Buti. who became the mother of the painter Filippino Lippi (*q.v.*) and who, according to Vasari, was depicted by Lippi in certain paintings.

Lippi died at Spoleto on Oct. 9, 1469.

See R. Oertel, *Fra Filippo Lippi* (1942). (J. W. P.-H.)

LIPPINCOTT, SARA JANE CLARKE (1823–1904), U.S. author and journalist, born Sept. 23. 1823, in Pompey, N.Y., was the daughter of Thaddeus and Deborah (Baker) Clarke. Educated in public and private schools, she published occasional verse at an early age and at nineteen was a contributor to *Godey's Lady Book*. Best known as "Grace Greenwood," she was the Washington correspondent for the *New York Times* and also the *New York Tribune*.

In 1853 she married Leander K. Lippincott and with him edited the *Little Pilgrim* for 12 years. She was the author of 18 books, including children's tales, historical sketches and travel books. Her last work. *Stories and Sketches*, was published when she was 70 years old. Her best known volumes are *Greenwood Leaves* (1850), a collection of articles and stories, and *Haps and Mishaps of a Tour in Europe* (1854).

She died at New Rochelle, N.Y.

LIPPMANN, GABRIEL (1845–1921), French physicist, invented the photographic reproduction of colour by what is known as the Lippmann interference process: for which he was awarded the 1908 Nobel prize in physics. He was born on Xug. 16. 1845, at Hollerich in Luxembourg of French parents who soon after his birth settled in Paris. He was educated at the École normale and the universities of Heidelberg and Berlin. becoming a member of the faculty of sciences in Paris in 1878. The whole of his life mas devoted to teaching and research. In 1883 he was appointed professor of physics and was subsequently director of the laboratory for physical research at the Sorbonne, and in the same year he was elected a member of the Paris academy of sciences. Of an original and independent mind, he made important contributions to many departments of physics, but especially to electricity. thermodynamics. optics and photochemistry. One of his earliest achievements was the construction of a capillary electrometer of extraordinary sensitivity. The principle of the Lippmann colour process was communicated to the academy of sciences in 1891, but it was not until 1908 that he was awarded the Nobel prize for physics for this work. He was president of the academy of sciences in 1912 and he was a foreign member of the Royal society of London. He died at sea on July 13, 1921. while returning from a visit to Canada. (W. J. Br.; X.)

LIPPMANN, WALTER (1889-), U.S. newspaper commentator and author of numerous books on public affairs. was born in New York city. Sept. 23, 1889. He graduated from Harvard in 1910. In writing on public events for more than 50 years thereafter: Lippmann made himself the foremost commentator in the United States and won a world-wide reputation. From the publication of his first book. *A Preface to Politics*, in 1913. it was evident that he had a discerning grasp of political trends at home and abroad. with a capacity to see where these trends were leading. After a brief apprenticeship with Lincoln Steffens on *Everybody's Magazine* and a briefer excursion into practical politics with the Socialist mayor of Schenectady, N.Y., he became one of the founders and associate editor of the *New Republic*. He was one of the brilliant young men who exerted a great influence on Woodrow Wilson, both through the pages of that liberal weekly and in direct consultation with the president. It was at Wilson's request that after wartime service with the U.S. military intelligence Lippmann served as an aide to Col. Edward M. House in Paris and contributed substantially to Wilson's fourteen points and to the concept of the League of Nations. Deeply disillusioned with the outcome of the Versailles conference, Lippmann returned to America and became editor of the *New York World*. When the *World* was sold, he began to write for the *New York Herald Tribune* an independent commentary that was syndicated to a large number of newspapers at home and abroad. Among more than a score of published books, his most influential works have been *Public Opinion* (1922), *A Preface to Morals* (1929) and *The Good Society* (1937). *Essays in the Public Philosophy* (1955) was criticized in some quarters because of its espousal of the concept of natural law as paramount. After 1938 Lippmann lived in Washington, D.C., with his wife, the former Helen Byrne Armstrong. In writing his commentary he traveled widely in the United States and in Europe, Asia and Latin America. (M. W. Ch.)

LIPPS, THEODOR (1851–1914), German psychologist and philosopher, was born July 28, 1851, at Wallhalben, and was professor successively at Bonn. Breslau and Munich. His fundamental principles assumed a dependence of consciousness upon the interaction between older experiences retained in a subconscious state and the entering sensations (apperception). Mind. he said, is the sum of these older experiences organized in a unity. The organization controls the course of perceiving, of recall and thinking and of action. Pleasure is harmonious interaction of the old upon the new; displeasure results from conflict of the different elements.

The best-known phase of his theory is his doctrine of *Einfühlung*, defined as projecting one's self into what is seen. One appreciates another's reaction by feeling one's self into the other. In his two-volume *Ästhetik* (1903–06) Lipps makes all artistic appreciation depend upon a similar self-projection into the object. Part of feeling is dependent upon definite induced bodily responses like imitation. A form is beautiful that is obviously adequate to a situation. A lithe but not emaciated human figure is beautiful. A column that is too slight apparently to support a weight put upon it arouses sympathy, it makes the observer strain unduly and so is unpleasant. In an experimental study of optical illusions (*Raumästhetik*, 1897) Lipps suggests that a vertical line is apparently longer than a horizontal one because it induces the observer to stretch up and the movement is assigned to the line. His publications include. in addition to those mentioned. *Grundtatsachen des Seelenlebens* (1883), *Die ethischen Grundfragen, zehn Vorträge*, 2nd ed. (1905), and *Leitfaden der Psychologie*, 3rd ed. (1926). Lipps died at Munich on Oct. 17, 1914. (W. B. Py.)

LIPPSTADT, a town in North Rhine-Westphalia, Ger., on the Lippe river, 20 mi. W. by S. of Paderborn by rail, on the main line to Dusseldorf. Pop. (1959 est.) 36,004. Lippstadt was founded in 1168 by the lords of Lippe. the rights over one half of the town passing subsequently to the counts of the Mark. which in 1614 was incorporated with Brandenburg. In 1850 the prince of Lippe-Detmold sold his share to Prussia. The Marien Kirche dating from the 13th century is built in the Transitional style. During World War II the town was bombed several times by the British R.A.F.

LIP-READING: *see* SIGN LANGUAGE.

LIPSCHITZ, RUDOLF OTTO SIGISMUND (1832–1903), German mathematician, was born in Konigsberg, East Prussia. on May 14, 1832. In 1847 he graduated from the Gymnasium and entered the University of Konigsberg. Later he was attracted to the University of Berlin by P. G. Lejeune Dirichlet, and on Aug. 9, 1853, he received his doctor's degree there. He spent his probationary year at the Gymnasium at Konigsberg and then taught at the Gymnasium of Elbing. In 1857 he became *Privatdozent* at Bonn. in 1862 he went to Breslau as *ausserordent-*

licher professor and in 1864 he returned to Bonn as *Ordinarius.* In 1873 he received an offer from Gottingen. but he declined it and remained at Bonn until his death on Oct. 7. 1903. For the year 1874–7j he was chosen unanimously as rector.

The mathematical work of Lipschitz was many-sided. including contributions ranging from the theory of numbers to mathematical physics. He did important work in the calculus of variations. Bessel's functions. Fourier series, potential theory and analytical mechanics. The direction of his thought was determined largely by Dirichlet and by the 1854 *Habilitationsschrift* of G. F. B. Riemann. Fundamentally an algebraist, he was yet interested in the foundations of mathematics. and in his *Lehrbuch der Analysis* (2 vol., Bonn, 1877–80) he sought to develop the subject from fundamental concepts. Following the lead of A. L. Cauchy. he formulated the well-known Lipschitz (or Cauchy-Lipschitz) condition in connection with the existence theorem for solutions of the differential $y'=f(x, y)$. His works include *Bedeutung der theoretischen Mechanik* (1866), *Wissenschaft und Staat* (1874) and *Untersuchungen über die Summen von Quadraten* (1886).

(C. B. Br.; X.)

LIPSIUS, JUSTUS (1547–1606), the Latinized name of Joest (Juste or Josse) Lips. Belgian scholar, born on Oct. 18 (Nov. 15, according to Amiel). 1547, at Overyssche. a small village in Brabant. near Brussels. He studied at the University of Louvain. In 1567 he published *Variarum Lectionum Libri Tres,* dedicated to Cardinal Granvella. who took him to Rome. where he stayed two years studying manuscripts and inscriptions. On his return he published *Antiquarum Lectionum Libri Quinque* (1 57j), which shows an advance forward. a sounder system of emendation by collation. He wandered over Europe a good deal. taught at Jena. Cologne. Louvain and Antwerp and finally became professor of history at Leyden. These changes must have involved some elasticity in the religions he professed. varying between Catholic at Cologne and Calvinist at Leyden. The 11 years at Leyden were his most productive period. It was then that he prepared his *Seneca,* perfected. in successive editions, his *Tacitus* and brought out a series of works. some of pure scholarship, others collections from classical authors. others again of general interest. Of this latter class was a treatise on politics (*Politicorum Libri Sex,* 1589), which caused trouble by his reactionary views on religious toleration. which was with difficulty smoothed down by the university authorities. In the spring of 1590 he went to Mainz, where he was reconciled to the Roman Catholic Church. The event deeply interested the Catholic world, and invitations poured in on Lipsius from the courts and universities of Italy. Austria and Spain. But he preferred to remain in his own country and finally settled at Louvain as professor of Latin in the Collegium Buslidianum. He continued to publish dissertations as before, the chief being his *De militia romana* (Antwerp, 1595) and *Lovanium* (Antwerp, 1605; 4th ed.. Wesel, 1671), intended as an introduction to a general history of Brabant. He died at Louvain on March 23 (some give April 24), 1606.

Lipsius' knowledge of classical antiquity was extremely limited. His greatest work was his edition of Tacitus. This first appeared in 1575, and was five times revised and corrected — the last time in 1606, shortly before his death. His *Opera Omnia* appeared in 8 vol. at Antwerp (1 585; 2nd ed.. 1637).

A full list of his publications will be found in van der Aa, *Biographisch Woordenboek der Nederlanden* (186j), and in *Bibliographie Lipsienne* (1886–88). In addition to the biography by A. le Mire (Aubertus Miraeus) (1609), the only original account of his liie, *see* M. E. C. Nisard, *Le Triumvirat littéraire au XVI^e siècle* (1852); A. Rass, *Die Convertiten seit det Reformation* (1867); P. Bergman's *Autobiographie de J. Lipse* (1,889); L. Galesloot, *Partirularitks sur la vie de J. Lipse* (1877); E. Amiel, *Un Publiciste du XVI^e siècle. Juste Lipse* (1884); and L. Miiller, *Geschichte der klassischen Philologie in den Niederlanden.* The articles by J. J. Thonissen of Louvain in the *Nouvelle Biographie générale,* and L. Roersch in *Biographie nationale de Belgique,* may also be consulted.

LIPSIUS, RICHARD ADELBERT (1830–1892) German Protestant theologian son of K H A Lipsius id 1861) nho was rector of the Thomasschule at Leipzig was born at Gera on Feb 14, 1830 He studied at Leipzig and eventually (1871) settled at Jena as professor. He helped to found the. Evangelical Protestant Missionary union and the Evangelical Alliance. and from 1874 took an active part in their management. He died at Jena on Aug. 19, 1892. Lipsius wrote principally on dogmatics and the history of early Christianity from a liberal standpoint. His chief works are *Philosophie und Religion* (1885) and *Lehrbuch der evang.-prot. Dogmatik* (1876; 3rd ed.. 1893).

His other works include *Die apokryphen Apostelgeschichten* (1883–90), *Hauptpunkte der christl. Glaubenslehre im Umriss dargestellt* (1889) and commentaries on the Epistles to the Galatians, Romans and Philippians in H. J. Holtzmann's *Handkommentar zum Neuen Testament* (1891–92).

See A. Neumann, *Grundlagen und Grundzüge der Weltanschauung oon R. A. Lipsius* (1896).

LIPTON, SIR THOMAS JOHNSTONE, 1st Bart. (1850–1931), British merchant and yachtsman, equally well known for his success with tea and for the gallant sportsmanship with which he accepted his failures in international yachting. was born at Glasgow, Scot.. on May 10, 1850. of Irish parents. who ran a small grocer's shop. He emigrated to the United States in 1865 and held various jobs for five years before returning to Glasgow.

There he opened a small provision shop, was very successful and established shops throughout the United Kingdom. To supply his retail shops on the most favourable terms. he purchased extensive tea, coffee and cocoa plantations in Ceylon and provided his own packing house for hogs in Chicago. He also acquired fruit farms, jam factories, bakeries and bacon-curing establishments in England. In 1898 his business was organized into Lipton, Ltd. He was knighted in 1898 and created a baronet in 1902, taking as his crest two arms holding sprigs of tea and coffee.

He was a keen yachtsman and as a representative of the Royal Clster Yacht club made five unsuccessful attempts between 1899 and 1930 to win the America's cup with yachts called "Shamrock" (*see* Yachting). Lipton won a reputation for being the "world's best loser," and in 1930 he was presented with a gold cup for sportsmanship by a group of Americans. He died in London on Oct. 2, 1931.

See Alec Waugh, *Lipton* Story (1950). (H. J. Sg.)

LIQUEFACTION OF GASES. It is somewhat uncertain when the idea that gases could be liquefied first arose. Lavoisier certainly expressed the view that if the earth were cooled to the temperature of outer space. part, at least, of its atmosphere would liquefy, but he made no attempt to liquefy any known gas. His associates. Monge and Clouet, were actually the first to succeed in this direction, liquefying sulfur dioxide by passing it into a glass tube cooled with a mixture of ice and salt. About the same time van Marum and Paets van Troostwyk (1790), compressing ammonia to see whether it obeyed Boyle's law, found that when a certain pressure was reached, the volume suddenly decreased rapidly and drops of liquid appeared. In the year 1799 Guyton de Morveau liquefied ammonia by cooling the gas to the temperature of a mixture of ice and calcium chloride. In 1805 Northmore compressed gases mechanically up to 1j atmospheres, and he appears to have liquefied chlorine.

The Early Work of Davy and Paraday.——No further experimental investigations can be traced until the year 1823, when papers were read before the Royal society by Sir H. Davy and his assistant M. Faraday (*Phil. Trans.,* 1923), describing experiments carried out at the Royal institution. In Faraday's first experiments chlorine hydrate, obtained by cooling chlorine water, was heated in a sealed tube to 100° C., when "chlorine was evolved from it under such pressure that it assumed the liquid form, appearing of a bright yellow colour, and sinking in the warm water without any tendency to mix with it." In a second paper he describes experiments with the apparatus shown in fig. 1. Compounds which liberated such gases as chlorine, or sulfureted hydrogen, were placed

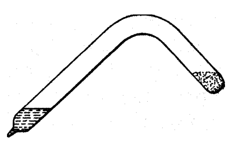

Fig. 1.—FARADAY'S EXPERIMENT

in the short limb of the tube, which was then hermetically sealed. The substance was heated, and the long limb of the tube was cooled in ice or in a freezing mixture; and in it the gases liquefied. A few weeks later Davy described the liquefaction of sulfureted hydrogen, and hydrochloric acid by compression! giving data for the pressures required to liquefy these gases at different temperatures. His paper is of importance. as it shows that in 1823 Davy had already installed apparatus for the compression and liquefaction of gases at the Royal institution. Ill health prevented him from continuing his researches in this direction.

Large Scale Liquefaction.— In 1834 Thilorier developed a method already in vogue for the manufacture of soda water and applied it to the condensation of carbon dioxide in large quantity. Two stout metal vessels. at first made of cast iron, but. after an accident, of copper, and lined with lead, served as the generator and receiver in Faraday's experiments. One of these was fitted with a cap which could be removed, and a cock, and in it was placed solid bicarbonate of soda and a vessel containing sulfuric acid. The other vessel was fitted with a stopcock only, and the two vessels were joined by a connecting tube which could be detached. The generator was charged and closed, and then rotated so as to mix the acid and soda. It was then connected with the receiving vessel, which was cooled in ice. and in this the gas liquefied. The stopcocks were then closed, the vessels were separated, and. by recharging the generator. a second and third charge of gas could be condensed in the receiver. Thilorier observed that the liquid expanded rapidly when heated. He also found that when the liquid was allowed to escape through a jet into a box lined with nonconducting material, a snowlike solid was formed. His observation that this solid carbon dioxide mixed with ether was a much more efficient refrigerant than the solid alone was a valuable contribution to the experimental side of the subject.

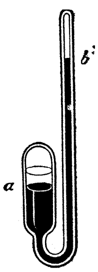
Faraday's Later Experiments.— The first to apply the results of Thilorier's work. which was carried out from a technical standpoint. to scientific investigations. was Faraday. His method of investigation was as follows. The mixture of solid carbon dioxide and ether was contained in an earthenware vessel of 100 cu.cm. capacity. which fitted into a larger earthenware vessel, three or four folds of dry flannel intervening. The temperature measured by an alcohol thermometer was —78° C., but by placing the apparatus under the receiver of an air pump and reducing the pressure to 1.2 in. of mercury, a temperature of —110° C. was reached.

There seems to be no definite evidence as to when the idea first originated that a pure liquid possessed a definite vapour pressure at a definite temperature. Dalton. early in the 19th century, had shown that the vapour pressure of water was independent of thc prcscncc of air in the space above it. and had measured the vapour pressures between the ice point and boiling point. Davy (*loc. cit.*) had observed that "the elasticity of vapours in contact with the liquids from which they are produced, under high pressures increases in higher ratio than the arithmetical one of temperature; but the exact law is not determined." and he had determined the relation of temperature and pressure for certain condensed gases. Faraday now took the subject up at the point at which Davy dropped it, and he determined the vapour pressures of all the gases which could be liquefied at teinperatures above —110° C., and at pressures up to 50 atmospheres. (*Phil. Trans.*, 1845.) Faraday was unable to liquefy hydrogen, oxygen. nitrogen. nitric oxide, and carbonic oxide, and the failure of others to succeed by using higher pressures gave rise to the idea that these gases were *permanent*, the term being still used. with recognized qualifications. An interesting investigation with the same object was that of Satterer (*Sitzungsberichte* d. *Wiener Akad., Ann. d. Phys., 1844–55*). Gases were compressed into a wrought-iron vessel. the pressure. which approached 3,000 atmospheres. being transmitted through mercury to a loaded piston. which acted as a manometer. The experiments failed in their object; but indicated the extent to which the permanent gases departed from Boyle's law regarding the relation between pressure, volume and temperature.

The Critical **State.**—We must now go back to 1822 when Cagniard de la Tour *(An. de Ch. et de Ph.* 21 and 22) proved that when a liquid was heated above a certain temperature it mas completely converted into vapour. He used the glass apparatus shown in fig. 2. the liquid being contained in the wide limb of the U-tube over mercury. the narrow limb serving as a manometer and the pressure being calculated from the volume of the air. The apparatus was heated in an air bath. He obtained the following results:

	Temperature of volatilization	Pressure
Ether	175° C.	38 atm.
Carbon bisulfide . .	258° C.	71 atm.

The experiments of Cagniard de la Tour are an example of the excellent nork carried out by French physicists of the period. They were. honever. completely lost sight of, and it was not till 1860 that the experiment nas repeated by Andrews, and the fundamental principle associated nith it was discovered. Andrews' discovery that for each substance there is a critical temperature above which it cannot be liquefied nas first made public in the 1863 edition of Miller's *Chenzical Physics* and in 1869 formed the subject of a Bakerian lecture under the title, "On the continuity of the gaseous and liquid states of matter."



FROM M. W. TRAVERS, "STUDY OF GASES" (MACMILLAN)

FIG. 2 —CAGNIARD LIE LA TOUR'S EXPERIMENT

Research of **Andrews.**—Andrews had attempted to liquefy the permanent gases by applying high pressures at temperatures down to —110° C. Failing to liquefy them. he turned his attention to the study of the process of liquefying carbon dioxide, with a view to throning light on the general problem of the liquefaction of gases. For this purpose he used an apparatus, now in the South Kensington museum. of which a diagram is shown in fig. 3. It consisted of twin steel tubes. flanged and capped at both ends, and connected laterally. Through glands in the upper caps glass tubes passed, of capillary bore above and closed at the top, the part inside the steel apparatus being 2.5 mm. bore, and open below. The tubes contained respectively carbon dioxide and air. over mercury with nhich the steel apparatus was filled. the air tube serving as a manometer. the pressure being assumed to be inversely proportional to the volume. Steel screw plungers passing through glands in the bottom of the apparatus served to regulate the volume and pressure. The glass tubes projecting outside the apparatus were surrounded by a nater bath with glass sides. He found that at temperatures below 31° C. liquid appeared in the tube containing the carbon dioxide when the air manometer indicated a definite pressure for each particular temperature, and that when liquefaction had commenced, the gas could be completely condensed nithout increase of pressure except such as could be attributed to the presence of traces of air in it. Near 31°, nhich he was the first to call the critical point. the space nhich had been occupied by the liquid at lower temperatures became filled with a "homogeneous fluid. which, nhen the pressure nas slightly reduced. or the temperature slightly lowered, exhibited a peculiar appearance of moving or flickering striae throughout its entire mass" At temperatures above 31° he found that the gas could be reduced in volume to that which it should occupy as liquid with complete continuity and without exhibiting a visible surface, hence the title under which the results of the work were published The results obtained are represented by the simple curves in fig. 4.

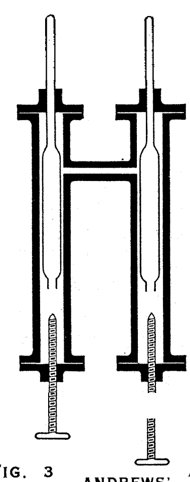


FIG. 3 —ANDREWS' APPARATUS USED IN INVESTIGATIONS ON THE CRITICAL STATE

These curves, called isothermals, representing the relationship of pressure and volume for a series of constant temperatures, are in heavy line. An isothermal for a temperature below the critical temperature represents the volume of the gas as diminishing as the pressure increases till the vapour pressure is reached, and the gas begins to liquefy. The volume then decreases without increase in pressure till the gas is completely liquefied, this part of the curve being a horizontal straight line. As the liquid is only slightly compressible the curve then ascends steeply. The part of the diagram within and below the dotted line represents conditions under which liquid and vapour can coexist. The critical isothermal has no horizontal portion, since the volumes of liquid and vapour are identical. Above the critical point the curves approach rapidly to the form of the hyperbola.

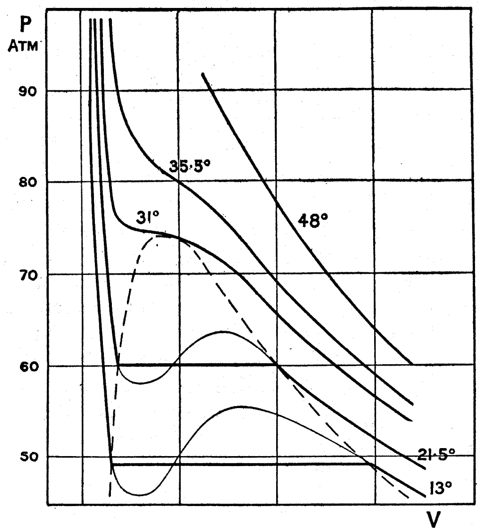

FIG. 4.—P.-V.-T. DIAGRAM FOR CARBON DIOXIDE. ILLUSTRATING THE WORK OF ANDREWS AND OF VAN DER WAALS

The experiments of Andrews fully explained his own failures, and those of Faraday and earlier investigators, to liquefy the so-called permanent gases. The significance of his work, can. however, be appreciated only when we consider the theoretical investigations to which it gave rise. Since the work of Regnault had first shown that the known gases departed more or less from the laws of Boyle and Gay-Lussac as expressed by the equation,

$$\frac{pv}{T}=R, \text{ a constant}$$

T being the temperature on the scale of a thermometer filled with the gas itself, approximately equivalent to the temperature on the absolute scale. to which reference will be made later. Many attempts had been made to modify the formula to accord with the facts so far as they were knoun. These, however, only included the volume and pressure relations of the gas, but in view of the discoveries of Andrews it was now obvious that the theoretical investigation must also take into account the existence of the liquid phase.

Van der Waals's Equation of State.—In 1873 there was published in Leyden a dissertation with the same title as Andrews' Bakerian lecture—"On the continuity of the liquid and gaseous states," by J. D. Van der Waals. The title has not, however, the same significance, and is used in a more exact sense than by Andrems. It implies that while the isothermals for temperatures which differ by a very small interval above and below the critical temperature are practically identical in form, the isothermal for the higher temperatures represents the gaseous state only. and that for the lower temperatures relates also to the liquid state. This was the first original paper published by the author who had for some years been engaged upon mathematical investigations, based upon the kinetic theory of gases and Laplace's theory of capillarity, and upon this work he based the theory which made him famous. Assuming the molecules of any particular gas to be all exactly similar hard elastic spheres of radius r, the volume occupied by n molecules in volume v is $b'=\frac{1}{6}nr^3\pi$. In accordance with the assumption as to the form of the molecule. the gas equation thus becomes $p(v-b)=RT$, where $b=4b'$. Now, while the molecules in the interior of a mass of gas are subjected to attractions by other molecules which are equal in all directions, so that the resultant attraction is negligible, the resultant attraction on the molecules in the surface layer is directed inward, and varies as the square of the volume. Allowing for the effect thus produced the equation now becomes:

$$\left(p+\frac{a}{v^2}\right)(v-b)=RT$$

This is known as the Van der Waals equation.

It may first be pointed out that the equation may also be written in cubic form

$$v^3-v^2\left(\frac{RT}{p}+b\right)+\frac{va}{p}-\frac{ab}{p}=0$$

One of the three roots of this equation must always be real, and the other two may be real or imaginary, so that for every value of p there may be one or three values of v. In a certain region, for the isothermals below the critical point. there are three real values of v for each value of p, so that the curves do not have the simple form indicated by the heavy lines but follow the sinuous lines.

The latter do not exhibit the discontinuity shown by the former, in which, for one particular value of p only, the vapour pressure, there are tao values of v, corresponding to the volumes of saturated vapour and of the liquid. This pressure and the corresponding volumes are indistinguishable on the Van der Waals curve, but at the same time, if the relations of volume, pressure and temperature under which the liquid and vapour phases are in equilibrium are known, the constants in the Van der Waals equation can be calculated from them with the same accuracy as from the data obtained from the compressibility of the gas. The meaning of the continuous curve has been the subject of much speculation. It has been suggested that the portion of it on the extreme right represents a condition of supersaturated vapour, and that on the left a state in which liquid exists at a pressure below its vapour pressure. The central portion must in any case bc without physical significance as it represent5 the pressure and volume as increasing together and decreasing together. As a matter of fact the Van der Waals equation is based upon the consideration of the behaviour of a single phase, which may change continuously into a second phase. but it does not contemplate discontinuity, or equilibrium between liquid and vapour. The form of the curve has no physical significance at all, but is merely a consequence of the mathematical treatment of the subject.

At the point C. the critical point $\frac{\partial p}{\partial v}=0$ and a line drawn parallel to the volume axis is tangential to the isothermal. At this point the three values of V are real and equal. and by a simple algebraical process we can obtain the values of the critical temperature, the critical pressure and the critical volume in terms of the constants of the equation:

$$T_c=\frac{8a}{27bR};\quad p_c=\frac{a}{27b^2};\quad v_c=3b;\quad p_cv_c=0.375RT_c$$

The following are the values of a and b for some of the common gases, when pressures are reckoned in atmospheres. and the volumes in litre-moles:

Gas	a	b
Hydrogen H_2	0.19	0.023
Oxygen O_2	1.36	0.0316
Carbon dioxide CO_2	3.61	0.0428
Sulfur dioxide SO_2	6.69	0.0565

The fundamental ideas which are expressed by the Van der Waals equation are undoubtedly true, but it could hardly be expected that from the simple assumptions upon which it was hased it would be possible to develop a complete theory of the gaseous and liquid state. The equation does not enable us to connect in a quantitative manner the properties of gases at low pressures. The ratio p_cv_c/T_c is not 0.375 pv/T, being generally nearer to 0.27 R/R. It is not possible to trace the isothermals for any distances by means of data calculated from the critical constants. However, the Van der Waals equation. even without modification, has been of very great value as a means of calculating the physical constants for gases and liquids approximately.

The Law of Corresponding States.—A second discovery which was made by Van der Waals is knonn as the law of corresponding states. This is really a mathematical consequence folloning on the assumption that the properties of the systems nith which we are dealing can be represented by an equation with two constants *a* and *b*, R depending merely on the quantity of material in this system, molar or otherwise. If then a series of diagrams are drawn like fig. 4, but representing the properties of different materials, such as carbon dioxide, benzene, etc.. it will be seen that they are very similar. and they can actually be made identical by altering the vertical and horizontal scales on which they are drawn. This may be done if we change the units from absolute units of temperature. pressure and volume. and represent these dimensions in terms of fractions or multiples of the values of the critical constants, thus,

for T we write $T/T_c=\theta$ the *reduced temperature*
,, p ,, ,, $p/p_c=\pi$ the *reduced pressure*
,, v ,, ,, $v/v_c=\phi$ the *reduced volume*

Equal values of θ, π and ϕ for different substances represent what are known as corresponding states. By substituting the reduced values in the equation it becomes

$$\left(\pi+\frac{3}{\phi^2}\right)\left(\phi-\tfrac{1}{3}\right)=\frac{8\theta}{3}$$

It will be noticed that the constants, *a*, b and *R* have vanished, and therefore all substances in corresponding states should behave alike. For instance, the isothermals of all gases represented in this manner should be identical. The law of corresponding states leads directly to certain useful approximations. The boiling point T_b of most liquids is approximately a corresponding temperature, since

$$T_b/T_c=0.62 \text{ (about)}$$

and as it can be shown that the latent heat of liquefaction L should be identical for liquid-gas systems at corresponding temperatures it follows that

$$L/T_b=\text{constant}$$

It was found by Trouton (*Phil. Mag.*, 1899) that for many liquids this rule holds good, thus:

Liquid	T_b	L	L/T_b
†Helium	4.29	22	5.1
†Hydrogen	29.4	214	10 5
†Oxygen	90.6	1,664	18.2
Ethyl ether	307	6,466	21.1
Chloroform	334.5	6,972	20.85
Benzene	353.2	7,370	20.85

Trouton's rule does not hold good for liquids at very low temperatures†, nor for associating liquids‡.

An interesting instance of the application of the discoveries of Van der \1'aals was that of the Polish physicist Witkowski in the early 1880s. He determined the compressibility of oxygen and hydrogen down to the lowest temperatures which in the case of hydrogen mas that of liquid oxygen. From the data. he was then able to calculate the constants in the equation. The critical constants and boiling point of oxygen being known, he was then able to calculate these constants for hydrogen with remarkable accuracy, as later investigations showed.

	Calculated	Experimental
Critical pressure	13 atm.	12.8 atm.
Critical temperature	−240° C.	−239.9° C.
Critical density	0.033 grams per cu.cm.	0.031 grams per cu.cm.
Boiling point	−250° C.	−252.8° C.

Later, Kammerlingh Onnes used a similar process to estimate the constants for helium. Again. Ramsay and Young (*Phil. Mag.*, 1886) discovered a simple relationship between the vapour pressures of pairs of liquids, which holds good for associating liquids, but tends to break down at very low temperatures. If T_x and T_y, $T_{x'}$ and $T_{y'}$, are the absolute temperatures at which a pair of liquids have vapour pressures p and p', then

$$T_x/T_y=T_{x'}/T_{y'}+k(T_x-T_{x'})$$

when k is a constant for each pair of liquids. This formula enables us to calculate the vapour pressure for any substance over a wide range of temperatures, when the vapour pressures corresponding to two or more temperatures are known. The following is an illustration of the use of the method. The case is taken in which the vapour pressure of krypton was to be determined and water was the reference substance.

The values in columns 1 and 2 were the result of observation. The values in column 3 are the temperatures for water corresponding to the pressures in column 1. The values in column 4 are the ratios of the values 2/3. We then plot the values in column 4 against those in column 3, and draw a straight line

1 P(mm)	2 T_{kr}	3 T_{aq}	4 T_{kr}/T_{aq}
386.6	112.7	353.1	0.3174
11,970	170.9	474.3	0.3603
30,837	201.0	525.1	0.3828

5 p(mm)	6 T_{aq}	7 T_{kr}/T_{aq}	8 T_{kr}
600	366.5	0.3229	118.35
4,000	427.2	0.3449	147.3
30,000	523.6	0.3801	199.0

through the points set out. Values of T_{aq} in column 6, equivalent to any derived pressure indicated in column 5, are then readily selected, and from the graph the corresponding values of T_{kr}/T_{aq} in column 7 are read off. Multiplying the values in column 6 by those in column 7 we obtain the values in column 8. Thus we can calculate the vapour pressures over any range, up to the critical point.

Modifications of Van der Waals' Equation.—Various attempts have been made to modify the Van der Waals' equation, and a very large number of equations, nearly all of which are empirical, have been put forward. Thus Clausius proposed an equation

$$\left\{p+\frac{a}{T(v+c)^2}\right\}(v-b)=RT$$

to represent the experimental results of Amagat at very high pressures. This, and other equations, were carefully examined by Kammerlingh Onnes and all were found to be unsatisfactory. D. Berthelot (*Bureau Int. des Poids et Mesures*, 1907, vol. xiii) proposed an equation which, in the reduced condition, and for low pressures, may be written

$$\left(\pi+\frac{16}{3}\cdot\frac{1}{\theta\phi^2}\right)\left(\phi-\frac{1}{4}\right)=\frac{32}{4}\theta$$

From this equation we obtain

$$\frac{\partial(\pi\phi)}{\partial\pi}=\frac{1}{4}\left(1-\frac{6}{\theta^2}\right)$$

while from the Van der Waals equation

$$\frac{\partial(\pi\phi)}{\partial\pi}=\frac{1}{3}\left(1-\frac{27}{8\theta}\right)$$

The former expression enables us to calculate the values of $\frac{d(pv)}{dp}$ over a very wide range of temperature with a surprising degree of accuracy, the results showing deviations from experimental values which are comparable with experimental errors. These constants are of importance in evaluating the deviations of the gas scale from the thermodynamic scale of temperature.

Dieterici, whose work has been reviewed by F. H. MacDougall (J. of *Am. Ch. Soc.* 1916), has put forward equations, which, like the equations of Van der Waals, have a true physical meaning. We will consider his second equation, which is based on the following reasoning. In the interior of a fluid the attractive forces betneen molecules are balanced; at the surface there are unbalanced forces, of which the resultant effect is directed inward. Molecules of low velocity are unable to reach the surface; therefore the surface layer will decrease in density from the interior outward to the surface, where the density will depend on the exterior pressure. Only molecules having a velocity above a certain value mill penetrate this inhomogeneous layer and exert pressure on the walls of the containing vessel. If, now, we determine what fraction of the total molecules has a velocity greater than this value, then the external pressure will be that same fraction of the internal pressure. Omitting the details of the reasoning, from this assumption he arrives at the formula:

$$p=\frac{RT}{v-b}e^{\frac{-A}{RT}}$$

where e is the base of a natural logarithm, b is a function similar to the Van der Waals b and A is a cohesion function measured by the work done by a molecule in penetrating to the surface. Making the simple assumption that A is proportional directly to the volume, the equation becomes

$$p=\frac{RT}{(v-b)}e^{\frac{-a}{vRT}}$$

This equation differs materially from that of Van der Waals in that a and b are really variable with the volume, which makes it very difficult to apply. In some respects it represents a real advance upon the work of Van der Waals, and from it we can derive the expression:

$$p_c v_c=0.27\ RT_c$$

which accords with experiment. Recent attempts to apply modern concepts of atomic structure to the derivation of an equation of state have not led to any noteworthy success.

Thermodynamical Treatment of the Subject.—The experiments of Andrews paved the way for the work of Van der Waals, and after describing those experiments, which open a new period in the history of our subject, it was convenient to describe the theoretical developments to which they gave rise. Before dealing with the next phase in the experimental study of liquid-vapour systems, it is convenient to consider the process involved from the standpoint of thermodynamics. The starting point is now the law of conservation of energy. also known as the first law of thermodynamics. To illustrate this law we will suppose that when we supply a quantity of heat Q to a gas, the heat is utilized in increasing the internal energy of the gas by an amount U. If the gas expands it must overcome resistance; in other words it must do work W; and if Q, U and W are expressed in the same units we may write:

$$Q=U+W$$

It is obvious that the heat is drann from the surroundings and that work is done on the surroundings. and the energy U, which remains associated with the gas. is now the difference between the quantities W and Q. We will now consider nhat changes take place in the values of W, Q and U nhen the gas undergoes changes in temperature. pressure and volume. So long as a system. which may be a gas or liquid, or may contain both gas and liquid. undergoes no such change its internal energy must remain constact, and under certain conditions the internal energy may remain constant when the system undergoes change. This is illustrated by the well-known experiment of Gay-Lussac (1806), afternard perfected by Joule (1844). Two large vessels, connected by a stopcock. are immersed in a water bath. one vessel being exhausted and the other containing gas under pressure. When the temperature is constant, the stopcock is opened, so that the gas can distribute itself between the two vessels. After an interval, the temperature of the water bath is observed, and it is found to be unchanged. The gas has expanded, and though this may be at first sight contrary to experience, its temperature has remained unchanged. Now the experiment is arranged so that the gas expanding into a closed exhausted space, produces no external effect, mechanical or thermal, so that, if we assume the truth of the first law, since

$$W=0 \text{ and } Q=0, \text{ it follows that } U=0$$ w

The result obtained in the Gay-Lussac-Joule experiment would always be observed in the case of an ideal gas which obeys the simple law $pv=$RT, and gases such as air approximate to this very closely at moderate pressures. For the genera1 elementary treatment of problems in thermodynamics it is often convenient, and permissible, to assume that we are dealing with a perfect gas, and that the internal energy at constant temperature is independent of the volume, which is expressed by

$$\left(\frac{\partial U}{\partial v}\right)_T=0$$

In the case of an actual gas, which obeys a more complicated la such as that of Van der Waals, the internal energy depends on the distance between the molecules, *i.e.*, on the volume. and a change of temperature is expected when it expands without doing external work. This may be either a cooling or a heating and can be observed in a modification of the experiment, which will he described later. In any case the internal energy, U, is a unique function of the pressure, p, and temperature, T.

The relation above applies to a perfect gas during any change of volume at constant temperature. Suppose the gas expands in a cylinder with perfectly conducting walls, so that the temperature is kept rigorously constant while the gas does work through the piston. If the volume increases by dv at pressure p we can represent the work done by

$$W=\int p\,dv$$

Since $pv = RT$
$$W=RT\int_{v_2}^{v_1}\frac{dv}{v}=RT\log_e\frac{v_1}{v_2}$$
$$=RT\log_e\frac{p_2}{p_1}$$

If W, the work done, and Q, the heat supplied, were measured we should find that $Q=W$ and that the gas had served merely as a means of converting heat into work, the internal energy remaining constant. Since the mechanism in this hypothetical experiment is supposed to be perfect, the work done is now the maximum work which can be done by the gas when expanding isothermally.

When a liquid evaporates at constant temperature the volume increases at constant pressure, and the external work done is again expressed by:

$$W=\int p\,dv$$

The total quantity of heat absorbed in the process is

$$Q=H_2-H_1=U_2-U_1+\int p dv$$

where U_2 and U_1 are the internal energies of the gas and liquid, respectively. The quantity, $H=U+\int pdv$, calculated from some standard initial condition (*e.g.*, liquid at its normal boiling point), is called the total heat. Like the internal energy, it is a definite function of pressure and temperature in the gas phase. It is a convenient quantity in which to express energy changes in refrigeration processes, and has been tabulated for all gases of interest. In the case of the evaporating liquid, the change of internal energy is much larger than the work of expansion. Thus, use of a liquid for refrigeration allows a greater exchange of energy than a gas. for a given change of volume.

Adiabatic **Expansion.**—We may now consider what happens when a gas is allowed to expand, doing work, hut in such a manner that no heat is absorbed, that is to say adiabatically. This actually happens in the high-pressure vessel in the Gay-Lussac-Joule experiment. and it becomes obvious when. in a modification of the experiment by Joule. the vessels are contained in separate water baths. Though the temperature of the water in the bath enclosing both vessels has not altered, in the modified experiment, the water around the high-pressure vessel generally becomes cooled, and the water around the low pressure vessel generally becomes equally heated. If the cock is closed the moment expansion has taken place. when the temperature has finally become uniform, the pressure in the high-pressure vessel is found to be less than in the low-pressure vessel. The gas which remains in the high-pressure vessel may be supposed to do work in imparting kinetic energy to that part of the gas which flows into the lox-pressure vessel. As the change takes place very rapidly no heat is absorbed. The kinetic energy of the moving mass of gas reappears as heat energy when the gas is brought to rest in the second vessel.

In order to analyze this problem we must first consider the change which takes place when a gas is heated. Suppose that one gram molecule of a gas is heated from T to $T+dT$, so that the pressure remains constant. The heat absorbed by the gas can be represented by $dQ=C_pdT$, where C_p is the (molar) specific heat at constant pressure.

If now we first of all consider the gas to be heated through an interval dT at constant volume, the increase in the internal energy is given by:

$$\left(\frac{\partial U}{\partial T}\right)_v dT=C_vdT$$

C_v being the specific heat of the gas at constant volume. If now the gas is allowed to expand. doing maximum work, till the original pressure is reached. the work done is:

$$dW=p\ dv=RdT$$

Then since dQ= $dU+dW$,

$$C_pdT=C_vdT+RdT$$
$$C_p=C_v+R$$

Now since in any adiabatic process $dQ=O$,

$$C_vdT+p\ dv=O$$

Substituting $p=RT/v$, and integrating:

$$C_v\log_eT+\mathrm{R}\ \log_ev=\text{Constant}$$

Writing γ for C_p/C_v, and substituting C_p-C_v for R,

$$\log_eT+(\gamma-1)\ \log_ev=\text{Constant}$$

or

$$Tv^{(\gamma-1)}=\text{Constant}$$

and writing gas equation in the form:

$$\log_eP+\log_ev-\log_eT=\text{Constant}$$

we obtain

$$\log_eP+\gamma\log_ev=\text{Constant}$$

or

$$pv^\gamma=\text{Constant}$$

This equation, which gives the form of the adiabatic curves for a perfect gas, shows that these. when represented on a pv diagram, are steeper than the isothermal curves. indicated by full lines (fig. 5). Suppose that a gas is compressed isothermally. so that the p–v relations are represented by the isothermal ab. When the point bb' is redched the gas is allowed to expand adiabatically. If the adiabatic curve (pv^γ=const.) passes nithin the region p–v on the diagram which represents conditions under which liquid can exist, as at d, partial liquefaction will result, as happened in the case of the experiments of Cailletet.

Liquefaction by Adiabatic **Expansion.**—When liquefaction does not take place the fall of temperature resulting on expansion from pressure p_1 to pressure p_2 is given by the following expression derived from the above.

$$\frac{T_1}{T_2}=\left(\frac{p_1}{p_2}\right)^{\frac{\gamma-1}{\gamma}}$$

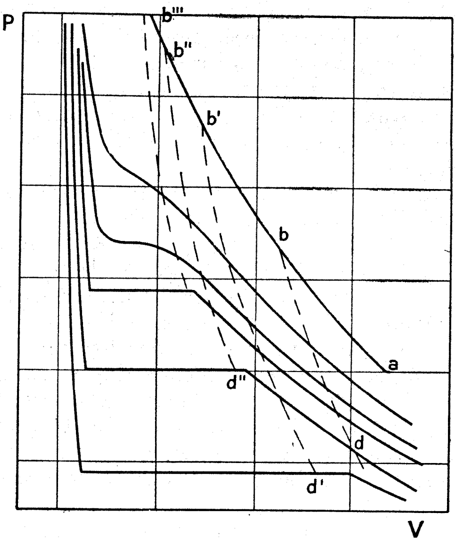

FIG. 5.— ADIABATICAND ISOTHERMAL CURVES FOR PURE GASES

The next experimental work of importance following the work of Andrews. and to which the theory which we have just considered applies, is that of Louis Cailletet. He used an apparatus, similar in principle to that of Andrews. The gas was confined over mercury in a glass tube. the capillary part of which projected outside a steel chamber, the lower part of which also contained mercury to which pressure was transmitted by means of water from a compression pump. The first gas to be investigated was acetylene, uhich was liquefied by pressure alone at the air temperature (critical temperature 35° C.). However, on one occasion when the acetylene had been compressed to a degree insufficient to liquefy it, the release valve on the compression pump was opened. and immediately, as the gas within expanded, the capillary tube was seen to be filled with a dense mist. Cailletet did not at first realize that the cause of the appearance of the mist nas the adiabatic cooling and partial liquefaction of the acetylene, and he put it down to the presence of impurity in the gas. As a second experiment with acetylene, prepared with great care, yielded the same result. he next filled the apparatus with nitrous oxide, and again observing the formation of mist on expanding the gas, he came to the conclusion that the phenomenon was due to the actual liquefaction of the gas. It was difficult to realize that such intense cooling could be effected by expanding so small a quantity of gas in a capillary tube, but having realized that this could be done, Cailletet at once proceeded to attack the problem of liquefying the so-called permanent gases. Methane, carbon monoxide and oxygen were in turn compressed to **300** atmospheres in the same apparatus, cooled to −29° C. in a bath of sulfur dioxide boiling under reduced pressure, and then allowed to expand by releasing the pressure.

In each case the tube was seen to fill with the dense mist, indicating that liquefaction had taken place, though no liquid was actually seen.

LIQUEURS. A liqueur (from the Latin *liquefacere,* "to make liquid") is a spirit which has been sweetened and flavoured with fruit or herbs. The alcoholic content of a liqueur, which is usually high, as well as the medical herbs which it frequently contains, are both agents which have been recognized as curative and digestive since the middle ages. Liqueurs are also often used as a liquid centre for chocolates.

There are three kinds of liqueur: (1) those with one herb predominating in their flavour; (2) those with only one fruit; (3) those with a mixture of flavouring agents. Kiimmel, made from caraway or cumin seeds, and framboise, made from raspberries, are good examples of the first two types, while Bénédictine is made of about 30 different herbs and other ingredients.

There are two main methods of making liqueurs. The first is by distilling all the ingredients together, the resulting distillate being sweetened and sometimes coloured. The second is to add an infusion of herbs, or fruits, to the base spirit; this is the method generally followed as it preserves the freshness, colour and bouquet of the ingredients. The best liqueurs are usually made upon a Cognac base.

It is easy to confuse liqueurs with spirits or with bitters (*q.v.*). When a liqueur is made upon a brandy or gin base it may be sold as a brandy or a gin, such as cherry brandy or sloe gin—but these are liqueurs, since they are sweetened. An unsweetened spirit cannot be called a liqueur; there is, for instance, a genuine unsweetened Hungarian and Yugoslavian brandy called Slivovitz, distilled from plums. Confusion may be deepened when the same name is used for both liqueurs and brandies; there is a sweet apricot brandy — a liqueur — as well as an unsweetened spirit made from apricots, and also known as apricot brandy. While sloe gin is a liqueur, lemon and orange gin are ordinary dry gins, with fruit added for flavouring. Although combined spirits are sometimes referred to as liqueurs, they should not be unless sweetened. Similarly, "liqueur brandy" is a misnomer; the word liqueur only refers here to its use as a *digestif* or to its specially good quality.

Bitters can be used as *digestifs* but they are usually *apkritifs.* They differ from liqueurs in that they are only very slightly sweetened, if at all.

The making of liqueurs was practised from earliest times. In 460 B.C. Hippocrates says that the ancients distilled herbs and plants, and because certain herbs were noticed to cure illness or to be effective as tonics, liqueur-making had a close association with early medicine and with medieval astrology. The Saxon word "wort" means a plant used for medicine. Certain plants were believed to keep away evil spirits, sometimes if they were merely pinned to a door. The remedies were certainly effective when they were administered; aniseed, caraway seed and mint, for instance, were long known to help digestion. Nicholas Culpepper, writing in the 17th century, advises "a water distilled from (angelica) root" for the same purpose; angelica is frequently used in liqueurs, together with many other herbs, such as coriander, fennel. wormwood, gentian, amber, hyssop and thyme. *(See* Culpepper's The *Complete Herbal.)*

A particular area of the world will often produce a variety of herb or fruit which is best for liqueur-making, and it is there that the industry will be situated. For example. the small apricot that is found in the fle-de-France is the only one that will make abricotine, and the wild blackthorn of Devon and Comwall makes the best sloe gin. The fruit must always be picked at its ripest, and even slightly blemished fruit discarded.

See M. I. Fisher, *Liqueurs* (1952). (C. C. H. F.)

LIQUIDAMBAR, LIQUIDAMBER or SWEET GUM, a product of *Liquidambar styraciflua* (family Hamamelidaceae), a tree native to the United States, Mexico and Central America. The earliest record of the tree appears to be in a Spanish work by F. Hernandez, published in 1651, in which he describes it as a large tree producing a fragrant gum resembling liquid amber, whence the name. In Ray's *Historia Plantarum* (1686) it is called *Styrax liquida.*

Liquidambar was introduced into Europe in 1681 by John Banister. a missionary collector sent out by Bishop Compton, who planted it in the palace gardens at Fulham. The gum resin yielded by this tree has no special medicinal virtues, being inferior in therapeutic properties to many others of its class. It has long been used in France as a perfume for gloves, etc. It is mainly produced in Mexico. *(See* SWEET GUM.)

LIQUIDATION. A British joint stock company, being a purely artificial body created by law, can only be brought to an end by legal process. This legal process is called liquidating or winding up the company.

A company may be wound up (1) Voluntarily, by the passing of a special or extraordinary resolution that it be wound up, and the appointment of a person to act as liquidator. The liquidator so appointed has to convene a meeting of creditors. and the creditors may, if they think fit, pass a resolution deputing some named person to apply to the court to appoint another person to act as liquidator, either with or in place of the existing liquidator. Ordinarily, the court would act upon such a request in cases where the company appeared to be insolvent. (2) Under the supervision of the court. This form of procedure is now practically obsolete. (3) Compulsorily. Here the procedure is analogous to that in bankruptcy. The official receiver takes charge of the company's affairs in the first instance! and it is the duty of the directors of the company to supply him with a sworn statement of its affairs. This statement of affairs is submitted by the official receiver to separate meetings of the creditors and contributories (or shareholders). Each meeting has a right to nominate a liquidator, who may be the official receiver; the official receiver reports the result of the meetings to the court, and the court thereupon appoints a liquidator.

Duties **of Liquidator.**—Whatever form the liquidation takes, it is the duty of the liquidator (1) to realize the assets of the company to the best advantage; (2) to adjust the rights of contributories *inter se, i.e.*, to determine what calls must be made upon the partly paid shares of the company (if any) in order to provide for the payment of its debts, and to do justice to the different classes of shareholders; (3) to investigate the causes of liquidation, and if necessary to institute proceedings against any persons who may have contributed to its failure; (4) to distribute the proceeds of the realization of the assets among those entitled to participate, having regard to the priorities provided by law; (5) to close the liquidation, and provide for the final dissolution of the company.

On the appointment of a liquidator, the directors and all the former officers of the company cease to function, and the liquidator becomes the only officer capable of acting in the name of the company and using its common seal. In so doing he acts as agent of the company only.

Debenture holders are secured creditors only to the extent of any specific or general charge that they may hold upon the assets of the company. Usually, a receiver is appointed to look after their special interests; but, in the absence of a receiver. it is the duty of the liquidator to see that. subject to payment of proper costs, the proceeds of the sale of all assets charged in favour of debenture holders are applied (subject only to the rights of preferential creditors) first in satisfaction of debenture holders' claims.

In the absence of express provision to the contrary, every share in the company carries equal rights and responsibilities. Thus, if all the shares are not fully paid, the rights of the respective holders cannot be adjusted until either the partly paid shares have been fully paid up, or a sum has been returned to the holders of fully paid shares equal to that uncalled upon the partly paid shares. But, of course, no return can be made to shareholders until all the debts of the company have been paid. (L. R. D.)

United States. — Although both liquidation and winding up are terms in use in the United States. the legal process is most frequently called dissolution; and the dual forms refer t~ voluntary and involuntary dissolution. Liquidation is often used in the narrower sense of the actual disposition of the company's assets.

In a voluntary dissolution the directors usually act as liquidating trustees. In involuntary dissolution the receiver appointed by the court will liquidate the assets. There is no formal creditors' meeting provided for although such meetings are often called and act in an advisory capacity.

In comparing involuntary dissolution with bankruptcy, it should be noted that the bankruptcy statute excludes from its operation railroad, banking and insurance companies. The United States supreme court has further held that in many circumstances a public utility company may be compelled to continue operating even though its stockholders wish to dissolve. In such a case neither bankruptcy nor liquidation would be available to a railroad company. It has, however, been held that when a railroad company is operating at a continuous loss the courts and legislatures must allow it to liquidate. (J. L. WE.)

LIQUID STATE, THE. The states of aggregation of chemical substances are classified as gas, liquid and solid. Gases and liquids are distinguished from solids by the property of fluidity. Elastic solids resist both tensile and shear deformation with stresses proportional to the strains. They are therefore capable of supporting shearing stress at equilibrium. The representative fluid, obeying the Newtonian law of viscosity, resists shear deformation only with a stress proportional to the rate of strain. Fluids are therefore incapable of supporting shearing stress and, under the action of gravity, flow to adapt their shapes to those of their containers. The mechanical distinction between fluids and solids is not sharp. Many substances, notably certain high polymeric materials, exist in states exhibiting mechanical properties intermediate between those of the elastic solid and the viscous fluid.

Each substance possesses a critical temperature above which there exists but a single fluid phase. Above the critical temperature there is no distinction between gas and liquid. At each temperature below the critical there exists a pressure, called the vapour pressure, at which two fluid phases are capable of coexistence. The more dense is designated as the liquid and the less dense as the vapour. At pressures exceeding the vapour pressure the liquid is stable. At pressures less than the vapour pressure the vapour or gas is stable.

The boiling point of a liquid under constant external pressure is the temperature at which the vapour pressure becomes equal to the external pressure. Heated at constant pressure, a liquid remains stable until its boiling point is reached, when it is transformed to vapour with the absorption of heat. The heat absorbed in the vaporization of unit mass of liquid is called the latent heat of vaporization.

In general, substances possess one or more crystalline solid modifications. Some or all of them may be capable of coexistence with the liquid phase. At a specified external pressure, the temperature at which a crystalline solid and the liquid coexist is called the melting point of the solid or the freezing point of the liquid. When a liquid is cooled to the freezing point, it is transformed into the solid with the liberation of heat. The heat liberated when unit mass of liquid is transformed into solid is called the latent heat of fusion. Noncrystalline solids, for example glassy or vitreous materials, generally do not possess definite melting points, but soften gradually to a liquid phase with increasing temperature. Noncrystalline solids are frequently unstable with respect to transformation to crystalline phases, but the rate of transformation may, as in the case of glasses, be exceedingly slow.

Substances are observed to possess triple points of specified temperature and pressure at which solid, liquid and gas may coexist. At pressures below that of the triple point the liquid is no longer stable. When the solid is heated below the triple point pressure, it sublimes to vapour without passing through an intermediate liquid phase.

Liquids in contact with their own vapours or with air possess a property called surface tension which, unless opposed by external forces, causes the interface to reduce to minimum area. Therefore, in the absence of gravity and other external forces, the stable form of a mass of liquid is spherical. Surfaces between a liquid and a solid or another immiscible liquid are also characterized by interfacial tensions, which determine whether the liquid in question will wet or spread on the other material.

As a rule, substances possess only one liquid modification. Exceptions are found in the case of helium which possesses two liquid forms and in certain substances, for example para-azoxyanisole, which possess optically anisotropic liquid crystalline phases as well as a normal liquid phase.

The Molecular Structure of Liquids.—The structure of substances on the molecular scale is determined by a balance between the ordering influence of intermolecular forces and the disordering influence of thermal motion. At low temperatures the influence of intermolecular forces predominates to give the well-ordered structural characteristics of the crystal lattice. At high temperatures the influence of thermal motion predominates to give the random and featureless structure of a gas. The structure of liquids corresponds to a degree of order intermediate between that of the crystalline solid and that of a gas.

The structure of an ideal crystal is characterized by a high degree of order and organization in the arrangement of the atoms and molecules of which it is composed. This order is described by the theory of space lattices. There exists a fundamental unit of structure composed of a small number of atoms or molecules in a definite geometrical configuration. The crystal lattice is built up as a periodic reproduction of the fundamental unit in the three directions of space. Real crystals possess various types of disorder such as mosaic structure and lattice dislocations as well as thermal disorder associated with lattice vibrations and lattice defects.

When a crystalline solid melts to the liquid, the long-range order of the crystal lattice is destroyed. However, a residue of local order persists in the liquid state. Each molecule maintains a partially ordered arrangement of its neighbours which is a blurred replica of that of the crystal lattice. This vestigial order lacks the long-range character of that of the crystal lattice and becomes imperceptible at distances greater than several molecular diameters.

The local order characteristic of the liquid state is described by the radial distribution function $g(R)$, defined as the ratio of the average local molecular density $\rho(R)$ at a distance R from an arbitrary molecule to the bulk density ρ_0 of the liquid.

$$\rho(R) = \rho_0 g(R) \qquad (1)$$

A radial distribution function everywhere equal to unity corresponds to a completely random or disordered structure. Departures of $g(R)$ from the value unity measure the local order established by a molecule in the arrangement of its neighbours. For the representative liquid, $g(R)$ is a curve which possesses a series of rapidly damped maxima and minima. The positions of the maxima roughly correspond to the first several co-ordination shells of the crystal lattice characteristic of the solid state of the material. The minima correspond to distances intermediate between co-ordination shells. The local order described by the radial distribution function lacks the sharpness of crystalline order and is appreciable only at distances of a few molecular diameters. The resemblance of liquid structure to crystalline structure is therefore limited to a domain of molecular dimensions in the vicinity of any molecule. The radial distribution function specifies only the average local density, from which significant statistical fluctuations must occur as the neighbours of a specified molecule are interchanged with other molecules in the course of thermal motion.

The experimental determination of the radial distribution function is based upon the measurement of angular distribution of intensity of X-rays scattered by the liquid, according to techniques developed by F. Zernicke and J. A. Prins and by P. Debye and H. Mencke. A beam of monochromatic X-rays is allowed to traverse a small sample of the liquid, confined in a glass capillary or in the form of a jet. The intensity of the scattered radiation is recorded as a function of scattering angle on a photographic plate, in an ionization chamber. or with a Geiger-Miiller counter. An X-ray scattering photograph of a liquid resembles to a certain extent a Debye-Scherrer powder diagram of a crystalline solid. However. instead of the well-defined rings of maximum intensity of the powder diagram, a liquid gives only a few broad and diffuse rings of rapidly diminishing intensity.

From the intensity $I(\vartheta)$ of the X-rays scattered by a liquid in a direction making an angle ϑ with the incident beam, the radial distribution function may be calculated with the aid of the Fourier integral theorem. The relationship may be expressed in the following manner,

$$g(R)-1=\frac{1}{2\pi^2 R}\int_0^\infty si(s)\sin(sR)ds$$
$$i(s)=(I/I_e-Nf^2)/Nf^2 \tag{2}$$
$$s=(4\pi/\lambda)\sin\theta/2$$

where I_e is intensity of radiation scattered by a single electron, λ the X-ray wave length, and f the form factor of the atoms of which the liquid is composed. The Fourier integral may be evaluated with the aid of an harmonic analyzer or other mechanical computing devices.

Although the X-ray scattering technique is strictly applicable only to a monatomic liquid, it may be employed in an approximate fashion to obtain worthwhile qualitative information concerning the structure of polyatomic liquids when the scattering can be principally attributed to a single type of atom or when the form factors of the several types of atoms composing the molecules are not significantly different in magnitude.

Quasi-crystalline models of local liquid structure may be used to advantage in the interpretation of the radial distribution function. While it is recognized that long-range crystalline order is absent, the local arrangement of the neighbours of each molecule is regarded as a blurred replica of the first several co-ordination shells of a single crystal lattice or of a superposition of several lattice types. The number of neighbours in each diffuse co-ordination shell is estimated as the integral of $4\pi R^2\rho_0 g(R)$ under the corresponding peak of the radial distribution function.

Quasi-crystalline analysis of the radial distribution functions of the liquid metals, for example sodium and mercury, leads to the conclusion that the local structure corresponds to a close-packed arrangement of spheres. J. D. Bernal and R. H. Fowler have employed the quasi-crystalline model with great success in interpreting the structure of liquid water. The liquid is regarded as a three-dimensional net in which each water molecule is linked to four neighbours by hydrogen bonds. By superposing co-ordination structures of the β-quartz, trydymite, and closed-packed types, a radial distribution function, yielding an X-ray scattering curve in substantial agreement with experiment, may be constructed. At low temperatures the β-quartz structure predominates, and at high temperatures the contribution of the closed-packed structure increases. Many of the anomalous properties of water, for example, the maximum density at 4° C., are accounted for by the Bernal-Fowler model.

The structure of the liquid paraffin hydrocarbons has been interpreted along similar lines by B. E. Warren. In these liquids, the structure approximates the arrangement realized in the axial close-packing of slender rods. The X-ray scattering curves of the aliphatic alcohols exhibit inner peaks not observed for the corresponding hydrocarbons. This peak may be qualitatively interpreted, if it is assumed that the alcohol molecules are linked in chains by hydrogen bonds between the hydroxyl groups, while the aliphatic radicals remain approximately close-packed as in the corresponding hydrocarbons. Similar qualitative interpretations of the structures of many organic liquids can be made.

The investigation of the relation between liquid structure and intermolecular forces involves difficult problems in statistical mechanics which have received only partial solution. The statistical mechanical theory of molecular distribution in liquids has been studied by J. E. Mayer and J. G. Kirkwood. An approximate integral equation relating the radial distribution function to the potential of intermolecular forces has been formulated by J. G. Kirkwood and solved by Kirkwood and E. Monroe for a system of rigid spherical molecules with out attractive forces. The theoretical distribution function possesses the general characteristics of the experimentally determined radial distribution functions for representative liquids.

The Thermodynamic and Mechanical Properties of Liquids.—The thermodynamic properties of an homogeneous liquid in equilibrium are determined by its equation of state,

$$p=f(T,v) \tag{3}$$

which specifies the pressure p as function of the temperature T and the specific volume v, and by its specific heat as a function of temperature at a constant value of the pressure. The equation of state cannot be expressed in closed form in terms of elementary mathematical functions, but simple analytical approximations may be used for limited ranges of the variables. In general, the compressibilities and thermal expansion coefficients of liquids are not very sensitive to pressure, away from the critical state. However, the compressibility decreases slowly with increasing pressure.

Heterogeneous equilibrium between liquid and vapour or liquid and crystalline solid is described by the Clapeyron equation.

$$\frac{dp}{dT}=\frac{L}{T\Delta v} \tag{4}$$

where L is the heat absorbed and Δv is the specific volume increment in the transition. This differential equation determines the pressure p as a function of temperature T for states of coexistence of the liquid and the contiguous phase. Thus, when applied to liquid-vapour equilibrium, it determines the vapour pressure as a function of temperature.

According to statistical mechanics, the thermodynamic behaviour of a liquid is determined on the molecular scale by the forces acting between the molecules of which it is composed. The intermolecular force between a pair of molecules is one of repulsion at small distances and one of attraction at large distances. The repulsion at small distances prevents molecules from interpenetrating to an appreciable extent and gives them an effective size. The attraction at large distances is called the van der Waals force and is responsible for the general cohesive properties of matter. The potential $V(R)$ of a pair of chemically saturated spherical molecules or atoms, for example argon, situated at a distance R from each other may be approximately represented by the expression, formulated by J. E. Lennard-Jones,

$$V(R)=\frac{\lambda_1}{R^s}-\frac{\lambda_2}{R^6} \tag{5}$$

where λ_1 and λ_2 are constants and s is an exponent in the neighbourhood of 12. The first term, dominating at small intermolecular distances, gives rise to repulsion, and the second, dominating at large distances, gives rise to the van der Waals attraction.

According to J. E. Mayer, the pressure p is related to the potential of intermolecular force $V(R)$ and the radial distribution function $g(R)$ in the following manner,

$$pv=RT-\frac{2\pi N}{3}\rho_0\int_0^\infty R^3\frac{dV}{dR}g(R)dR \tag{5}$$

where V is the molar volume, N is Avogadro's number, R the gas constant, and T the absolute temperature.

The molar heat of vaporization is related to the potential of intermolecular force and the radial distribution function through the formula,

$$L=RT-2\pi N\rho_0\int_0^\infty R^2V(R)dR \tag{6}$$

where the symbols have the same significance as in equation (5).

The statistical mechanical theory of liquid structure has been approached from another standpoint by H. Eyring and J. Hirschfelder and by J. E. Lennard-Jones and A. F. Devonshire. In these theories the quasi-crystalline model of local liquid structure is employed to estimate the free volume accessible to each molecule, in which it is supposed to execute gas-like thermal motion. The free volume is much smaller than the total volume per molecule, since each molecule is caged by its neighbours. According to the free volume theories, the equation of state has the form,

$$p=RT\left(\frac{\partial\log v_f}{\partial v}\right)_T-\left(\frac{\partial E}{\partial v}\right)_T \tag{7}$$

where v_f is the free volume and E is the molar internal energy. The several free volume theories prescribe different models upon which to base the calculation of v_f. They have been very successful in reproducing the empirical equations of state of many liquids.

In fluid mechanics the relation between the stress tensor σ and the rate of strain $\dot{\epsilon}$ is of primary importance. For the Newtonian fluid in which the principal shearing stresses are proportional to the corresponding rates of strain, this relation is

$$\sigma=-(p+\tfrac{2}{3}\eta\nabla\cdot u)1+2\eta\dot{\epsilon} \tag{8}$$

where 1 is the unit tensor, u the fluid velocity and η the coefficient of viscosity. The stress law of equation (8) when introduced into the equation of motion leads to the Navier-Stokes equation,

$$\rho\frac{du}{dt}=\rho F-\nabla p+\eta\nabla^2 u+\frac{\eta}{3}\nabla\nabla\cdot u \tag{8}$$

where ρ is the density and F is the external force acting on unit volume of the fluid. The Navier-Stokes equation together with the equation of continuity,

$$\nabla \cdot (\rho u) = -\partial\rho/\partial t \tag{10}$$

describes the motion of viscous fluids. The study of the solutions of these equations under appropriate initial and boundary conditions constitutes the science of hydrodynamics.

The coefficient of viscosity of a liquid is related to its structure and the intermolecular forces in a complicated way. According to Eyring, it may be represented in the form,

$$\eta = \frac{a_1 h}{a_2 a_3 a^2} e^{-\Delta F \pm /RT} \tag{11}$$

where h is Planck's constant and AF* is the free energy of activation for the elementary flow process. In this equation, a_1 is the dimension of the unit of flow perpendicular to the direction of flow, a_2 and a_3 the dimensions parallel to the direction of flow, and a the distance moved by the unit of flow in the elementary process.

Electrical and Optical Properties of Liquids.—With the exception of the liquid metals, molten salts, and solutions of salts in ionizing solvents, the electrical conductivities of liquids are very small. In the liquid metals the conductivity is electronic. In molten salts and solutions of salts the conductivity is electrolytic, that is the electric current is carried by the ions of the salt. For example, in an aqueous solution of sodium chloride, the current is carried by the ions Na^+ and Cl^-.

The dielectric constants of nonpolar liquids, for example benzene, the molecules of which do not possess permanent electric dipole moments, do not differ greatly from unity and generally are in the range 1.00 to 3.00. The dielectric constants of polar liquids, for example water, the molecules of which possess orientable electric dipole moments, are generally one or two orders of magnitude larger than those of nonpolar liquids. Thus the dielectric constant of water is approximately 80 at 25 C. With the exception of liquid crystalline phases, liquids are optically isotropic. In nonpolar liquids the refractive indices for the visible spectrum do not differ greatly from the square roots of their dielectric constants measured in the radio or audio frequency spectrum. In polar liquids, the refractive indices for light in the visible spectrum are of the same magnitude as those of nonpolar liquids.

The absorption spectra of liquids in the visible and ultra-violet region of the spectrum reflect the electronic structure of their component molecules and do not differ markedly from the absorption spectra of the substances in the vapour state. However, on account of the perturbing influence of intermolecular forces, changes in frequency and intensity, as well as the broadening and blurring of the band structure of the vapor spectrum, are observed. The infra-red and Raman spectra of liquids may differ markedly from those of their vapours, because of the presence of structural irequencies characteristic of the liquid state. Such structural frequencies are analogous to the lattice vibrational frequencies which give rise to the residual ray spectrum of ionic crystals.

LIQUORICE. The hard and semi-vitreous sticks of paste, black in colour and possessed of a sweet, somewhat astringent taste, known as liquorice paste or black sugar, are the inspissated juice of the roots of a leguminous plant, *Glycyrrhiza glabra,* the *radix glycyrrhizae* of pharmacopoeia. The plant is cultivated throughout the warmer parts of Europe, especially on the Mediterranean shores, and to some extent in Louisiana and California. The roots for use are obtained in lengths of three or four feet, varying in diameter from $\frac{1}{4}$ to 1 in., they are soft, flexible and fibrous, and internally of a bright yellow colour, with a characteristic, sweet pleasant taste. To this sweet taste of its root the plant owes its generic name *Glycyrrhiza* (the sweet-root), of which the word liquorice is a corruption. The roots contain grape-sugar, starch, resin, asparagine, malic acid and the glucoside glycyrrhizin, $C_{24}H_{36}O_9$, a yellow amorphous powder with an acid reaction and a distinctive bitter-sweet taste. On hydrolysis, glycyrrhizin yields glucose and glycyrrhetin.

Stick liquorice is made by crushing and grinding the roots to a pulp, which is boiled in water over an open fire, and the decoction separated from the solid residue of the root is evaporated till a sufficient degree of concentration is attained, after which, on cooling, it is rolled into the form of sticks or other shapes for the market. The preparation of the juice is a widely extended industry along the Mediterranean coasts; but the quality best appreciated in Great Britain is made in Calabria and sold under the names of Solazzi and Corigliano juice. Liquorice enters into the composition of many cough lozenges and other demulcent preparations; and in the form of aromatic syrups and elixirs it has a remarkable effect in masking the taste of nauseous medicines.

LIQUOR LAWS AND LIQUOR CONTROL. Laws to regulate or prohibit the manufacture, sale and transportation of beverage alcohol or intoxicating liquors are of ancient origin everywhere and are growing more numerous and complex in all countries. They are found more often and in greater variety as tax measures ostensibly for the purpose of raising revenue, but even here the dominant motive is usually the social aim to combat the evils of alcoholism and promote public health, public order and social welfare.

Another factor of growing importance from the middle of the 19th century has been the rapid urbanization, industrialization and mechanization of modern life in the leading nations of the world. There is a consequent wider recognition of the need for sobriety as a safeguard to public order and physical efficiency.

There are four general methods of legislative control of the liquor traffic:

1. *Licensing,* the oldest and most widely used method.
2. *The no-private-profit Scandinavian or company system,* which seeks to ensure disinterested management by entrusting a monopoly of sale of liquor to a body of citizens who have no personal interest or profit in it.
3. *State monopoly,* where the state retains the wholesale or retail trade, or both, in its own hands, takes the profits as public revenue and of course retains complete control.
4. *Restriction or limited prohibition,* which is usually a system of high licence with local option or local veto.

The licence systems of the United Kingdom and the United States respectively exemplify two main principles of licensing. In the U.K. is found a single homogeneous system gradually evolved after centuries of experience with the licensing principle, whereas in the U.S. before and after the era of national prohibition many different systems were coexistent as a result of the quasi sovereignty of the individual states. Also, U.S. law and legislative practice have never varied the traditional common-law theory of a licence as a temporary permit, revocable for violation of the conditions upon which it was granted and terminable at the will of the issuing authority upon the expiration of the brief term —usually one year—for which it was granted, and without vesting any property right in the expectation of renewal.

THE UNITED KINGDOM

The English System.—The common law of England imposes no control on the keeping of inns, taverns and alehouses, apart from the requirement that they shall not constitute a nuisance. Statutory control, however, commenced in the reign of Edward VI with the act of 1552, which introduced the system of licensing and brought common ale, or tippling, houses under the vigilance of justices of the peace. The licensing system, with its object of suppressing the vice of drunkenness by limiting the number of public houses and by other controls, developed through the centuries and was extended by the insistence that the granting of a magistrate's certificate was a condition precedent to the allocation of an excise licence, which constitutes the sole authority for the sale of liquor.

Control by the lay justices, exercising their local knowledge within the framework of the general law as to the desirability of granting applications, is accordingly the foundation of liquor control in the country. Such control by the justices is practically complete, but there are for historical reasons certain exemptions from their control. In the case of R. v. *Graham Campbell ex parte A. P. Herbert* (1935 1 *K.B.* 594), in which an application was made for summonses against the kitchen committee of the house of commons for having unlawfully sold by retail intoxicating liquor within the precincts of the house, it was held that the bulk of the provisions of the Licensing acts were quite inapplicable to the house of commons, and that the jurisdiction of the courts was excluded by the privilege of parliament. All who are free of the Company of Vintners in the City of London derive exemption from letters patent of James I; and similarly unprejudiced by the licensing legislation are the chancellors, masters and scholars of the University of Cambridge who need neither a justices' nor an excise license for the sale of wine. Naval and military canteens also enjoy exemption. The Carlisle area stands outside the general scheme of licensing control being subject to a system of state ownership instead. No person unless acting on behalf of the secretary of state for home affairs may sell intoxicating liquor by retail in the Carlisle district or supply it in any licensed premises or registered club. Ancillary functions exercisable by the home secretary in this area include the provision and maintenance of hotels and inns where accommodation and inns are provided and alcoholic liquor is sold. The state management of the liquor trade in operation in the Carlisle area was extended to all "new towns" declared to be such by the New Towns act, 1946, but state management of the trade in these towns was withdrawn in 1952 and became once more confined solely to the Carlisle area. Committees, however, were constituted in the new town areas to determine the number, nature and distribution of licensed premises in these places. In extending the system of state management the government had followed a recommendation made by the royal commission on licensing which was appointed in 1929 and had reported in 1932 (Cmd. 3988). Other recommendations included the retention of existing closing hours: the more rapid reduction of licences; more definite encouragement of specific education on the subject of alcohol; and the creation of a national licensing commission to supervise and assist the proposed reform measures. No action was taken on the last two proposals, and the question of the grant or refusal of licences remains exclusively nithin the competence of the local benches, subject to appeal to and confirmation by quarter sessions, as explained below.

The main provisions relating to the law of licensing administration were eventually consolidated, and are for the most part to be found in the Licensing act, 1953, and the Customs and Excise act, 1952. The 1953 act defines intoxicating liquor to mean spirits, wine, beer, porter, perry and sweets (i e , liquor made from fruit and sugar which has undergone fermentation) and any fermented, distilled or spirituous liquor that cannot for the time being be sold without an excise licence, but does not include beer or porter which on analysis of a sample is found to be of an original gravity not exceeding 1,016 degrees and to be of a strength not exceeding 2 degrees of proof. The 1952 act classifies the excise liquor licences that may be authorized under the folloning heads. (1) manufacturers'; (2) wholesale dealers'; (3) retailers'; (4) occasional; (j) passenger aircraft; (6) passenger vessel; (7) railway passenger vehicle.

Methods and Conditions of Licensing. — For the purpose of granting a retailers' licence England and Wales are divided into licensing areas comprised oi committees of five or five members of the petty sessional division of a county and a borough having a separate commission of the peace. The divisional licensing justices (there must be a quorum of at least three) receive applications for the granting of a new licence, or the renewal or transfer of an old, at their general annual meeting which takes place at the "brewster sessions" in the first fortnight in February in each year, and they are empowered to exercise their unrestricted discretion in dealing with these applications as they think fit and proper. Before the hearing of a request in respect of a licence the applicant must give certain public notices in the local press and also advertise his intention to the local police and outside the parish church. The meeting of the justices must take place in public. The proceedings are of a quasi-administrative order, the meeting of the justices not constituting a court of summary jurisdiction for licensing purposes. All qualified justices are entitled to sit. The discretion of the justices although an absolute one is required to be exercised judicially. Any person liable to suffer from real bias may not sit as a licensing justice and if he does the order may be quashed on that ground. A person financially interested in a brewery. for example. may not sit though a teetotaller may. The justices in the exercise of their discretion must take into consideration both the character of the application and of the premises. The applicant must not be any sheriff's officer, or a person who has been convicted of felony or certain other offenses. and must be of good repute. The premises must be structurally adapted to the class of licence required. The magistrates may in granting the licence impose such conditions as to the alteration of the structure of the premises as they think fit. S o alteration in any on-licensed premises may be made without the consent of the justices. At the hearing any member of the public may be heard in objection to the application provided that such objection is advanced on public grounds. All evidence must be tendered on oath.

The decision of the justices whether to grant the application is by majority vote. Once granted the licence continues in force for a period of one year. The grant of a new licence requires confirmation by the county or borough Confirming and Compensation committee at quarter sessions. In the event of failure to renew an old licence, compensation is payable after reference has been made to the compensation authority which may award a figure to be paid as calculated on the difference between the value of the premises as licensed and as unlicensed; such a sum is met out of an "insurance" fund subscribed to by all licence holders, the compensation being thus subsidized by the trade itself. This principle of compensation was first introduced by the Balfour act in 1904 and has been responsible for bringing about a reduction in the number of public houses in the country.

Any person who thinks himself aggrieved by the refusal of the licensing justices of any licensing district to grant a renewal of a licence may appeal to quarter sessions. There is, however, no such right of appeal against the refusal to grant a new licence. The appeal takes the form of rehearing and quarter sessions has power to hear and determine the matter and to make any such order as it thinks fit. No appeal is permissible to the superior courts of the country. But the divisional court of the queen's bench division exercises a supervisory jurisdiction over inferior bodies acting in a judicial capacity by means of the prerogative writs of mandamus, certiorari and prohibition, and is thus enabled to remedy any defects in justice which may have been done. The writ of mandamus was described by Sir William Blackstone as "a command issuing in the King's name from the King's Bench and directed to any person, corporation or inferior court of jurisdiction, requiring them to do some particular thing therein specified, nhich appertains to their duty or office." Thus, as in R. v. *Walsall Justices* (3 C L.R. 100), the justices can be ordered to hear and determine an application that they had refused to entertain. The issue of the writ is at the discretion of the court. The writ of certiorari permits the divisional court to examine the proceedings of the inferior body to see whether its order has been made within its jurisdiction and enables it to quash a decision when it is made in excess of jurisdiction, as for example where bias or fraud has been present, or where an error of law appears on the face of the record. Prohibition is the warrant which can issue from the divisional court to prevent the justices from exceeding their jurisdiction, or from infringing the principles of natural justice.

The grant of a justices' licence entitles the holder as of right to an excise licence which constitutes the authority for the sale of liquor, but upon forfeiture of the justices' licence the excise licence becomes void. Any person who sells by retail any intoxicating liquor without a justices' licence authorizing him to hold an excise licence is liable to a fine of £50 or to a period of imprisonment for one month. The holder of a justices' licence shall cause to be painted on the premises in a conspicuous position his name with the addition of the word "licensed"

Under the common law of England the holder of a licence is not under a legal duty to open during the permitted hours, nor to serve all comers unless he be a common innkeeper. in which case special rights and obligations as between landlord and guest arise, giving the licence holder no right to pick and choose whom he will serve. In general throughout the United Kingdom there is strict supervision of the beverage liquor traffic. and in addition to the penalties provided under the Licensing act the stringent sanction of disqualification is available with which to deal with defaulting licensees. Hence it is incumbent on the holder of a licence not to permit drunkenness or any violent, quarrelsome or riotous conduct to take part on the premises, or sell any intoxicating liquor to a drunken person. He must not permit his premises to be the habitual resort of reputed prostitutes, or knowingly harbour thieves or reputed thieves. He must not knowingly harbour or allow any constable being on duty to remain on the premises unless he is there in the execution of his duty. He must not allow his house to be used for gaming or betting. He must close his premises. if ordered by the justices so to do, in the event of a riot.

Permitted Hours.—The 1953 act fixes the permitted hours during which on-licensed premises may remain open to the public. The conception of limitation of hours of opening has been found to be the most effective means of reducing abuse of alcoholic beverages, and for psychological reasons the legislature deemed the word "permitted" to be more acceptable than "closing" or "forbidden." It is an offense. punishable by £30 fine, for any person to serve to another any intoxicating liquor to be consumed on or off the premises. outside the permitted hours, unless he is resident on the premises or is consuming a drink with a meal which has been ordered within half an hour after the conclusion of the permitted hours. or unless he is a bona fide friend of the landlord being entertained on the premises at the landlord's own expense. The permitted hours are as follows:

On *Week* Days.—A period of eight hours a day beginning not earlier than 11 A.M. and ending not later than 10 P.M. with a break of at least two hours after noon. The justices are, however, authorized to alter the hours to suit special requirements of the district to a period of eight and a half hours a day commencing not earlier than 8 A.M. and finishing not later than 10.30 P.M. If no hours are fixed by the justices then these will prevail: 11.30 A.M. to 3 P.M. and 5.30 P.M. to 10 P.M. In the metropolis the hours are different. The metropolis is the administrative county of London together with an area outside that county but within the four-mile radius from Charing Cross. There nine hours are permitted. with a break of at least two hours in the afternoon! commencing not earlier than 10 A.M. and finishing not earlier than 10.30 P.M. and not later than 11 P.M. The justices may make special orders of exemption in exceptional circumstances such as on an occasion of local or national rejoicing.

On Sundays, *Christmas* Day *and* Good Friday.—The number of permitted hours in both the metropolis and elsewhere is limited to five, of which not more than two shall be between noon and 3 P.M.; and not more than three between 6 P.M. and 10 P.M.; except that in Wales and Monmouthshire there shall be no permitted hours on Sundays or on Christmas day when it falls on a Sunday. Unless the justices resolve to the contrary Sunday hours are from 12.30 P.M. to 2.30 P.M. and from 7 P.M. to 10 P.M.

Protective Provisions.—The 19j3 act contains protective provisions in respect of young persons. No child under the age of 14 is allowed into any bar. Liquor is not allowed to be sold for consumption on the premises to any person under the age of 18; but if, however, the individual is 16 or over he may take beer, porter, cider or perry with his meal provided that it is consumed in an open part of the premises and not at the bar. A bona fide error as to the age of the child is a good defense to a charge under this head. By the Children and Young Persons act, 1933, it is an offense for anybody to give intoxicating liquor to any child under the age of five save in a case of medical necessity.

The Licensing act protects the customer by making it an offense to sell liquor otherwise than in a standard imperial measure. Credit sales are forbidden and a customer must pay cash for the drink at the time that it is sold. Furthermore by the Sale of Spirits acts, 1750 and 1862 (popularly known as the Tippling acts), no action can be brought to recover any debt or sum of money alleged to be due in respect of the sale of any ale. porter, beer, cider or perry which was consumed on the premises where sold or supplied: or in respect of any money or goods lent or supplied, or of any security for, in or toward the obtaining of any such ale, porter, beer, cider or perry. There is a right of recovery if the spiritous liquor was bona fide bought at any one time to the amount of 20*s*. or more, or sold to be consumed off the premises and delivered at the residence of the purchaser in quantities less at any one time than a reputed quart.

Clubs.—Clubs which sell intoxicating liquor come under the control of the Licensing act. 1953, the provisions of which require registration as a condition to the supply of sale of drink. The secretary of a registered club is bound in the January of each year to furnish to the clerk of the justices a return containing certain statutory particulars. At the same time he must deliver to the commissioners of inland revenue a statement of purchases of intoxicating liquor over the period of the preceding year. Penalties are imposed for the supplying or keeping of liquor in an unregistered club. Magistrates are empowered if reasonable cause be shown to issue search narrants for the entry into clubs by constables to ensure that the lam is not being evaded. The permitted hours for the sale of drinks in clubs is fixed as a period not exceeding nine hours in the metropolis. falling between 11 A.M. and 11 P.M.; and of eight hours without the metropolis, falling between 11 A.M and 10 P.M. The rules restricting sales within these hours are. however, not applicable to a member of the club who is residing on the premises.

Scotland and Northern Ireland.—A practically parallel method to the system of licensing control of liquor as in force in England and Wales is to be found in Scotland and Northern Ireland. The duties and powers of the Scottish licensing courts are laid down in the Licensing (Scotland) acts, 1903 to 1949. The registration of clubs is a function of the sheriff. Applications for certificates for the sale of excisable liquor in Scotland for the year ending 1953 numbered 8,435 of which 8.343 were granted. In Clster control is effected in the main by the Intoxicating Liquor Licensing acts (Northern Ireland), 1923 and 1927. Provision is made thereby for the closing on Sunday and Christmas day of licensed premises and the permitted hours are fixed at an hour beginning not earlier than 10 A.M. and ending not later than 9 P.M. for rural areas, and 10 P.M. in urban districts or towns.

Rules on Drunkenness.—The Licensing act exemplifies the preventive measures taken to control liquor at its source. Other statutory provisions are also designed to discourage drunkenness and to strengthen liquor control. Underlying the criminal law of the country is the principle expounded by the house of lords in the leading case of R. v. Beard (1920 A.C. 249). Beard had ravished a girl of 13 and in order to prevent her from screaming had placed his hand on her mouth and at the same time pressed his thumb upon her throat with the result that she died of suffocation. On his trial for murder his sole defense was that he was so drunk that the jury ought to return a verdict of manslaughter. Lord Birkenhead, the lord chancellor, in his judgment laid down the modern rules on drunkenness as follows: (1) that insanity whether produced by drunkenness or otherwise is a defense to the crime charged; (2) that evidence of drunkenness which rendered the accused incapable of forming the specific intent essential to, constitute the crime should be taken into consideration with the other facts proved in order to determine whether or not he had this intent; (3) that evidence of drunkenness falling short of a proved incapacity in the accused to form the intent necessary to constitute the crime, and merely establishing that his mind was affected by drink so that he more readily gave way to some violent passion, did not rebut the presumption that a man intended the natural consequences of his acts. In *R.* v. *McCarthy* (1954 2 A.E.R. 262) it was held by the court of criminal appeal that unless a man is in such a complete and absolute state of intoxication as to make him incapable of forming the intent charged, drunkenness which may lead him to attack another in a manner which no reasonable, sober man would do cannot be pleaded as provocation reducing the crime from murder to manslaughter if death results.

Drunkenness by the common law of England is not an offense in itself. But by statute drunkenness accompanied by some other action may be. Thus if a person is found drunk in any highway or other public place, whether a building or not: and is incapable of taking care of himself he is liable to be apprehended and on conviction to pay a fine of 10*s*. Every person who in any highway or other public place, whether a building or not, is guilty while drunk of riotous or disorderly behaviour, or who is drunk while in charge on any highway or other public place of any carriage, horse, cattle or steam engine, or who is drunk when in possession of any loaded firearm, commits an offense. Any person who, being on any premises licensed for the sale of any intoxicating liquor whether for consumption on or off such premises, shall procure or attempt to procure any intoxicating liquor for consumption by any drunken person, or who shall aid and abet any drunken person in obtaining or consuming any intoxicating liquor on any premises so licensed, shall be liable on summary conviction to a fine not exceeding £2 or to imprisonment for one month. By the London Hackney Carriages act, 1843, it is an offense to be drunk during employment as a driver of a hackney or stage carriage. By s. 287 of the Merchant Shipping act, 1894. it is an offense to be drunk and persist, after being refused admission on that account, in attempting to enter a passenger steamer; it is also an offense, being drunk on board a passenger steamer, to refuse to leave when requested; and similar provisions are made applicable to air travel by virtue of the Civil Aviation act, 1949.

By s. 15 of the Road Traffic act, 1930, any person who when driving or attempting to drive, or when in charge of a motor vehicle on a road or other public place, is under the influence of drink or drugs to such an extent as to be incapable oi having proper control of the vehicle may be arrested without warrant and is liable on summary conviction to a fine not exceeding £50 or to a term of imprisonment not exceeding four months. The accused may elect, before the hearing of the case by the magistrates, to trial by judge and jury; if he does so. he is liable on conviction to a term oi imprisonment not exceeding six months or to a fine or to both. In addition a person so convicted shall be disqualified for a period of 12 months from the date of the conviction from holding or obtaining a driving licence unless the court for "special reasons," peculiar to the facts which constitute the offense (as opposed to personal matters of hardship to the accused), thinks fit to order otherwise, and without prejudice to the power of the court to order a longer period of disqualification.

The Inebriates acts, 1879–98, make provisions for the licensing by local authorities of retreats and reformatories for habitual drunkards. A "habitual drunkard" is a person who, not being amenable to any jurisdiction in lunacy. is notwithstanding by reason of habitual intemperate drinking of intoxicating liquor at times dangerous to himself or others, or incapable of managing himself or his own affairs. Whether drunkenness is occasional or habitual is a question of fact for the court. A separation order can be made by a court of summary jurisdiction in favour of a wife on the ground that her husband is a habitual drunkard or a drug addict. Any habitual drunkard who is found to be such may upon conviction on indictment of an offense, and if the court be satisfied that the offense was committed under the influence of drink, be ordered by the court to be detained in a reformatory for a period not exceeding three years.

TABLE I.—*Offenses of Drunkenness Proved in England and Wales, 1938–53*

Year	Men	Women	Total	Number per 10,000 of population aged 15 years and over
1938 .	46,832	7,686	54,518	16.84
1942 .	22,772	4,663	27,435	9.23
1946 .	17,090	3,455	20,545	6.04
1952 .	48,694	5,194	53,888	15.78
1953 .	48,539	5,035	53,574	15.65

Offenses **of** Drunkenness.— In a home office White Paper on *Offences* of *Drunkenness* (Cmd. 9284) presented by the home secretary to parliament in 1954, statistics of the number of offenses of drunkenness proved in England and Wales for the year 1953 as compared with the number of offenses proved in previous years are available. These statistics, dealing as they do with the incidence of drunkenness at different age groups according to national police districts, show that drink never became the problem in World War II that it was in World War I. They also show that the contemporary problem of drink is principally a big-town problem.

TABLE 11.—*Number of Offenses of Drunkenness Proved in 1953 per 10,000 of Population Aged 15 Years and Over, by Districts*

Cities and boroughs	Number per 10,000
London city	288.17
Liverpool city	63.30
Birmingham city	48.28
Portsmouth	24 67
Brighton	14.67
Carlisle city	:0.57
Exeter city	9.36
Bristol city	8.84

The report of the commissioner of police of the metropolis for the year 1953 (Cmd. 9236) showed that the number of premises licensed in London for the sale of intoxicating liquor was 7,818 for that year and the number of off-licensed premises 3.665; and that there were 41 licences for wine and spirit (excise dealers) and 78 for theatres. There were 19.022 arrests (16,276 men and 2,746 women) for drunkenness and drunkenness with aggravations within the metropolitan police district and proceedings were taken under s. 15 of the Road Traffic act, 1930, against 576 persons deemed to be under the influence of drink or a drug when driving or in charge of motor vehicles; of these last 414 were convicted, 24 being sentenced to terms of imprisonment and 396 being disqualified for holding or obtaining a driving licence. A total of 361 persons were charged with drunkenness and at the same time with more serious offenses; 6 men and 1 woman were convicted of drunkenness attributed to the drinking of methylated spirits; and 8 men and 1 woman were convicted of drunkenness believed to be attributable to the drinking of surgical spirit. Of the 77,545 arrests in the metropolitan police district which were dealt with in the courts. 24.5% were on account of drunkenness. Drink or drugs were considered by the police to be contributory factors in 0.3% of road accidents caused by drivers and motorcyclists. (P. B. C.; W. T. Ws.)

TABLE IV.—*Net Receipts From Excise, 1951–54*

Year ended March 31	Beer	Spirits	Liquor and other licences
1951	£249,146,244	£75,813,968	$4,423,823
1952	£248,165,812	£67,077,362	£4,461,071
1953	£243,372,425	£74,647,061	£4,490,018
1954	£242,031,712	£81,068,978	£4,509,469

THE **BRITISH** COMMONWEALTH

In Canada liquor legislation was based fundamentally on the licence system of the United Kingdom, but in its development it also followed closely the United States system. Thus, while the provinces had laws of varying stringency, they usually provided for licences modified by local veto. In 1901 the privy council decided the constitutional controversy over the respective powers of the dominion and the provinces; importation and manufacture were to be controlled by the dominion, distribution and sale by the provinces. Exceptions are the Northwest Territories and the Yukon, where retail is controlled by the dominion. Also, the Canada Temperance act is a dominion statute which applies to the whole of Canada.

The Canada Temperance act, 1878 (the Scott act), provided for local option in any city or county on petition oi one-fourth of the electors at three-year intervals. Under this act a rapid growth of dry areas in the maritime provinces took place, while in other areas where the Scott act was unpopular dry territory spread under provincial statutes. National prohibition. which received a majority of 13.68; in a total vote of more than 500,000 in an 1898 plebiscite. never gained enough support to secure enactment by the dominion government. Xfter 1901 there was much legislation analogous to the C.S. Wilson and Webb-Kenyon acts *(see* PROHIBITION) to protect dry territory from invasion from surrounding n-et areas. Unlike the United States. Canada. in abandoning total prohibition, abandoned also the licence system in favour of state monopoly. The Canada Temperance act. 1952, provided that upon the petition of one-fourth of the electors in any city or county an election must be held and if a majority is in favour part ii of the act takes effect by order in council. This prohibits the sale or keeping for sale of intoxicating liquor in the city or county. and the taking of liquor into it. Liquor purchased outside the city or county for personal use may be delivered to a person at his residence. A petition to revoke part ii results in a vote. and if a majority in favour is obtained a further order in council declares it revoked. Manufacturers' licences are granted to distillers and brewers under the Excise act. 1952. Under the Importation of Intoxicating Liquors act. 1952, the importation of liquor into any province from outside Canada or from another province is prohibited unless consigned to her majesty, the executive government or a government agency vested with the right of dealing in intoxicating liquor. (C. E. Ww.)

Other British commonwealth countries have in general followed the English model and have been less repressive in their policies of licensing and liquor control than Canada.

In Australia the existing licence legislation in all six states makes provision for some sort of local option and for machinery for the reduction of the number of licences where it seems desirable or where local opinion votes are in favour of reduction. In 1928 a special state-n-ide referendum was taken in New South Wales on state-wide prohibition with compensation. It resulted in a majority of 500,000 against prohibition in a total vote of 1,268,119, being more than 88% of the qualified voters. All the states except South Australia have a fixed maximum for licences above which the licence board may not go except under special conditions such as demand of increased population. The licence reduction boards in New South Wales and Victoria (and similar machinery in all other states) exist for the reduction of licences where it seems desirable or local-option votes so direct. Funds for compensation for licences refused renewal are derived from special taxes usually assessed on the volume of the liquor trade. Provision is made for a poll usually about once every seven years. and in some states total prohibition may be voted on when these polls are taken.

In New Zealand three state-wide polls were taken after 1919 on prohibition without compensation. state purchases and continuance of licence. Continuance won bv small majorities in all three. though prohibition obtained a plurality in tno polls.

In the Union of South Africa since the Licence act of 1928 some reduction in the number of licensed premises has taken place. (S. McC. L.)

CONTINENTAL EUROPE

Before World War I continental European countries gave little legislative attention to the liquor traffic. It was generally licensed for revenue purposes but control of beverage alcohol as a means of combating the evils of alcoholism was left to the local authorities and to ordinary police regulation. There were notahle exceptions. In Russia. Sweden. Norway, Finland and Estonia important experiments were made with various forms of liquor control and prohibition. A strong and growing temperance and total abstinence movement in most countries. wholly individualistic in character, dated from the latter part of the 19th century in the countries of northern Europe. especially in Finland. Norway, Sweden and Denmark. It was only a little less active in northern central countries like Germany. Switzerland. Belgium and the Netherlands. but was weaker in France and Slav countries and ineffective or nonexistent in southern Europe—Italy, Greece, Spain and Portugal. World War I stimulated liquor control because of the need for food and manpower conservation, but most legislative measures aimed at reducing the consumption of beverage alcohol were weakened or disappeared in the postwar years. After the outbreak of war in 1939, in spite of greater food shortages and the need for the conservation of alcohol and grains for war uses. there was less governmental interference with beverage alcohol except in Germany, and partially in Switzerland and France.

Cnder the basic Licensing act of 1880 France imposed some restrictions on places with on licences but left their regulation largely to local authorities. The number of public houses increased to 1 to every 81 persons in 1900 and was reported to be 1 to 80 in 1938, a proportion only exceeded by Belgium. The Local Government act. 1894, empowered municipal authorities to fix the usual conditions, hours of closing, etc.. attached to licences. Taxation of the trade, then light. was greatly increased. Manufacture and sale of absinthe was prohibited by the act of March 16, 1913, but the act was weakly enforced and there were many equally deleterious substitutes. The whole tax and regulatory policy, as far as there was one, was directed against spirits and to protect the wine industry. Even the consumption of spirituous liquors greatly increased. The per capita consumption of distilled liquor in France in the period 1928–32 was 5.52 litres, five times that of Denmark, four times that of Great Britain. more than twice that of Norway or the Netherlands and 25% higher than Sn-eden. Home distillers were said to number 1,500,000 and they enjoyed a tax exemption on ten litres of pure alcohol for personal use.

After World War II both the production and consumption of alcoholic drinks in France went down, but according to some estimates 8.000.000 persons were still engaged either directly or indirectly in the liquor trade in France in 1955. The premier P. Mendès-France announced measures in Nov. 1954 for the tightening up of the liquor laws. In an endeavour to combat the national problem of alcoholism the following restrictions were announced: no alcoholic drinks might be sold for consumption on the premises between 5 A.M. and 10 A.M.; taxes on drinks were to be increased by 20%; stricter penalties were to be imposed for offenses of drunkenness and against the licensing laws. Café proprietors breaking these laws rendered themselves liable to a fine of 1.000.000 fr. or to a term of imprisonment for one year; previously the penalty had been a fine of 24.000 fr. and imprisonment for eight days. (See also PROHIBITION.)

UNITED STATES

Adoption of the 21st amendment to the U.S. constitution on Dec. 5, 1933, ended the experiment in national prohibition and returned to the states the primary responsibility for regulating the liquor traffic. But the federal government retained an important role, as demonstrated by the following list of its more significant activities in the field of alcoholic beverage control: licensing those (except brewers) who produce, sell at wholesale. rectify, blend, bottle or import alcoholic beverages, and conditioning the licence on observance of all federal laws relating to alcoholic beverages; imposing detailed requirements concerning the construction and equipment of plants in which alcoholic beverages are produced, stored. bottled or rectified: supervising and inspecting the operation of those plants; regulating the labelling and advertising of alcoholic beverages in interstate commerce: prohibiting unfair trade practices involving exclusive outlets. "tied houses." commercial bribery and consignment sales; restricting bulk sales; regulating bottle manufacturers and bottle sizes; requiring reports concerning materials used in the manufacture of distilled spirits; levying and collecting taxes; and prohibiting the transportation and importation of alcoholic beverages into states in violation of state laws. The federal liquor control agency is the alcohol and tobacco tax division of the internal revenue service of the department of the treasury. The administration of the division is decentralized into geographical regions.

h'otwithstanding the extent and significance of federal regulation, liquor control is essentially a state problem. There were in the mid-1950s three general systems of state control: (1) statewide prohibition (Mississippi and Oklahoma); (2) state monopoly, *i.e.*, state-owned stores for the sale of alcoholic beverages (Alabama, Idaho, Iowa, Maine, Michigan, Montana, New Hampshire, North Carolina, Ohio. Oregon, Pennsylvania, Utah, Vermont, Virginia, Washington, West Virginia and Wyoming; (3) licensing of those engaged in the liquor traffic (all of the rest of the states and the District of Columbia). This classification is accurate only in the roughest sense, because. (1) In approximately three-fourths of the states there are provisions for local option which permit voters of a particular subdivision of the state to prohibit the sale of certain kinds of alcoholic beverages in the subdivision; the Distilled Spirits institute estimated that on Jan. 1, 1954, approximately 24,000,000 people, including those in Mississippi and Oklahoma, resided in areas which prohibited the sale of distilled spirits. (2) In both the prohibition and monopoly groups there are states which license certain classes of retail outlets. Thus the "dry" states of Mississippi and Oklahoma respectively license the sale of beverages which contain not more than 4% and 3.2% of alcohol by weight; the "monopoly" in Wyoming extends only to wholesale sales; other monopoly states limit their operations to package sales for off-premise consumption, while licensing other types of retail sales.

Despite the monopoly experiment in a number of states, the dominant mechanism of post-repeal liquor control in the states was licensing private trade.

Prior to national prohibition, administration of alcoholic beverage control legislation generally was vested in local officials, with results that were not always wholesome. At repeal, persuasive voices urged the desirability of a single state licensing board. A few states followed that recommendation and gave a state agency exclusive control; at the other extreme, some states resurrected the system of local control; but the majority of states licensing the sale of alcoholic beverages provided for local and state participation in the licensing process. In the latter group there were wide variations in the degree of responsibility allocated to local and state officials. An additional complicating factor was the circumstance that a number of states provided for a de novo judicial review of licensing determinations. These provisions caused duplication, diffused the licensing responsibility, hindered uniform application of licensing standards and tended to put the judiciary into politics.

The evils of the saloon were in large part responsible for adoption of national prohibition, and the resolve to prevent revival of the saloon explained many features of post-repeal licensing statutes. Thus, although before prohibition the saloon licence usually authorized sales of all kinds of alcoholic beverages for both on-premises and off-premises consumption, post-repeal statutes generally required separate licences for different kinds of beverages and provided for sales by the package for off-premises consumption or for sales by the glass for on-premises consumption. Some states restricted sales of spirituous liquors to hotels, restaurants and clubs. Approximately two-thirds of the regulatory statutes provided for limitation of the number of licences issued; about half of these directed licensing authorities to take into consideration factors such as public convenience and advantage, reasonable public demand or the public interest; the remainder prohibited issuance of new licences when the ratio of existing licences exceeds a stated proportion of licences to population. Other measures designed to prevent recurrence of evils associated with the pre-prohibition saloon included limiting hours of sales, requiring that the premises be visible from the outside, prohibiting sales to minors, habitual drunkards and other interdicted persons, banning deceptive acts or those tending to induce the purchase or consumption of alcoholic beverages (such as sales on credit), regulating advertising, forbidding interlocking relationships between manufacturers. wholesalers and retailers, granting licences only to citizens of good repute and moral character not convicted of a felony or of violating state or federal alcoholic beverage control laws.

LIRA (plural LIRE), equal to 100 centesimi, the monetary unit of Italy.

The lira has its origin in the monetary system introduced in Europe by Charlemagne, who based it on the pound *(libra)* of silver. No lira coins were struck during the middle ages and the lira remained strictly a money of account. By the 16th century several of the Italian states actually struck lira coins which varied considerably, however, in weight. One of the states which used the lira as its monetary unit was the kingdom of Sardinia, and this currency was adopted in all of Italy when it became unified under Sardinian leadership.

In 1862 the lira. which up to then had been divided into 20 solidi, was redefined and the decimal system was introduced. In 1866 Sardinia joined the Latin Monetary union and the value of the lira became equal to the French. Swiss and Belgian francs. Because of the wars of unification Italy had great difficulties in maintaining the value of the lira at par with that of the other currencies of the Latin Monetary union. There were periods of payments restriction, regulated exchanges and other measures infringing upon the freedom of money markets. Budget reforms in the 1880s and a banking reform in 1894, as well as the general improvement in the world economic situation after 1896, contributed to a stabilization of Italy's international accounts around the turn of the century and from 1903 to 1914 the lira showed stability and strength.

As in most other European countries, World War I wrought havoc with the Italian currency, and the effect of World War II was as disastrous. With the devaluation of the pound in Sept. 1949, the Italian dollar exchange was also affected, and the lira fell from 575 to $1 to 628 to $1. In the latter 1950s the exchange rate was 62j lire to U.S. $1. (B. F. H.)

LIRI or GARIGLIANO, a river of central Italy (anc. Liris), which rises at Cappadocia. 7 mi. W. of Avezzano, and traverses a beautiful valley between lofty mountains, followed by the railway from Avezzano to Roccasecca. At Isola del Liri are two fine waterfalls.

Below Ceprano, the ancient Fregellae. after it has issued from the mountains, the Liri is joined by the Sacco (anc. Trerus) formed by the union of several torrents between Palestrina and Segni, and the Melfa from the mountains northeast of Atina, and runs through a broader valley. It then turns through the mountains southwest of the Via Latina and falls into the sea just below Minturno, after a course of 104 mi.

LISA, MANUEL (1772–1820), pioneer Missouri river fur trader, was born in New Orleans on Sept. 8, 1772. The son of Christopher de Lisa, a native of Spain, he entered the fur trade at St. Louis at an early age and soon became one of the leading traders on the upper Mississippi. A monopoly of the trade with the Osage Indians (granted to him by the Spanish government in 1802) ended with the transfer of the upper portion of the Louisiana territory to the U.S. in 1804.

Lisa became associated with a number of successful fur companies, including the St. Louis Missouri Fur company, of which William Clark of the famous Lewis and Clark expedition was resident agent. Lisa himself led a number of expeditions and in 1807 established a trading post at the mouth of the Big Horn river. The following year he built Ft. Raymond there for trade with the Crow Indians. It was later known as Ft. Manuel, and was the first such outpost in the area.

Ft. Manuel was abandoned in 1811. In a famous race that year the river barge of a party led by Lisa overtook, at the Niobrara river, a group of boats sent out by the John Jacob Astor interests. Near what later became the site of Omaha, Lisa established Ft. Lisa, which from 1813 to 1822 was the most important post on the Missouri, controlling trade with the Omaha, Pawnee, Otoe and other neighbouring Indians.

In 1814 William Clark, who had left the fur company and become governor of the Missouri territory, appointed Lisa subagent for the Indian tribes on the Missouri above the mouth of the Kansas river.

Lisa died at St. Louis on Aug. 12, 1820.

LISBON (LISBOA), the capital and chief port of Portugal, stands at the westernmost point of Europe, on the right bank of the Tagus (Tejo), near its entrance to the sea. Built on the slopes of a range of small hills above the river's mouth and estuary (the former a channel two miles wide and eight miles long, and the latter a bay two miles long and seven miles broad), the city is one of the most spectacular in Europe, rivaling Naples and Istanbul in its wide views, the distinctive silhouette of its buildings and its enclosed situation. Round its tiled and multicoloured buildings is a belt of vines, parks, gardens and woods, broken by villas, cottages and farms. The entrance to the fine natural harbour is protected by coastal defenses along the river mouth and on the hills behind. The climate. at its best in the autumn. is temperate (average annual temperature 60° F., average rainfall 29.45 in.). Pop. (1960) 818,382.

ROGER COSIER FROM MONKMEYER

THE ALFAMA, THE OLDEST PART OF LISBON, HAS NARROW AND WINDING STREETS

Its position as the centre of government gives Lisbon the movement and vitality of a great capital. There is, however, a difference in character between its different districts. The oldest part of the city is the Xlfama. or eastern district. where narrow, winding streets crowd down to the river between a jumble of houses. Above them towers the castle, Moorish in origin, but named after St. George to commemorate the Anglo-Portuguese alliance (1386). In this area is the Sé, the Roman-Gothic cathedral, built in 1147 and partially destroyed by the earthquakes of 1344 and 17jj. It contains the tomb of St. Vincent, who was accompanied in his search for the "Sacred Headland" by two legendary ravens which form part of the city's coat of arms. The nearby monastery of São Vicente, rebuilt at the end of the 16th century by Filipe Terzi, contains the pantheon of the Portuguese kings. Other notable buildings in this area are the church of S. Antonio, near the Se, built in honour of St. Anthony of Lisbon; the 1jth-century ruined palace, Casa dos Bicos; the remains of the Moorish walls; and the façade of the Conceicao (formerly Misericordia) church. Each hill of the line running to the north is crowned by a church or monastery, and on the slopes of São Gens is the district of the Mouraria, the old quarters of the converted Saracens.

The central district of Lisbon is the Baixa, which was built after the earthquake of 1755 and stretches from the river bank to the old outskirts in the north. The streets are broad. geometrically aligned and broken by spacious squares, of which the most central is the Terreiro do Paço with its fine equestrian statue (1775) of King Joseph I, which gives the square its English name—Black Horse square. This square, which was planned by the marquis de Pombal as the official entrance to the town, is approached through a triumphal arch. In Rossio square, the converging point of Lisbon's traffic, are two decorative fountains and the beautiful Dona Maria II theatre. This square is also famous for its black and white mosaic, 100 yd. wide. The Baixa is still the centre of Lisbon's commercial life. and in it are concentrated most of the public services.

To the west extend a number of districts, each possessing its own distinctive character, reflecting the epoch in which it was built.

The most modern part of the town lies to the north. The expansion of Lisbon in this direction, begun at the end of the 18th century, took on a new impetus when the parts known as the Avenidas Novas were planned after the opening of the Avenida da Liberdade, Lisbon's most famous avenue, in 1880. Forty years later, another great expansion took place, and entirely new districts were urbanized, absorbing the small villages on the fringe of the town. The transference of various public offices there relieved traffic congestion in the Baixa; there are also such modern buildings as the airport, sports stadiums, hospitals, schools, etc.

Despite the destruction of the great earthquake of 1755, Lisbon still has many notable old buildings. Besides those already mentioned in the Alfama district are the Carmo church. an old 14th-century convent, with crossed arches open to the sky; the Estrela Basilica, built at the request of Queen Maria I, the towers and dome of which are visible from all points; the bold Águas Livres aqueduct, built in the time of John V, which brings water from the reservoir north of the town to supply the public fountains, drinking troughs and domestic services; the 15th-century Jerónimos church, built to commemorate the discovery of the sea route to India; and the Tower of Belem, built at the same time, which stands like a sentinel at the mouth of the Tagus and forms part of Lisbon's coat of arms. The national assembly sits in an old 16th-century Benedictine convent; the same building houses the collection of national archives, called: after its original home, the Torre do Tombo collection. There are two notable palaces, the Ajuda, a richly furnished early 19th-century building, and the palace of Belem at the foot of the Ajuda slopes, the residence of the president.

There are many signs of the close bonds between Portugal and the British Isles—the English have always been the largest foreign colony after the Spaniards, and in former days there was a private quay for English ships. The Corpo Santo monastery was founded in the 17th century by Irish Dominicans; there is a Presbyterian church, an English college, and in the English cemetery, founded in 1717 and planted with cypresses, are buried Henry Fielding, the novelist, and Philip Doddridge, the Nonconformist divine.

Many of Lisbon's 18th-century squares contain statues, of which, besides the statue of Joseph I, already mentioned, the most notable are the Obelisco dos Restauradores, commemorating the campaign which freed Portugal from Spain; the monument to King Peter IV. who gave the country its constitutional charter, in Rossio square; and the monument to the marquis de Pombal in the square that bears his name.

As well as the squares. which give a spacious feeling to the central district, there are several parks and gardens. At the northern end of the Avenida da Liberdade is the Parque Eduardo VII, so-called to commemorate Edward VII's visit to the city. Others are the Parque Florestal at Monsanto, planted since the 1920s to protect the town from the prevailing wind; the Campo Grande, a big wooded promenade to the north; the botanical garden at Ajuda; and the zoological garden in the Parque das Larangeiros.

One of the most interesting of many museums is the Museu dos Coches, in the old royal riding school, which possesses an unrivaled collection of state carriages, coaches, two-wheeled chaises and 17th-, 18th- and 19th-century sedan chairs. Others include those for ancient and modern art, archaeology, ethnology and military objects. There are two municipal museums also.

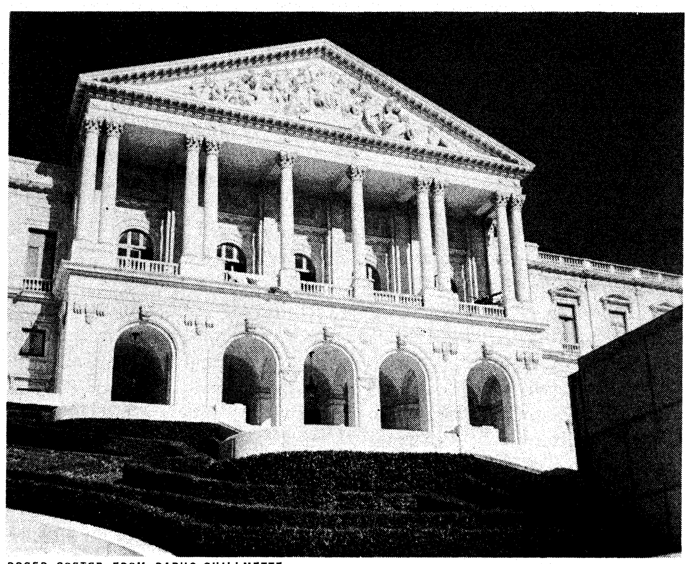
The university was re-established in Lisbon in 1911 and a technical university was founded in 1930.

The surroundings of Lisbon form part of its charm. On both banks of the Tagus are noble country houses set in beautiful gardens. On the north bank, apart from Sintra (*q.v.*), is the 18th-century palace of Queluz, built by a French and a Portuguese architect in the style of a French chhteau. On the opposite bank is the 16th-century Bacalhoa, famous for its azure tiles. The coastal strip north of the Tagus from Algés to the south of Cape Roca is known as the "Portuguese Riviera" and attracts many visitors. Its centre is Estoril.

Communications, Trade and Industries. — Lisbon has four railway stations; communication with its outlying districts is by electric train. Within the city four escalators facilitate transportation in the most hilly districts. Between the two banks of the river, which are lined with landing stages, docks and warehouses, there is a constant service of launches and ferries.

Its position at the westernmost point of Europe has made Lisbon an important port of call. Its airport, Portela de Sacavem, 63 mi. outside the town, is an intersection point for many world airlines; its estuary and fine natural harbour give anchorage for naval vessels as well as for liners and cargo boats; and it is connected by road and railway with the great European capitals, as well as with the Portuguese hinterland. It is an important transshipping and entrepôt centre, handling about 60% of Portugal's foreign trade. Its exports are chiefly agricultural and forestry produce (olive oil, wine, fruit, cork, timber) and tinned fish (sardines in particular). The chief imports are coal, raw cotton, mineral oil and cereals. The city's industries include the making of chemicals, textiles, soap, pottery and paper, sugar refining, flour milling and ship repairing.

History. — The origin of Lisbon is clouded by a number of fantastic legends. The derivation of its name from the word *Olisipo* gave rise to the story that it had been founded by Ulysses: it may actually have been Phoenician in origin. During the Roman domination (205 B.C. to the 4th century A.D.) it was elevated to the dignity of a *municipium* by Julius Caesar, and called *Felicitas Julia.* Occupied by the Alani (Alans), the Suebi (Suevi) and the Visigoths in the jth century, it was captured by the Moors at the beginning of the 8th century and called by them Lixbuna, a name derived from an old *citania* or Roman castle on the summit of the hill on which stands the Castel de S. Jorge. Few traces remain of these successive dominations: some stones recall the famous Roman theatres, temples and baths; there are traces of the primitive fortifications of the Visigoths as they were modified by later invaders; and of the Moorish domination little is to be seen except the nucleus of the castle and traces of agricultural customs and methods in the surrounding countryside. The city was invaded twice during the Moorish domination — by the Normans in 844 and by Alphonso VI of Leon in 1093 — and in 1147 was captured for Christendom by Afonso Henrigues, after a siege lasting several months: in which he was helped by a Christian crusade including Normans. Flemish and English. In 1256 Afonso III transferred the seat of his government and court to Lisbon from Coimbra. The town, which had 15,000 inhabitants at the time of the conquest, doubled its population and extended westward. King Diniz (Denis) founded the university in 1290 (it was transferred to Coimbra in 1537), and after the town had been besieged, devastated and burned by the Castillians in 1375, it was further strengthened by additional defenses which enabled it to withstand the second Castillian invasion in 1384.



ROGER COSTER FROM RAPHO-GUILLMETTE

PALACIO DAS CORTES AT LISBON. WHERE THE NATIONAL ASSEMBLY SITS, WAS IN THE 16TH CENTURY A BENEDICTINE CONVENT AND BECAME A GOVERNMENT BUILDING IN 1834

In 1390 Lisbon was made an archbishopric, and in the following centuries its importance grew with the opening of the sea route to India, the discovery of Brazil and the widespread voyages of Portuguese mariners. It became a great commercial port and the centre for the distribution of the riches of the Spanish overseas empire from 1580 to 1640. It was from Lisbon that the Spanish Armada sailed in 1588. The city's political importance was diminished during the union of the Castilian and Portuguese monarchies, but it regained its old splendour under John V.

Because it is built on rocks of tertiary formation, Lisbon has always been subject to earthquakes, those of the 15th and 16th centuries being notably destructive. In Nov. 1755 it suffered its severest shock; a great part of the town was destroyed and about 40,000 people were killed. The tremor was felt throughout Europe and much valuable aid was received, especially from England, Portugal's oldest ally. It was reconstructed by engineer-architects under the direction of the marquis de Pombal, who can be said to have created a new town based on internationally accepted principles but with a markedly Portuguese style.

During the late 18th and early 19th centuries, political events prevented Lisbon's progress. The three invasions by Napoleon's troops and the subsequent Peninsular War, in which the two rival factions at court struggled for possession of the throne, so disturbed Lisbon's life that it took a long time to settle down. In the 20th century there was considerable development, and during World Wars I and II Lisbon was able to offer refuge to about 200,000 foreigners. (G. DE. M. S.)

LISBURN, a market town and urban district of County Antrim, N.Ire., on the Lagan river, 8 mi. S.S.W. of Belfast by road. Pop. (1961) 15,691.

Lisburn is the cathedral city of the diocese of Down and Connor. The cathedral. with its conspicuous spire, was built in 1623 in "Plantation Gothic" style. The English author. Jeremy Taylor, was bishop of Lisburn from 1661 until his death in 1667. In 1627 the town was granted by Charles I to Viscount Conway who built the castle and introduced English and Welsh settlers. The castle was besieged in 1641 during the Irish wars and accidentally burned down, along with the rest of the town, in 1707 and the grounds are now a public park. The district was the scene of further warfare when Cromwell's forces occupied it from 1649, and the town served as winter quarters for the duke of Schomberg's army in 1689 before the Boyne campaign. The town and district of Lisburn became the centre of the Ulster linen industry when William III invited Louis Crommelin and other French Huguenot refugees to settle there and establish it. Flax spinning and linen manufactures are still carried on in Lisburn, and at Lambeg, 1½ mi. toward Belfast, is a linen-bleaching centre and the Linen Research institute. Furniture is made at Lisburn and carpets at Finaghy nearby.

The ruins of Castle Robin, 3 mi. N. of the town, stand on the slopes of White mountain; the building dates from the time of Queen Elizabeth I. Lisnagarvey Broadcasting station, the Northern Ireland transmitter of the British Broadcasting corporation, is on Blaris moor, 2 mi. S. of Lisburn.

LISIEUX, a town of northwestern France, capital of an *arrondissement* in the *département* of Calvados, lies in the valley of the Touques, 30 mi. E. of Caen by rail. Pop. (1954) 14,511. In the time of Julius Caesar, Lisieux, under the name of Noviomagus, was the capital of the Lexovii.

Though destroyed by the barbarians, by the 6th century it had become one of the most important towns of Neustria. Its bishopric, suppressed in 1802, dated from that period. In 911 it was included in the duchy of Normandy by the treaty of St. Clair-sur-Epte. Civil authority was exercised by the bishop as count of the town.

In 1136 Geoffrey Plantagenet laid siege to Lisieux, which had taken the side of Stephen of Blois; it fell in 1141. In 1152 the marriage of Henry II of England to Eleanor of Guienne was celebrated in the cathedral. Thomas à Becket took refuge there, and some vestments used by him are shown in the hospital chapel. Taken by Philip Augustus and reunited to France in 1203, the town was a frequent subject of dispute during the Hundred Years' War, the religious wars and those of the League.

Being an important road junction, Lisieux was a target for Allied bombs in World War II, two-thirds of the city being destroyed in June 1944. It was rebuilt on modern lines. Sixteenth-century towers are all that remain of the old fortifications. Most of the ancient Norman houses, formerly a feature of the town, were burned down.

Of the church of St. Jacques (late 15th century), which contained Renaissance glass and old stalls and frescoes, only the walls were left.

St. Peter's cathedral (12th–16th century), the oldest Gothic church in Xormandy, contemporary with those of Canterbury and Sens, is still standing, with its lantern tower over the crossing, and the two towers surmounting the west façade. The old episcopal palace, now used for civil purposes, contains a beautiful hall (the salle *dorée*). Most of the manufacturing industries—brewing, tanning, machinery and condensed milk manufacture—have been moved out of town. Yet trade in grain! cattle, butter, cheese and apples, is still carried on. Lisieux has become a centre of pilgrimages to Ste. Thérèse, the Little Flower, a young Carmelite who died in 1897 and was canonized in 1925. The Basilique, a massive building in the Romano-Byzantine style, dedicated to her, was consecrated by Pope Pius XII, then nuncio to France, in 1937. (C. Pn.)

LISKEARD, a market town and municipal borough of Cornwall, Eng., 13 mi. E. of Bodmin by road, in the Bodmin parliamentary division. Pop. (1951) 4,391. Area 4.2 sq.mi.

Liskeard stands 6 mi. from the sea on high (400 ft.) ground between the deep wooded valleys of the East Looe and Seaton rivers. The name (*Ilys* caer) indicates that in Celtic times it was a seat of jurisdiction and was fortified. Ruins of a castle nere still visible in the 16th century. William the Conqueror gave the manor to Robert of Mortain, from whom it passed to the earls of Cornwall. Liskeard was the centre of the Cornish kings, the last of whom, King Doniert (d. *c.* goo), lived there. In 1240 it was created a free borough by Richard, earl of Cornwall, king of the Romans, who vested in the burgesses nearly al! the rights of a corporate town. The corporation in its modern form dates from 1 j86.

Liskeard was one of the four Cornish tin-mining towns. An agricultural town, Liskeard became known for its cattle fairs held every Monday and the great annual fair of St. Matthew held on Oct. 2. The public library acquired the Leonard Courtney collection of rare Cornish books.

LISLE, ALICE (*c.* 1614–1685) commonly known as Lady Alice Lisle: was born about 1614. In 1630 she married John Lisle (d. 1644), who was one of the judges at the trial of Charles I, and became a member of Cromwell's house of lords. for which reason she acquired her courtesy title. After her husband's death, Lady Alice lived at Moyles court, near Ringwood. Although of royalist leanings, she showed sympathy with the dissenting ministers under the persecutions they suffered during the reign of Charles II.

On July 20, 1685, a fortnight after the battle of Sedgemoor, the elderly Lady Alice agreed to shelter John Hickes, a well-known Konconformist minister, at Moyles court. Hickes, a fugitive from Monmouth's army, brought with him Richard Nelthorpe, also a partisan of Monmouth, and under sentence of outlatvry. The two men passed the night in the house. On the following morning they were arrested, and their hostess, who had denied their presence in the house, was charged with harbouring traitors.

Her case was tried by Judge Jeffreys at the opening of the "Bloody Assizes" at Winchester. She pleaded that she had no knowledge that Hickes's offense was anything more serious than illegal preaching, that she had known nothing previously of Nelthorpe (whose name was not included in the indictment, but was, nevertheless, mentioned to strengthen the case for the crown) and that she had no sympathy with the rebellion. The jury reluctantly found her guilty and, the law recognizing no distinction between principals and accessories in treason, she was sentenced to be burned. James II allowed beheading to be substituted for burning. Jeffreys ordered that the sentence should be carried out that same afternoon, but a few days' respite was granted and she u-as executed in Winchester market place on Sept. 2, 1685.

By many her death was regarded as a judicial murder, and one of the first acts of the parliament of William and Mary reversed the attainder on the ground that the prosecution was irregular and the verdict injuriously extorted by "the menaces and violences and other illegal practices" of Jeffreys.

See Cobbett's Complete Collection of State Trials, compiled *by T.* B. Howell, 33 vol. (London, 1809–26).

LISMORE, an island in the entrance to Loch Linnhe, Argyllshire, Scot., 5 mi. N.W. of Oban, 94 mi. long and 1¾ mi. broad. Pop. (1951) 191. It divides the lower end of the loch into two channels, the Lynn of Morvern on the west and the Lynn of Lorne on the east.

The name is derived from the Gaelic *lios mòr,* "great garden," from the fertility of the soil. The shallow limestone lochs have an extremely rich flora. Several ruined castles stand on the coast, and the highest point is 500 ft. Steamers call at Achnacroish, and there is a ferry to Port Appin. A Columban monastery was founded in Lismore by St. Moluag about 592. About 1200 the see of Argyll was separated from Dunkeld by Bishop John, "the Englishman," and Lismore soon afterward became the seat of the bishop of Argyll. The small cathedral has been restored, and is used as the parish church.

The Rev. John Macaulay, grandfather of Lord Macaulay, and the Rev. Donald M'Nicol (1735–1802), who took up the defense of the Highlands against Samuel Johnson, were ministers of Lismore.

LISMORE, a town in the northeast of New South Wales, Austr., situated on the Richmond river (*q.v.*), 6j mi. from its mouth at Ballina and 22 mi. from the same town by road. Coal occurs in the neighbourhood and the timber reserves were formerly largely exploited. Lismore is the centre of the chief dairy district of the state (average annual temperature: 76°–57.6° F.; average annual rainfall: 52.37 in.), with butter factories which export to the United Kingdom. The growing of sugar cane, after a decline, has recovered ground.

The town is well built. lies on the main North Coast railway (Sydney and Brisbane), has connections by motor coach with the northern highlands (Tenterfield, etc.) and with Brisbane, and, by river steamer, with Ballina and the sea (coastal trade). Pop. (1947), 15,214.

LISMORE, a little market town and furmer seat of a diocese in Co. Waterford, Ireland. 43 mi. W.S.W. of Waterford by rail. Pop. (1951) 1,089. It is situated on a hill rising steeply from the Blackwater.

The original name of Lismore was Maghsciath. A monastery founded there by St. Carthagh in 633 became celebrated as a seat of learning. The bishopric, said to have originated with this foundation, was united to that of Waterford in 1363. In the 9th and beginning of the 10th centuries the town was repeatedly plundered by the Danes, and in 978 the town and abbey were burned by the men of Ossory. Henry II received in Lismore castle the allegiance of the archbishops and bishops of Ireland. In 1581 the manor was granted to Sir Walter Raleigh. The Roman Catholic bishop of Waterford and Lismore has his seat in Waterford city. The Protestant dioceses of Waterford and Lismore were united in 1833 with those of Cashel and Emly, and the bishop of these united sees has his seat in Waterford.

The baronial castle, erected by King John in 1185, was the residence of the bishops till the 14th century. It was besieged in 1641 and 1643, and in 1645 it was partly destroyed by fire. On the summit of the height is the cathedral of St. Carthagh mostly of the 17th century, with portions probably of the 12th and 13th and considerable additions in the 19th. There is some river trade and the town is the centre of a salmon fishery district.

LISSA (Serbo-Croatian Vis; Lat. Issa), an island in the Adriatic sea belonging to Yugoslavia and occupied by Italy in World War I Lissa lies 31 mi. S. by W. of Spalato, and is the outermost island of the Dalmatian archipelago. Its greatest length is $10\frac{1}{2}$ mi.; its greatest breadth $4\frac{1}{2}$ mi. In shape it is long, as are most of the islands on this longitudinal coastline. The central plain is fertile. Its culminating point is Mount Hum (1,942 ft.), on the southwest. Lissa, the capital. contains the palace of the old Venetian counts Gariboldi, the former residence of the English governor, the monastery of the Minorites and at a little distance to the west the ruins of the ancient city of Issa.

Lissa is said to have been settled by people from Lesbos, the Issa of the Aegean. The Parians, assisted by Dionysius the Elder of Syracuse, introduced a colony in the 4th century B.C. During the First Punic War (265–241 B.C.) the Issaeans with their beaked ships helped the Roman Duilius; and the great republic, having defended their island against the attacks of Agron of Illyria and his queen Teuta, again found them serviceable allies in the war with Philip of Macedon (*c.* 215–211). As early as 996 the Venetians ruled the island, and, though they retired for a time: before the Ragusans, their power was effectually established in 1278. Velo Selo, then the chief settlement, was destroyed by Ferdinand of Naples in 1483 and by the Turks in 1571. The present city arose shortly afterward. During the Napoleonic wars, the French held Lissa until 1811, and during this period the island prospered greatly, its population increasing from 4,000 to 12,000 between 1808 and 1811. In the latter year the French squadron was defeated by the British (see below). In 1812 the British established an administrative system, under native officials, in Lissa and the adjoining islands of Curzola and Lagosta. All three were ceded to Austria in 181j. The islanders gain their livelihood by viticulture, for which Issa was once famous, by sardine fishing and by the distillation of rosemary oil. Pop, about 10,100. After World War I Lissa passed to Yugoslavia.

Battles of Lisa.—Two naval actions have been fought in modern times near this island. The first took place on the 13th of March 1811, and was fought between a Franco-Venetian squadron, under the command of an officer named Dubourdieu (of whom little or nothing else is known), and Captain (afterward Sir) William Hoste with a small British force. The Franco-Venetian squadron (Venice was then part of the dominions of the emperor Napoleon) consisted of six frigates, of which four were of forty guns, and of five corvettes or small craft. The British squadron was composed of three frigates, the "Amphion." 32 (Capt. William Hoste), the "Cerberus" (Capt. Henry Whitby) and the "Active," 38 (Capt James A. Gordon). With them was the "Volage," 22 (Capt. Phipps Hornby). The action has a peculiar interest because the French captain imitated the method of attack employed by Nelson at Trafalgar. He came down from windward in two lines parallel to one another, and at an angle to the British squadron. Captain Hoste was not compelled to lie still as the allies did at Trafalgar. He stood on, and as the two French lines had to overtake him as he slipped away at an angle to their course, one of them got in the way of the other. Captain Hoste materially forwarded the success of his manoeuvre by leading the foremost French ship, the "Favorite," 40, on to a reef, which was known to himself, but not to the enemy. Both squadrons then turned, and the Franco-Venetians falling into great confusion mere defeated in spite of the gallant fighting of the individual ships. Two prizes were taken and Dubourdieu was killed.

The second naval battle of Lissa was fought between the Austrian and Italian navies on the 20th of July 1866. The island, then in possession of the Austrians, was attacked by an Italian squadron from Ancona of 12 ironclads and 22 wooden vessels. One of the ironclads was damaged in a bombardment of the forts. and two were detached on other service, when an Austrian squadron of 7 ironclads, one unarmoured warship the "Kaiser" and a number of small craft which had left Fasano under the command of Admiral Tegethoff came to interrupt their operations. The Italian admiral Persano arranged his ships in a single long line ahead, which allowing for the necessary space between them meant that the Italian formation stretched for more than 2 mi. Just before the action began Admiral Persano shifted his flag from the "Re d'Italia." the fourth ship in order from the van, to the ram "Affondatore," the fifth. This made it necessary for the "Affondatore" and the ships astern to shorten speed, and, as the leading vessels stood on, a gap was created in the Italian line. Admiral Tegethoff, who was on the port bow of the Italians, attacked with his squadron in three divisions formed in obtuse angles. The Italians opened a very rapid and ill-directed fire at a distance of 1,000 yds. The Austrians did not reply till they were at a distance of 300 yds. Under Tegethoff's vigorous leadership, and aided by the disorder in the Italian line, the Austrians brought on a brief, but to the Italians destructive, mêlée. They broke through an interval between the third and fourth Italian ships. The unarmed Austrian ships headed to attack the unarmed Italians in the rear. At this point an incident occurred to which an exaggerated importance was given. The Italian ironclad "Re di Portogallo" of 5,600 tons, in the rear of the line, stood out to cover the unarmoured squadron by ramming the Austrians, She was herself rammed by the wooden "Kaiser" (5,000 tons), but received little injury, while the Austrian was much injured. The "Kaiser" and the wooden vessels then made for the protection of Fort San Giorgio on Lissa unpursued. In the centre, where the action was hottest, the Austrian flagship "Ferdinand Max" of 5,200 tons rammed and sank the "Re d'Italia." The Italian "Palestro" of 2,000 tons was fired by a shell and blew up. By midday the Italians were in retreat, and Tegethoff anchored at San Giorgio. His squadron had suffered very little from the wild fire of the Italians. The battle of July 20 was the first fought at sea by modern ironclad steam fleets, and therefore. attracted a great deal of attention. The sinking of the "Re d'Italia" and the ramming of the "Portogallo" by the "Kaiser" gave an immense impulse to the then popular theory that the ram would be a leading, if not the principal, weapon in modern sea warfare. This calculation has not been borne out by more recent experience, and indeed was not justified by the battle itself, in which the attempts to ram were many and the successes very few. The "Re d'Italia" was struck only because she was suddenly and most injudiciously backed, so that she had no way on when charged by the "Ferdinand Max."

For the first battle of Lissa see James's *Naval History,* vol. v (1837). A clear account of the second battle will be found in Sir S.

Eardley-Wilmot's *Development* of *Navies* (London, 1892); *see* also H. W. Wilson's *Ironclads in Action* (London, 1896). (D. H.)

LISSITZKY, EL (ELIEZER) (1890–1941j, Russian abstract painter. designer and architect, was born in Smolensk, on Nov. 10, 1890. He studied engineering at Darmstadt, Ger., and returned to Russia in 1919, where he painted his first constructivist composition, "Proun No. 1." Chagall then appointed Lissitzky as a teacher of art in Vitebsk. In 1921 he became professor at the state art school in Moscow, but left Russia at the end of the year when the Soviet government turned against modern art. He went to Germany first and later to Switzerland. Between 192j and 1928 Lissitzky lived in Hanover and on request of the Landesmuseum (directed by Alexander Dorner) designed an "abstract gallery" (destroyed 19363 on entirely original principles. In the U.S. Lissitzky exhibited first in 1924 at the Société Anonyme. He was co-founder of a number of periodicals propagating the most progressive tendencies of the 1920s. In the winter of 1928–29 he returned to Moscow, where he executed his advanced constructivist ideas in official soviet exhibitions and publications for abroad. Lissitzky died in 1941. His experiments in spatial constructions led him to devise new techniques in exhibiting, printing, photomontage and architecture, which have been of considerable influence in western Europe.

LI SSU (280?–208 B.C.), Chinese statesman; devoted a lifetime to the task of welding the warring Chinese states of his time into a single centralized bureaucratic empire, applying for this purpose the efficient but ruthless ideas of the totalitarian political philosophy known as Legalism. As minister to the ruler of the state of Ch'in, he saw his goal realized when, in 221 B.C., that monarch completed his conquest of the other Chinese states and assumed the title of Shih Huang Ti, "First Sovereign Emperor."

Li was born a commoner in the state of Ch'u (at the present Shang-ts'ai, southeastern Honan), studied under the Confucian philosopher Hsiin-Tzu (*q.v.*), and then (247) entered Ch'in to begin almost 40 years of service under the later first emperor. For most of the radical political and cultural innovations made in the Ch'in empire after 221 (for which *see* SHIH HUANG TI), Li, rather than the first emperor, was primarily responsible. Most spectacular (but not most significant) was the "burning of the books" of 213, for which Li has been execrated by later scholars.

Following the first emperor's death in 210, Li became involved in the plot of the eunuch Chao Kao to void the proper succession. In 208 this eunuch turned on Li himself and had him executed at a time when the Ch'in empire was already disintegrating as the result of rebellion. Despite this tragic end to Li and his work he set a lasting imprint on Chinese history in a way that few other men succeeded in doing.

LIST, (GEORG) FRIEDRICH (1789–1846), German advocate of tariff protection to stimulate national industrial development. mas born in industrial Reutlingen. Württemberg, on Aug. 6. 1789. Largely a self-educated man. he advanced rapidly in government service. taught briefly at Tübingen university, then rose to prominence as founder and secretary of an association of middle- and south-German industrialists favouring abolition of the tariff barriers dividing the German states. Exiled to the U.S. in 1825 for his liberal viens. List encountered in Philadelphia the Hamiltonian view of national development, the "American System" of Henry Clay and the anti-Ricardianism of Henry Carey, After becoming a naturalized C.S. citizen he returned to Germany in 1832 as U.S consul at Leipzig. List professed a qualified version of his original position in favour of free trade. A national economy in an early state of industrialization requires tariff protection, List argued, and although protectionism entails the loss of certain immediate gains of foreign trade, this loss constitutes the equivalent of an "educational capital" invested in unfolding a nation's productive potentialities. List feared that entrepreneurs in long-established centres of industry would by unfair means of international competition prevent a young country's industrialization, thus: (1) preserving for the old countries not only markets but a flow of cheap raw materials as well; and (2) maintaining the old country's ability to accumulate capital at an accelerating rate. while retarding capital accumulation in underdeveloped areas of the world.

These persuasive arguments for tariff protection ignore the fact that honever politically divided might be the nations of western civilization, they were in List's time as they are now, the common heirs of a basic technology of mechanized production, transportation and communication. This commonalty of technology synchronized their mutual economic development more closely and more harmoniously than List supposed. By contrast, economic nationalism splinters the common market and decimates the common technology. Strident economic nationalism in backward areas (those without technology) so far from inducing a home-growth of capital, disrupts the inflow of needed capital equipment and technical personnel.

The works of List, principally the *National System of Political Economy* (1909; German original, 1841), have the residual value of exposihg at its roots the fallacy of generalizing into a plea for economic nationalism the occasionally relevant temporary policy of protecting "infant industries." List died by his own hand on Nov. 30, 1846, in Kufstein. Aus.

BIBLIOGRAPHY.—Margaret E. Hirst's *Life of Friedrich List* (1909) contains a bibliography and a reprint of List's *Outlines of American Political Economy* (1827); *see* also H. Ritschl, *Friedrich List: Leben und Lehre* (1947); C. Brinkmann, *Friedrich List* (1949). (G.W. Z.)

LISTA Y ARAGON, ALBERT0 (1775–1848), Spanish poet, critic and mathematician, was born in Triana, a suburb of Seville, Oct. 1j, 1775. As a youth he showed unusual mathematical talent, and at the age of 20 he was made professor of mathematics in a nautical college in Seville. He distinguished himself as a poet and critic and was appointed to the chair of rhetoric and poetry in the university of Seville in 1807.

During the French invasion he was exiled in France, where he remained for four years. Among his many published works were, *Lectures on the Dramatic Literature of Spain* and a *Treatise on Pure and Mixed Mathematics.*

He died on Oct. 15, 1848.

LISTED SECURITIES. The two principal subdivisions of the market for outstanding securities are the securities exchanges and the over-the-counter markets. Listed securities are those which are marketed through the facilities of the exchanges. All other securities are unlisted and are transferred in the over-the-counter markets.

Each securities exchange has its own set of listing requirements, those of the New York stock exchange being the most comprehensive. A company acquires a listed status by making formal application to the department of stock list of the exchange. The formal application, however, is usually preceded by preliminary discussions to discover any obstacles to listing. The company must submit its financial statements and must divulge information concerning its history and business, properties owned, management, capitalization, and business, financial and accounting policies. The company also shows on distribution forms the number of security holders and total number of shares held in each size bracket and also the ten highest holdings of the security. The exchange prefers a wide distribution of stock, with a minimum of 1,500 stockholders. The company must have substantial assets or demonstrated earning power. It must also sign certain listing agreements requiring it to make financial statements available to the public and to perform certain acts considered to be in the interests of security holders.

The application is passed upon first by the department of stock list and then by the board of governors of the exchange. If approved, the exchange certifies this fact to the Securities and Exchange commission. The company then files a registration statement with the commission. Normally registration becomes effective 30 days after receipt by the commission of the registration statement and the exchange certification, and trading in the security begins on the effective date.

On the American Stock exchange (formerly the New York Curb exchange) listed and unlisted issues are traded—an exception to the statement above that unlisted issues are traded only in the over-the-counter market. Before 1934 a member of the curb exchange could request the exchange to permit trading in an unlisted issue. This is in contrast to fully listed issues, application for which is made by the issuing company. After 1934 the Securities Exchange act virtually prevented additions of unlisted issues to the stock trading list, but trading in unlisted issues accepted before that date remained important. However, the New York stock exchange, where all issues are fully listed, is so important relative to the curb and other exchanges. that the total volume of trading in unlisted issues is small. In Jan. 1951, for example, securities sold on the New York stock exchange totalled 87% of the market value of security sales on all U.S. exchanges.

The American Stock exchange and other exchanges are less rigid in their requirements than is the stock exchange; they are more willing to list securities of companies in a developmental stage; and most have lower listing fees.

The London stock exchange publishes an official list of securities admitted to quotation. Companies whose securities are admitted to this list furnish about the same data as in listing on the New York stock exchange. Financial statements are especially emphasized. A complete record of price movements from day to day is published for securities on this list. There is also published a supplementary list of securities not officially quoted. These securities are of some public interest but the companies have not complied with the rules required for entry on the official list.

When a company's securities are well-known and widely distributed, it may be advantageous to list the security and thus attract the interest of investors who insist upon purchasing only listed securities. The company may find that the price-earnings and price-dividend ratios of outstanding securities are thus increased, and the cost of funds decreased when new issues are sold. On the other hand, listing often involves loss of interest on the part of over-the-counter dealers who have theretofore been making a market for the issue, with resultant decreases in price after listing has occurred.

LISTER, JOSEPH JACKSON (1786–1869), English scientist and father of Joseph Lister, was born in London, Jan. 11, 1786. He became a wine merchant by trade, but his interest lay in lenses even as a child, and in 1824 he began the work on the compound microscope which was to be his chief contribution to science. In 1830, in a paper, "On the Improvement of Compound Microscopes," which he read before the Royal society, he made public the results of six years' work on the microscope. During that time he had discovered the principle of aplanatic foci, which enabled him to outline to W. Tulley, a noted optician, the methods for constructing a powerful achromatic microscope which mould transmit images with almost no distortion. It was distortion which had previously prevented the microscope from taking its proper place in scientific research.

In addition, Lister made important studies on mammalian blood and invented the photographer's tripod. He died in Upton, Essex, Oct. 24, 1869.

LISTER, JOSEPH LISTER, 1ST BARON (1827–1912). English surgeon and founder of antiseptic surgery, was born at Upton, Essex, on April 5, 1827. His father, Joseph Jackson Lister, F.R.S., became eminent in optical science by perfecting the achromatic lens and improving the compound microscope. Joseph Lister received his M.B. and F.R.C.S. at University college, London, in 1852, having been trained under the two noted physiologists, Wharton Jones and William Sharpey. In the autumn of 1853, Lister went to Edinburgh with an introduction from Sharpey to James Syme (*q.v.*) whose house surgeon he became. In 1856 he married Syme's daughter, and soon afterward was made assistant surgeon to the Royal infirmary, where he gave his first course of lectures on surgery. In the following year he produced his classic paper on "The Early Stages of Inflammation," an investigation in which his interest had already been roused by his contact with gangrene and pyaemia in University college hospital, London. About the same time, he began work on the coagulation of blood, a subject related to the early stages of inflammation.

On his appointment to the chair of surgery at Glasgow in 1860, Lister at first busied himself with his articles on amputation and on anaesthetics for Timothy Holmes' *A System of Surgery, Theoretical and Practical.* He then resumed his researches on inflammation, which took on a new meaning after his attention was drawn in 1865 to the work of Louis Pasteur. Pasteur (*q.v.*) had shown that putrefaction, like other fermentations, was due to microbes coming from the air. Lister at once saw that if putrefaction was caused neither by the spontaneous generation of germs nor by the oxygen in the air—two predominating theories of his day—there was some chance of preventing it. But how were the organisms in the air to be destroyed before they entered the wound? Of three possibilities, filtration, heat and chemical agents, he selected the last for experiment.

The first experiment was made in 1865 upon a compound fracture, the agent used being carbolic acid. It was applied to the wound undiluted, so as to form with the blood a dense crust. The results, after a first failure, were so satisfactory that Lister wrote his paper "On a New Method of Treating Compound Fracture, Abscess, etc.," for the *Lancet* between March and July 1867, and at the British association in Dublin, in the same year, spoke of the value of his methods. However, the caustic property of undiluted carbolic acid made it unsuited for general surgery. It was necessary to mitigate its action by blending it with some inert substance, and the endeavour to find this substance which would provide antiseptic efficiency with the least possible irritation of the tissues formed the subject of experiments continued for many years. Lister found most satisfactory a mixture of crystallized carbolic acid and shellac (lac plaster) which, when spread on calico and painted with a solution of gutta-percha in benzine, passed through the gutta-percha without adhering to the skin so firmly as to prevent drainage.

Lister now turned his attention to the arrest of haemorrhage in aseptic wounds. It had long been the practice to employ silk or flax for tying arteries, long ends being left to provide escape of the pus. Lister hoped that if, by antiseptic means, the thread were deprived of microbes, it would no longer cause suppuration, but might be left with short cut ends to become embedded permanently among the tissues of the wound. An extensive series of experiments led him to adopt ultimately a sulphochromic catgut.

In 1869 Lister succeeded his father-in-law, Syme, in the chair of clinical surgery of Edinburgh. There his chief accomplishments were his researches in bacteriology, his substitution of the dressings of absorbent gauze for the nonabsorbing lac plaster and his attempt to provide an atmosphere free from microbes by means of a spray of a 1–20 watery solution of carbolic acid. The irritating properties of this spray soon led to its abandonment and replacement by the principles of asepsis whereby bacterial infection was avoided by scrupulous cleanliness of operating room, instruments and personnel.

In 1877 Lister accepted the chair of surgery at King's college, London, which he held for 15 years. While there, the publication of Robert Koch's book on the aetiology of traumatic infectious diseases led him to experiment with various mercurial preparations as disinfectants. In 1896 he retired from practice, but not from scientific study. From 1895 to 1900 he was president of the Royal society, and in 1896 president of the British association. In 1883 he was created a baronet, and in 1897 was raised to the peerage as Baron Lister of Lyme Regis. Among the coronation honours in 1902, he was nominated an original member of the new Order of Merit. He died at Walmer, Kent, on Feb. 10, 1912. The best monument to Lister is the Lister Institute of Preventive Medicine, London—of which he was one of the founders at its inception as the British Institute of Preventive Medicine in 1891. It was modelled on the Pasteur institute in Paris. On the continent he was even more renowned, the German surgeons, especially Karl Thiersch and Richard von Volkmann, being the first to adopt his ligature technique and his aseptic treatment, which had greatly reduced the prevalent surgical pests—pyaemia, septicaemia, erysipelas and hospital gangrene. Among Lister's contributions to general surgery, R. J. Godlee *(see* below) mentions his new amputation through the condyles of the femur, his new operation for excision of the wrist joint and for carcinoma of the breast, his improved surgery of the bladder and urethra and his introduction of such instruments as the aortic tourniquet, the wire needle: the ear hook, the sinus forceps, the urethral bougies and the forceps for extracting stones from the prostatic urethra.

LISTER, THOMAS HENRY (1800–1842), English author, was educated at Cambridge university. He held several minor government positions until 1836, when he was made the first registrar-general of births, deaths and marriages of England and Wales, the office having just been created. His best-known literary work was his novel *Granby* (1826), which was well thought of in the early 19th century. He was also the author of six other novels, *Herbert Lacy, Romance of Real Life, Flirtation, Yes and No, Arlington* and *Hulse House;* a play, *Epicharis;* and a biography, *The Life and Administration of Edward, First Earl of Clarendon, with Original Correspondence and Authentic Papers never before published.* He died June 5, 1842, at Knightsbridge.

LISU (LISAW, YAWYIN), a tribe inhabiting the Salween valley in northern Burma, believed to have migrated southward from the Tibeto-Chinese borders, and still in a migratory condition. They belong to the group called *protomorphus* by Haddon, otherwise described as having Caucasian affinities. They are divided into clans with names suggesting totemism, *e.g.,* fish-, bee-, hemp-people. Some customs suggest Indonesian affinities, viz., spirit- and ancestor-worship; burial in the fields; use of bark or leather cuirasses. They keep hunting dogs, use cross-bows with poisoned arrows and cultivate maize and buckwheat. Houses are built on the ground. The men wear short hair or pigtail, the women two plaits or horns over the ears.

LISZT, FRANZ (1811–1886), Hungarian pianist and composer, was born on Oct. 22, 1811, at Raiding, Hungary. His appeal to musicians was made in a threefold capacity, and we have, therefore, to deal with Liszt, the unrivalled pianoforte virtuoso (1830–48); Liszt, the conductor of the "music of the future," at Weimar, the teacher of Taussig, Bulow and a host of lesser pianists, the eloquent writer on music and musicians, the champion of Berlioz and Wagner (1848–61); and Liszt the prolific composer, who for some 3j years continued to put forth pianoforte pieces, songs, symphonic orchestral pieces, cantatas, masses, psalms and oratorios (1847–82). As virtuoso he held his own for the entire period during which he chose to appear in public; but the militant conductor and prophet of Wagner had a hard time of it; and the composer's place is still in dispute.

Liszt's father, a clerk to the agent of the Esterhazy estates and an amateur musician of some attainment, was Hungarian by birth and ancestry, his mother an Austrian-German. The boy's gifts attracted the attention of certain Hungarian magnates, who furnished 600 gulden annually for some years to enable him to study music at Vienna and Paris. At Vienna he had lessons in pianoforte, playing from Karl Czerny of "Velocity" fame. and from Salieri in harmony and analysis of scores. In his 11th year he began to play in public there, and Beethoven came to his second concert in April 1823. During the three years following he played in Paris, the French provinces and Switzerland. and paid three visits to England. In Paris he had composition lessons from Paer. and a six months' course of lessons in counterpoint from Reicha. In the autumn of 1825 the handsome and fascinating *enfant gâté* of the salons and ateliers—"La Neuvième Merveille du monde"—had the luck to get an operetta *(Don Sancho)* performed three times at the Académie Royale. The score was accidentally destroyed by fire! but a set of studies *à la* Czerny and Cramer, belonging to 1826 and published at Marseille as 12 Études, op. i, is extant and shows remarkable precocity. After the death of his father in 1828 young Liszt gave pianoforte lessons in Paris, got through a good deal of miscellaneous reading and felt the influence of the religious, literary and political aspirations of the time. He attended the meetings of the Saint-Simonists, lent an ear to the romantic mysticism of Père Enfantin and later to the teaching of Abbé Lamennais. He also played Beethoven and Weber in public—a very courageous thing in those days.

The appearance of the violinist Paganini in Paris, 1831, marks the starting point of the supreme eminence Liszt ultimately attained as a virtuoso. Paganini's marvellous technique inspired him to practise as no pianist had ever practised before. He tried to find equivalents for Paganini's effects, transcribed his violin caprices for the piano and perfected his own technique. After Paganini he received a fresh impulse from the playing and the compositions of Chopin, who arrived in 1831, and yet another impulse of equal force from a performance of Berlioz's *Symphonie Fantastıque, épisode de la vie d'un artute,* in 1832. Liszt transcribed this work, and its influence ultimately led him to the composition of his "Pokmes symphoniques" and other examples of orchestral program music.

From 1833 to 1848—when, with characteristic indifference to material considerations, he gave up playing in public—he was the prince of pianists. Five years (1835–40) were spent in Switzerland and Italy, in semi-retirement in the company of the comtesse d'Agoult (*q.v.*), by whom he had three children, one of them afterward Frau Cosima Wagner. These years were devoted to further study and were interrupted only by occasional appearances at Geneva, Milan, Florence and Rome and by annual visits to Paris, when a famous contest with Thalberg took place in 1837. The enthusiasm aroused by Liszt's playing and his personality—the two are inseparable—reached a climax at Vienna and Budapest in 1839–40, when he received a patent of nobility from the emperor of Austria and a sword of honour from the magnates of Hungary in the name of the nation. During the eight years following he was heard at all the principal European centres. He gained much money and gave large sums in charity. His munificence with regard to the Beethoven statue at Bonn made a great stir. The monument was completed at his expense and unveiled at a musical festival conducted by Spohr and himself in 1845.

In 1848 he settled at Weimar with Princess Sayn-Wittgenstein (d. 1887), and remained there till 1861. During this period he acted as conductor at court concerts and on special occasions at the theatre, gave lessons to a number of pianists, wrote articles of permanent value on certain works of Berlioz and the early operas of Wagner and produced those orchestral and choral pieces upon which his reputation as a composer mainly depends. His efforts on behalf of Wagner, then an exile in Switzerland, culminated in the first performance of *Lohengrin* on Aug. 28, 1850. Among other works produced during this period for the first time or revived with a view to the furtherance of musical art were Wagner's *Tannhauser, Der fliegende Hollander, 'Das Liebesmahl der Apostel,* and *Eine Faust Overtüre,* Berlioz's *Benvenuto Cellini,* the *Symphonie Fantastique, Harold en Italie, Roméo et Juliette, La Damnation de Faust,* and *L'Enfance du Christ*—the last two conducted by the composer—Schumann's *Genoveva, Paradise and the Peri,* the music to *Manfred* and to *Faust,* Weber's *Euryanthe,* Schubert's *Alfonso und Estrella,* Raff's *König Alfred,* Cornelius' *Der Barbier von Baghdad* and many more.

It was Liszt's habit to recommend to the public such works as he produced not merely by performing them as admirably as possible but also by explanatory articles or essays, such as his two masterpieces of sympathetic criticism, the essays *Lohengrzn et Tannhäuser à Weirnar* and *Harold en Italie,* which articles found many readers and proved very effective. They are now included together with articles on Schumann and Schubert, Chopin and others in his *Gesammelte Schriften* (6 vol., Leıpzig).

The compositions belonging to the period of his residence at

Weimar comprise two pianoforte concertos, in E flat and in A, the *Todtentanz,* the *Concerto pathétique* for two pianos, the solo sonata *An Robert Schumann,* sundry *Études,* 15 *Rhapsodies Hongroises,* 12 orchestral *Poèmes symphoniques, Eine Faust Symphonie,* and *Eine Syrnphonie zu Dante's "Divina Cornmedia,"* the 13th Psalm for tenor solo, chorus and orchestra, the choruses to Herder's dramatic scenes "Prometheus," and the Missa solennis known as the *Graner Fest Messe.*

Liszt retired to Rome in 1861 and joined the Franciscan order in 1865. The Princess Wittgenstein, it has been said, was determined to marry him, and since neither he nor her family wished their connection to take this form, Cardinal Hohenlohe quietly had him ordained. From 1869 onward he—now the Abbé Liszt—divided his time between Rome and Weimar, where, during the summer months, he received pupils—gratis as formerly—and from 1876 up to his death at Bayreuth on July 31, 1886, he also taught for several months every year at the Hungarian Conservatoire of Budapest.

Liszt's pianoforte technique was based on the teaching of Czerny, who brought up his pupil on Mozart, a little Bach and Beethoven, a good deal of Clementi and Hummel, and a good deal of his (Czerny's) own work. Classicism in the shape of solid, respectable Hummel on the one hand, and Karl Czerny, a trifle flippant, perhaps, and inclined to appeal to the gallery, on the other, these gave the musical parentage of young Liszt. Then appears the Parisian Incroyable and grand seigneur—"Monsieur Lits," as the Parisians called him. Later, we find him imitating Paganini and Chopin, and at the same time making a really passionate and deep study of Beethoven, Weber, Schubert, Berlioz. Thus gradually was formed the master of style—whose command of the instrument was supreme and who played like an inspired poet.

Liszt's strange musical nature was long in maturing its fruits. At the pianoforte his achievements culminated in the two books of studies, twice rewritten, and finally published in 1852 as *Etudes d'exécution transcendante,* the *Etudes de concert* and the *Paganini Studies;* the two concertos and the *Todtentanz,* the sonata in B Minor, the Hungarian Rhapsodies and the fine transcriptions of Beethoven's symphonies (the 9th for two pianofortes as well as solo), and of Berlioz's *Symphonie Fantastique,* and the symphony *Harold en Italie.* In his orchestral pieces Liszt was the great apostle of program music *(q.v.),* and in that capacity may be said to have established his most conspicuous claim, apart from his achievements as a pianist, to a place in musical history.

Of his own orchestral works the *Dante* and *Faust* symphonies are generally considered the best. The subject of the *Dante symphony* (1847–55) was particularly well-suited to Liszt's temperament and offered good chances for the display of his peculiar powers as a master of instrumental effect. In the *Faust symphony* (1854–57) the moods of Goethe's characters—Faust, Gretchen and Mephistopheles—are depicted in three instrumental movements, with a chorus of male voices supplying a kind of comment, by way of close. The method of presentation in both symphonies is by means of representative themes *(Leztmotif),* and their combination and interaction. Incidents of the poem or play are illustrated or alluded to as may be convenient, and the exigencies of musical form are not unfrequently disregarded for the sake of special effects. Of the 12 Poèmes symphoniques, *Orphke* is perhaps the most consistent from a purely musical point of view and is exquisitely scored, while *Les Prkludes, Tasso* and *Mazeppa* contain many happy pages.

In the choral numbers of the five masses, and in the oratorios *Die Heilige Elisabeth* and *Chrzstus,* there are also fine movements, even if those works as a whole can never be regarded as commensurate with the high aims and genuine religious fervour which went to their making. More truly inspired than most of these larger works are some of Liszt's songs.

Speaking generally of Liszt it may be said that the man was greater than his music. Distinguished by the rarest magnanimity of nature and generosity of soul, he laboured even more energetically to advance the cause of others than his own; most conspicuously of all. of course, in the case of Wagner. and if only for his labours in this regard, and as a fearless champion of all that was noblest in the art, alike ancient and modem, he deserves ever to be held in lasting honour and remembrance.

BIBLIOGRAPHY.—Liszt's writings, *Gesammelte Schriften,* were collected by Lina Ramann (6 vols., Leipzig, 1880–83). His correspondence appeared in 9 vol., 1894–1904, edit. by La Mara, and various additional volumes were published later, including *Briefwechsel zwischen Wagner und Liszt,* edit. E. Kloss (2 vol., 3rd ed., 1910). For biographical material *see* L. Ramann, *Franz Liszt als Künstler und Mensch* (3 vol., 1880–94; Eng. trans. by E. Cowdray, 2 vol., 1882); Cosima Wagner, *Franz Liszt* (1912); B. Schrader *Franz Liszt* (1914); J. Kapp, *Franz Liszt* (1909, 1926); R. Wetz, *Franz Liszt* (1925); A. Hahm, *Franz Liszt, Symphonische Dichtungen erläutert* (1920).

LISZT, FRANZ VON (1851–1919), German jurist, cousin of the composer, Franz Liszt, was born in Vienna on March 2, 1851. He qualified in 1875 as a teacher of criminal law at Graz in Austria, was a professor at Giessen (1879), Marburg (1882), Halle (1889), and in Berlin in 1899. In 1912 he became a member of the Fortschrittliche Volkspartei (Progressive People's party) in the Reichstag.

Liszt's life work was the scientific foundation and reform of the criminal law of which the basic principles are contained in his treatise *Der Zweckgedanke im Strafrecht* (1882). It opposes the principle of regarding punishment as a reprisal and sets up the claim of systematic prevention of a special nature. In the fight against the law-breaker, Liszt, together with the Dutchman Van Hamel and the Belgian Prins, founded the *Internationale Kriminalistische Vereinigung* (International Criminalist Union) in 1889, in which all reforms which became the basis of modern criminal law were initiated.

Liszt's claims in favour of conditional sentence and pardon as well as postponement of punishment later passed into practice. At Marburg he created the Criminalist seminary, at which later in Halle and especially in Berlin students from all lands met. Liszt was also a leading authority on international law. He died at Seeheim on June 22, 1919.

His chief works are *Meineid und falsches Zeugnis* (1876); *Lehrbuch des deutschen Strafrechts* (1881, 21st ed. 1919); *Lehrbuch des Völkerrechts* (1898, 11th ed., 1918); *Strafrechtsfälle zum akademischen Gebrauch* (13th ed. 1922); *Strafrechtliche Aufsatze und Vorträge* (1905). *See* also *Abhandlungen des Kriminalistischen Seminars* (1889, etc.); *Mitteilungen der Internationalen Kriminalistischen Vereinigung* (1890, etc.).

LITANY, a word used by Eusebius and Chrysostom, commonly in the plural, in a general sense, to denote a prayer or prayers of any sort, whether public or private. It is similarly employed in the law of Arcadius *(Cod. Theod.* xvi tit. 5, leg. 30). But some trace of a more technical meaning is found in the epistle *(Ep.* 63) of Basil to the church of Neocaesarea, in which he argues, against those who were objecting to certain innovations, that neither were "litanies" used in the time of Gregory Thaumaturgus. The nature of the recently introduced litanies, which must be assumed to have been practised at Neocaesarea in Basil's day, can only be conjectured. Probably they had many points in common with the *rogationes,* which, according to Sidonius Apollinaris, had been coming into occasional use in France about the beginning of the 5th century, especially when rain or fine weather was desired, and, so far as the three fast days before Ascension were concerned, were first fixed, for one particular district at least, by Mamertus, or Mamercus, of Vienne in A.D. 477. It is assumed that they were penitential and intercessory prayers offered by the community while going about in procession, fasting and clothed in sackcloth.

In the following century the manner of making litanies was to some extent regulated for the entire eastern empire by one of the *Novels* of Justinian, which forbade their celebration without the presence of the bishops and clergy, and ordered that the crosses which were carried in procession should not be deposited elsewhere than in churches, nor be carried by any but duly appointed persons. The first synod of Orleans (A.D. 511) enjoins for all Gaul that the "litanies" before Ascension be celebrated for three days. On these days all menials are to be exempt from work, so that everyone may be free to attend divine service. The diet is to be the same as in Quadragesima; clerks not observing these rogations are to be punished by the bishop. In A.D.

517 the synod of Gerunda provided for two sets of "litanies," the first of which were to be observed with fasting for three days, from Thursday to Saturday in the meek after Pentecost; the second for three days from November 1. The second council of Vaison (529), consisting of 12 bishops, ordered the *Kyrie eleison*, first introduced at this time from the eastern Church, to be sung at matins, mass and vespers.

A synod of Paris (573) ordered litanies to be held for three days at the beginning of Lent, and the fifth synod of Toledo (636) appointed litanies to be observed throughout the kingdom for three days from December 14. The first mention of the word litany in connection with the Roman Church goes back to the pontificate of Pelagius I (555–560) but implies it was at that time already old. In 590 Gregory I, moved by the pestilence which had folloned an inundation, ordered a "litania septiformis," sometimes called *litania major*, that is to say, a sevenfold procession of clergy, laity, monks, virgins, matrons, widows, poor and children. It must not be confused with the *litania septena* used in church on Easter Even. He is said also to have appointed the processions or litanies of April 25 (St. Mark's day), which seem to have come in the place of the ceremonies of the old Robigalia. In 747 the synod of Cloveshoe ordered the litanies or rogations to be gone about on April 25 "after the manner of the Roman Church," and on the three days before Ascension "after the manner of our ancestors." The latter are still known in the English Church as rogation days. Games, horseracing and junketings were forbidden; and in the litanies the name of Augustine was to be inserted after that of Gregory. The reforming synod of Mainz in 813 ordered the major litany to be observed by all for three days, barefoot and clothed in sackcloth and ashes. The sick only were exempted.

As regards the form of words prescribed for use in these "litanies" or "supplications," documentary evidence is defective. Sometimes it would appear that the "procession" or "litany" did nothing else but chant *Kyrie eleison* without variation. There is no reason to doubt that from an early period the special written litanies of the various churches all showed the common features which are now regarded as essential to a litany, in as far as they consisted of (1) invocations, (2) deprecations, (3) intercessions and (4) supplications. In details, however, they must have varied immensely. The offices of the Roman Catholic Church recognize two litanies, the "Litaniae majores" and the "Litaniae breves," which differ from one another chiefly in the fullness with which details are entered upon in each of the four parts. It is said that in the time of Charlemagne the angels Orihel, Raguhel and Tobihel were invoked, but the names were removed by Pope Zacharias as really belonging to demons. In some mediaeval litanies there were special invocations of S. Fides, S. Spes and S. Charitas.

The litanies, as given in the breviary, are at present appointed to be recited on bended knee, along with the penitential psalms, in all the six week-days of Lent when ordinary service is held. Without the psalms they are said on the feast of Saint Mark and on the three rogation days. A litany is chanted in procession before mass on Holy Saturday. The "litany" or "general supplication" of the Church of England, which is appointed "to be sung or said after morning prayer upon Sundays, Wednesdays and Fridays, and at other times when it shall be commanded by the ordinary," closely follows the "Litaniae majores" of the breviary, the invocations of saints being of course omitted. A similar German litany will be found in the works of Luther. In the Roman Catholic Church there are a number of special litanies peculiar to particular localities or orders, such as the "Litanies of Mary" or the "Litanies of the Sacred Name of Jesus."

There was originally a close connection between the litany and the liturgy (*q.v.*). The ninefold *Kyrie eleison* at the beginning of the Roman mass is a relic of a longer litany of which a specimen may still be seen in the Stowe missal. In the Ambrosian liturgy, the threefold *Kyric eleison* or Lesser litany occurs thrice, after the *Gloria in excelsis*, after the gospel and at the end of the mass. On the first five Sundays in Lent a missal litany is placed before the *Orntio super populum* and, on the same five Sundays, in the Mozarabic rite before the epistle. In Eastern liturgies, litanies are a prominent feature, as in the case of the deacon's litany at the beginning of the *Missn fidelium* in the Clementine liturgy and immediately before the *Anaphora* in the Greek liturgy of St. James.

LITCHI (LYCHEE; also spelled lichi, leechee. etc.), the fruit of *Litchi chinensis*, a tree of the family Sapindaceae, believed to be native to southern China and adjacent regions. It has been the favourite fruit of the Cantonese since ancient times; neither the orange nor the peach is held to equal if. Its introduction into the western world, however. came relatively late. It is recorded to have reached Jamaica in 1775.

The first lychee fruits to mature in Florida—where the tree has attained commercial importance—are said to have ripened in 1916. A fen trees introduced into California in the 19th century have occasionally produced fruits but. in general. conditions there are apparently unfavourable for their successful establishment. Around the Mediterranean are a few hearing trees; in South Africa a small horticultural industry is based upon lychee production. The tree is cultivated in numerous parts of India and has received horticultural attention in the Hawaiian Islands. Occasional trees are to he seen in tropical America.

The lychee will tolerate about as much cold as the orange. It does not produce rood crops in climates which are hot and humid throughout the year. The tree must be subjected to a period of cold weather annually or. failing this. a long dry season. In short. something must discourage vegetative growth and induce flowering. Even at best. the lychee has a strong tendency toward alternate or irregular production.

The tree is a handsome one, developing a compact crown of bright green foliage. beautiful the year round. The leaves are compound. composed of two to four pairs of elliptic to lanceolate leaflets two to three inches long. The flowers, small and inconspicuous. are borne in terminal panicles sometimes a foot in length. The fruits. which are produced in clusters. arc oval to round. strawberry-red in colour and an inch or slightly more in diameter. The brittle outer covering encloses white, translucent flesh and one large seed. The flavour is subacid. sprightly, delicious, suggesting that of a Muscat grape.

About 50 varieties have been described from southern China. of which No Mai and Haak Ip are considered to be among the best. In Florida the Brewster, from Fukien province in China. has attained commercial importance; Groff, a Hawaiian production, and Bengal, from India inhere there are several varieties). are considered excellent. In South Africa the most important commercial lychee is one which had its origin in Mauritius.

The tree is propagated by seed and by air layering. When moved to the permanent orchard. lychees are set 25 to 3j ft. apart. They require very little pruning and no unusual cultural attention. though they should have abundant moisture around the roots most of the time. The trees come into production at three to five years of age. (W. Po.)

LITERARY AND HISTORICAL SOCIETIES. Literary societies may he generally divided into three sorts: the academy, established as an arbiter of literary taste and linguistic correctness: the authors' club. a fellowship of authors to further individual or collective creative work; and the learned society of letters, an organization devoted to criticism and scholarship in the field of literature.

The academy; best exemplified by the French Académie Française (founded 1635), has historically been an important literary power on the European continent. hut has never really existed in the English-speaking countries. The British Academy (1901) and the American Academy of Arts and Letters (1904), although similar societies, have made no claims as official literary courts.

Authors' clubs have generally been short-lived unions, unable to survive the original members or even the original members' personal squabbles. Among the better knon·n have been the Scriblerus club (formed about 1713) of Alexander Pope, Jonathan Swift, John Gay. Richard Congreve and others; the Literary club (formed 1764) of Samuel Johnson, Edmund Burke, Oliver Goldsmith. Joseph and Thomas Warton. Edward Gibbon and others;

and the earnest Transcendental club (formed 1836) of Ralph Waldo Emerson, Bronson Alcott, Henry David Thoreau, Margaret Fuller and others in Concord, Mass.

The learned societies, so important today, represent one of the earliest forms of modern literary organization. The Society of Antiquaries of London was founded in 1572, but characteristically it was not incorporated until 1751, when widespread interest in such scholarly activity was first beginning. For the remainder of the 18th century and throughout the 19th the number and the activities of such literary groups continued to grow: the Society of Antiquaries of Scotland (1780); the Manchester Literary and Philosophical society (1781); the Royal Society of Literature (182 j); the Philological society (1842); the American Philological association (1869); the Modern Language Association of America (1883); and the Modern Language association (1893).

The movement in renewed vigour continued into the 20th century with the founding of such societies as the English association (1906), the Modern Humanities Research association (1918) and the English institute (1939).

The learned societies perform a valuable service to letters by offering centres for discussion, an organized means of preservation of literary monuments and literary knowledge and an opportunity for scholarly publication. The periodical and occasional publications of many of the societies have long been of first importance in literary scholarship.

Some societies, more restricted in scope, have been devoted to individual authors or to particular literary periods and interests and have accordingly served as similar but more limited centres of activity. Representative among these have been the Shakespeare society (1840), the New Shakespeare society (1874) and the Shakespeare association of America (1923); the Dickens fellowship (1902); the Melville society (1945); the Early English Text society (1864); the Folk-Lore society (1878); the Linguistic Society of America (1924); and even the Grolier club (1884), devoted to bibliography and the aesthetics of printing.

BIBLIOGRAPHY.—*The World of Learning,* 5th ed. (1954); *Scientific and Learned Societies of Great Britain* (annual); Robert E. Spiller *et al.* (eds.), *Literary History of the United States,* rev. ed. (1953); H. R. Steeves, *Learned Societies and English Literary Scholarship* (1913). (E. T. BN.)

Historical **Societies.**—Man seems to be born with an instinct for history just as he has a gregarious instinct and a desire for food. The historical instinct is not as elemental as that of self-preservation, but once man has reached a stage of civilization sufficient to satisfy his desire for food and other physical needs he will want a history. And the knowledge of the past he wants is always the history of the group or unit or institution that he considers the most important. Judgment as to this has varied from time to time but certainly during the 19th and 20th centuries the all-important group to which ultimate allegiance has been given is the nation. People have thought in terms of it and consequently the history which the American people have needed and sought has been the history of the United States. In spite of the dominance of national history mankind has always wanted to have a history of the other groups, religious, social, economic or professional, to which he belongs and of the local areas in which he lives.

The result has been the establishment of a multitude of societies to promote the study and writing of the history of all sorts of human activities and interests. Nowhere, perhaps, are there more such societies than in the United States. If more prolific in organizing societies, the Americans were only continuing one of the many practices known in the mother country. The earliest of the learned societies in Great Britain was the Society of Antiquaries of London founded in 1572 and from 1717 continuously active in promoting historical and archaeological knowledge.

In the United States the American Historical association. founded in 1884, is the national organization for professional scholars in all branches of history. Its membership is open to anyone who wishes to join, but in fact nearly all who do join are on the faculties of the institutions of higher learning. Nearly always they are also members of one or several of the other national societies which are devoted solely to some branch of history.

Thus the Mississippi Valley Historical association, which was organized in 1907 for scholars living in the central portion of the United States but which by mid-century included members from all sections, concerns itself solely with American history. The Economic History association. the Mediaeval Academy of America, the Southern Historical association, the Business Historical society. the Agricultural History society, the American Catholic Historical association and the Hispanic-American Historical association are typical examples of national groups composed of persons interested in the branches of history indicated by the names of the organizations. Again, although anyone can join these societies, the members are nearly all professors of history in colleges or universities. As a rule these societies have no building of their own nor any fixed location other than the office of the scholar who serves as secretary. They meet regularly once or twice a year either on a university campus or in some large hotel when numerous scholarly papers containing the results of the research of the authors are read and the small internal business of the organization is transacted. In every case a journal or scholarly periodical is published. In fact the publication of such a journal with many book reviews by means of which the members can keep abreast of the latest findings in the field is frequently a chief reason for forming the society. Some of the groups also publish volumes of documents or other historical materials. Often fellowships or prizes are awarded to assist young scholars and to encourage superior work. The small expenses of these organizations are met by income from the annual dues paid by the members.

Although these national societies dominate and set the standards for historical scholarship, they are greatly exceeded in number, range of activities and wealth by the various state historical societies. In the older states historical societies were founded long before there was a historical profession and when the writing and study of history were avocations of clergymen, lawyers and retired businessmen. Prominent among these are the Massachusetts Historical society (1791), the Historical Society of Pennsylvania (1824), the Maryland Historical society (1843) and the New York State Historical association (1899).

In the states west of the Allegheny mountains the state historical societies were established when a different climate of opinion prevailed. They typically receive most of their financial support from state appropriations rather than from membership dues and are frequently associated physically and functionally with the state university.

Unlike the national organizations the state historical societies have among their members many who are not professors of history but who join either because of an active interest in local history or because of the social prestige of being known as a fellow member of the "first" families in that locality. The scholarly activities are normally controlled by the professional scholars among the members. The most valuable service performed by the state societies is the collection and preservation of historical materials. Nearly every society has its own building and in many of these are rich archives which make it possible for historians to do original research. The Draper collection in the State Historical Society of Wisconsin library and the gift of the Adams family papers to the Massachusetts Historical society are notable examples of what has been done. Supplementing the manuscript collections are libraries which in some instances are both large and valuable. Most of the state societies publish journals containing articles, usually by members of the academic world, and original source materials. Efforts are made in these periodicals to make good history available and attractive to the public. Success is not always achieved. The same desire to reach the public is responsible for the many historical museums maintained and operated by the state historical societies.

Still more numerous but of much less importance are the large number of societies which are concerned with the history of some small area or city or town. Typically they receive little or no support from government and their ability to carry on extensive activities is correspondingly low. Typically also they have a much higher percentage of nonacademic members. The richer and better ones are likely to have a historical museum.

In Great Britain there is no one national organization occupying a dominant position comparable with that of the American Historical association. The Royal Historical society and the Historical association are not so clearly the agency of the historical profession. In England too there are many societies devoted to some particular aspect of history. Corresponding to the American state historical societies are the English county societies which exist in nearly every county. There are also numerous societies which focus their attention on smaller areas. (W. S. HT.)

LITERATURE (ARTICLES ON). Literature in its varied aspects is treated extensively in the *Encyclopedia Britannica.* For information on specific subjects or writers the reader should consult the Index volume; this article is a general survey.

Literatures of the World.—The two great branches of classical literature are discussed in detail under GREEK LITERATURE and LATIN LITERATURE. The various literatures of the world are surveyed on national lines. in such articles as ENGLISH LITERATURE: FRENCH LITERATURE; AMERICAN LITERATURE: JAPANESE LITERATURE; RUSSIAN LITERATURE; etc.

These articles are supplemented by biographies of all major authors: SHAKESPEARE. WILLIAM; DANTE; GOETHE. JOHANN WOLFGANG VON; TOLSTOY, LEO NIKOLAYEVICH; and of schools of writers, such as ANNALISTS. In the case of authors commonly known by a pseudonym, the biography is under that form of the name: "Mark Twain," for example, is under the heading TWAIN, MARK rather than Samuel L. Clemens. Major anonymous works are treated in separate articles; *e.g.,* ANGLO-SAXON ,CHRONICLE and ROMAN DE LA ROSE. Various folk and legendary figures are the subjects of separate articles; *e.g.,* FAUST and BUNYAN, PAUL; see also FOLKLORE and FOLK-SONG.

Ideas. institutions, and movements that are closely related to the literature of the period are frequently the subject of separate articles; in connection with the Transcendentalist movement in the U.S., for example, *see* BROOK FARM.

Literary **Genres.**—Many articles are concerned with literature with respect to style, form or purpose. The two major divisions of imaginative literature—prose and poetry—are each the subject of a major article. Various genres are treated in separate articles: *e.g.,* COMEDY; SATIRE; PARODY; and PASTORAL. The article DRAMA is extensive. The various forms of prose writing are discussed in such articles as NOVEL; SHORT STORY: BIOGRAPHY; MYSTERY AND DETECTIVE STORIES: and SCIENCE FICTION. There are also separate articles on the kinds of poetry—EPIC POETRY; BALLAD; etc. (For the various stanzaic forms *see* below.)

Literary Composition.—The article STYLE is a general discussion of the subject. RHETORIC is primarily a survey of the art of eloquent speech: PUBLIC SPEAKING discusses some modern techniques. VERSE is a statement oi the principles of prosody; METRE discusses metrics in English. There are a number of articles on the different metres, *e.g.,* HEXAMETER and DACTYL: *see* also such articles as BLANK VERSE and FREE VERSE and the articles on the various stanzaic forms—SOYNETSPENSERIAN STANZA; and others. The different kinds of metaphorical language are discussed in the article FIGURES OF SPEECH.

Criticism and Scholarship.—The criticism of literature—both its history and its method—is discussed in CRITICISM; a particular area is discussed in DRAMATIC CRITICISM. The article AESTHETICS is concerned with theories of the beautiful in literature. The method of literary scholarship is discussed at some length in TEXTUAL CRITICISM. A related article. BIBLIOGRAPHY, deals to some extent with bibliography of subject matter, and INDEX indicates where subject bibliographies are to be found. CLASSICAL SCHOLARSHIP is a historical survey of the study, in all its aspects, of the civilization of ancient Greece and Rome. Learned societies are listed in the article LITERARY AND HISTORICAL SOCIETIES. Additional information will be found in the biographies of critics and scholars.

Related Articles.—The way in which the contents. form, making, distribution and use of books are related to one another in the society that they serve is the subject of the article BOOK. Public collections are discussed in LIBRARIES: information on private collections will be found in BOOK COLLECTING. which is mainly concerned with the principles and methods of building a specialized collection. Specific kinds of books are discussed in such articles as DICTIONARY and ENCYCLOPAEDIA. The study of books as physical objects is the primary subject of the article BIBLIOGRAPHY; related to this area of study are the articles BOOKBINDING; BOOK COLLECTIXG; and BOOKPLATE. Also of interest, though somewhat further afield. are the articles PALAEOGRAPHY and ILLUMINATED MANUSCRIPTS.

Books for children are discussed in CHILDREN'S LITERATURE. The article PUBLISHING is primarily concerned with book publishing; related articles include CENSORSHIP and COPYRIGHT. The article JOURNALISM offers in brief compass a survey of the field; NEWSPAPER traces the development of newspapers in many countries and discusses the organization of a newspaper office; PERIODICAL treats of journals and magazines. Specialized aspects are discussed in PROOFREADING and REPORTING. See also references under "Literature (Articles on)" in the Index volume.

LITHGOW, a town of New South \Vales, Austr., lying on the central tableland in a valley of the Blue mountains. 96 mi. N.W. of Sydney by rail. Altitude 3,000 ft. Pop. (1954) 15,128.

Lithgow stands in the heart of the western coal field which possesses steam as well as coking coal. The state coal mine and a state electricity power station are in Lithgow. It is one of the chief industrial centres of Australia with a small-arms factory. brickworks, woolen mills, sawmills and many light industries. Near by is the famous zigzag railway, an engineering marvel now superseded by tunnels. and Hassans Walls lookout, from which can be seen a vast panorama of Blue mountain valleys.

LITHIUM, a chemically reactive metallic element which resembles somewhat the other alkali metals. sodium, potassium, rubidium and caesium with which it is classified in group I of

TABLE I.—*Uses of Lithium*

Field	Application	Form
Agriculture	Tobacco culture	Lithium carbonate
	Soil moisture retention	
	Fungicides	
Air Conditioning . .	Moisture absorption	Lithium bromide
	Dehumidification	Lithium chloride
Atomic Energy .	Proton production	Lithium metal
	Tritium production	Lithium hydride
	Power development	
	Atomic hydrogen	
Batteries	Primary cells (dry batteries)	Lithium chloride
	Storage batteries (alkaline type)	Lithium hydroxide
Bleaching . . .	Production of solid, soluble, and stable bleaching agents	Lithium hypochlorite Lithium peroxide
Ceramics	Porcelain enamels	Lithium carbonate, manganite, titanate, silicate, zirconate and cobalite
	Ground coats and cover-coats on steel and aluminum for acid resistance, improved bonding, lower firing temperature	Lithium minerals
	Pottery glazes	
	Special glasses	
Chemicals . . .	Production of miscellaneous litliium compounds	Lithium carbonate
	Catalysts	
Gas Puriiication . .	Removal of trace impurities in helium, argon, etc.	Lithium metal
	Carbon dioxide removal	Anhydrous litliium hydroxide
Heat Transfer . .	Stable low melting point	Lithium nitrate
	Salt mixtures	
Iron and Steel . .	Nodular iron grain refinemerit in steels	Lithium metal and alloys
	Desulfurization of steel	Lithium carbonate
Nonferrous Metals	Chrome bronzes, high-conductivity copper castings	Magnesium alloys High-purity litliium metal
	Bronze, nickel, silver, monel and precious metal castings	
	Bearing metals	
	Aluminum castings	
	Lithium metal cartridges	
Petrolcum . .	Catalyits	Lithium metal
	Sulfur removal	Lithium hydride
	Lubricants	Lithium hydroxide
	Low-temperature greases	Lithium stearate
Pharmaceuticals	Reagent to produce antihistamines	Lithium amide
	Reagent to produce synthetic vitamins	Lithium metal
Plastics . .	Stabilizers	Lithium stearate
	Catalysts	Lithium lactate Lithium carbonate
Rescue and Signal Work	Balloon inflation	Lithium hydride
	Flares	Lithium nitrate
Welding	Fluxes for aluminum and magnesium	Lithium chloride Lithium fluoride

the periodic system. However, as the first member of the group, lithium is unique and has certain properties which render it distinct from its congeners and somewhat similar to magnesium and several other metals of group II. For example, lithium is the only element of its group to react with nitrogen to form a nitride, Li_3N, whereas all of the metals of group II undergo a similar reaction. It is also unusual in that it is the lightest of all solid elements and at ordinary temperatures has a higher specific heat than any other substance except water.

Lithium was discovered in 1817 by A. Arfvedson in Sweden who, while analyzing the mineral petalite, found that the sodium compounds which he separated were contaminated by an alkali which did not respond to the chemical tests for the only other known alkali. potassium. The name lithium (from the Greek, *lithos*, "stone") was proposed by J. J. Berzelius. Small amounts of the free metal were probably obtained in the early 1880s by Sir Humphry Davy but it was first isolated in quantity in 1855 by R. Bunsen and A. Matthiessen who electrolyzed fused lithium chloride.

Uses.—Lithium was generally unknown and had few uses for more than a century after its discovery. The United States, the world's largest producer, averaged 290,000 lb. of lithium carbonate (or its equivalent) per year for 1935–39. During World War II a peak of 2,790,000 Ib. was reached (1944); this was exceeded in every year after 1950, reaching more than 30,000,000 lb. per year before 1960. The metal has been used as a constituent of certain light metal alloys, with magnesium and aluminum-zinc alloys and in heavy-duty lead bearing alloys. It is used as a degasifier in the production of high-conductivity copper and bronze castings and is also used in the synthesis of vitamin A. Lithium compounds are used in lubricants and ceramics, which consume the largest quantities. and in air conditioning. welding and brazing. Nuclear applications include H-bombs, nuclear power and high-energy fuels.

Occurrence and Production.—It is estimated that lithium constitutes about 0.0065% of the igneous rocks of the earth. Because of its high chemical activity, the element occurs only in combination and its compounds are widely distributed hut in small concentrations. Traces of lithium are found in animal tissue. plants (especially tobacco), the soil and a large number of minerals. Small quantities occur in sea water and in some springs. The few minerals which contain lithium in quantities sufficient for commercial extraction are: spodumene $LiAl(SiO_3)_2$, petalite $LiAl(SiO_2)_2(SiO_3)_2$, Iepidolite $(Li,K,Na)_2Al_2(F,OH)_2(SiO_3)_3$, amblygonite $LiAl(F,OH)PO_4$ and triphylite $Li(Fe,Mn)PO_4$.

Producing countries of lithium minerals include the United States and Canada. Australia, Argentina and Brazil and a number of countries in Africa (Southern Rhodesia in the Federation of Rhodesia and Nyasaland, South-West Africa, Uganda, Republic of South Africa, Republic of the Congo and Mozambique).

Lithium compounds are separated from the minerals by various methods. Generally, in the case of spodumene, the ore is heated to approximately 1,100° C. to decrepitate the mineral from the y, or hard form. to the β, or soft form (see SPODUMENE). The decrepitated material is ground. mixed with strong H_2SO_4, and heated to 150°–2joo C. to render the lithium soluble as a sulfate.

In the second case (petalite) limestone is mixed with the ore or concentrates and heated to approximately 1,100° C. The decrepitated material thus formed with the calcined lime is ground and leached to produce a solution of lithium hydroxide.

Phosphate ores (amblygonite) are treated with strong sulfuric acid recovering the lithium as sulfate and recovering also the phosphorus as a sodium or calcium acid phosphate. The lithium and other soluble sulfates are extracted with water and from the purified solution the crude lithium carbonate is precipitated.

The crude carbonate is converted to the dry anhycirous chloride or bromide which is separated from the impurities by use of an organic solvent. *e.g.*, amyl alcohol, a mixture of ethyl alcohol and diethyl ether. or pyridine.

Lithium metal is obtained by the electrolysis of a fused lithium chloride and potassium chloride salt mixture containing 40%–50% of lithium chloride. Other methods of reduction have been tried but fused salt electrolysis is the process used commercially.

Properties.—Lithium is a white metal with a silvery lustre which quickly tarnishes when exposed to moist air. Its symbol is Li. atomic number 3, chemical atomic weight 6.940. Two naturally occurring stable isotopes with mass numbers 6 (7.5%) and 7 (92.5%) are known; radioactive isotopes, 8 (half life 0.83 sec.) and 9 (0.17 sec.) have been prepared. It has a hardness of 0.6 on Mohs' scale and is harder than the other alkali metals but softer than lead which it resembles in ductility. The crystal lattice of the metal is of the body-centred cubic structure with the distance of closest approach of the nuclei equal to 3.03 Å (angstrom unit $= 10^{-8}$ cm.). Its spectrum like those of the other alkali metals is comparatively simple and is characterized by a bright-red line (6,708 Ă) and a fainter orange line (6,104 Å).

For additional physical and atomic properties see Table II.

TABLE II.—*Numerical Properties of Lithium*

Electron configuration	$1s^2\ 2s^1$
Density of solid at 20° C., g. per c.c.	0.53j
Atomic volume c.c.	12.97
Melting point °C.	186
Boiling point °C.	1336

Heat of sublimation at 25° C, kg.cal. per mole	36 44
Specific heat at 27° C., cal. per g.	0.81
Metallic radius, Å	1.55
Ionic radius in crystals, A	0.60

Lithium is an active metal and a strong reducing agent. readily giving up its 2s electron to form lithium ion, Li^+. It reacts with water at ordinary temperatures liberating hydrogen and forming a solution of lithium hydroxide. a strong base or alkali. Lithium burns in air forming the oxide. Li_2O; at red heat it unites with hydrogen forming the hydride. LiH; it reacts with the halogens and at higher temperatures with phosphorus, arsenic. antimony. carbon, silicon, sulfur and selenium. It is not as reactive as the other alkali metals but in common with them dissolves in liquid ammonia to give a highly conducting coloured solution. It is thought that the colour is caused by single electrons and electron pairs which are trapped in cavities of the liquid rather than by solvated electrons. The normally stable nuclei of lithium undergo transformations when bombarded with rapidly moving particles: with protons. $Li^6H^1 \rightarrow He^4 + He^3$ and $Li^7 + H^1 \rightarrow 2He^4$; with deuterons, $Li^i + H^2 \rightarrow Li^8 + H^1$; with neutrons, $Li^6 + N^1 \rightarrow He^4 + H^3$. In the last reaction, used to prepare tritium, the lithium is bombarded with slow moving neutrons which are produced in a uranium pile (*see* DEUTERIUM AND TRITIUM).

Compounds.—The compounds of lithium are predominantly ionic and their chemical properties are in part those of the lithium ion. This ion. the smallest of the alkali group. attracts an electron more strongly than the others and is more easily reduced to the metal. It also attracts water molecules most strongly with the liberation of a large amount of energy. thereby facilitating the reaction of lithium metal with water. As a result, lithium has a high electrode potential in water solution. greater than that of caesium, instead of the lowest of the group which might be expected from the ionization potential.

Lithium hydride is a white solid with a crystalline structure of the sodium chloride type and a melting point of 680° C. Electrolysis of the fused compound liberates lithium at the cathode and hydrogen at the anode. It is typical of the class of ',saltlike" hydrides which are formed by the elements of groups I and II. Lithium aluminum hydride. $LiAlH_4$, and lithium borohydride, $LiBH_4$, in common with lithium hydride are strong reducing agents and react with water to liberate hydrogen and form the metal hydroxides. Lithium aluminum hydride is extensively used as a reducing agent in organic syntheses.

Lithium carhonate, Li_2CO_3, a sparingly soluble salt is used in the preparation of a number of other lithium compounds, in ceramics for producing glazes and in manufacturing special grades of glass. The bicarbonate, $LiHCO_3$, is soluble in water. Lithium fluoride. LiF, has the highest heat of formation of all of the alkali halides and is one of the most stable compounds known. It is somewhat insoluble and is used in soldering and welding fluxes. The bromide. LiBr. used as a drying agent in air conditioners and the iodide, LiI, used in photography are both soluble. The nitrate, $LiNO_3$, the sulfate, Li_2SO_4, the sulfide, Li_2S, and the perchlorate, $LiClO_4$, are all soluble while the normal phosphate, Li_3PO_4, and the oxalate, $Li_2C_2O_4$, are insoluble.

Organolithium compounds; *e.g.,* butyllithium. C_4H_9Li, and phenyllithium, C_6H_5Li, used for introducing alkyl or aryl groups into organic molecules, are prepared by the reaction of lithium with the appropriate organic halides. The reaction of these organolithium compounds with a variety of other substances is a common preparative procedure: resembling somewhat the methods involving the Grignard reagents (organomagnesium compounds). Organic salts of lithium, the benzoate, citrate. salicylate and the acid tartrate as well as inorganic salts were formerly employed in medicine, some for the elimination of uric acid in the treatment of gout and rheumatic conditions. However. the tolerated dose of lithium cannot form the relatively soluble lithium urate in the presence of the quantities of sodium and potassium normally in the blood serum and accordingly lithium salts have been largely superseded in medicine by other diuretics.

Determination. — Lithium may be identified by the use of a spectroscope or by the red colour it imparts to a flame. It is gravimetrically determined in the presence of the other members of the group by extraction of the chloride with amyl alcohol. Another procedure involves the use of the flame photometer; a lithium salt solution is fed to a flame, the light passes through a prism and one of the characteristic lines impinges upon a photoelectric cell. *See* also Index references under "Lithium" in the Index volume.

LITHOCARPUS is a genus of about 100 species of evergreen onklike trees of the beech family, all native to Asia except one species that is abundant along the coast of Oregon and California. This native species. *L. densiflora* (formerly *Quercus densiflora*), commonly known as tanbark oak. is important for its bark which is used in tanning leather. Because of the ornamental value it is adapted in warmer temperate regions as a garden and lawn tree. (J. M. BL.)

LITHOGRAPH, a planographic print made by a process that relies on the natural antipathy of grease to water. This article considers the lithograph in art; for the commercial printing process *see* LITHOGRAPHY. Lithographs as an art form are printed on specially constructed presses from a drawing. usually on stone (hence the name. from the Greek *lithos,* "stone," and *graphein,* "to write"), but metal plates can also be used. These processes are described in the section on technique, which follows the section on history.

HISTORY

ORIGIN

Lithography is one of the very few graphic mediums that has a recorded origin; it was invented in 1798 by a Bavarian. Aloys Senefelder, who documented his discovery and subsequent experiments in *Vollstandiges Lehrbuch der Steindruckerey* (1818; Eng. trans., A *Complete Course of Lithography*). The term *Steindruck* ("stone printing," *i.e.,* lithography) was not Senefelder's original name for the process. Actually the use of stones mas incidental to his experiments, which were concerned with what he termed chemical printing; his objective was a cheap form of commercial printing that would enable him to publish his own dramatic productions. According to Senefelder, the use of stone as a printing surface came to him in 1796. when, by force of circumstance. he jotted down a laundry list for his mother with a greasy pencil on a piece of stone. It occurred to him that the markings on the stone could be left in relief if the rest of the surface were etched away. His earliest experiments were from these etched stones. as well as metal plates, printed in relief. Further experimentation led, in two years, to the type of flat-surface printing that is called lithography. By the time his book appeared in 1818. Senefelder had experimented with and described every process in modern lithography.

Senefelder'? interest in lithography was a purely commercial one. To this end he accepted an offer from the music publisher Johann Anton André to establish himself at Offenbach and to train persons in the new process. As a result of this kind of partnership, and at André's suggestion, patents were secured in various localities, including London.

19TH CENTURY

Germany. — In Bavaria, under the impetus of Senefelder's press at Munich, commercial lithography proceeded to develop as a reproductive medium; the first important publication was a facsimile edition of Albrecht Dürer's *Missal of Maximilian* in 1808, redrawn on stone by Johann Nepomuk Strixner. Other reproductive lithographs were produced in great quantities by the Quaglios, Karl von Piloty and others.

An abortive attempt to produce an original lithograph was made by the Bavarian count Torring-Seefeld in 1800. His views of the Lake of Worth. as well as similar attempts by Professor Mitterer and his pupil Angelo Quaglio, failed. E. J. Aurnhammer, a professor at the Gymnasium of Regensburg, sent 12 landscape subjects on stone to Senefelder in 1802 for printing in Munich, but only 6 survived. In the publication *Polyautographische Zeichnungen vorzüglicher Berliner Künstler* of 1804 appeared a lithograph by Johann Gottfried Schadow, who can be credited with being the first German artist of merit to take up lithography. Schadow produced 45 lithographs in all. Another contributor to this publication. as well as its publisher, was the painter Wilhelm Reuter. who had interested himself with the process since 1801. The architect Karl Friedrich Schinkel also made a few lithographs; one of a Gothic church done in 1810 is an exceptionally fine pen lithograph. For the greater part of the 19th century, lithography was not very highly regarded by the most competent artists. However. mention should be made of Joseph Kriehuber, the favourite portraitist of the Vienna school, who drew many of his heads on stone. Adolf von Menzel, also well known as a book illustrator in wood engraving, kept the art alive with competent technical knowledge and accomplished drawing, displaying a special virtuosity with the white scratched-line technique. Toward the end of the century. Hans Thoma took up the medium. experimenting with colour prints and encouraging other artists; and Otto Greiner worked many of his figure studies on stone.

France. — The first attempt at lithography in France was unsuccessfully conducted by Frederic Andre, while the earliest effective French trials by Pierre Nolasque Bergeret were published not in France but by an English art dealer, Bell, in 1801. The first lithograph drawn and produced in France is considered to be "Le Mercure" by Bergeret, done in 1804. However. lithography did not receive official recognition until 1809, when the director-general of museums, Vivant Denon, drew a Holy Family at Senefelder's shop in Munich.

Lithography developed in France as in no other country. Gradually taking hold of the imagination of both amateur and professional artists. the new medium appealed as an autographic way to reproduce drawings. Most of the work of the early French lithographers, Carle Vernet. N. T. Charlet. who produced around 1,000 prints. Eugène Lami and Denon, was drawn in simple black lines with a minimum of shading. The painter Eugène Delacroix took up lithography and became a master of the technique; his professional stature added prestige to the new process, by which he produced nearly 100 prints, including illustrations to *Faust, Hamlet* and other dramas. Other outstanding artists of this early period were Eugène Isabey and the immensely influential Théodore Géricault, who lithographed many studies of horses. Pierre Paul Prud'hon, Théodore Chassériau and Auguste Raffet were other significant contributors to the art.

From 1820 to 1863 there appeared a monument to lithographic illustration in the form of Baron I. J. S. Taylor's *Voyages pittoresques et romantiques dans l'ancienne France,* with contributions by Isabey, Géricault, Célestin Nanteuil and many others.

The most prolific figure in 19th-century French lithography was undoubtedly Honoré Daumier, who, between 1830 and his death, in 1879, made nearly 4,000 caricatures. These appeared in the political journals and newspapers of his era and earned him an unshakable place in the great tradition of art and humour. Paul Gavarni followed closely as a chronicler of fashionable Paris.

A decline set in everywhere around mid-century, due not only to excessive commercialization of lithography but also to the newly developed technique of photography and its application to the various reproductive processes. A revival from this setback came about in the decade of the '70s. Camille Corot began working in the medium in 1871; his work includes 18 pieces. Edgar Degas tried lithography for the first time in 1874; a tireless innovator, he saw in it yet another outlet for his versatile talents. Édouard Manet, whose first work on stone was done in 1862, illustrated Poe's "The Raven" in 1875; Camille Pissarro made his first 12 lithographs in 1874. Rodolphe Bresdin created some lithographs, even transferring some of his etchings to stone. His pupil Odilon Redon practically abandoned painting for lithography from 1883 to 1899, creating eerie and mystical subjects.

Colour lithography, already used by Manet for his plate "Polichinelle" in 1876 and by Jules Chéret, a pioneer of the colour poster, reached its zenith in the 1890s. Henri de Toulouse-Lautrec, a technical innovator, a magnificent poster artist and a great portrayer of the theatre and the arts of the 19th century, executed his "Moulin Rouge"—his first colour poster—in 1891. To the Impressionists also, colour was all important; Édouard Vuillard was producing such colour masterpieces as his *Douze Lithographies en couleurs* during this decade; and Pierre Bonnard. his *Quelques Aspects de la vie de Paris.* Other powerful artists who turned their hands to lithography in the last quarter of the century were Paul Gauguin, Eugène Carrière, Pierre Puvis de Chavannes and Ignace Fantin-Latour.

England.—Lithography in England received its initial impetus from Senefelder himself and his business associates. In 1800 they went to London to obtain a patent and to arouse interest in the new process. The patent was obtained in 1801; the promotional effort took the form of a publication entitled *Specimens of Polyautography . . .* appearing in 1803. Several well-known artists contributed to this first example of lithographic production in England: Benjamin West, Henry Fuseli and Thomas Stothard among others. West's design of the angel at the tomb of Christ is dated 1801 and may be considered the first lithograph of true merit to have been produced.

Despite this promising start, the English did not seem to take to the new medium very readily. Charles Hullmandel issued a series of *Twenty-four Views of Italy* in 1818 and later, in 1821, brought out 12 designs of *Various Subjects Drawn From Life on Stone* by Géricault, who was in London at the time. James Ward did a series of 14 *Celebrated Horses* in 1823, and Richard Parkes Bonington executed some very accomplished colour lithographs, particularly for Baron Taylor's book. Other English artists, such as Samuel Prout, James Duffield Harding and Thomas Shotter Boys, helped continue the tradition; but the process fell into the general pattern of decline until revived in the latter decades of the century by the American expatriate James Abbott McNeill Whistler. Although his work seems slight—particularly his delicate nudes—his influence was strongly felt, perhaps because his colourful career gave an added interest to anything with which he concerned himself.

Elsewhere in Europe.—Lithography had but one important adherent elsewhere on the continent—the great Spanish painter and etcher Francisco Goya, who drew, in all, 23 lithographs. Among them are four bullfight scenes that are a landmark of technical virtuosity and compositional strength.

United States.—The first lithograph produced by an American was the one mentioned above by West in 1801, for he was actually an American working in England. So far as lithography on the American continent is concerned, however, the introduction of the process to the United States is credited to Bass Otis of Philadelphia, Pa. In 1818 Otis etched on stone a portrait of Abner Kneeland for a frontispiece to a book of sermons by that clergyman. However, a little view of a mill, appearing in the July 1819 issue of the *Analectic Magazine,* is regarded as the first true American lithograph. Rembrandt Peale was among the first artists to employ the medium. Other important early figures were Thomas Doughty; George Lehman, who lithographed scenes in Pennsylvania; J. C. Wild, who executed an important set of Philadelphia views; August Kollner; Christian Schussele, an influential art instructor; Albert Newsam, a deaf-mute artist and lithographer of hundreds of portraits; and M. E. D. Brown.

When reviewing lithography of the 19th century in the U.S.. there must be taken into account the tremendous output of the publishers Nathaniel Currier and James Merritt Ives, who produced well over 6.000 lithographs after the designs of such well-known artists as George Inness, A. F. Tait, Louis Maurer. F. F. Palmer. Eastman Johnson and many others (*see* CURRIER & IVES). The publishing houses of Sarony and Major, and the Kelloggs, were also prolific. Not to be forgotten is Winslow Homer, who made a strong contribution with his *Campaign Sketches* of the American Civil War.

20TH CENTURY

The painter-lithographer tradition again declined during the early part of the 20th century. French artists, such as Degas, Paul Signac, Auguste Renoir, Bonnard, Jean Louis Forain, Vuillard, Maurice Denis, T. A. Steinlen and Mary Cassatt, as yet unrecognized in her native America, seemed to be working in isolation so far as their work influenced the medium elsewhere. In England the Senefelder club was formed in 1909 to provide an outlet for artists working in lithography. Augustus John. John Copley, Ethel Gabain, Charles H. Shannon and William Rothenstein were a few who kept the art lively. In Germany the Expressionist school was coming to the fore. Though its work was not immediately understood or appreciated, it gradually received recognition as one of the most powerful molders of 20th-century art. Käthe Kollwitz, the Norwegian Edvard Munch, Lovis Corinth, Max Slevogt, Max Liebermann, E. L. Kirchner, Emil Nolde, Max Beckmann, Ernst Barlach, Oskar Kokoschka, Paul Klee, the American Lyonel Feininger and George Grosz were among the group that challenged the ideal of beauty by rugged emotional display.

In the United States Joseph Pennell, whose work both in the U.S. and England, as well as his book on lithography (1st ed., 1898), made him an important proponent of the medium, led a strong group followed by George Bellows, "Pop" Hart, Bolton Brown. Albert Sterner, Arthur B. Davies, Childe Hassam, Rockwell Kent and hlabel Dwight, as well as Max Kahn, Stow Wengenroth. Benton Spruance, Adolf Dehn, Francis Chapin, George Biddle, William Gropper and Robert Riggs.

During this century an exciting group of lithographs came from the leading painters of Mexico: José Clemente Orozco, Diego Rivera, David Alfaro Siqueiros, Jean Charlot and Rufino Tamayo. In England, where lithography never was very popular, the names of Graham Sutherland, Henry Moore and Robert Colquhoun stand out.

It was from the school of Paris. however, that a vigorous revival of lithography came. To those giants of painting, Henri Matisse. Marc Chagall, Georges Rouault, Fernand Léger, Georges Braque and, above all, Pablo Picasso, with his prodigious output, is owed the tremendous popularity of the medium. Their influence has been international not only in stimulating all the graphic arts but also in freeing them from superficial limitations of size, technique and other preciousness. The colour lithograph, along with other colour-print processes, now rivaled paintings in size and attractiveness.

Printers and Publishers.—It should be remembered that most of the work of the school of Paris came about through the availability of dedicated lithographic printers. In Paris the firms of Fernand Mourlot and "Papa" Desjobert, with their enthusiasm and encouragement. made possible much of mid-20th-century lithography, Their accomplishment, however, is a timeless one, for it has ever been true that the greatest flowerings of lithography have come about as a result of the dedication of a few printers serving many artists — stimulating and easing the way for the production of great lithographs. Senefelder himself spent his life spreading information on the technique that he invented and stimulating production through his ability to print. The names of Bolton Bronn, Lawrence Barrett and Lynton Kistler are to be remembered in the U.S.; Thomas R. Way, Whistler's printer in England, and before him. Hullmandel will not be forgotten. In France the names of Clot, Rose Joseph Lemercier, Godefroy Engelmann, Charles Motte, Delpech and Charles Philibert de Lasteyrie du Saillant will be recalled, as well as those of the publishers Ambroise Vollard and David Kanweiler. In Germany Paul Cassirer and the Marées society were important as publishers. (K. McN.)

TECHNIQUE

Lithographs are made as follows: (1) The stone is grained. (2) The outline of the picture to be reproduced is drawn on the stone. (3) The drawing is done with tusche or crayon containing grease. (4) The stone is etched. placed in position on the press bedplate and washed with turpentine. which removes the soap and wax from the tusche or crayon. (5) The stone is dampened and rolled (inked). The drawing on the stone repels the water. The thin film of nater on the bare parts, in addition to repelling ink, actually prevents the inked roller from touching those areas of the stone. Therefore, only those parts of the stone that have been drawn on with the grease material receive the ink, and all bare parts of the stone that have been moistened nith water do not take the ink and do not print. It is then covered first with a piece of dampened printing paper, then with backing. which consists of two or three clean blotters, next with the tympan (a piece of hard fibreboard) and printed. The stone is dampened and rolled for each successive print. Hundreds, or thousands if necessary, of prints can be made from a stone or zinc plate. Lithographs can be made in multiple colours by printing with coloured inks. using a separate stone for each colour.

The Stone. — The best lithographic stones come from Solnhofen and Kelheim in Bavaria. Of a form of limestone found deep in the earth, they are of even thickness and perfectly flat. Stones are classified according to colour: blue (hard), blue-gray (medium) and yellow (soft). Blue-gray stones are preferred by artists. Both stones and metal plates must be grained with an abrasive to prepare them for the drawing. Stones are grained by rubbing together in a circular motion two stones with wet carborundum grit between them. Their positions are occasionally reversed, and more grit and water are added until any former design has completely disappeared. The size of the grit determines the texture of the drawing surface. Care must be taken to protect the stone from grease, dandruff. saliva or fly specks. A piece of cloth. tissue or a barrel stave is used as a bridge to prevent the hand from touching the stone while the artist is working on it.

The Drawing. — A nongrease crayon is used to sketch the outline of the drawing on the stone. The drawing should be reversed. since a print comes off the stone as a mirror image of the drawing.

Several drawing techniques are used in making lithographs. Lithographic crayons are supplied in both stick and pencil form in a wide range of grades from no. 0 (very soft) to very hard Copal no. 5. Tusche is supplied in bottles and in stick form. The liquid kind, often called ink, makes solid black areas nhen applied with a brush, and thin, sensitive lines when applied with a pen. Stick tusche, uhich must be dissolved in water. is used for wash lithographs called lithotints and for dry-brush lithographs. Smutty, close-grained dark grays are made by rubbing dark areas with a piece of felt or by scraping and shaving with a razor blade. Razor blades are used to soften hard. dark edges and sometimes are used to lighten or scrape out parts and make interesting textures. When a lithograph is to have a solid, dark-gray undertone for the background, such a tone can be laid on the clean, blank stone with a lightly inked composition roller Parts of the tone can be scraped away or washed out with gasoline to make light areas, and dark areas can be added with tusche and crayon.

Areas can he lightened and textured by laying a piece of tissue paper on the stone and crosshatching over it with a lead pencil or stylus When the tissue paper is peeled off some of the crayon will adhere to the underside of the paper. Crisp white lines are scratched into dark areas with sharp-pointed tools: razor blade, needle, penknife. etc. The result often resembles a wood engraving. Sharp tools are useful for making dark tones lighter by picking out some of the dots that make up the tone. Small areas can be erased by placing a pinch of carborundum grit or flint on the spot and regrinding with the flat bottom surface of a glass bottle stopper. Striking textural effects are obtained by use of an ink eraser.

To make a lithographic engraving, a fairly soft stone is grained with extra fine carborundum grit or flint. The stone is lightly etched. smoothed nith cloth and dried. The drawing is made with a lithographer's engraving needle. which has five facets. Wide shallow lines are made by pulling the needle — not pushing it — to scratch through the gum, barely into the stone. Errors are corrected by applying a thin gum covering. which then can be engraved again. When the engraved drawing is finished, first light machine oil. then lithographic ink, is rubbed in. The printing is done in the usual way, described below.

Lithographic printing is a difficult and complicated operation and is usually done by a professional printer rather than by the artist.

The Etch. — Before printing, lithographs must be etched. to set the drawing to the stone, and cleaned of excess grease that has spread out from the drawings. The etching solution for stones is prepared by pouring a few ounces of gum solution. *i.e.*, about equal parts by volume of water and gum acacia, into a small bowl and adding half a teaspoonful of nitric acid. The gum solution desensitizes the surface not drawn on, decreasing its affinity for grease; the acid eats away any invisible particles of grease that may be on the surface but, when in the correct solution, does not affect the drawing itself. which is protected by the wax in the lithographic crayon. Etching solution is applied to the stone with a large soft brush.

The amount of acid required for the etch solution depends upon many factors. such as room temperature, hardness of the stone, type and age of the drawing and strength of the acid. Often, some parts of the drawing that require a stronger etch than other parts must be gone over with a brush and a stronger solution.

Printing. — Having properly etched the stone, the printer removes the excess gum with a rubber plate scraper and fans it dry. Then he gently rubs it with a damp cloth and a few drops of gum solution. After it has dried, the printer washes off the crayon drawing with turpentine and a soft cloth, leaving the drawing invisible. apparently destroyed; but it is preserved. of course, in the grease still remaining in the pores of the stone. He then rubs ink or asphaltum into the stone. As soon as this has dried, the stone is sponged with water and rolled with a grained roller well charged with lithographic ink. Lithographic ink comes out of pound cans in tarlike chunks; it must be kneaded and thinned with lithographic varnish before using. A small amount is spread onto a slab of stone. and the roller is charged with ink by rolling it briskly over this slab until it produces an audible hissing sound

A lithograph is printed on a specially constructed press, which has a traveling bedplate that carries the freshly inked stone with dampened paper. backing and tympan under a leather-covered scraper. When the crank is turned. the inked image is rubbed or scraped off the stone onto the paper as it is forced through the press. The scraper is kept well greased to reduce friction. Lithographic presses weigh several hundred pounds.

The first few prints "pulled" (printed) are light. because the stone has absorbed some of the first ink applied. Printing can be interrupted at any time to make corrections. Small areas can be scratched out or lightened with a razor blade and the areas lightly swabbed with a 2% solution of phosphoric acid When additional work is to be added, the stone must first be counteretched. This is done by inking the stone, dusting it with rosin to dry the ink and washing it with a saturated solution of alum (called counter-etch solution). The new work is added and the stone etched again. Then the whole process of preparation and printing is done exactly as before.

If the prints keep getting darker as the edition progresses, the stone must be re-etched. To do this the printer inks it, dusts it. etches it again, washes it out and prints it as before. If the stone is to be put away for future printing, it should be rolled, dusted, etched very lightly and covered with thin paper while wet.

Transferring. — Many print makers prefer to draw lithographs on paper and have a printer transfer the drawing to stone or zinc for printing. Such transfers often require some additional work to be done on the plate or stone. either by the artist or printer before printing. Transfer lithographs are easily identified because their texture is like the paper they were drawn on. Special transfer papers are available. but any thin paper will do. When an artist draws on paper for transfer he does not have to reverse the drawing. The drawing medium must contain grease.

The drawing must be softened by soaking it for a few minutes in a tray filled with a solution of about 30 drops of nitric acid for each quart of water. The stone or plate used for the transfer must be larger than the print, smoothly grained and warmed slightly. The lithographic press is used to transfer a drawing to the stone. In transferring the drawing while still moist, it is placed face down on the stone or plate and covered with aluminum foil, backing and tympan. The press is adjusted and set for extra pressure to make transfers.

The drawing, when transferred to stone or plate, will appear weak. but some of the grease will have penetrated the stone, and the design will come up stronger when it is printed. Transfer lithographs should be lightly etched before printing; otherwise they are printed in the same manner as originals. Sometimes transfer lithographs darken during the printing and must be etched again.

Metal Plates. — Lithographs can be made in the same manner on zinc or aluminum plates, which are bought already grained. Metal plates are preferred by some artists because of their convenience in handling. They are very sensitive to grease and are especially suitable for transfers and for lithotints. The technique for drawing on zinc is the same as for drawing on stone. Textural effects are limited. The metal is hard and cannot be scraped or scratched for corrections.

The process for preparing plates varies slightly from that used for stones. After a zinc or aluminum plate has been drawn upon, it is regummed and dried. Then it is etched, washed out with turpentine and nater, rubbed up with asphaltum, washed with water, rolled with ink and printed without being allowed to dry again until the edition has been printed.

The etch solution for zinc plates is about 4 oz. of gum solution and 1 tsp. of chloric acid and 12 drops of phosphoric acid; for an aluminum plate, 4 oz of gum arabic and 15 or 20 drops of phosphoric acid. Commercial preparations are sold for etching zinc and metal plates.

See also ETCHING; references under "Lithograph" in the Index volume; and articles on most of the artists mentioned in this article. (L. BA.)

LITHOGRAPHY is one of the most widely used methods of printing. In its usual commercial or industrial application it is known as offset lithography because the inked image is first printed on a rubber cylinder, which then offsets or transfers the image to paper or other material. The process is also known as photolithography, photo-offset, offset and planography. Because of the flexibility of the rubber cylinder, lithography can be used to print on tin, wood, cloth, leather and rough, as well as smooth, paper. For a discussion of lithography as an art farm, *see* LITHOGRAPH.

In lithography the matter to be printed is neither raised above (as in letterpress) nor sunk below (as in intaglio) the surface of the plate but remains on the surface, or plane. For this reason the process is sometimes called planography. Lithography is based upon the principle that grease and water do not mix: ink is deposited on grease-treated printing areas, while the nonprinting parts, which hold water, reject the greasy ink.

Lithography is used mainly to produce printed matter that is required in large quantities; *e.g.,* calendars, greeting cards, bank checks and deposit slips, booklets, letterheads, books, magazines, newspapers, maps, posters, billboards, stamps, labels on tin cans, packaging and other advertising matter. Posters can be lithographed on rotary presses either by offset or by direct printing from the plate. Since most posters require strong colour, direct presses are usually used.

Offset lithography is particularly advantageous in long runs (over 10.000) of large-sized sheets. Only gravure can compete with it in certain types of work. Letterpress plates cannot be made so large as offset plates, while silk-screen and collotype methods are suited, for other reasons, mainly for short press runs. *(See* PRINTING PRESS.)

History. — The lithographic process was invented by Aloys Senefelder (*q.v.*) of Munich, Ger., in 1798. Senefelder had experimented for several years in an effort to discover a cheap method of printing plays and sheet music. In making the first lithographs he used a variety of calcium carbonate stone (limestone) that is found mainly in Bavaria; it has a porous texture that absorbs grease and water. He also suggested the use of grained metal plates. *i.e.,* plates treated so as to give them a granulated surface, but they did not come into general use until the 20th century, when they gradually replaced Bavarian limestone. However, stone is still preferred by artists for making hand-printed lithographs.

Up to 1818, when Senefelder published a technical description of lithography, the process was used sparingly because the procedural techniques were kept secret. Artists in England, France and Germany published work from 1803 on, but the first lithograph in the United States, drawn by Bass Otis, was not published until 1819 (in the *Analectic Magazine).* After 1825 lithography advanced rapidly.

Many firms were established for producing a variety of commercial work and for distributing popular topical, historical and religious subjects to a wide audience. The best known of these publishers was Currier & Ives (*q.v.*) of New York. The firm was founded in 1857, although Nathaniel Currier published work from 1834 on. The lithographs were printed in black ink and were often hand-coloured by an assembly line of women, each of whom applied a separate tint of water colour.

Some good early work was done in colour lithography (using printed colours) by Godefroy Engelmann in 1837 and Thomas S. Boys in 1839, but the method did not come into wide commercial use until 1860. It then became the most popular method of colour reproduction for the remainder of the 19th century. These products were called chromolithographs. chromos or oleographs. They were made by preparing a separate stone by hand methods for each colour (tint) to be used and printing one colour in register over another. Sometimes as many as 30 stones were employed for a single subject.

The steam-driven lithographic press was perfected by Hughes & Kimber of England about 1865 and introduced into the United States in 1866. These presses utilized automatic rollers to moisten and ink the stone, while the paper was pressed into contact by a revolving cylinder. P. S. Duval, writing in the *American Encyclopaedia of Printing* (1871), said that about 450 hand presses and 30 steam presses were in operation in the country at that time. The power press made it possible to print larger stones than ever before, with sizes up to about 44 by 64 in. Although the offset method of printing was first patented by John Strather of England in 1853, the first practical application of this principle came in the 1870s. when rubber offset rollers were used on flat-bed presses for printing on tin and other metals.

The rotary press for lithographic printing came into use in the late 1890s. Lightweight zinc sheets, which could substitute for the heavy stones, were curved around cylinders for rotary printing. Two main cylinders were used, one for carrying the plate and the other for carrying the paper. Early rotary presses could

As soon as photography became a practical process in 1839 because of work by Louis J. Daguerre of France and William Henry Fox Talbot of England, efforts were made to adapt it to lithography. Among early experimenters nho reproduced line drawings were Joseph Dixon of the Cnited States in 1840 (his technical description, however. was not published until 1854) and Frédéric Zurcher of France in 1842.

Late in 1852 Rose Joseph Lemercier, a Parisian lithographer, together with Charles Barreswil, Nicolas P. Lerebours and Louis Alphonse Davanne, made the first photolithographic half tones (prints in a gradation of tones). They used bitumen of Judea (asphalt) for sensitizing the surface of a grained lithograph stone and developed the image, made through a paper negative, with ether. This slow, expensive and dangerous method was superseded by the albumin process patented by Alphonse Poitevin in 1855: this process, which was essentially the same as the albumin process still used in the early 1960s, employed dichromated solutions of albumin, gum or gelatin as light-sensitive coatings.

In 1857 Eduard I. Asser in Holland invented the phototransfer process, which he patented in England in 1860. In this process a photographic image on sensitized paper is inked and transferred to the printing surface. Henry James of England, in 1859, first used grained zinc to replace stones in making phototransfers. J. W. Osborne of Australia improved the transfer process in 1859 and made it commercially feasible for reproducing engravings, pen and ink drawings, maps and other line work.

James A. Cutting and Lodowick H. Bradford made the first lithographic half tones in the United States, in 1858. The first use of the half-tone screen in lithography was made by Edward and James Bullock of England in 1866. They employed a glass surface or a translucent paper sprinkled with opaque dots. These produced half-tone prints with a granular texture

William A. Leggo of Canada made half tones in 1869 through a glass screen coated nith darkened collodion and ruled with crossing lines drawn with a diamond point. The resulting prints had a dot structure similar to that made from a modern half-tone screen. (This is composed of two sheets of glass, each covered with fine lines runaing in a diagonal direction; the sheets of glass are fastened together so that the lines form right angles. The resulting crosslined squares break up a reflected image into dots of varying sizes. depending upon the amount of light that penetrates the transparent squares.)

Offset methods for printing on paper were developed separately in the United States shortly after 1900 by Ira W. Rubel of New Jersey. Alex Sherwood of Illinois and A. W. and Charles Harris of Ohio. Rubel, in collaboration with Sherwood, made the first good press in 1906; this later became the Potter press. The Harris brothers, about one month after the Rubel press appeared on the market, made the first press to be commercially exploited. Many of the initial steps in improving offset lithography were taken by William C. Huebner of the United States, who developed the precision all-metal camera, step-and-repeat machines (widely used to produce multiple images on an offset plate) and plate-coating machines.

The use of colour half tones, which was limited before 1920. expanded rapidly after that date because of the introduction of improved methods of dot etching and improved techniques of registration (superimposing one colour over another) The new etching method permitted better tone control by making it possible to reduce the size of the dots when desired.

Offset presses vary greatly in size. The largest can accommodate sheets as large as 52 by 76 in. and can print up to six colours in a single run. Paper can be fed from a roll (web printing) and cut to the desired size in the press after printing. Usually. however, single sheets are fed in. Some offset presses can print on both sides of the paper simultaneously.

Hand Methods. — The method of preparing stones for hand printing. which is still the lithographic method preferred by artists, has remained substantially unchanged since Senefelder's time. The materials and procedures of the 19th-century lithographer are duplicated in almost every respect by the contemporary hand printer. Three types of stone are used: blue-gray, gray and yellow. The latter, which is very soft, is for coarse work only. The stone is grained to provide an even texture for receiving the drawing. This is done by sprinkling a hard. powdered abrasive. such as flint or carborundum, on the stone. adding water as a lubricant and rubbing with another stone in a flat, rotating motion. After the graining is completed, the drawing is made on the stone or is transferred from a sheet of specially prepared paper. The stone is etched by brushing on a solution of gum arabic (acacia) and nitric acid; the solution also desensitizes the surface to, *i.e.*, lowers its affinity for, grease. Next the stone is rubbed with a solution of gum arabic, the drawing is washed off with turpentine and the stone is rubbed with asphalt (asphaltum) to strengthen the greasy areas. Finally, the stone is coated with water and inked for printing.

The printing is done on a press that exerts a sliding or scraping pressure. The pressure is exerted through a bar of wood that is immovably fixed at the top and is covered at the bottom by a strip of greased leather. The stone to be printed is covered with dampened paper and a flexible backing board and is placed on the press bed, which is then raised by a lever to make firm contact with the scraper. The printer moves the bed horizontally, and the paper is pressed against the inked stone by the sliding pressure of the scraper. When the scraper reaches the end of the stone. the bed is lowered and the backing board and the inked paper are removed.

Types of Plates. — There are four basic types of offset plates: paper. albumin, deep-etch and bimetallic. Copy can be typed directly on special paper for printing on small office-type presses; such plates can produce 5,000 to 10,000 copies under average conditions. The albumin and deep-etch processes, which employ photographic techniques, are for longer runs. Albumin plates can produce up to 25.000 impressions; deep-etch plates are capable of several times this number. Bimetallic plates, which also are made photographically. are extraordinarily durable, being capable of printing more than 1,000.000 impressions. These plates are made from two different metals, one of which holds water and repels grease, while the other, which composes the printing image. attracts greasy ink.

Preparation of **Copy** and Plates. — Photolithography: since it is a duplicating process, requires material to reproduce. This material. which is known as copy. can consist of typographic matter. water colours, oil paintings, line drawings, hand lettering and photographs, either alone or in combination.

Copy is usually prepared as a paste-up that combines type matter with other line copy (black and white. such as line drawings). The type matter is taken from proofs ("repro proofs") of type that are made on high-quality proof presses especially constructed for reproduction ("repro") purposes. Type matter also may be taken from photocomposition. (See TYPESETTING: *Filmsetting.*) If photographs and other tone copy are to be included in the plate. their position and size are indicated on the paste-up by outline. A photographic negative is then made of the paste-up. This can be enlarged or reduced as desired.

A negative of the tone copy (photographs or wash drawings) is made separately in a camera that holds a half-tone screen. which breaks up the tone image into tiny dots. The half-tone negative is cropped to proper size; *i.e.*, the size that fits the space left for it on the paste-up. The line negative and the half-tone negative are "stripped" (fastened) together on a glass-topped layout table over a light. This unit (combination of line and half-tone negatives) is placed on a sheet of paper called "goldenrod" because of its colour; the goldenrod is translucent enough to be seen through on a layout (stripping) table but opaque enough to block light during exposure for platemaking. Openings are cut in the goldenrod paper where the negatives are positioned. The negatives are then fastened in place with opaque cellophane tape. The entire layout. or flat, is now ready for exposure on the thin. light-sensitive. albumin-coated metal plate.

The zinc or aluminum plate is grained or roughened to produce a foundation that will hold the sensitized coating firmly. hold water in the nonprinting parts and prevent the ink from spreading in the printing areas. The usual method of graining is to fasten the plate in a trough. cover it with water and an abrasive, such as sand or carborundum powder, and add a layer of steel marbles. The trough is geared to move horizontally and slightly up and down. This causes the marbles to roll and rub the abrasive into the plate, thus creating a fine, even texture. Plates are sometimes grained by chemicals — a hot solution of a monobasic salt of phosphoric acid, *e.g.*, monobasic sodium phosphate, for zinc and a hot solution of sodium hydroxide or aluminum potassium sulfate for aluminum. Most lithographic printers purchase and use pregrained plates rather than graining their own.

The grained plate is thoroughly washed and then counteretched, usually in a solution of acetic acid or hydrochloric acid. Counteretching removes dirt and metal oxides and sensitizes the plate to. *i.e.*, increases its affinity for. grease. Some shops etch the plate to make it more water receptive. The plate is now coated with a solution of albumin and light-sensitive ammonium dichromate. This operation is carried out on a machine that whirls the plate and spreads the coating evenly. The entire layout, or flat, is placed on the sensitized plate, and both plate and layout are locked in a vacuum frame, from which the air is withdrawn to ensure close contact for sharp photographic printing. The frame is exposed to strong light. usually from an arc lamp. which penetrates the transparent areas of the negative (type. lines and half-tone dots) and hardens the albumin underneath. The albumin under the opaque areas of the negative and the goldenrod paper remains soft and water soluble.

Exposure is often made on a photocomposing, or step-and-repeat, machine. This device produces multiple images of the original subject on one large plate. After an exposure is made! the subject is moved to the next position and again exposed. This procedure is continued as long as desired. or until the entire plate is covered. Since the machine is a precision instrument, with accuracy to one-thousandth of an inch. it is particularly valuable in colour work in which exactness of register is essential. All kinds of copy can be handled by this machine. which also is adaptable to all other photographic printing processes.

The exposed plate is then rubbed with greasy developing ink to strengthen the printing image. After the developing ink is washed off with water. which also removes the soft albumin, the plate is etched with a solution of gum arabic. This desensitizes the bare grained metal to grease and dissolves any albumin that might cling to the edges of the image. Cellulose gum (sodium carboxymethyl-cellulose\. which often is substituted for gum arabic. produces a more durable printing surface. The plate is now ready for printing.

Plates made by the deep-etch process can be used for longer runs than plates made by the albumin process. The printing areas of deep-etch plates are slightly below the surface of the plate. These plates. therefore. hold more ink and are less subject to wear. This platemaking method differs slightly from the albumin process. The plate is sensitized in the usual may but in the vacuum frame is exposed behind a positive rather than a negative. It is then developed with a lactic acid solution to remove the unhardened coating. Next it is etched in the image areas to eat away the bare metal: the light-hardened film is not affected. After being washed with anhydrous alcohol to remove the etch, it is dried and covered with lacquer. After being developed in the usual way, the plate is scrubbed with water to remove the light-hardened film that covers the unetched portions. These unetched areas will hold water in printing, while the etched areas will hold the ink.

Printing. — Offset printing is done on a press that is composed, basically. of three rotating cylinders — a plate cylinder, to which the metal plate is fastened; a blanket cylinder covered by a sheet of rubber; and an impression cylinder that presses the paper into contact with the blanket cylinder. The plate cylinder comes in contact first with a series of moistening rollers that deposit a thin film of water in the granulations of the bare metal. A series of inking rollers then passes over the plate. The ink is rejected by the water-holding areas but is accepted by the greasy image. after which it is transferred to the rubber blanket. This inked image (type. drawings, half tones) is then offset to the paper traveling around the impression cylinder.

Decalcomania. — Decalcomanias are designs that are printed on specially prepared paper to form films that can be transferred to any surface. These films, which usually are called decals (transfers), are widely used for decorating and labeling any objects that cannot be run through a press. Decals are made in a variety of ways. depending upon the needs to be served. The regular decal applied to such objects as typewriters and trucks, for example. begins with a sheet of porous paper coated with a solution of starch, albumin and glycerin. The design that will be seen is printed first; several coats of opaque white. which will not be seen after application, are then added: and the decal is finished with a coat of water-soluble glue called "stickative." When the decal is moistened and applied to the object, to which it adheres. the moistened backing paper is removed, and the design becomes permanently affixed. The stickative becomes water resistant soon after application.

Decals applied to windows are printed in reverse order. The layers of opaque white ink are printed first and the design last in order to be seen when in contact with the glass. Decals for china and kitchen ranges are printed with mineral colours and are fired to resist heat.

Office Offset Presses. — Small offset presses. or duplicators, are used in offices. as well as in printing shops. They can print on sheets from 3 by 5 in. to $9\frac{3}{4}$ by 14 in. at speeds from *3,000* to *6.000* impressions per hour. Paper-base plates, or masters. can be made by typing with a special ribbon or by drawing. writing. tracing or lettering with a special pencil or ink. Corrections can be made with an ordinary eraser. For reproducing photographs, type and illustrations. zinc or aluminum plates are prepared as in the standard commercial offset method. However, these images appear rather gray because they require heavier inking than can be supplied by the duplicator's inking mechanism. The press is especially useful for printing office forms. sales letters and other matter on letterheads. Numerous kinds of paper-base plates have been developed for short or long runs, and plastic plates have come into use.

LITHOPONE, a mixture of barium sulfate, $BaSO_4$, and zinc sulfide. ZnS, in approximately equal molecular proportions used as a white pigment in the manufacture of paints. *See* PAINTS. CHEMISTRY OF.

LITHOSPHERE, the solid crust of the earth (Gr. *lithos*, "a stone," and *sphaira*, "a sphere"). Below the loose soil and subsoil is solid crustal bedrock, which consists of such sedimentary rocks as sandstone and limestone, resting on a thicker base of igneous and metamorphic rocks. These materials form an outer granitic layer from 6 to 20 mi. thick. Below is a second somewhat thicker stratum probably composed of a basaltic rock. These two layers form the earth's crust. Beneath them is heavier rock that may be partly molten. The earth's crust is affected by tectonic movements which are manifested by folds and breaks in the crustal rocks and by the rise of molten lava which may erupt at the surface in volcanoes. (W. E. P.)

LITHUANIA (Lith. LIETUVA, Pol. LITWA, Ger. LITAUEN), a country of northeastern Europe, bounded north by Latvia, east and southeast by Belorussia, south by Poland and west by the Kaliningrad *oblast*, Russian S.F.S.R., U.S.S.R., and the Baltic sea.

The territory so defined forms the so-called ethnic Lithuania. Historic Lithuania covered a far larger territory, comprising the whole of Belorussia and, for a time, part of the Ukraine. From Aug. 3. 1940, ethnic Lithuania was a component republic of the U.S.S.R.

Physical Geography. — The country is flat and low lying, its northwestern half being less than 300 ft. above sea level. while the southeastern half lies between 300 ft. and 600 ft. above sea level. In the west there is hilly land with a highest altitude of 748 ft. south of Siauliai, but the highest point in Lithuania is a hill of 843 ft. west of Trakai (Troki). The country is overlaid with glacial deposits. in some places 400 ft. thick. The typical bottom moraine. with erratics from Finland. extends over most of it, and glacial furrows. striae and elongated troughs run northwest and southeast. as do the eskers. Sand dunes extend along the shores of the Baltic. The Lithuanian plain is chiefly watered by the Niemen (Nemunas), which rises in Belorussia and empties into the Kuronian gulf. Its right-bank tributaries are the Neris (Wilia) and Dubysa (Dubissa). In the north the Musa is an affluent of the Latvian Lielupe river, while another Latvian river. the Venta, has its source south of Telsiai. Nearly 2.000 small lakes, Drysviaty being the largest, dot the landscape. The climate varies from maritime along the coast to modified continental in the east. Centrally located Kaunas has an average temperature of 23.3° F. in January and of 65.3" F. in July, with an average precipitation of 24 in. For four months of the year the temperature is usually below freezing point and 160 days are rainy, half of these in late summer. Except for a little alluvial soil, principally near the major rivers, most of the country's farmland is low in organic material.

In 1939 forests covered about 17% of the area, while 49% was arable land, 25% meadows and pastures and 8% peat bogs, marshes and swamps. The most important trees are fir (40%), pine (28%) and aspen (13%); but birch, alder and oak are of some consequence. More than 226 kinds of birds. 35 kinds of wild animals, 12 kinds of amphibians and 7 kinds of reptiles are native. Especially common are hares, foxes, wolves, badgers, squirrels, deer, wild hogs and otters. Elk, beaver, grouse and black stork became almost extinct during World War I. About 40 species of fish can be enumerated in the fresh waters, while the Kuronian gulf is rich in brill, whiting, smelt, sole and herring. There are no mineral resources worth mentioning.

HISTORY

Lithuanians belong to the Baltic group of nations, which included also the Prussians to the west and the Latvians to the north. The Prussians were exterminated by the Teutonic Order in the 13th century. The Latvians, together with the Finno-Ugrian Estonians, were conquered during the first three decades of the 13th century by the German Knights of the Sword who in 1237 joined the Teutonic Order. (See ESTONIA.) The Lithuanians. protected by the primeval forest which almost entirely covered their land, resisted the German pressure. However, Samogitia (Lithuanian Zemaitija), the cradle of the Lithuanian people. lying between Prussia and Livonia, two lands already in the hands of the Teutonic Order, was an object of German covetousness. Under this threat the Lithuanian tribes united in the middle of the 13th century under Mindaugas (Mendog or Mindove). He and his family were baptized in 1251 and two years later, in his capital at Kernave (Kiernow) on the Neris, he was crowned the first and only king in Lithuanian history by the authority of Pope Innocent IV. Mindaugas was assassinated in 1263 and the Lithuanians returned to paganism.

In the second half of the 13th century Traidenis (Trojden) was the ruler of Lithuania (1269–82). He probably was the founder of the dynasty known as that of Gediminas or Gedymin (*q.v.*). Under Mindaugas, shortly after the destruction of Kievan Rus by the Tatars, Lithuania began to expand eastward and southward to the lands inhabited by Belorussians, but Gediminas was the real empire builder of what later became known as historic Lithuania. He made Vilnius (Wilno) the capital in 1323. When he died in 1341, Lithuania's frontiers extended across the upper Dvina to the northeast, to the Dnieper to the southeast and to the Pripet marshes in the south. The warlike but small Lithuanian nation could not colonize this vast territory. but it maintained its control over it because the ruling class had shown an undoubted political talent and a spirit of religious toleration.

Gediminas divided his empire among his seven sons. Soon, however, only two remained to continue their father's policy of expansion. Algirdas (*q.v.*), who had Vilnius as his capital. succeeded to the title of grand duke and undertook the defense of Lithuania against the Tatars and Muscovy; Kestutis (Kiejstut), with his seat at Trakai, reigned over ethnographic Lithuania and as such defended it against the Teutonic Order. Algirdas died in 1377 and left to his son Jagiello (Jogaila) an empire including Kiev, which came under Lithuanian suzerainty in 1361 or 1363. Jagiello's position was difficult because in 1381 his uncle Kestutis drove him from Vilnius, proclaiming himself grand duke of Lithuania. His Orthodox elder brothers tried to convince him that Lithuania's interests lay in an alliance with Muscovy and accession to the Orthodox Church, while his pagan younger brothers recommended a pro-Polish policy with acceptance of Roman Catholicism. In 1382 Jagiello defeated Kestutis.

Polish-Lithuanian Union. — The German danger was great because in 1365 the Teutonic Knights took Kaunas and from 1378 the whole of Samogitia was in their hands. The feud between Jagiello and Kestutis' son Vytautas (Witold or Witowt, *q.v.*) was a further complication. Having escaped from Jagiello's prison, Vytautas found sanctuary in the Teutonic Order's land. On Aug. 14, 1385, at Kreva (Krewo), Jagiello concluded with Polish ambassadors an agreement that he would forever unite Lithuania and Rus with the Polish crown if he could marry the 12-year-old Queen Jadwiga of Poland and become king of Poland. Jagiello went to Cracow, was baptized on Feb. 15, 1386, receiving the name of Wladyslaw, married Jadwiga and on March 4 was crowned king of Poland.

The Lithuanians outside the German-occupied Samogitia were baptized by the Polish clergy in 1387. In 1392 a reconciliation took place between Jagiello and Vytautas. who became lieutenant governor of Lithuania. A great warrior. Vytautas dreamed of the conquest of Moscow and destruction of the Golden Horde. To consolidate his rear, in 1398 he confirmed the cession of Samogitia to the Teutonic Order, but on Aug. 12, 1399, on the Vorskla river, suffered a defeat at the hands of the Tatars. His eastern dream having vanished, Vytautas became more inclined to accept Jagiello's policy of turning in concert against the Teutonic Order.

In 1401 new Polish-Lithuanian agreements were concluded at Vilnius and confirmed at Radom between Jagiello and Vytautas and between the two estates. The Lithuanian boyars promised that in the event of Vytautas' death they would recognize the king of Poland as the grand duke of Lithuania, while Polish nobility accorded to Vytautas the title of grand duke of Lithuania, declaring that if Jagiello died without an heir they would not elect a new king without consulting the Lithuanians. Almost immediately after these agreements. Vytautas supported the revolt of the Samogitians against the German rule. The knights replied by a military expedition against the grand duchy. As the Poles and the Lithuanians were not yet in a position to risk a major war, Samogitia had once more to be abandoned (1404). Five years later, however, a new Lithuanian rebellion was in progress. Once more the order accused Vytautas of treachery and asked the Poles whether they would assist the Lithuanians again. Grand Master Ulrich von Jungingen was informed of the absolute solidarity between the two nations. A great war was inevitable.

The claim of the Teutonic Order to be combating Polish-Lithuanian "pagans" deceived many a western European knight into moving east to save Christianity. The decisive battle, one of the most important in European history, took place on July 15, 1410, at Grunwald, near Tannenberg, and Polish-Lithuanian forces inflicted a crushing defeat upon the order. German supremacy in the Baltic countries was broken, although the first peace treaty of Torun (Thorn), concluded on Feb. 1, 1411, was a moderate one. Samogitia returned to Lithuania until the death of Jagiello and Vytautas. On Sept. 27, 1422, however, the order was forced to agree that Samogitia, by now baptized, was Lithuanian forever.

In the meantime, at Horodlo, on Oct. 2, 1413, a new pact of union was concluded between Poland and Lithuania. The principles of the union remained unchanged, but the autonomy of the grand duchy was made permanent: after Vytautas' death the king of Poland would appoint another grand duke in agreement with the representatives of both countries. Vytautas died on Oct. 27, 1430, and Jagiello on May 31, 1434, but the latter was survived by the two sons he had by his fourth wife, Zofia (Sophia) Holszanska, a Lithuanian princess whom he married in 1422. His second son, Casimir IV (1447–92), king of Poland and grand duke of Lithuania, continued the struggle against the Teutonic Order and his efforts were crowned by the second treaty of Torun (Oct. 14, 1466) when the order had to restore Pomorze to Poland. After the death of Casimir a crisis arose in Polish-Lithuanian relations because the Lithuanian boyars elected grand duke Casimir's son Alexander, while the Poles chose his brother John Albert (Jan Olbracht). The Polish-Lithuanian personal union lapsed, but, on the death of John Albert in 1501, the Lithuanians insisted that their grand duke should be king of Poland too.

The Poles agreed and the senates of the two countries decided at Piotrkow that thenceforth the king of Poland should always be grand duke of Lithuania. The Teutonic Order was no longer a menace, but in the east there appeared another and greater danger. Ivan III, the grand duke of Muscovy, in 1480 assumed the title of sovereign of all Rus and the major part of historic Lithuania was Belorussian-speaking. Belorussian was the language in which was written the statute of the grand duchy adopted in 1529 (revised in 1566 and 1588).

On July 1, 1569, at Lublin, a common Polish-Lithuanian sejm or parliament transformed the personal union into a real one. In the course of the ensuing two centuries both the Lithuanian and Belorussian nobilities of historic Lithuania became Polonized, but the two peasantries continued to use their own languages. On the eve of the partitions of Poland, the grand duchy of Lithuania covered an area of 120,500 sq.mi. with a population (1791 est.) of about 3,850,000. There were 1,420,000 Belorussians (36.9%), 1,005,000 Poles (26.1%), 770,000 Lithuanians (20%), 385,000 Jews (10%), 140,000 Russians, 95,000 Latvians (in Latgale), 30,000 Germans and 5,000 Karaims. From the point of view of religion this population comprised 1,500,000 Uniates, 1,470,000 Roman Catholics, 250,000 Orthodox, 140,000 Raskolniki (dissidents from the Orthodox Church), 60,000 Protestants, 385,000 Jews, 40,000 Moslems (Polish or Belorussian-speaking Tatars) and 5,000 Karaims.

Under Russian Rule.—While at the first (1772) and the second (1793) partitions of Poland only Belorussian lands of the grand duchy of Lithuania were annexed by Russia, at the third partition (1795) ethnic Lithuania suffered the same fate, the only exception being the province of Suwalki, the northern part of which was Lithuanian speaking, which became part of Prussia, now the name of a German kingdom. In 1806 Suwalki was incorporated into the duchy of Warsaw, which in 1815 was annexed by Russia. The congress of Vienna added to the style of the Russian tsars the titles of king of Poland and grand duke of Lithuania.

Under Russian rule historic Lithuania comprised six provinces (gubernyas): Vilnius (Vilna in Russian), Kaunas (Kovno), Grodno, Minsk, Mogilev and Vitebsk, with a governor general residing at Vilnius. When the Poles rose against Russia in 1830–31 the insurrection extended to the Lithuanian provinces before it was suppressed. The Polish rising of 1863 also spread into Lithuania and its repression there was particularly severe, 180 insurgents being hanged and 9,000 deported to Siberia.

On March 25, 1839, the Uniates were forced to join the Orthodox Church and the next year the Lithuanian statute was replaced by Russian codes. The tsarist government treated the "Territory of the Northwest"—as historic Lithuania was called after 1832—as an integral part of Russia. From 1864 to 1905 the policy of Russification extended to every domain of public life. It was forbidden to publish newspapers, periodicals or books in Polish or Belorussian, while books in Lithuanian could be printed if the Russian alphabet was used. Russian was the only language of teaching in the schools. The Roman Catholic religion was persecuted.

Lithuanian Renaissance.—The Lithuanian people resisted the policy of Russification because they remained faithful to ancient language and traditions, and to their religion. By abolishing the serfdom of peasants throughout the empire in 1861, the tsarist government hoped that in the lands inhabited by non-Russian populations a wedge would be introduced between the peasants and the gentry and that the former, by acquiring the right to be proprietors, would be more easily Russified. The Russians hoped that such a process would be easier in Lithuania proper where the landlords were mainly Poles. It was a miscalculation. Besides the clergy, a new Lithuanian intelligentsia of peasant origin began to emerge in the 1880s. In 1883 Jonas Basanavicius (1851–1927), a country doctor, launched the first Lithuanian newspaper, Ausra ("Dawn"): published at Tilsit (East Prussia) and smuggled into Lithuania. Ausra was suppressed three years later, but in 1889 was replaced by *Varpas* ("Bell"), edited by Vincas Kudirka (1858–99); it continued to appear until 1904.

When the manifesto of Oct. 30, 1905, granted freedom of speech to the peoples of the Russian empire, two daily newspapers appeared at Vilnius, one Polish (Kurjer *Litewski*) and one Lithuanian (*Vilniaus Zinios*). On Dec. 4–5, 1905, Basanavicius called a congress of about 2,000 delegates to Vilnius. The congress demanded territorial autonomy for Lithuania with a democratically elected *seimas*. The frontiers of the national Lithuanian state were to be drawn according to the freely expressed wish of the peoples concerned. Soon afterward the teaching of Lithuanian language in schools was granted.

Independence Restored.—During World War I the Germans occupied a great part of historic Lithuania. On Sept. 18, 1915, the German armies entered Vilnius. The German government authorized the gathering at Vilnius, on Sept. 18–22, 1917, of a congress of 200 Lithuanian delegates and the election of the 20-member *Lietuvos* tnrybu or council of Lithuania. The congress called for an independent Lithuanian state within the ethnographical frontiers and with Vilnius as capital. As the leaders of the tnryba (Antanas Smetona [*q.v.*], Steponas Kairys, Jurgis Saulys and others) rejected all idea of union or federation with Poland, the local Poles refused to co-operate with the *taryba*. On Feb. 16, 1918, the taryba proclaimed an independent Lithuanian state and the dissolution of all political connections that had existed with other nations. Germany recognized this on March 24 with the proviso of a "perpetual alliance" of Lithuania with the reich. On July 11 the crown of Lithuania was offered to Wilhelm von Urach, a Roman Catholic duke of Wurttemberg, but the offer was withdrawn on Nov. 2, and the final solution of the question of the form of government mas referred to the constituent assembly. Meanwhile, the supreme power was vested in a three-man presidium (Smetona, Fr. Justinas Staugaitis and S. Silingas) which on Nov. 5 designated Augustinas Voldemaras (1883–) as the first premier of independent Lithuania. He formed a government on Nov. 11, 1918.

Lithuania was still under German occupation, but when the German troops had evacuated Vilnius, the city was entered on Jan. 5, 1919, by the Red army and a Communist Lithuania government, appointed by the All-Russian Central Executive committee on Dec. 23, 1918, was installed. It was headed by Vincas Mickevicius-Kapsukas (1880–1935). The Voldemaras government moved to Kaunas which, on Jan. 17, however, was also occupied by the Red army. The Germans remained in the western part of Lithuania, which from Feb. 1919 was controlled by the German army under Gen. Count Rudiger von der Goltz.

The *Polish-Lithuanian* Dispute.—Marshal Joseph Pilsudski, the head of the restored Polish state, proposed two alternatives for Lithuania. Either an independent state might be set up within purely ethnographic frontiers, that is, without Vilnius and its region which had a Polish majority, or a larger state including Vilnius; but in the latter case some sort of a federal link with Poland would be indispensable. On April 20, 1919, the Polish army led by Pilsudski took Vilnius from the Red army, which enabled the Lithuanians to re-enter Kaunas. In the following summer the Polish forces moved to the Dvina in the north and to the Berezina in the east. Against Lithuania they occupied the demarcation line fixed by the Inter-Allied committee presided over by Marshal F. Foch. This "Foch" line. adopted by the Supreme council on July 27, 1919, ran to the west of the Grodno-Vilnius-Daugavpils railways and more or less coincided with the eastern ethnographic frontier of Lithuania. On July 12, 1920, when the Polish army was retreating, the Kaunas government concluded in Moscow a peace treaty by which the Soviet Union "ceded" to Lithuania not only Vilnius, but also Lida and Grodno. After Pilsudski's final victory, the Red army, which occupied Vilnius on July 14, left it on Aug. 26 while the Lithuanian army entered the city. On Sept. 5, 1920, the Warsaw government appealed to the League of Nations. A Polish-Lithuanian conference met at Suwalki and a partial armistice was signed on Oct. 7. Nevertheless Pilsudski ordered Gen. Lucjan Zeligowski to seize Vilnius. with its mainly Polish population, and this was done on Oct. 9. Zeligomski set up a government of central Lithuania. A new armistice. restoring the Foch line, was signed on Nov. 29, 1920.

Meanwhile the council of the League of Nations had made many attempts to settle the Polish-Lithuanian dispute. The last of the series was a Polish-Lithuanian conference which opened in Brussels on April 20. 1921, at which a plan for a Lithuania composed of two cantons, Kaunas and Vilnius. each with separate self-government, and federated with Poland, was recommended. But the Lithuanians wanted Vilnius without any ties with Poland. Zeligowski then ordered elections to be held in central Lithuania on Jan 8, 1922, to a special diet of 106 members which would decide the future of the area in dispute; 55% of the inhabitants took part in the poll in Vilnius city and 65% in the province. On Feb. 20, 1922. the diet voted for the incorporation of the province with Poland. However, under the treaty of Versailles, the principal Allied powers had to determine the Polish frontiers that remained undefined. In the Polish-Soviet peace treaty signed at Riga (March 18. 1921), the Soviet government had declared its disinterestedness in the Polish-Lithuanian dispute. The council of the League of Nations, on Feb. 3, 1923, adopted a final resolution fixing a Polish-Lithuanian line of demarcation almost identical with the Foch line, leaving the decision as to the frontier to the Conference of Ambassadors in Paris. On March 15, 1923, the Conference of Ambassadors recognized the line of Feb. 3 as the final frontier between the two states. Lithuania, however, refused to accept this decision. (See also VILNIUS.)

Foreign Relations. — Lithuania was received into the membership of the League of Nations on Sept. 22, 1921. On Sept. 28, 1926, a Soviet-Lithuanian treaty of nonaggression was signed in Moscow. On Sept. 12, 1934, at Geneva, a treaty of good will and cooperation was concluded by Lithuania. Latvia and Estonia. Lithuania's relations with Germany were jeopardized by nazi propaganda in the Klaipeda (Memel) territory.

In March 1935, at a trial of Klaipeda nazis, most of the accused were found guilty of high treason. On March 17, 1938, Poland demanded of Lithuania the immediate opening of the frontier, acceptance of the cession of Vilnius and the establishment of normal diplomatic relations. Lithuania yielded to these demands. In February and May 1938 the Lithuanian government released the convicted nazis and in October abolished martial law in the Klaipeda territory. On Dec. 11, at the election of the Klaipeda *Landtag,* the nazis won 25 seats out of a total of 29. On March 21, 1939, Lithuania was presented with another ultimatum which meant the loss of its only port. (See also MEMEL.)

Home Politics.—On April 4, 1919, Smetona became provisional president of the republic and Kazys Slezevicius (1890–), a Social Democratic leader, succeeded Voldemaras as premier. On May 15, 1920, the newly elected constituent assembly met at Kaunas and its right-centre majority elected as president Aleksandras Stulginskis, the leader of the Farmers' union. On Aug. 1, 1922, a democratic constitution was adopted providing for a seimas of 80 elected for three years by proportional representation. As the *seimas* elected on Nov. 12, 1922, had no clear-cut majority, it was dissolved and a new election on June 5, 1923, restored the right-centre majority. The election of May 8-10, 1926, gave a small majority to the left-wing parties. On June 7, 1926, Kazys Grinius (1866–1950), the leader of the Peasant party, was elected president while Slezevicius became premier. However, in the night of Dec. 16-17, 1926, a coup d'état took place in Kaunas. It was prepared by the small Nationalist party and backed by the army. Grinius resigned and Smetona was elected president; Voldemaras was again premier. On May 15, 1928, he issued a new constitution which was to be submitted to a national referendum within ten years; but on Sept. 19, 1929, he was forced to resign and his Fascist organization, the Iron Wolf, was dissolved. Smetona was now in full control. Voldemaras, attempting to regain power in 1934, was arrested and imprisoned for high treason committed with German support, but was granted an amnesty in 1938. A new constitution, adopted on Feb. 12, 1938, was to provide the basis for a return to parliamentary institutions.

Independence Lost.—A secret protocol to the German-Soviet treaty of nonaggression of Aug. 23, 1939, stipulated that in the event of a territorial and political rearrangement in the areas belonging to the Baltic states, the northern boundary of Lithuania should represent "the boundary of the sphere of influence of Germany and the U.S.S.R." During the German-Polish war German diplomacy made frantic efforts to induce Lithuania to attack Poland so that the former might thus become an ally and protégé of the reich. Lithuania chose to remain neutral and the secret protocol to the German-Soviet treaty of Sept. 28, 1939, revised the previous agreement by deciding that "the territory of Lithuania falls on the sphere of influence of the U.S.S.R."

First Soviet Occupation. — On Oct. 10, 1939, a mutual assistance treaty was signed in Moscow, in accordance with which Lithuania was compelled to admit Soviet garrisons and to grant air bases. The Vilnius area was given to Lithuania, but was limited to 3,680 sq.mi. with a population of 549,000. (The province of Vilnius "ceded" by the U.S.S.R. in 1920 had measured about 12,450 sq.mi. and had a population of 1,275,000.) On June 15, 1940, however, Lithuania was confronted with an ultimatum demanding immediate formation of a "friendly" government. On the same day the country was occupied by the Soviet army. Smetona fled to Germany and later left for the United States. (He died in Cleveland, O., on Jan. 9, 1944.) Antanas Merkys, the premier, Stulginskis, the former president, and many other Lithuanian leaders were arrested and deported to Siberia. An obscure journalist, Justas Paleckis, became premier. A rigged election of July 14–15 produced a seimas which, on July 21, unanimously requested the incorporation of Lithuania in the Soviet Union. On Aug. 3, 1940, the Moscow supreme soviet readily acceded to the request and Lithuania was declared a constituent republic of the U.S.S.R. In the night of June 14–15, 1941, 30,455 members of the Lithuanian intelligentsia were deported to Siberia. Including other deportees and about 5,000 political prisoners executed at the time of the hasty departure of the Soviet forces, the country suffered during the first Soviet occupation a loss of about 45,000 people.

German Occupation.—A few days after the German attack on the Soviet Union (June 22, 1941) the whole of Lithuania was in German hands. On July 17, 1941, Hitler announced the creation of the "Ostland" province including the three Baltic states and Byelorussia. The commissioner general for Lithuania was Adrian von Renteln who, on Aug. 5, dissolved the provisional government formed on June 23. A policy of German colonization was inaugurated and by July 1943 about 4,700 German families were settled in Lithuania. The Germans executed almost all Lithuanian Jews.

Second Soviet *Occupation.*—Vilnius was taken by the Soviet army on July 13, 1944, and by the end of the year Lithuania was again under Soviet occupation. Fleeing before the Soviet armies, about 80,000 Lithuanians reached the western zones of Germany, but about 60,000 were rounded up in the eastern zone and sent to Siberia. In Lithuania proper, during 1945–46, about 145,000 Lithuanians were removed from their native land. The third mass deportation, ordered in connection with the forced collectivization of agriculture, took place on March 24–27, 1949, when about 60,000 Lithuanians were sent to north Russia or Siberia.

POPULATION AND ECONOMY

Territory and Population.— In its frontiers from 1923 to 1938 the area of Lithuania was 55,670 sq.km. or 21,494 sq.mi., including the Klaipeda (Memel) territory (1.081 sq.mi.). Between 1923 and 1939 the population of Lithuania, excluding Klaipeda, rose from 2,029,000 to 2,441,800. The latter figure included 2.056,100 Lithuanians (84.2%), 78,100 Poles (3 2%), 185.600 Jews (7.6%), 61.000 Russians (2.5%), 47,000 Germans and 14,000 others. The population of the Klaipeda territory was estimated in 1938 at 154,000, including 86,000 Lithuanians, 59 000 Germans and 9,000 Jews. In March 1939 Lithuania lost Klaipeda. but in October it gained the Vilnius territory (3,680 sq.mi.), nhose population was estimated at 549,000, including 369 000 Poles, 84,000 Jews, 61.000 Lithuanians, 17,000 Russians. 15,000 Byelorussians and 3,000 others. At that time Lithuania had an area of 24,093 sq.mi. with a total population of about 2,990,800. After World War II Klaipeda returned to Lithuania, which now covered an area of 65,200 sq km. or 25,174 sq.mi.

Normally, that is, without deportations and war losses, the total population within post-1945 frontiers would have been about 3,032,000. Of 447,100 Poles perhaps 100,000 were deported during the first Soviet occupation; between 1946 and 1948 about 178,-000 were repatriated to Poland. The number of Lithuanians living in Lithuania fell between 1939 and 1949 from 2,203,100 to about 1,809,000. According to official Soviet sources, the population of Lithuania in 1959 was 2,713,000.

Vilnius, the capital, in 1931 had 196,345 inhabitants, including 128.600 Poles, 54,600 Jews and about 2,000 Lithuanians; by 1959 its population had increased to 235.000, including about 80,000 Russians, 70,000 Lithuanians and 40,000 Poles, Kaunas had in 1959 a population of 214.000, Klaipeda (1959) 89,000, Siauliai (1959) 60,000 and Panevezys (1957 est.) 37,100.

Religion.— According to the 1923 census, excluding Klaipeda, Roman Catholics formed 80.5% of the population, Protestants 9.5%, Orthodox 2.5% and Jews 7.3%. In the Klaipeda territory were 91.7% Protestants and 5.3% Roman Catholics. In April 1926 the Vatican declared Lithuania a church province with an archbishop at Kaunas and four bishops at Vilkaviskis, Telsiai, Kaisedorys and Panevezys.. According to a Vatican source, by July 1950, out of 1,332 clergy left free until 1947, about 1.000 had been arrested and deported.

Education.--On Jan. 31, 1938, there were 2,599 primary schools with 5,613 teachers and 301,188 pupils. There were 100 secondary schools with 19,939 pupils as compared with 38 schools and 9,213 pupils in 1919. There were also eight institutions of higher education, including Kaunas university, with a total of 4,400 students. In 1955 there were about 3,200 primary schools with 430,000 pupils, 230 vocational schools with 21 5,000 pupils. 110 secondary schools with 35,000 pupils, and 14 institutions of higher education (including the universities of Vilnius and Kaunas) with 4,500 students.

National Economy.— Before World War II Lithuania was a predominantly agricultural country and in the 19jos still kept this character, although industrialization had made great progress. In 1938 about 2,742,600 ha. were arable land. The land reform of Feb. 16, 1922, fixed 80 ha. as a maximum limit for a farmstead; it expropriated 717,968 h a belonging to about 2,300 large landowners (Poles, Russians and Germans) and created about 45,000 new farms. Although the entire agricultural land was divided into about 287,380 small and medium farmsteads of from 4 ha. to 24 ha., agricultural production considerably increased.

After World War II agriculture was collectivized. In 1950 there were 6,549 collective farms; by 195j they were reduced to 1,795 bigger ones. But production in the mid-1950s was believed to have dropped by 60% as compared with the 1937–39 annual averages.

Peat is the only national fuel, reserves of hydroelectric power are modest and timber and flax are the main local raw materials. In 1946 the country had 2,192 industrial enterprises, but food processing formed about a half of the total value of industrial production. The production of electricity amounted in 1950 to about 190,000,000 kw.hr. In 195j plans were adopted for a hydroelectric power station at Petrasunai, near Kaunas, on the

Table I.—*Agricultural Production*
(in metric *tons*, pre-1939 area)

Crop	1909–13	1919–23	1937–39

*Pre-1939 area. †Post-1945 area.

Niemen river, which, when completed, was to produce annually about 350,000,000 kw.hr. Between 1939 and 1951 the number of persons employed in agriculture was reduced from 1,126,100 to 975,400, while the number employed in industry and handicrafts rose from 153,300 to 370,800.

Finances.—The 1939 budget of independent Lithuania was balanced at 341,785,274 lits. The lit, a national currency introduced on Aug. 16, 1922, was worth 10 U.S. cents, but in 1935 it rose to 16.67 U.S. cents. In Dec. 1939 the note circulation was 165,930,000 lits. After the annexation of the country by the U.S.S.R. the lit was exchanged at the rate 0.90 roubles= 1 lit. Under the Soviet regime Lithuania, as every other soviet socialist republic. contributed to the common budget and from the total revenues of the union a certain part was allotted to local expenditure. In 1953, for instance, the total revenue from Lithuania amounted to 4.081,500,000 roubles, but only 1,j10.801.000 roubles were allotted to the republic's budget. In 1956 the allocation was 1,908,122,000 roubles.

Communications.—In 1948 the country had 2,087 km. of railways, including j26 km. of narrow gauge. Except for about three winter months, the Niemen is navigable from Kaunas to Klaipeda (260 km.) for steamships and throughout its length within Lithuanian frontiers for floating and rafting. The port of Klaipeda was entered in 1938 by 1,544 vessels totalling 910,819 net registered tons, as compared with 789 vessels of 303,000 net registered tons in 1913. Annual goods traffic in the port in 1935–38 averaged 630,000 metric tons. including 145,000 tons in export.

LITHUANIAN LANGUAGE. The Lithuanian language, spoken by over 3,000,000 people, primarily in Lithuania, but also by numerous emigrants in the U.S.. Canada. South America, Australia and Siberia, belongs to the Baltic branch of the Indo-European family. It did not become an official administrative language until 1918.

History.—Although not officially recognized, a literary language had been in existence since the 16th century. The earliest Lithuanian text, which is also the earliest Lithuanian document, is a translation of a Polish Protestant Catechism (1547) by Mosvydas (Mosvidius or Mažvydas, d. 1563). All Lithuanian writings of' the 16th century are of religious character. The most important for the study of the language is the *Postilė* of 1599 by Mikalojus

Daukša (1527–1613). The language differs in many respects from modern Lithuanian: longer endings (especially in the dative plural), a directive and an adessive case, strong Slavonic influence in vocabulary and syntax differences in accentuation. Essentially the same characteristics are found in the language of the first half of the 17th century as represented by Constantine Sirvydas (1579–1631), the first Lithuanian lexicographer.

The Lithuanian literary language, from its beginning through the 19th century, is not uniform, but is based on the dialects of the various authors The dialects are divided into two main groups, Low Lithuanian or Shamaitish (sometimes called Samogitian) and High Lithuanian or Aukshtaitish. High Lithuanian is more archaic. Modern standard Lithuanian is based on the southern subdivision of the West High-Lithuanian branch, which is also the language of the Prussian Lithuanian pastor-poet Christian Donalaitis-Donalitius (1714–80). In the 19th century however, three literary languages were competing for recognition: (1) a Low-Lithuanian form. mainly represented by Dionizas Poška (1757–1830), Simon Stanevičius (1799–1848), Simon Daukantas (1793–1864), and Bishop Matthew Valančius (1801–75); (2) the East High-Lithuanian poetic language of Bishop Anton Baranauskas (1835–1902); and (3) the West High-Lithuanian language used in various underground publications as well as in East Prussia. The dialect used by Donalaitis was elevated to a standard language for all of Prussian Lithuania by the grammarian and lexicographer Friedrich Kurschat (1806–84) whose work was seconded by G. H F. Nesselmann (1811–81) and August Schleicher (1821–68). In the 1880s, Jonas Jablonskis (1861–1930), born in Suvalkų Naumiestis (not far from the former Russian-German border), became interested in his own native language while studying at the University of Moscow under F. Fortunatov (1848–1914), and began to study it with the help of Kurschat's and Schleicher's grammars. Jablonskis became the "father of the modern Lithuanian standard language." based on his own dialect.

Characteristics.— Lithuanian is highly inflected, mith eight cases. nominative (*miẽstas* "city"), genitive (*miẽsto*), dative (*miẽstui*). accusative (*miẽstą*). vocative (*miẽste*). instrumental (*miestù*), locative (*miestè*). illative (*miẽstan* "into the city"). In the modern standard language there are also remnants of a directive case (*galóp* "toward the end") and an adessive case (*Dieviẽp* "with God"), both of which occur regularly in the texts of the 16th and 17th centuries. There are three numbers: singular, plural and dual (the latter optional). In the nominative singular the nouns. which are grouped into five declensions, have one of the following endings: -as, -is, *-ys, -a, -ė*, -i, *-us, -uo*. There are regularly two grammatical genders (masculine and feminine) with some traces of the Indo-European neuter in the adjective. No article is used with nouns. Adjectives appear in two forms: indefinite and definite. While otherwise very conservative, the language is unexpectedly progressive in the formation of the comparative and superlative degrees of the adjectives and adverbs, there being no irregular comparison. The illative, directive and adessive cases are innovations which did not exist in the Indo-European parent language. While the Old Lithuanian (16th century) locative plural in *-su* is apparently inherited from Indo-European, the modern locative plural in -se is a former illative; *i.e.*, the accusative case extended by means of a postposition

The inherited verbal system is simplified to some extent. There are only four simple tenses: present, future (formed with *-s-*), preterite or past, and imperfect or habitual preterite. Each of these tenses forms only an indicative. There is only one subjunctive (derived from the infinitive) for all tenses. The imperative is formed from the infinitive and the infinitive ends always in -ti (*eĩti* "go," *dúoti* "give," *darýti* "do." dirbti "work," etc.). Lithuanian, like Sanskrit, is rich in participles. There are two sets of participles (active and passive) for the present, future, and preterite; the imperfect has only an active participle. The passive participles are used in the formation of the passive voice. Like Russian and Polish, Lithuanian makes a rigid distinction between durative and perfective aspects, but it differs by not using the perfective aspect as a substitute for the future tense. The reflexive verb is highly developed. While in the main the Lithuanian verb continues the Primitive Indo-European &conjugation (thematic verbs), there are some traces of the mi-conjugation (nonthematic verbs). As in declension, there are three numbers also in conjugation (dual optional). On the other hand, there is only one form for the third person of the three numbers in each of the tenses.

Lithuanian is extremely rich in diminutives and endearing forms which are derived from nouns and adjectives alike. Diminutive nouns may express either smallness or affection or even contempt, while diminutive adjectives express intensification of the meaning. The strong emotional appeal of the diminutives supplies the language with effective poetic expressions and gives the Lithuanian folk-songs their appeal. The vocabulary is immensely rich, abounding in onomatopoetic formations. The language is possessed of a continually productive creative power; no dictionary can ever include all Lithuanian words.

The word accent is free. It is not indicated in the orthography, except in grammars and texts especially prepared for students. There is no general rule fixing the accent; nor does the main stress alnays remain on the same syllable throughout the whole paradigm. Furthermore dialects vary widely in their accentual systems. The standard accent of every Lithuanian word, with all indications necessary to ascertain its shifts in various paradigms, is given in the Lithuanian-German dictionary (see Bibliography, below).

Lithuanian is written in the Latin alphabet with 32 letters, some of which are conventional letters supplied with diacritic signs. All consonants, except j (= y as in "you"), have a hard or velar and a soft or palatalized pronunciation. There are roughly 11 different vowels (monophthongs), 6 short and j long, all of them clear cut without any diphthongization. There are also the diphthongs ai, *au*, ei, *ui*, ie, *uo*, and the combinations (treated as diphthongs) al, ar, *am, an*, el, er, *em, en, il*, ir, *im*, in, *ul, ur, um, un*.

LITHUANIAN LITERATURE. The beginning of the history of Lithuanian literature was, in comparison mith that of other European peoples; greatly retarded. Although in the 13th and 14th centuries the Lithuanians had already created a great empire extending from the Baltic to the Black sea, yet in state affairs their native language was not used in writing but gave place to Ruthenian (Byelorussian) and, in later centuries, Latin. This circumstance undoubtedly impeded the use of Lithuanian in literature. Only in the 16th century did the temporary spread of Protestantism in Lithuania and the complementary Roman Catholic Counter-Reformation engender concern for the popular welfare and so create more favourable conditions for development. Lithuanian literature may be divided into four epochs.

1. The first known Lithuanian printed book is the Catechism of M. Mažvydas (Konigsberg, 1547). Later there appeared the religious writings of J. Bretkūnas (J. Bretke, 1535–1602). In 1701 the New Testament mas published and in 1727 the entire Scriptures. Until 1700 books were almost exclusively of a religious character. There are, however, several publications outside this category, among which the first dictionary of the Lithuanian lan-

guage, K. Sirvydas' *Dictionarium trium linguarum* (1629), is noteworthy. To this epoch belong 8 j authors and 70 publications.

2. In the 18th century religious literature was mingled with books of a secular tendency, including grammars, dictionaries and popular songs. Also to this period belongs the celebrated poem of Kristionas Donelaitis (Donalitius) (1714–80) entitled "The Four Seasons," written in hexameters and depicting village life throughout the year (printed in 1818). The 18th century gave Lithuanian literature 61 authors and 198 printed publications.

3. The 19th century heralded a new trend in Lithuanian literature. During its first half a significant national and literary movement, mostly emanating from the alumni of the Vilnius university, was characterized by an attempt to create a Lithuanian literary language and to extol the ancient history of Lithuania and its heroic figures. The most noteworthy names of this period are: Simanas Stanevičia (1799–1848), Dionyzas Poška (between 1 745 and 1765–1830), Simanas Daukantas (1793–1864) and many others less well known. Worthy of mention at the beginning of the 19th century is the poet Rev. A. Strazdas-Strazdelis (1763–1833), who does not belong to the foregoing group. and was the author of many religious and secular songs. A typical feature of Lithuanian literature of this epoch is its pseudo-classicism and a sentimentality borrowed from the west. Only in a few writers does romanticism appear, generally as idealization of the past.

Two events signalize the second half of the 19th century. The first was the prohibition in 1864 by tsarist Russia of the printing of Lithuanian books and writings in Latin characters, Lithuania being then under Russian rule. The second was the national renaissance movement. Lithuanians boycotted the prohibition by printing books and newspapers in so-called Lithuania Minor or Prussian Lithuania, then under German rule, which were smuggled across the frontier. Lithuanian literature of the national renaissance epoch is characterized by a specific utilitarianism. Its aim was to rouse the national consciousness, to fight against denationalizing alien influences (Russian, Polish, German) and to rally the Lithuanian people for the struggle to achieve national and political independence of Russia. Two writers who do not properly speaking belong to that period but rather to its preparatory stage are Bishop M. Valančius (1801–75), noted for his religious, educational and other writings in the sphere of belles-lettres, and Bishop A. Baranauskas (1835–1902), a poet, whose *Anykščių Šilelis* ("The Grove of Anykščiai") is his greatest work.

The Lithuanian national renaissance extends from 1883, when Jonas Basanavičius founded in Lithuania Minor the newspaper *Aušra* ("Dawn"), until 1904, when the Russian government repealed the prohibition against the printing of Lithuanian books in Latin characters. To this epoch belong the following distinguished names: Basanavičius (*q.v.;* 1851–1927), famous as a collector of folklore and publicist, commemorated as the "father of the Lithuanian national renaissance"; Vincas Kudirka (1858–99), a publicist and short-story writer; J. Mačiulis-Maironis (1862–1932), the most famous Lithuanian poet, called the "poet-prophet of the Lithuanian renaissance," noted for both his dramatic and lyrical poetry; V. Storasta-Vydūnas (1868–1953), born in Lithuania Minor, a philosopher, poet and dramatist; J. Biliūnas (1879–1907), a short-story writer; and J. Tumas-Vaižgantas (1869–1933), a publicist and literary critic. Authoresses included J. Zymantiené-Žemaité (1845–1921), the most famous short-story writer of the period; and S. Pšibilauskiené-Lazdynų Peléda (1867–1926) and N. Pečkauskaité-Šatrijos Ragana (1878–1930), both of whom wrote novels and short stories.

4. After 1904 and especially during the period of Lithuania's independence (1918–40) Lithuanian literature gradually lost its adaptable character and undertook the task of educating the reader. The young poets and prose writers of this period showed a tendency to formalism but this crisis was speedily overcome and the new Lithuanian literature became more expressive. New and more prominent literary names came to the fore, such as V. Krévé-Mičkevičius (1882–1954), the novelist and dramatist; V. Putinas-Mykolaitis (1893–), a novelist, dramatist and pioneer of the modern Lithuanian romance; J. Baltrušaitis (1873–1944), a lyrical poet of the first rank in Lithuanian and Russian; B. Sruoga (1896–1947), and K. Binkis (1893–1942), both poets and dramatists; J. Savickis (1891–1952), novelist and story writer; F. Kirša (1891–), poet; P. Vaičiūnas (1890–), dramatist; K. Šeinius (1889–), novelist and short-story writer; and S. Čiurlioniené (1886–), novelist and dramatist. Poets of the younger generation included J. Aistis-Aleksandravičius (1904–); B. Brazdžionis (1907–); A. Miškinis (1905– d. ?); H. Radauskas (1910–).

Among younger prose writers were A. Vaičiulaitis (1906–), novelist, short-story writer and literary critic; J. Grušas (1901–), novelist and dramatist; J. Jankus (1906–), novelist; V. Alantas (1902–), novelist and dramatist; F. Neveravitius (1900–), historical novelist and dramatist; L. Dovydénas (1906–), novelist; B. Babrauskas (1910–), literary critic. Among authoresses were N. Mazalaité (1907–), novelist and short-story writer; P. Orintaité (1907–), novelist; K. Grigaityté (1910–), poetess; S. Neris (?–1945), poetess; G. Tulauskaité (1908–), poetess; and many others.

When Lithuania in 1940 and again in 1944 was occupied by the Soviet Union the Lithuanian writers remaining in the country were compelled to follow the line dictated to them by the Communists. Those working in the free world, about 100 in number, tried to continue the creation of a Lithuanian national literature.

LITKE, FYODOR PETROVICH, COUNT (1797–1882), Russian arctic explorer, geographer and naval officer whose influence on Russian science, geography in particular, was very great, was born on Sept. 28, 1797, in St. Petersburg. His grandfather (who spelled his name Liitke) had emigrated from Germany. In 1812 Litke joined the imperial navy and took part in a voyage round the world under V. M. Golovnin in 1817–19. During the four summers 1821–24 Litke commanded an arctic expedition which mapped the west coast of Novaya Zemlya and studied the adjacent southeastern part of the Barents sea. In 1826–29 he went round the world again, this time in command of a scientific expedition in the sloop "Senyavin." and made important surveys and collections in the Bering strait region and the western Pacific (Bonin and Caroline Islands). From 1832 to 1848 he was tutor to Tsar Nicholas I's second son Constantine. Litke was one of the founders of the Russian Geographical society in 1845 and was at its head from that time until 1873, with the exception of the seven years 1850–57 when he was admiral in command of the ports of Revel (Tallin) and Kronstadt. He was president (1864–81) of the Imperial Academy of Sciences, taking particular interest in astronomy and magnetism. He wrote a large volume on each of his two major expeditions, and many scientific papers. The Geographical society instituted a Litke medal upon his retirement. He died on Oct. 20, 1882. (T. E. A.)

LITMUS, a mixture of dyes, the chief constituents of which are azolitmin and erythrolitmin. It is the oldest and most commonly used acid-base indicator. In an acid solution the dye turns red and in a basic solution it turns blue. Litmus was originally prepared by the action of air, ammonia and an alkali carbonate on certain species of lichens (*Lecanora tartarea* and *Roccella tinctoria*) found in the Netherlands. It can be synthesized directly from β-orcinol. Litmus is usually used in the form known as litmus paper, an absorbent paper impregnated with the dye. When moistened with the solution under test, the paper changes colour. An alcoholic solution of litmus is sometimes used. A few drops added to the solution under test causes the whole solution to turn colour. *See* also INDICATOR, CHEMICAL.

LITOPTERN, any of the herbivorous, hoofed mammals (ungulates) of the order Litopterna, an extinct group confined to South America during the long period of isolation of that continent from all others. Litopterns, derived from the most primitive hoofed mammals, the condylarths. were abundant from the Paleo-

cene to the Pliocene epochs (about 70,000,000 to 2,000,000 years ago) and finally became extinct during the Pleistocene (about 1,000,000 years ago). They were represented very early by two distinct families. Proterotheriidae and Macraucheniidae.

Early proterotheriids were barely distinguishable from condylarths. By the Miocene epoch (about 25,000,000 years ago) the feet in some genera showed a remarkable specialization, the number of toes having been reduced from five to three and even to one. The foot of *Thoatherium* closely resembled that of the present day one-toed horse, but had progressed even further in the reduction of the lateral digits. Conservative members of this family persisted into the Pliocene, the time of extinction of this branch of the litopterns.

The Macraucheniidae reached a three-toed condition early in their history, but did not progress beyond this stage. The teeth of macrauchenids, in contrast to those of proterotheriids, develop high crowns with complex patterns of crests and ridges in the molars. The last genus known, *Macrauchenia,* was probably camellike in size and appearance. The skull was marked by a reduction of the nasal bones and development of a short proboscis. The neck and limbs were long. the body and tail short. Remains were first brought to light in Patagonia by Charles Darwin. and since his discovery, numerous specimens, including complete skeletons, have been found in the pampean deposits of Argentina.

During the late Pliocene and the Pleistocene a land corridor developed between North and South America, permitting invasion of the southern continent by herbivores and carnivores from the north. Concurrently some South American mammals pushed northward, but many of the once highly successful groups, such as the litopterns, already somewhat impoverished, were unable to survive the competition with their North American adaptive counterparts. Among the casualties was *Macrauchenia,* whose extinction marked the end of the once abundant litopterns. *See* UNGULATA.

See A. S. Romer, ***Vertebrate Paleontology*** (1945); W. B. Scott, ***A History of Land Mammals in the Western Hemisphere,*** rev. ed. (1937).

(E. C. O.)

LITOTES, a rhetorical figure in which emphasis is secured for a statement by turning it into a denial of the contrary, *e.g.,* "a citizen of no mean city," *i.e.,* a citizen of a famous city. *See* FIGURES OF SPEECH: *Figures of Degree of Emphasis.*

(G. W. A.)

LITTLE ENTENTE, a mutual defense arrangement among Czechoslovakia, Yugoslavia and Rumania during the period between World Wars I and II directed against German and Magyar dominance in the Danubian area and destruction of the freedom and territorial acquisitions won by those states in 1918 as a consequence of World War I. It was based upon the treaty of Aug. 14, 1920 concluded at Belgrade between Yugoslavia and Czechoslovakia, joined by Rumania in treaties with Czechoslovakia on April 23 and with Yugoslavia on June 7, 1921. By a treaty of Aug. 31, 1922 the three states undertook broader obligations of economic and political co-operation and by that of May 21, 1929 they agreed that the renewal of the treaty of Alliance should be automatic at the end of each five-year period. At the same time they signed a treaty for the peaceful settlement of their differences in accord with the League of Nations model treaty of conciliation and arbitration of 1928.

Fascist Italy had been an enemy of the little entente from the beginning but the advent of Adolf Hitler to power in Germany on Jan. 30, 1933 challenged the whole structure of central Europe. On Feb. 16, 1933 the little entente states strengthened their bonds against this menace. Under the able leadership of Eduard Benes, Nicolae Titulescu and Bogoljub Jevtic, as well as King Alexander of Yugoslavia, a veritable, if short-lived, diplomatic federation was constituted. The new pact created a permanent council composed of the three foreign ministers or their delegates to meet three times a year and to direct a common policy. A permanent secretariat was established, one section of which was to function at Geneva, the seat of the League of Nations.

The little entente took a lead in urging effective sanctions against Japan from 1931 to 1933 and successfully protested against Mussolini's proposal in March 1933, of a four-power pact to revise treaties without consultation with the smaller states of Europe in substitution of the League's processes. Though signed in June 1933 by Italy, Germany, Great Britain and France this project was not implemented. On July 4, 1933 the little entente signed a nonaggression agreement with the U.S.S.R.; on Feb. 9. 1934 Yugoslavia and Rumania joined Turkey and Greece to form the Balkan entente (*q.v.*); and on May 16, 193j Czechoslovakia. motivated by the Nazi menace, signed an alliance with the U.S.S.R., following the French-Soviet alliance by two weeks. From its first meeting at Prague in Jan. 1934, the economic council of the little entente laid foundations for closer economic collaboration among the three countries, attempting to include in this work Austria and Hungary.

The assassination of King Alexander of Yugoslavia and Jean Louis Barthou, foreign minister of France. at Marseilles on Oct. 9, 1934 weakened the little entente. Prince Paul, the regent of Yugoslavia, supported Milan Stojadinovic, who dominated the country as premier from 193j to 1939, in a policy of rapprochement toward Italy, Bulgaria and Germany, thus striking at the vitals of both the little entente and the Balkan entente. The vacillating foreign policy of France and the division between France and Britain in respect to Italy and Germany further weakened the little entente. At the Bratislava conference of Sept. 1936. Yugoslavia seemed determined to follow an independent policy and the council of the little entente virtually acknowledged the right of each of the member states to do so. The last conference of the council was held at Yugoslavia, on Aug. 21, 1938. An unsuccessful attempt was made to conciliate Hungary by an offer of equality in armaments in return for the promise of a peaceful policy. Despite the reluctance of the Stojadinovic government, both Yugoslavia and Rumania, at the time of the Munich crisis! in accordance with the terms of their alliance, warned Hungary not to attack Czechoslovakia. But with the appeasing attitude of Great Britain and France, there was little question of the outcome. The Munich accord of Sept. 30, 1938 permitted Germany to annex the Sudeten area of Czechoslovakia. and destroyed the little entente by destroying Czechoslovakia. the keystone of the system. (Q. 'If',)

LITTLEHALES, GEORGE WASHINGTON (1860–1943), U.S. hydrographer, was born in Schuylkill county, Pa.. on Oct. 14, 1860. and graduated irom the U.S. naval academy in 1883. He then studied at Columbian (later George Washington) university, Washington, D.C. He was hydrographic engineer of the U.S. Hydrographic office irom 1900 until his retirement in 1932, and professor of nautical science at George Washington university from 1913 to 1927. From 1919 to 1922 he was chairman of the American Geophysical union's section of physical oceanography and from 1921 to 1932 vice-president of the oceanography section of the International Union of Geodesy and Geophysics. He was the author of numerous works on navigation, hydrography and related subjects. Littlehales died on Aug. 12, 1943.

LITTLEHAMPTON, a seaport, seaside holiday town and urban district in the Arundel and Shoreham parliamentary division of West Sussex, Eng., at the mouth of the Arun, 14 mi. E.S.E. of Chichester by road. Pop. (1951) 13,939. Area 4 sq.mi. Backed by the South Downs and with long sandy beaches, it caters to many vacationists every year and also has a harbour, accessible in good weather, with a small home and foreign trade. Timber, granite and fertilizers are imported and grain for seed exported. Lifeboats are made in the local boatyards.

LITTLE MAGAZINE, the term applied to a certain kind of periodical published irom 1890 through much of the 20th century. Little magazines flourished in the United States and England. though French writers (especially the *symboliste* poets and critics, 1880–*c.* 1900) often had access to a similar type of publication and German literature of the 1920s was also indebted to them. The name, probably derived by analogy from "little theatre," signifies most of all a nonprofessional and noncommercial manner of editing, managing and financing. A composite description of the little magazines' motives for existing and of their careers would most usefully take this iorm: a little magazine usually begins with the object of publishing literary work of some artistic merit which is unacceptable to commercial magazines for any one or all of three reasons—the writer is unknown and therefore not a good risk; the work itself is unconventional or experimental in form; or it violates one of several popular notions of polite moral, social or aesthetic behaviour. In addition, several little magazines were employed as direct forums for the advancement of entirely new ideas in literature such as those of the *symbolistes* of France and the imagists of the United States and England, or of social and political perspectives on a culture as in the leftist magazines of the 1930s in the United States and England.

As a consequence of these peculiarities, little magazines mere frequently in the advance guard of modern literature. They lacked both the financial stability and the restrictive editorial controls of established commercial magazines and were likely for both reasons to take risks and make bold moves beyond the limits set by public taste at any given time. Frequently the little magazines advanced new developments in literature which were subsequently assimilated by a culture, the time lag usually being about two decades. Foremost in the ranks of such sponsorship of literature were *Poetry: a Magazine of Verse* (1912), especially in its early years under the vigorous guidance of Harriet Monroe; the more erratic and often more sensational *Little Review* (1914–29) of Margaret Anderson; a group of English magazines in the second decade of the 20th century, of which the *Egoist* (1914–19) and *Blast* (1914–15) were most conspicuous; and Eugene Jolas' *transition* (1927–38). In all but the last of these, a major guiding spirit was the L.S. poet and critic, Ezra Pound; he served as "foreign correspondent" of both *Poetry* and the *Little Review,* maneuvered the *Egoist* from its earlier beginnings as a feminist magazine (*The New Freewoman,* 1913) to the status of an *avant garde* literary review, and with Wyndham Lewis jointly sponsored the two issues of *Blast.* In this case, the little magazines showed the stamp of a single vigorous personality; similar strong and dedicated figures in little magazine history were the U.S. poet, William Carlos Williams (whose name appears in scores of little magazines. in one capacity or another); the British critic and novelist, Ford Madox (Hueffer) Ford, editor of the *Transatlantic Review* (1924–25) and contributor to many others; and Gustave Kahn, a minor French poet but a very active editor associated with several French *symboliste* periodicals.

From the point of view of the writer, the little magazines rendered two essential services: their pages were accessible to him when he was still unknown, and they conducted campaigns designed to publicize and broadcast reputations in foreign countries. Both of these services persisted throughout little magazine history, though the stress upon them varied in the several stages of that history.

There were four principal periods in the general history of little magazines. In the first, from 1890 to about 1915, French magazines served mainly to establish and explain a literary movement; British and U.S. magazines, to disseminate information about and encourage acceptance of continental European literature and culture. In the second stage, 1915–30, when other magazines, especially in the United States. were in the vanguard of almost every variation of modern literature, a conspicuous feature was the expatriate magazine, published usually in France but occasionally elsewhere in Europe by young U.S. and British critics and writers. The major emphasis in this period was upon literary and aesthetic form and theory and the publication of fresh and original work, such as that of Ernest Hemingway (in the *Little Review, Poetry, This Quarter* and elsewhere), T. S. Eliot (in *Poetry,* the *Egoist, Blast),* James Joyce (in the *Egoist,* the *Little Review, transition),* and many others. The third stage, the 1930s, saw the beginnings of many leftist magazines, started with specific doctrinal commitments which were often subjected to considerable editorial change in the career of the magazine. *Partisan Review* (1934) was perhaps the best-known example of these in the U.S., as was the *Left Review* (1934–38) in England.

The fourth period of little magazine history began about 1940. One of the conspicuous features of this period was the critical review supported and sustained by a group of critics, who were in most cases attached to a university or college. Examples of this kind of periodical were, in the L.S., *The Kenyon Review,* founded by John Crowe Ransom in 1939, and in Great Britain, *Scrutiny,* edited by F. R. Leavis (1932–53). This and related kinds of support such as that of publishers maintaining their own reviews or miscellanies. represented a iorm of institutionalism which was radically different from the more spontaneous and erratic nature of the little magazines of earlier years. These magazines generally favoured criticism over creation and tended to stabilize and slow the growth of experiment in new literature. In the second half of the 20th century the prospects were, however, that the little magazine might at any time break out from newly established limits and recover at least in part its earlier freedom, if only as a protest against the dangers of too strict a standardization of the creative life.

See also the articles on most of the editors and writers mentioned above.

(F. J. HN.)

LITTLE ROCK, the largest city and capital of Arkansas, U.S., the seat of Pulaski county, is on the south bank of the Arkansas river near the centre of the state at a dividing line between the mountains and the plains. It is the principal centre of commerce and manufacturing for the region. The population was 102.213 in 1950, and 107.813 in 1960. The population of the Little Rock–North Little Rock standard metropolitan statistical area, which includes North Little Rock, Jacksonville. Cammack Village and Sherwood, was 156,085 in 1940; 196.685 in 1950 and 242,980 in 1960.

Bernard de la Harpe, exploring the Arkansas in 1722, saw two conspicuous rock formations on the river banks which he named *La Petite Roche* and *La Grande Roche* (or *Le Rocher Français*). Near the smaller rock was a settlement of Quapaw Indians, and La

Harpe made this his trading post. In later years, the "little rock" became the abutment for a railway bridge. The "big rock," on the North Little Rock side of the river and two miles upstream from the smaller formation, was the site of an army post and later became the location of a veterans administration hospital. In 1812, William Lewis, a hunter and trapper, built his home at the "little rock." In 1819 Arkansas became a territory with its capital at Arkansas Post. The site of Little Rock was surveyed in 1821, and the territorial capital was moved there the same year. Little Rock was incorporated as a town in 1831 and chartered as a city in 1836. A board-manager form of municipal government was adopted in 1957.

Little Rock was strongly anti-Union at the outbreak of the American Civil War, and the U.S. arsenal which had been strengthened by the federal government was seized by state authorities Feb. 8, 1861. In Sept. 1863, Gen. Frederick Steele's Union troops occupied the city, and a pro-Union government was set up. In the 1880s Little Rock became an important communication centre with the expansion of the state railways, and began to develop commercially and industrially. Industry in the greater metropolitan area experienced a marked and diversified growth in the 1940s mainly because of the proximity of raw materials and an adequate labour supply, and in the 1960s included cottonseed, wood products, light bulbs, roofing granules, watches and clocks, electric motors, nonwoven fabrics and food products. There are large railroad shops across the river, and bauxite mines just outside the city. The surrounding agricultural region produces large crops of cotton, alfalfa, potatoes, rice! fruits and vegetables. Within a short distance are vast stands of high grade timber and large deposits of coal. oil and natural gas. Other mineral resources in the region are marble, clay. flint, granite and barite.

Little Rock is noted for its three capitols, one of which served the territorial government. The meeting place of the territorial legislature between 1821 and 1836 is preserved in the Territorial Restoration, along with a block of buildings of the period including the first print shop of the *Arkansas Gazette,* one of the first newspapers to be published west of the Mississippi. The Old Statehouse. the capitol from 1836 until 1912, is a remarkable work of antebellum architecture. It is on the site of an Indian burial ground and has a commanding view of the Arkansas river. The Territorial Restoration and the Old Statehouse. containing interesting authentic furnishings, are open to the public. The present state capitol is on a knoll near the business district and is flanked by other governmental buildings. It is of Xrkansas marble and is patterned after the capitol at Washington! D.C.

Several state institutions are located at Little Rock, including the main branch of the state mental hospital, the schools for the blind and deaf; also medical units, a graduate centre and graduate institute of technology of the University of Arkansas. Other educational institutions include Little Rock university (1927), privately endowed; Philander Smith College (1868), a Methodist school for Negroes; the Arkansas Law school (1916), a private institution; St. John's Seminary (1930), Roman Catholic; Arkansas Baptist college, for Negroes (1884) and Shorter college (established as Bethel institute in 1886), an African Methodist Episcopal school for Negroes at North Little Rock. Little Rock's Robinson Memorial auditorium houses a convention hall, lecture hall: committee rooms and a music hall seating 3.000 persons.

The metropolitan area has several parks, including MacArthur park which surrounds the birthplace of Gen. Douglas MacArthur and is the former site of an army post at which the general's father was stationed. The 36 ac. of shaded grounds include a museum of natural history, a band shell and a museum of fine arts. The 200-ac. War Memorial park has a zoo, a swimming pool, a golf course, an archery range, an amusement park, a baseball park and the War Memorial stadium. The Arkansas Livestock showgrounds at Little Rock is centred about the T. H. Barton coliseum. The Governor's mansion, at the opposite end of Center street from the Old Statehouse, is a stately structure completed in 1950. The Georgian colonial two-story brick executive mansion is on a 6.25-ac. plot. The Albert Pike Memorial temple, state headquarters for Freemasonry, is a magnificent block long structure in the downtown area. Adams field, the municipal airport, is one mile from the main street. Veterans', Roman Catholic and Baptist hospitals are in the area. Camp Pike of World War I, renamed Camp Joseph T. Robinson in the 1940s, was an important military training centre. In the mid-1950s, the Little Rock air force base was built near Jacksonville.

Bishops of the Roman Catholic (St. Andrew's cathedral), Protestant Episcopal (Trinity cathedral), Methodist and African Methodist Episcopal churches maintain residence at Little Rock, and several other denominations have state headquarters and churches there.

From Sept. 1957 the city was the focus of world attention. The immediate issue was the right of nine Negro children to attend Central high school under a gradual desegregation plan adopted by the city school board, in accordance with the 1954 decision of the U.S. supreme court holding racial segregation in public schools as unconstitutional. Their attendance set off a series ,of legal battles and one of the 20th century's great tests of power between the federal and a state government. Gov. Orval E. Faubus ordered state militia to prevent Negroes from attending school, but the state was enjoined from interf ring by Pres. Dwight D. Eisenhower who sent federal troops to maintain order throughout the year 1957–58. After various legal maneuvers, the city's public high schools were closed during the following school year, but were reopened in Aug. 1959 with several Negroes in attendance at Central and Hall high schools. City police dispersed a small mob of whites at Central on opening day, and token integration was accomplished without further incident. (K. W. P.)

LITTLE SISTERS OF THE POOR, a religious order of the Roman Catholic Church, was founded in Brittany, France, in 1839 for the care of destitute old people. The order depended and still depends on alms as its sole means of support.

One of its founders was a servant girl, Jeanne Jugan, who was interested by Abbé Augustin Marie le Pailleur of the town of St. Servan in joining other young women in charitable work for the aged. The order provided shelter and support for its charges and based its constitutions on the rule of St. Augustine. adding the vow of hospitality to those of poverty, chastity and obedience.

Homes were established in various parts of France and the order soon spread to other countries. Its first home in the Cnited States was opened at Brooklyn, N.Y., in 1868. The general mother house was at St. Pern, France.

LITTLE THEATRE MOVEMENT: *see* THEATRE: *20th Century: United States: Community Theatre.*

LITTLETON, SIR THOMAS (c. 1407–1481), English judge. best known as the author of *Littleton on Tenures,* was born, it is supposed. at Frankley House, Worcestershire. perhaps in 1407, and certainly not later than 1422. He is said by Sir Edward Coke to have "attended one of the universities." He was probably a member of the Inner Temple where he lectured on the statute *De Donis Conditionalibus.* He appears to have been recorder of Coventry in 1450; he became sergeant-at-law in 1453 and was afterward a justice of assize on the northern circuit. .In 1466 he was made a judge of the common pleas and in 1475 a knight of the Bath. He died, according to the inscription on his tomb in Worcester cathedral, on Aug. 23, 1481.

Littleton wrote his *Tenures,* a brief text on property, the first of the classical texts on English law not written in Latin and uninfluenced by Roman law, probably after his appointment to the common pleas, for the instruction of his son. Richard. It soon became the most celebrated treatise on English law and was acclaimed by Sir Edward Coke "the most perfect and absolute book that was ever written in any human science." Composed in law French. the *Tenures* was principally a scientific account of the English land law of the middle ages unmodified either by the doctrines of the chancellors. such as uses, or by later common law innovations: such as contingent remainders and conveyances barring entails. Intended as a first book in law, it served countless generations of lawyers not only in England but also in America both before and after the Revolution.

The edition by Lettou and Machlinia of 1481 or 1482 was the earliest treatise on English law ever printed and among the first ten books to be published in London. An English translation by William Rastell appeared early in the 16th century. The division of the text into sections dates from the edition of William West (1581). The most famous form of the *Tenures* was Sir Edward Coke's *First Institute,* known as *Coke Upon Littleton,* the first edition of which appeared in 1628.

See E. Wambaugh, *Littleton's Tenures in English* (1903); W. S. Holdsworth, *History of English Law,* 2:571–590 (1936). (S. Tt.)

LITTLE TURTLE (*c.* 1752–1812), American Indian chief of the Miami tribe, who became a popular hero among the settlers, was born in a village (later named after him) on the Eel river near Fort Wayne, Ind. Noted for military prowess and oratorical ability: Little Turtle was one of the most important Indian leaders in the Northwest territory. On Nov. 4, 1791, he led the Indians to a crushing victory on the Wabash river over federal troops under the command of Gen. Arthur St. Clair. In 1795, after the defeat of the Indians by Gen. Anthony Wayne at Fort Recovery and Fallen Timbers, Little Turtle, who was not in command at the latter battle, signed the treaty of Greenville, by which the Indians ceded to the United States much of Ohio and parts of Illinois, Indiana and Michigan. Thereafter he was a strong advocate of peace, and he successfully resisted the efforts of the Shawnee chief Tecumseh to induce the Miami to join his confederacy. He subsequently signed other treaties with the United States before his death at Fort Wayne on July 14, 1812.

LITTRÉ, MAXIMILIEN PAUL ÉMILE (1801–1881), French philologist and positivist philosopher, whose dictionary is one of the outstanding, lexicographic accomplishments of all time, was born at Paris on Feb. 1, 1801. He was educated at the Lycée Louis-le-Grand, where he had for friends Louis Hachette and Eugène Burnouf. He then studied the English and German languages, and classical Sanskrit literature and philology. Littré intended to become a doctor, and had completed his studies when his father's death in 1827 made it necessary for him to begin earning money. He began to teach classics, and in 1835 became a regular contributor to the *National,* and eventually director of the paper. In 1839 appeared the first volume of his edition (completed 1862) of the works of Hippocrates, which secured his election the same year into the Académie des Inscriptions et Belles-Lettres. He also became a friend of Auguste Comte and popularized his ideas.

About 1844 he started working on his great *Dictionnaire de la langue française.* In the revolution of July 1848 he took part in the repression of the extreme republican party in June 1849. His essays, contributed during this period to the *National,* were collected together and published under the title of *Conservation, révolution et positivisme* in 1852, and show a thorough acceptance of Comte's doctrines. Later he differed with Comte's more mystic ideas, but he concealed his differences.

After Comte's death in 1858 Littré felt free to publish his own ideas in his *Paroles de la philosophie positive* (1859), and at still greater length in his work in *Auguste Comte et la philosophie positive* (1863).

About 1863, after completing his Hippocrates and his Pliny, he set to work in earnest on his French dictionary. In the same year he was proposed for the Académie Française, but rejected, owing to the opposition of Mgr. Dupanloup, bishop of Orleans, who denounced him as the chief of the French materialists. He also at this time started with G. Wyrouboff the *Philosophie Positive,* a review which was to embody the views of modern positivists. Literary work absorbed him until the overthrow of the empire compelled him to take a part in politics. He felt himself too old to undergo the privations of the siege of Paris, and retired with his family to Brittany, from which he was summoned by Gambetta to Bordeaux, to lecture on history; and then to the senate to which he had been elected by the department of the Seine. In Dec. 1871 he was elected a member of the Académie Française in spite of the renewed opposition of Dupanloup, who resigned his seat rather than receive him.

Littré's dictionary was completed in 1873. An authoritative interpretation is given of the use of each word, based on the various meanings it had held in the past. He died on June 2, 1881.

LITURGICAL MOVEMENT, ROMAN CATHOLIC. New insight into the corporate nature of the liturgy, as "the worship rendered by the Mystical Body of Christ in the entirety of its Head and members" (Pius XII, *On The Sacred Liturgy,* p. 20, America Press, New York, 1954), produced the Catholic Liturgical movement. Besides the essential sacramental efficacy of mass and sacraments *ex opere operato,* it exploits graces available *ex opere operantis Ecclesiae,* enabling priests and people to take a more active part in these rites. "The Mass by its very nature," states a papal instruction of Pius XII, "requires that all those who are present should take part in it each in the way proper to him" *(Sept. 3 Instruction on Participation in the Mass.* Copyrighted by The Order of St. Benedict, Inc., Collegeville. Minn., 1958, p. 8).

St. Pius X, with chant restoration in mind, stressed the Christian spirit to be had by taking active part in the common song and prayer of the church. He favoured missal translations and made possible daily communion and early first communion for children. He also tried to establish congregational singing and in 1913 started breviary reforms not yet completed by the early 1960s. Gradually such measures had far-reaching effects.

Fired by the pontiff's vision of active lay participation, liturgical scholars (Benedictines mainly) began promoting liturgy. Missal use, dialogue mass, vernacular vespers or compline and study weeks were found in Austrian, Belgian, Dutch, French, German and other centres. These local and widely differing liturgical movements came, with the accession of Pius XII in 1939, under papal direction, and bishops were asked to appoint diocesan directors. Indeed, Pius XII made the movement a major part of his regime. Three encyclical letters, *On the Mystical Body* (1943), *On the Sacred Liturgy* (1947) and *On Sacred Music* (1955), and countless minor documents relating to the movement came from his pen. He provided for bilingual rituals, a new Latin psalter, Holy Week reform, evening mass, a new eucharistic fast and simpler rubrics as a first phase of breviary reform; he also promoted the World Congress of Pastoral Liturgy: at Assisi (1956). The instruction quoted above, *On Active Participation,* was issued only a few days before the collapse that ended in his death. Some of these measures were optional, others mandatory. Each one was part of a program which he appraised: "The liturgical movement is thus shown forth as a sign of the provident dispositions of God for the present time, of the movement of the Holy Ghost in the Church, to draw men more closely to the mysteries of the faith and riches of grace which flow from the active participation of the faithful in the liturgical life." ("Allocution," in *The Assisi Papers,* 1957. Copyrighted by The Order of St. Benedict, Inc., Collegeville, Minn.) Practice naturally follows more slowly; rigid uniformity in nonessentials is hardly to be expected. The movement strongly influences sacred music, art and architecture; it is felt more and more in educational circles, and gives greater depth to pastoral ministry.

Bibliography.—Papal documents for the church at large are in *Acta Sanctae Sedis* (prior to 1909) and in *Acta Apostolicae Sedis* (after 1909). Liturgical items are collected by A. Bugnini, *Documenta Pontificia ad Instaurationem Liturgicam Spectantia,* vol. i (1953), vol. ii (1959); Gerald Ellard, *The Mass in Transition* (1956), lists papal documents on pp. 386–387. *See* also E. B. Koenker, *The Liturgical Renaissance in the Roman Catholic Church* (1954); P. Marx, *Virgil Michel and the Liturgical Movement* (1957); J. H. Srawley, *The Liturgical Movement: Its Origin and Growth* (1954); L. Beaduin, *Liturgy, the Life of the Church* (1926); L. Bouyer, *Liturgical Piety* (1955); E. LITURGY, in the technical language of the Christian Church, the order for the celebration and administration of the Eucharist. The word (from the Greek meaning public service) came to be used in a more general sense to denote any or all of the various prescribed forms of public worship. In this article the liturgy is treated in the stricter sense.

There are nine main families or groups of liturgies, four of them being of Eastern and five of them of Western origin and use. They are known either by the names of the apostles with whom they are traditionally connected, or by the names of the countries or cities in which they have been or are still in use.

The Syrian Rite (St. James).—The principal liturgies to be enumerated under this group are the Clementine liturgy, so called from being found in the eighth book of the Apostolic Constitutions, which claim in their title, though erroneously, to have been compiled by St. Clement, the 1st-century bishop of Rome; the Greek liturgy of St. James; the Syriac liturgy of St. James. Sixty-four more liturgies of this group have existed, the majority being still in existence. Their titles are given in F E. Brightman's *Liturgies,* Eastern and Western (1896), pp. lviii.–lxi

The Egyptian Rite (St. Mark).—This group includes the Greek liturgies of St. Mark, St. Basil and St. Gregory, and the Coptic liturgies of St. Basil, St. Gregory, St. Cyril or St. Mark; together with certain less known liturgies the titles of which are enumerated by Brightman (*op.* czt. pp. lxxiii. lxxiv.). The liturgy of the Ethiopian church ordinances and the liturgy of the Abyssinian Jacobites, known as that of the Apostles, fall under this group.

The Persian Rite (**SS. Adaeus** and Maris).—This Nestorian rite is represented by the liturgy which bears the names of SS. Adaeus and Maris together with two others named after Theodore of Mopsuestia and Nestorius. This group has sometimes been called "East-Syrian." The titles of three more of its now lost liturgies have been preserved, namely those of Narses, Barsumas and Diodorus of Tarsus. The liturgy of the Christians of St. Thomas, on the Malabar coast of India, formerly belonged to this group, but it was almost completely assimilated to the Roman liturgy by Portuguese Jesuits at the synod of Diamper in 1599.

The Byzantine Rite.—The Greek liturgies of St. Chrysostom, St. Basil and St. Gregory Dialogus, or The Presanctified, also extant in other languages, are the living representatives of this rite. The Greek liturgy of St. Peter is classified under this group, but it is merely the Roman canon of the Mass, etc., inserted in a Byzantine framework, and seems to have been used at one time by some Greek communities in Italy. To this group also belongs the Armenian liturgy, of which ten different forms have existed in addition to the liturgy now in general use named after St. Athanasius.

The Hispano-Gallican Rite (St. John).—This group of Latin liturgies, which once prevailed very widely in Western Europe, has been aimost universally superseded by the liturgy of the Church of Rome. Where it survives, it has been more or less assimilated to the Roman pattern It prevailed once throughout Spain, France, northern Italy, Great Britain and Ireland The term "Ephesine" has been applied to this group or family of liturgies, chiefly by English liturgiologists, and the names of St. John and of Ephesus, his place of residence, have been pressed into service in support of a theory of Ephesine origin, which, however, lacks proof and may now be regarded as a discarded hypothesis. Other theories represent the Gallican to be a survival of the original Roman liturgy, or an importation into Western Europe from the East through a Milanese channel.

The Mozarabic Liturgy.—This was the national liturgy of the Spanish church till the close of the 11th century, when the Roman liturgy was forced upon it. Its use, however, lingered on, till in the 16th century Cardinal Ximenes, anxious to prevent its becoming quite obsolete, had its books restored and printed, and founded a college of priests at Toledo to perpetuate its use. It survives now only in several churches in Toledo and in a chapel at Salamanca, and even there not without certain Roman modifications of its original text and ritual.

Gallican Liturgy.—This was the ancient and national liturgy of the church in France till the commencement of the 9th century, when it was suppressed by order of Charlemagne, who directed the Roman missal to be everywhere substituted in its place. All traces of it seemed for some time to have been lost until three Gallican sacramentaries were discovered and published by Thomasius in 1680 under the titles of *Missale Gothicum, Missale Gallicum* and *Missale Francorum,* and a fourth was discovered and published by Mabillon in 1687 under the title of *Missale Gallicanum.* Fragmentary discoveries have been made since. Mone discovered fragments of eleven Gallican masses and published them at Carlsruhe in 1850. Other fragments from the library at St. Gall have been published by Bunsen (*Analecta Ante-Nicaena,* iii. 263–266), and from the Ambrosian library at Milan by Cardinal Mai (*Scriptt.* Vet Vat. *Coll.* iii. 2. 247). A single page was discovered in Gonville and Caius College, Cambridge, published in Zeitschrift fiir Kath. Theologie, vi 370.

Ambrosian Liturgy.—Considerable variety of opinion has existed among liturgical writers as to the proper classification of the "Ambrosian" or "Milanese" liturgy. If we are to accept it in its present form and to make the present position of the great intercession for quick and dead the test of its genus, then we must classify it as "Petrine" and consider it as a branch of the Roman family If, on the other hand, we consider the important variations from the Roman liturgy which yet exist, and the traces of still more marked variation which confront us in the older printed and ms. copies of the Ambrosian rite, we shall detect in it an original member of the Hispano-Gallican group of liturgies, which for centuries underwent a gradual but ever-increasing assimilation to Rome. We know this as a matter of history, as well as a matter of inference from changes in the text itself Charlemagne adopted the same policy towards the Milanese as towards the Gallican church. He carried off all the Ambrosian church books which he could obtain, with the view of putting Roman books in their place, but the completion of his intentions failed, partly through the attachment of the Lombards to their own rites, partly through the intercession of a Gallican bishop named Eugenius (Mabillon, *Mus.* Ital. tom. i. Pars. ii. p 106). It has been asserted by Joseph Vicecomes that this is an originally independent liturgy drawn up by St. Barnabas, who first preached the Gospel at Milan (De *Missae* Rit. 1 capp. xi, xii), and this tradition is preserved in the title and proper preface for St. Barnabas Day in the Ambrosian missal (Pamelius, ***Liturgicon,*** i. 385, 386), but it has never been proved.

The Roman Rite (St. Peter).—There is only one liturgy to be enumerated under this group, viz. the present liturgy of the Church of Rome, which, though originally local in character and circumscribed in use, has come to be nearly co-extensive with the Roman Catholic Church, sometimes superseding earlier national liturgies, as in Gaul and Spain, sometimes incorporating more or less of the ancient ritual of a country into itself and producing from such incorporation a sub-class of distinct Uses, as in England, France and elsewhere. Even these subordinate Uses have for the most part become, or are rapidly becoming, obsolete.

The date, origin and early history of the Roman liturgy are obscure. The first Christians at Rome were a Greek-speaking community and their liturgy must have been Greek, and is possibly represented in the so-called Clementine liturgy. But the date when such a state of things ceased, when and by whom the present Latin liturgy was composed, whether it is an original composition, or, as its structure seems to imply, a survival of some intermediate form of liturgy—all these are questions which are waiting for solution.

The Roman liturgy seems to have been introduced into England in the 7th, into France in the 9th and into Spain in the 11th century, though no doubt it was known in both France and Spain to some extent before these dates. In France certain features of the service and certain points in the ritual of the ancient national liturgy became interwoven with its text and formed those many varying mediaeval Gallican Uses which are associated with the names of different French sees.

The chief distinguishing characteristics of the Roman rite are these: (a) the position of the great intercession for quick and dead within the canon, the commemoration of the living being placed just before and the commemoration of the departed just after the words of institution; (b) the absence of an "Epiklesis" or invocation of the Holy Ghost upon the elements; (c) the position of the Pax or "Kiss of Peace after the consecration" and before the communion, whereas in other liturgies it occurs at a much earlier point in the service.

LITURGIES OF THE BRITISH ISLES

Period I. The Celtic Church.—Until recently almost nothing was known of the character of the liturgical service of the Celtic church which existed in these islands before the Anglo-Saxon conquest, and continued to exist in Ireland, Scotland, Wales and Cornwall for considerable though varying periods of time after that event. But in recent times a good deal of light has been thrown on the subject, partly by the publication or republication of the few genuine works of Patrick, Columba, Columbanus, Adamnan and other Celtic saints; partly by the discovery of liturgical remains in the Scottish Book of Deer and in the Irish Books of *Dimma* and *Mulling* and the *Stowe* Missal, etc.; partly by the publication of mediaeval Irish compilations, such as the Lebar Brecc, Liber Hymnorum, Martyrology of *Oengus,* etc., which contain ecclesiastical kalendars, legends, treatises, etc., of considerable but very varying antiquity. The evidence collected from these sources is sufficient to prove that the liturgy of the Celtic church was of the Gallican type. In central England the churches, with everything belonging to them, were destroyed by the heathen invaders at the close of the 5th century; but the Celtic church in the remoter parts of England, as well as in the neighbouring kingdoms of Scotland and Ireland, retained its independence for centuries afterwards.

An examination of its few extant service-books and fragments of service-books yields the following evidence of the Gallican origin and character of the Celtic liturgy: (a) the presence of collects and anthems which occur in the Gallican or Mozarabic but not in the Roman liturgy; (b) various formulae of thanksgiving after communion; (c) frequent biddings or addresses to the people in the form of Gallican Praefationes; (d) the Gallican form of consecration, being a prayer called Post-Sanctus leading up to the words of institution; (e) the complicated rite of "fraction" or "the breaking of bread," as described in the Irish treatise at the end of the *Stowe* Missal, finds its only counterpart in the elaborate ceremonial of the Mozarabic church; (f) the presence of the Gallican ceremonial of ***Pedilavium*** or "Washing of feet" in the earliest Irish baptismal office. (See F. E. Warren, Liturgy and Ritual of the Celtic Church, 1881.)

Period II. The Anglo-Saxon **Church.**—We find ourselves here on firmer ground, and can speak with certainty as to the nature of the liturgy of the English church after the beginning of the 7th century. Information is drawn from liturgical allusions in the extant canons of numerous councils, from the voluminous writings of Bede, Alcuin and many other ecclesiastical authors of the Anglo-Saxon period, and above all from a considerable number of service-books written in England before the Norman Conquest. Three of these books are missals of more or less completeness: (1) the Leofric Missal, a composite 10th- to 11th-century ms. presented to the cathedral of Exeter by Leofric, the first bishop of that see (1046–1072), now in the Bodleian library at Oxford; edited by F. E. Warren (Oxford, 1883); (2) the missal of Robert of Jumibges, archbishop of Canterbury (1051–1052), written probably at Winchester and presented by Archbishop Robert to his old monastery of Jumièges in the neighbourhood of Rouen, in the public library of which it now lies; edited by H. A. Wilson (1896); (3) the Red Book of Derby, a ms. missal of the second half of the 11th century, now in the library of Corpus Christi College, Cambridge.

The Anglo-Saxon church owed its foundation to a Roman pontiff, and to Roman missionaries, who brought, as we are told by Bede, their native liturgical codices with them (*Hist. Eccles.* lib. ii. cap. 28). Accordingly, when we speak of an Anglo-Saxon missal, we mean a Roman missal.

Period III. Anglo-Norman Church.—The influx of numerous foreigners, especially from Normandy and Lorraine, which preceded, accompanied and followed the Conquest, and the occupation by them of the highest posts in church as well as state had a distinct effect on the liturgy of the English church. These foreign ecclesiastics brought over with them a preference for and a habit of using certain features of the Gallican liturgy and ritual, which they succeeded in incorporating into the service-books of the church of England. One of the Norman prelates, Osmund, count of Séez, earl of Dorset, chancellor of England, and bishop of Salisbury (1078–1099), is credited with having undertaken the revision of the English service-books; and the missal which we know as the Sarum Missal, or the Missal according to the Use of Sarum, practically became the liturgy of the English church. It was not only received into use in the province of Canterbury, but was largely adopted beyond those limits—in Ireland in the 12th and in various Scottish dioceses in the 12th and 13th centuries.
